Conclusions: We hope this study provide scientific evidence of the effectiveness of rehabilitation exercise individualized and performed at home in patients with breast cancer. This type of care is now extended to other French centers.
No conflict of interest.

1959 POSTER

Evaluation of proliferation and apoptosis markers in circulating tumor cells (CTCs) of women with early breast cancer who are candidates for tumor dormancy

M. Spiliotaki[1], H. Markomanolaki[1], G. Kallergi[1], M.A. Papadaki[1], V. Georgoulias[2], D. Mavroudis[2], S. Agelaki[2]. [1]*University of Crete School of Medicine, Laboratory of Tumor Cell Biology, Heraklion, Greece;* [2]*University General Hospital of Heraklion, Medical Oncology, Heraklion, Greece*

Background: Clinical dormancy is frequently observed in breast cancer (BC). In the present study, we aimed to characterize CTCs in dormancy candidates (DC) with BC in terms of proliferation and apoptosis.
Material and Methods: Cytospins of peripheral blood mononuclear cells (PBMCs) were obtained from DC ($n = 122$) disease-free for $\geqslant$5 yrs and from metastatic pts ($n = 40$) on relapse that occurred $\geqslant$5 yrs after surgery. Sequential samples ($n = 27$) of 8 DC with late relapse and from 8 relapse-free ($n = 38$), were also analyzed. 10^6 PBMCs were stained with pancytokeratin antibody along with ki-67 and M30 as proliferation and apoptosis markers, respectively.
Results: CTCs were identified in 40 (32%) of 122 DC and in 15 (37.5%) of 40 metastatic patients. In all patients, ki-67(−)/M30(−) CTCs were detected. Specifically, 25 DC (61.5%) had only ki-67(−)/M30(−) CTCs, 11 (27.5%) had ki-67(+) and 8 (20%) M30(+) CTCs. Among 243 CTCs detected, 201 (82.5%) were ki-67(−)/M30(−), 14 (5.7%) ki-67(+) and 29 (11.9%) M30(+). Seven (46.6%) of 15 CTC(+) metastatic patients had ki-67(+) CTCs ($p = 0.037$) whereas 58 (41%) of total CTCs were ki-67(+) ($p < 0.001$). No M30(+) CTCs were detected. When sequential samples of the 8 DC who relapsed were analyzed, exclusively ki-67(−)/M30(−) CTCs were detected in 2 (25%) pts, ki-67(+) in 6 (75%) and M30(+) CTCs in 4 (50%). The respective numbers in the non-relapsed group were 4 (50%), 3 (37.5%) and 3 (37.5%). Moreover, ki-67(+) CTCs were more frequently observed in samples of the relapsed pts (47% vs 23.8%). Among 382 CTCs detected in all sequential samples from the relapsed group, 337 (88.14%) were ki-67(−)/M30(−), 26 (6.7%) ki-67(+) and 20 (5.1%) M30(+), whereas the respective percentages among 77 CTCs in non-relapsed pts were 78%, 6.5% and 15.8% ($p = 0.001$).
Conclusions: The great majority of CTCs detected in DC with BC express neither proliferation, nor apoptosis markers. However, the apoptotic index in CTCs is increased during clinical dormancy, whereas the proliferation index is increased on relapse. In addition, apoptotic CTCs are more frequently encountered during follow-up in DC free of relapse. The above observations suggest that monitoring proliferation and apoptosis in CTCs during clinical dormancy could be used to predict subsequent late relapse.

1960 POSTER

Planning and memory function in breast cancer patients − an fMRI study

S. Menning[1], M.B. De Ruiter[1], W. Boogerd[2], D.J. Veltman[3], L. Reneman[4], S.B. Schagen[1]. [1]*The Netherlands Cancer Institute, Department of Psychosocial Research and Epidemiology, Amsterdam, Netherlands;* [2]*The Netherlands Cancer Institute, Department of Neuro-oncology, Amsterdam, Netherlands;* [3]*VU University Medical Center, Department of Psychiatry, Amsterdam, Netherlands;* [4]*Academic Medical Center of the University of Amsterdam, Department of Radiology, Amsterdam, Netherlands*

Background: Cognitive function in breast cancer (BC) patients may be compromised before the start of adjuvant chemotherapy (CT). Four task-fMRI studies showed some pretreatment alterations, but had a small sample size and/or did not include cancer-specific controls. Here we report fMRI results of two tasks in a relatively large sample of BC patients scheduled to receive CT (CT+), BC patients not indicated to undergo CT (CT-) and healthy controls (HC).
Material and Methods: Baseline recruitment for this prospective study is near complete. Here, we report results from a selected sample of subjects matched on age and IQ. 33 CT+ (50.5$\pm$8.6 yrs; IQ 101.8$\pm$12.8) and 33 CT- (52.1$\pm$7.7 yrs; IQ 103.8$\pm$13.7) were assessed post-surgery, but before adjuvant treatment. 32 HC (51.4$\pm$7.5 yrs; IQ 105.9$\pm$10.6) were also tested. Each assessment included neurocognitive tests and 3T multimodality MRI. This included an fMRI version of the Tower of London (TOL) assessing planning ability. Memory encoding and retrieval was measured with of a visual paired associates task.
Results: Performance was within normal range with no significant group differences. For the TOL, CT+ showed hypoactivation of dorsolateral prefrontal cortex (DLPFC) and lateral parietal areas compared to HC. With increasing task difficulty CT+ patients showed hypoactivation of DLPFC compared to CT-. During memory encoding, inferior parietal areas where more active in the CT+ group compared to both other groups. No significant group differences were found for memory retrieval.
Conclusions: Although we found no indications for pre-treatment cognitive impairment in BC patients, we did observe differences in brain activation during planning and memory encoding, but not memory retrieval, using fMRI. This finding stresses the need for baseline assessment when studying the effects of adjuvant treatment on brain function and structure. Our follow up measurements will show whether the brain regions in which we observed baseline differences are most vulnerable to the effects of CT.

Analysis of ANC recovery from a Phase III study of lipegfilgrastim versus pegfilgrastim in patients with breast cancer receiving doxorubicin/docetaxel chemotherapy

I. Bondarenko[1], P. Bias[2], R. Elsässer[2], A. Buchner[2]. [1]*Dnepropetrovsk Municipal Clinical Hospital 4, Dnepropetrovsk, Ukraine;* [2]*Teva Ratiopharm, Ulm, Germany*

Background: Lipegfilgrastim is a once-per-cycle, fixed-dose glycoP-EGylated granulocyte-colony stimulating factor (G-CSF) under review for the prevention of severe neutropenia in cancer patients receiving chemotherapy (CTx). The efficacy of lipegfilgrastim was previously demonstrated in a Phase III study conducted in CTx-naive breast cancer patients. We present here secondary efficacy endpoints related to absolute neutrophil count (ANC) decrease and recovery in lipegfilgrastim- and pegfilgrastim-treated patients.
Methods: Patients with high-risk Stage II, III, or IV breast cancer were randomized to a single 6 mg subcutaneous (s.c.) injection of lipegfilgrastim or pegfilgrastim on Day 2 of each CTx cycle. Full-dose CTx (doxorubicin 60 mg/m^2 + docetaxel 75 mg/m^2) was started on Day 1 of each cycle

for up to four consecutive cycles. Secondary endpoints included time to ANC nadir, time to ANC recovery (time from CTx administration to ANC recovery to $\geqslant 2.0 \times 10^9$/L after expected nadir), and time to recovery from ANC nadir to ANC $\geqslant 1.5 \times 10^9$/L. Times within each cycle were compared using Poisson regression and ANCOVA, with treatment, country, therapy type, and weight class as categorical variables, and baseline ANC as covariable.

Results: In the intent-to-treat population for CTx Cycle 1, the time to ANC nadir was comparable for lipegfilgrastim (n = 101) and pegfilgrastim (n = 101), with a median time of 6 days in both treatment groups in all cycles. Results were also comparable in Cycles 2−4. Time to ANC recovery was significantly shorter for patients receiving lipegfilgrastim versus pegfilgrastim in Cycles 1−2.

Mean time to ANC recovery, days±SD	Lipeg (n = 101)	Peg (n = 101)	Lipeg–Peg Least Squares Mean (95% CI)	*P-value**
Cycle 1	5.8±3.3	7.4±3.6	−1.570 (−2.547 to −0.592)	0.0018
Cycle 2	3.8±4.1	5.3±4.7	−1.349 (−2.528 to −0.171)	0.0250
Cycle 3	3.9±4.7	5.0±4.3	−1.120 (−2.317 to 0.077)	0.0665
Cycle 4	3.6±4.2	4.3±4.6	−0.458 (−1.714 to 0.799)	0.4734

*Poisson regression.

The time to recovery from ANC nadir was numerically shorter for lipegfilgrastim- versus pegfilgrastim-treated patients in all cycles, but the differences were not statistically significant.

Conclusions: In patients with breast cancer treated with lipegfilgrastim versus pegfilgrastim, time to ANC recovery was significantly shorter in Cycles 1−2 of myelosuppressive chemotherapy. Differences were not statistically significant for Cycles 3−4 and for time to ANC recovery from nadir.

1962 POSTER

Effect of small tumor size (⩽2 cm) on outcome of node negative breast cancer in BRCA1-associated versus matched sporadic patients

D. Akdeniz[1], A. Jager[1], L.B. Koppert[1], C.H.M. Van Deurzen[1], M.K. Schmidt[2], P. Devilee[3], M.G.E.M. Ausems[4], H. Collaborators[1], C. Seynaeve[1], M.J. Hooning[1]. [1]*Erasmus MC Cancer Institute, Medical Oncology, Rotterdam, Netherlands;* [2]*Netherlands Cancer Institute, Oncology, Amsterdam, Netherlands;* [3]*Leiden University Medical Center, Oncology, Leiden, Netherlands;* [4]*University Medical Center Utrecht, Oncology, Utrecht, Netherlands*

Background: It has been suggested that tumor size has a different prognostic value in T1 BRCA1-associated compared to sporadic BCs, among others since BRCA1-associated BC mainly has a poor differentiation grade and triple-negative phenotype. To investigate this we evaluated survival of patients with small (T1), node negative (N0) BC in BRCA1 mutation carriers and sporadic patients.

Patients and Methods: We included 101 BRCA1-associated BC patients with T1N0 BC, identified through Dutch clinical genetic centers and diagnosed between 1990 and 2011. These patients were individually matched in a 1:2 ratio to 198 sporadic BC patients, selected from population-based registries, for tumor size (T1a, T1b, T1c), N0 status, year of diagnosis and birth. The Kaplan–Meier method was used to analyse 10-year breast cancer specific (BCSS) and distant disease free survival (DDFS). Cox proportional hazard models were used to compare survival between the BRCA1 and sporadic group, and to investigate the impact of tumor size (as a continuous variable) in both groups.

Results: The mean time of follow-up in the BRCA1 and sporadic group was 7.4 (range 1.1–17.5) vs. 8.2 (range 1.0–20.3) years, respectively (p = 0.082), the mean age was 41.9 years (range 23−70). BRCA1 patients more often had ER negative disease (78.7% vs. 21.1%), poor differentiation grade (74.2% vs. 34.8%), more frequently underwent mastectomy (65.3% vs. 15.2%) and were more frequently treated with chemotherapy (59.0% vs. 27.3%) than sporadic patients (p < 0.001 for all). For T1a/bN0 tumors, 10-years BCSS and DDFS in BRCA1 mutation carriers were 100% and 92% versus 95% and 85% in sporadic patients (p = 0.427 and p = 0.318). For T1cN0 tumors, 10-years BCSS and DDFS in BRCA1 mutation carriers were both 81% versus 87% and 85% for sporadic patients (p = 0.134 and p = 0.352). Overall, no univariate differences were observed between BRCA1 and sporadic patients regarding BCSS (HR 1.55 [95% CI 0.69–3.47]) and DDFS (HR 1.12 [95% CI 0.56–2.25]). Within the BRCA1 group, tumor size yielded HRs for BCSS and DDFS of 1.26 (95% CI 1.04–1.53) and 1.15 (95% CI 1.00–1.33), while the association was just not significant in the sporadic group (HRs 1.10 [95% CI 0.98–1.23] and 1.05 [95% CI 0.97–1.14]).

Conclusion: T1a/bN0 tumors in BRCA1-associated BC have a favorable prognosis. Also, in T1N0 BRCA1-associated BC, tumor size is a prognostic factor, supporting the value of BC detection at small size.

No conflict of interest.

1963 POSTER

Cognitive function and cerebral white matter in breast cancer survivors 10 years after treatment

M.M. Stouten-Kemperman[1], M.B. De Ruiter[1], W. Boogerd[2], L. Reneman[3], S.B. Schagen[1]. [1]*Netherlands Cancer Institute, Department of Psychosocial Research and Epidemiology, Amsterdam, Netherlands;* [2]*Netherlands Cancer Institute, Department of Neuro-Oncology, Amsterdam, Netherlands;* [3]*Academic Medical Center, Department of Radiology, Amsterdam, Netherlands*

Adjuvant chemotherapy (CT) for breast cancer (BC) is associated with cognitive problems and alterations in brain structure and function. In a previous study we found detrimental effects on brain white matter of patients exposed to high-dose adjuvant CT (Hi-CT) compared to patients who only received radiotherapy (RT), 10 years post-treatment. In the current study, we extended our measurements to BC survivors who received conventional-dose adjuvant CT (Con-CT) ⩾10 years earlier and healthy controls (HC). Our aim was to compare neurotoxicity profiles of different treatment strategies.

Twenty Con-CT (5 cycles 5-fluorouracil, epirubicin, cyclophosphamide [FEC], 60.5±5.7 yrs) and 20 HC (58.9±3.9 yrs) were assessed using neurocognitive tests and 3T MRI (Diffusion Tensor Imaging (DTI) and 1H-MR Spectroscopy (MRS)). Data were compared to previously reported results in 17 Hi-CT (4xFEC + 1x high-dose cyclophosphamide, thiothepa, carboplatin, [CTC], 57.1±5 yrs) and 15 RT only patients (58.2±5.8 yrs). All patients were exposed to RT. All CT patients received endocrine treatment for 2−5 yrs. Cognitive status was evaluated with an overall performance score for each participant (Mahalanobis Distance [MhD].

The MhD was significantly lower for the RT group vs. HC, indicating worse overall cognitive performance. However, although the Hi-CT group showed higher MhD values (41.7) compared to CON-CT (37.2), RT only (30.4) and HC (10.6), other groups differences did not reach statistical significance. DTI revealed significantly higher mean diffusivity (MD) values in the Hi-CT vs. Con-CT group in several anterior and posterior areas in the brain. The Hi-CT group also had significantly larger MD values than the RT only group in similar brain areas, albeit to a lesser extent. A higher MD was also found in the RT only group vs. the HC group in anterior brain areas. 1H-MRS showed that, compared to other treatments, Hi-CT was associated with a reduction of N-acetyl aspartate (NAA).

Our findings suggests that the cognitive performance (expressed in an overall distance score) in BC survivors ⩾10 years post-treatment doesn't show a clear dependency on treatment type, possible due to a limited sample size. Our imaging findings do suggest widespread negative Hi-CT effects on WM compared to other treatments as evidenced by increased MD and lower NAA, the latter being suggestive of impaired axonal function. The effects of RT only are less pronounced and warrant further investigation.

No conflict of interest.

1964 POSTER

Breast cancer molecular profile according to BMI and menopausal status

G. Arpino[1], A. Crispo[2], R. Thomas[3], C. De Angelis[1], S. Cicala[1], P. Gargiulo[1], M. Milano[1], M. De Laurentiis[4], S. De Placido[1], M. Montella[2]. [1]*University of Naples "Federico II", Medical Oncology, Naples, Italy;* [2]*National Cancer Institute "Fondazione G. Pascale", Epidemiology, Naples, Italy;* [3]*"Clinica Mediterranea" Hospital, Breast Cancer, Naples, Italy;* [4]*National Cancer Institute "Fondazione G. Pascale", Breast Cancer, Naples, Italy*

Background: Several studies have shown a positive association between body mass index (BMI) and the development of estrogen receptor (ER)-positive breast cancer. However, correlation of BMI, menopausal status and molecular subtypes has not been established yet.

Material and Methods: Overall 1,004 patients with early breast cancer (EBC) were recruited for this study. Clinical and tumor characteristics such as age, menopausal status, weight, height, tumor size (T), grading, ER, progesterone receptor (PgR), human epidermal growth factor receptor 2 (HER2) status, were prospectively collected. BMI was categorized into three groups (low: ⩽25; intermediate: 26−30; high: >30) and associations between BMI and clinicopathological variables were performed by $\chi 2$ test.

Results: Overall 615 (61.3%) pre-menopausal and 389 (38.7%) post-menopause women were enrolled. Among premenopausal patients (Table 1), high BMI correlates with increased ER and lower HER2 expression and less aggressive tumor subtypes as luminal A. In the same patients group, women with low BMI were more likely to develop a Luminal B, HER2 like or TN breast cancer. No correlation was observed between tumor phenotypes and BMI among postmenopausal women.
Conclusions: Among premenopausal patient, high BMI is associated with less aggressive and more endocrine sensitive EBC. This is consistent with the hypotheses that higher estrogen exposure of breast tissue in women with higher BMI may drive growth of these cancers. If further confirmed, our data suggests that weight control in this subset of women may help to prevent cancer development.
No conflict of interest.

1965 POSTER

Intimacy and sexual health care program for breast cancer patients

H. Roelstraete[1], T. Van Keymeulen[1], J. Van den Haute[1], C. Vanhecke[2], A. De Grauwe[1], L. Houbracken[1], A. De Clercq[1], L. Bonduelle[1], P. Enzlin[2]. *[1]Onze Lieve Vrouw Ziekenhuis Aalst, OLV Breast Clinic, Aalst, Belgium; [2]Leuven University, Institute of Familial and Sexological Sciences, Aalst, Belgium*

Background: Based on study results we aim at efficiently elaborating a multidisciplinary health care program related to intimacy and sexual health. This study has a twofold objective, i.e. 1) listing the effects of breast cancer and its treatment on the sexual functioning, and 2) determining the professional assistance women expect to receive at the hospital.
Material and Methods: 139 follow-up breast cancer patients (up to 5 years) have been asked to complete surveys. 73 women who did not want to participate, have been requested to indicate the reason for their refusal. The survey package comprised a Distress Barometer, HADS, a questionnaire on breast cancer, intimacy and sexual health, FSFI and SSFS for women.
Results: Up to 44% of the respondents shows lower sexual arousal, however 22% of them suffer from this problem. There are also problems concerning sexual excitement and pain. Women with depressive complaints report significantly more sexual dysfunction.
55% of the respondents shows a different experience of sexuality and intimacy. Being together, caressing and cuddling are experienced as more important than kissing and having sexual contact. Sexual satisfaction is significantly lower after cancer.
47.7% needs professional assistance in finding answers to their questions on sexual functioning. 73.8% believes that more intramural attention is to be paid to the patient's perception of sexuality.
Conclusions: This study already suggests emerging tendencies. Breast cancer and its treatment have a clear effect on the patient's intimacy and sexual health. The majority of the women would like to receive more information. They want to receive an information leaflet, spontaneous discussions on this topic during contacts with health care professionals at the hospital and information sessions with companions. They want to talk (in decreasing order of importance) with the gynaecologist, the oncologist, the sexologist and the psychologist.
However some limitations should be considered. The study was based on a small number of participants. Also further research is necessary into the implementation of a multidisciplinary health care program related to intimacy and sexual health. More knowledge of the expectations and information need of health care professionals can be added.
The elaboration of a health care program is deemed necessary and strongly advisable and needs to involve medical, sexological and psychosocial health care professionals.
No conflict of interest.

1966 POSTER

ER/PR/HER2 receptor discordance between primary tumors and corresponding axillary metastases in curatively resected node positive breast cancer patients

M. Ozturk[1], H. Turna[1], O. Aydin[2], D. Tural[1], F. Demirelli[1], M. Ozguroglu[1], E. Buyukunal[1], S. Ilvan[2], S. Serdengecti[1]. *[1]Istanbul University Cerrahpasa School of Medicine, Medical Oncology, Istanbul, Turkey; [2]Istanbul University Cerrahpasa School of Medicine, Pathology, Istanbul, Turkey*

Background: ER/PR/HER2 status of the primary (P) breast cancer (BC) and corresponding distant metastases may show discordance in part to the change in biology. This discordance may change the ultimate treatment decisions and oncologic outcomes. Today, we only use the receptor status of the PBC while deciding the treatment options for node positive disease. Currently, there are no recommendations regarding the receptor status examination of axillary lymph nodes (ALN) which may have clinical importance. We, therefore, aimed to analyze the ER/PR/HER2 receptor status change in P & A tumor tissues of 107 node positive BC patients who were treated with adjuvant chemotherapies + radiotherapy ± trastuzumab in our institution.
Material and Methods: After approval by the local ethics committee, P and corresponding A tumors were synchronously reevaluated using routine immunohistochemical procedures. Patient's files and hospital electronic database system were checked for clinical data, and phone calls were made as needed. Relation of clinical and pathological variables with receptor discordance and its effects on survival were analyzed.
Results: A very high rate of receptor concordance between P&A was seen. PA receptor discordance for ER, PR and HER2 were, 8%, 11.4%, and 6.2%, respectively. ER&PR changes may have caused treatment decision change in 1% of the patients. HR discordance was mostly seen in patients having ⩽30% ER or PR in the P tumor. No discordance that may cause treatment decision change was seen in terms of HER2. A negative but weak correlation between absolute PR change and tumor diameter & grade were seen. Receptor discordance had no effect on both survival parameters.
Conclusions: We detected a very high receptor concordance between P BC and corresponding A metastases. On the other hand we particularly detected the HR subgroup, which had the most HR discordance between P&A. Neither the discordance in individual receptors per se nor the discordance in defined HR groupings had an effect on survival which might have been a matter of small sample size. In the light of our findings we think that, HR discordance in patients having ⩽30% ER or PR in the P tumor and the efficacy of specific hormonal treatments in this group of patients are points that warrants further investigation.
No conflict of interest.

1967 POSTER

High prevalence of additional contralateral and ipsilateral malignant findings by MRI in patients with invasive (ducto)lobular breast cancers

E. Postma[1], M. El Sharouni[1], M.A. Van den Bosch[2], A.J. Witkamp[1], H.M. Verkooijen[2], P.J. Van Diest[3]. *[1]University Medical Centre, Surgery, Utrecht, Netherlands; [2]University Medical Centre, Imaging, Utrecht, Netherlands; [3]University Medical Centre, Pathology, Utrecht, Netherlands*

Background: In patients with invasive lobular cancer, preoperative MRI detects additional contralateral or ipsilateral malignant findings in up to 50% of patients. Invasive breast cancer comprises a spectrum of histological changes with purely lobular cancer on one side and purely ductal cancer on the other, with many mixed lesions in between ('ductolobular cancer'). The role of preoperative MRI in these lesions with such mixed differentiation had not been evaluated.
Patients and Methods: All patients diagnosed with breast cancer containing a lobular component of any proportion between Jan 2008 and Oct 2012 were prospectively offered preoperative MRI. MRI findings were compared to findings on conventional imaging (mammography and ultrasound). Clinically relevant additional findings on MRI (defined as ⩾5.0 mm discrepancy in tumour size, additional ipsi- and contralateral lesions) were verified histologically and reviewed by an expert breast pathologist.
Results: Of all 155 patients diagnosed with (ducto)lobular cancer, 109 (70%) patients underwent preoperative MRI. In 44 patients the lobular component comprised 1−30% of the cancer, in 17 patients it comprised

31−70% and in 47 patients it comprised 71–100%. Preoperative MRI detected 95 additional findings in 69 (63%) patients.Further work- up revealed contralateral breast cancer in 10 patients (9%), additional ipsilateral malignant foci in 20 patients (18%) and more extensive disease in 22 (20%) patients. On the patient level, MRI led to the detection of additional malignant findings in 54/109 (50%) patients. The probability of detecting relevant additional findings did not increase with the proportion of the lobular component (i.e. 48% for 1−30% lobular component, 53% for 30 −70% and 49% for 70–100%, p = 0.526).
Conclusion: In breast cancer patients presenting with lobular differentiation at core needle biopsy, preoperative MRI leads to the detection of clinically relevant additional finding in a substantial amount of patients irrespective of the proportion of the lobular component. Therefore, preoperative MRI should be part of the routine work-up of this selected patient category.

1968 POSTER

Identifying the different courses of cognitive functioning across time in patients with breast cancer treated with chemotherapy

M.J.J. Pullens[1], J.K. Vermunt[2], J.A. Roukema[3], J.M.G.H. Van Riel[3], H.T.J. Roerdink[4], J. De Vries[1]. *[1]Tilburg University, Medical Psychology and Neuropsychology, Tilburg, Netherlands; [2]Tilburg University, Statistics, Tilburg, Netherlands; [3]St. Elisabeth Hospital, Internal Medicine, Tilburg, Netherlands; [4]TweeSteden Hospital, Internal Medicine, Tilburg, Netherlands*

Introduction: Results of existing studies suggest the existence of subgroups within patients with breast cancer (BC) who are treated with chemotherapy with regard to problems with cognitive functioning. Therefore, the aims of this study were to (i) examine cognitive functioning across time in BC patients compared to patients with a benign breast disease (BBD) by evaluating the group means across time, (ii) identify longitudinal development classes for cognitive functioning in BC patients treated with chemotherapy, (iii) describe the sociodemographic and clinical characteristics of the resulting groups, and to compare the groups on their psychological functioning across time.
Methods: BC patients who were scheduled to receive adjuvant chemotherapy (N = 86) and a control group of women with a benign breast disease (BBD) (N = 95) participated in the study. BC patients completed validated questionnaires and a neuropsychological test battery before chemotherapy started, three months and one year after ending chemotherapy (and at comparable moments for the BBD group).
Results: Concerning verbal memory BBD patients stayed stable across time, while it declined in BC patients three months after ending chemotherapy but increased at one year after ending chemotherapy (though they remained below their baseline verbal memory functioning) (p = 0.033). Three longitudinal developmental classes were identified: 'consistently high/average/low cognitive functioning'. This last group had a higher age, lower educational level, and less often salaried work/retirement compared to the other subgroups. Furthermore, they scored worse on state anxiety and depressive symptoms three months after ending chemotherapy compared to the other subgroups.
Conclusion: Verbal memory is affected in BC patients treated with chemotherapy. Three subgroups can be defined within the BC patients: 'consistently high/average/low cognitive functioning'. Further research with a larger sample size is warranted to examine the vulnerability of this last subgroup to develop problems with cognitive functioning after BC treatment.

1969 POSTER

Metformin use correlates with molecular subtype of invasive breast carcinoma

I. Edhemovic[1], N. Satej[2], N. Besic[3]. *[1]Institute of Oncology Ljubljana, Surgical Oncology, Ljubljana, Slovenia; [2]Community Health Centre Ljubljana, Diabetes, Ljubljana, Slovenia; [3]Institute of Oncology, Surgical Oncology, Ljubljana, Slovenia*

Background: Metformin has anti-proliferative effects in primary breast carcinoma (BC) tumors. Gene set analysis revealed in BC patients without diabetes mellitus (DM) reduced expression of p53, BRCA1 and cell cycle pathways after treatment with metformin for two weeks. Our aim was to find out if long lasting use of metformin correlates with histologic type and molecular subtype of BC.
Material and Methods: A chart review of 253 patients (mean age 67 y.) with operable invasive BC and DM was done. Altogether 128 patients were on metformin, while 125 were not receiving metformin. They were surgically treated at our institute from 2005–2011. Control group consisted of 320 patients with invasive BC without DM (mean age 59 y.), who were consecutively surgically treated at our institute in 2006. Data on clinical and histopathology factors were collected. Subtypes were classified by immunohistochemical surrogates as luminal A (estrogen receptor [ER]+ and/or progesterone receptor [PR]+, HER2−), luminal B (ER+ and/or PR+, HER2+), HER2 (ER−, PR−, HER2+), triple negative/basal (ER−, PR−, HER2−). Contingence tables and non-parametric tests were used for statistical analysis.
Results: There was a trend for higher rate of ductal type of BC in patients with DM on metformin in comparison to those not receiving metformin (90% vs. 82%, p = 0.09). Patients with DM on metformin, with DM not on metformin and control group had different molecular subtype of BC (p = 0.01): luminal A subtype was found in 78%, 83% and 71%, luminal B in 12.6%, 9% and 11%, HER2 in 0.8%, 1.6% and 8%, triple negative/basal like subtype in 8.6%, 6.4% and 10%, respectively. Patients' age, body mass index, tumor diameter and pathological tumor stage were statistically different in patients with DM on metformin, DM not on metformin and patients without DM. There was no statistical difference in presence or mean number of metastatic regional lymph nodes.
Conclusion: Metformin use correlates with molecular subtype of BC in diabetics on metformin in comparison to diabetics not on metformin and patients without DM.
No conflict of interest.

1970 POSTER

Correlation between quality-of-life (QoL) and muscolo-skeletal (MSKs) symptoms in early breast cancer (BC) patients (pts) during treatment with aromatase inhibitors (AIs): Preliminary results of a single-institution, prospective study

M. Cazzaniga[1], A. Valentini[2], F. Gallina[3], N. Giuntini[2], L. Tagliabue[3], F. Villa[2], F. Cicchiello[2], F. Riva[2], D. Cortinovis[2], P. Bidoli[2]. *[1]Ospedale Nuovo San Gerardo, Monza, Italy; [2]Ospedale Nuovo San Gerardo, Medical Oncology, Monza, Italy; [3]Ospedale Nuovo San Gerardo, Psychologic Unit, Monza, Italy*

Background: AIs are the milestone adjuvant treatment for postmenopausal early BC pts. Non-steroidal AIs induce a significant oestrogen deprivation, responsible in approximately 40% of the pts for MSKs and for discontinuation in 25%. Median time to arthralgia onset is 6 months. This study shows the preliminary data about the impact of AIs-related muscolo-skeletal events on QoL and their correlation with quantitative (NRS Pain Scale) and qualitative (Trigger-Points − TRPs) Items.
Patients and Methods: QoL has been evaluated by using SCL 90-r for psychological symptoms, SF-36 for the self-perception of the health status and COPE-NVI for evaluation of coping. All the questionnaires have been self-administered with the support of a dedicated psychologist at baseline (T0) and at 3 (T1), 6 (T2), 12 (T3) and 18 (T4) months thereafter. Presence and intensity of pain were measured by NRS 11-points scale and by Trigger Points (TGPs) evaluation at the same intervals, as well as 17-OH-Vitamin D and oestradiol blood levels. Pearson correlation analysis was used to calculate correlations between Pain Scale, Physical Synthetic Index of Sf-36 and NRS/TRPs scores. Wilcoxon's Test was used to compare baseline scores with subsequent ones.
Results: From September 2011 to February 2012, 60 early BC pts entered the study. Exclusion criteria included severe osteoporosis or other comorbidities that contraindicate therapy with AIs and documented diagnosis of psychosis and cognitive deterioration. Median age was 68 years (43−88). Seven (11.7%) pts had previously received adjuvant chemotherapy, in 4 cases with taxanes. For the present preliminary analysis, 30 pts have been considered, for whom T0 and T1 measurements were available. At baseline, 22 pts (73.3%) had a NRS score >0; pain was mild (NRS 1−4) in 3 pts (13.6%), moderate (NRS 5−7) in 5 (22.7%) and severe (NRS>7) in 4 of them (18.1%). At T1 evaluation, we did not observed any difference in the total number of pts with pain (18 vs 14), whereas a significant increase in the number of pts with mild pain (9, 56.2%) was reported, whereas MSKs symptoms were present in 6 pts (20%). At T0, 26.7% of the pts had a TRPs score $\geqslant$1. No significant difference was reported for TRPs evaluation between baseline and T1. At baseline, 76.7% of the pts presented a deficiency of 17-OH-Vitamin D (median: 20.35 ng/mL, range: 3−59.9 ng/ml). No modifications have been observed at T1 regarding Vit D levels. At baseline, there was a statistically significant correlation between Physical Pain Scale of SF-36 and NRS Pain score (p = 0.001) and between Physical Synthetic Index of SF-36 and NRS Pain Score (p < 0.001) No differences have been found for SF-36 scales between T0 and T1. On the contrary, for COPE-NVI, at T1 there was a statistically significant reduction in terms of avoidance strategies (p = 0.002) and a significant increase in problem solving (p = 0.02). No differences have been observed in terms of NRS score (p = 0.97).
Conclusion: During the first 3 months of AIs, there are no modification in terms of qualitative and quantitative pain score evaluation, except for mild

pain. The more time since BC surgery has passed, the more pts seem to use better strategies to cope their cancer condition.

1971 POSTER

Inconsistent selection and definition of local and regional study endpoints in breast cancer trials

M. Moossdorff[1], L.M. Van Roozendaal[2], R. Schipper[2], L.J.A. Strobbe[3], A.C. Voogd[4], V.C.G. Tjan-Heijnen[5], M.L. Smidt[1]. *[1]Maastricht University Medical Centre, Surgery, Maastricht, Netherlands; [2]Maastricht University Medical Centre, Surgery and Radiology, Maastricht, Netherlands; [3]Canisius-Wilhelmina Hospital, Surgery, Nijmegen, Netherlands; [4]Maastricht University Medical Centre, Epidemiology, Maastricht, Netherlands; [5]Maastricht University Medical Centre, Medical Oncology, Maastricht, Netherlands*

Background: In breast cancer research, results are reported using study endpoints. Most are composite endpoints (e.g. disease-free survival), consisting of several components (e.g. regional recurrence or death), in turn consisting of specific events (e.g. recurrence in supraclavicular lymph node). Inconsistent selection and definition of study endpoints may limit mutual comparison of study outcomes, resulting in unjustified conclusions. This study aims to determine which local and regional endpoints are used in breast cancer studies, and how these endpoints and their components are defined.
Methods: A PubMed search was performed for breast cancer studies (e-)published in 2011 in *Annals of Surgery, Annals of Surgical Oncology, British Journal of Surgery, Journal of Clinical Oncology, Journal of the American Medical Association, Lancet, Lancet Oncology, New England Journal of Medicine,* and *Radiotherapy & Oncology*. Articles using endpoints with a local or regional component were included and definitions were compared.
Results: From 44 articles, 23 different endpoints with a local or regional component were extracted. Most frequently used were disease-free survival (n = 25 articles), recurrence-free survival (n = 7), local control (n = 4), locoregional recurrence-free survival (n = 3), and event-free survival (n = 3). Different endpoints were used for similar outcomes. Of the 23 endpoints, 5 were not defined at all, the remaining 18 at least partially. Of these, 17/23 contained a local and 13/23 a regional component. The events included in the local and regional components were not specified in 57% and 54% respectively. If provided, definitions of local components were inconclusive with respect to inclusion of carcinoma *in situ* and recurrence in surgical scar, and inconsistently included skin- and chest wall recurrences. In regional components, skin- and chest wall recurrences were inconsistently included and specific nodal sites that were considered regional recurrences were either not provided in the article, or varied between different studies.
Conclusion: In breast cancer studies, many different endpoints with a locoregional component are used. Endpoint definitions are often not provided or incomplete with respect to the included events. Additionally, events included in the components of these endpoints vary between studies. This limits transparency and may cause unjustified conclusions.
No conflict of interest.

1972 POSTER

Transforming follow-up: Patients as true partners in a major multi-disciplinary change project

B. Lavery[1], S. Orton[1], H. Baker[2], J. Ross[3], R. Walsh[3], R. Stevens[4], N. Clarke[1], F. Fairman[5], K. Mitchell[1], A. Clements[6]. *[1]University of Oxford Hospitals, Oncology, Oxford, United Kingdom; [2]Oxfordshire Primary Care Trust, Planned Care, Oxford, United Kingdom; [3]University of Oxford Hospitals, Patient Representative, Oxford, United Kingdom; [4]NHS Oxfordshire, General Practice, Oxford, United Kingdom; [5]Oxfordshire Primary Care Trust, Clinical Effectiveness, Oxford, United Kingdom; [6]University of Oxford, Primary Care Health Services, Oxford, United Kingdom*

Background: A multi-disciplinary working group was established within the Oxford University Hospitals NHS Trust to develop and implement a radically transformed breast cancer follow-up pathway. This new pathway aims to be in line with Cancer Survivorship principles, to generate a safe framework within which patients can be supported in self-management, and to ensure limited resources are used in the most effective ways to improve patient outcomes.
Materials and Methods: The working party included representatives of patients, service commissioners, charitable partners, primary care physicians (GPs), multi-disciplinary hospital specialists (breast nursing, surgery, imaging, oncology, administration, management and patient liaison) and university research partners. In addition to regular group meetings there were separate facilitated patient focus groups, GP education meetings, imaging and IT discussions, nursing team meetings and oncology education sessions. Open days for patients also provided opportunities for wider public comment.
Results: A radically shortened follow-up path was developed; patients are discharged from routine hospital follow-up 6 months after the completion of hospital-based therapy (surgery, chemotherapy, biological therapy, radiotherapy). This has been implemented from early 2013. The pathway includes formal preparation for discharge during the 6 months following treatment completion: a holistic needs assessment is carried out in a nurse-led clinic, with attention to individual information needs, and signposting to supportive programmes run by cancer charity partners (Breast Cancer Care and Maggie's Centre). After discharge patients with problems can self-refer directly to a new rapid review service, a specific recommendation from our patient representatives. A dedicated e-mail help-line for GPs has also been set up, and a mechanism established to call patients for all routinely required breast imaging for at least 5 years from diagnosis, with results sent promptly direct to the patient and their GP.
Conclusions: Implementing dramatic change in established practice is challenging. Early collaboration and full engagement with all parties including patients makes the likely success much higher. At the end of the planning phase all members of the group acknowledged how much they had learnt from each other, how this had changed the pathway developed, and how this would influence their future practice in a positive way. This work has given us a robust template for meaningful patient involvement in the transformation of established cancer pathways, and is already being used to implement similar changes in other cancer clinics and in neighbouring hospitals.
No conflict of interest.

1973 POSTER

Clinical impact of breast specific gamma imaging on the management of patients with indeterminate breast lesions

P. Neyenhuis[1], F. Smit[2], A.F. Van der Hoeven[2], A.M. Zeillemaker[1], L.M.H. Wijers[3]. *[1]Rijnland Hospital, General Surgery, Leiderdorp, Netherlands; [2]Rijnland Hospital, Nuclear Medicine, Leiderdorp, Netherlands; [3]Rijnland Hospital, Radiology, Leiderdorp, Netherlands*

Background: Mammography, combined with ultrasound (US), remains the mainstay for breast cancer detection but has its limitations in certain situations like dense breasts. Although MRI can be used as an adjunct modality, its major limitation is the poor specificity. Molecular breast imaging techniques, such as breast-specific gamma imaging (BSGI), are increasingly being used as adjunctive diagnostic techniques to mammography and ultrasound. In this study we tried to determine the possible impact of BSGI on the management of the breast patient population especially the group with indeterminate breast lesions. For this group national guidelines advocate repeated imaging within 1 year which keeps the individual patient in uncertainty for that long period.
Method: Data were analysed from all patients who where referred for BSGI in the period from January 2011 until August 2012 presenting with indeterminate breast lesions, defined as breast lesions classified as BI-Rads 3 on mammography, ultrasound and/or MRI. In these patients a BSGI scan was performed and images classified according to the functional grading system as defined by the Society of Nuclear Medicine. These findings were registered and if necessary further analysis was performed and recorded. Pathologic analysis after second look ultrasound or BSGI guided biopsy was performed in case of upstaging. If biopsy was not conducted, follow-up imaging after 1 year was used as the reference standard.
Results: In total 55 patients were included in the study. The prevalence of malignancy in this group was 5 patients (9.1%) In 10 patients resulted in upstaging, of whom 4 showed a malignancy = 40%. In 17 the BI-Rads classification remained 3 and follow-up took place. Repeated imaging showed one malignancy within 1 year. In the remaining 28 patients the suspicion level was downgraded tot BI-Rads 1 or 2 and after repeated imaging no further pathology was demonstrated.
Sensitivity for the BSGI scan in this study is 80%, specificity 88%. The positive predicted value is 40% whereas its negative predictive value 98%.
Conclusion: Breast-specific gamma imaging could play an important role in the management of patients with indeterminate findings in the breast, mainly due to its high negative predictive value. Positive findings need to be confirmed by histology. But if downstaging takes place the individual patient can be successfully reassured and repeated imaging is not necessary.
No conflict of interest.

1974 POSTER

Incidence of bone pain in patients with breast cancer treated with balugrastim or pegfilgrastim: An integrated analysis from the phase II and III studies

O. Gladkov[1], C. Volovat[2], A. Buchner[3], S. Barash[4], H. Voliovitch[5], T. Erez[5], N. Lang[3], N. Avisar[5], I. Bondarenko[6]. [1]*Oncology Center Chelyabinsk, Chelyabinsk, Russian Federation;* [2]*Centrul de Oncologie Medicala, Iasi, Romania;* [3]*Teva Ratiopharm, Ulm, Germany;* [4]*Teva Biopharmaceuticals Inc., Rockville, USA;* [5]*Teva Pharmaceuticals Inc., Netanya, Israel;* [6]*Dnipropetrovsk State Medical Academy, Dnipropetrovsk, Ukraine*

Background: Balugrastim is a once-per-cycle, fixed-dose human recombinant protein composed of human serum albumin and granulocyte-colony stimulating factor (G-CSF) developed as an alternative to pegfilgrastim (Neulasta®) for the prevention of severe neutropenia in cancer patients receiving chemotherapy (CTx). All G-CSF products have the potential to cause bone pain, which is generally transient in nature and mild to moderate in intensity. Using data from a Phase II and a Phase III study in patients with breast cancer receiving CTx, we compared the incidence of bone pain-related (BPR) symptoms in patients treated with balugrastim versus those treated with pegfilgrastim and the relation to G-CSF treatment and CTx.
Methods: All patients received CTx (doxorubicin 60 mg/m^2 + docetaxel 75 mg/m^2) and at least one subcutaneous injection of balugrastim 30, 40, or 50 mg or pegfilgrastim 6 mg on Day 2 of each cycle for up to four cycles. The incidence and severity of treatment-emergent adverse events (TEAEs) were recorded up to 30 days after the last dose of study medication. BPR TEAEs comprised the preferred terms arthralgia, back pain, bone pain, musculoskeletal chest pain, musculoskeletal discomfort, musculoskeletal pain, myalgia, neck pain, non-cardiac chest pain, and pain in extremity. All BPR TEAEs designated by the investigator as related to G-CSF or CTx treatment were defined as TEAE drug reactions (TEADRs).
Results: No BPR TEAEs were serious or led to study discontinuation. A relationship was observed between balugrastim dose and the number of patients experiencing G-CSF-related BPR TEADRs. These TEADR rates were 0.0%, 8.1%, and 12.5% for balugrastim 30 mg (n = 10), 40 mg (n = 335), and 50 mg (n = 104) groups, respectively (pooled rate of 8.9%, N = 449), compared with 6.1% for the pegfilgrastim group (N = 262). CTx-related BPR TEADRs were experienced by 10.0%, 17.0%, and 23.1% of patients in the balugrastim 30, 40, and 50 mg groups, respectively, resulting in a pooled rate of 18.3% for all balugrastim doses compared with 14.1% of patients in the pegfilgrastim group.
Conclusions: The incidence and severity of G-CSF-related bone pain symptoms were low and comparable between the pooled balugrastim and pegfilgrastim treatment groups. The incidences of CTx-related bone pain symptoms were comparable between the pooled balugrastim and pegfilgrastim treatment groups and as expected for patients with breast cancer.

1975 POSTER

Controversial issues in early stage breast cancer: ESMO and Jules Bordet Institut collaborative survey

D. Zardavas[1], F. Ades[1], I. Bozovic-Spasojevic[1], L. Pugliano[1], M. Capelan[1], M. Paesmans[2], E. De Azambuja[1], M. Piccart[1]. [1]*Institut Jules Bordet, Medical Oncology, Bruxelles, Belgium;* [2]*Institut Jules Bordet, Data Centre, Bruxelles, Belgium*

Background: Knowledge of early-stage breast cancer represents a dynamically evolving field. However, several clinical issues remain unresolved and the use of recent advances remains heterogeneous. This survey explored the current clinical practice in the management of early-stage breast cancer patients, identified areas of controversies and interrogated how treating physicians implement newest advances.
Methods: We conducted a 27-item survey. Multiple choice questions captured demographic characteristics of the participants and addressed multiple issues of clinical management. We followed a 2-stage dissemination of the survey: paper distribution at selected breast cancer track sessions at ESMO 2012 Congress, and dedicated mailing messages to ESMO members with interest in breast cancer. Descriptive statistical analysis was applied as well as logistic regression analysis exploring potential associations between the demographic characteristics of the participants and the replies provided. To this end, we defined what we considered as correct answers according to the level of evidence from the literature.
Results: A total of 512 physicians from 79 countries participated in the study, with 465 (91%) fully completed questionnaires. The majority of the participants were ESMO members (66%), medical oncologists (86.5%), working in multidisciplinary teams (91.6%). Heterogeneous results were captured, as the following: 40.9% of the participants consider no genetic test useful for adjuvant treatment decisions; 15.3% consider PET-CT a useful imaging modality for staging; 68.8% consider that postmenopausal patients with hormone receptor positive disease should always be offered an aromatase inhibitor as part of their adjuvant therapy; 78.7% prefer to administer trastuzumab concurrently with the taxane component of chemotherapy; and 27% would consider bevacizumab in the neoadjuvant setting. The logistic regression analysis did not identify any strong predictor of the probability to give a reply fully compatible with the literature evidence.
Conclusions: This study captures the clinical practice and the implementation of newest advances in early stage breast cancer across an extended number of treating physicians, with significant individual differences. Areas of controversy were detected and they deserve further exploration for the generation of 'tailored' educational tools, with the final goal being the standardization of the treatment of early-stage breast cancer.
No conflict of interest.

1976 POSTER

Comparison of Axillary nodal status between clinical, PET scan and pathological staging in breast cancer

P. Rajkumar[1], A. Sripriya thiruvengadathan[2], A.C. Sureshkumar[3]. [1]*Dr. Kamahsi Memorial Hospital, Chennai, India;* [2]*Dr. Kamahsi Memorial Hospital, Radiology, Chennai, India;* [3]*Dr. Kamahsi Memorial Hospital, Nuclear Medicine, Chennai, India*

Background: Axillary lymph node dissection in breast cancer patients poses significant morbidity. Even though sentinel lymph node can determine the earliest metastases and guide in avoiding axillary dissection, still it is an invasive procedure. We have studied the sensitivity and specificity of PET scan in determining the axillary nodal metastases.
Materials and Methods: All breast cancer patients non metastatic at presentation were evaluated. Patients who found to have distant metastases/supraclavicular nodes during workup were excluded. Over a period of one year 45 patients without any distant metastases at presentation were worked up with 18-FDG PET scan. Those who had distant metastases or N3 disease were excluded. The clinical axillary nodal was then compared with PET scan status of the axillary nodes. All the 45 patients then underwent modified radical mastectomy and axillary nodal clearance from level I–III. Standard histopathological examination was carried out in all the patients and this pathological N status was compared with clinical and PET scan results.
Results: The above results were then analyzed with Bayesian statistical analyzer. The sensitivity and specificity of clinical examination alone in detecting pathological nodes was 54%and 74% respectively whereas that with PET scan was 83% and 82% respectively. Two of the false positive PET patients were with h/o autoimmune disease.

PET and Path. N status Clinical Vs pathological N status

	pN+	pN−	Total
Clinical			
cN+	14	5	19
cNo	12	14	26
Total	26	19	45
PET scan			
Positive	19	4	23
Negative	4	18	22
Total	23	22	45

Conclusion: 18-FDG PET scan has high sensitivity and specificity in detecting pathological axillary nodes compared to clinical examination alone. Future studies comparing sentinel lymphnodes and PET scan are required to find their exact specificity. Results in patients with autoimmune disorders have to be interpreted with caution.
No conflict of interest.

1977 POSTER

Correlation and prognostic significance of lymphangiogenesis and vascularity in breast cancer

V. Srivastava[1], V. Singh[1], M.A. Ansari[1], A. Kumar[1]. [1]*Institute of Medical Sciences, Surgery, Varanasi, India*

Background: Prognostic markers predict the clinical course and subsequent outcome in cancer patients. Lymph node metastasis is the most

important prognostic marker in breast cancer and lymphatic microvessel density (LMVD) along with lymphatic vessel invasion (LVI) can serve as a proxy prognostic marker to lymph node involvement. Tumour vascularity is the key factor responsible for tumour growth and metastasis which can serve as a prognostic marker. Color Doppler ultrasonography parameters of vascularity can be measured by resistivity index (RI), pulsatility index (PI) and maximum flow velocity (Vmax). The correlation between lymphangiogenesis and angiogenesis in breast cancer has not been studied till date.
Methods: We studied the correlation of LMVD and LVI by immunohistochemistry using D2−40 antibody with colour Doppler ultrasonography findings in 30 early invasive breast cancer patients. The patients were classified as low or high category (lymphangiogenesis and vascularity) based on their mean value. The LMVD, LVI and colour Doppler parameters were correlated with each other and also with other clinico-pathological parameters.
Results: The mean ± Standard Deviation (SD) of age was 44.40±10.37 years. The mean±SD of LMVD, RI, PI and Vmax were 8.37±2.59, 0.89±0.12, 2.42±0.12 and 20.80±8.27 respectively. There was a significant correlation between LMVD with RI (r 0.596; p 0.001) and PI (r 0.573; p 0.001), LVI with RI (r 0.418; p 0.022) and between LMVD and LVI (r 0.503 p 0.022). Tumour size, number of positive lymph nodes, grade of tumour and receptor status correlated with RI, PI, LMVD and LVI (p value <0.05) but not with Vmax.
Conclusion: The result of present study supports the positive correlation between lymphangiogenesis (LMVD and LVI) using D2−40 antibody and RI and PI by Doppler study in breast cancer. Further these parameters also correlate with clinico-pathological parameters.
No conflict of interest.

1978 POSTER

Overexpression of P53 is prognostic for aromatase inhibitor (AI) resistance in early stage postmenopausal patients with ER-positive breast cancer: A retrospective analysis in AI-treated patients

X.Q. Jia[1], Q. Hong[1], J.Y. Cheng[2], J.W. Li[1], Y.J. Wang[1], M. Mo[3], Z.M. Shao[1], Z.Z. Shen[1], G.Y. Liu[1]. *[1]Shanghai Cancer Center, Breast Surgery, Shanghai City, China; [2]Shanghai Cancer Center, Nuclear Medicine, Shanghai City, China; [3]School of Public Health, Fudan University, Epidemiology*

Background: Studies have demonstrated that P53 overexpression is a significant factor in predicting resistance to 3rd generation aromatase inhibitors (AI) in hormone-sensitive recurrent or advanced breast cancer, however, the prognostic significance of P53 in early stage breast cancer is uncertain.
Patients and Methods: Patients who received aromatase inhibitors (n = 293) with complete baseline data in the Cancer Hospital of Fudan University, Shanghai, China between 2000 and 2006 were included. All patients were postmenopausal with positive ER and/or PgR tumors. The clinicopathological factors included the following: age, hypertension, DM, TNM stage, histology grade, vascular invasion, lymph node status, P53 status, PR, HER2/neu, chemotherapy and radiotherapy. The expressions of PR, p53 and HER2 were evaluated by immunostaining. The disease-free survival (DFS) was compared. Survival analysis was performed using Kaplan–Meier method. Cox proportional hazards models were used to evaluate the prognostic value of P53 expression for DFS. The p-values less than 0.05 were regarded as significant.
Results: The median follow-up was 72 months (range, 6–140 months). Only 4 of 12 variables analysed remained significantly prognostic for survival in the Cox proportional hazards model. These included age (HR = 1.988, 95% CI = 1.511–2.617, P < 0.005); pathological stage (HR = 2.270, 95% CI = 1.399–3.681, P =0.001); histological grade (HR = 2.328, 95% CI = 1.312–4.133, P =0.004); and P53 expression (HR = 1.729, 95% CI = 1.038–2.880, P =0.035). The 5-year disease free survival rate in P53 positive and P53 negative patients were 78% and 89%, respectively.
Conclusion: This retrospective analysis demonstrates that P53 overexpression correlated strongly with AI resistance in early stage postmenopausal patients with ER-positive breast cancer patients who were treated with AI and confirmed the relevance of previously described prognostic factors. If validated by larger studies, the p53 overexpression may become a key factor in determining treatment strategies for postmenopausal hormone-sensitive disease.
No conflict of interest.

1979 POSTER

Sleep disturbances and changes in the urinary metabolite of melatonin (aMT6s) levels in patients with breast cancer undergoing lumpectomy

M.V. Hansen[1], M.T. Madsen[2], G. Wildschiødtz[3], J. Rosenberg[1], I. Gögenur[1]. *[1]Herlev University Hospital, Department of Surgery, Herlev, Denmark; [2]Herlev University Hospital, Department of Breast Surgery, Herlev, Denmark; [3]Rehabilitation- and Research Centre for Torture Victims, Rehabilitation- and Research Centre for Torture Victims, Copenhagen, Denmark*

Background: Sleep disturbances and changes in self-reported discomfort and melatonin secretion are common in the postoperative period. We aimed to study the distribution of sleep stages in the pre- and postoperative period and evaluate changes in the secretion of the melatonin metabolite aMT6s and subjective parameters of sleepiness, pain, general well-being and fatigue in patients undergoing breast cancer surgery.
Materials and Methods: Twelve patients, 30−70 years, undergoing a lumpectomy were included in the study. PSG monitoring was made the night before surgery (PREOP), the night after surgery (PO1) and approximately 14 days after surgery (PO14). Recordings were scored as awake, light sleep (stage 1 and 2), slow wave sleep (stage 3 and 4) and rapid eye movement (REM) sleep. Sleep stages were analyzed as percent of total sleep time. Self-reported discomfort was assessed using questions about the level of fatigue, general well-being and pain and sleepiness was assessed by Karolinska Sleepiness Scale. Urinary aMT6s was measured by a radioimmunoassay.
Results: Table 1 shows sleep data. There was significantly decreased REM sleep on PO1 (5.9% of total sleep time) compared with the night before surgery (18.7% of total sleep time) (p < 0.005). Patients had fewer episodes of REM sleep on PO1 compared with PREOP (p < 0.005). An increase in light sleep was observed on PO1 (68.4% of total sleep time) compared with the night before surgery (55.0% of total sleep time) (p < 0.05). No significant changes in total sleep time, sleep latency, sleep period or total time awake were found. The observed sleep changes were normalized after two weeks. No significant changes were found in pain, general well-being, fatigue or sleepiness. aMT6s night secretion showed a non-significant trend towards a decrease from PREOP to PO1 (p = 0.09) and a normalization on PO14 (p < 0.05 between PO1 and PO14).
Conclusion: Patients with breast cancer undergoing a lumpectomy had significantly disturbed sleep architecture the night after surgery and these changes were normalized after two weeks.
Trial registration: Clinicaltrials.gov identifier: NCT01171508

Lack of circadian variation and reduction of heart rate variability in women with breast cancer undergoing lumpectomy

M.V. Hansen[1], J. Rosenberg[2], I. Gögenur[2]. *[1]Herlev University Hospital, Department of Breast Surgery, Herlev, Denmark; [2]Herlev University Hospital, Department of Surgery, Herlev, Denmark*

Background: Changes in the autonomic nervous system with increased sympathetic tone may be a cause of postoperative short-, and long-term cardiovascular complications. Heart rate variability (HRV) is assessed by Holter-monitoring as a measure of autonomic tone and has not been investigated in patients with breast cancer undergoing surgery. We aimed to investigate evening- and night-time HRV after lumpectomy.
Material and Methods: Twelve patients were included in this descriptive study. HRV was measured the night before surgery (PREOP), the night after surgery (PO1) and 14 days after surgery (PO14) from 1900 h-0700 h.

For calculation of HRV, time domain parameters (SDNN-standard deviation of all NN intervals around the mean NN for the period of measurement, pNN50-percentage of beats where the change from one beat to the next is more than 50msec, rMSSD-root mean square of successive differences) were used. We analyzed the variation of the overall time period and the circadian variation between evening and night (sympathetic vs. parasympathetic tonus).

Results: Table 1 shows mean heart rate and time domain parameters (SDNN, pNN50, rMSSD) for overall time-period 19−07 on PREOP, PO1 and PO14. Mean heart rate increased from PREOP to PO1 ($p < 0.001$) and also increased between PREOP and PO14 ($p < 0.05$). SDNN ($p < 0.001$) and PNN50 ($p < 0.001$) decreased from PREOP to PO1. There was also a significant decrease between PREOP and PO14 for both parameters ($p < 0.005$ and $p = 0.05$ respectively). SDNN increased from PO1 to PO14 ($p < 0.005$). rMSSD decreased from PREOP to PO1 ($p < 0.001$). A circadian variation was found in the mean heart rate for all 3 monitoring periods ($p < 0.005$). Circadian variation was also present on PREOP for pNN50 ($p \leqslant 0.05$) and rMSSD ($p < 0.05$). This variation was missing for both PO1 and PO14.

Conclusion: Patients had a shift of autonomic tone with reduced parasympathetic activity and lack of circadian variation 14 days after lumpectomy.

Trial registration: Clinicaltrials.gov identifier: NCT01171508

No conflict of interest.

Table 1. Mean heart rate and time domain parameters (SDNN, pNN50, rMSSD) for overall time-period 19−07 on PREOP, PO1 and PO14

	PREOP	PO1	PO14	Repeated measures test
Mean heart rate	68 (49–110)[a]	72 (51–105)	70 (49–101)[c]	<0.001
SDNN (ms)	44 (20–164)[a]	36 (9–166)[b]	42 (9–112)[d]	<0.001
pNN50 (%)	6.4 (0–42.1)[a]	1.5 (0–52.0)	3.5 (0–38.5)[c]	<0.001
rMSSD (ms)	29 (11−94)	23 (7−99)	26 (7−79)	<0.05

Values are median (range). P-values (Wilcoxon Signed-Rank test and Friedman analysis of variance) $\leqslant 0.05$ are shown. Comparisons were made between PO1 versus PREOP, PO14 versus PREOP and PO14 versus PO1. Only significant changes are depicted in the table.

[a] p <0.001, PO1 vs. PREOP.
[b] p <0.005, PO14 vs. PO1.
[c] $p \leqslant 0.05$, PO14 vs. PREOP.
[d] p <0.005, PO14 vs. PREOP.

1981 POSTER

Prognostic value of Ki67LI in HER2 negative luminal (HNL) early breast cancer (EBC): A single institution experience with long follow up

A. Ferro[1], L.M. Russo[1], C. Eccher[2], R. Triolo[1], A. Caldara[1], M.C. Dipasquale[1], M. Barbareschi[3], M.V. Cuorvo[3], E. Galligioni[1]. *[1]Santa Chiara Hospital, Medical Oncology, Trento, Italy; [2]FBK, Oncology, Trento, Italy; [3]Santa Chiara Hospital, Pathology, Trento, Italy*

Background: Several studies have emphasized Ki67LI biologic and prognostic value and its potential application of its assessment in routine practice, particularly to define prognostic subgroups of luminal/hormone receptor-positive (HR+) tumors.

Methods: Ki67LI was identified by immunohistochemical staining in 3760 EBC pts treated from 1995 to 2008 in our institution. Median age was 61 y. The relationship with clinic-pathological parameters and the prognostic significance of KI67LI were investigated in all EBCs and in HER2 negative luminal (2380 HNL) cases stratified on homogeneous grading (594 G1, 1282 G2, 504 G3).

Results: Median Ki67LI values were 22% in all cases, 20% in HNL and 10, 20 and 35% in different HNL grading group (HNL-GG). Ki67LI >22% (1873 pts) was significantly ($p < 0.001$) associated with younger age, ductal type, greater size, positive N, poor G, absent or low ER /PR level, positive HER-2 status, triple negative subtypes. Local and Distant Relapses were 138 (7.3%) and 355 (18.9%) in < or >22% Ki67LI respectively. Median time to first event was 31.7 ms in >22% *vs* 50.1 ms in <22% Ki67.

At median f-up of 77 months EFS and OS were 91.9 and 92.1% in <22% *vs* 78.9% and 81% in >22% Ki67 respectively ($p < 0.001$).

Prognosis in term of DFS and OS was consistently worse for >22% compared to <22% Ki 67 in all clinical-pathological subsets, except in negative ER Group. In multivariate analysis, KI 67mantained an independent prognostic significance for DFS and OS.

In HNL, EFS and OS were 93.7 and 92% in <20% *vs* 81.7 and 83.3% in >20% Ki67($p < 0.001$). Using median ki67LI value for different homogenous HNL-GG as cutoffs, we stratified these populations in low and high risk. The results are shown in the table.

Conclusions: Our study confirms prognostic value of Ki67LI in EBC, associated with other clinical-pathological characteristics. Cutoffs are different into HNL-GG. They can cathegorize at least two biological entities in every grading group providing additional prognostic information in planning therapies and outcome prediction.

Comparative study of the follow-up of long-term survivors of breast cancer in primary-care versus specialist attention

P. Ramírez Daffós[1], S. Estalella[2], P. Rosado[2], C. Cortes[2], E. Arriola[2], A. Rueda[2], J.A. Contreras[2], J.M. Baena[2]. *[1]Hospital Puerta Del Mar, Cadiz, Spain; [2]Hospital Puerta Del Mar, Medical Oncology, Cadiz, Spain*

Background: We sought to describe the long-term breast cancer survivors evolution according to type of care provided (primary or specialized follow-up), measuring the impact on health outcomes, cost, quality of life and satisfaction.

Material and Methods: Retrospective cohort study with disease-free patients followed in Oncology for at least 5 years. Using personal survey, the type and cost of follow-up, events, quality of life and satisfaction were analyzed, depending on whether they had been referred for primary care or followed in Oncology.

Results: 98 women were interviewed, 60 from primary care and 38 from specialized care. No differences in the diagnosis of metastases and new primary tumors were found. 0.98 (0.48) visits per patient and year were conducted in primary care and 1.11 (0.38) in specialized ($p = 0.19$). In primary, 44.6% were scheduled, and 55.4% were unscheduled. In specialized, 94.6% were scheduled, and 5.4% were unscheduled ($p = 0.0001$). The primary follow-up costs were lower, with 112.86 € (77.54) vs 184.61 € (85.87) per patient and year ($p = 0.0001$). No differences in quality of life were observed. 80% of patients expressed a preference for specialized, 10% for primary and 10% were indifferent. Women were more satisfied with specialized in all dimensions of the questionnaire.

Conclusions: Adherence to follow-up protocol was high in both areas. Specialized care visits were mainly scheduled and almost half of primary care visits were unscheduled. In our setting, primary care is more efficient than specialized, but women express greater satisfaction and prefer specialized follow-up.

No conflict of interest.

Guidelines for time-to-event endpoints' definitions in cancer randomized controlled trials (RCTs) for breast cancer − results of the DATECAN initiative (Definition for the Assessment of Time-to-event Endpoints in CANcer trials)

S. Gourgou-Bourgade[1], S. Dabakuyo-Yonli[2], D. Cameron[3], F. Cardoso[4], P. Poortmans[5], B. Asselain[6], D. Azria[7]. *[1]Institut du Cancer de Montpellier (ICM)- Val d'Aurelle, Biostatistics Unit, Montpellier, France; [2]Centre Georges-François Leclerc Regional Comprehensive Cancer Center, Biostatistics unit, Dijon, France; [3]Western General Hospital, Medical Oncology, Edinburgh, United Kingdom; [4]Champalimaud Cancer Center, ESO Breast Cancer Program Coordinator, Lisbon, Portugal; [5]Institute Verbeeten, Radiation Oncology, Tilburg, Netherlands; [6]Institut Curie, Biostatistic Unit, Paris, France; [7]Institut du Cancer de Montpellier (ICM)- Val d'Aurelle, Radiation Oncology, Montpellier, France*

Background: With the necessity of reducing randomized clinical trial (RCT) duration, cost and number of patients, surrogate endpoints are increasingly being used as replacement for overall survival (OS) in cancer RCTs. However, most of these endpoints currently lack of standardized definition enabling a comparison of RCT results. Some recommendations have been proposed for specific cancer sites but they do not rely on a formal consensus methodology. The objective of the DATECAN initiative (Definition for the Assessment of Time-to-event Endpoints in CANcer trials) is to provide guidelines to standardize definitions of time-to-event (TTE)

endpoints in RCTs for different cancer sites. We present results for Breast cancer (BC) (similar abstract submitted for Sarcoma and GIST).
Methods: We relied on the modified Delphi consensus method, a validated formalized consensus process for the development of practice guidelines. International experts with various backgrounds and expertise were involved. First, the coordinating committee, a group of statisticians and epidemiologists involved in the design and conduct of RCTs, led a comprehensive literature review to identify the existence of guidelines or TTE endpoints and clinical events of interest. The steering committee, which included additional medical experts prepared the questionnaire based in part on Hudis et al. proposal (JCO 2007) and sent for rating to an independent expert committee.
Results: The consensus process involved two rounds of rating (31 experts) and one in-person meeting (Chicago 2012). Each expert had to rate on a 1−9 scale if s/he agreed to include clinical events (e.g. death from BC) in the definition of TTE endpoints (e.g. progression-free survival). Consensus was reached for 57% of the events after the rounds of rating and was finalized at the meeting for the remaining events except one. Guidelines for the definition of 11 TTE endpoints were established (e.g. disease-free survival, time-to-progression, etc) in adjuvant or metastatic settings.
Conclusions: The DATECAN guidelines should help standardize definitions of commonly used TTE endpoints. They should (i) facilitate the comparison of RCTs, (ii) improve the quality of trial reporting and (iii) improve the quality of future RCTs. These guidelines will be presented at ASCO'13. However, communicating about these recommendations at ESMO/ECCO is also a key step towards wide scale dissemination and implementation of these guidelines.
No conflict of interest.

1984 POSTER

Expression of androgen receptor in breast cancer in younger age with special relation to molecular subtypes and response to anterior chemotherapy

A.A. Agarwal[1], A.A. Sonkar[1], J.K. Kushwaha[1], N. Hussain[2]. *[1]King George's Medical University, Surgery, Lucknow, India; [2]RML Institute of Medical Sciences, Pathology, Lucknow, India*

Background: Breast cancer, a heterogeneous disease comprises different tumour subtypes associated with varied clinical characteristics. Prognostic factors including age, tumour size, histological subtype and grade, lymph node status and the expression of estrogen receptor (ER), progesterone receptor (PR) and human epidermal growth factor receptor 2 (HER2) currently assist routine clinical management. Breast cancer in younger age BCYA (under 40 years old) has different clinicopathological characteristics than in the elderly, a more aggressive phenotype with a larger tumor size, more lymph node involvement, and advanced stages. Despite adjuvant treatment recurrence, metastasis and death were still higher than in elderly patients. In the present study an attempt has been made to evaluate AR expression in BCYA and response to taxane and/or anthracycline based standard chemotherapy regimen.
Materials and Methods: Between May 2011 and Sept 2012, 116 breast cancer patients were enrolled. Tissue sections were immunostained for ER, PR, Her2 Neu and AR. n = 35 patients with BCYA were sub-grouped. n = 24 patients were subjected to neoadjuvant taxane and/or anthracycline based chemotherapy according to standard treatment guidelines. Clinical response was evaluated using revised RECIST guidelines (version 1.1).
Results: Mean age of presentation was 36.1 years (20−40 years) with 22/35 (62.9%) BCYA AR+ve. In particular, AR expression was commonly observed in luminal A 9/11 (81.8%) and B 5/7 (71.4%) cancers, but was less frequently seen in HER2 cancers 6/11 (54.5%). Despite being defined by the absence of ER, PR and Her2 neu expression and being considered hormonally unresponsive, 2/6 (33.3%) of TNBC expressed androgen receptor. 24/35 (68.6%) BCYA were given NAC, 12/24 (50%) were AR positive. BCYA AR+ve showed better response to NAC as 10/18 (55.5%) were partial or complete responders compared to 2/6 (33.3%) showing stable or progressive disease.
Conclusion: Expression of AR is seen in approximately two-third of BCYA, with positively stained BCYAs showing to have better response to chemotherapy; providing further evidence that BCYAs represent a heterogeneous group. As AR is confirmed as biologically relevant in breast cancer, it is possible that hormonal manipulations targeting it could be useful in treatment but large sample size is needed to deduce the final statement.
No conflict of interest.

1985 POSTER

Clinical impact of breast specific gamma imaging on the surgical management of patients with proven breast cancer

P. Neyenhuis[1], F. Smit[2], A.F. Van der Hoeven[2], A.M. Zeillemaker[1], L.M.H. Wijers[3], L.M. Pereira Arias-Bouda[2]. *[1]Rijnland Hospital, General Surgery, Leiderdorp, Netherlands; [2]Rijnland Hospital, Nuclear Medicine, Leiderdorp, Netherlands; [3]Rijnland Hospital, Radiology, Leiderdorp, Netherlands*

Background: Mammography, combined with ultrasound (US), remains the mainstay for breast cancer detection, MRI can be used as an adjunct modality for surgical planning but its major limitation is the poor specificity. Molecular breast imaging techniques, such as breast-specific gamma imaging (BSGI), are increasingly being used as adjunctive diagnostic techniques to mammography and ultrasound. In this study we tried to determine the possible impact of BSGI in assisting surgical planning.
Method: Data were analysed from all patients who where diagnosed with invasive breast cancer and planned for surgical treatment the period from January 2012 until April 2013. Patients who obviously had an indication for a mastectomy where excluded as no BSGI scan was performed in these patients. After diagnosis a BSGI scan was performed and the results were analyzed. If necessary additional imaging and if indicated biopsy was performed. Depending on these additional results the surgical strategy was altered.
Results: In total 232 patients were diagnosed with breast cancer in this study. In 186 a BSGI scan performed of which 39 demonstrated a mismatch with the conventional imaging. In 18 patients =9.7% additional cancer sites, 7 ipsilateral and one contralateral or a larger tumor area in 7 patients were demonstrated and proven by biopsy. In 3 patients conventional imaging remained equivocal and the malignancy was only demonstrated with BSGI scan. In these patients surgical management was altered. In 10 patients additional lesions could not be proven on second look imaging. In 2 of those patients malignancy could only be proven by BSGI guided biopsy. On the other side BSGI failed to visualize 11 lesions, which were detected on conventional imaging. These consisted of grade 1 invasive carcinomas in 5 patients, ductal carcinoma in situ in 5 patients and a <5 mm grade 2 invasive tumor in one patient. The sensitivity and specificity of BSGI in this study were 46% and 93% respectively.
Conclusion: Breast-specific gamma imaging could play an important role in the management of patients with proven malignancy of the breast by detecting synchronous lesions that altered patient surgical management. Its high specificity makes it a better additional tool for surgical planning than the MRI.
No conflict of interest.

1986 POSTER

Retrospective multivariate analysis of risk factors of breast cancer in a high-risk population using a logistic regression model

F. Lumachi[1], D.A. Santeufemia[2], S. Tumolo[2], G. Lo Re[2], E.M. Pasqual[3], G.B. Chiara[4], S.M.M. Basso[4]. *[1]University of Padua School of Medicine, Department of Surgery Oncology & Gastroenterology, Padova, Italy; [2]S. Maria degli Angeli Hospital, Medical Oncology, Pordenone, Italy; [3]S. Maria della Misericordia Hospital, Department of Surgery, Udine, Italy; [4]S. Maria degli Angeli Hospital, Surgery 1, Pordenone, Italy*

Background: Breast cancer (BC) is the most common malignancy among women in western society, and its prevalence varies widely in different Countries. Several risk factors (RF) have been reported, but none was able to give reliable epidemiological information on clinical outcome for each patient population. The aim of this study was to provide information about relationship between BC and different RF to be considered at the time of diagnosis in women residing in a high-risk region of Italy.
Patients and Methods: The study included 375 BC cases (median age 60 years, range 26−89) and 1,261 population-based age-matched controls. All patients lived in the same urban area and underwent clinical breast examination spontaneously. Patients with other or previous cancer were excluded. The following parameters were considered: age, family history of BC, menstrual and reproductive factors (age at menarche, menstrual pattern, number of births and abortions, age at first birth, lactation), use of oral contraceptives and hormonal replacement therapy, smoking, alcohol consumption, occupational and sedentary activity, body mass index (BMI).
Results: Univariate analysis showed significant differences ($p < 0.01$, Student's t-test and chi-squared test) between cases and controls in: (1) age at menarche (12.3±1.6 vs. 12.7±1.5 years) and menopause (49.5±4.1 vs. 47.3±5.3 years), (2) number of births (1.4±1.1 vs. 1.8±1.3) and age of first birth (25.2±4.3 vs. 24.4±3.6 years), (4) estrogen replacement therapy (43.9±30.3 vs. 33.7±28.1 months), (5) smoking (5.9% vs. 12.5%), and (6) alcohol abuse (5.7% vs. 2.3%). Multivariate analysis using a logistic regression model showed that only

four independent parameters correlated with BC: age at menarche (years), number of births, lactation, and estrogen replacement therapy. Odds ratio for BC calculated from the observed vs. predicted values obtained using the logistic regression function was 5.05 (95% CI 3.6−7.1), while the OR of single variables was <3 (95% CI 1.51–4.32).
Conclusions: The results display that the prolonged (>3 years) use of estrogen replacement therapy, is strongly related to the onset of BC. However, in this study, many classical parameters did not result useful as RF, suggesting that to correctly select the high risk population both different primary RF and other environmental and external factors should be considered for each patient.
No conflict of interest.

1987 POSTER

Validation and calibration of breast cancer nomogram for predicting risk of ipsilateral breast tumour recurrences in asian population with ductal carcinoma in situ after local excision

F. Wang[1], H.H. Li[2], P.H. Tan[3], F.Y. Wong[4]. [1]*National Cancer Centre, Singapore, Singapore;* [2]*Singapore General Hospital, Clinical Research, Singapore, Singapore;* [3]*Singapore General Hospital, Pathology, Singapore, Singapore;* [4]*National Cancer Centre, Radiation Oncology, Singapore, Singapore*

Background: Over a quarter of screen detected breast cancers in Singapore are ductal carcinoma in situ (DCIS). At our centre, DCIS is commonly treated with wide excision followed by adjuvant radiotherapy, i.e. breast conservation therapy (BCT). The primary concern of BCT is the risk of ipsilateral breast tumour recurrences (IBTR). The aims of our study are to review the outcomes of DCIS treatment in our patients and to evaluate a recent nomogram for predicting IBTR from Memorial Sloan-Kettering Cancer Centre (MSKCC) in our Asian population.
Methods: Chart reviews of 716 patients with pure DCIS treated from 1992 to 2011 were performed. Univariable Cox regression analyses were done to evaluate the effect of the ten prognostic factors of the MSKCC nomogram on IBTR. NCCS nomogram was generated based on multivariable Cox regression via reduced model selection by applying the stopping rule of Akaike's information criterion to predict IBTR free survival. The abilities of NCCS nomogram and MSKCC nomogram to predict IBTR of individual patients were evaluated with bootstrapping of 200 sets of resamples and NCCS dataset, respectively. An adequacy index was used to quantify the percentage of the variation explained by a subset of predictors (NCCS nomogram and MSKCC nomogram separately) compared with the information contained in the full set of predictors (both NCCS and MSKCC nomogram) by means of log likelihood. Harrell's c-index was calculated for each nomogram to evaluate the concordance between predicted and observed responses of individual subjects.
Results: The study cohort was followed up for a median of 70 months. Over 95% of patients received adjuvant radiotherapy. The 5-year and 10-year actuarial IBTR free survival rates for the cohort were 95.5% and 92.6% respectively. In the multivariable analysis, independent prognostic factors for IBTR include use of adjuvant endocrine therapy, presence of comedonecrosis and younger age at diagnosis. These factors formed the basis of our NCCS nomogram. Similar C-index (NCCS: 0.696; MSKCC: 0.687) and adequacy index (NCCS: 81.1%; MSKCC: 79.4%) of the nomograms suggests similar power of the NCCS nomogram in predicting IBTR despite including fewer predictors.
Conclusion: Local results of DCIS treated with BCT are comparable to published studies. External validation of the MSKCC nomogram on our cohort of Asian patients demonstrates predictive power similar to that of the NCCS nomogram which uses fewer prognostic factors.
No conflict of interest.

1988 POSTER

p53 protein expression in early breast cancer (EBC) and its correlation with molecular features

G. Giardina[1], R. Gueli[1], S. Gobba[1], I. Vallini[1], D. Boghi[1], A. Pastore[1], G. Pinotti[1]. [1]*Ospedale di Circolo − Fondazione Macchi, Medica Oncology, Varese, Italy*

Background: The p53 gene is located on chromosome 17p13 and encodes a 53-kDA nuclear phosphoprotein that is essential in regulation of the cell cycle. It has been suggested that wild type p53 is a 'guardian of the genome' preventing proliferation of cells with genetic damage. Alterations in this gene are reported in nearly a third of all EBC and loss of p53 function seems to result in a more aggressive disease and worse clinical outcome. The prognostic and predictive role of p53 in EBC is still uncertain and the rate of p53 mutations vary depending upon the subtype.
The aim of our study was to correlate p53 expression with known prognostic factors.
Materials and Methods: In this retrospective study p53 immunohistochemical detection was performed in a series of consecutive patients (pts) with EBC over a period of 1 year. Prognostic factors such as hormonal receptors, HER-2 status and ki67 index were simultaneously measured; p53 was defined mutated with a nuclear staining >10%. Molecular subtypes were classified accordingly to St. Gallen 2011 criteria.
Results: From January 2012 to December 2012 p53 was measured in 287 pts, with a median age of 60 yrs (range 32−88): 223 pts (81%) had p53 $\leqslant$10% while 64 pts (19%) had p53 >10%. A significant correlation was found with ER negativity and Ki67 index.
The table shows the relationship between p53 expression and molecular subtypes.

	p53 $\leqslant$10%	p53 >10%	p value
Luminal A	*65 (95%)*	*4 (5%)*	*p < 0.0001*
Luminal B HER2−ve	*141 (87%)*	*22 (13%)*	*P < 0.0001*
Luminal B HER2+ve	*14 (61%)*	*9 (39%)*	*ns*
HER2+ve	*4 (40%)*	*6 (60%)*	*ns*
Triple Negative	*9 (41%)*	*13 (59%)*	*p < 0.0002*

Conclusions: Our study supports findings that p53 expression is highly linked to tumour subtypes, being significantly low in Luminal A and Luminal B-HER2−ve tumours and high in Triple Negative ones. According to these data the role of p53 as a prognostic factor should be reconsidered in EBC.
No conflict of interest.

1989 POSTER

Incidence of bone pain in patients with breast cancer treated with lipegfilgrastim or pegfilgrastim: An integrated analysis from the phase II and phase III studies

I. Bondarenko[1], P. Bias[2], R. Elsässer[2], A. Buchner[2]. [1]*Dnepropetrovsk Municipal Clinical Hospital 4, Dnepropetrovsk, Ukraine;* [2]*Teva ratiopharm, Ulm, Germany*

Background: Lipegfilgrastim is a once-per-cycle, fixed-dose glycoPEGylated granulocyte-colony stimulating factor (G-CSF) being developed as an alternative to pegfilgrastim (Neulasta®) for the prevention of severe neutropenia in cancer patients receiving chemotherapy (CTx). All G-CSF products have the potential to cause bone pain, which is generally transient in nature and mild to moderate in intensity. Using data from the Phase II and III studies in patients with breast cancer receiving CTx, we compared the incidence of bone pain-related (BPR) symptoms in patients treated with lipegfilgrastim versus those treated with pegfilgrastim and the relation to G-CSF treatment and CTx.
Methods: All patients who received CTx (doxorubicin 60 mg/m^2 + docetaxel 75 mg/m^2) and at least one subcutaneous injection of lipegfilgrastim or pegfilgrastim were included in the analysis. BPR TEAEs comprised the preferred terms (PT) arthralgia, back pain, bone pain, musculoskeletal chest pain, musculoskeletal discomfort, musculoskeletal pain, myalgia, neck pain, non-cardiac chest pain, and pain in extremity. All BPR TEAEs were defined as TEAE drug reactions (TEADRs), except those specifically assessed as 'not related'.
Results: See the table.

Table: All TEAEs by SOC and PT

	Number of patients (%)*	
	Lipegfilgrastim 6 mg (N = 151)	Pegfilgrastim 6 mg (N = 155)
All BPR TEAEs	38 (25.2)	34 (21.9)
Arthralgia	7 (4.6)	4 (2.6)
Back pain	3 (2.0)	2 (1.3)
Bone pain	24 (15.9)	22 (14.2)
Musculoskeletal chest pain	1 (0.7)	0 (0.0)
Musculoskeletal pain	1 (0.7)	1 (0.6)
Myalgia	16 (10.6)	9 (5.8)
Pain in extremity	0 (0.0)	1 (0.6)

*Patients could be counted more than once and only categories with $\geqslant$1 patient reporting a TEAE are listed.

For BPR TEADRs by PT, 28/151 (18.5%) of the lipegfilgrastim patients experienced 64 events, whereas 26/155 (16.8%) of the pegfilgrastim patients experienced 57 BPR TEADRs; this difference was not statistically

significant. None of these BPR TEADRs were serious or led to study discontinuation and all resolved.
Conclusions: Overall, there were no significant differences in all BPR TEAEs between treatment groups. The incidence and severity of treatment-related symptoms of bone pain by PT were low and comparable between lipegfilgrastim and pegfilgrastim.
Conflict of interest: *Ownership: Peter Bias, Reiner Els*sser, and Anton Buchner are all employees of Teva and own stock in Teva Pharmaceuticals*

1990 POSTER

Prognostic impact of Ki-67 in Croatian women with early breast cancer (single-institution prospective observational study)

I. Bilic[1], N. Dedic Plavetic[1], M. Kralik[2], P. Podolski[1], A. Kosi Kunac[1], D. Vrbanec[1]. [1]*Clinical Hospital Center Zagreb, Oncology, Zagreb, Croatia;* [2]*Clinical Hospital Center Zagreb, Radiology, Zagreb, Croatia*

Background: Review of available literature revealed scarcely published data on prognostic factors in Croatian women suffering from early breast cancer. Here we present single-institution data on proliferation marker Ki-67 in patient cohort with primary operable breast cancer treated in Breast cancer unit of University Hospital Center Zagreb during years 2002 and 2003.
Materials and Methods: From initial 215 patients (pts.) 6 were excluded from the analysis when proved to be initially metastatic, or lost to follow-up, giving final total number of 209 pts. Median age at diagnosis was 56 years (min 30, max 87). Median follow up is 9.38 years (min 8 months, max 10.4 years). 135 pts. were menopausal at diagnosis. All pts. were diagnosed by pathohistological examination of extirpated tumor including immunohistochemistry (IHC) for estrogen (ER) and progesterone (PR) receptor, as well as Her-2 and Ki-67 determination. Her-2/neu confirming methods were FISH or CISH for suspected amplification (++ by IHC). Adjuvant therapy followed according to TNM stage and accepted ESMO guidelines, with exception of adjuvant trastuzumab, which was not reimbursed by health insurance at that time. Pts. are grouped according to Ki-67 expression (cut-off value 14% − percentage of positive nuclei per hundred tumor cells), grade, stage and ER/PR/Her-2 profiles (five breast cancer subtypes according to St. Gallen recommendations). Kaplan–Meier curve with log-rank test, Kruskal-Wallis or Mann-Whitney test with Bonferroni correction were used for univariate, and Cox regresion analysis for multivariate models.
Results: Overall survival (OS) singificantly differs in Ki-67 positive vs. negative group (positive >14%, OS=77.9 vs. 62.2, $p = 0.023$). Accordingly, pts. that died during follow-up have significantly higher Ki-67 value (16 vs. 9.67, $p = 0.003$). Ki-67 value correlated with histologic grade (10 vs. 16.8 vs. 38.9% in grades I to III, respectively − $p < 0.001$, $\chi^2 = 15.204$). Kruskal-Wallis analysis confirmed non-equity of Ki-67 among grade-groups, but non-parametric test between I and II grade failed to reach statistic significance. Tumor grade had prognostic impact on OS (after 10 years, 90.1vs.77.7 vs. 57.4 in grades I to III, respectively − $p = 0.006$) and on disease free survival (DFS) as well. Stratification according to five molecular intrinsic subtypes of breast cancer, using ER/HR/Her-2 and Ki-67 (luminal A (1) and B (2), Her-2 enriched luminal (3) and non-luminal (4) and (5) triple-negative) revealed significantly lower Ki-67 expression in luminal A-like and significantly higher in luminal B-like group than Her-2 enriched and triple negative-like groups ($P<0.005$). In multivariate regresion analysis Ki-67 expression did not reveal significant impact on OS and DFS of patients stratified in aformentioned subtype-like groups.
Conclusion: Ki-67 alone had prognostic value on OS at 10 years follow-up in our cohort, whereas DFS was not significantly affected by Ki-67. Ki-67 level and tumor grade showed correlation, mostly significant, but tumor grade appeared to have stronger prognostic value than Ki-67. After grouping in molecular intrinsic-like subtypes of breast cancer according to IHC measurements of ER/PR/Her-2/Ki-67, Ki-67 differed significantly between luminal A and B-like and the rest of subtypes, but no significant difference in OS and DFS between groups was observed.
No conflict of interest.

1991 POSTER

Breast cancer: Value of evaluation exams 5 years after the diagnosis and treatment

A. Rosinha[1], M. Cassiano Neves[1], C. Vieira[1], A. Ferreira[1], N. Afonso[1], H. Rodrigues[1]. [1]*Ipo-Porto, Medical Oncology, Oporto, Portugal*

Background: The aim of this study was to analyze the diagnostic value of evaluation exams in asymptomatic patients, 5 years after the diagnostic and treatment of invasive breast cancer.
Methods: Retrospective study of patients with the diagnosis of invasive breast cancer during 2005 and that were submitted to evaluation exams before being referenced to surveillance in primary health care. We analyzed the diagnosis rate of metastatic disease after these exams in each stage. For each diagnostic test (BS, LUS, CXR), we analyzed the diagnosis rate of metastasis defined as the number of patients with diagnosis of metastatic disease after an imaging technique divided by the total number of patients tested. In addition, sensitivity and specificity were calculated. We considered as clinically significant, diagnostic rates superior to 1%.
Results: Of the 751 patients admitted in 2005, 228 had been submitted to BS, LUS, CXR five years after being diagnosed and treated for their breast cancer. 226 were female. The median age was 57 years (23−90 years). The most frequent histological type was invasive ductal carcinoma (80.7%); 90.5% had positive hormone receptors; the HER-2 was unknown in the majority of cases. *The most frequent stage was stage II* (110 patients). The re-staging exams had diagnosed metastatic disease in 8 patients (3.5%): 3 patients in stage II (1.32%) and 5 in stage III (2.19%). BS was carried out in 199 patients, LUS in 186 patients and CXR in 188 patients. BS detected skeletal metastases in 2% of patients, LUS detected liver metastases in 0.53% of patients and CXR detected lung metastases in 0.52% of patients. The median overall survival after the diagnosis of metastasis was 25.2 months.
Conclusions: These findings suggest that a complete re-staging work-up to detect metastases in asymptomatic patients five years after the diagnosis and treatment of breast cancer is unnecessary in stage I.
In stages II and III, the prevalence of metastatic disease with these exams was superior to 1%, which indicates a possible benefit in doing evaluation exams in these patients routinely.
No conflict of interest.

1992 POSTER

Survival analysis of breast cancer patients in Northwest Iran

J. Eivazi Ziaei[1], Z. Sanaat[1], A.L.I. Pourzand[2], J. Vaez[3]. [1]*Tabriz University of Medical Sciences, Haematology and Oncology Research Center, Tabriz, Iran;* [2]*Tabriz University of Medical Sciences, Department of Surgery, Tabriz, Iran;* [3]*Tabriz University of Medical Sciences, Haematology and Oncology Research Center, Tabriz, Iran*

Introduction: In Iran, breast cancer (BC) is ranked first among malignancies of women, comprising 24.4% of all neoplasms with a crude incidence rate of 17.81 in the year of 2006. However, studies specifically describing the clinicopathologic features, stages, and age distributions of BC in Iran are limited; thus, it is difficult to predict the present and future patterns of BC and carry out the most appropriate preventive and therapeutic measures to decrease the burden of the disease in Iran. Some studies in southern Iran about survival pattern of BC found three- and five-year overall survival rates of 76% and 58% respectively. The aim of this study was to determine the survival rate and prognostic factors of BC in northwest Iran.
Methods and Patients: A cohort study of 271 patients recruited from 1376−87, in Tabriz, northwest of Iran. In this study we analysed the age, tumour diameter, nodal status, hormone receptor status, pattern of metastasis and survival rate of breast cancer patients who referred to a university clinic in Tabriz, the city in the northwest of Iran and compared it with the results of other cities in Iran and other countries.
Results: Mean age was 48(26−82), 116 were ER and PR positive, 104 and 103 were negative. In fifteen years follow up 52 patients died. 14 patients were below 40 years old. 109 patients were premenopause, 83 post-menopause, and 43 unknown. 36.1% had tumour>4 cm and 9.5% <2 cm. 18.6% had N1, 14.4% N2, 12.8% N3, 16.7% unknown, 27.5% negative, 53.5% positive. 51.1% with metastasis, (26.6% nonskeletal, 24.5% skeletal, 1.4% both).
Life table analysis showed one, three, five, seven and ten years overall survival of 96, 86, 81, 79, and 76% respectively. It showed statistically significant correlation of survival with age less or above 40 years. Patients less than 40 years old had one, three and five years survival of 82, 74, and 65 % while patients over 40 had 95, 86, and 83% respectively (log rank=0.22). Diameter of the tumour had minimal effect to survival (T>4 cm had lower survival, $P = 0.08$).
Discussion: Two studies have previously reported 5-year overall breast cancer survival rates in Tehran and these were 60% and 62%. Our study shows similar results and denotes that Iran has considerably poorer survival than European countries and the United States.
Age less than 40 may be a prognostic factor in northwest Iran.
No conflict of interest.

1993 POSTER

HER-2/neu status in Syrian women with breast carcinoma

M. Salamoon[1], M. Kenj[2], T. Hussein[3], F. Ahmad[4], S. Sarhan[4], Z. Marawi[5], M. Bachour[5]. [1]*Bairouni University Hospital, Medical Oncology, Damascus, Syria;* [2]*Kenj Lab, Cytogenetics, Damascus, Syria;* [3]*Tishreen Hospital, Pathology, Damascus, Syria;* [4]*al Bairouni University Hospital, Pathology, Damascus, Syria;* [5]*al Bairouni University Hospital, Medical Oncology, Damascus, Syria*

Background: Her-2/neu is a member of epidermal growth factor receptors (EGFR) implicated in the pathogenesis of breast cancer. Her-2/neu is known to be overexpressed in 30% of breast cancers, furthermore it is considered as an important prognostic factor.
Objective: The study is aimed at determining the prevalence of Her-2/neu overexpression in Syrian women diagnosed with breast cancer and to assess both progression free survival and overall survival rates.
Material and Methods: The study is a retrospective one where we collected data from 10355 Syrian women diagnosed with breast cancer during the period 2007 through 2012 at Al Bairouni University Hospital in Damascus (Syria). Paraffin samples were reviewed by a central lab and another reference lab using both immunohistochemistry staining and fluorescence in situ hybridisation (FISH), [Hercep test (DAKO Inc)]. Both Her-2 (++ and +++) were checked again by FISH to determine Her-2/neu gene status.
Results and Discussion: 4013 out of 10355 were Her-2 positive (2+ and 3+) representing 38% of patients with a mean age of 42 years old at diagnosis, in the other hand the remaining 62% were Her-2 negative (0 and +1). A further investigation showed that Her-2 by FISH is positive in 2822 out of 4013 forming 70% of the positive group as follows: 1413/2344 (2+ patients) versus 1409 /1669 (3+ patients), in other word 16% of (3+) patients by immunohistochemistry showed to be negative by FISH. Of the 2822 patients, 1920 patients (68%) progressed with a median progression event of 19 months while the survival was 28 months in median.
Conclusions: The prevalence of Her-2/neu in Syrian women having breast cancer in this study is 27%. The study reflects the distribution of real Her-2/neu gene expression among the Syrian women diagnosed with breast cancer because Her-2 amplification was detected by FISH in all patients, further the sample covered 6 years and more than 10,000 patients. Finally, Her-2/neu overexpression accompanied with a bad prognosis in light of short progression and overall survival time.
No conflict of interest.

1994 POSTER

Progesterone receptor status and Ki-67 index provide prognostic value for early relapse in luminal B/HER2 negative breast cancer patients

Y. Zong[1], L. Zhu[1], J. Wu[1], X. Chen[1], O. Huang[1], X. Fei[2], J. He[1], W. Chen[1], Y. Li[1], K. Shen[1]. [1]*Ruijin Hospital, Comprehensive Breast Health Center, Shanghai, China;* [2]*Ruijin Hospital, Pathology Department, Shanghai, China*

Background: Few studies has documented early relapse in luminal B/HER2 negative breast cancer. We examined prognostic factors of early relapse among these patients to improve treatment decision.
Patients and Methods: Total 399 patients with luminal B/HER2 negative breast cancer were included in the study. After 2 years of median follow-up, Kaplan–Meier curves were applied to estimate disease free survival (DFS) and overall survival (OS), while Cox proportional hazards regression to identify prognostic factors.
Results: Absence of progesterone receptor (PR) expression was associated with higher tumour grade (p<. 001) and higher Ki-67 index (p=. 008). PR absent tumours received more chemotherapy than PR present group (p=. 005). Multivariable logistic regression suggested absence of PR was strongly related to higher tumour grade (p <.001). After a median follow-up of 2 years, 17 patients (4.3%) had early relapses while 6 patients(1.5%) died. In univariate models, PR absence group was associated with poor DFS (HR = 3.679, 95% CI 1.369–9.882) when compare with PR present group. Furthermore, patients within high Ki-67 index group (>30%) had a reduced DFS (HR = 3.125, 95% CI 1.085–8.999) when compare with low Ki-67 index group($\leqslant$30%). In multivariate analysis, absence of PR expression was significantly associated with a reduced DFS (HR = 3.774, 95% CI 1.214–11.738) when compare with PR present group.
Conclusion: PR absence might be a prognostic factor for early relapse in luminal B/HER2 negative breast cancer,while high Ki-67 index may also suggest higher risk of early relapse.
No conflict of interest.

1995 POSTER

Do all node positive breast cancer patients undergoing axillary clearance need staging?

M. Fernandez[1], F. Vaz[1], R. Lord[1], E. Leung[1], H. Khan[1]. [1]*University Hospitals Coventry & Warwickshire NHS Trust, Surgery, Coventry, United Kingdom*

Background: Currently all patients who undergo axillary node clearance (ANC) with node positive disease are routinely imaged as part of their staging investigations at our institution. It is well reported that axillary node status, and particularly the absolute number of positive nodes, is the most important prognostic factor in breast cancer. Our study addresses the question of whether routine imaging is necessary in patients with a low burden of node positive disease.
Methods: We collected data for all patients who underwent full ANC from 1st January − 31st December 2011. Patient parameters, number of lymph nodes retrieved and final number of positive nodes were recorded. Imaging investigations were examined for the presence of metastatic disease. We compared the number of positive lymph nodes and lymph node ratio (LNR) between those with and without metastatic disease. A P value <0.05 was considered significant.
Results: Eighty patients (79 female, 1 male) underwent full ANC during the study period. Mean age was 61.4 years (38−86 years). Sixty-nine (69) out of the 80 patients were found to have one or more positive lymph nodes after full ANC. These node positive patients underwent routine imaging with one or more of the modalities as follows: chest X-ray with liver ultrasound scan (37/69 patients), CT chest/abdomen/pelvis (35/69 patients), and isotope bone scan (27/69 patients).
Four out of the 69 (5.8%) node positive patients were found to have metastatic disease which was detected by routine imaging. Patients with metastatic disease were found to have significantly higher numbers of positive lymph nodes (average 18.3 vs 3.7, $P = 0.019$) and significantly higher average LNR (0.87 vs 0.31, $P = 0.003$) than patients without metastatic disease.
Conclusion: Imaging investigations should not be routine for patients with a low burden of node positive breast cancer. This should be reserved for those with a large number of positive nodes (or high LNR) or in patients with symptoms suggestive of metastatic disease.
No conflict of interest.

1996 POSTER

The association of nipple discharge color with malignant breast pathology

J.E.R.E. Wong Chung[1], S.A.H. Jeuriens − van de Ven[1], L.J.A. Strobbe[1]. [1]*Canisius Wilhelmina Hospital, Surgery, Nijmegen, Netherlands*

Background: Nipple discharge usually has a benign cause. However, unilateral single duct nipple discharge is associated with an increased risk for underlying malignancy. To date, there is no consensus whether the color of nipple discharge independently indicates the risk of malignancy. Therefore, we sought to assess the relationship between the color of discharge and the risk of malignancy.
Materials and Methods: A retrospective study was performed in patients with unilateral single duct nipple discharge from the database of the Canisius Wilhemina ziekenhuis Nijmegen, who underwent a diagnostic microdochectomy between 1993 and 2012. All patients presented with no abnormalities on clinical and radiological examination. Nipple discharge colors and aspects of interest were classified as bloody/brown, white, yellow, green, serous, purulent and clear. Multiple logistic regression was performed to assess the relationship between color of nipple discharge and malignancy accounting for age. Statistical significance was set at $p < 0.05$.
Results: 173 patients with a median age of 52 y (range 19−84) were included. The median age of patients with breast carcinoma was 66 y (range 23−78), while patients with a benign diagnosis had a median age of 51 y (range 19−84). Histologic examination revealed an underlying (in situ or invasive) breast carcinoma in 21 (12.1%) patients. In addition, 17 (9.8%) patients were diagnosed with a lesion associated with a propensity to progress to breast cancer. Malignancy was associated with bloody/brown discharge in 76.2% of cases (OR 1.71; 95% CI 0.56–5.17). None of the other colors were significantly associated with malignancy either. Patients >60 y had an increased risk (OR 3.6; 95%-CI 1.42–9.20) of being diagnosed with malignancy versus patients $\leqslant$60 y (OR 0.28; 95%-CI 0.11–0.71).
Conclusions: Uniductal unilateral nipple discharge is a sign of underlying malignancy in a substantial proportion of cases. While the majority of patients diagnosed with breast cancer presented with bloody/brown discharge, its association with malignancy is not strong enough to distinguish high risk patients. The presence of the other colors couldn't exclude malignancy or identify low risk patient groups either. Therefore,

patients with unilateral single duct nipple discharge without radiological abnormalities should always be offered invasive diagnostic procedures like microdochectomy to search for underlying malignancy.
No conflict of interest.

1997 POSTER

Quality of life after mastectomy: What about moroccan patients?

M.R. Khmamouche[1], R. Aassab[1], A. Debbagh[1], S. Lkhoyaali[1], M. Ichou[2], H. Errihani[1]. *[1]National Institute of Oncology, Medical Oncology, Rabat, Morocco; [2]Military Hospital Mohamed V, Medical Oncology, Rabat, Morocco*

Introduction: Breast cancer is the first cancer that affects the Moroccan woman and it's a public health problem.
In recent years, great interest was shown for the consequences of breast cancer and its treatment methods on the quality of life of patients.Mastectomy is widely regarded as a destructive experience in the life of a woman. It leads to women of all ages a disturbance of the body image and femininity. The aim of our work is to study the impact of psycho-pathological quality of life among women attending the National Institute of Oncology,in Rabat, Morocco for localized breast cancer who underwent mastectomy in the estimated components self, family and sexual satisfaction.
Materials and Methods: This is a prospective study evaluating the quality of life in patients after mastectomy for localised breast cancer.
A questionnaire was developed to assess the quality of life of these patients in terms of body image and sexual satisfaction.
Results: Our study included 113 patients, the average interval between mastectomy and the questionnaire was 17 months, the average age of our patients was 49.ans, 58% are young (<50 years) and 67% of them are married, 79.% of patients live in urban areas, and the illiteracy rate was 58%.
The majority of our patients are housewives. The right breast was slightly affected by the mastectomy in 53% of cases. 33% of patients surveyed showed their preference for a lumpectomy to conserve their body image.
Denial of postoperative mutilation interested 60 patients, there was still persistent in 9% of cases. The anxiety and fear of death were found in half of our patients. Symptoms presented during the interrogation were dominated by: pain at the scar in 46% of cases and intramammary chronic pain in 51% of cases. In addition, 35% of patients had a fear of touching their cicatrice and46% of women reported a disturbance in body image.
Feelings of depression has affected half of the patients, and only 9% of them have a consultation with a psychiatrist, clinical signs frequently found were: insomnia in 42% of cases, loss of appetite in 49 % and weight loss in 30% of cases.
Loss of interest in pleasurable activities usually was found in 46% of cases, and fear of prolonged exercise has been described in 91% of cases.
Regarding the fear of going to Moorish Bath, it was found in half of the patients, the major cause was the fear of people's eyes.
On the sexual plane, 30% of the patients had sexual dysfunction, which are increased to 77.% Of them; against sexual satisfaction by concerned 53% of patients. 47% of women have shown their desire mastectomy breast reconstruction, either immediate or delayed (after treatment).
Conclusion: Our study demonstrates the importance of exploring further dimension of self-esteem when suffering from a serious disease like breast cancer. Moroccan women especially young, had mental suffering after mastectomy.
No conflict of interest.

1998 POSTER

Patients' perceptions on breast cancer clinical trials

S. Tax[1], J. Elberse[2], C. Pittens[3], J. Broerse[3], A. Van Leeuwen-Stok[4], M. Schrieks[5]. *[1]Dutch Cancer Society, Amsterdam, Netherlands; [2]VU MC, Amsterdam, Netherlands; [3]VU MC, Amsterdam, Netherlands; [4]BOOG, Amsterdam, Netherlands; [5]BVN, Utrecht, Netherlands*

The Dutch Cancer Society (KWF) and the Breast Cancer Study Group (BOOG) believe that design and execution of clinical trials could be improved when patients become actively involved. A qualitative study is conducted − involving breast cancer patients, health care providers, researchers and stakeholder organizations − to explore possibilities for active patient involvement in breast cancer clinical trials.
The study started with consultation of 52 stakeholders (of which 27 patients). Then an advisory committee of 6 female breast cancer patients was established. Facilitated by a researcher they produced during three meetings an advisory report, based on the data from the consultation, on possibilities for active involvement clinical trials. In a dialogue meeting with different stakeholders, feasibility and preconditions for successful implementation of the advice were discussed.
Based on the results of the consultation and advisory committee three potential forms of patient involvement were formulated: (1) appointment of an advisory committee of patients who monitor the entire process of clinical trials (from design to follow-up), (2) inclusion of a patient (representative) in the research team as an equal member, and (3) involvement of individual patients for different aspects in a clinical trial. Within each phase of a clinical trial (design, information and recruitment, treatment, and follow-up and feedback) several aspects were identified in which patients' input from the three different levels could have additional value, e.g. contribution to questionnaires, outcome measurements, logistics, patient information, sharing experiences, feedback.
Active patient involvement of (ex)breast cancer patients in clinical trials is promising. The BOOG and BVN are started implementing the results of this study by conducting an advisory committee.
This project is a collaboration between the Dutch Cancer Society, the Dutch breast cancer trialists group and the Dutch breast cancer patient organization, and is performed by the Athena Institute, VU University Amsterdam.
No conflict of interest.

1999 POSTER

A survey of the patient's experience of participation in a clinical study at the Netherlands Cancer Institute

V. Skinner[1], H. Hauer[2], M.T.F.D. Vrancken Peeters[2], H.S.A. Oldenburg[2]. *[1]Antoni van Leeuwenhoek Ziekenhuis, Amsterdam, Netherlands; [2]Antoni van Leeuwenhoek Ziekenhuis, Surgical Oncology, Amsterdam, Netherlands*

Background: The purpose of this study is to make an inventory of patient experience participating in clinical studies during the primary systemic therapy for breast cancer. The ultimate aim is to use this insight to improve active participation and patient experience in future studies within our institute.
The Netherlands Cancer Institute is currently running a large-scale study monitoring various clinical aspects during the primary systemic therapy for breast cancer. The purpose is to evaluate the response of the tumour to neo-adjuvant therapy and to adjust the treatment regime if the response appears to be unfavourable.
There is, at present, no clear picture of how patients experience participation in this research program. As a result, the reasons for not taking part or dropping out during the course of the study are not known. A better understanding of these reasons would help to improve practices with regard to patient inclusion and help to improve patient experience.
Material and Method: The research involves collecting data from 80 patients who were treated with primary systemic therapy for breast cancer during the year 2011 and who were asked to participate in the PETscan study. The research population is sub-divided into the following groups:
1. Non-responders: patients who were asked to participate in the study but refused.
2. Responders: patients who were asked to participate in the study and accepted. This group was further divided into two sub-groups:
2.1. **Compliers:** a sub-group who completed the clinical study;
2.2. **Non-compliers:** a sub-group who did not complete the clinical study.
Data has been collected from interviews with patients from each group. Data in the form of individual patient characteristics has been collected from patient files and will be correlated with the data from the interviews. The following questions will be addressed: What reasons are given by the patients for their (non)response and (non)compliance? Are there any background differences between (non)responders and (non)compliers?
Results: Collecting and processing the results of this research will be completed by the end of May 2013 and will be presented at the ECCO.
Conclusion: A preliminary evaluation of the data generated suggests that patient experience will have an impact upon the way that research procedures are conducted.
No conflict of interest.

2000 POSTER

BRCA 1−2 Ashkenazi mutations in Argentinian patients at high risk of hereditary breast cancer

F. Arganaraz[1], A. Hannois[1], A. Dannunzio[1], G. Pascón[1], E. Richardet[1], L. Perelli[1], G. Uranga[1], S. Bella[1], N. Giacomi[1], E. Ortiz[1]. *[1]Argentinian Association of Clinical Oncology (AAOC), Research, Buenos Aires, Argentina*

Background: BRCA1−2 Ashkenazi Mutations (AM) have been found in Hispanic populations with non direct Jewish ancestry. There is no data about their frequency in argentinian patients (pts) with breast cancer at high risk of hereditary breast ovarian cancer syndrome (HBOCS). The AM tests were the only ones available in our country by the time of the study

design. The purpose of this study was to evaluate the frequency of the three AM in BRCA 1 and 2 genes in a selected population of women with breast cancer at high risk of HBOCS.
Material and Methods: From September 2009 to may 2011, breast cancer pts from a research collaborative group who full-filled inclusion criteria for HBOCS were evaluated. After genetic counseling consultation and informed consent, data about patient-tumor characteristics and family history were obtained and direct DNA sequencing from a blood sample was performed searching for the 3 Ashkenazi mutations 185delAG- BRCA1exon 2; 5382insC-BRCA1 exon 20 and 6174delT-BRCA2 exon 11.
Results: 97 pts were tested. Median age at diagnosis was 27 years (23−50). 70% ⩽40 years, 29% < than 35, 41% between 35−40 and 30% between 41−50. 7% (7 pts) had ashkenazi ancestry, 32% a 1º relative with breast/ovarian cancer before age of 50, 42% a 2º relative with breast/ovarian cancer before age of 50. Clinical presentation was bilateral in 11%, localized disease 79%, locally advanced 17% and metastatic 4%. 75% had conservative surgery and 21% a mastectomy. Sentinel node biopsy was performed in 22% and an axillary disection in 78%. 48% of the pts had positive lymph nodes. Median tumor size was 2 cm (0.2−10 cm). Invasive ductal carcinoma 83% and lobulillar 10%. Hystologic grade III 54%. Estrogen and progesterone receptors were positive in 64% and 61% of the pts respectively. Her 2 positive 26%. Triple Negative 14%.
Mutational analysis performed at the central laboratory was negative in 99% of the pts (n 96). The only positive patient had Ashkenazi ancestry and a BRCA 1 185delAG heterozygous mutation was found.
Conclusions: In a highly selected population of Argentinian pts with HBOCS the study of the 3 founder AM showed to be unuseful, even in the Ashkenazi subgroup of patients.
No conflict of interest.

2001 POSTER

Role of tumor cellularity in the assessment of response to neoadjuvant chemotherapy treated locally advanced breast cancer

S. Kumar[1], B.A. Badhe[1], K.M. Krishnan[1], D. Kadambari[2]. *[1]JIPMER, Pathology, Pondicherry, India; [2]JIPMER, Surgery, Pondicherry, India*

Background: Breast cancer is the most common invasive malignancy in women worldwide. The advent of neoadjuvant chemotherapy has radically changed the management of locally advanced breast cancer and complete response is reported to have significantly improved disease free survival. Traditionally, clinical response has been assessed by tumor size. In this study, an attempt has been made to see if tumor cellularity could be a better prognostic factor and also to see what impact the correlation of tumor size with cellularity has on the response assessment in locally advanced breast cancer patients.
Materials and Methods: 37 patients of locally advanced breast cancer treated by neoadjuvant chemotherapy during the period of December 2008 to May 2009 were selected for the study and from their case records, tumor size, clinical response and demographic details were gathered. Tumor cellularity was assessed prior to chemotherapy in core needle biopsy sections and matched with subsequent mastectomy specimens. Tumor size and cellularity were then correlated with the different treatment response groups and statistically analysed using the SPSS 13.0 software.
Results: After neoadjuvant chemotherapy, the tumor size and cellularity was found to be significantly reduced in the breast carcinomas ($p < 0.05$, paired t test). The relative changes in cellularity were highly variable between individual patients and different clinical response groups, particularly in the partial response and no response categories. The product of cellularity and size dramatically changed the distribution of residual tumor pathology causing a shift towards complete response.
Conclusions: The current study shows that the product of tumor size and cellularity may be a better prognostic indicator of clinical response in neoadjuvant chemotherapy treated locally advanced breast cancer patients and would enable a new definition for clinical response in the future.
No conflict of interest.

Traditional Chinese acupuncture for treatment of chemotherapy and hormonal therapy adverse events in breast cancer patients

S. Saracchini[1], L. Foltran[1], P. Alborghetti[2], A. Del Conte[1], G. Lo Re[1], D.A. Santeufemia[1], M. Bertola[1], S. Tumolo[1]. *[1]Azienda "S. Maria degli Angeli", Oncology, Pordenone, Italy; [2]Private clinic, Acupuncturist, Pordenone, Italy*

Background: Adverse events from chemotherapy and hormonal therapy are frequently reported by breast cancer patients. Some side effects are difficult to control with best supportive care. Acupuncture has demonstrated to improve chemotherapy-related nausea/vomiting but its efficacy remains uncertain for other symptoms (Garcia MK, J Clin Oncol 2013).
Methods: 118 women with advanced or early breast cancer receiving chemotherapy or hormonal therapy at our Oncology Department were treated with acupuncture. A total of 1.180 acupuncture sessions were retrospectively reviewed. Each session lasted about 1 hour to allow relax both the patient and acupuncturist. Acupuncture was administered in a clinic outside the hospital, quiet and cozy. The program was divided in two sections. The first section sought to treat chemotherapy-related side effects such as nausea, vomiting, constipation, asthenia, dyspepsia and sensory neuropathy. This included two acupuncture sessions after the cycle of chemotherapy and then one session weekly up to maximum 10 sessions. The second section aimed to improve climacteric syndrome due to hormonal therapy, in particular hot flushes, tachycardia, anxiety or depression, insomnia and arthralgie. The treatment consisted of 10 weekly sessions of acupuncture.
We evaluated the severity of symptoms using a scale from 0 to 10, at baseline, in mid and at the end of treatment.
Results: The majority of patients obtained a significant reduction of severity of symptoms after the acupuncture, as shown in the Table. The scoring was at least halved for most of symptoms. Many patients did not require additional supportive care.

	Score (media) depending on time of the treatment		
	Baseline	Mid-treatment	At end of treatment
Chemotherapy-related adverse events			
Asthenia	8.5	6.07	5.07
Dyspepsia	7.5	4	1
Sensory neuropathy	7.72	5.6	4.7
Vomiting	6	0	0
Nausea	8.83	4.33	2.16
Constipation	8.2	5	4.4
Symptoms of climacteric syndrome			
Insomnia	8.31	5.18	3.81
Arthralgie	8.6	4.6	3.8
Tachycardia	8	4.5	2.5
Anxiety or depression	8.63	6.13	5.13
Hot flushes	7.5	1.5	1.5

Conclusions: We think that acupuncture is a promising complementary treatment to manage chemotherapy toxicities and climacteric syndrome. It may avoid the use of supportive therapies and their side effects. In addition, acupuncture has no adverse events related and it may prevent reductions or delays of anticancer treatment preserving its efficacy.
No conflict of interest.

Table (abstract 2001). Categorization of the change in tumor cellularity, tumor size (cm), and tumor size multiplied by cellularity according to clinical response and residual tumor stage

Variable	No.	Change in tumor cellularity			Tumor size (cm)		Tumor size × cellularity		
		Median	Range	Mean±SD	Median	Mean±SD	Median	Range	Mean±SD
CR	7	−0.25	6.24 (−0.58, 5.66)	0.66±2.22	4.9	5.5±2.1	1.09	39.7 (−34, 5.7)	−3.7±13.5
PR	16	0.12	6.47 (−0.92, 5.56)	0.41±1.49	1.3	1.88±1.7	−0.08	15.2 (−11.1, 4)	−0.74±3.2
NR	6	0.39	2 (−0.92, 1.12)	0.26±0.8	−0.05	−0.03±0.18	0	0.39 (−0.3, 0.09)	−0.03±0.14

Cognitive functioning before adjuvant chemotherapy for breast carcinoma

P. Andryszak[1], B. Zurawski[2], J. Tujakowski[3], P. Izdebski[1], M. Wilkosc[1]. *[1]Kazimierz Wielki University in Bydgoszcz, Institute of Psychology, Bydgoszcz, Poland; [2]Centre of Oncology, Outpatient Chemotherapy, Bydgoszcz, Poland; [3]Centre of Oncology, Chemotherapy Unit, Bydgoszcz, Poland*

Background: The influence of chemotherapy on cognitive functioning has not been adequately described yet, and results of previously published studies provide equivocal results. Moreover, some studies show that cognitive decline may be present before introducing chemotherapy. The aim of the study is to assess and to compare cognitive functioning of patients starting different regiments of adjuvant chemotherapy for breast cancer.
Material and Methods: 66 patients with breast cancer qualified to neoadjuvant chemotherapy with AC (n = 41, mean age=54±8) or AC followed by T (n = 25, mean age=49±11) participated in the study.
Each patient was participated in a clinical interview, numerical rating scales to assess fatigue, sleep, mental and physical self-efficiency, depression and anxiety assessment using the Modified Hospital and Anxiety Depression Scale (HADS − M) and distress using the Distress Thermometer. The evaluation of cognitive functioning was carried out using the Trail Making Test A and B (TMT A &B) and the Stroop Color-Word Interference Test (SCWIT) and the Digit Symbol Substitution Test (DSST).
Results: It was found that patients qualified to AC performed significantly slower than patients qualified to AC followed by T in the TMT A ($z = -2.28$, $p = 0.023$), the TMT B ($z = -2.07$, $p = 0.039$) and second part of the SCWIT ($z = -3.17$, $p = 0.002$). In AC followed by T group significant negative correlation ($r = -0.42$, $p = 0.03$) between mental self-efficiency and time of performing TMT B was found. In this group significant positive correlation ($r = 0.4$, $p = 0.04$) between depression and time of performing SCWIT part 1 was found. In both groups significant positive correlations between distress, depression and anxiety were found.
Conclusions: Our results indicate that some aspects of cognitive functioning, such as psychomotor speed, attention or executive functions may differ in patients starting different regiments of adjuvant chemotherapy for breast cancer. Further analyzes will be performed.
No conflict of interest.

Post-mastectomy radiotherapy: Before or after reconstruction? A systematic review of the literature

L. Boersma[1], J. Berbers[1], R. Houben[2], M. Bessems[3], M. Smidt[3], E. Heuts[3], K. Keymeulen[3], A. Van Baardwijk[1]. *[1]Maastricht University Medical Centre, Department of Radiation Oncology (Maastro clinic), Maastricht, Netherlands; [2]Maastro Clinic, Department of Radiation Oncology, Maastricht, Netherlands; [3]Maastricht University Medical Centre, Department of Surgery, Maastricht, Netherlands*

Background: The aim of this review is to investigate whether a difference exists in complication rate and satisfaction with cosmetic outcome between radiotherapy (RT) before or after breast reconstruction for autologous and implant reconstructions separately.
Methods: PubMed was searched for the period between January 2000 and December 2012. Of the 37 eligible studies, the type and incidence of complications were recorded, and if mentioned patient and physician satisfaction with cosmetic outcome. We calculated the weighted mean including confidence intervals for the incidence of complications and cosmetic outcome overall, and also per subgroup: 1) RT followed by autologous reconstruction; 2) RT followed by implant; 3) autologous reconstruction followed by RT; 4) implant followed by RT. Forrest plots were made for the most relevant complications.
Results: The reported data showed a large variation in complication rates (8.7%-70.0%) and acceptable cosmetic outcome (41.4%-93.3%). No significant differences were found in complication rate and cosmetic outcome, between the weighted means of the four subgroups. If the analyses were confined to studies that directly compared two groups (group 1/2 vs group 3/4), we found that overall, complications occurred less if RT was followed by reconstruction (OR 0.60 [0.38–0.96]. This was mostly ascribed to the subgroup of patients with an implant reconstruction (OR 0.22 [0.10–0.48] (Table). However, serious complications such as flap or implant failure occurred more if RT was followed by reconstruction (OR 5.02 [0.62–40.89] and OR 3.08 [1.62–5.86]), respectively. No significant difference was found for both patient and physician satisfaction regarding cosmetic outcome.
Conclusions: Reconstruction should be performed after RT, to minimize the total number of complications. However, to minimize the incidence of serious complications, it seems like RT given after reconstruction is better. Timing or type of reconstruction results in no statistical difference regarding cosmetic outcome.
No conflict of interest.

Table: Odds Ratio (OR) and 95% confidence intervals RT first versus reconstruction first. OR < 1: favours RT first; OR > 1 favours reconstruction first.

Study	OR RT first/reconstruction first	
	Autologous	Implant

Carlson (2008)	0.64 [0.17–2.41]	
Anderson (2009)		0.32 [0.09–1.14]
Overall per type of reconstruction	1.07 [0.58–1.96]	0.22 [0.10–0.48]
Overall	0.60 [0.38–0.96]	

2005 POSTER

Clinical outcomes of the association trastuzumab–locoregional breast radiotherapy: A prospective monocentric study

J. Jacob[1], L. Belin[2], J.Y. Pierga[3], A. Gobillion[2], R. Dendale[1], P. Beuzeboc[3], F. Campana[1], A. Fourquet[1], Y. Kirova[1]. *[1]Institut Curie, Radiation Oncology, Paris, France; [2]Institut Curie, Biostatistics, Paris, France; [3]Institut Curie, Medical Oncology, Paris, France*

Background: Trastuzumab and adjuvant breast radiotherapy (RT) have individually proved their oncologic efficacy in terms of disease-free and overall survival. The aim of our study is to assess the clinical outcomes of the concurrent administration of trastuzumab to locoregional breast RT.
Material and Methods: Prospective monocentric study of 308 patients (pts) treated between 2000 and 2009 by trastuzumab administered concurrently to normofractionated adjuvant RT for localized breast cancer. Trastuzumab was delivered every three weeks for one year (8 mg/kg at the first infusion, then 6 mg/kg). Survival data were defined as the time from the histological diagnosis of breast cancer until the occurrence of the first event (locoregional or distant recurrence, or death). Locoregional or distant recurrence-free and alive pts were censored at the date of their last known contact. Survival and interval rates as well as their confidence interval (CI) were calculated using the Kaplan–Meier method. Multivariate analyses were performed using the Cox model.
Results: Median follow-up was 50 months (13–126). Median age at diagnosis was 52 years (25−83). The clinical tumour size at diagnosis was: T0 or T1 in 131 pts (43.4%), T2 in 122 pts (40.4%), and T3 or T4 in 49 pts (16.2%). A clinical lymph node involvement was observed in 132 pts (42.9%). Lumpectomy was performed on 189 pts (61.4%) and total mastectomy on 105 pts (34.1%). The median dose of trastuzumab was 6145 mg (1845–29180). Anthracycline- and taxane-based regimens were administered to 280 (90.9%) and 293 pts (95.1%), respectively. Hormonotherapy was prescribed to 157 pts (51.0%).
At 48 months, locoregional control rate was 95% 95% CI [92;98], distant control rate 93% [90;96] and overall survival rate 98% 95% CI [96;100]. Locoregional and distant recurrences were reported in 16 (5.2%) and 20 pts (6.5%), respectively. The main sites of locoregional and metastatic recurrence were the treated breast in 10 pts (3.2%) and the central nervous system in 5 pts (1.6%), respectively. In multivariate analysis, the clinical lymph node involvement at diagnosis and the absence of the hormone receptors expression were significantly associated with an increased risk of locoregional recurrence.
Conclusions: In this prospective study, the concurrent administration of trastuzumab to adjuvant breast RT leads to favourable outcomes in terms of locoregional and distant control. Further follow-up is needed to confirm these results.
No conflict of interest.

2006 POSTER

Five year outcomes of the hypofractionated three-dimensional conformal simultaneous integrated boost irradiation in breast conserving therapy

E.J. Bantema-Joppe[1], E.J. Vredeveld[1], G.H. De Bock[2], D.M. Busz[1], M. Woltman-van Iersel[1], H.P. Van der Laan[1], J.A. Langendijk[1], J.H. Maduro[1]. *[1]University Medical Center Groningen, Radiation Oncology, Groningen, Netherlands; [2]University Medical Center Groningen, Epidemiology, Groningen, Netherlands*

Background: In 2005, we adopted three-dimensional conformal radiotherapy with a hypofractionated simultaneous integrated boost (3D-CRT-SIB)

technique as standard after breast conserving surgery. The aim of this report was to present the 5-year clinical outcomes of a large consecutive series of women with invasive breast cancer treated with 3D-CRT-SIB irradiation after breast conserving surgery and second to study prognostic factors for any recurrence.
Material and Methods: This retrospective study was composed of a consecutive series of 752 invasive breast cancer patients (stages I−III) treated with 3D-CRT-SIB as part of breast conserving therapy, from January 2005 to January 2008. Patients were irradiated with 28 fractions of 1.8 Gy to the whole breast and 2.3 Gy (76%) or 2.4 Gy (in case of focal irradicality) to the surgical bed. Median age was 58.4 (range 26−84) years. Survival curves, including the unadjusted 5-year actuarial rates of local control (LC), distant metastases free-survival (DMFS), and overall survival (OS) were estimated with the Kaplan–Meier method. Multivariate Cox proportional hazard analysis was used to investigate prognostic factors of any recurrence.
Results: Median follow-up was 60 (range 3−93) months. In total, 7 (1%) patients had an isolated in-breast recurrence, of which 5 were invasive and 2 pure DCIS histology. The unadjusted 5-year actuarial rates of LC, DMFS, and OS were 98.9% (95% CI 98.1–99.7), 94.2% (95% CI 92.4–96.0), and 93.3% (95% CI 91.3–95.3), respectively.
Patients with triple negative tumours (i.e., oestrogen receptor negative, progesterone receptor negative, and human epidermal growth factor receptor negative) and with larger tumours (>2 cm) were at higher risk of recurrent disease, compared to patients with receptor positive breast cancer (HR 2.0, 95% CI 1.0−4.0) and small tumours (HR 2.5, 95% CI 1.4−4.5). Furthermore, patients with more than 3 positive lymph nodes developed more recurrent disease, than patients with few or no positive lymph nodes (HR 2.7, 95% CI 1.2−6.0, N0 as reference group).
Conclusions: The use of the hypofractionated 3D-CRT-SIB as part of breast conserving therapy results in excellent 5-year local control rates. Triple negative tumours, tumours of >2 cm, and >3 positive lymph nodes were associated with recurrent disease.
No conflict of interest.

2007 POSTER

Multi-centre prospective randomised trial on breast conservative surgery (BCS) with and without whole breast irradiation (WBI) in postmenopausal women aged 55−75 and low in-breast-recurrence (IBR) risk: Analysis after 9 years medium follow-up − RT 55−75 Study Group

W. Gatzemeier[1], C. Andreoli[1], A. Costa[2], M.A. Gentilini[3], C. Tinterri[1], V. Zanini[4], L. Regolo[4], C. Pedrazzoli[5], E. Rondini[5], C. Amanti[6], G. Gentile[7], M. Taffurelli[8], P. Fenaroli[9], C. Tondini[9], G. Sacchetto[10], P. Sismondi[11], R. Murgo[12], M. Orlandi[13], E. Cianchetti[14]. *[1]Cancer Center Humanitas, Breast Unit, Milan, Italy; [2]European School of Oncology, European School of Oncology, Milan, Italy; [3]Center of Epidemiology and Clinical Evaluation, Center of Epidemiology and Clinical Evaluation, Trento, Italy; [4]The Maugeri Foundation, Pavia, Italy; [5]Arcispedale Santa Maria Nuova Reggio Emilia, Italy; [6]University La Sapienza, Rome, Italy; [7]S. Maria della Misericordia Hospital, Udine, Italy; [8]S. Orsola Malpighi Hospital, Bologna, Italy; [9]General Hospital Bergamo, Italy; [10]General Hospital Alba, Italy; [11]Cancer Research Centre Torino, Turin, Italy; [12]Casa Sollievo della Sofferenza Hospital, S. Giovanni Rotondo, Italy; [13]General Hospital Cirie', Italy; [14]General Hospital Ortona, Italy*

Breast conserving therapy (BCT) including postoperative WBI has become treatment of choice for most patients with early stage breast cancer. The question whether WBI is mandatory in all patients still remains a heavily debated matter in BCT. In January 2001 a randomized prospective multi-centre study was launched to further explore the question. Until December 2005, 749 postmenopausal from 11 centres all over Italy were enrolled in the study. Patients aged 55−75, with completely excised unifocal infiltrating breast cancer up to 25 mm and widely clear margins, 0−3 positive axillary lymph-nodes, no extensive intraductal component or lymph-vascular invasion were eligible and were randomised between BCS + WBI (Arm 1: 373 pts) or BCS alone (Arm 2: 376 pts). Baseline characteristics were fairly well balanced between the two arms. Treatment allocation was centralized and stratified per site. All patients were included in efficacy analyses, which were conducted on intention-to-treat basis. All time events were computed from the date of randomization and Kaplan–Meier method was used for survival analysis with 95% confidence interval. Log rank test (alpha=0.05) was applied to evaluate the difference between the two arms. 50 % of the patients were aged 65 yrs or older, 88% had pT1, 85% pN0, 92% ER +ve, 87% G1 or G2 disease. EIC or LVI was absent in all cases. 87 % received adjuvant endocrine therapy alone.15 % adjuvant chemotherapy alone or in combination with hormonal treatment. Primary end-points of the study were to assess the cumulative incidence IBR and overall survival (OAS) after BCS with or without WBI. After median follow-up of 9 years, 12 IBR (3.4%) were observed in arm 1 and 16 (4.4%) in arm 2. OAS was 81.4% in arm 1 and 83, 7% in arm 2. There was no statistically significant difference regarding IBR and death in the two treatment groups. These data are promising and suggest that WBI after BCS can be omitted in selected patients without increased risk of IBR and death.
No conflict of interest.

Treatment arm	Type of disease progression					
	No	Distant	Local		Contralateral BC	Total
			Other quadrants	Index quadrant

2008 POSTER

Skin and oesophageal toxicities of the association trastuzumab-locoregional breast radiotherapy: A prospective monocentric study

J. Jacob[1], L. Belin[2], J.Y. Pierga[3], A. Gobillion[2], R. Dendale[1], P. Beuzeboc[3], F. Campana[1], A. Fourquet[1], Y. Kirova[1]. *[1]Institut Curie, Radiation Oncology, Paris, France; [2]Institut Curie, Biostatistics, Paris, France; [3]Institut Curie, Medical Oncology, Paris, France*

Background: Trastuzumab and breast radiotherapy (RT) both expose the treated patients (pts) to an increased risk of cardio-vascular events. However, the adverse effects regarding the other healthy organs are less well-known. The aim of our study is to assess the skin and oesophageal toxicities of concurrent trastuzumab with adjuvant RT in breast cancer.
Material and Methods: Prospective monocentric study of 308 pts treated between 2000 and 2009 by concurrent trastuzumab to normofractionated locoregional RT for localized breast cancer. Trastuzumab was delivered every three weeks for one year (8 mg/kg at the first infusion, then 6 mg/kg). All toxicities were described using the *Common Terminology Criteria for Adverse Events* v3.0. Clinical assessment was performed weekly during RT, and, after the completion of the irradiation, every 6 months for 5 years, then annually.
Results: Median follow-up was 50 months (13–126). Median age at diagnosis was 52 years (25−83). Anthracycline-, taxane- and 5-fluorouracil-based chemotherapy regimens were administered to 280 (90.9%), 293 (95.1%), and 242 pts (78.6%), respectively. Median dose of trastuzumab was 6145 mg (1845–29180).
RT treated the mammary gland and the chest wall in 193 (62.7%) and 115 pts (37.3%), respectively. The internal mammary nodes (IMN) were irradiated in 227 pts (73.7%). Median delivered doses were: 50 Gy (41−55) to the breast, 50 Gy (43−52) to the chest wall, 66 Gy (41−77) to the tumour bed, and 46 Gy (40−52) to the IMN.
In the 6 months following the initiation of RT, acute epithelitis was reported in 305 pts (99.0%), with 226 (73.4%) grade 1, 67 (21.8%) grade 2 and 12 (3.9%) grade 3 skin reactions. Acute oesophagitis was observed in 31 pts (10.1%): 26 (8.4%) grade 1, 4 (1.3%) grade 2 and 1 (0.3%) grade 3.
With a median time of 23 months (1−54) since the completion of RT, the first clinical assessment regarded 286 pts (92.9%). Among them, grade 1 late skin fibrosis was described in 53 pts (18.6%), grade 2 in 20 pts (7.0%); grade 1 telangiectasia in 14 pts (4.9%) and grade 2 in 10 pts (3.5%). Grade 1 mammary pain was observed in 39 pts (13.7%), grade 2 in 8 pts (2.8%), and grade 4 in 2 pts (0.7%; no grade 3 reported). Grade 1 late oesophagitis occurred in 1 patient (0.3%).
Conclusions: In this prospective study of pts treated by concurrent trastuzumab with locoregional breast RT, the skin and oesophageal toxicities remained mild. Further follow-up is warranted to verify these results.
No conflict of interest.

2009 POSTER

An objective assessment of cosmetic outcome after intraoperative radiotherapy or external beam radiotherapy for early breast cancer in patients from a randomized controlled trial

M. Keshtgar[1], N.R. Williams[2], T. Corica[3], M. Bulsara[4], C. Saunders[5], H. Flyger[6], N. Bentzon[6], J. Cardoso[7], N. Michalopoulos[1], D. Joseph[3]. *[1]Royal Free Hospital, Surgery, London, United Kingdom; [2]Clinical Trials Group UCL, Centre for Clinical Science and Technology, London, United Kingdom; [3]Sir Charles Gairdner Hospital, Radiotherapy, Perth, Australia; [4]University of Notre Dame, Statistics, Fremantle, Australia; [5]Sir Charles Gairdner Hospital, Surgery, Perth, Australia; [6]Herlev Hospital, Surgery, Copenhagen, Denmark; [7]INESC, Engineering, Porto, Portugal*

Background: Non-inferiority between the novel technique of TARGIT (Intra-operative radiotherapy with Intrabeam ®) and conventional whole-breast external beam radiotherapy (EBRT) in women with early breast cancer, in terms of the primary outcome measure of risk of local relapse within the treated breast, has been demonstrated in the international randomised contolled TARGeted Intraoperative radioTherapy (TARGIT) trial. The very low recurrence rates have increased the importance of cosmesis as an outcome after breast conserving treatment with both surgery and radiotherapy. This study was performed to determine if the single high dose of TARGIT leads to impaired cosmesis, compared with a fractionated dose of radiotherapy given as EBRT.
Material and Methods: BCCT.core software is a validated, objective assessment tool for the evaluation of cosmetic outcome from frontal digital photographs. Images were analysed at baseline (before TARGIT or EBRT) and yearly thereafter for up to five years. The analysis produces a composite score (Excellent, Good, Fair, Poor) based on symmetry, colour and scar.
Results: 342 patients from two centres participating in the TARGIT Trial were assessed. All were over 50 years old with a median age at baseline of 64 years (IQR 59 to 68). Scores were dichotomised into Excellent and Good (EG), and Fair and Poor (FP). There were statistically significant increases in the odds of having an outcome of EG for patients who received TARGIT group relative to those who received EBRT group at year 1 (OR=2.07, 95% CI 1.12 to 3.85, p = 0.021) and year 2 (OR=2.11, 95% CI 1.0 to 4.45, p = 0.05).
Conclusions: This objective assessment of aesthetic outcome in patients from a randomised setting demonstrates that those treated with targeted intraoperative radiotherapy have a superior cosmetic result compared with those patients who received conventional whole-breast external beam radiotherapy.
No conflict of interest.

2010 POSTER

Analysis of different clinical target volumes of whole breast after breast-conserving surgery based on three-dimensional CT and four-dimensional CT images

S.Z. Wang[1], J.B. Li[1], H.X. Xing[2], Y.J. Zhang[1], Q.I.A.N. Shao[1], M.I.N. Xu[1], T.Y. Fan[1], F.X. Li[1]. *[1]Shandong Cancer Hospital & Institute, Department of Radiation Oncology, Jinan, China; [2]Shandong Cancer Hospital & Institute, Department of Anaesthesiology, Jinan, China*

Background and Purpose: The four-dimensional CT (4D-CT) has more information of tumour movement comparing with three-dimensional CT (3D-CT) during the whole respiratory. However, the workload of target delineation for the whole breast was heavier and the capacity of workload on the target delineation was increased greatly. In order to identify the necessary of the 4D-CT used for simulation in the IMRT of the whole breast after breast-conserving surgery, this study investigated the difference of the clinical target volumes of whole breast (CTVs) based on 3D-CT and the 4D-CT for patients after breast-conserving surgery.
Materials and Methods: Thirteen patients after breast-conserving surgery underwent 3D-CT simulation scans followed by 4D-CT simulation scans of the thorax during free breathing. Then data sets for 3D-CT and 4D-CT scans were transferred to Eclipse treatment planning software. The clinical target volumes (CTVs) of whole breast were manually delineated on the registered images of the 3D-CT, 4D-CT and maximum intensity projection (MIP) images by a radiologist under the same delineation criteria. And all the CTV delineated on the 10 phases of the 4D-CT images were fused into an internal target volume (ITV). The CTV_0, CTV_{20}, CTV_{50}, CTV_{MIP}, CTV_{3D} were defined on 0%, 20%, 50%, MIP and 3D-CT images. The volumes of the CTV, the matching index (MI) and the degree of inclusion (DI) were compared respectively.
Results: There was no difference in the CTV delineated by the same radiologist no matter based on 3D-CT or 4D-CT (P >0.05). The volume demonstrated no significant difference between CTV_{3D} and CTV_0, CTV_{20}, CTV_{50}, CTV_{MIP} (P >0.05). The difference of the MI and DI between CTV_{3D} and CTV_0, CTV_{20}, CTV_{50} was not statistically significant as well. The volume of ITV was larger than that of CTV_{3D} and CTV_{MIP}, the DI of ITV in CTV_{3D} and CTV_{MIP} Vs. DI of CTV_{3D} and CTV_{MIP} in ITV were significant as well (P <0.05).
Conclusions: The 3D-CT and MIP showed limited target movement information and it would not be a reliable clinical approach to replace 4D-CT by 3D-CT and MIP images when the clinical target volume of the whole breast was been delineated. It was more reasonable to construct ITV of whole breast based on 4D-CT after breast-conserving surgery.
No conflict of interest.

2011 POSTER

Breath hold and volumetric IMRT for accelerated partial breast irradiation (APBI)

S.O.S. Osman[1], M. Essers[1], P.H. Poortmans[2]. *[1]Dr. Bernard Verbeeten Institute, Medical Physics and Instrumentation, Tilburg, Netherlands; [2]Dr. Bernard Verbeeten Institute, Radiation Oncology, Tilburg, Netherlands*

Purpose/Objective To investigate the effect of using volumetric modulated arc therapy (VMAT) and/or voluntary moderately deep inspiration breath-hold (vmDIBH) for patients treated with external beam APBI.
Materials and Methods: For three left-sided breast cancer patients, two CT-scans were acquired, in free breathing (FB) and in vmDIBH. On each scan, five tumour volumes were contoured: upper-inner, lower-inner, central, upper-outer, and lower-outer. For each tumour location 3D conformal radiotherapy (3D-CRT) and VMAT plans both in FB and vmDIBH were made. The prescribed dose was 38.5 Gy given in 10 fractions, two fractions per day. Dose parameters for the planning target volume (PTV), heart, lungs, ipsilateral (IL) non-involved and contralateral (CL) breast were assessed and compared.
Results: VMAT dose conformity was significantly better compared to that of 3D-CRT (conformity index =0.8±0.1 vs. 0.6±0.1). The PTV volume covered with 95% of the prescribed dose increased from 94.6% for 3D-CRT to 98.7% for VMAT. IL breast receiving ⩾50% of the prescribed dose was on average reduced by 30% with VMAT compared to 3D-CRT. For dose to heart and ipsilateral lung, the tumours were grouped: 1) inner and central location, and 2) outer location. For group 1, the mean heart dose decreased from 2.1±1.8 Gy for 3D-CRT(FB) to 1.0±0.9 Gy with VMAT(FB), and 0.6±0.5 Gy for VMAT(vmDIBH). The heart V5 Gy was reduced to 2.3% with VMAT(vmDIBH) compared to 14.9% and 3.8% with 3D-CRT(FB) and 3D-CRT(vmDIBH). For group 2, the mean heart dose was 0.2−0.5 Gy for all techniques. The heart V5 Gy was 3.2% in 3D-CRT(FB) plans, while no heart received 5 Gy in VMAT(vmDIBH). VMAT(vmDIBH and FB) resulted in significant reduction of the ipsilateral lung dose: V5 Gy = 8.8±7.6% vs. 24.2±1.7% for 3D-CRT(FB). VMAT showed a slight but acceptable increase in the maximum CL breast dose (from 0.8 to 4 Gy), with the mean dose always below 1 Gy.
Conclusions: APBI with VMAT offers improved PTV dose conformity and delivers lower doses to the ipsilateral breast and lung compared with 3D-CRT, at the cost of a slightly higher but acceptable dose to the contralateral breast. VMAT shows the largest reduction in heart dose for patients with tumours in the inner and central parts of the breast. Combining VMAT and vmDIBH only slightly reduces the heart dose further.
No conflict of interest.

2012 POSTER

Screening patients for deep inspiration breath hold to reduce cardiac doses for adjuvant left breast irradiation

R. Carlson[1], K. Hiemstra[1], X. Qiu[2], S. Pearson[1], W. Xu[2], A. Fyles[1], C. Chung[1]. *[1]Princess Margaret Cancer Centre, Department of Radiation Oncology, Toronto, Canada; [2]Princess Margaret Cancer Centre, Department of Biostatistics, Toronto, Canada*

Background: When delivering radiotherapy to left-sided breast cancers, deep inspiration breath hold (DIBH) using active breath control (ABC) can significantly reduce radiation dose to heart and coronary arteries in selected patients. Currently, at our institution a cutoff of heart V50% >10cc is used to determine which patients require ABC. This dose-volume measurement requires generation of a radiation plan to select patients for ABC, delaying the second ABC CT simulation. The purpose of this study is to determine if simple 2-D measurements of the heart at the time of CT simulation can adequately screen patients for ABC. This would facilitate a streamlined process that minimizes delays for left-side breast radiation.
Materials and Methods: This study evaluated CT simulation scans from 50 randomly selected left-sided breast cancer patients treated with tangent RT alone from November 2009 to August 2012 (era when ABC was standard), where 50% of these patients were treated with ABC and 50% were not. On each CT dataset, a tangential line was drawn between the medial

and lateral tattoo and the following heart measurements were recorded by a blinded observer at 2, 3, 4, and 5 cm below the tattoos: (1) maximal heart distance (MHD) perpendicular to this line and (2) heart length (HL) along this line. The first 20 cases were measured by 2 observers to test interobserver variation. Correlation between each measurement and heart V50 (from the delivered RT plan) was calculated using linear regression. T-test was used to evaluate the association between heart measurements and ABC use. Predictive models were created using two strategies; (1) using a step wise approach utilizing the most significant factor and (2) using principle component analysis.
Results: 49 patients were analyzable as the heart dose from one patient was not available. Analysis of the first 20 patients shows the heart measurements between the two observers were similar with a correlation coefficient of 0.93 for the MHD and 0.94 for HL. For the 49 patients, the HL at 2 cm had the highest association with V50 (R^2 = 0.45; p < 0.0001). The other values that were significantly associated with V50 were HL at 3 cm (R^2=0.37; p= <0.0001), MHD at 2 cm (R^2=0.25; p = 0.0003), MHD at 3 cm (R^2=0.23; p = 0.0006) and HL at 4 cm (R^2=0.17, p = 0.0035). The predictive model using the most significant variable (HL at 2 cm) gave an adjusted R^2=0.4385 (P<0.0001). Adding other variables into the predictive model did not improve the adjusted R^2.
Conclusions: The results of this study suggests that a simple 2-D heart measurement, heart length across a line connecting the 2 tattoos at 2 cm, shows moderate correlation with the irradiated heart volume in the delivered RT plan. Although the correlation was modest, this may serve as an easy screening tool to select patients who may benefit from ABC. Appreciating the limitations of our retrospective study, validation of this predictive model is ongoing.

2013 POSTER

Irradiation of the internal mammary nodes in breast cancer patients with morphologically verified metastasis at this zone

A. Petrovsky[1], A.A. Zaytseva[1], A.V. Trigolosov[1], V.A. Uimanov[1], Y.A.V. Vishnevskaya[2], I.A. Gladilina[1], M.I. Nechushkin[1]. *[1]Russian Cancer Research Center, Radiosurgery, Moscow, Russian Federation; [2]Russian Cancer Research Center, Pathology, Moscow, Russian Federation*

Objective: Detection of regional lymph nodes involvement is an extremely important step in the diagnosis and treatment of breast cancer. As with axillary lymph node metastases, parasternal lymph nodes metastases are an important prognostic factor.
Goal: To detect metastasis in the internal mammary lymph nodes (IMN) and to find out the best way of radiation therapy at this zone.
Material and Methods: Retrospective study of 1125 patients with breast cancer who underwent thoracoscopic internal mammary lymphadenectomy in 1998–2008 was performed. Metastases were found in 204 of 1125 cases (18.3%), representing 33.9% of all cases of regional metastases (n = 601). Only patients with metastasis had radiation therapy at IMN zone. Standard regimen (2 Gy x 25, total 50 Gy) underwent 87 patients (42.6%) − Group A, hyperfractionated regimen (3 Gy x 13, total 39 Gy) − 80 patients (39.2%) − Group B, no radiation − 37 patients (18.1%) − Group C.
Results: No difference in overall survival was registered in all three groups. Median disease free survival was significantly worth in Group C (5.5 years) in comparison with Group A (7.8 years) and Group B (not achieved).
Conclusion: We believe that the thoracoscopic internal mammary lymphadenectomy should be a part of the diagnostic process in patients with breast cancer. Irradiation of IMN leads to better disease-free but not to overall survival at 8.1 years median follow up. Hyperfractionated regimen could be safely used for breast and IMN irradiation.
No conflict of interest.

2014 POSTER

Case selection for targeted intraoperative radiotherapy (TARGIT)

J.S. Vaidya[1], F. Wenz[2], M. Bulsara[3], J.S. Tobias[4], S. Massarut[5], D. Joseph[6], M. Baum[1]. *[1]University College London, Division of Surgery and Interventional Science, London, United Kingdom; [2]Universitätsmedizin Mannheim, Klinik für Strahlentherapie und Radioonkologie, Mannheim, Germany; [3]University of Notre Dame, Institute of Health Research, Fremantle, Australia; [4]University College London Hospitals, Radiation Oncology, London, United Kingdom; [5]Centro di Riferimento Oncologico, Surgery, Aviano, United Kingdom; [6]Sir Charles Gairdener Hospital, Radiation Oncology, Perth, Australia*

Background: The TARGIT-A randomised trial compared a risk-adapted approach using targeted intraoperative radiotherapy (TARGIT) with whole breast external beam radiotherapy (EBRT) after lumpectomy for early breast cancer. At the San Antonio update, it was suggested that the preferred option is to give TARGIT concurrently with lumpectomy (prepathology). In this analysis we describe patient and tumour factors that may help select patients for TARGIT based on the results of an *a priori* statistical analysis plan.
Methods: In this large international trial, 3451 patients (age>=45, unifocal invasive ductal carcinoma, size $\leqslant$3.5 cm) from 33 centres in 10 countries were randomly allocated to either TARGIT or EBRT. Primary outcome was ipsilateral breast recurrence and secondary included mortality. Before unblinding for this analysis, we hypothesised that progesterone receptor (PgR) status, as an expression of a functionally active oestrogen receptor (ER), is a surrogate for radiation responsiveness and could predict a difference between the outcome for local control in the two randomised groups and pre-specified a detailed analysis by PgR status. We also assessed whether a Cox proportional hazard model including age, margin status, tumour grade, ER, PgR, HER2, vascular invasion and node positivity was consistent with our results.
Results: For PgR positive cases, there was no significant difference in the primary outcome of Ipsilateral breast recurrence between TARGIT and EBRT (2.3%(1.3−4.3) vs. 1.5%(0.75−3.0) p = 0.51, while in PgR negative cases there were significantly more local recurrences after partial breast irradiation using TARGIT: 7.0%(3.5–13.6) vs. 0.5%(0.1−3.7) p = 0.017. By contrast, age, margin status, tumour grade, tumour size, vascular invasion, node positivity, ER and Her2 status were not found to be significant predictors. Even age younger than 50 or grade 3 cancers had similar outcome with TARGIT or EBRT. Exploratory analyses in conjunction with the timing of TARGIT, revealed that when TARGIT was given concurrently in PgR positive cases (n = 1625) the results were (TARGIT vs. EBRT): ipsilateral breast recurrence 4 vs. 5, 5-year risk 1.4%(0.46−3.9) vs. 1.2%(0.48−2.9) HR 0.82(0.22–3.06), and overall mortality 18 vs. 31, 5-year risk 3.3%(1.83–6.04) vs. 6.4%(4.3−9.6) HR 0.60(0.34–1.08).
Conclusions: It appears that progesterone receptor status is useful in selecting cases for using the TARGIT concurrently with lumpectomy for breast cancer. Progesterone receptor negative patients may fall in the cautious or unsuitable category and progesterone receptor positive cases are in the suitable category for partial breast irradiation with TARGIT.

2015 POSTER

Late toxicities and outcomes after one year of adjuvant radiotherapy associated with concurrent bevacizumab in patients with non-metastatic breast cancer

V. Pernin[1], L. Belin[2], P. Cottu[3], P. Bontemps[4], C. Lemanski[5], B. De La Lande[6], P. Baumann[7], F. Missohou[8], C. Levy[9], Y. Kirova[1]. *[1]Institut Curie, Radiotherapy Department, Paris, France; [2]Institut Curie, Department of Biostatistics, Paris, France; [3]Institut Curie, Oncology Department, Paris, France; [4]CHU Jean Minjoz, Radiotherapy Department, Besançon, France; [5]Institut régional du Cancer de Montpellier, Radiotherapy Department, Montpellier, France; [6]Institut Curie, Radiotherapy Department, Saint Cloud, France; [7]Centre d'Oncologie de Gentilly, Radiotherapy Department, Nancy, France; [8]Centre Henri Becquerel, Radiotherapy Department, Rouen, France; [9]Centre François Baclesse, Radiotherapy Department, Caen, France*

Background: Few data are available regarding the safety of the concurrent combination of bevacizumab (BV) with adjuvant locoregional radiotherapy (RT) for breast cancer, especially in terms of late toxicity. The aims of this study were to determine late toxicities and outcomes among patients with non-metastatic BC treated with this combination.
Materials and Methods: In our multicenter prospective and descriptive study, we analyzed toxicities of adjuvant RT in patients with non-metastatic BC receiving concurrent BV. Early and late toxicities were assessed by the Common Terminology Criteria for Adverse Events (v3.0). Evaluation was done 12 months after the end of RT. All patients provided written informed consent before enrollment.
Results: Among patients enrolled in our study from October 2007 to August 2010, evaluation at 12 months was available for 63 patients. Mean age was 51 years. Among tumors, 17% were luminal BC, 24% HER2+ and 70% triple negative. A total of 56 patients had an invasive ductal carcinoma. Nineteen patients were stage I (30%), 21 patients stage II (33%) and 22 patients stage IIIB (35%) without patients stage IV (no data for one patient). A total of 23 patients (37%) received neoadjuvant chemotherapy plus BV followed by surgery then RT whereas 40 patients (63%) had surgery followed by adjuvant chemotherapy plus BV then RT. A total of 28 patients (44%) achieved post mastectomy RT and 35 patients (56%) had a whole breast RT with a boost in the surgical bed. Lymph node RT was performed in 42 patients (67%) with internal mammary chain RT in 25 patients (40%). Concurrent trastuzumab with RT and BV was performed in 15 patients (23%). Mean time of BV treatment was 10.2 months (2−13)

and mean total dose of BV was 15085 mg (960–28080). One year after the end of the RT, the most common late toxicities were grade 1−2 pain (11%), grade 1 arm lymphedema (6%), grade 2 arm lymphedema (2%), grade 1 fibrosis (5%). No patients were identified to have ⩾ grade 3 late toxicity. One patient had a grade 1 arterial hypertension and one patient had a grade 1 ventricular extrasystoles. An asymptomatic grade 2 left ventricular systolic dysfunction occurred in one patient. One year after RT and concurrent BV, overall survival was 100% and no locoregional or metastatic relapse were reported.

Conclusions: Our results indicate that concurrent BV with loco-regional RT provide acceptable late toxicities after one year in patients with non-metastatic BC.

No conflict of interest.

2016 POSTER

Intraoperative radiotherapy using the Intrabeam® device as intraoperative boost in breast conserving therapy − a single institution experience after the first 200 cases

H. Kolberg[1], M. Stephanou[1], L. Akpolat-Basci[1], G. Lövey[2].
[1]Marienhospital Bottrop, Klinik für Gynäkologie und Geburtshilfe, Bottrop, Germany; [2]BORAD, Strahlentherapie, Bottrop, Germany

Background: The concept of breast conserving therapy in breast cancer consists of a segmental resection followed by whole breast irradiation with a dose of 50 Gray. The expected local recurrence rate in 5 year follow-up is 7.6%, after adding a boost irradiation of the index region with a dose of 10 to 16 Gray 4.3%. The boost irradiation as an intraoperative procedure using the Intrabeam® device showed a further decrease of local recurrence rates down to 1.75% in 5 year follow up. In our study we investigated the influence of this procedure on the duration of the operation, the postoperative hospitalisation and the cosmetic results.

Methods: We collected the data of the first 200 patients treated with the Intrabeam® device during breast conserving therapy in our institution since April 2010. 60 (30 %) of the 200 patients had been treated with neoadjuvant chemotherapy +/− Trastuzumab. After the end of the whole breast irradiation we collected data concerning the satisfaction of the patients and their doctors with the cosmetic outcome. To investigate the influence on the duration of the operation and the hospital stay, we then compared the data of the first 200 patients treated with the Intrabeam® with the data of 200 patients, who had breast conserving therapy, before we started using the Intrabeam® but who would have been feasible for intraoperative radiotherapy.

Results: The data concerning the satisfaction with the cosmetic result are described in table 1.

Table 1. Satisfaction with the cosmetic results after completion of the whole breast irradiation (in %)

	Excellent	Good	Satisfying	Acceptable	Poor	Inacceptable
Patients	6	63	23	6	2	0
Gynecologists	9	59	27	2	3	0

The average duration of the surgical procedure was 99.61 min in the cohort with intraoperative radiotherapy. We could see a learning curve between the first 100 and the second 100 cases. In the first 100 cases the time duration was 104.29 min, in the second 100 cases this time was markedly shorter with 94.93 min. The average duration of the operation in the cohort without intraoperative radiotherapy was 67.07 min. The average prolongation of the duration of the surgical procedure was 32.54 min.

The hospital stay differed moderately with 2.2 days without and 3.3 days with intraoperative radiotherapy. The reason for the prolongation in most of the cases was a need for a later removal of the drainage in the intraoperatively radiated patients.

Conclusions: Intraoperative Radiotherapy with the Intrabeam® device is easy to integrate into daily clinical practice. The prolongation of the duration of the surgical procedure of about half an hour and of the hospital stay of one day are absolutely tolerable if seen in relation to the expected better local control. The satisfaction with the cosmetic result in 92% of the patients and 95% of the physicians is an indicator, that intraoperative radiotherapy doesn't lead to a compromise in the oncoplastic approach.

No conflict of interest.

2017 POSTER

Comparison of the volume and localization of internal gross tumor volume and planning target volume delineated by clips and seroma based on 4DCT scan for external-beam partial breast irradiation after breast conserving surgery

Y. Ding[1], J.B. Li[1], W. Wang[1], S.Z. Wang[1]. *[1]Shandong Tumor Hospital & Institution, Department of Radiation Oncology, Jinan, China*

Background: To explore the volume and localization of internal gross tumor volume(IGTV) and planning target volume delineated separately by metal clips, seroma, both clips and seroma based on four-dimensional computed tomography (4DCT) during free-breathing(FB).

Material and Methods: Fifteen early-stage breast cancer patients after breast-conserving surgery were recruited for EB-PBI. The gross tumor volume formed by clips, seroma, both clips and seroma were defined as GTVc, GTVs and GTVc+s, respectively. GTVc, GTVs and GTVc+s were delineated by one radiation oncologist on the ten sets CT images. The IGTVc, IGTVs, IGTVc+s were combined by GTVc, GTVs and GTVc+s on ten sets CT images, respectively. The PTVc, PTVs, PTVc+s were formed by adding 15 mm margin to IGTVc, IGTVs, IGTVc+s, respectively. The IGTV and PTV volume and the distance between the center of IGTV/IGTV, PTV/PTV were recorded. Dice similarity coefficient(DSC) of IGTV/IGTV, PTV/PTV were calculated.

Results: The volume of IGTVc+s was significantly larger than IGTVc and IGTVs($p < 0.05$), and the volume of PTVc+s was significantly larger than PTVc and PTVs($p < 0.05$). DSC of PTVc/PTVs, PTVc/PTVc+s, PTVs/PTVc+s were significantly superior to IGTVc/IGTVs, IGTVc/IGTVc+s, IGTVs/IGTVc+s. DSC of IGTVc/IGTVs (0.56 ± 0.14) was significantly inferior to IGTVc/IGTVc+s (0.76 ± 0.12) and IGTVs/IGTVc+s (0.69 ± 0.15). The difference among DSC of PTV/PTV was not statistically significant($F=0.408$, $p = 0.668$). DSC of IGTVc/IGTVc+s, IGTVs/IGTVc+s, PTVs/PTVc+s were negatively correlated with their centroid distance($r<0$, $p < 0.05$).

Conclusion: The volume of IGTVc+s was significantly larger than IGTVc and IGTVs, and the volume of PTVc+s was significantly larger than PTVc and PTVs. DSC of PTV/PTV was significantly superior to IGTV/IGTV. The spatial mismatch of IGTVc/IGTVc+s, IGTVs/IGTVc+s, PTVs/PTVc+s were negatively correlated with their centroid distance.

No conflict of interest.

2018 POSTER

Changes in tumor shadows and microcalcifications on mammography image analysis in elderly patients with stage I/II breast cancer following KORTUC II, a new radiosensitization treatment

A. Tsuzuki[1], Y. Ogawa[1], A. Nishioka[1], S. Yaogawa[1], K. Itoh[1], Y. Yamada[1], T. Sasaki[1], N. Yokota[1], S. Tokuhiro[1], N. Hayashi[1]. *[1]Kochi Medical School, Radiology, Kochi, Japan*

Background: We have employed non-surgical therapy using a novel enzyme-targeting radiosensitization treatment, Kochi Oxydol-Radiation Therapy for Unresectable Carcinomas, Type II (KORTUC II) for patients with early-stage breast cancer treatment. KORTUC II can convert low linear energy transfer (LET)-radioresistant tumors into radiosensitive tumors on the basis of the radiosensitizing action of one of its components, hydrogen peroxide.

The purpose of this study was to examine changes in tumor shadows and microcalcifications on mammography (MMG) in elderly patients with breast cancer following KORTUC II treatment.

In addition to MMG, positron emission tomography-computed tomography (PET-CT) was performed to detect both metastasis and local recurrence.

Material and Methods: Patients with breast cancer but no clinical evidence of distant metastasis were enrolled in the KORTUC II trial.

Radiation therapy (RT) with 4 MV X-ray. Hypofractionated RT was administered using a tangential field approach: the total dose was 44 Gy administered as 2.75 Gy/fraction.

The new radiosensitizer was injected into the breast tumor tissue twice a week under ultrasonographic guidance.

Therapeutic effects of KORTUC II were evaluated in terms of the changes in size of tumor shadows and microcalcifications shown on the monitor before and after KORTUC II. Changes of tumor density on MMG were also analyzed using image analysis software image-J. PET-CT was also performed during follow-up to detect both metastasis and local recurrence.

Results: In all 14 patients in this study, tumor shadows on MMG completely disappeared within several months after KORTUC II treatment. Microcalcifications also disappeared or markedly decreased in number.

As a result the image analysis that disappearance of the tumors was also confirmed by the profile curve of tumor density on MMG following KORTUC II treatment; density fell and eventually approached that of the peripheral mammary tissue in 3 months following KORTUC II treatment.

These 14 patients have so far shown neither local recurrence nor distant metastasis also on PET-CT with a mean follow-up period of approximately 72 months at the end of October 2012.
Conclusion: We concluded that breast-conservation treatment using KORTUC II followed by aromatase inhibitor is a promising therapeutic method for elderly patients with breast cancer, in terms of avoiding any surgical procedure. Moreover, MMG is considered to be useful for evaluating the efficacy of KORTUC II.
No conflict of interest.

2019 POSTER

Actual dose delivery of vmDIBH in breast cancer patients is at least as good as in free breathing

P. Brouwers[1], T. Lustberg[1], L. Murrer[1], S. Nijsten[1], L. Boersma[1].
[1]*MAASTRO-clinic, Radiotherapy, Maastricht, Netherlands*

Purpose: Different breathing movement management techniques have been described which effectively spare the heart in tangential breast irradiation. The easiest and cheapest way is voluntary moderately deep inspiration breath hold (vmDIBH), but reproducibility, and thus actual dose delivery, of this method is unclear. The aim of this study is to determine whether the 2D measured delivered transit dose during vmDIBH is comparable to the dose delivered during free breathing (FB).
Material and Methods: Data of 30 patients irradiated during vmDIBH and 29 patients irradiated in FB were analyzed. Patients were irradiated to a total dose of 42.7−50 Gy in 16−25 fractions using a forward IMRT technique and a Shrinking Action Level protocol (α=10, n = 3) for set-up verification. 2D transit EPID dosimetry for the tangential fields was performed on various days, resulting in 580 measurements in 16 vmDIBH patients and 257 measurements in 15 FB patients. The measured transit dose was compared with a predicted transit dose by calculating percentage of pixels exceeding gamma criteria, using 5% as the dose-difference criterion and 5 mm as the distance-to-agreement criterion. The percentage of pixels exceeding 10% was determined for each measured fraction, for both latero-medial and medio-lateral beams. Mean values of this parameter for vmDIBH patients were compared to FB patients. Measurements exceeding 10% gamma were visually classified in translations (set-up error/organ motion) or other causes (breast shape, rotation). The translation classification is assumed the only cause of differences in measured dose between vmDIBH and FB.
Results: The percentage of pixels exceeding gamma criteria was 12.2% (+/−10.9) in vmDIBH patients and 10.9% (+/−10.1) in FB patients ($p > 0.05$). The percentage of fractions that exceeded the 10% gamma criteria was 44 +/− 11% (1 SD) in vmDIBH patients and 36 +/−11 % (1 SD) in FB patients. In both patient groups, 11.0% of the measured abnormalities were caused by translations.
Conclusion: Dose delivery in breast cancer patients irradiated during vmDIBH, as verified *in vivo* with 2D EPID dosimetry, is as accurate as in patients irradiated during FB.
No conflict of interest.

2020 POSTER

Dosimetry and toxicity among patients treated in the prone versus dorsal position with intensity modulated radiotherapy (IMRT)

E. Moser[1], O. Pares[2], G. Louvel[2], S. Vieira[3], J. Stroom[3]. [1]*Champalimaud Foundation, Lisbon, Portugal;* [2]*Champalimaud Foundation, Radiotherapy/Breast Unit, Lisbon, Portugal;* [3]*Champalimaud Foundation, Radiotherapy, Lisbon, Portugal*

Background: Since 2011, all adjuvant breast cancer patients are treated with fixed-angle IMRT or VMAT at the Champalimaud Cancer Center (n = 369). The standard fractionation scheme has become 16 × 2.66 Gy or 15 × 2.7/3.2 Gy with integrated boost. Plans show excellent target coverage, also in lymph node areas (48% of our patients), low maximum dose (Dmax average, 107.28%) and good dose homogeneity (median 1.05). With a minimum of 6 months' follow-up, the treatment was very well tolerated, including women with large breast volumes. In the first patients pneumonitis was observed (8 cases at 6 months), probably due to a large low dose bath (V5>70%). Since the introduction of a stricter dose constraint for V5 only one new case (large breasts) has been observed. To reduce further the pulmonary dose, a prone board (CIVCO Horizon) was introduced.
Methods and Materials: All patients, since January 2013 (n = 47) were planned in both dorsal and prone position with full fixed angle IMRT. Treatment was mostly performed in dorsal position but all patients underwent at least one conebeam scan in prone position to evaluate the reproducibility.
Results: IMRT resulted in good target coverage and homogeneity in both dorsal and prone position. In means of lung and heart exposure not all patients benefitted from prone position. For the left sided patients, often, more heart dose was required for PTV coverage without exposure of the contralateral breast. Delineation of lymph node regions and boost was often debatable among doctors. For treatment repositioning in prone was more difficult, needing more tattoos, security margins and daily conebeam scans.
Conclusion: Altogether, hypofractionated breast full fixed angle IMRT results in homogeneous dosimetry and yields a confirmed benefit in terms of toxicities. The extra benefit of prone position is moderate and not only anatomy dependent. Prone positioning needs daily imaging and extra tattoos to be as reproducible as the dorsal treatment. Further investigation is needed to harmonize target definition and improve reproducibility of prone irradiation before accepting prone IMRT as a standard of care.
No conflict of interest.

2021 POSTER

Adjuvant radiotherapy for skin-sparing mastectomy versus conventional mastectomy − retrospective comparative analysis from a single institution

I. Silva Fernandes[1], J.M. Fernandes Junior[2], A. Pereira Quinto[2], G. Zucca Mattes[3], R.J. Afonso Junior[2], A. Arthur Jacinto[2], A. Molotievschi[2], M. Duarte De Mattos[2]. [1]*Hospital do Cancer de Barretos, Barretos, Brazil;* [2]*Hospital do Cancer de Barretos, Radiotherapy, Barretos, Brazil;* [3]*Hospital de Câncer de Barretos, São Paulo, Brazil*

Background: The Skin-Sparing Mastectomy (SSM) advocates the preservation of the skin and allows immediate breast reconstruction with better cosmetic results and higher patient satisfaction. Although the widespread of SSM technique, there is still some concern if native skin preservation could increase the risk of local recurrence in breast cancer.
Endpoint: *Primary endpoints*: To evaluate the recurrence-free survival (RFS) of patients submitted to SSM and conventional mastectomy (CM) and its impact on adjuvant radiotherapy decision.
Secondary endpoints: To assess the rates of distant recurrence and complications/loss of the prosthesis with different techniques.
The endpoints were also studied according to the following variable: age, tumor grade histology, angiolymphatic invasion (ALI), margins status, stage, nodal involvement, and associated treatments.
Materials and Methods: From January 2009 to December 2010 260 patients were submitted do mastectomy at Barretos Cancer Hospital, Brazil. All the records and chart were retrospectively evaluated. Adjuvant radiation therapy was defined according to physician discretion, although there was no recommendation to change the approach for SSM.
The chi-square test was used for comparison between variables and. Kaplan–Meier and long-rank test were used to evaluate outcomes and the confidence interval adopted was 95%.
Results: The median follow-up was 32.4 months. Two years RFS for all patients was 94.4% and there was no statistically difference between RFS according to mastectomy approach (SSM =100% vs MC =93.2%, $p = 0.053$). Pathological and clinical stage, tumor grade histology, tumor size, nodal involvement, angiolymphatic invasion, adjuvant and neoadjuvant chemotherapy were prognostic factor for RFS.
Complications were more frequent in SSM (26.7% vs. 3.7%, $p < 0.001$).
Skin sparing mastectomy was not associated with different criteria for adjuvant radiation therapy when compared with the institutional protocol for CM.
Conclusion: In our experience SSM does not appear to result in higher local recurrence in 2 years when compared to CM. Radiation oncologist did not change their criteria to define RT despite of mastectomy technique.
No conflict of interest.

2022 POSTER

Acute and late toxicity with hypofractionated radiation therapy for early breast cancer compared to conventional radiotherapy

P. Ciammella[1], M. Galeandro[1], A. Podgornii[1], R. Micera[1], D. Ramundo[1], E. Cagni[1], C. Iotti[1]. [1]*Arcispedale Santa Maria Nuova, Radiation Department, Reggio Emilia, Italy*

Background: The purpose is to evaluate toxicity and cosmetic outcome in breast cancer survivors treated with hypo-fractionated radiotherapy (HFRT) and to identify risk factors for toxicity. For comparison, a group of 65 patients with similar characteristics and consecutively treated with conventional fractionation was retrospectively selected.
Materials and Methods: From April 2010 and September 2012, 240 women with early breast cancer were treated with HFRT, after conserving surgery. The patients received 40.05 Gy in 15 fractions. The boost to the tumour bed was administered with a total dose of 9 Gy in 3 consecutive fractions in 74 women due to young age (<50 yrs) or to positive margins. Eligibility criteria were: T<5 cm, age>18 years, no indication to lymph nodal RT (<3 positive lymph-nodes). Physician-rated toxicity and

cosmetic outcomes were prospectively assessed during yearly follow-up after radiotherapy.
Results: In the HFRT group, the mean age was 69 years. 11% and 32% patients were affected by diabetes mellitus and hypertension, respectively. 13% had tumours that were 2 cm or larger in diameter; pTis = 17%, pT1a= 6%, pT1b= 23%, pT1c=41%, pT2=13%; 10% had oestrogen-receptor-negative disease and 29 % had high-grade disease. Pre-operative chemotherapy was administered in 10 patients; adjuvant systemic therapy and hormone therapy were given in 24 patients, while 11 and 205 patients received chemotherapy or hormone therapy alone, respectively. The mean follow-up was 19 months (range 6−32 months). The median time from surgery was 29 days, with overall median treatment duration of 22 days. By the end of RT 18% of the patients treated with HFRT developed no toxicity, while 55.7% showed grade 1 and 13.3% grade 2 acute skin toxicity. Only one patient experienced a grade 3 acute skin toxicity. In the control group, early G1 reactions were observed in 24 patients (42%); 19% of patients showed G2 acute toxicity and only one patient developed G3 acute reaction. Late toxicity was assessed after 6 months from RT completion in 120/190 patients in the HFRT and in 51/65 patients in the standard RT group. Late toxicity according to the RTOG criteria was observed in 9 patients (7.5%) in the HFRT group and in 4 patients (8%) in the conventional fractionated radiation group. The difference was not statistically significant. Cosmetic result was assessed and scored at the RT end and 6 months later: at last follow up, 71% of women in the control-group as compared with 68.8% of the women in the HFRT group had a good or excellent cosmetic outcome. The boost and chemotherapy resulted predictive factors of radiation-induced toxicity ($p < 0.03$). We don't found any significant association between cosmetic outcome and the examined variables.
Conclusions: Our results confirm the feasibility of the HFRT in patients with breast cancer. If compared with conventional RT group, the HFRT not seems to increase the late toxicity. Long-term follow up is needed to confirm this finding.
No conflict of interest.

2023 POSTER

A comparative study on the displacement of surgical cavity center defined separately by clips and seroma based on 4DCT scan for external-beam partial breast irradiation

Y. Ding[1], J.B. Li[1], W. Wang[1], T.Y. Fan[1], M. Xu[1], Q. Shao[1], Z.F. Ma[1], S.Z. Wang[1], C.Q. Liang[1]. *[1]Shandong Tumor Hospital & Institution, Department of Radiation Oncology, Jinan, China*

Background: To compare the displacement of surgical cavity center delineated by metal clips and seroma based on the four-dimensional computed tomography (4DCT) in the free-breathing(FB) state for external-beam partial breast irradiation(EB-PBI) after breast conserving surgery.
Material and Methods: Fourteen breast cancer patients after breast-conserving surgery were recruited for EB-PBI. All of the metal clips in the cavity were delineated on each of the 10 respiratory phase. All of the metal clips were marked as the geometry. The gross tumor volume formed by the clips and the seroma were defined as GTVc and GTVs, respectively. The centra displacements of the geometry, GTVc, GTVs and the selected boundary metal clips in the left-right(LR), anterior-posterior(AP)and superior-inferior(SI) were measured and compared. Three dimensional displacement vectors of the geometry, GTVc and GTVs were calculated.
Results: The displacements in the LR, AP and SI directions were 2.20 mm, 1.80 mm and 2.70 mm for geometry center; 0.90 mm, 1.05 mm and 1.20 mm for GTVc center; 0.80 mm, 1.05 mm and 0.80 mm for GTVs center. For every center the displacements in the LR, AP and SI directions don't have significant difference (X2=3.837, 2.051, 3.647, P = 0.147, 0.359, 0.161). In the three dimensional directions, the displacements of the geometry were larger than GTVc and GTVs ($P<0.05$). The displacement of GTVc was larger than the GTVs center in SI direction ($Z = -2.048$, $P = 0.041$). The displacement of the three cavities were larger than the four selected clips.
Conclusion: In the FB state,the centra displacements of the geometry resulted from the respiration movement were larger than GTVc and GTVs,and also larger than the four selected boundary metal clips in three directions, but there was no significant difference between GTVc and GTVs.
No conflict of interest.

2024 POSTER

Mastectomy with immediate reconstruction: A challenge to the radiation oncologist? Dosimetric analysis

R.T. Ugino[1], P.P.R. Ferreira[1], B.M. Minotti[1], I.G.N.M. De Araujo[1], S.A. Hanna[1], G.N. Marta[1], E.L. Pelosi[1], H.A. Carvalho[1]. *[1]Hospital Sírio-Libanês, Radiation Oncology, São Paulo, Brazil*

Background: Most women with breast cancer will receive radiotherapy (RT) as part of their treatment, with benefit in both local control and survival. The purpose of this study was to evaluate the impact of immediate breast reconstruction (IBR) in postmastectomy radiotherapy dose distributions in the reconstructed breast, heart, lungs, and contralateral breast. Also, to evaluate the changes made in the standard opposed tangents treatment planning to adequate the target coverage and if there was any difference between IBR with tissue expanders (EXP) or prostheses (PRO).
Materials and Methods: Forty-eight patients submitted to IBR with either EXP or PRO. All patients were treated with 50 or 50.4 Gy (1.8 to 2 Gy/day) with 3-dimensional conformal RT, initially planned with opposed tangents and 'field-in-field' technique for better dose homogeneity. Volume delineation was made according to the Radiation Therapy Oncology Group recommendations. Dosimetric variables related to target coverage and organs at risk (OAR) doses were analyzed. PTV coverage was evaluated according to the ICRU 50 and 62 recommendations, with a 5 mm margin beneath the skin surface. OAR dose constraints were established according to 'QUANTEC'. The mean values of the studied variables were compared between patients with EXP and PRO (Student-t test) with the significance level set at 5% ($p \leqslant 0.05$).
Results: Among the 48 studied patients, 34 were reconstructed with PRO and 14 with EXP. In all situations CTV and PTV coverage was considered adequate. However, 6 (12.5%) patients had their treatment planning modified in order to achieve a proper coverage of the target. The major reason was inclusion of internal mammary nodes (IMN) in the treatment (4 patients). The group with PRO presented higher CTV mean doses (D90 = 48 Gy versus 47 Gy in EXP) and lower lung doses when compared to EXP ($p \leqslant 0.05$). Nevertheless, there was a higher proportion of patients with lymph nodes irradiation in the EXP group. All the OAR dose constraints were kept below the recommended limits.
Conclusion: Proper target coverage was achieved in all patients, despite the fact that, in a small proportion of cases, the standard opposed tangents planning had to be modified. PRO seems to be better than EXP regarding 'breast' coverage. The lower lung doses the PRO group were possibly related to the lesser IMN irradiation.
No conflict of interest.

2025 POSTER

Acute skin toxicity in Korean breast cancer patients carrying BRCA mutations

H. Park[1], D.H. Choi[1], J.M. Noh[1], S.J. Huh[1], W. Park[1], S.J. Nam[2], J.E. Lee[2]. *[1]Samsung Medical Center Sungkyunkwan University School of Medicine, Radiation Oncology, Seoul, Korea; [2]Samsung Medical Center Sungkyunkwan University School of Medicine, Surgery, Seoul, Korea*

Background: In contrast to *in vitro* studies, most clinical trials testing the radiosensitivity of *BRCA* mutations do not find a correlation between *BRCA* status and enhanced radiosensitivity. These trials include different ethnicities, and there is a lack of clinical data on *BRCA1/2* mutation carriers and radiosensitivity in non-Caucasian patients. The goal of this study was to investigate acute skin toxicity, as a part of radiosensitivity, in breast cancer patients with *BRCA1/2* mutations.
Material and Methods: *BRCA* mutation analysis was performed for 213 patients who underwent breast-conserving therapy using radiotherapy. Skin toxicity was scored according to the radiation therapy oncology group (RTOG) criteria during treatment and during one-month follow-up after radiation therapy.
Results: Forty-six patients had *BRCA1/2* mutations and 57 patients showed higher than grade 2 (RTOG) skin toxicity. In multivariate analysis, significant associations were found between mean breast volume and acute skin toxicity. *BRCA* mutation status, however, failed to show a significant correlation. Some single nucleotide polymorphisms (SNPs) were associated with increased acute skin toxicity.
Conclusions: Our results indicate that carriers of *BRCA1/2* mutations among non-Caucasian breast cancer patients showed no enhancement in radiation sensitivity. Although some *BRCA* SNPs have marginal correlation with skin toxicity, the clinical impact is undetermined. Multiple genetic markers may be correlated with normal tissue responses after radiotherapy. Further studies are needed to identify genetic predispositions to normal tissue responses after radiotherapy.
No conflict of interest.

2026 POSTER

Multicatheter brachytherapy under local anesthesia for accelerated partial breast irradiation

P. Wojcieszek[1], M. Lewandowska[2], B. Bialas[1], S. Kellas-Sleczka[1], M. Fijalkowski[1]. [1]*Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Brachytherapy, Gliwice, Poland;* [2]*Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Anesthesiology, Gliwice, Poland*

Background: Accelerated partial breast implantation (APBI) becomes important adjuvant modality for early breast cancer patients. There are several techniques of brachytherapy (BT). Multicatheter interstitial APBI is performed in our department. One of the disadvantages is implantation procedure under anesthesia. Due to age many of women have increased risk of complications during general anesthesia. We decided to perform catheters implantation in local anesthesia to avoid that. This study aimed on quality of local anesthesia during multicatheter implantation procedure.
Material and Methods: 85 consecutive APBI patients filled anonymously the anesthesia quality questionnaire (AQQ). Part one was filled before procedure and part two after it. Third part was given to patient after removing catheters. Questions asked about fear of APBI, former anaesthesia and pain during procedure. Pain Intensity was evaluated in 10 points scale. Patient had usually interstitial catheters implantation on Monday. Fractionation schedule was 8 fractions, twice a day (6 hours gap) for four days. Catheters were removed immediately after last fraction.
Local anesthesia region was chosen directly after preplanning. Oral 7.5 mg midazolam was used. Breast skin after disinfection was anesthetized with 1.5% lignocaine. Only this parts of skin was anesthetized, which were covered with template.
Results: Every AQQ was valid, however there were information lacking in several questionnaires. Median age was 63 years (range 49−80). 11 women had ischemic heart disease (IHD), 38 patients had hypertension and 15 patients had diabetes. Only 4 women had depression, 11 more were neurotic with occasional sedative use. 8 patients had diabetes and hypertension. 7 women had IHD and hypertension. Two patients had IHD, hypertension and diabetes.
Even after usual doctor conversation and signing consent, 59 patients had concerns of APBI. 26 women were afraid of pain during catheter placement. 7 patients was afraid of pain after procedure. 10 patients were afraid of combination of these. 40 patients were anxious of APBI.
Median score on fear scale was 4 points (range 0−10). Median score on pain scale after the catheter implantation was 2 points (range 0−8). 45 women suggested that the most painful procedure was breast skin anesthetization.
70 women gave maximum of 10 points, when asked to evaluate APBI on last day. Median score was 10 points (range 7−10). All of the patients did not regret they chose APBI BT. Moreover they would recommend it to their friends.
In univariate analysis fear of pain strongly correlated with pain during implantation (HR:7.5; p-0.000). Also APBI anxiety was linked to pain during procedure (HR:2.96; p-0.007).
Conclusions: Local anesthesia for multicatheter implantation in APBI patients is good alternative to general anesthesia. Breast cancer patients were content of choosing this option of adjuvant treatment.
No conflict of interest.

2027 POSTER

Lung and heart sparing in breast cancer patients treated in the lateral decubitus position

G. Capezzali[1], Y. Kirova[1], F. Campana[1], E. Costa[1], A. Chilles[1], C. Aristei[2], A. Zygogianni[1], A. Fourquet[1]. [1]*Institut Curie, Radiotherapy, Paris, France;* [2]*Perugia Hospital, Radiotherapy, Perugia, Italy*

Background: The isocentric lateral decubitus position (ILD) is an original radiotherapy technique developed at the Institute Curie for 17 years and thousand patients have been treated using it. We have introduced computed tomography planning for all patients treated in the ILD position. The purpose of this study is to evaluate the doses to two principal organs at risk (OAR): heart and lung.
Materials and Methods: Fifty patients (pts) with left breast cancer treated using 3D ILD have been studied. The patient undergoes a planning CT scan in this position used dedicated device. Using virtual simulation, two isocentric tangential beams-medial and lateral-with matching posterior borders are set-up. Then individual dosimetric planning is realized with Eclipse (Varian) and algoritme photon_AAA. The treatment is performed by photons of 6 or 4 MV. In all patients the breast volume, heart and lung were delineated and evaluated its dose-volume histograms (DVH). We measured the central lung distance (CLD) and maximal heart distance (MHD) in all patients and analysed the results.
Results: Fifty consecutive left side early stage breast cancers were studied, of them: 33 received a total dose of 66 Gy/33 fractions (50 Gy on breast and boost to 16 Gy),16 pts a dose of 41.6 Gy/13 fractions/5 weeks, 1 pt 47.25 Gy. 14% of pts treated have a part of heart in the treatment field; the average value of MHD is of 0.4 cm. 28% of pts treated have their lung in the treatment field. In the 33 pts who received a total dose of 66 Gy: the heart and the lung received respectively a mean dose of 1.71 Gy [1.28;2.69], σ=0.57 and a mean dose of 0.97 Gy [0.57;1.61], σ=0.31. In the 16 pts who received a total dose of 41.6 Gy: the heart and the lung received respectively a mean dose of 0.77 Gy [0.33;1.60], σ=0.28 and a mean dose of 0.71 Gy [0.23;1.90], σ=0.53. The mean dose to the heart covers in average 38% of cardiac volume; the mean dose to the lung in average 30% of left lung volume.
Conclusions: Irradiation of the heart and lungs is extremely low in 3D ILD position and is associated with a limited risk of complications. In many cases the dose received by OAR is released outside the irradiation field so it is important to validate the accuracy of dose calculation model of the TPS in these regions of low dose.
No conflict of interest.

2028 POSTER

Hypofractionated radiotherapy in the conservative treatment of breast cancer

I. Linares[1], R. Del Moral[1], J. Expósito[1], P. Vargas[1], M.A. Gentil[1], M.I. Tovar[1], M.R. Guerrero[1], M. Zurita[1], M. Martínez[1], M. Navarro[1]. [1]*Hospital Virgen De Las Nieves, Radiation Oncology, Granada, Spain*

Background: The scheme of standard radiotherapy for breast cancer treatment involves a high total dose in 25 fractions. However, a decrease in the total dose, together with an increase in the dose per fraction (hypofractionation) is discussed to be at least as safe and effective as standard treatment. The objective of this study is to analyse the results in local control, acute and late toxicity and cosmetic outcome in patients treated with hypofractionated radiation therapy after conservative surgery for breast cancer in our center.
Material and Methods: A retrospective analysis of all women diagnosed with breast cancer and treated with breast-conserving surgery followed by hypofractionated scheme from 2006 to 2011. Total dose on mammary gland: 42.4 Gy to 2.65 Gy/fraction, 1 fraction day, 5 days a week, for a total of 16 sessions with concomitant boost to 7.7 Gy (0.48 Gy/fraction). We included patients treated with chemotherapy, hormonal therapy and trastuzumab. Acute and late toxicities were scored according to the Common Terminology Criteria for adverse Events (CTCAE v4).
Results: We have treated 143 women with hypofractionated scheme. After a median follow up of 30 months, the local recurrence rate was 0%, only 2.2% experienced nodal relapse, one patient developed a contralateral breast cancer and 7.4% had distant metastases. There was no acute toxicity in 28.4% of cases, being the most frequent grade 1 radiodermatitis (61.1%). Regarding late toxicity, this was not observed in 65.6%, being grade 1 fibrosis in the treated area the most common. The aesthetic result was good or excellent in 90% of patients treated. At the end of the study, 88.1% remained alive without disease, 5.2% alive with disease, 3% exitus due to tumour and 3.7% were died due to other causes.
Conclusion: The hypofractionated scheme after conservative surgery in breast cancer provides a good control of the disease without causing excessive toxicity and providing good aesthetic results. Similar results to standard treatment can be obtained with a significant reduction in overall treatment time.
No conflict of interest.

2029 POSTER

Impact of adjuvant systemic chemotherapy on wound healing and cosmetic outcome in 224 consecutive patients treated with accelerated partial breast irradiation (APBI) using interstitial brachytherapy

A. Budrukkar[1], P. Pandit[1], R. Jalali[1], S. Gupta[2], V. Parmar[3], R. Upereti[4], T. Seth[5], R. Badwe[3], R. Sarin[1]. [1]*Tata Memorial Hospital, Radiation Oncology, Mumbai, India;* [2]*Tata Memorial Hospital, Medical Oncology, Mumbai, India;* [3]*Tata Memorial Hospital, Surgical Oncology, Mumbai, India;* [4]*Tata Memorial Hospital, Radiation Physics, Mumbai, India;* [5]*Tata Memorial Hospital, Pathology, Mumbai, India*

Background: Accelerated Partial breast Irradiation (APBI) is being increasingly used as an alternative to whole breast radiation. However there is lack of data regarding timing and impact of systemic chemotherapy on wound healing and cosmetic outcome in this group of women. This study was aimed to evaluate the impact of adjuvant systemic chemotherapy on wound healing and cosmetic outcome in women treated with APBI for early-stage breast cancer.

Materials and Methods: Between August 2000 to December 2011, 224 women diagnosed with early breast cancer were treated with APBI using High Dose Rate (HDR) brachytherapy (post-op or intra -op) using ^{192}Iridium afterloading system. Women with age >40 years, tumours </= 3 cm and clinically negative axillary lymph nodes were considered suitable for the procedure. Two to four plane implants were done based on the volume of excision. Adjuvant systemic chemotherapy was administered as per the standard guidelines. Three weeks gap between radiation and chemotherapy was considered during the treatment. Patients were treated to a dose of 34 Gy in 10 fractions over 1 week with 2 fractions per day.
Results: Median age of presentation was 56 years (Range: 30−79 years). Median pathological T size was 2 cm with IDC being the most common histology (96%). Intraoperative placement of catheters was done in 136 (60%) and postop in 88 (40%). Adjuvant chemotherapy was given in 114 women (50%). Sixty three (56%) received chemotherapy after APBI and 51 (44%) before it. Wound complications were observed in 15 patients (7%). Ten patients in chemotherapy group and 5 patients in no chemotherapy group developed wound complications ($p = 0.20$). Four patients developed ulcer. All these were treated with intraoperative placement of catheters and 2 had inadvertently received chemotherapy within 15 days of completion of brachytherapy. In all these patients ulcer developed during chemotherapy as a radiation recall phenomenon. Six patients required additional antibiotics and 4 patients required secondary suturing. Wound issues resulted in fair to poor cosmetic outcome in 7 (47%) women.
Conclusion: Wound complications in women receiving APBI were within acceptable limits however were marginally higher in those who received adjuvant systemic chemotherapy. The risk was more in women who were treated with intraoperative placement of catheters. Time gap of upto 3 weeks appears important between the two modalities. Wound complications had poorer impact on cosmetic outcome in women treated with APBI.
No conflict of interest.

2030 POSTER

Incidental irradiation of internal mammary nodes in breast cancer: comparison between conventional and tridimensional conformal techniques between two institutions

E.T.T. Leite[1], R.T. Ugino[1], M.A. Santana[2], D.V. Ferreira[2], M.R. Lopes[1], G.N. Marta[1], H.A. Carvalho[1]. *[1]Hospital Sírio-Libanês, Radiation Oncology, São Paulo, Brazil; [2]Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo., Radiation Oncology, São Paulo, Brazil*

Background: The increasing use of tridimensional conformal radiotherapy (3D RT) reveals that in local treatment of breast cancer patients adjacent structures may be occasionally irradiated. This study purposes to evaluate the incidental irradiation of the IMN in patients treated with opposed tangents fields, planned with conventional (2D) or 3D RT, and to compare the results between both techniques.
Materials and Methods: Eighty patients, with no indication of RT of the IMN, were selected for this study: 40 submitted to 2D RT with computed tomography for dosimetric control (public institution), and 40 to 3D RT (private institution). Total prescribed dose was 50 or 50.4 Gy (1.8 or 2 Gy/day). Treatment plans were reviewed and a Clinical Target Volume (CTV) for the IMN was defined according to the Radiation Therapy Oncology Group (RTOG) recommendations. The volumes of IMN irradiated by the tangent fields were analyzed: percentage of the volume that received 45 Gy (V45), dose in 95% of volume (D95), minimum (Dmin), maximum (Dmax) and mean (Dm) doses, volume that received 50% of the dose (V25) and the dose in 50% of the volume (D50).
Results: No difference related to the treatment side (right/left), type of surgery (mastectomy, breast conserving surgery, and mastectomy with immediate reconstruction) and delineated IMN volumes between the two institutions (mean 6.8 versus 5.9cc, respectively for 2D and 3D, $p = 0.411$) were observed. All dosimetric parameters presented higher mean values on the 3D plans ($p < 0.05$), except for Dmin. The median Dmax with 3D was 50.34 Gy, but the mean dose to the IMN was 7.93 Gy with 2D, and 20.64 Gy with 3D technique.
Conclusion: None of the analyzed techniques delivered enough doses to the IMN for subclinical disease control. With 3D technique, however, all the dosimetric analyzed parameters were significantly higher when compared to 2D.
No conflict of interest.

2031 POSTER

Breast cancer recurrence after ROLL lumpectomy − ten year experience

R. Jois[1], A. Kalia[2], S. Carini[1], O. Harris[3], R. Thind[3], S. Desmond[3], A. Ray[1], L.S. Chagla[1], N. Bulgasim[1], R.A. Audisio[1]. *[1]Whiston Hospital, Surgery, Liverpool, United Kingdom; [2]Southport District General Hospital, Surgery, Southport, United Kingdom; [3]Whiston Hospital, Radiology, Liverpool, United Kingdom*

Background: Very few literatures are available on the long term outcomes after Radioguided Occult Lesion Localisation (ROLL) guided lumpectomy for non palpable invasive breast cancer. We previously published a recurrence of 1.9% with median follow up of 33 months. This is the first observation reporting after a Ten year experience with ROLL.
Materials and Methods: A continuous prospective series of patients undergoing ROLL for non palpable invasive breast cancers is followed with 6 monthly clinical exam and an annual mammography for five years. All patients' clinical records and investigation are checked for diagnosis of recurrence (local/systemic). All patients who had clinical or radiological suspicion of local recurrence underwent clinical or image guided core biopsy or fine needle cytology to prove the recurrence. Similarly, when there is clinical suspicion of systemic recurrence, patients underwent relevant imaging to rule out or to confirm systemic recurrence. Statistical analysis is carried out by using SPSS 14.
Aim: What is the long term outcomes after ROLL for non-palpable invasive breast cancers?
Results: 460 ROLL lumpectomies were performed for invasive breast cancers during Nov 2002–Dec 2012. Median tumour size was 12 mm. Median follow up time is 60 months. Neo-adjuvant therapy was given to 41 pts (8.9%). Presence of tumour (<1 mm) at margins (including superficial and deep margin) was +ve in 113 (24.4%). However, when superficial and deep margins were excluded as it did not affect clinical decision, margin +ve for tumour are 69 (15.4%). Median number of cavity shavings; 2 (0−7). Cavity shavings containing tumour were observed in 38 pts (8.2%). 10 pts (2.2%) developed local recurrence more frequently among patients with tumours having Lympho Vascular Inavasion ($P < 0.003$), ER negative and HER 2 negative ($P < 0.001$) and among those with Cavity shaving involved with tumor ($P < 0.063$). Tumour grade & margin status failed to associate with local recurrence ($p = 0.985$). Biological variables associated with systemic recurrences [23 (4.9%)] were; Lymph node metastases ($p < 0.022$), +ve Cavity shave ($p < 0.001$), +ve LVI ($P < 0.019$) and grade 3 tumours ($p < 0.044$), those needing neo-adjuvant therapy ($p < 0.004$). Margin status, Invasive tumour size, failed to achieve statistical significance.
Conclusions: The local recurrence observed is very low (2.2%) and is affected by biological status of the tumour more than the margin status. Similarly systemic recurrence (4.9%) after ROLL is once again affected by the biological behaviours of the tumour.
No conflict of interest.

2032 POSTER

Pre-operative selection of patients with limited disease of the axilla using ultrasonography of the axilla: Might additional lymph node dissection (ALND) be safely omitted in the future?

A.M. Moorman[1], R. Bourez[2], H.J. Heijmans[1], E.A. Kouwenhoven[1]. *[1]Ziekenhuis groep Twente, Surgery, Almelo, Netherlands; [2]Ziekenhuis groep Twente, Radiology, Almelo, Netherlands*

Background: The sentinel lymph node biopsy (SLNB) procedure is the method of choice for the identification and monitoring of regional lymph node metastases in patients with breast cancer. In the case of a positive sentinel node additional lymph node dissection is still warranted for regional control, though 40−60% have no additional axillary disease. Recent studies showed that after breast-conserving surgery, SLNB and adjuvant systemic therapy there is no significant difference between recurrence-free interval and overall survival if there are 2 or less positive axillary nodes.
Purpose: Preoperative identification of patients with limited axillary disease ($\leqslant$2 macrometastases) using ultrasonography (US).
Method: Between January 2007 and August 2011, data from 1102 consecutive primary breast cancer patients who underwent surgery in our hospital were collected into a single database. Patients were selected by clinical tumours smaller than 50 mm (cT1−2), no palpable adenopathy (cN0) and a maximum of 2 SLNs containing macrometastases. The variable of interest was ultrasonography of the axilla. The population was divided into two groups: the group with 2 or fewer positive nodes and the group with more than 2 positive nodes in the axilla after ALND.
Results: After selection, 1060 patients remained of which 102 (9.6%) had more than 2 positive axillary nodes on ALND. Selected by unsuspected US, the chance of having more than 2 positive lymph nodes is substantially lower (4.2%). This is significant on univariate and multivariate analysis. The

chance of more than 2 positive lymph nodes was 12.8 times as big in case of a positive axillary US. When we select this subgroup even further by excluding the patients with extra capsular extension (ECE) on SLN, the chance of more than 2 positive lymph nodes is only 2.6%. Subdivided by clinical tumour size the chances are 0.96% in case of cT1 tumour and 7.0% in case of a cT2 tumour. For pathological T-status the numbers are respectively 0.87% en 5.0%. For pT1−2 this is 2.2%.
Conclusion: The risk of more than 2 positive axillary nodes is relatively small in patients with cT1−2 breast cancer. Ultrasonography of the axilla helps in further identifying patients with a minimal risk of additional axillary disease, putting ALND up for discussion.
No conflict of interest.

2033 POSTER

Axillary dissection vs no axillary surgery in T1N0 breast cancer patients: A randomized clinical trial (INT 09/98)

R. Agresti[1], G. Martelli[1], M. Sandri[2], E. Tagliabue[2], I. Maugeri[1], C. Pellitteri[1], G. Bianchi[3], C. Ferraris[1], L. Lozza[4], S. Menard[2]. *[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Surgery, Milano, Italy; [2]Fondazione IRCCS Istituto Nazionale dei Tumori, Experimental Oncology, Milano, Italy; [3]Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Oncology, Milano, Italy; [4]Fondazione IRCCS Istituto Nazionale dei Tumori, Radiotherapy, Milano, Italy*

Background: Although axillary surgery is still considered as a fundamental part of breast cancer management, it may no longer be necessary either as treatment or as guide to adjuvant treatment. We conducted a single-center randomized trial (INT 09/98) to determine the impact of avoiding axillary surgery in patients with T1N0 breast cancer and planning chemotherapy based on biological factors of the primary tumor on long-term disease control.
Methods: From June 1998 to June 2003 565 T1N0 breast cancer patients, aged 30−65 years, were randomized to quadrantectomy with (QUAD) or without (QU) axillary dissection; 517 patients were finally evaluated. All patients received radiotherapy in the operated breast only. Chemotherapy in the QUAD arm was decided on nodal status, estrogen receptor (ER) status and tumor grade. Chemotherapy in the QU arm was based on ER status, tumor grade, HER2-receptor and laminin-receptor status, defining an unfavorable (QU/Poor Panel(PP) or favorable (QU/Good Panel(GP)) prognostic groups, treated or less with chemotherapy, respectively.
Overall survival (OS) was the primary endpoint. Disease-free survival (DFS), rate and time of axillary relapse in QU arm were the secondary end-points.
This trial is registered with ClinicalTrials.gov.NCT01508546.
Results: After a median follow-up of more than 10 years [127.5 months, interquartile range (IQR)=112.5–141.1], OS was 93.3% (95% CI=89.4–95.8) and 91.5% (95% CI=87.0–94.4) in the QUAD and QU arms, respectively. In the QUAD arm, 10-year DFS was 92.4% (95% CI=88.5–95.1) and 91.3% (95% CI=86.7–94.3) in the QU arm. Estimated adjusted HR of the QUAD vs. QU arms was 1.09 (95% CI=0.56–1.94;p = 0.898) for DFS and 1.09 (95% CI=0.59–2.00;p = 0.783) for OS. These results indicate no statistically significant difference between survival curves in study arms. In the QU arm, 22 of 245(9.0%) patientsQU experienced axillary relapse. Axillary relapse occurred in 16/158(10.1%) of QU/GP and 6/87(6.9%) of QU/PP patients (p = 0.488). The median time of axillary relapse from breast surgery was 30.0 months (IQR=24.2–73.4); 35.8 months (IQR=27.6–82.5) in QU/GP patients and 22.8 (IQR=9.1–28.0) in QU/PP patients (p = 0.033).
Conclusion: T1N0 breast cancer patients did not benefit from immediate axillary surgical staging in terms of DFS and OS. Biological characteristics of the primary tumor appear adequate for guiding adjuvant treatment.
No conflict of interest.

2034 POSTER

The impact of preoperative MRI on the surgical management in invasive breast cancer with a lobular component of any size

M. El Sharouni[1], E.L. Postma[2], C.C. Van der Pol[2], R.M. Pijnappel[3], P.J. Van Diest[4], H.M. Verkooijen[3], A.J. Witkamp[2]. *[1]University Medical Centre Utrecht, Utrecht, Netherlands; [2]University Medical Centre Utrecht, Surgery, Utrecht, Netherlands; [3]University Medical Centre Utrecht, Imaging, Utrecht, Netherlands; [4]University Medical Centre Utrecht, Pathology, Utrecht, Netherlands*

Background: Invasive breast cancer comprises a spectrum of histological changes with purely lobular cancer on one side and purely ductal cancer on the other and many mixed lesions in between, by some denoted as ductolobular cancer. Magnetic resonance imaging has shown to be of added value in the diagnostic work-up of pure invasive lobular cancer (ILC) as it detects additional contralateral and ipsilateral findings in up to 32% of patients. The impact of preoperative MRI on management of patients with such a mixed differentiation is still unclear. Our aim is to determine the impact of preoperative MRI on TNM-classification and surgical management in patients diagnosed with invasive breast cancer and any proportion of lobular component at core needle biopsy.
Material and Methods: All patients diagnosed with breast cancer containing a lobular component between Jan 2008 and Oct 2012 were prospectively offered preoperative MRI. Histological slides were reviewed by a dedicated breast pathologist and the percentage of lobular component was determined. Patients were allocated to either the 1−30%, 31−70% or 71–100% lobular component group. In a multidisciplinary setting comprising experienced breast surgeons and breast radiologists, TNM-classification and surgical policy were determined based on mammography and/or ultrasound only, and for a scenario including additional preoperative MRI.
Results: A total of 109 patients were eligible for this study. Preoperative MRI changed TNM-classification in 43% of patients and altered surgical policy in 38% of patients. The surgical plan changed from breast conserving therapy (BCT) to mastectomy (MST) in 12 (11%) patients, from BCT to neoadjuvant chemotherapy (NEO) in 4 (4%) patients, from MST to NEO in 4 (4%) patients, from NEO to MST in 2 (2%) patients and a wider excision was performed in 8 (7%) patients. In 10 (9%) patients MRI revealed contralateral malignancies necessitating surgery. There was no correlation between the percentage of lobular component and change in TNM-classification or surgical policy (P-value respectively 0.345 and 0.413).
Conclusions: In patients presenting with breast cancer with a lobular component at core needle biopsy, preoperative MRI leads to changes in both TNM-classification as well as surgical policy. This is independent of the size of the lobular component.
No conflict of interest.

2035 POSTER

Quality improvement in surgical breast cancer care: A decrease in positive surgical margins after first breast conserving surgery

A.C.M. Van Bommel[1], T. Van Dalen[2], H.S. Snijders[1], P.J. Westenend[3], S. Siesling[4], M.W.J.M. Wouters[5], E.J.T. Rutgers[5], M. Van der Heiden − van der Loo[4]. *[1]Leiden University Medical Center, Department of Surgery, Leiden, Netherlands; [2]Diakonessenhuis Utrecht, Department of Surgery, Utrecht, Netherlands; [3]Laboratory for Pathology Dordrecht, Department of Pathology, Dordrecht, Netherlands; [4]Comprehensive Cancer Centre the Netherlands (IKNL), Department of Research, Utrecht, Netherlands; [5]National Cancer Institute (NKI) − Antoni van Leeuwenhoek Hospital, Department of Surgery, Amsterdam, Netherlands*

Background: In recent years there has been a growing public interest in quality of breast cancer care. In the Netherlands, hospitals are obliged to report on the percentage of patients with positive margins after first breast conserving surgery (BCS) since 2007. In BCS, a delicate balance exists between the cosmetic result and completeness of the surgery. This indicator may unintentionally lead to the perverse incentive of aiming for the lowest possible positive margin rates by reducing the rate of breast conserving surgeries.
This study describes positive margin rates after BCS since the introduction of this quality indicator in the Netherlands. Furthermore, the occurrence of a shift towards higher mastectomy rates instead of BCS is investigated.
Material and Methods: All early breast cancer patients (T1−2, any N, M0) diagnosed between July 1, 2008, to December 31, 2011 that underwent surgical resection were selected from the Netherlands Cancer Registry (NCR). Type of first surgery was coded as BCS or mastectomy. Margin status was coded as clear, focally positive margins (tumour in a limited area of the inked surface, i.e. on or two foci of tumour, with a maximum of 4 mm), more than focally positive margins or unknown.

Table 1. Surgical margin status after initial BCS for 23,628 breast cancer patients, 2008–2011.

	2008*		2009		2010		2011	
	n	%	n	%	n	%	n	%
Clear margins	2,580	78.4%	5,315	80.1%	5,337	79.7%	5,759	82.1%
Focally positive margins	324	9.8%	641	9.7%	675	10.1%	726	10.3%
More than focally positive margins	321	9.8%	571	8.6%	493	7.3%	471	6.8%
Unknown or inconclusive	67	2.0%	109	1.6%	194	2.9%	55	0.8%

*Data from 2008 includes 6 months (July 1 through December 31).

Results: Of the 38,380 included patients, 62% (23,628 patients) received BCS in 89 hospitals in the Netherlands. The percentage of mastectomies as first surgery slightly decreased over time (39% and 38% in 2008 and 2011 respectively; χ^2 for trend: p = 0.029). The percentage of positive tumour margins significantly decreased over time; 9.8% in 2008 versus 6.8% in 2011 (table 1; X^2 for trend: p = 0.001).

Conclusion: The percentage of patients with positive surgical margins after first BCS for breast cancer decreased between 2008 and 2011. This decrease in positive margins was not accompanied by an increase in mastectomies. The fear for an increase in mastectomies since the introduction of the indicator is therefore not justified.
No conflict of interest.

2036 POSTER

Intra-operative specimen radiography reduces re-excision rates in palpable breast cancers undergoing wide local excision

A. Peckham-Cooper[1], E. Li[1], V. Gopalan[1], S. Narayanan[1], R. Kirby[1], S. Soumian[1]. [1]*University Hospital of North Staffordshire, Department of Oncoplastic Breast Surgery, Stoke on Trent, United Kingdom*

Background: Safe breast conserving surgery (BCS) for cancer necessitates clear excision of margins whilst providing reduced morbidity and improved cosmesis. Reported re-excision rates for close or involved margins range from 10−37%. Current guidelines recommend the use of intra-operative specimen imaging (IOSR) for all impalpable breast cancers. This study assesses the use of in theatre specimen imaging to guide BCS for all **palpable** lesions with a view to reducing re-excision rates.
Methods: Retrospective comparison of two randomly selected discrete cohorts (n = 200, 100/cohort) was undertaken for patients undergoing BCS for palpable breast cancers before and after the inauguration of the use of IOSR (Faxitron Bioptics, Tucson, AZ) in our centre. Comparative data analysis included patient demographics, tumour size and characteristics and intra-op and further secondary operative excision rates. Data were analysed using SPSS Statistics 20.
Results: See the table.

	WLE		*p* value
	pre-IOSR	with IOSR	
Age	59.5±12.0	61.5±12.6	0.293
Laterality L : R	53 : 47	47 : 53	
Excision volumes	364 cm^3 (IQ range 148–414)	205 cm^3 (IQ range 92–253)	<0.001
Tumour size	19.3 mm±10.3	22.1±11.2	0.079
Closest excision margin			0.273
Mean	6.8 mm±5.9	6.0 mm±3.7	
Range	0−40 mm	0−20 mm	
Percentage of patients undergoing further intra-operative excision of margins	10%	31%	<0.001
Percentage of patients requiring further re-operative excision of margins following MDT discussion	35% 11/35 histological positive	17 % 12/17 histological positive	0.004

Conclusion: Intra-operative specimen imaging using Faxitron for palpable breast cancer reduces both excision volumes and the need for post-operative further margin re-excision. Reduced morbidity, improved cosmetic outcomes, cost effectiveness and earlier patient access to adjuvant therapies must make this the gold standard in all breast conserving surgery for palpable tumours.
No conflict of interest.

2037 POSTER

Outcomes of immediate perforator flap reconstruction after skin-sparing mastectomy

K. Narui[1], T. Ishikawa[1], T. Satake[2], K. Shimada[1], D. Shimizu[1], M. Tanabe[3], T. Sasaki[3], S. Sugae[4], Y. Ichikawa[5], I. Endo[4]. [1]*Yokohama City University Medical Center, Breast and Thyroid Surgery, Yokohama, Japan;* [2]*Yokohama City University Medical Center, Plastic Surgery, Yokohama, Japan;* [3]*Yokohama City University Medical Center, Pathology, Yokohama, Japan;* [4]*Yokohama City University Graduate School of Medicine, Gastroenterological Surgery, Yokohama, Japan;* [5]*Yokohama City University Graduate School of Medicine, Clinical Oncology, Yokohama, Japan*

Background: Perforator flap reconstruction after skin-sparing mastectomy (SSM) seems to be useful because it is characterized with autologous graft, less invasive than myocutaneus flap and excellent aesthetic result. Immediate reconstruction is also patient-friendly, because it is less expensive, and limits exposure to anesthesia risk. Objective of this study is to clarify surgical complications and oncological outcomes of an immediate perforator flap reconstruction after SSM.
Patients and Methods: From 2004 to 2012, 201 consecutive patients underwent immediate perforator flap reconstruction after SSM for biopsy-proven breast cancer. The mean age of them was 42.3 years (23−64) and mean body mass index was 21.1 (16.0–28.2). Skin sparing mastectomy was performed by breast surgeons and reconstruction was performed by plastic surgeons concurrently or consequently. Nipple-areolar complex (NAC) was resected for cases with apparent tumor invasion, whereas nipple-sparing mastectomy (NSM) was performed for cases without NAC involvement by pre-operative imaging. Frozen section intra-operative pathological diagnosis of margin just below the NAC was routinely performed when performing NSM. We used various kinds of perforator-flaps. Deep inferior epigastric perforator (DIEP) flap, superior gluteal artery perforator flap/inferior gluteal artery perforator flap or posterior median thigh perforator flap were taken from the inferior abdomen, the gluteal region and the thigh, respectively. The blood flow of grafts was monitored intensively with a Doppler ultrasonography after surgery. Patients were followed with 3−6 month intervals during first 5 years and 3−12 month intervals thereafter. The surgical complications and oncological outcomes were reviewed retrospectively.
Results: The mean duration of this procedure was 499 minutes (range 235–857) and the mean amount of bleeding counted 244 ml (range 5–730). Nipple was preserved in 151 cases (75%). Donor sites of free perforator flap were lower abdomen (101 cases, 50%), gluteal region (52 cases, 26%) and thigh (48 cases, 24%). Seven patients developed graft ischemia. The emergent revascularization was performed for all 7 cases and salvaged the grafts in 6 of them, resulted in a loss of graft in 1 case. The median length of stay after surgery was 8 (range 6−37). As to oncological outcome, a total of 8 patients (4%) developed recurrence with the median follow-up time of 2.8 years. Local recurrence was found in 3 of them (1.5%).
Conclusion: The outcome of immediate perforator flap reconstruction after SSM is acceptable as a procedure of oncoplastic surgery. However, it accompanies longer duration of surgical procedure, and requires intensive monitoring and occasional emergent surgery. Thus, this technique should be performed with a team combined with breast- and plastic-surgeons meticulously.
No conflict of interest.

2038 POSTER

Guiding breast conserving surgery in 383 patients with non-palpable breast cancer − comparison of two techniques: Radioactive seed localization versus radioguided occult lesion localization with 99m Technetium colloid

M.E.M. Van der Noordaa[1], K.E. Pengel[2], M.I. Lopez-Yurda[3], M.J. Vrancken Peeters[1]. [1]*The Netherlands Cancer Institute, Surgical Oncology, Amsterdam, Netherlands;* [2]*The Netherlands Cancer Institute, Radiology, Amsterdam, Netherlands;* [3]*The Netherlands Cancer Institute, Bioinformatics and Statistics, Amsterdam, Netherlands*

Background: Radioguided Occult Lesion Localization with 99mTechnetium colloid (ROLL-99mTc) and Radioactive Seed Localization with a radioactive iodine-125 seed (RSL) are both alternatives to wire localization for guiding breast conserving surgery (BCS) of non-palpable breast lesions. The aim of this study was to evaluate and compare the efficacy of ROLL-99mTc and RSL.
Methods: We retrospectively analyzed 383 patients with one or more unifocal non-palpable ductal carcinoma in situ (DCIS) or invasive carcinoma who were treated with BCS at the Netherlands Cancer Institute. In total, 403 non-palpable lesions were diagnosed. The disease was localized either by ROLL-99mTc (N = 275) or by RSL (N = 128). Logistic regression and propensity scores were used to compare positive margins in the RSL and the ROLL-99mTc group after adjusting for clinical variables.
Results: In the RSL group (n = 128), more lesions were DCIS (58.6%) as compared to the ROLL group (n = 275), in which only 32.0% were pure DCIS. Nevertheless, the proportion of focally positive margins (10.9% vs. 9.8%) and extensive positive margins (8.6% vs. 8.7%) was comparable between the RSL and the ROLL-99mTc group (p = 0.225), resulting in the same re-excision rate in both groups (9.4% vs. 10.2%). Patients with positive sentinel node status were more likely to have positive margins than those with negative node status (odds ratio 0.35, 95% CI 0.15 to 0.80). Median specimen weight was significantly lower in the RSL group than in the ROLL-99nTc group (29 vs. 38 g; p < 0.001) as well as median volume (70 vs. 90 cc; p = 0.001), whereas the median tumor size was identical for both groups.
Conclusion: Margin and re-excision rates were comparable for the ROLL-99mTc technique and I-125 seed localization in patients with non-palpable breast lesions. Because of the lower median weight and volume of the resected specimen, we favor RSL over ROLL-99mTc to guide breast-conserving therapy.
No conflict of interest.

2039 POSTER

The incidence of metastases to the sentinel lymph node and other axillary lymph nodes in particular molecular subtypes of breast cancer

A. Stanislawek[1], S. Lukasiewicz[2], F. Szubstarski[3], K. Solowiej[2], M. Rzaca[4], M. Zajac[4]. *[1]Centrum Onkologii Ziemi Lubelskiej, Chair of Social Health Care, Lublin, Poland; [2]Centrum Onkologii Ziemi Lubelskiej, Department of Surgical Oncology, Lublin, Poland; [3]Centrum Onkologii Ziemi Lubelskiej, Department of Pathology, Lublin, Poland; [4]Medical University, Department of Oncology, Lublin, Poland*

Background: The possibility of determining such groups of breast cancer female patients where the procedure of complete axillary lymph nodes dissection (ALND) could safely be abandoned despite a positive sentinel node is still under investigation. The division of breast cancers into molecular subtypes creates new possibilities of searching for the probability of metastases in consecutive lymph nodes in the case of a positive sentinel lymph node.
Aim: The aim of the study was to assess the number of positive lymph nodes depending on a cancer molecular subtype in female patients operated for breast cancer.
Material and Methods: The study comprised all the female patients operated for breast cancer and diagnosed as having lymph node metastases in COZL oncological surgery department in 2011. The division of tumours into molecular subtypes was performed on the basis of tumour receptor status, and qualifying for luminal subtype A and luminal B HER 2 negative depended on Grading of a tumour. In 2011 in COZL oncological surgery department there were performed 244 sentinel lymph node biopsies (SLNB), and in 52 cases the results were positive. There were conducted 199 prim aryALND connected with wide local excision (WLE) or simple amputation. In a total of 251 cases of female patients operated for breast cancer metastases to the lymph nodes were found either by preoperative diagnostics or SLNB. The examination also included the number of positive lymph nodes in 3 brackets/1; 2−3; 4 or more/.
Results: In the group of patients with 1 positive lymph node/ **121** patients/ luminal A cancers constituted 53.7%, luminal B/ Her2 negative/ ones −19%, luminal B/ Her2 positive/ ones − 8.3%, non-A non-B ones/ 4.9%, basal ones − 4.1%, special subtypes/ 9.9%. In the group with 2 −3 positive lymph nodes/ **50** patients/ luminal A cancers consituted 16%, luminal B/ Her2 negative/ ones − 44%, luminal B /Her2 positive/ ones − 18%, non-A non-B ones/ 10%, basal ones − 8%, special subtypes − 4%. In the group with 4 positive lymph nodes or more/ **76** patients/ luminal cancers A constituted 9.2%, luminal B /Her2 negative/ ones −44.7%, luminal B /Her2 positive/ ones 21%, non-A non-B ones- 10.5%, basal ones- 10.5%, special subtypes − 3.9%.
Conclusions: The division of breast cancers into molecular subtypes alone cannot be a factor determining the presence of metastases in consecutive lymph nodes in the case of positive SLNB results. It is necessary to continue the analysis of the following factors: patient's age, tumour size and its molecular subtype/especially luminal A/ in order to determine a group of patients with positive SLNB results in whom performing of ALND could safely be abandoned.
No conflict of interest.

2040 POSTER

Evaluation of one step nucleic acid amplification (OSNA) molecular assay for intraoperative diagnosis of sentinel lymph node (SLN) metastasis

A. Hasan[1], A. Peckham-Cooper[1], V. Gopalan[1], A. Basit[1], S. Soumian[1], R. Kirby[1], S. Narayanan[1]. *[1]University Hospital of North Staffordshire, Department of Oncoplastic Breast Surgery, Stoke on Trent, United Kingdom*

Background: In the management of breast cancer, histopathological assessment from a sentinel lymph node biopsy (SLNB) for evidence of metastatic spread is the gold standard for accurate staging, patient prognosis and to determine need for further axillary surgery. This process is currently two-stage, requiring patients with positive SLNB to return for a subsequent axillary clearance, increasing patient risk and reducing effective theatre utilisation.
OSNA is an innovative molecular diagnostic assay that identifies lymph node metastases in breast cancer utilising cytokeratin 19mRNA as a molecular marker. The technique was recently introduced into our institution. With the National Institute for Health and Care Excellence (NICE) due to publish guidelines in July 2013, 'Intra-operative tests for detecting sentinel lymph node metastases in breast cancer' this study aims to assess prospectively the accuracy and usefulness of OSNA for intraoperative detection of SLN metastases in one single centre.
Method: Fifty-five patients with clinically and ultrasonographically negative axillae underwent SLNB via a standard dual agent technique. Following excision, lymph nodes were processed and prepared into multiple slices with alternate sections sent for traditional histopathology and OSNA respectively. 93 SLN in total were compared prospectively utilising both techniques. Further parameters were recorded including length of operation and time taken from removal of node to OSNA report.
Results: 16 of 93 (17%) lymph nodes were positive on OSNA assay, 15 of these nodes demonstrated metastatic disease histologically. There were no metastatic tumour cells identified by the histolopathologist in the slices of the remaining OSNA positive node. An overall concordance rate of 93.75% is reported for OSNA versus histopathology in the identification of macro-metastasis. An increased discordance however, was revealed with respect to micro-metastasis. 7 SLNs had micro-metastasis on OSNA assay whilst only two of the half lymph nodes were reported to show micro-metastasis on histology. The average time for the OSNA assay was 55 minutes.
Conclusions: OSNA is a reliable and rapid diagnostic tool for intraoperative detection of lymph node metastases in patients with breast cancer. It can prevent diagnostic delay or need for second surgery for nodal positivity identified postoperatively. Our institution is now utilising the technique routinely for all SLNB using whole nodes. Current local guidelines preclude further immediate surgery for those patients with OSNA identified single micro-metastasis but a normal second gland. There is still debate regarding patients who have micro-metastases identified in more than one node.
No conflict of interest.

2041 POSTER

Detection of breast cancer using near-infrared fluorescence imaging and methylene blue

Q.R.J.G. Tummers[1], F.P.R. Verbeek[1], B.E. Schaafsma[1], M.C. Boonstra[1], J.R. Van der Vorst[1], G.J. Liefers[1], C.J.H. Van de Velde[1], J.V. Frangioni[2], A.L. Vahrmeijer[1]. *[1]Leiden University Medical Center, Department of Surgery, Leiden, Netherlands; [2]Beth Israel Deaconess Medical Center, Department of Medicine and Radiology, Boston, USA*

Background: Despite recent developments in preoperative breast cancer imaging, intraoperative localization of the tumor can be challenging. As a result, irradical resections during breast-conserving surgery are still a major problem.
With Technetium(^{99m}Tc)-sestamibi (MIBI), a pharmaceutical agent used in nuclear medicine, preoperative identification of breast cancer is possible in 84−94% of patients.
Based on chemical structure, we hypothesized that Methylene Blue (MB) might have a comparable biodistribution as the nuclear tracer used for a MIBI scan. Moreover, MB in low dosage can be used as a fluorescent tracer during near-infrared fluorescence (NIRF) imaging. The aim of this study was to determine feasibility of MB as fluorescent tracer for the identification of breast cancer with NIRF imaging.
Methods: Twenty-four patients with breast cancer, all planned for surgical resection, were included. N = 12 patients per group were administered 1.0 mg/kg MB intravenously either immediately before or 3−4 h before surgery The mini-FLARE imaging system was used to identify the fluorescent signal during surgery and on post-resected specimens transferred to the pathology department. Fluorescence microscopy images were obtained with the Odyssey Infrared Imaging System.
Results: 20/24 (83%) of breast tumors (carcinoma (N = 21) and ductal carcinoma in situ (N = 3)) were identified in the resection specimen with NIRF. Overall tumor-to-background ratio (TBR) was 2.4±0.8. There was no significant difference between TBR and background signal between administration groups ($P = 0.50$ en $P = 0.23$). Four resections were irradical (17%), and in one of these cases, tumor tissue was identified intraoperatively in the wound bed using NIRF imaging. Direct re-resection was performed, after which the tumor was radically removed. No fluorescent tumor signal was seen in the second irradical case, and in the third case, no intraoperative fluorescent images were available. In the fourth irradical case, clear fluorescent spots were identified in the wound bed, but these were characterized as benign on visual inspection. Therefore, no addition resection was performed. During histopathological assessment, the resection was found to be irradical at this margin.
Histological validation with fluorescence microscopy showed a clear overlay between fluorescent signal and tumor tissue. No adverse reactions associated with the use of MB or fluorescent imaging were observed.
Conclusion: This feasibility study shows that the identification of breast cancer with NIRF imaging and MB was possible in 83% of tumors. This is in agreement with the sensitivity of a MIBI scan for breast cancer of 84−94%. In 2/4 (50%) of patients, breast cancer tissue identified in the wound bed during surgery using NIRF would have changed patient management. Intraoperative NIRF imaging with MB has thereby the potency to increase the number of radical resections in breast cancer patients.
No conflict of interest.

2042 POSTER

Is there a role for microdochectomy in the treatment of nipple discharge and the detection of breast cancer?

L. Wheeler[1], I. Duggan[1], M. Walters[1], K. Thakur[1]. [1]*Queen Elizabeth Hospital, Breast Surgery, London, United Kingdom*

Background: Nipple discharge is a recognised symptom of breast cancer, although most malignant cases present with a mass. The aim of this study was to determine whether microdochectomy is a valid procedure in the treatment of nipple discharge and the detection of breast cancer.
Method and Materials: Between January 2002 and December 2012, 49 microdochectomies were carried out on 47 patients by a single breast surgeon at a breast unit. The indication for 48 of these procedures was persistent nipple discharge, defined as greater than 3 months duration. Nipple discharge was blood stained in 32 patients. A retrospective study was conducted, using cytology, histological records and operative notes, to investigate the effectiveness of microdochectomy as a treatment for nipple discharge and the detection of breast cancer.
Results: Following microdochectomy, 45 patients (96%) did not have recurring nipple discharge. Histological findings showed 17% (7/49 cases) were malignant. All 7 patients presented with either frank blood stained discharge or discharge which was positive for blood on dipstick. All patients had benign cytology and 5 of the 7 cases had normal radiological imaging. All 7 cancers were ductal carcinoma in situ (DCIS) which were managed with wide local excision of the tumour. Three patients went on to have total mastectomies.
Conclusion: This audit found that microdochectomy is a valid procedure for nipple discharge with 96% of patients experiencing symptomatic relief. This procedure found 17% of patients with nipple discharge (all blood stained discharge) had breast cancer. This reflects the incidence previously reported in recent literature. These patients had no other symptoms of breast cancer and would otherwise have been missed or presented at a later stage. We conclude that since negative imaging does not exclude malignancy, microdochectomy is an effective procedure in the early detection of breast cancer.
No conflict of interest.

2043 POSTER

The anatomy of intercostobrachial nerve in nerve-sparing axillary lymph node dissection

M. Kostanyan[1]. [1]*National Centre of Oncology, Yerevan, Armenia*

Background: The intercostobrachial nerve (ICBN) is the lateral cutaneous branch of the second intercostal nerve (T2). From its origin, it crosses the axilla and supplies sensory fibers to the medial aspect of the upper arm, axillary skin, and upper lateral breast. Previous studies have shown that preservation of the ICBN during axillary lymph node dissection (nerve-sparing ALND) produces minimal postoperative alterations in sensitivity significantly improving quality of life of operated patients.
Material and Methods: The purpose of this study was to evaluate the anatomical variants of the ICBN in 115 patients who underwent level-2 nerve-sparing ALND for operable breast cancer at our institution in the period of 2005–2010 years. The mean age of the patients was 47.8±12 years.
Results: We encountered 3 main types of anatomical variants of the ICBN (according to Cunnick classification, 2001). Type I (nerve arises from T2 alone and does not give off any branches) accounted for 76/110 (69.1%) of the cases. Type II (nerve arises from T2 alone and divides into a large main trunk and a much smaller branch) and type III (nerve arises from T2 alone and divides equally into two branches) occurred in 22/110 (20%) and 8/110 (7.3%) cases, correspondingly. The incidence of 3 other types (IV, V, VI) was very rare (3.6%).
Conclusion: If an attempt at ICBN preservation is the standard practice for the majority of patients, it will be necessary to understand the anatomy and anatomical variants of this nerve to prevent severe complications of nerve damage.
No conflict of interest.

2045 POSTER

Closing the stable door after the horse has bolted: Sentinel lymph node biopsy in breast cancer; before or after neodjuvant chemotherapy?

A. Hamad[1], W. Taher[1], G.K. Mahadev[1]. [1]*Mid Cheshire Hospitals NHS Foundation Trust, Surgery, Crewe Cheshire, United Kingdom*

Background: Axillary lymph node status is the most significant prognostic factor in breast cancer patients. Assessment and management of axillary lymph nodes is still an area of debate in breast cancer. Sentinel lymph node biopsy (SLNB) is now a standard tool to evaluate nodal status in clinically and radiologically node-negative cancer patients. Neoadjuvant chemotherapy is increasingly being offered in breast cancer. The timing of sentinel lymph node biopsy in neoadjuvant chemotherapy setting is debatable due to possible impact of chemotherapy on the accuracy of positive lymph node detection. Inaccurate assessment of sentinel lymph node may lead to axillary disease mismanagement.
Material and Methods: Literature review was undertaken using the following keywords: sentinel lymph node biopsy, breast cancer, Neoadjuvant chemotherapy, and preoperative chemotherapy on PubMed, Medscape, Cochrane library and other online resources.
Results: All articles were collected including 19 prospective studies, 9 retrospective studies and 2 further reviews. Four studies demonstrated high accuracy of detection of metastatic disease in sentinel lymph nodes prior to Neoadjuvant chemotherapy with a false negative rate of 0 to 1%. Thirteen studies showed that both timings for sentinel lymph node biopsy of breast cancer patients with neoadjuvant chemotherapy were feasible and accurate with a false negative rate of 0 to 22%. However, 3 of these studies recommended further evaluation of sentinel lymph node biopsy after neoadjuvant chemotherapy. Fourteen studies have clearly advocated performing sentinel lymph node biopsy prior to initiation of neoadjuvant chemotherapy due to unacceptably high false negative rate in the post chemotherapy patients.
Conclusion: It is recommended that sentinel lymph node biopsy should be performed prior to Neoadjuvant chemotherapy as it is associated with significantly lower rates of false negative results and accurately delineates the axilla.

Local excision alone for patients with small size ductal carcinoma-in-situ of the breast: A Korean single institutional experience

H. Kim[1], J.M. Noh[1], J. Lee[2], D.H. Choi[1], S.J. Nam[3], J.E. Lee[3], W. Park[1], S.J. Huh[1]. [1]*Samsung Medical Center Sungkyunkwan University School of Medicine, Radiation Oncology, Seoul, South Korea;* [2]*Ewha Womans University Medical Center, Radiation Oncology, Seoul, South Korea;* [3]*Samsung Medical Center Sungkyunkwan University School of Medicine, Surgery, Seoul, South Korea*

Background: To determine the risk of local recurrence in Korean patients with small size ($\leqslant$1 cm) ductal carcinoma in situ (DCIS) after local excision alone without radiotherapy.
Material and Methods: From December 1999 to December 2009, 498 patients with DCIS received breast-conserving surgery at Samsung Medical Center. Among the patients, 107 patients who had DCIS measuring $\leqslant$1 cm with microscopic margin widths of $\geqslant$0.3 cm were treated with excision alone per institutional protocol. The medical records of the patients were retrospectively reviewed.
Results: Median age of the patients was 46 years (range, 23−80). Tamoxifen was used in 89% of the patients. The 92% of the patients had low- or intermediate grade tumor, and the 77% of women had resection margin of $\geqslant$1.0 cm. With a median follow-up time of 58 months, 5 patients developed local recurrence. Three patients experienced recurrence with invasive disease and 2 patients had recurrence of DCIS. The rate of recurrence at 5-year and 10-year were 6.1% and 10.4%, respectively. Patients with resection margin of <1.0 cm had significantly higher recurrence rate than the patients with resection margin of $\geqslant$1.0 cm (23.1% vs. 1.5% at 5-year, $p = 0.02$).
Conclusions: The recurrence in the patients who had small size DCIS with resection margin of $\geqslant$1.0 cm was acceptably low following excision alone. For the patients with resection margin of <1.0 cm, the risk of recurrence was substantial when treated with excision alone, suggesting that radiotherapy is necessary in these patients.

2047 POSTER

The impact of preoperative real-time virtual sonography (RVS) in the surgical management of breast cancer: A single-institution review

M. Yoshida[1], S. Nakano[1], K. Fujii[1], J. Kousaka[1], Y. Shiomi[1], R. Tetsuka[1], T. Andou[1], T. Imai[1], T. Fukutomi[1]. [1]*Aichi Medical University, Breast and Endocrine Surgery, Aichi, Japan*

Background: Real-time virtual sonography (RVS) is a newly developed modality which enables us to synchronize sonographic images and MRI-MPR images of the same section in real time. The aim of this study was to evaluate the impact of preoperative RVS in the surgical management of primary breast cancer.

Material and Methods: We reviewed 88 breast cancer patients who were identified as candidates for breast-conserving surgery (BCS) on the basis of conventional assessment, and underwent radical surgery at Aichi Medical University between January 2011 and December 2012. All of them preoperatively underwent an ordinary bilateral breast MRI in a prone position using a double-breast coil, unless contraindications were present. Of the breast in which the additional MRI lesion was detected, we performed second-look sonography (US). When we were not able to detect the additional MRI lesion by second-look US without using RVS, we additionally performed a unilateral MRI with the patient in a supine position using a flexible body surface coil and second-look US with RVS which enables the synchronization with supine MR images. The additional MRI lesions that were detectable by second-look US or RVS, if necessary, were confirmed preoperative pathological diagnosis by image-guided needle biopsy. Finally, from pathological examination of the resected specimens, we verified the accuracy of preoperative assessment of tumor extent by the combined use of conventional imaging modality, MRI and RVS.
Results: Out of a total of 85 women; 46 additional ipsilateral MRI lesions were detected in 43 breasts. With conventional second-look US, the detection rate for the additional ipsilateral MRI lesions was 43% (20/46), while the rate went up to 91% (42/46) when using RVS. Of these 46, 38 lesions in the 37 breasts were suspected of malignancy from second-look US/RVS findings and (or) preoperative pathological examination and we made changes to the extent of resection (BCS with wider margins than anticipated: Mastectomy = 17: 20). In 38 of a total of 43 breasts in which the additional ipsilateral MRI lesions were detected (88%), the addition of second-look US/RVS assessment favorably affected the determination of the extent of resection. Although the rate of positive margins after BCS (the presence of tumor cells on the edge of the resection) was still as high as 14% (9/67), incomplete resection of invasive disease was only 2% (1/67). As the additional contralateral MRI lesions, only one lesion was preoperatively diagnosed as malignant. We also performed an additional contralateral breast surgery.
Conclusions: Our results suggest that using preoperative MRI and RVS in combination with conventional imaging modalities can determine the extent of resection more precisely and reduce the rate of incomplete resection of invasive diseases after BCS.
No conflict of interest.

2048 POSTER

Using both a 125I seed and a Tc-99 nanocolloid source in nonpalpable breast-conserving surgery: Interference or not?

I.M.C. Van der ploeg[1], S. Muller[2], M.T.F.D. Vrancken − Peeters[1]. [1]*The Netherlands Cancer Institute, Surgery, Amsterdam, Netherlands;* [2]*The Netherlands Cancer Institute, Radiology, Amsterdam, Netherlands*

Background: The challenge of nowadays widely performed breast-conserving surgery is to achieve tumor-free margins while excising no more breast tissue than necessary. This issue especially concerns non-palpable breast lesions. Radioactive seed localization (RSL) is a new localisation method. A ^{125}I seed is placed in the centre of the lesion and the gamma probe using the 125I setting guides the local excision. An intratumoral injection of ^{99m}Tc-nanocolloid is needed to perform the sentinel node procedure. The wavelengths of the radiopharmaceutical and the I-125 seed may overlap.
The purpose of the present study was to investigate any interference when a ^{125}I seed and an injection of ^{99m}Tc-nanocolloid are combined.
Material and Methods: Between the 14th of February and the 27th of June 2012 consecutive patients with a nonpalpable breast lesion were included. An iodine-125-radiolabelled seed and technetium-99m-nanocolloid were inserted intratumorally using mostly ultrasound guidance. Respectively the 125I setting and 99mTc setting of the gamma-probe guided the wide local excision and the sentinel node procedure. Maximum counts were measured at the tumor site and two centimetres away from the site.
Results: In the 25 included patients the I-125 seed was placed 26 days before surgery. The average strength of this source was 5.5 MBq on the day of insertion and 4.0 MBq on the day of surgery. An average amount of 115 MBq technetium-99m-nanocolloid was injected the day before surgery. The average counts of the ^{125}I seed at the tumor site were almost 4 times higher than the Tc-99 nanocolloid source. The counts depicted 20 mm away from the tumor site were comparable. The average residual counts were 3 times less for the ^{125}I seed. The sources could be well distinguished in 92% of the patients.
Conclusions: The ^{125}I seed and Tc-99 nanocolloid can be used in one procedure without interference in radiation energy. Nonpalpable breast lesions can be safely excised based on the ^{125}I seed in an area of radioactivity created by the Tch injection. Moreover, the ^{125}I seed acts as a point source and has no tendency to scatter its surrounding. The usage of the ^{125}I seed is a next step within fine-tuning breast-conserving surgery that should lead to further investigation.
No conflict of interest.

2049 POSTER

The clinical relevance of axillary reverse mapping (ARM) − a multicenter randomized controlled trial

M.A. Beek[1], P.D. Gobardhan[1], E.G. Klompenhouwer[2], A.C. Voogd[3], E.J.T. Luiten[1]. [1]*Amphia Hospital, Surgery, Breda, The Netherlands;* [2]*Catharina Hospital, Radiology, Eindhoven, The Netherlands;* [3]*Maastricht University, Epidemiology, Maastricht, The Netherlands*

Background: Axillary lymph node dissection (ALND) has potential negative procedural related side effects including upper extremity lymphedema. Axillary reverse mapping (ARM) is a recently described technique which enables discrimination of the lymphatic drainage of the breast from the upper extremity in the axillary lymph node basin. If upper extremity lymphedema is caused by cutting axillary lymphatic's, then being able to see and identify them would allow them to be preserved. In a feasibility study on ARM we found a high visualization rate using blue dye only (86.0–94.0%). Further we found that sentinel lymph node patients (SLN?-group, N = 43), indicated for a complementary (c)ALND did not have metastases in the arm nodes. Clinical positive lymph node patients (CP?-group, N = 50) had arm-metastases in 22% (P = 0.001). In the latter group arm-metastases, in patients treated with neo-adjuvant chemotherapy (NAC) was 24.6 vs 44.4% for patients who did not (P = 0.046). Because the cohort of patients treated with NAC is limited, these results need to be confirmed in a larger cohort.
In a multicenter randomized controlled trial we will investigate the clinical relevance of ARM expressed by the occurrence of postoperative complications. To minimize the risk of overlooking arm-node metastases, we will only include patients with an indication for a cALND based on a tumour-positive sentinel lymph node. Patients with an indication for an ALND based on a clinical positive axilla will be included in a registration study. Subgroup analysis of patients treated with NAC vs primary surgery will be performed.
Methods and Design: Patients diagnosed with invasive breast cancer with axillary metastasis and an indication for a cALND based on a positive SLN will be randomized between an ARM-ALND (in which arm-nodes and lymphatic's will be left in situ) and a standard ALND (at least level I−II). The primary outcome is the presence of breast cancer related lymphedema. The secondary outcome measurements include other postoperative complications (pain, paresthesia, numbness and loss of shoulder mobility), quality of live and axillary recurrence ratio.
The postoperative outcome will be measured after 6, 12 and 24 months. De quality of life and local recurrence rate will be documented. Lymphedema will be measured with the water displacement method and the circumference method. Paresthesia and numbness will be documented with the aid of a standardized questionnaire developed for breast cancer patients. Pain will be measured through a VAS-score and the shoulder function of the affected upper extremity will be compared with the not affected upper extremity.
Discussion: The study is funded by Pink Ribbon, a breast cancer foundation of the Netherlands. Recently obtained approval from the medical ethical committee. At the moment six breast cancer centers in the Netherlands will participate. The study will finish as soon as 280 patients are included and is expected to finish by January 2016.
No conflict of interest.

2050 POSTER

The effect of gentamicin-collagen sponges on the incidence of seroma and surgical site infections following mastectomy

B. Ten Wolde[1], F.J.H. Van den Wildenberg[1], F. Polat[1], J.M.W. Bertholet[1], L.J.A. Strobbe[1]. [1]*Canisius Wilhelmina Hospital, Surgery, Nijmegen, Netherlands*

Background: Seroma is the most frequent reported complication following breast cancer surgery, urging the search for preventive measures. Clinically significant seroma (CSS) is associated with secondary problems like pain and discomfort. Repeated aspirations are often necessary resulting in a higher risk of surgical site infections (SSI). Gentamicin-collagen (GC) sponges are hypothesized to lower the CSS and SSI incidence.
Method: A retrospective analysis was performed. Two consecutive cohorts of patients who underwent a mastectomy (ME) with or without an axillary lymph node dissection (ALND) were compared. One cohort received GC sponges, the other cohort was treated conventionally. Endpoints were the incidence of CSS and SSI, the mean number of aspirations and the mean aspirated volume.
Results: GC sponges lowered the CSS incidence from 73.7% to 38.5% (p = 0.002). The mean number of aspirations, the mean aspirated volume

and the SSI incidence were not affected. SSI incidence was 15.8% in the conventional cohort compared to 7.7% in the GC cohort (p = 0.227).
Conclusion: Application of GC sponges significantly lowers the CSS incidence compared to the conventional cohort, the SSI incidence was not influenced.
No conflict of interest.

2051 POSTER

Targeted intraoperative radiotherapy using low-kilovoltage X-rays for early breast carcinoma: single centre case series with 5-year follow-up

M. Jankiewicz[1], A. Kurylcio[2], J. Romanek[2], J. Mielko[2], M. Lewicka[2], B. Cisel[2], W.P. Polkowski[2]. [1]*Medical University Hospital Lublin, St. John's Cancer Center Lublin, Department of Surgical Oncology;* [2]*Medical University Hospital Lublin, Department of Surgical Oncology, Lublin, Poland*

Background: Intraoperative radiotherapy (IORT) delivered immediately after the removal of a tumour is increasingly used in breast conserving therapy (BCT) of patients with early breast carcinoma. The aim of the study is to analyze the results of BCT in these patients who undergo IORT using low energy X photons.
Materials and Methods: Eighty five females with early invasive breast carcinoma, who had IORT during breast conserving surgery between December 2005 and March 2008 were included in the study. The follow-up time was at least 54 months (from 54 to 80; median was 63; mean 63.7 months). For the IORT, INTRABEAM® PRS 500 system (Carl Zeiss Meditec AG, Jena, Germany) was used, which generates low energy (⩽50kV) X-rays. 20 Gy dose was applied to the surface of the tumour bed. Two groups of patients were investigated: 1) IORT group (n = 19), where it was the only form of radiation therapy; 2) IORT plus EBRT (external beam radiotherapy) group (n = 61), where the whole breast irradiation with 50 Gy was delivered additionally. The analysis focused on early (RTOG/EORTC scale) and late (LENT-SOMA scale) toxicity, long-term outcomes, and aesthetic effect.
Results: Early complications occurred in 20% of patients, but there were no serious complications that would prolong hospitalisation. The most frequent early complications were: prolonged wound healing (20%), inflammation of the tumour bed (14.1%), and breast inflammation (7.1%). Early radiation toxicity was observed in 15.3% of patients. The most frequent (11.3%) late complication was grade 2 fibrosis limited to the treated quadrant, which were reasons for diagnostic difficulties in the follow-up period. In over 10% of patients the fibrosis was a reason for subsequent surgical re-intervention. The intensity of fibrosis decreased with the time from surgery. No grade 3 or 4 fibrosis was detected in a 48-month of follow-up. Fluid collections (seroma) were most frequently (37.7%) observed. In the IORT group, local recurrence was detected in one patient 40 months after the treatment. There were no local recurrences in the IORT plus EBRT group. Five-year overall and disease-specific survival was 100% in the IORT group, whereas 95.1% and 96.7% in the IORT plus EBRT group, respectively. Excellent and good aesthetic outcome was achieved in about 90% of patients.
Conclusions: The IORT using INTRABEAM® PRS 500 system with low energy 50 kV X-ray irradiation, combined with breast conserving surgery in early breast carcinoma, is a well-tolerated and safe method, with a low complication rate. It provides good local control in 5-year follow-up. This is an effective procedure that provides high survival rate and provides fine aesthetic effect.
No conflict of interest.

2052 POSTER

Survival outcomes of breast conserving therapy via reduction mammoplasty in breast cancer patients

M.A. Gulcelik[1], L. Dogan[1], E. Baskan[1], N. Karaman[1], C. Ozaslan[1], E. Reis[1]. [1]*Ankara Oncology Hospital, Surgery, Ankara, Turkey*

Background: Reduction mammoplasty (RM), which has long been used for the treatment of macromastia, has recently become a preferred technique in the surgical treatment of breast cancer patients with macromastia. There is limited evidence in the literature on the oncologic safety and aesthetic outcome of the oncoplastic procedures. There is a small amount of data on its impact on local recurrences, distant metastasis, and overall survival. In the present study, we have reported the late results of the 117 breast cancer patients with macromastia treated with this technique.
Patients and Methods: 117 breast cancer patients with macromastia who underwent BCT via RM between 2003 and 2011 at Ankara Oncology Hospital were enrolled in the study. The patients who underwent with lower or upper pediculated flaps as a reduction technique are included. All of the patients were stage I, II and IIIA. Age, histopathological type, tumor size, local recurrence, distant metastasis, weight of the reduction mammoplasty specimens were analyzed.
Results: The median follow-up time was 31 months. Median age was 52.5 years. Median weight of the reduction mammoplasty specimen for the cancerous side was 950±20 g, for the other side was 960± 32g. During follow-up one loco-regional recurrence was noted. Seventeen patients developed distant metastases. The 5-year disease free survival (DFS) rate was 69% and the overall survival (OAS) rate was 79%. In stage I 5-year disease free survival rate was 100 % and the overall survival rate was 100%. In stage II 5-year disease free survival rate was 60 % and the overall survival rate was 78%. In stage III 5-year disease free survival rate was 24 % and the overall survival rate was 31%.
Conclusion: Reduction mammoplasty provides techniques to achieve good esthetic results while also providing possibility for wide excision margins. Few studies report on long-term oncological results of oncoplastic surgery, our findings indicate that BCS via RM are as effective and safe as standard surgical procedures in breast cancer patients with macromastia.
No conflict of interest.

2053 POSTER

Application of artificial neuronal networks for predicting presence of non-sentinel lymph node metastases in breast cancer patients with positive sentinel lymph node biopsies

T. Nowikiewicz[1], P. Wnuk[2], W. Zegarski[3]. [1]*Oncology Centre Bydgoszcz, Clinical Department of Breast Cancer and Reconstruction Surgery, Bydgoszcz, Poland;* [2]*Collegium Medicum Nicolaus Copernicus University, Clinical Department of Thoracic Surgery andLung Cancer and Reconstruction Surgery, Bydgoszcz, Poland;* [3]*Oncology Center Bydgoszcz, Surgical Oncology Clinic Collegium Medicum Nicolaus Copernicus University, Bydgoszcz, Poland*

Background: We should expect involvement of other axillary lymph nodes in about 40% of breast cancer patients with metastatic lesions diagnosed in sentinel lymph node biopsy (SLNB). The goal of this work is to present a new model of predicting presence of metastatic lesions in non-sentinel lymph nodes (nSLNs).
Material and Methods: Among 1583 patients with non-advanced breast cancer (cN0) subjected to SLNB between 2004 and 2012 we found metastatic lesions in sentinel lymph nodes excised from 348 patients (22%). Accessory ALND was performed in the majority of cases (94%). Involvement of nSLNs was identified in 32.1% of patients following ALND. Among patients with SLN metastases we examined the correlation between nSLN involvement and selected epidemiological data as well as primary tumor features and details of diagnostic and therapeutic management. Artificial neural networks were used to create a nomogram.
In the analyzed subjects we also assessed the predictive value of other prognostic systems (MSKCC, Tenon and Stanford nomograms).
Results: There were 347 women and 1 man included in the study group with median patient age of 55.2±9.9 years (from 23 to 80 years). Mean size of the excised primary lesions was 21.7±10.7 mm (4−70 mm). A mean of 2.8±1.6 lymph nodes (1−13) were excised during SLNB, with median number of metastatic SLNs amounting to 1.4±0.7 (1−6 nodes).
We made surgical treatment more radical by performing ALND in 94.0% of patients with SLN metastases (327/348). We identified nSLN lesions in 32.1% of patients (105/327). Mean patient follow-up time was 25.1 months (3−66).
Multidimensional analysis of the evaluated factors was performed using an artificial neural network with MLP 40−5−2 architecture. It included patients with a set of necessary clinical data (237 patients). Taking into consideration the presence of SLN capsule infiltration, vascular embolisms, palpability and multifocal nature of the tumor, involvement of the other breast, HER2 status, clinical staging, familial occurrence of breast cancer, hormonal therapy, presence of *comedo* component, tumor location, histological and molecular type of the tumor and Ki-67 value, we obtained AUC coefficient equal to 0.87. Sensitivity of the test amounted to 69%, specificity to 86% and accuracy − 80%.
In case of MSKCC nomogram the calculated AUC value was 0.71, for Stanford nomogram − 0.68, for the Tenon model − 0.67.
Conclusions: In the analyzed group of patients, only the MSKCC nomogram and the new model for prediction of nSLN involvement exhibited AUC values exceeding the expected level of 0.70.
During creation of our test, unlike previous nomograms, for the first time we used variables such as biological tumor subtype and Ki-67 index value.
No conflict of interest.

2054 POSTER

Unexpected ductal carcinoma in-situ is associated with a higher re-operation rate following breast conserving surgery

R. Pallas[1], C.A. Gateley[2], M. Elhassan[2], R. Foulkes[2]. [1]*Royal Gwent Hospital, Newport, United Kingdom;* [2]*Royal Gwent Hospital, Breast Unit, Newport, United Kingdom*

Introduction: It has recently been reported that the reoperation rate after breast conserving surgery is surprisingly high at 20% and higher when in-situ disease is present (29.5% v 18%). This was reported on postoperative histology. We examined how often the postoperative histology was at variance to the preoperative core biopsy and analysed the reoperation rate by the core biopsy.
Methods: We analysed pre-operative core biopsy, post-operative histological reports and reoperation rates on a series of 174 patients undergoing breast conserving surgery, whose pre-operative core biopsy found invasive ductal carcinoma only.
Results: Out of 174 patients, 100 (57%) had ductal carcinoma in situ as well as invasive carcinoma reported on the post-histopathology, that had not been identified pre-operatively. This was associated with a subsequent higher reoperation rate of 19% compared with 8% ($p < 0.05$ Chi-square).
Conclusions: Reoperation following breast conserving surgery was higher when in-situ disease was unexpectedly identified postoperatively. Discussion with breast histopathologists reveals that not all would report the presence of in-situ disease in a core biopsy containing mainly invasive carcinoma. We recommend a standard proforma for preoperative core biopsy reports to include both invasive and in-situ components.
No conflict of interest.

2055 POSTER

A portable gamma camera for intraoperative real time imaging of sentinel lymph nodes in early breast cancer

D. Ghosh[1], N.V. Michalopoulos[1], T. Davidson[1], C. Wickham[2], V. Stafyla[1], S. Banerjee[1], S. Jamali[1], N.R. Williams[3], M.R. Keshtgar[1]. [1]*University College London Royal Free London NHS Foundation Trust, Dept. of Surgery, London, United Kingdom;* [2]*Royal Free London NHS Foundation Trust, Nuclear Medicine Dept., London, United Kingdom;* [3]*Clinical Trials Group UCL Division of Surgery and Interventional Science, Centre for Clinical Science and Technology, London, United Kingdom*

Background: Access to nuclear medicine department for sentinel node imaging remains an issue in number of hospitals in the UK and many parts of the world. Sentinella® is a portable imaging camera used intra-operatively to produce real time visual localisation of sentinel lymph nodes.
Material and Methods: Sentinella® was tested in a controlled laboratory environment at our centre and we report our experience on the first use of this technology from UK. Moreover, preoperative scintigrams of the axilla were obtained in 144 patients undergoing sentinel node biopsy using conventional gamma camera. Sentinella® scans were done intra-operatively to correlate with the pre-operative scintigram and to determine presence of any residual hot node after the axilla was deemed to be clear based on the silence of the hand held gamma probe.
Results: Sentinella® detected significantly more nodes compared with CGC ($p < 0.0001$). Sentinella® picked up extra nodes in 5/144 cases after the axilla was found silent using hand held gamma probe. In 2/144 cases, extra nodes detected by Sentinella® confirmed presence of tumour cells that led to a complete axillary clearance.
Conclusions: Sentinella® is a reliable technique for intra-operative localisation of radioactive nodes. It provides increased nodal visualisation rates compared to static scintigram imaging and proves to be an important tool for harvesting all hot sentinel nodes. This portable gamma camera can definitely replace the use of conventional lymphoscintigrams saving time and money both for patients and the health system.
No conflict of interest.

2056 POSTER

Comparison of FNA, touch print, and crush print with permanent pathology in the diagnosis of breast lumps in patients in Shohada Hospital of Khorramabad

M. Ahmadinejad[1], A. Alea Pour[2], Z. Amiri[3], M. Meisami[3]. [1]*Lorestan University of Medical Science, Khoram Abad, Iran;* [2]*Lorestan University of Medical Science, Department of Pathology, Khoram Abad, Iran;* [3]*Lorestan University of Medical Science, University of Medical Science, Khoram Abad, Iran*

Introduction: Breast mass is a common disease and one of the most common complaints of patients in clinics of breast surgery. Breast mass is one of the most important symptoms of cancer. In addition to the methods of imaging and clinical examinations, fine needle aspiration (FNA) preoperatively along with Touch Print, Crush Print, and Frozen Section intraoperatively are applied to reach the diagnosis. In this study, in addition to the epidemiologic and clinical characteristics of the disease, the results of Crush Print and Touch Print methods intraoperatively were compared with permanent pathology.
Materials and Methods: This cross-sectional, epidemiological, analytical study was conducted on 107 patients with breast masses, who had been referred to Shohada Hospital of Khorramabad in 2012. The epidemiologic and clinical features of the patients were collected using a questionnaire. FNA was performed preoperatively, and Touch Print and Crush Print were prepared intraoperatively and sent to the Pathology Ward. The results were compared with permanent pathology. For all the methods, the diagnostic values of sensitivity, specificity, positive predictive value, negative predictive value, false positive percentage, and false negative percentage were calculated.
Results: The comparison between Touch Print and Crush Print with pathological diagnosis in detecting breast cancer showed the sensitivity, specificity, positive predictive value, negative predictive value, false positive percentage, and false negative percentage to be 97/8%, 100%, 98/4%, 0%,2/2% The comparison between the diagnostic values of FNA with pathological diagnosis in the diagnosis of breast cancer showed the rates to be 80.4%, 98%, 97.3%, 87.7%, 2%, and 19.6% respectively.
Conclusion: Considering the sensitivity, specificity, and positive predictive values of Touch Print and Crush Print methods in detecting breast cancer, we recommend the use of these easy and quick methods for these patients.
No conflict of interest.

2057 POSTER

Management of nipple discharge: should we operate when advanced digital mammography fails to detect cancer?

M. Hwang[1], H. Khan[1]. [1]*University Hospitals Coventry & Warwickshire Trust, Breast Surgery, Coventry, United Kingdom*

Background: There are no clear guidelines for the management of nipple discharge when triple assessment indicates benign features. The aim is to assess the outcome of microdochectomy and total duct excision as a management of nipple discharge.
Material and Methods: Patients who underwent a total duct excision or microdochectomy between 2008 and 2012 in a single centre were identified. Patient demographics, outcomes of triple assessment and final histology, including the need for further surgery were analysed, and the Fisher's exact test used.
Results: Of the total 81 patients, 4% ($n = 3$) were male and the median age at presentation was 51 years. Total duct excision was performed in 86% of patients and microdochectomy in 14%. On final histology, 12% ($n = 9$) were diagnosed with malignant disease. The rate of malignancy in women over the age of 50 was 20% compared to 0% in those younger ($p < 0.01$). A malignancy rate of 38% was observed in women over 70. Of the 3 male patients 1 had ductal carcinoma in situ (DCIS), 1 developed invasive ductal carcinoma at 17 months and the other had a papilloma with associated atypical ductal hyperplasia. Papillomas were found to be the cause of symptoms in 24% of cases. Blood stained discharge was the most common presentation in patients treated surgically (43%) and also in those found to have malignancy (90%). In patients with malignant disease, benign features were identified in 90% on clinical examination, 50% on radiological examination; and core biopsies were undertaken in 60%. Of the 10 confirmed cases of malignancy, triple assessment only identified 2 cases as suspicious, and 1 case as malignant.
Conclusions: In the era of advanced digital mammography, a malignancy rate of 12% indicates the need to continue to offer surgical excision for patients with persistent symptoms or atypical history, especially women over 70 and men of any age. Young women under 50 can be managed conservatively with close follow up.
No conflict of interest.

2058 POSTER

Oncoplastic surgery of breast cancer in developing countries

A. Martinovic[1], M.K. Kocic[1], M.B. Buta[1], I.D.J. Djurinic[1]. [1]*Institute of Oncology and Radiology, Surgery, Belgrade, Serbia*

Background: Breast cancer is the most common malignant tumor in women. Due to trauma and deformity occurring after mastectomy oncoplastic surgical approach has become routine and necessary. Primary breast reconstruction is regular procedure on Institute for Oncology and Radiology of Serbia in Belgrade. Result is an adequate oncological surgery with improved quality of life, aesthetics and psychosocial rehabilitation. Because of limited funds expander prosthesis are not implanted.

Materials and Methods: On our clinic for oncological surgery 76 breast reconstructions were performed in year 2012. Primary reconstruction was performed on 66 patients (86.8%). Secondary reconstruction was performed on 10 patients (13.1%).
Results: Primary subcutaneous mastectomy with axillary node dissection and frozen section examination of retromamilar cone with implantation of subpectoral endoprothesis was performed on 55 patients(83.3%). At the same time, on 4 patients (6.06%) augumentation of contralateral breast was done because of simetralisation.
In 6 patients (9.09%) retromamilar cone was positive on malignancy so excision of areola and mamila was performed. In one patient endoprothesis was placed subcutaneously because of defect reconstruction due to DCIS resection.
Secondary reconstruction was performed on 10 patients, on 4 because od prosthesis perforation (described by Ultra Sound or NMR) and in 6 patients because of skin necrosis due to radiotherapy.
Conclusion: Oncoplastic approach to breast surgery is continuously evolving. Given the psychosocial trauma that is more or less common in all patients in addition to appropriate surgical intervention adequate multidisciplinary team is necessary consists by medical oncologist, radiotherapist, physiotherapist, psychologist etc. Survival rates are almost the same but effect in term of life quality are significantly better.
No conflict of interest.

2059 POSTER

Evaluation of the inferior pedicle therapeutic mammoplasty as a primary procedure for upper quadrant breast cancer

A.D.E.L. Denewer[1], W. Elsoudi[1], O. Hussein[1], A. Khater[1], W.A.E.L. El-sadda[2], K. Abouelkher[2]. *[1]Mansoura Oncology Center, Surgical Oncology Departement, Mansoura, Egypt; [2]Mansoura University Hospital, Clinical Oncology Departement, Mansoura, Egypt*

Background: The treatment of breast cancer in large breast patients represents a great challenge to both surgeons and radiation oncologist. The aim of this study is to evaluate the outcome of inferior pedicle therapeutic mammoplasty in patients with upper quadrant early breast cancer and have large breast.
Materials and Methods: Thirty-five patients with early breast cancer and have macromastia were included in this study. Simultaneous bilateral inferior pedicle therapeutic mammoplasty was performed.
Results: The age of the patients ranged from 36 to 61 (median 46) years and tumour size ranged from 1 to 3.5 cm. the weight of the tissue removed ranged from 350gm to 780gm and the tumour safety margins ranged from 3 to 8 cm. Wound dehiscence was the commonest post operative complications and affect 6 patients (17.6%). the cosmetic outcome were excellent in 22 patients (64.5%), 9 patients (26.5%) showed good results, two patients (6%) were satisfactory and one patient (3%) showed poor result. The follow up period ranged from 6 to 42 months with one case (3%) of systemic metastasis.
Conclusion: Inferior pedicle therapeutic reduction mammoplasty for upper quadrant early breast cancer in large breasted women is a surgically and oncologically safe procedure and carries a satisfactory esthetic outcome.
No conflict of interest.

2060 POSTER

Immediate breast reconstruction of segmentectomy defects using extended lattisimus dorsi flap via single axillary incision

H. Khalifa[1], R. Oreaba[2]. *[1]National Cancer Institute, Cairo, Egypt; [2]National Cancer Institute, Surgical Oncology, Cairo, Egypt*

Background: Aim of this study is to describe the technique of extended autologous latissimus dorsi flap to reconstruct segmentectomy defects via single axillary incision and to assess the outcomes of this procedure.
Methods: Between December 2008 and December 2012, 88 patients with early breast carcinoma, underwent extended latissimus dorsi flap for reconstruction of segmentectomy defects (reaching about 20−30% of breast volume). Measured outcomes included: surgical complications, cosmetic outcome, and functional disability.
Results: Acceptable results were noticed with this technique as regard: postoperative complications (4 patients) with no further surgical intervention, sensory loss (nipple-areola complex; 4 patients, quadrant; 18 patients), restricted activities in 4 patients. Considering aesthetic evaluation, very much acceptable results were noticed as regard panel assessment and patient satisfaction.
Conclusion: This technique is associated with few adverse surgical and physical sequalae, without compromising cosmetic outcome, representing good alternative to mastectomy (if similar), avoiding additional scars and use of prosthesis.
No conflict of interest.

2061 POSTER

Periareolar single-port surgery of skin-sparing mastectomy by video-assisted breast surgery (VABS) is better aesthetic and lower invasive

K. Yamashita[1], K. Shimizu[2], H. Takei[1]. *[1]Nippon Medical School, Department of Breast Surgery, Tokyo, Japan; [2]Nippon Medical School, Department of Surgery, Tokyo, Japan*

Background: Early-stage breast cancer, such as DCIS, may force to complete removal of the mammary gland because of its wide spread in the breast. For such cases, skin-sparing mastectomy (SSM) should be recommended. However, the conventional oncoplastic surgery leaves some ugly scars on the breast due to large skin incisions. By applying the endoscopic video-assisted breast surgery (VABS), we can provide more aesthetic surgery with single periareolar port approach, leaving only a small and inconspicuous scar on the breast.
Methods: VABS of SSM consists of periareolar skin incision, dissection of whole mammary gland, sentinel node (SN) biopsy, and axillary node (AN) dissection. After SSM, the breast reconstruction was performed by the delayed or simultaneous method. We use the implant for simultaneous reconstruction. SN biopsy was performed endoscopically with only 1 cm incision in the axilla which was marked with 3D-CT lymphography prior to surgery. For SSM, we made a skin incision of 2.5−3.5 cm incision at the foot-side edge of the areola, to preserve blood flow around the areola. We cut across the gland near the nipple and quickly checked the transected stump by fast frozen section. Subcutaneous detachment was applied to the entire gland. Back of the gland was peeled just above the pectoralis major muscle fascia. The liberated gland was removed through the port with a plastic bag.
Results: We performed VABS on 300 patients since 2001, and SSM on 30 patients. Tumor size is 1.6 cm on average. Age is 57.2 years. 23 nipples were preserved. 17 cases were DCIS. 4 were invasive lobular carcinoma. 9 were invasive ductal carcinoma. 2 cases had SN metastasis. One case had AN metastasis. Between VABS and the conventional surgery, there was no difference in the amount of blood loss and operation time. Postoperative aesthetics was particularly good after simultaneous reconstruction. They had less sensory disturbance and high satisfaction. After 38 months, there have been no distant metastases, no postoperative deaths, and one local recurrence).
Conclusions: VABS SSM with periareolar skin incision approach makes better aesthetic results.
No conflict of interest.

Baseline results of the EORTC 10041/MINDACT TRIAL (Microarray In Node 0−3 positive Disease may Avoid ChemoTherapy)

E. Rutgers[1], M.J. Piccart-Gebhart[2], J. Bogaerts[3], S. Delaloge[4], L.J. Van 't Veer[5], I.T. Rubio[6], G. Viale[7], U. Nitz[8], J.Y. Pierga[9], A. Vindevoghel[10], E. Brain[11], P. Ravdin[12], C. Messina[13], F. Cardoso[14], On behalf of the MINDACT TRANSBIG Studygroup. *[1]The Netherlands Cancer Institute, Department of Surgery, Amsterdam, Netherlands; [2]Institut Jules Bordet, Department of Chemotherapy, Brussels, Belgium; [3]EORTC HQ, Statistics, Brussels, Belgium; [4]Institut Gustave Roussy, Department of Medicine, Villejuif, France; [5]UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, USA; [6]Hospital general Vall D'Hebron, Unidad de Patologia Mamaria, Barcelona, Spain; [7]Istituto Europeo Di Oncologia, Department of Pathology, Milano, Italy; [8]Bethesda Krankenhaus, Brustzentrum, Moenchengladbach, Germany; [9]Institut Curie, Departement d'Oncologie Medicale, Paris, France; [10]Clinique et Maternite Ste Elisabeth, Namur, Belgium; [11]Hopital Rene Huguenin, Saint-Cloud, France; [12]University of Texas Health Sciences Center, San Antonio, USA; [13]EORTC HQ, Brussels, Belgium; [14]Champalimaud Cancer Center, Breast Cancer Unit, Lisboa, Portugal*

Background: The EORTC 10041-MINDACT TRIAL investigates whether the 70-gene profile (MammaPrint®, MP) selects the right patients for adjuvant chemotherapy (CT) as compared to standard clinical pathological (CP) criteria.
Methods: Pts consented to MP prior to surgery with results reported as MP genomic high (Gh) or low (Gl) risk. Conditional on nodal status, successful gene testing and other eligibility criteria, pts were then enrolled into the trial. CP prognostic risk was assessed through a modified version of Adjuvant! Online (CP low risk (Cl) is >88% 10-years breast cancer specific survival for ER+ disease and >92% for ER negative). Genomic (G) and clinical (C) high risk pts were proposed adjuvant CT and were randomized between a non-anthracycline vs. a taxane-based CT regimen. G-low and C-low risk patients were not proposed for adjuvant CT and could be randomized between Tamoxifen 2 years, followed by Letrozole 5 years vs. Letrozole

7 years. Discordant patients, either G-low/C-high (Gl/Ch) or G-high/C-low (Gh/Cl) were randomized by MP risk or CP risk for CT decision.
Results: From March 2007 to July 2011, 11289 patients were screened in 112 sites over 9 countries, of which 6694 (59%) were enrolled. In the final stages, accrual averaged 385 per month.
Main reasons for non-enrollment after screening were: inadequate/absent sample (13%), patient/investigator decision (19%), genomic testing infeasible (27%, mostly <30% tumor cells), too high LN involvement (16%). After data cleaning the 4 risk groups were Gl/Cl 2743 patients (41%), Gh/Cl 592 (9%), Gl/Ch 1550 (23%) and Gh/Ch 1807 (27%). Using the two risk assessment methods for CT decision, there was 14% decrease in CT assignment when using MP.
Clinical parameters show a relatively favorable population (72% tumor size $\leqslant$2 cm, 67% >50 yrs old), though not uncommon for present-day breast cancer.
Interestingly, CP parameters are only partially reflected in MP assessment: Gl vs. Gh: LN- 79% vs 80%, tumor size $\leqslant$2 cm 76% vs 64%, grade 1 31% vs 5%, ER and/or PgR+ 99% vs 69%, HER2 neg 95% vs 83%.
When comparing CT policies, MP vs. CP would lead to following CT modifications: −5% in N0, −51% in N+, −17% in ER+, +2% in ER-. Actual CT administration data are still in collection.
Conclusions: 1) The logistically complex MINDACT trial turned out to be feasible across several countries 2) 31% of tumors showed discordant MP/CP risk assessment (Gh/Cl or Gl/Ch) 3) as intended, MP stratification only partly overlaps with CP risk (e.g. nodal status (0 vs 1−3) was not correlated with MP risk, r = 0.01).

2063 POSTER

Trastuzumab-based adjuvant chemotherapy for breast cancer: Early myocardial dysfunction detected by "speckle tracking echocardiography" (STE)

M. Dessì[1], C. Cadeddu[1], A. Piras[1], C. Madeddu[1], G. Mercuro[1], G. Mantovani[1]. [1]*University of Cagliari, Department of Internal Medical Sciences: Medical Oncology and Cardiovascular Diseases, Cagliari, Italy*

Background: Trastuzumab (TZB), an anti HER-2 receptor monoclonal antibody, was shown to be effective in breast cancer patients over-expressing HER-2 in the neo-adjuvant, adjuvant and metastatic setting. Careful cardiac monitoring is required when administered in combination with anthracyclines (ANT) which can increase its toxicity. Myocardial deformation indexes associated with STE myocardial imaging were shown to be very sensitive in identifying left ventricular (LV) dysfunction.
Patients and Methods: A phase IV, prospective, non-randomized study was designed to assess by STE technique the amount, timing and type of TZB-induced pre-clinical cardiac dysfunction when administered after epirubicin (EPI) in patients with HER-2 positive breast cancer. The schedule of TZB treatment was 6 mg/kg q3w for 1 year following EPI. Inclusion criteria: 18−70 yrs, histologically confirmed HER-2 positive breast cancer, LVEF $\geqslant$55%; ECOG PS score 0−2, no history of cardiac disease. ECOG PS score, conventional echocardiography and 2D STE parameters (circumferential and longitudinal S and SR, LV torsion), circulating levels of proinflammatory cytokines (IL-6 and TNF-α), reactive oxygen species (ROS) were assessed at baseline, after EPI treatment and one week after each TZB administration up to the 8th TZB administration.
Results: Thirty-eight patients (mean $\pm$ SD age 51$\pm$10 yrs) were enrolled from May 2012. A significant reduction in SR longitudinal peak (0.71$\pm$0.16 s-1 vs 0.81$\pm$0.14 s-1; $p < 0.05$) and a significant increase in circumferential function (1.03$\pm$0.31 s-1 vs 0.71$\pm$0.13 s-1; $p < 0.01$) were observed after EPI treatment. From the third TZB dose a marked reduction in circumferential function (0.69$\pm$0.18 s-1 vs 1.03$\pm$0.31 s-1; $p < 0.01$) and LV rotation (15.26$\pm$5.38 vs 22.88$\pm$6.41; $p < 0.001$) and no further reduction in longitudinal function were detected. A slight but significant reduction of the LVEF occurred soon after the fourth dose of TZB. ROS increased significantly after EPI treatment but did not change thereafter, while IL-6 and TNF-α were in the normal range throughout the treatment.
Conclusions: We showed that after treatment with EPI longitudinal function was impaired while a compensatory increase in LV circumferential function and LV torsion was observed. TZB treatment had a negative impact on mid and sub-epicardial fibres function, responsible mainly for circumferential function and left ventricle torsion. These effects could be attributed to the higher toxicity of TZB on hyperactive myocardial fibres after EPI treatment. The study is in progress and longer follow-up will show if this mid and sub-epicardial myocardial impairment persists over time and eventually results in an overt clinical cardiac dysfunction.
No conflict of interest.

2064 POSTER

Protein expression profiling in patients with large residual breast cancer (>1 cm) following primary systemic chemotherapy

S. Morales[1], A. Novell[2], M.F. Demarchi[3], F. Vilardell[2], V. Carañana[3], M.J. Panades[2], P. Navarro[4], E. Iglesias[5], X. Matias-Guiux[2], A. Llombart-Cussac[3]. [1]*IRBd-HUAV, Medical Oncology, Lleida, Spain;* [2]*IRBd-HUAV, Pathology, Lleida, Spain;* [3]*FISABIO − Hospital Arnau Vilanova, Medical Oncology, Valencia, Spain;* [4]*FISABIO − Hospital Arnau Vilanova, Pathology, Valencia, Spain;* [5]*IRBd-HUAV, Breast Cancer Unit, Lleida, Spain*

Background: Primary systemic chemotherapy (PSC) is a common approach for Early Breast Cancer (EBC). Persistence of large residual tumor following PSC is the strongest predictor of tumor relapse. Identification of molecular markers in the residual tumor may predict relapse risk and identify molecular targets.
Material and Methods: Patients with EBC and PST treated from 1996 to 2010 in two institutions were analyzed. Mayor inclusion criteria: (i) Histologically confirmed Stage II − III BC, (ii) anthracycline and/or taxane based PSC, (iii) residual breast tumor larger than 1 cm and >10% viable tumor cells, (iv) preserved tumor, and (v) signed consent form. A tissue matrix-array was generated with Immunohistochemistry analysis of 29 potential molecular markers associated to phenotype, apoptosis, signaling, deregulation, metastasis, transcription and adhesion. A histo-Score (0–300) was used for cytoplasmatic (cyt)/nuclear (nuc) markers, and a classic (0 to 3) for membrane cell markers. The analysis was done for distant disease-free survival (DDFS).
Results: A total of 256 patients were included. With a median follow-up of 53 months, 80 metastatic events (32%) were reported with a 5 years DDFS of 71%. Univariate analysis identified several predictors of DDFS: ER (p 0.005), Ki67 (0.0002), Cyt-HER4 (<0.04), Bcl2 (<0.05), BP1 (0.02), nuc-Ciclin D1 (0.02), nuc-PTEN (0.02); Cyt-p65 (0.03) and nuc-p65 (0.03). A multivariate model (stepwise method) for DDFS obtains a molecular signature with 6 markers of poor prognosis: ER [= 0], cyt-p65 [<85], cyt-HER4 [>75], cyt-PTEN [= 0], BCL2 [<78] and Ki67 [>20]. The 5-year DDFS for 0−1, 2−3 or $\geqslant$4 conditions were 84.8%, 70.7% and 34.2% ($p < 0.00001$).

Number of conditions satisfied	Progression-free survival time Cox Regression Model		
	HR	95% CI	p-value
0 or 1	1	–	–
2 or 3	2.15	(1.2−3.9)	0.01
4, 5 or 6	5.73	(3.0–11.1)	<0.00001

An analysis stratifying by ER-status identifies dissimilar markers. ER negative [=0]: cyt-HER4 (p 0.01), nuc-P65 (0.01), BP1 (0.001) cyt-65 (0.02) and cyt-ECad (0.04). For ER-positive [>0]: nuc-CiclinD1 (p 0.02), Ki67 (0.02), nuc-Survivin (0.02) and cyt-pAKT (0.03).
Conclusions: A molecular signature in the residual tumor following PSC for EBC identifies patients with low, moderate or high risk of distant progression. ER expression is a determinant prognostic factor differentiating two populations with specific markers. A validation study is ongoing.

2065 POSTER

Changes in breast cancer subtype between primary tumor and residual disease after neoadjuvant systemic chemotherapy (NSC)

M. Chavez-MacGregor[1], N. Parinyanitikul[1], X. Lei[1], E. Mittendorf[2], J. Litton[1], W. Woodward[3], A. Zhang[4], A.M. Gonzalez-Angulo[1]. [1]*UT MD Anderson Cancer Center, Breast Medical Oncology Department, Houston TX, USA;* [2]*UT MD Anderson Cancer Center, Division of Surgery, Houston TX, USA;* [3]*UT MD Anderson Cancer Center, Division of Radiation Therapy, Houston TX, USA;* [4]*UT MD Anderson Cancer Center, Division of Pathology, Houston TX, USA*

Background: Breast cancer treatment and prognosis is determined by tumor subtype. Tumor heterogeneity and lack of stability in ER, PR and HER2 has been described between primary tumor and metastatic disease. We evaluate the changes in tumor subtype between primary tumor and residual disease after treatment with NSC and its association with outcome.
Methods: A total of 398 women with known biomarker status in the primary tumor and in the residual disease after NSC were identified between 1992–2012. For each biomarker we evaluated stability and changes from positive to negative or negative to positive. Descriptive statistics were used;

Kaplan–Meier method was used to estimate the 5-year OS and RFS by receptor status change. Cox proportional models were fit to determine the association of receptor status changes with outcomes after adjustment for important patient and disease characteristics.
Results: From the 398 patients included, 162 (40.7%) experienced a change in at least one breast cancer biomarker between the primary tumor and the residual disease. Twenty-nine (40.2%) of the 72 patients with HER2+ primary tumors, changed to HER2−; and of the 320 HER2− tumors, 11 (3.4%) changed to HER2+. Among the 35 trastuzumab-treated patients, 16 (45.7%) of them changed to HER2-. Twenty-three (10.9%) of 211 ER+ tumors changed to ER−; and among 187 ER− tumors, 39 (20.8%) changed to ER+. Fifty-seven (35.2%) of 162 PR+ tumors changed to PR-; and 28 (11.9%) of 235 PR- primary tumors changed to PR+. With a median follow-up of 40 months, the 5-year OS of patients with and without any biomarker status change was 75% and 63% respectively ($p = 0.07$). The 5-year PFS was 63% and 48% for patients with and without biomarker status change ($p = 0.003$). In the multivariable model, a change in any of the tumor biomarkers was associated with improved RFS (HR 0.63, 95% CI 0.44−0.9) but had no statistical impact in OS (HR 0.79; 95% CI 0.53–1.18).
Conclusions: Changes in ER, PR and HER2 between the primary tumor and the residual disease are common. Lack of stability in tumor biomarkers can be associated with issues associated with the test itself, tumor heterogeneity, clonal selection and differential treatment response. In this retrospective study, a change in biomarker status was associated with improved RFS. Further prospective studies are needed to confirm our findings in larger cohorts and to determine the impact that changes in therapy have in the outcome of this group of patients.
No conflict of interest.

2066 POSTER

Outcome of 561 non-metastatic triple negative breast cancer patients: Multi-center experience from Turkey

B. Budakoglu[1], K. Altundag[2], V. Berk[3], M. Ozkan[3], E. Algin[4], G.G. Dogu[5], H. Harputluoglu[6], C. Ugur[4], A. Isikdogan[7], I. Turker[1]. *[1]Dr.Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Department of Medical Oncology, Ankara, Turkey; [2]Hacettepe University Institute of Oncology, Department of Medical Oncology, Ankara, Turkey; [3]Erciyes University Faculty of Medicine, Department of Medical Oncology, Kayseri, Turkey; [4]Gazi University Faculty of Medicine, Department of Medical Oncology, Ankara, Turkey; [5]Pamukkale University Faculty of Medicine, Department of Medical Oncology, Denizli, Turkey; [6]Inonu University Faculty of Medicine, Department of Medical Oncology, Malatya, Turkey; [7]Dicle University Faculty of Medicine, Department of Medical Oncology, Diyarbakir, Turkey*

Triple negative breast cancers account for 15% of all breast carcinomas. Triple negative cancers presenting as an early stage breast cancer is associated with high recurrence and early distant metastasis risk than hormone receptor positive and human epidermal growth factor receptor (HER-2) positive breast cancers. In the presenting study basic clinico-pathologic characteristics, prognostic factors and recurrence patterns of the triple negative breast cancers were evaluated retrospectively. Between 2000 and 2010 medical records of 561 non-metastatic triple negative breast cancer patients admitted to 8 different cancer centers in Turkey were evaluated retrospectively.
Frequency of triple negative breast cancer was 12% in our study. All patients were women whose median age was 48. Three hundred and eleven (55.4%) of the patients were premenopausal. Majority of patients had early stage breast cancer at the time of diagnosis (16.8% stage I, 48.1% stage II, 35.1% stage III). Invasive ductal carcinoma was the most frequent histology (84.1%). Frequency of grade II and grade III was 27.1% and 48.5%, respectively. As an adjuvant therapy, 94.3% and 41.2% of women received chemotherapy and radiotherapy, respectively.
Median follow up period was 28 (range: 3–290) months. During follow up period 134 (23.8%) patients were diagnosed as recurrent disease. Recurrence sites were mostly bone and soft tissue. Factors affecting disease free survival (DFS) and overall survival (OS) were age (both $p < 0.001$), lymph node involvement (both $p < 0.001$), lymphovascular invasion (LVI) ($p < 0.001$ and $p = 0.004$) and the stage of the tumour (both $p < 0.001$) and adjuvant administration of antracycline based chemotherapy (both <0.001) and the type of surgery (NS for DFS but $p = 0.05$ for OS). In our study group, 3-year DFS and OS were 72.0% and 93.0% respectively. Age, lymph node involvement, LVI, stage, and adjuvant chemotherapy choice were determined prognostic factors in our study. Prevalent recurrence sites were bone, soft tissue and the lung. Further adjuvant prospective randomised trials are needed to confirm prognostic and predictive factors in this quite unique patient population.
No conflict of interest.

2067 POSTER

A prospective, randomized, multicenter, comparative and open-label study on hepatotoxicity of anastrozole compared with tamoxifen in adjuvant therapy in postmenopausal women with hormone receptor+ early breast cancer

Y. Lin[1], J.L. Liu[2], X.H. Zhang[3], L. Li[4], R. Hu[5], J. Liu[6], Y.C. Deng[7], D.D. Chen[8], Y.B. Zhao[9], S.M. Wang[10]. *[1]The First Affiliated Hospital of Sun Yat-Sen University, Breast Surgery, Guangzhou, China; [2]Guangxi Tumour Institute & Hospital, Nanning, China; [3]The First Affiliated Hospital of Wenzhou Medical College, Wenzhou, China; [4]First Affiliated Hospital of Dalian Medical University, Dalian, China; [5]Sichuan Cancer Hospital, Chengdu, China; [6]Fujian Provincial Tumor Hospital, Fuzhou, China; [7]Second Affiliated Hospital Zhejiang University College of Medicine, Hangzhou, China; [8]Yunnan Tumor Hospital, Kunming, China; [9]West China Hospital Sichuan University, Chengdu, China; [10]The First Affiliated Hospital Sun Yat-Sen University, Breast Surgery, Guangzhou, China*

Background: Tamoxifen and aromatase inhibitors are widely used in adjuvant therapy for breast cancer patients, but their hepatotoxicity has not been fully investigated. This study (NCT00537771) was the first study to compare the liver safety of tamoxifen and anastrozole.
Materials and Methods: 353 Chinese postmenopausal women with Hormone Receptor positive early breast cancer, after completion of primary therapy (surgery±radiotherapy±chemotherapy), were randomised 1:1 to anastrozole (1 mg P.O daily) or tamoxifen (20 mg P.O daily). Patients were followed for fatty liver disease, abnormal liver function and treatment failure until 3 years after randomization. The primary endpoint fatty liver disease is defined as a liver-spleen ratio of less than 0.9 on hepatic CT scan. Hepatotoxicity was analyzed in ITT (all randomized subjects) set and safety was analyzed in Safety set (all subjects who took at least one dose of the study medication).
Results: Demographic and other baseline characteristics were well balanced in two groups. Patients in anastrozole group developed less fatty liver disease in years 1, 2 and 3. The cumulative incidence of fatty liver disease after 3 years in anastrozole group was statistically significantly lower than tamoxifen group (14.6% vs. 41.1%, $p < 0.0001$; RR = 0.30, 95% CI: 0.21, 0.45) in ITT population. The cumulative incidence of abnormal liver function after 3 years' treatment showed no significant difference between tamoxifen group and anastrozole group (24.6% vs. 24.7%, $p = 0.6186$). Tamoxifen group had higher treatment failure rate than anastrozole group in 1, 2 or and 3 years. The median time to treatment failure for tamoxifen group was 15.1 months (454 days) and 37.1 months (1112 days) for anastrozole group (HR = 0.27, 95% CI: 0.20, 0.37, log-rank $p < 0.0001$). The most commonly reported adverse events were 'reproductive system disorders' in tamoxifen group (17.1%) and 'musculoskeletal disorders' in anastrozole group (14.6%).
Conclusion: The results from this study indicate that postmenopausal women receiving adjuvant anastrozole showed less fatty liver disease and therefore had a favourable hepatic safety profile than those receiving tamoxifen for hormone receptor positive early breast cancer.
No conflict of interest.

2068 POSTER

A prospective multi-centre study of the impact of Oncotype DX® on adjuvant treatment decisions in patients in the UK with estrogen receptor positive early breast cancer

J. Braybrooke[1], A. Kuchel[1], T. Robinson[1], C. Comins[1], M. Shere[2], M. Varughese[3], G. Sparrow[4], L. Saunders[2], A. Sahu[2], S. Cawthorn[2]. *[1]Bristol Haematology and Oncology Centre, Bristol, United Kingdom; [2]North Bristol NHS Trust, Bristol, United Kingdom; [3]Taunton and Somerset NHS Trust, Taunton, United Kingdom; [4]Yeovil District Hospital NHS Foundation Trust, Yeovil, United Kingdom*

Background: The proportion of patients (pts) with estrogen receptor positive (ER+) early breast cancer that benefit from adjuvant chemotherapy (CT) is modest. Onco*type* DX®, a validated multigene assay, provides prognostic and predictive information beyond traditionally used parameters. The test can help in making more informed treatment decisions. It is not routinely used in the UK.
Materials and Methods: 147 patients with ER+, HER2 negative early breast cancer, recommended to discuss adjuvant CT by the multi-disciplinary teams in 3 NHS hospitals were offered Onco*type* DX. Pts with any T stage, N0 and, if >50 yrs old also N1 (1−3 + nodes) disease were eligible. Questionnaires were independently completed by patients and the same oncologist at two consultations, before and after receiving the Onco*type* DX Recurrence Score result. Data from a preliminary analysis, on the first 85 evaluable patients, seen by 10 oncologists, was available at

the time of abstract submission. The final data from 147 pts included in the study will be presented at the meeting.
Results: Median age 56 years (range 31 −74 years). Tumour characteristics: T1 58%, T2 42%. Grade 1 7%, Grade 2 64%, Grade 3 29%. VI+ 20%. N0 68%, N1(mic) 9%, N1 21%, Nx 2%. Mean Recurrence Score = 18: 51% low (<18), 42% intermediate (18−30), 7% high (>31). Oncologists treatment recommendation changed in 36 pts (29 CT to no CT, 7 no CT to CT) Overall, oncologists recommended CT in 55% of pts pre Onco*type* DX and 28% post Onco*type* DX. For 25 pts the Recurrence Score result clearly changed their initial decision; 11 to CT, 14 to no CT. Patient confidence in their decision increased post Onco*type* DX. For 66 pts, after the second consultation, there was concordance between oncologists and pts about treatment (19pts CT; 47pts no CT). For the other 19 pts, 8 chose CT when the oncologist advised there was only likely to be a small benefit, 4pts declined CT despite it being recommended, 1pt decided against CT before the Recurrence Score was available and for 6 pts there was no clear decision documented.
Conclusions: This prospective study confirms the uncertainty pts and oncologists have about adjuvant CT in ER+ early breast cancer. Using Onco*type* DX® was associated with a significant change in treatment decisions and an overall reduction in chemotherapy being recommended. Use of the test was associated with increased patient confidence in their treatment decision.The data are consistent with those presented from Wales, Germany, Spain and the US.
Conflict of interest: *Advisory board: Genomic Health*

2069 POSTER

Preliminary results of the TEAMIIA trial: Efficacy of six months neoadjuvant exemestane therapy in postmenopausal hormone receptor-positive breast cancer patients − a Dutch Breast Cancer Trialists' Group study

D.B.Y. Fontein[1], A. Charehbili[1], W.M. Meershoek-Klein Kranenbarg[1], S.C. Linn[2], G.J. Liefers[1], J.R. Kroep[3], J.W.R. Nortier[3], C.J.H. Van de Velde[1]. *[1]Leiden University Medical Center, Surgery, Leiden, Netherlands; [2]Netherlands Cancer Institute, Molecular Pathology, Amsterdam, Netherlands; [3]Leiden University Medical Center, Medical Oncology, Leiden, Netherlands*

Background: Neoadjuvant treatment is playing an increasing role in the clinical management of breast cancer (BC). Several studies have shown that estrogen receptor-positive (ER+) BC patients are less sensitive to neoadjuvant chemotherapy than ER-negative patients, and may be best treated with neoadjuvant hormonal therapy (NHT) instead. There is currently no consensus on the optimal duration of NHT. Here we present an overview of the preliminary outcomes of the TEAMIIA trial, a multicenter, prospective, phase II trial investigating the efficacy of six months of neoadjuvant exemestane in postmenopausal, strong estrogen receptor-positive (ER+, >50%) BC patients.
Methods: Primary endpoint was clinical response at 3 and 6 months as measured by palpation. Secondary endpoint was radiological response as measured by Ultrasound/MRI and/or mammography. Paired samples T-tests (95%confidence interval (CI)) were used to compare mean changes in tumor size (in mm) between baseline and 3 months, and between 3 and 6 months after randomization. We also evaluated conversion rates from mastectomy to breast conserving surgery (BCS).
Results: 107 patients (stage T2-T4ac) were included in the study (median 72 years (53−88)). Clinical and radiological response data were available for 64 patients at 3 months, and for 34 and 40 patients at 6 months respectively. Overall response rate (partial response + complete response) at 3 months was 48.4% and increased to 67.5% at 6 months. Mean tumor size at the start of treatment was 48.6 mm (SD 81.8), and decreased to 29.3 mm (standard deviation (SD) 12.5) and 24.9 mm (SD 14.3) at 3 and 6 months respectively ($p = 0.001$ at month 3 and 6). Mean decrease in tumor size was 26.6% (SD 24.5) between 0 and 3 months and 9.3% (SD 21.8) between 3 and 6 months ($p = 0.006$). Out of 35 patients (32.7%) who were not eligible for BCS at baseline, 14 (25.5%) underwent BCS after 6 months of NHT, which translates to a conversion rate of 40%.
Conclusion: This study shows that neoadjuvant exemestane therapy is effective in strong ER+ breast cancer patients and persisted after 6 months of treatment. BCS rates also improved following 6 months of NHT.
No conflict of interest.

2070 POSTER

Fertility counseling in young women with breast cancer: A cross-sectional study

D.L. Van Abbema[1], J. Roijen[1], R. Golde[2], C. Hoving[3], M.W. Dercksen[4], H. Bosch[4], V.C.G. Tjan-Heijnen[1]. *[1]Maastricht University Medical Centre, Medical Oncology, Maastricht, Netherlands; [2]Maastricht University Medical Centre, Obstetrics and Gynaecology, Maastricht, Netherlands; [3]Maastricht University Medical Centre, Health Promotion, Maastricht, Netherlands; [4]Maxima Medical Centre, Medical Oncology, Eindhoven, Netherlands*

Background: Adjuvant chemotherapy in young patients with breast cancer can cause permanent infertility. Loss of fertility after breast cancer treatment negatively impacts quality of life in young patients. It is therefore important to counsel patients before treatment and to provide the opportunity for fertility preservation. This cross-sectional study investigated the association of fertility counseling and quality of life in young women with breast cancer.
Material and Methods: Sixty-five women who were diagnosed with early stage breast cancer between the ages of 18 and 42 years completed several quality of life questionnaires. Participants were asked if they received counseling by a fertility specialist and if they underwent fertility preservation treatment. The following validated questionnaires were used: Functional Assessment of Cancer Therapy for Patients with Endocrine Symptoms (FACT-ES) and the Hospital Anxiety and Depression Scale (HADS).
Results: Mean age of the women at diagnosis was 34.4 years (range 26−42 years, SD $\pm$ 4.4). Twenty-five patients (38.0%) received only basic information about fertility before chemotherapy by their treating oncologist, while 22 women (33.8%) received intensive counseling by a on this topic specialized medical oncologist and fertility specialist. Ten women with intensive counseling (15.4%) underwent fertility preservation prior to breast cancer treatment. Both patients with fertility counseling by their oncologist or by a dedicated specialized oncologist and fertility specialist scored significantly higher compared to patients without counseling on social well-being ($p = 0.001$), physical well-being ($P = 0.04$) and functional well-being ($p = 0.02$). Fertility preservation in women was significantly related to a wish to have more children ($p = 0.05$) and to fertility counseling ($P = 0.03$).
Conclusion: Fertility counseling prior to breast cancer treatment has a positive influence on quality of life in young women with breast cancer. We recommend to refer women with a wish to have more children to a dedicated medical oncologist and fertility specialist for intensive counseling. In women without a wish to have children, basic information provided by an oncologist is sufficient.
No conflict of interest.

2071 POSTER

Impact of metformin in luminal subtype breast cancer

H. Kim[1], S.H. Ahn[1]. *[1]Asan Medical Center, Surgery, Seoul, Korea*

Background: Recent observation have shown that metformin use decrease both breast cancer and mortality. Metformin use is also associated with response of neoadjuvant treatment. In the current study, we explored the association between metformin use and survival outcomes in patients with diabetes and non diabetes.
Patients and Method: We analysed the data from Asan medical center breast cancer database from 1997 to 2007.
Total 9916 patients were analysed in this study. Patients were categorized by diabetes status and metformin use. The Kaplan–Meier product method was used to calculate Disease free survival (DFS), cancer specific survival (CCS) and overall survival (OS).
Results: This study cohort was comprised of 8274 non diabetic patients, 251 diabetic patients with metformin, and 250 patients diabetic patients not receiving metformin. At a median 65 months follow up, non diabetic patients group showed better DFS, CSS, OS than diabetic patients ($p < 0.05$). For diabetic patients, metformin group showed better survival than non metformin group ($p < 0.05$). but for subgroup analysis according to the intrinsic subtype, this survival difference was shown only luminal subtypes.
Conclusion: Metformin use impact survival outcomes in diabetic patients especially luminal subtypes.
No conflict of interest.

2072 POSTER

Accuracy of treatment response assessment modalities after neoadjuvant therapy: A Dutch Breast Cancer Trialists' Group (BOOG) substudy

A. Charehbili[1], D.B.Y. Fontein[2], V.T. Smit[3], M.N. Wasser[4], A.E. Van Leeuwen-Stok[4], E.M. Meershoek-Klein Kranenbarg[2], C.J.H. Van de Velde[2], G.J. Liefers[2], J.W.R. Nortier[3], J.R. Kroep[3]. *[1]Leiden University Medical Center, Medical Oncology and Surgery, Leiden, Netherlands; [2]Leiden University Medical Center, Surgery, Leiden, Netherlands; [3]Leiden University Medical Center, Medical Oncology, Leiden, Netherlands; [4]Leiden University Medical Center, Radiology, Leiden, Netherlands*

Background: Studies suggest that MRI is an accurate means of assessing residual tumor size after neoadjuvant chemotherapy (NAC) and neoadjuvant hormonal therapy (NHT). However, little comparative data is known comparing response evaluation using MRI, clinical examination (palpation), and/ or ultrasound with histopathologic response following taxane-based NAC of patients with stage II/III HER2-negative breast cancer treated in a prospective phase III trial.
Methods: From July 2010 to April 2012, 250 patients from 26 participating sites received NAC (6 courses docetaxel, doxorubicin and cyclophosphamide) with or without zoledronic acid. Clinical response (MRI, palpation, and ultrasound measurements) were performed at baseline, after 3 cycles, and post-NAC. Clinical and pathological responses were recorded. Accuracy measures ((true-positives+true negatives)/total cases) were calculated and clinically and pathologically assessed tumor sizes were correlated using Spearman correlation coefficients. Tumor size over- and underestimation were quantified.
Results: The accuracy of MRI (n = 208), palpation (n = 77) and ultrasound (n = 33) for determining pathological response was 75%, 58% and 78% respectively. The correlation coefficient for the comparison between MRI and pathological measurements was 0.44 ($p<0.001$). Correlation coefficients were different for ER-negative ($r = 0.76$, $p < 0.001$) and ER-positive ($r = 0.42$, $p < 0.001$) breast tumors. MRI under- or overestimated the tumor size in 14% and 61% of the patients. In cases of substantial tumor size underestimation (>2 cm) with MRI, surgical margins tended to be tumor positive more often than when tumor size was well- or overestimated (37% vs. 15%, $p=0.06$).
Conclusions: In this relative large HER2-negative breast cancer population, MRI was more accurate than palpation in assessing tumor response. However, MRI measurements correlated only moderately with tumor size on the surgical specimen. MRI predicted residual tumor size more reliably in ER-negative than ER-positive tumors. Therefore, post-NAC MRI should be interpreted carefully in the context of response monitoring with tumor characteristics taken into account.
No conflict of interest.

2073 POSTER

Difference between brand and generic docetaxel in breast cancer treatment

M. Salamoon[1], Y. Alsaleh[2], N. Jaafar[2], M. Bachour[2]. *[1]Bairouni University Hospital, Damascus, Syria; [2]Bairouni University Hospital, Medical Oncology, Damascus, Syria*

Background: Docetaxel has emerged as a good option for treatment of breast carcinoma in combination with anthracyclines in both adjuvant and metastatic setting. Recently, several generic formulations were introduced and used in practice.
Objective: The objective of this study was to compare both brand and generic docetaxel in term of toxicity in adjuvant setting and efficacy in metastatic setting.
Material and Methods: The study was performed at Al Bairouni University Hospital in Damascus (SYRIA). In 2011 the brand docetaxel was offered to all patients diagnosed with breast cancer while the generic one was employed to treat breast cancer patients in 2012. In adjuvant setting, the study aimed at comparing toxicity profile between the two formulations while both toxicity and efficacy were evaluated in metastatic setting. Patients included in the study were 1820 patients in 2011 versus 1526 patients in 2012.
Results and discussion: Among the 1820 patients evaluated in 2011, 913 patients presented with metastatic disease either chemonaive or after progression on another line while 710 out of 1526 were metastatic in 2012. Most toxicities were mucosal ulceration, skin burns and cellulitis with different degrees observed in 413 out of 1820 patients in brand arm versus 1224 out of 1526 in the generic arm (P.value 0.039) which favors the brand docetaxel. In term of response, a complete response was reached in 684/913 in brand versus 393/710 in generic arm (P.value 0.14).
Conclusions: Brand docetaxel was shown to be a good option to treat breast cancer in both adjuvant and metastatic setting in the light of good efficacy and toxicity profile. In the other hand, generic docetaxel showed an acceptable efficacy in metastatic setting, however, its toxicity profile does not put it at the top options. It was also noticed that there was an inverse proportion between adverse events and response to treatment in the generic arm, the thing that could be attributed to dose reduction to cope with high grades toxicity.
No conflict of interest.

	Patients	Metastatic disease	Complete response	P value
Brand arm	1280	913	684	0.14
Generic arm	1526	710	393	

2074 POSTER

Evaluation of Ki67 as a potential predictive marker for adjuvant chemotherapy in estrogen receptor-positive and human epidermal growth factor receptor 2-negative breast cancer patients without nodal metastases

N. Niikura[1], N. Kumaki[2], M. Terao[1], R. Oshitanai[1], B. Tuda[1], T. Okamura[1], Y. Saito[1], Y. Tokuda[1]. *[1]Tokai University School of Medicine, Breast and Endocrine Surgery, Kamagawa, Japan; [2]Tokai University School of Medicine, Pathology, Kamagawa, Japan*

Background: Immunohistochemical (IHC) staining for Ki67 has previously been shown to be a potential prognostic and predictive marker for breast cancer. At the St. Gallen Consensus Meeting, it was determined that the Ki67 labeling index is particularly important for distinguishing between 'Luminal A' and 'Luminal B (human epidermal growth factor receptor 2 [HER2] negative)' subtypes and is a predictive marker for chemotherapeutic efficacy. However, evidence on the Ki67 index being a predictive marker for adjuvant chemotherapy is limited. This study aimed to assess the predictive value of Ki67 in breast cancer patients without lymph node metastases.
Methods: We retrospectively identified 1726 patients in the Tokai University breast cancer database for whom IHC Ki67 data were available between January 2002 and December 2010. Of these, 219 were excluded because of distant metastases (n = 38), a diagnosis of ductal carcinoma in situ (n = 181), or the presence of lymph node metastases (n = 883). Thus, data for 624 patients were evaluated. The Ki67 index was defined as low if <10% of cells stained positive for this marker and high if $\geqslant$10% of cells stained positive. To assess Ki67 levels and survival outcomes, survival curves were calculated using the Kaplan–Meier method and compared using the log-rank test and Cox regression model.
Results: We identified 624 patients with estrogen receptor (ER)-positive, HER2-negative breast cancer and no lymph node metastasis. Of these patients, 27 relapsed and 10 died of breast cancer. Patients with a high Ki67 index (n = 155) had significantly poorer relapse-free survival (RFS) (hazard ratio [HR], 2.335; 95% confidence interval [CI], 1.092–4.990; P = 0.029) and tended to have poorer overall survival (OS) (HR, 3.470; 95% CI, 0.930–12.938; P = 0.064) than patients with a low Ki67 index (n = 468). Adjuvant chemotherapy did not prolong RFS in patients with either a high (HR, 0.966; 95% CI, 0.311–3.004; P = 0.953) or low (HR, 1.131; 95% CI, 0.360–3.555; P = 0.834) Ki67 index.
Conclusion: Our results suggest that Ki67 is a prognostic marker for patients with ER-positive, HER2-negative breast tumors with no lymph node metastases. However, Ki67 is not a predictive marker for the outcome of adjuvant chemotherapy in these patients.
No conflict of interest.

2075 POSTER

Multicenter phase II study of weekly paclitaxel followed by doxorubicin plus paclitaxel as neoadjuvant chemotherapy for triple negative breast cancer (SBCCSG#12, Saitama Breast Cancer Clinical Study Group, Japan)

S.E. Nagai[1], K. Inoue[1], K. Futsuhara[2], T. Saito[2], T. Sakurai[2], H. Takei[3], T. Kai[2], M. Kurosumi[4], T. Tabei[2]. *[1]Saitama Cancer Center, Breast Oncology, Saitama, Japan; [2]Saitama Breast Cancer Clinical Study Group, Saitama, Japan; [3]Saitama Cancer Center, Breast Surgery, Saitama, Japan; [4]Saitama Cancer Center, Pathology, Saitama, Japan*

Background: Neoadjuvant studies suggest that chemotherapy is effective in triple-negative breast cancer (TNBC). Pathological complete response (pCR), demonstrate an excellent survival in this subtype. In contrast, the outcome of patients who still have residual disease after treatment is relatively poor. These observations suggest that there is a subgroup of TNBC whose tumors are extremely sensitive to chemotherapy. However,

there is no preferred standard regimen of chemotherapy for TNBC, and treatment might be selected as it is for other cancer subtypes. Loesch et al demonstrated that in adjuvant setting, doxorubicin plus paclitaxel followed by weekly paclitaxel (AP-P) is equally effective and tolerable option compare to doxorubicin plus cyclophosphamide followed by weekly paclitaxel (AC-P). In subgroup analysis, TNBC approached significance ($p = 0.07$) that favored AP-P (JCO 28, 2010). Alphonse et al demonstrated that paclitaxel decrease the interstitial fluid pressure and improve oxygenation in breast cancers in patients. Based on this result, to maximize the tumor response, paclitaxel might be administered before doxorubicin in neoadjuvant setting (JCO 23, 2005).
Methods: Patients who were locally confirmed TNBC, tumor size>2 cm and/or with axillary lymphnodes metastases, ECOG PS 0−1 and age over 20 were enrolled in Saitama, Japan. Neoadjuvant chemotherapy was performed as follows: weekly paclitaxel 80 mg/m^2 x 12 followed by doxorubicin 50 mg/m^2 plus paclitaxel 150 mg/m^2 q3W (P-AP). Primary endpoint was pCR (ypT0/is ypN-/+) rate. Secondary endpoints were objective response rate (ORR), breast conserving rate (BCR) and safety.
Results: Sixty-three patients were recruited between July 2008 and August 2011. pCR rate was 30%. BCR and ORR were 60% and 46.8%, respectively. Predominant G3/4 toxicities were neutropenia (24.1%), febrile neutropenia (13.8%) and neuropathy (8.6%).
Conclusions: Sequential P-AP as neoadjuvant treatment for operable TNBC is effective but modest. (UMIN1205)
No conflict of interest.

2076 POSTER

Risk estimations and treatment decisions in early stage breast cancer; agreement among oncologists and the impact of the 70-gene signature

C. Drukker[1], H.C. Van den Hout[2], G.S. Sonke[3], S.C. Linn[3], M.K. Schmidt[2]. *[1]Netherlands Cancer Institute, Department of Surgical Oncology, Amsterdam, Netherlands; [2]Netherlands Cancer Institute, Department of Molecular Pathology, Amsterdam, Netherlands; [3]Netherlands Cancer Institute, Department of Medical Oncology, Amsterdam, Netherlands*

Background: Estimating the risk of recurrence and related adjuvant systemic treatment (AST) decisions for patients with early stage breast cancer remains challenging, even with the aid of guidelines using clinico-pathological factors. Gene expression classifiers, like the 70-gene signature, have been added to clinical guidelines to improve accuracy and refine risk estimations. This survey evaluated the impact of adding the 70-gene signature on clinicians' risk estimation and AST decisions.
Patients and Methods: In two written questionnaires, 12 medical oncologists assessed 37 breast cancer cases and estimated the risk of recurrence (high versus low) and gave a recommendation for AST (none, endocrine therapy, chemotherapy, trastuzumab, or a combination). The first questionnaire solely presented the clinico-pathological factors age, tumor size, grade, mitose-index, estrogen- and progesterone receptor status, HER2 receptor status, type of surgery, given radiotherapy and the result of the sentinel node biopsy. The second questionnaire in addition disclosed the 70-gene signature result.
Results: The level of agreement among the oncologists in risk estimation (κ=0.55) and AST recommendation (κ=0.57) was moderate. Adding the 70-gene signature result significantly increased the level of agreement to substantial. Risk estimation changed from high risk to low risk in 8% of the cases and 11% less chemotherapy was recommended.
Conclusion: Oncologists' risk estimations and recommendations of AST vary greatly. Our results underline the need for a better standardization in clinical decision-making. Integration of the 70-gene signature may aid to provide each patient with individualized, but more standardized treatment.
No conflict of interest.

2077 POSTER

Monitoring and management of cardiac toxicity in breast cancer patients treated with adjuvant trastuzumab, Northern Ireland Cancer Centre experience

A. Jalil[1], R. Douglas[1], A. Beirne[1], M. Harbinson[1], J. Hurwitz[1]. *[1]Northern Ireland Cancer Centre, Belfast, N. Ireland, United Kingdom*

Background: The incidence of invasive HER2+ breast cancer is 18−20%. These patients (pts) are mostly offered adjuvant trastuzumab therapy which carries a 0.7−7% risk of cardiac toxicity (CT), predominantly declining left ventricular ejection fraction (LVEF). Current practice in Northern Ireland for delivery of adjuvant trastuzumab is based on the HERA trial protocol. We base monitoring and management of trastuzumab-related CT on the updated UK NCRI guidelines which suggest that with early detection and management of declining LVEF, utilising appropriate breaks in therapy and addition of cardioprotective therapies such as Angiotensin Converting Enzyme (ACE) inhibitor drugs, these pts may safely continue trastuzumab treatment. We conducted an audit of institutional practice of cardiac monitoring and management of CT in pts treated with adjuvant trastuzumab.
Methods: A retrospective case note review of 77 consecutive pts treated with adjuvant trastuzumab for invasive breast cancer between December 2010 and December 2011 was performed. We analysed the incidence of adverse cardiac events, their relationship with known cardiac risk factors and the percentage of pts with declining LVEF who were able to complete trastuzumab treatment with the addition of an angiotensin converting enzyme inhibitor (ACEI).
Results: Amongst pts analysed, 13 (16.8%) experienced CT. The incidence of cardiac risk factors was 38% in both those who experienced CT and those who did not. The median age of all pts was 52 (range 31−75), and that of those experiencing CT was 55 (range 31−72). All except one pt experiencing CT received anthracycline-based chemotherapy. One pt (1.3%) had a symptomatic decline in LVEF and 3 (3.9%) had a decrease in LVEF $\leqslant$40%. 9 pts were able to continue and complete treatment with introduction of ACEI, 6 weekly echocardiographic monitoring and referral to cardiology. Of the 4 pts who initially discontinued trastuzumab, 1 was able to restart and complete treatment following an improvement in LVEF with ACEI.
Conclusion: Our management of trastuzumab-related CT was compliant with NCRI guidelines. Our data suggest the rate of trastuzumab-related CT in clinical practice is higher than that reported in most clinical trials. However, treatment with an ACEI allowed the majority of pts who experienced CT to recover LV function and safely complete trastuzumab treatment.
No conflict of interest.

2078 POSTER

Metabolic and anthropometric changes in early breast cancer patients receiving adjuvant therapy

G. Arpino[1], C. De Angelis[1], V. Forestieri[1], S. Malgieri[1], D. Bruzzese[2], R. Lauria[1], A. Colao[2], M. De Laurentiis[3], R. Thomas[4], S. De Placido[1]. *[1]University of Naples "Federico II", Medical Oncology, Naples, Italy; [2]University of Naples "Federico II", Public Health, Naples, Italy; [3]National Cancer Institute "Fondazione G. Pascale", Breast Cancer, Naples, Italy; [4]"Clinica Mediterranea" Hospital, Breast Cancer, Naples, Italy*

Background: Weight gain and metabolic changes are common during the first year after breast cancer diagnosis. In this study, we examined clinical factors associated with body size at diagnosis and weight gain during the subsequent year.
Material and Methods: An inception cohort of 465 women with newly diagnosed early breast cancer (EBC) underwent anthropometric [BMI (kg/m^2), weight (kg), waist and hip circumferences (cm), waist-to-hip ratio] and metabolic [insulin level (mU/ml), glucose level (mg/dl), H1Ac (%), total cholesterol level (mg/dl), HDL cholesterol level (mg/dl), LDL cholesterol level (mg/dl), triglycerides level (mg/dl), HOMA score] parameters measurements at baseline and 1 year post diagnosis. Information on tumor- and adjuvant treatment-related variables was collected. All women received adjuvant therapy.
Results: Fifty-seven % of women were postmenopausal, 37% were premenopausal and 7% were unknown. The mean ages were 43.2$\pm$5.8 and 61.9$\pm$7.7 years among premenopausal and postmenopausal women respectively. Overall, mean weigh, waist and hip circumferences, BMI, total cholesterol level, triglycerides level, significantly increased among premenopausal women: +2.1 kg [95% confidence interval (CI), 1.2 to 3.0], +2.3 cm [95% CI, 1.1 to 3.6], +1.5 cm [95% CI, 0.3 to 2.7], +0.8 kg/m^2 [95% CI, 0.5 to 1.2], +10.1 mg/dl [95% CI, 3.8 to 16.4], +29.0 mg/dl [95% CI, 16.9 to 41.1] respectively. Most of the changes were observed in women receiving hormonal therapy with or without chemotherapy. Among postmenopausal women, mean triglycerides level increase: +24.0 mg/dl [95% CI, 11.6 to 36.3] and a significant decrease of H1Ac, HDL and LDL cholesterol levels: −0.2 [95% CI, −0.43 to −0.03], −5.9 mg/dl [95% CI, −11.4 to −0.5], −9.6 mg/dl [95% CI, −18.4 to −0.8] respectively were the only significant metabolic changes. Adjuvant therapies do not seem to affect glucose, insulin and HOMA score levels in our dataset.
Conclusions: Profound metabolic changes and weight body distribution occur in patients receiving adjuvant therapies after EBC diagnosis. These changes are more relevant in premenopausal women. Use of adjuvant chemotherapy and the onset iatrogenic induced amenorrhea (either with chemotherapy or hormonal treatment) may play a major role. Further follow up is needed to correlate such changes with patient prognosis.
No conflict of interest.

2079 POSTER

Prognosis of breast cancer patients with chemotherapy resistant disease following neo-adjuvant chemotherapy is dependent on luminal status

V. Plested[1], A.S. Dhadda[2], K. Grover[3], P. Kneeshaw[3], T. Mahapatra[3], P. McManus[3]. *[1]Castle Hill Hospital, Hull East Yorkshire, United Kingdom; [2]Castle Hill Hospital, Clinical Oncology, Hull East Yorkshire, United Kingdom; [3]Castle Hill Hospital, Breast Surgery, Hull East Yorkshire, United Kingdom*

Background: Patients who remain heavily node positive (ypN2) after neo-adjuvant chemotherapy may be deemed to have chemotherapy resistant disease. The future prognosis of patients was determined according to luminal status of the primary tumour.
Materials and Methods: All patients who received neoadjuvant chemotherapy, operated in Castle Hill Hospital, Hull, UK between January 2005 and December 2011 for early breast cancer and found to have 4 or more nodes involved on pathological assessment were identified. Neo-adjuvant chemotherapy consisted of 4 cycles of EC followed by 4 cycles of docetaxel. All patients received post-operative radiotherapy to intact breast/chest wall and SCF to a dose of 40 Gy in 15 fractions. Adjuvant endocrine treatment and trastuzumab was prescribed as appropriate. All patients had baseline staging investigations to exclude metastatic disease with CT chest,abdomen, pelvis and isotope bone scan. Luminal status was defined as: a ER/PR + HER2 -; b ER/PR+ HER2+; HER2 ER/PR- HER2+, Basal ER/PR/HER2 -. Disease free and overall survival was assessed using Kaplan–Meier analysis. Median follow-up was 30 months (range 1−92 months).
Results: 65 patients were identified who fulfilled the above criteria. Median age was 50 years (range 27−78 years). Luminal status significantly predicted long term disease free and overall survival. The median disease free survival for basal and HER2 subtypes was poor at 7 and 1 months respectively with median overall survival being 13 months for both groups. On univariate analysis grade, age, luminal status, and lymphovascular invasion significantly predicted for survival. On multivariate analysis using Cox Regression luminal status was the strongest predictor of long term survival ($p < 0.0001$).
Conclusions: In patients who have an initial poor pathological response to neo-adjuvant chemotherapy future prognosis is heavily dependent on luminal status. The prognosis for such patients who are triple negative or ER/PR − HER2+ is extremely poor. Alternative adjuvant strategies for such patients must be explored.
No conflict of interest.

2080 POSTER

Fertility preservation in early breast cancer patients: A survey among Italian oncologists

A. Frassoldati[1], D. Amoroso[2], E. Collovà[3], S. Barni[4]. *[1]AOU Ferrara, Oncology, Ferrara, Italy; [2]Versilia Hospital Tuscany Cancer Institute, Oncology, Lido di Camaiore, Italy; [3]Ospedale Civile di Legnano, Oncology, Legnano, Italy; [4]Azienda Ospedaliera Treviglio, Oncology, Treviglio, Italy*

Background: Patient's desire for fertility preservation is a frequently underestimated problem in oncology clinical practice. A survey to evaluate how this problem is managed by Italian oncologists has been performed.
Methods: Between April and July 2011, an electronic questionnaire regarding the treatment attitude in early breast cancer in premenopausal women has been completed by 611 Italian oncologists, (female 52%, age range 25−65, 81% from general hospitals, 19% from research institute). We compared the survey results regarding the fertility preservation (examined according to sex, age, working institution and geographic origin) with the recommendations available from guidelines of oncology and gynecology societies.
Results: A pregnancy test before starting chemotherapy is considered mandatory only by 49.5% of oncologists, independently from age and type of treatment.
The results of survey are reported in the table, compared with guidelines recommendation.

	Type of Recommendation for fertility preservation during chemotherapy			
	Eggs freezing	Embryo freezing	Ovarian tissue freezing	LHRH-analogs
ASCO (USA, 2006)	Investigational	Standard	Investigational	Investigational
CASA (Australia, 2012)	Standard	Standard	Investigational	Investigational
AIOM (Italy, 2012)	Standard	Non allowed by law	Special cases	Investigational
Present survey	24.8%	<1%	6%	68.2%

The majority of Italian oncologists considered the administration of LHRH-analog the treatment of choice to maintain fertility (independently from the hormone receptor status of the tumor in 83% of cases), being the monthly injection used in 2/3 of cases. No significant differences as by type of institution, geographic location (north, centre or south Italy), and physician's age has been observed.
Conclusions: The use of LHRH-analog would be the preferred method by Italian oncologists for fertility preservation. A recent analysis of literature regarding the use of LHRH-analogs by Italian Society for Medical Oncology using the GRADE method suggest an important role of this drugs, even if not yet conclusive for their efficacy (level of evidence 1+, Recommendation 'slightly positive'). Potential barriers to other more evidence-based methods can be the limited number of specialized centres for oocyte freezing, and the frequent lack of a multidisciplinary approach to the problem.
No conflict of interest.

2081 POSTER

Experience with aprepitant as antiemetic prophylaxis in combination with anthracycline plus cyclophosphamide: Should we include it from the first cycle?

P. Ramírez Daffós[1], T. González-Carrascosa[2], M.J. Martinez[2], M.J. Gomez[3], S. Estalella[3], C. Cortes[3], P. Rosado[3], J.M. Baena[3]. *[1]Hospital Puerta Del Mar, Cadiz, Spain; [2]Hospital Puerta Del Mar, Pharmacy, Cadiz, Spain; [3]Hospital Puerta Del Mar, Oncology, Cadiz, Spain*

Background: Nausea and vomiting are frequent and troubling adverse effects during chemotherapy. This usually affects treatment adherence and could impair the quality of life.
MASCC/ESMO, ASCO, NCCN and SEOM guidelines recommend adding aprepitant from cycle 1 as antiemetic prophylaxis in patients with cyclophosphamide-based chemotherapy plus anthracyclines.
In 2006 aprepitant was authorized in our hospital, in breast cancer patients treated with cyclophosphamide plus anthracycline and refractory to approved protocol (5-HT3 and corticosteroids for prophylaxis of acute emesis and corticosteroids for delayed emesis days 2−3) or in patients with some risk factors (age <55 years, PS>1, sickness or hyperemesis gravidarum and low alcohol consumption).
This study aims to evaluate the effectiveness of aprepitant in the control of nausea and vomiting in patients with TAC (docetaxel, doxorubicin and cyclophosphamide) and the incremental cost that would supposed including aprepitant from the cycle 1 in an antiemetic prophylaxis protocol.
Material and Methods: It's a retrospective observational study, and include patients between 2010 and 2012.
Data collection included health records, chemotherapy regimen, emesis risk factors and presence of nausea and vomiting of any grade on the second visit.
Primary end point: complete response (CR) (no emetic episodes and no use of rescue therapy) over the overall period (0–120 h). Secondary endpoint: incidence of nausea and vomiting and cost.
To assess the incremental cost we calculated the difference between the actual consumption of aprepitant and the cost that would suppose if we had included all patients from the cycle 1.
In patients who had not received aprepitant from the cycle 1, we reviewed if they had started aprepitant in any of the subsequent cycles and how many tablets consumed.
Results: Of the 84 patients receiving TAC, 31 received aprepitant from cycle 1. CR was achieved in 84% patients with aprepitant and 86% in those receiving the original protocol. The incidence of nausea in the aprepitant group was 21/31 and without aprepitant 28/51 (RAR: −12.8 [−34.22, 8.54]). The incidence of vomiting in the aprepitant group was 5/31 and without aprepitant 7/51 (RAR: −2.4 [−18.43, 13.62]). No differences in risk factors for emesis between both groups of patients were found. In addition, there was no correlation between the recommendations for the use of aprepitant in our protocol and usual practise. Aprepitant was added in three patients after cycle 1 (two patients in the second and one in the third). The total cost of aprepitant in the study period was 11.200 €. The cost that would have supposed if we started with aprepitant in all patients would be € 27.552.
Conclusions: According to results, and despite the limitations of the study, we could not recommend the inclusion of aprepitant from baseline in this. Aprepitant was no better than standard therapy in our patients.
No conflict of interest.

Presence of breast cancer stem cells (BCSCs) on diagnosis in younger breast cancer patient: A predictor of chemotherapy

P. Bhadra[1], S. Gangopadhyay[1], A. Mukhopadhyay[2]. [1]*Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Cell Biology, Kolkata, India;* [2]*Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Medical Oncology, Kolkata, India*

Background: As breast cancer is found to be an extremely heterogeneous disease, we hypothesize that the invasive and mesenchymal properties of Breast Cancer Stem Cells (BCSCs) with $CD44^{+}/CD24^{low}/ALDH1^{+}$ phenotype has made them potential competence that can play a crucial role for the development of specific target therapies by eradicating metastases of primary tumorsin younger breast cancer patientsthus it can be considered as a potential alternative for 'event free survival' in breast cancer.
Materials and Methods: Fifty young breast cancer patients (age<30) were selected randomly. Breast cancer cells were isolated from whole tumor and cultured for in vitro drug sensitivity towards platinum, anthracycline and docetaxel and correlation was drawn between cell differentiation and drug response. BCSCs were also isolated from the whole tumor, cultured and in vitro drug sensitivity was checked and chemotherapy was designed according to the results.
Results: Among positive samples, 70% of patients showed platinum sensitivity and rest were found to be anthracycline sensitive. No sensitivity towards docetaxel was observed. In lieu of this, cisplatin was applied ex vivo and percentage of BCSCs came down to 6.58% from an initial 11.16%.
Conclusion: Thus the primary aim to target BCSCs to control metastasis and relapse of disease was achieved to some extent. We further plan to show a relationship ratio of selected markers present in patients in pre- and post-chemotherapeuticcondition with time to recurrence, mortality, morbidity and progression-free survival.
No conflict of interest.

2083 POSTER

Investigation of the molecular profile of breast carcinoma comparing polychemotherapy vs endocrine therapy in neoadjuvant mode

I.B. Shchepotin[1], O.S. Zotov[1], J.I. Zaivelieva[1], R.V. Lyubota[1], O.O. Katerynich[2], A.M. Neiman[2]. [1]*National Medical University O.O.Bogomolets, Oncology Chair, Kyiv, Ukraine;* [2]*Kyiv City Clinical Oncological Center, Surgical Department, Kyiv, Ukraine*

Background: Despite of considerable achievements in the management of breast carcinoma (BC), it's still a major public health problem. The current algorithm in selecting therapies for breast cancer is based on a combination of clinical, pathological and molecular factors. An important aspect is the individualization of neoadjuvant treatment. We investigated retrospectively the impact of polychemotherapy (PCT) vs endocrine therapy (ET) to changes in the molecular portrait of BC used in neoadjuvant mode.
Material and Methods: 48 patients with verified BC was performed core-biopsy with immunohistochemical typing of tumors before start of neoadjuvant treatment. The molecular profiles of tumors were evaluated before and after neoadjuvant therapy by clinical response, RECIST-criteria, Allred score and histopathological features. For statistical data processing we used the fourfold tables analysis method and the 2xK tables analysis.
Results: After neoadjuvant treatment tumor's molecular portrait unchanged in 45.8% of patients. Among them Luminal A − 8.3%, Luminal B − 29.2%, Her2 type − 4.2%, Triple negative − 8.3%. In 54.2% of patients changed molecular status of tumor (Table 1).
A decrease in Allred score after neoadjuvant therapy was in 25% of patients. Among them PCT received 83%, ET − 17%.

Table 1.

	PCT	ET	Total
Luminal A»Luminal B	6 (12.5%)	0	6 (12.5%)
Luminal B»Luminal A	8 (16.7)	4 (8.3%)	12 (25.0%)
Luminal»BHer2 type	6 (12.5%)	0	6 (12.5%)
Luminal»Triple negative	2 (4.2%)	0	2 (4.2%)
Total	22 (45.9%)	4 (8.3%)	26 (54.2%)

$p < 0.05$.

Conclusions: Application as induction therapy PCT leads to loss of tumor's steroid receptors, a kind of molecular 'conversion' in less favorable subtypes.
Application of ET in neoadjuvant mode lets to save molecular markers of more prognostic favorable luminal tumor types.
Using as first-line neoadjuvant therapy of BC endocrine medicines does not change the molecular profile, which in its turn may positively effect on the long-term results.
Progression of tumor clone that has no ER/PR, may can be a source of recurrent tumors with poor prognosis.
No conflict of interest.

2084 POSTER

Is adjuvant hormonal therapy in premenopausal breast cancer women linked to gender of oncologist? An Italian survey

S. Barni[1], A. Frassoldati[2], D. Amoroso[3], E. Collovà[4], C. Borgonovo[1]. [1]*Azienda Ospedaliera Treviglio, Oncology, Treviglio, Italy;* [2]*Azienda Ospedaliera Universitaria Ferrara, Oncology, Ferrara, Italy;* [3]*Versilia Hospital Tuscany Cancer Institute, Oncology, Lido di Camaiore, Italy;* [4]*Ospedale Civile di Legnano, Oncology, Legnano, Italy*

Background: The increasing age of first pregnancy among italian women and the number of available therapy in premenopausal patients make adjuvant hormonal therapy an hot topic justifying a survey on the therapeutical approach of italian oncologists to breast cancer. In particular we wanted investigate if oncologist's gender modifies therapeutic choice.
Material and Methods: From April to July 2012 a 11 items electronic questionnaire was submitted to italian oncologists and 611 filled questionnaires were collected, 294 male (M) and 317 female (F), age range 25−65, 211 from north Italy, 173 form centre and 227 from south; 495 from general hospitals, 116 from research institutes. The results were examined globally and according to sex of the oncologists.
Results: 97.7% of patients aged less than 40 years needing only hormonal therapy would receive both tamoxifen (TAM) and LHRH analog (LHRHa)(97.6% M and 97.8% F); 2.3% TAM or LHRHa alone (2.4% M and 2.2% F). 93.6% of patients aged over 40 years would receive the combination (92.5% M and 94.6% F) whereas TAM or LHRHa was offered to 6.4% of women (7.5% M and 5.4% F).
In patients aged under 40 with chemotherapy induced amenorrhea, the oncologists would prescribe: TAM in 22.4% (25.5% M and 19.6% F), TAM and LHRHa in 68.1% (62.9% M and 72.9% F) with LHRHa prescribed for 5 years in 55.3% (58.4% M and 52.8% F), for 3 years in 22.1% (20.5% M and 23.4% F), for 2 years in 22.6% (21.1% M and 23.8% F), aromatase inhibitor (AI) +/− LHRHa in 6.6% (8.2% M and 5% F), LHRHa alone in 2.9% (3.4% M and 2.5% F). A greater number of patients would be treated with AI among women aged over 40: 11.6% M and 10.4% F.
The reasons to add LHRHa to TAM and the length of treatment would be: higher efficacy of the combination: 45.5% (51% M and 40.4% F); patient's age: 30.1% (26.2% M and 33.75% F); risk of recurrence: 20.8% (20.4% M and 21.1% F); and side effects: 3.6% (2.4% M and 4.7% F).
Conclusions: A high concordance between the Italian Oncologist attitude and the Oncological International guidelines is confirmed by this large survey, nevertheless we note a wide preference for a TAM/LHRHa combination.
No substantial difference was noted in questionnaire responses as regards sex of the oncologists. Nevertheless − although number of responses was small − we observed a larger interest (two fold) between female than male in hormonal side effects when they decide the length of LHRHa prescription.
No conflict of interest.

2085 POSTER

Quality of life in women with breast cancer that receive adjuvant chemotherapy

S. Estalella Mendoza[1], C. Cortes Carmona[1], M.J. Gómez Reina[1], P. Ramirez Daffós[1], P. Rosado Varela[1], E. Arriola Arellano[1], A. Rueda Ramos[1], J.A. Contreras Ibañez[1], J.M. Baena-Cañada[1]. [1]*Hospital Puerta Del Mar, Medical Oncology, Cadiz, Spain*

Background: Breast cancer and adjuvant chemotherapy adversely affect different aspects of women's lives. Acute side effects of chemotherapy condition a definite impact. The purpose of this study is to analyze the effect of adjuvant chemotherapy on quality of life (QOL) of women.
Material and Methods: A cohort of women with breast cancer eligible to receive chemotherapy (neo)-adjuvant and participants in a randomized clinical trial of non-pharmacological intervention (ClinicalTrials.gov Identifier: NCT00964522) completed questionnaires prospectively validated CV (EORTC QOL -C30, version 3.0 and QOL-BR23), before chemotherapy, and half of it and at the end. We studied the differences according to clinical and biographical variables.
Results: 193 patients were enrolled in the trial of which 49 (25.3%) completed the three questionnaires between January 2007 and December 2009. Differences were identified in the different scales according to clinical

and biographical variables of patients (age, stage, type of chemotherapy, marital status, education level, social status and employment status).
Global health/QOL worsened over time (P = 0.01). Physical functioning (P = 0.0001) and body image (P = 0.002) were more deteriorated scales and asthenia (P = 0.004), nausea/vomiting (P = 0.05), anorexia (P = 0.025), xerostomia (P < 0.0001), conjunctivitis (P < 0.0001) and hot flashes (P < 0.0001), symptoms more temporary impact of chemotherapy. It was noted that the changes in physical functioning and xerostomia (P = 0.01), age influenced (P = 0.04) and conjunctivitis were influenced by the type of chemotherapy (P = 0.006).
Conclusion: Adjuvant chemotherapy worse QoL in patients with breast cancer, primarily in the area of physical functioning and body image. Asthenia, gastrointestinal toxicity, conjunctivitis and hot flashes are the side effects that most affect patients (Funding Health Research Fund # FIS 07/0141).
No conflict of interest.

2086 POSTER

Anthracycline-based regimens and trastuzumab related cardiotoxicity after adjuvant therapy in early breast cancer: A single center experience

A. Iannace[1], E. Franzese[2], T. Losanno[1], G. Manna[1], F. Longo[1], L. Filomeno[2], D. Rossini[1], P. Seminara[2]. *[1]Policlinico Umberto I − Sapienza University, Experimental Medicine Oncology A Unit, Rome, Italy; [2]Policlinico Umberto I − Sapienza University, Clinical Medicine Oncology A Unit, Rome, Italy*

Background: Quality of life of patients who survive breast cancer can be compromised by Anthracycline-based regimens (ABR) and Trastuzumab (TZB) cardiotoxicity-related side-effects. The aim of our retrospective study was to evaluate left ventricular systolic and diastolic function performance in women with early breast cancer (EBC) treated with ABR associated or not to TZB.
Materials and Methods: One hundred and thirteen women, median age 51 (range 25 to 79), without basal alteration of left ventricular ejection fraction (LVEF) and diastolic function were considered.
Forty-four patients received 6 cycles of FAC (n = 19) or 6 cycles of FEC100 (n = 25). Forty-four patients received 4 cycles of EC plus 4 cycles of Docetaxel (D). Twenty-five patients with Her2-positive EBC received 4EC+4D+TZB up to 1 year. Management of cardiac function was assessed by Doppler echocardiogram at baseline (T0) during chemotherapy (T1) and 5-years of follow-up (T2). Cardiac toxicity was defined according to CTCAE-NCI-2.0 and NYHA class.
Results: A decrease of LVEF less than 10% was found in all patients at T1. No cardiac heart failure (CHF) event was observed at T2 for the patients treated with 4EC+4D or 4EC+4D+TZB. Two CHF events occurred in patients treated with FAC and FEC100, 5 years after the end of the FAC treatment (LVEF: 35%) and 2 years after the end of the FEC100 treatment (LVEF: 40%), respectively.
In the group of patients receiving ABR, the incidence of Grade 1 diastolic dysfunction was 37% and 50% at T1 and T2, respectively. In Her2 positive EBC patients treated with TZB, the incidence of diastolic dysfunction was 23% at T1 and it was increased to 27.7% at T2.
Conclusions: Our data show that 4EC+4D regimen has a good cardiac safety related to low cumulative dose of Epirubicin (400 mg/m^2). Cardiotoxicity incidence (1.76%) observed in patients treated with FAC/FEC100 regimens agrees with other studies. The addition of Trastuzumab in HER2+patients has not caused systolic dysfunction. Data on incidence of Grade 1 diastolic dysfunction, compared between the two groups, at T1 and T2, were no statistically significant. Therefore, Trastuzumab treatment does not increase the risk of occurrence of diastolic dysfunction.
No conflict of interest.

2087 POSTER

Outcome in patients treated with primary endocrine therapy and neoadjuvant endocrine therapy for breast cancer: A single centre experience

B. Kim[1], S. Rajan[1], J. Mann[1], R. Achuthan[1], P. Turton[1], E. Verghese[2], M. Lansdown[1]. *[1]St James's University Hospital, Department of Oncoplastic Breast Surgery, Leeds, United Kingdom; [2]St James's University Hospital, Department of Histopathology, Leeds, United Kingdom*

Background: Our use of primary endocrine therapy (PET) and neoadjuvant endocrine therapy (NAET) is increasing. The aim of the former is to prevent disease progression, and the latter is used with an aim to downstage tumour prior to surgery. Our study examines the pattern of use, and patient outcome in terms of response and survival.
Methods: Retrospective data analysis was performed using a prospectively maintained database of early breast cancer patients treated with endocrine therapy for a minimum of 4 months (2005–2012). Clinico-pathological parameters, radiological features and reasons for endocrine therapy were determined. Response to endocrine therapy was defined by the change in tumour size from the pre-treatment ultrasound (USS) to the interval USS. Kaplan–Meier survival analysis was performed to determine the overall survival (OS), disease free survival (DFS), and progression free survival (PFS).
Results: 138 patients were treated with endocrine therapy (98 PET and 40 NAET). The reasons for PET were due to co-morbidities (74.7%) and patient choice (25.3%). Median duration of endocrine therapy was 33.5 months (PET) and 7.5 months (NAET). Median patient age was 83 years old (PET) and 71.5 years old (NAET). Tumour characteristics were similar apart from the higher rate of axillary metastasis (55.8% versus 9.2%; p < 0.0001), and larger initial tumour size (30 mm versus 22.5 mm; p = 0.01) in the NAET group. This was reflected by a mastectomy rate of 52.5% in the NAET group. NAET regimen consisted of anastrozole (45%), letrozole (45%), or tamoxifen (10%). Anastozole was used more commonly in the PET group (61.2%), compared to letrozole (27.6%) or tamoxifen (11.2%). Interval USS was selectively performed in 19/40 cases (47.5%) in the NAET group, resulting in a tumour volume reduction of 60.6% (median time to USS: 4.8 months). Similarly, interval USS was selectively performed in 36/98 case (36.7%) in the PET group, resulting in a tumour volume reduction of 49.7% (median time to USS: 14.2 months). 5 year OS of 56.1% was seen in the PET group with PFS of 97%. However, 5 year OS of 82.5% was seen in the NAET group with DFS of 87.5%.
Conclusion: Good outcome is seen in patients treated with PET, reflected by the high rate of PFS. The DFS rate was lower in the NAET group, reflected by the poor prognostic pathological features. The type of regime, timing and indications for interval USS requires standardisation.
No conflict of interest.

2088 POSTER

Efficacy of dose-dense neoadjuvant chemotherapy in patients with stage II or III breast cancers

I. Zarcos[1], I. Blancas[2], A. Calvo[3], M. Legeren[2], J.M. Jurado[2], M. Delgado[2], R. Fonseca[3], A.R. Gonzalez[4], L. Suarez[5], J.L. Puche[5]. *[1]Hospital Clínico San Cecilio, Medical Oncology, Granada, Spain; [2]Hospital Clínico San Cecilio, Medical Oncology, Granada, Spain; [3]Hospital Clínico San Cecilio, Radiation Oncology, Granada, Spain; [4]Hospital Clínico San Cecilio, Biomedical Research Fundacion Eastern Andalusia, Granada, Spain; [5]Hospital Clínico San Cecilio, Junta de Andalucía Centre for Genomics and Oncological Research, Granada, Spain*

Background: This study will evaluate the efficacy of dose-dense neoadjuvant chemotherapy and the safety of this treatment, in potentially operable and locally advanced breast cancers.
Material and Methods: We retrospectively collect data from 50 women with stage II−III breast cancer, from april 2008-november 2012. Patients were treated preoperatively with 4 cycles of doxorubicin 60 mg/m^2 -cyclophosphamide 600 mg/m^2 every 2 weeks, with filgrastim at 5 g/kg days 3 to 10 of each cycle, followed by 4 cycles of docetaxel 100 mg/m^2 every 3 weeks, with or without trastuzumab 6 mg/kg (loading dose of 8 mg/kg) every 3 weeks, according to human epidural growth factor receptor 2 status(HER2).
Results: Median age was 46 years, 72% were stage II and 28% stage III, 64% were clinically node positive. Tumours were classified into four phenotype subtypes. 90% of patients received complete treatment. 22% included trastuzumab preoperatively.
The primary study end point was to evaluate rate of pathologic complete response (pCR), defined as the absence of invasive cancer in the breast and nodes at the time of surgery, 15 patients(30%) achieved pCR rate.

Tumour phenotype	N (%)	Pathologic response (N+T)*	
		pCR, 15 (30%)	Non pCR, 35 (70%)
Luminal A	6 (12)	2 (33.3%)	4 (66.7%)
Luminal B	24 (48)	6 (25.0%)	18 (75.0%)
Her 2	3 (6)	2 (66.7%)	1 (33.3%)
Basal Like	17 (34)	5 (29.4%)	12 (70.6%)

*When Pearson's χ^2 test was performed, no statistical association was found between pCR and tumour phenotype, nor with age, tumour size, lymph node status, ki 67, hormonal receptor and HER2. Pathologic complete response was significantly associated with stage II (p = 0.02) and high tumor grade (p = 0.04).

Secondary objectives: pathologic tumor complete response was observed in 17 patients (34%), and high tumor grade was significantly corre-

lated with this (p = 0.02).18 patients (36%) achieved clinical complete response (cCR). cCR was correlated with small tumor size, (p = 0.04) and high tumor grade (p = 0.01).
Breast-conserving surgery was possible in 35 patients (70%). The reported grade 3/4 toxicities were: asthenia 7(14%), skin toxicities including hand and foot syndrome 4(8%), nausea and vomiting 5(10%), 14(28%) neutropenia, less than 4(8%) of patients reported febrile neutropenia.
Conclusions: Our results indicate that dose dense neoadjuvant chemotherapy is highly active for breast cancer and is not accompanied by an increase in toxicity.
No conflict of interest.

2089 POSTER

Effect of oral cyclophosphamide use on pathologic complete response rate in the neoadjuvant treatment of breast cancer

M. Luque[1], P. García-Teijido[2], D. Rodriguez[1], Y. Fernandez[1], T. Sampedro[3], V. Reguero[3], M. Izquierdo[3]. *[1]University General Hospital of Asturias, Medical Oncology, Oviedo, Spain; [2]San Agustin Hospital, Medical Oncology, Aviiles, Spain; [3]San Agustin Hospital, Medical Oncology, Aviles, Spain*

Background: Continuous exposure to cyclophosphamide (C) can result in selective cytotoxicity for endothelial cells, followed by antiangiogenic effects on tumor cells. In this study we analyzed the pathological complete response (pCR) rate in a cohort of patients (p) diagnosed with locally advanced breast cancer (LABC) treated with neoadjuvant chemotherapy (CT) based on anthracyclines and taxanes, depending on the route of administration of C (intravenous (IV) and oral arms).
Material and Methods: We retrospectively studied a consecutive series of p. with LABC treated with neoadjuvant CT in 2 hospitals in Asturias. The regimens used were CE100F, FA60C, AC (regimens with IV C) or oral CAF (C 100 mg/m^2/day orally x 14 days, doxorubicin 30 mg/m^2 day 1 and 8 and 5-FU 500 mg/m^2 days 1 and 8 every 28 days) x 4 cycles. The anthracycline regimen was followed by weekly paclitaxel or docetaxel every 3 weeks. If HER2 overexpression, trastuzumab was given in combination with the taxane.
Results: We identified 170 p., 128 of them treated with oral C and 42 with IV C (CEF 3 p., FAC 6 p. and AC 33 p.). The median age was slightly higher in the p. treated with C IV (52.0 vs. 48.5, p = 0.036), which also received a higher number of cycles (7.2 vs. 6.7, p = 0.006) and a higher anthracycline dose intensity (93.6% vs 88.5%; p < 0.001). There were no significant differences in tumor size, lymph node involvement, grade, estrogen receptor (ER) or HER2. The rate of pCR was significantly higher in p. receiving oral C (38.9% vs 10%, p < 0.001). Grade 3, negative, estrogen receptors and HER2 were also significantly associated with a higher rate of pCR. On multivariate analysis only oral C, ER negative and HER2 positive were independent factors associated with pCR. With a median follow up of 25.5 months (95% CI 22.4 to 28.6), there have been 37 recurrences, 21 (16.4%) in the continuous arm and 16 (29.6%%) in the standard arm, without significant differences in disease free survival.
Conclusions: Our results suggest that the pCR rate can be higher using oral C in the neoadjuvant treatment of LABC based on anthracyclines and taxanes. This hypothesis should be confirmed in a randomized and prospective study.
No conflict of interest.

2090 POSTER

Comparison of dose dense adjuvant chemotherapy with conventional three weekly chemotherapy in triple negative early breast cancer patients in Indian population

K. Ashwin[1], S.P. Somashekhar[1], R. Amit[2], Z. Shabber[1], P. Poonam[2]. *[1]Manipal Comprehensive Cancer Center, Surgical Oncology, Bangalore, India; [2]Manipal Comprehensive Cancer Center, Medical Oncology, Bangalore, India*

Background: Patients with triple negative breast cancer tend to present at a younger age, with higher histologic grade, higher relapse rates and poorer survival than other subtypes. At present, even though it is an aggressive disease, the adjuvant chemotherapy used in this subgroup is the same as in hormonal receptor positive patients.
Materials and Methods: At our institution 128 patients with triple negative early breast cancer who underwent surgery followed by adjuvant chemotherapy were identified. We compared two groups of patients based on the adjuvant chemotherapy received. The dose dense adjuvant chemotherapy **(DD)** group received 4 cycles of AC (Adriamycin, Cyclophosphamide) − two weekly followed by 4 cycles of Paclitaxel − two weekly. The conventional chemotherapy **(CC)** group had three weekly regimen; 3 cycles of FEC 100 (5-fluorouracil, Epirubicin, Cyclophosphamide) followed by 3 cycles of Docetaxel or six cycles of TAC (Taxol, Adriamycin, Cyclophosphamide). Radiotherapy was given to patients as indicated. We retrospectively evaluated patients in both groups for age, stage at presentation, pathology, relapse rates, mortality rates and 5 year disease free survival (DFS) and overall survival (OS).
Results: The median age at diagnosis, pathology and stage at presentation were matched in both groups. 60 (46.87%) patients were pre-menopausal. 66 (51.56%) patients belonged to DD group and 62 (48.44%) patients belonged to CC group. Neuropathy was higher in DD arm, while fatigue, vomiting and neutropenia were higher in CC arm. The median follow up of was 98 months. 30 patients (23.43%) were diagnosed to have systemic relapse. Recurrence was more common in the CC group 18 patients (60%) than in DD group 12 (40%). The common sites of relapse were bones (17%), lungs (19%) and brains (12%). The 5 year relapse free rate was significantly better in DD group (81.81% vs 70.97%, P = 0.014). The 5 year DFS was significantly longer in DD group than CC group (30.83 vs 26.72 months P = 0.004). The 5 year mortality rate was slightly better in DD group (9.1% vs 14.5%, P = 0.340). The 5 year OS although longer in DD group, was not statistically significant (52.50 vs 48.56 months, P = 0.647).
Conclusion: In early stage triple negative breast cancer, patients who received dose dense adjuvant chemotherapy had lower relapse rates with prolonged DFS in comparison to conventional chemotherapy. But OS was the same in both groups.
No conflict of interest.

2091 POSTER

Tumor immune subtypes distinguish tumor subclasses with clinical implications in breast cancer patients

E.M. De Kruijf[1], C.C. Engels[1], W. Van de Water[1], E. Bastiaannet[1], V. Smit[2], C.J.H. Van de Velde[1], G.J. Liefers[1], P.J.K. Kuppen[1]. *[1]Leiden University Medical Center, Surgery, Leiden, Netherlands; [2]Leiden University Medical Center, Pathology, Leiden, Netherlands*

Background: Various interactions underlie the balance between immune control and tumor immune escape. We defined tumor immune subtypes and investigated their prognostic effect in a training and validation cohort of breast cancer patients.
Material and Methods: Our training and validation cohort (n = 822) consisted of all early breast cancer patients primarily treated with surgery in our center between 1985 and 1996. Patients diagnosed with breast cancer between 1985 and 1990 (n = 440) were selected as the training cohort; between 1990 and 1996 (n = 382) as the validation cohort. Sections of formalin-fixed paraffin-embedded tumor tissue were immunohistochemically stained for CD8 (CTL) and PEN5 (NK cells) to determine tumor-infiltrating immune cells. Tumor expression of classical and non-classical HLA class I, and tumor-infiltrating Tregs were previously determined. Tumor immune subtypes were constructed based on quantification of these markers and biological rationale.
Results: Patients with data available for all mentioned immune markers were analyzed for tumor immune subtypes for the training cohort (n = 293) and validation cohort (n = 219). High, intermediate and low immune susceptible tumor immune subtypes were found in respectively 16%, 63% and 20% of patients in the training cohort and respectively 16%, 71% and 13% in the validation cohort. Tumor immune subtypes showed to be statistically significant prognostic for relapse free period (RFP) (p < 0.0001, intermediate versus high immune susceptible: hazard ratio (HR) 1.95 95% confidence interval (CI) 1.13–3.39; low versus high immune susceptible HR 2.98 95% CI 1.62–5.48) and relative survival (RS) (p = 0.006, low versus high immune susceptible HR 3.84 95% CI 1.62–9.09; intermediate versus high immune susceptible: HR 4.26 95% CI 1.70–10.70), independent of known clinicopathological parameters and with high discriminative power. Validation of these outcome analyses confirmed the independent prognostic associations for RFP (p = 0.025) and RS (p = 0.040).
Conclusion: The tumor immune subtypes that we present here represent a prognostic profile with solid underlying biological rationale and with high discriminative power. In addition, results were validated in a separate cohort, confirming the statistically significant relations with patient outcome. Tumor immune subtype profiling is a promising method for prognosis prediction and may aid in achievement of tailored treatment for breast cancer patients.

Breast cancer survival of young patients: The impact of BRCA1/2 germline mutations

M.K. Schmidt[1], A.J. Van den Broek[2], R.A.E.M. Tollenaar[3], F.E. Van Leeuwen[2], L.J. Van 't Veer[4]. [1]*Netherlands Cancer Institute- Antoni van Leeuwenhoek Hospital, Molecular Pathology and Department of Epidemiology, Amsterdam, Netherlands;* [2]*Netherlands Cancer Institute- Antoni van Leeuwenhoek Hospital, Epidemiology, Amsterdam, Netherlands;* [3]*Leiden University Medical Center, Surgery, Leiden, Netherlands;* [4]*Netherlands Cancer Institute- Antoni van Leeuwenhoek Hospital, Molecular Pathology, Amsterdam, Netherlands*

The pathological biology of *BRCA1/2*-associated tumors supports the hypothesis that patients carrying a germline *BRCA1/2* mutation might have a worse breast cancer prognosis compared to non-carriers. Earlier studies showed inconsistent results and *BRCA1/2* mutation status is currently not taking into account, outside e.g. PARP-inhibitor trials, for primary breast cancer treatment. The aim of this study was to evaluate the impact of *BRCA1/2* mutations on breast cancer outcome in a multicenter, consecutive cohort of breast cancer patients.

We included invasive pathologically-confirmed breast cancers, diagnosed before <50 years of age, in the period 1970–2002, in ten Dutch centers, in patients with no previous malignancies. DNA for *BRCA1/2* analyses was isolated from formalin-fixed, paraffin-embedded tissue blocks containing normal (non-tumor) tissue. A selection of most frequently occurring *BRCA1/2* mutations was analyzed, capturing ~70% of all Dutch pathogenic mutations. Clinico-pathological data and follow-up were collected and part of the tumor characteristics (grade, ER, PR, HER2) was obtained by revision. Metastasized patients were excluded. Hazard Ratios (HRs) from cox proportional hazard models were adjusted for grade, size, nodal status, adjuvant treatment, ER (if applicable) and age.

Among 5391 breast cancer patients we found 3.5% *BRCA1* and 1.2% *BRCA2* mutation carriers. Mean follow-up of the cohort was 11.3 years. *BRCA1* and *BRCA2* carriers had worse 15-year overall survival (OS) compared to non-*BRCA*; HR unadjusted 1.4 (95% CI: 1.1−1.8) p = 0.002 and 1.4 (1.0−2.1) p = 0.054, respectively; HR adjusted 1.2 (1.0−1.5) p = 0.116 and 1.3 (0.9−1.9) p = 0.145, respectively. The proportions of ER-positive breast cancers in non-*BRCA*, *BRCA1* and *BRCA2* mutation carriers were 68%, 29% and 82%. Within ER-positive tumors OS was significantly worse in *BRCA2* mutation carriers (HR 1.8 (1.1−2.8) p = 0.011; HR adjusted 1.5 (1.0−2.4) p = 0.059) but we found no evidence for a worse OS in *BRCA1* carriers. Within ER-negative tumors there was a tendency for worse OS in *BRCA1* (HR 1.2 (0.8−1.6) p = 0.358; HR adjusted 1.3 (0.9−1.8) p = 0.101); for *BRCA2* analysis there was insufficient power. Adjuvant chemotherapy was found to be an important confounder in the analyses.

Results are preliminary and further tumor subtype and treatment analyses including breast cancer-specific and recurrence-free survival will be presented after update of follow-up. To our knowledge this is the first large unselected breast cancer cohort in the Netherlands in which *BRCA1/2* has been genotyped and breast cancer outcome evaluated. We found evidence for difference in outcome for *BRCA1/2* germline mutation carriers in specific tumor subtypes. If confirmed this might be used in treatment decisions for *BRCA1/2* mutation carriers.

No conflict of interest.

2093 POSTER

Mesenchymal phenotype of CTCs-enriched blood fraction and lymph node metastasis formation potential

A. Markiewicz[1], M. Ksiazkiewicz[2], B. Seroczynska[3], J. Skokowski[4], J. Szade[5], A.J. Zaczek[2]. [1]*Intercollegiate Faculty of Biotechnology University of Gdansk and Medical University of Gdansk/Postgraduate School of Molecular Medicine, Department of Medical Biotechnology, Gdansk/Warsaw, Poland;* [2]*Medical University of Gdansk, Department of Medical Biotechnology, Gdansk, Poland;* [3]*Medical University of Gdansk, Bank of Frozen Tissues and Genetic Specimen, Gdansk, Poland;* [4]*Medical University of Gdansk, Department of Surgical Oncology, Gdansk, Poland;* [5]*Medical University of Gdansk, Department of Pathomorphology, Gdansk, Poland*

Background: The occurrence of epithelial–mesenchymal transition might influence the seeding potential and aggressiveness of tumor cells. It is not well known how this process affects molecular characteristics of tumor cells present in different compartments.

The aim of this study was to analyze the expression of epithelial, mesenchymal and invasion/metastasis related genes in CTCs-enriched blood factions, a subset of matched primary tumors and lymph node metastases from breast cancer patients and correlate it with each other and clinico-pathological data.

Materials and Methods: Blood samples (n = 94), formalin-fixed, paraffin embedded (FFPE) primary tumors (PT) (n = 25) and FFPE lymph node metastases (LNM) (n = 14) were collected from 94 breast cancer patients (pT1−4, pN1−3) before therapy initiation. Blood samples were subjected to CTCs enrichment by density gradient centrifugation and immunomagnetic depletion of CD45-positive cells. Expression of mammary epithelial: cytokeratin 19 (*CK19*), mammaglobin 1, as well as mesenchymal: vimentin (*VIM*), *TWIST1, SNAIL, SLUG* and invasion/metastasis-related genes: *HER2, CXCR4, uPAR* was measured with qRT-PCR. As a control material blood samples from nine healthy controls, sections of healthy FFPE breast and lymph nodes were analyzed and processed the same way as patients' samples. Gene expression level was analyzed in a relative manner using two reference gene (*GAPDH* and *YWHAZ*) and a calibrator using qBase^{PLUS} software.

Results: Expression of *CK19* and/or *VIM* in CTCs-enriched blood fractions was associated with lymph node involvement (p = 0.002). Mesenchymal status of CTCs-enriched blood fraction correlated with higher number (>5) of involved lymph nodes (p = 0.0008). Moreover, CTCs-enriched blood fraction of N1 patients, in comparison to N0 patients, were more frequently positive for *CXCR4* (52% vs. 33%, p = 0.07) and *uPAR* (73% vs. 50%, p = 0.02). Expression of *CXCR4* and *uPAR* was associated with increased hazard of developing lymph nodes metastases HR 2.4 (CI 1.03−5.5, p = 0.02) and HR 2.2 (CI 1.1−4.3, p = 0.02), respectively. Interestingly, the percentage of samples positive for *CXCR4* and *uPAR* decreased from PT to LNM with respective 55% (6/11) and 27% (3/11) conversion rates in matched samples.

Conclusions: Mesenchymal phenotype (*CK19-/VIM+*) of CTCs-enriched blood fraction contains cells more potent in lymph node metastases formation, which might be related to the increased expression of CXCR4 and *uPAR* receptors. Significance of these receptors seems to be of lower importance in LNM.

No conflict of interest.

2094 POSTER

The impact of baseline and genetic parameters on progression free survival and overall survival in breast cancer patients receiving neoadjuvant or adjuvant chemotherapy with fluorouracil, epirubicin, cyclophosphamide (FEC) and docetaxel (D)

C. Vulsteke[1], A.M. Pfeil[2], M. Schwenkglenks[2], R. Paridaens[1], A.S. Dieudonné[3], R. Pettengell[4], S. Hatse[1], P. Neven[3], D. Lambrechts[5], H. Wildiers[1]. [1]*Catholic University Leuven, General Medical Oncology, Leuven, Belgium;* [2]*University of Basel, Institute of Pharmaceutical Medicine (ECPM), Basel, Switzerland;* [3]*Catholic University Leuven, Oncology, Leuven, Belgium;* [4]*St George's University of London, Cellular and Molecular Medicine, London, United Kingdom;* [5]*Catholic University Leuven, Translational Genetics, Leuven, Belgium*

Background: Several studies assessed the influence of genetic variability on outcome in breast cancer patients, but most studies were small or were limited to a few genes only. We assessed the impact of a wide range of patient-, tumor- and chemotherapy-related factors on progression-free survival (PFS) and overall survival (OS) in patients receiving fluorouracil, epirubicin, cyclophosphamide and docetaxel (FEC-D).

Methods: Female patients with early breast cancer receiving neoadjuvant or adjuvant chemotherapy with 3 cycles FEC and 3 cycles D were eligible. Patient-related factors (age at diagnosis, body mass index, body surface area and germ line genetic polymorphisms), chemotherapy-related factors (cycles received and growth factor use), baseline biochemical variables (white blood cell count, absolute neutrophil count, platelets, aspartate aminotransferase, alanine aminotransferase, total bilirubin and creatinine), tumor-related factors (stage and subtype) and severe toxicity occurrence (febrile neutropenia) were assessed (missing data <10%). The germ line genetic polymorphisms were selected based on our recent publication describing the impact of genetic variability on toxicity of FEC (Vulsteke et al, Ann Oncol. 2013 Feb 7). Univariate survival analysis of OS and PFS were performed.

Results: Among 529 patients planned to receive 3 cycles of FEC followed by 3 cycles of D during a mean follow-up of 4.2 years, 54 (10.2%) developed distant metastasis, 8 (1.5%) had a locoregional relapse and 26 (4.9%) died. In the univariate analysis, significant associates with a better OS and a better PFS were: higher relative dose intensity (RDI) of epirubicin (p < 0.04), lower stage (p < 0.003), luminalA or luminalB subtype (p < 0.0001) and homozygous carriers of the C-allele of rs2107538 in the RANTES gene (p < 0.01). Higher absolute neutrophil count, carriers of the T-allele of rs1801133 in the MTHFR gene, carriers of the C-allele of rs1800566 in the NQO1 gene and carriers of the TA-allele of rs2032582 in the MDR1/ABCB1 gene were significantly associated with worse OS (p < 0.05), whereas no growth factor use and carriers of the homozygous A-allele of rs776746 in the CYP3A5 gene were significantly associated with a better PFS (p < 0.03).

Conclusions: In this study, genetic variability, chemotherapy-related factors and tumor-related factors were significantly associated with OS and PFS in a large cohort of early breast cancer patients treated with 3 cycles of FEC followed by 3 cycles of D. A multivariate analysis will be performed to confirm the results and the findings will be presented at the meeting.

Tamoxifen pharmacokinetics influenced by circadian rhythm?

L. Binkhorst[1], J.S.L. Kloth[1], P. De Bruijn[1], H. Burger[1], R.J. Van Alphen[2], P. Hamberg[3], T. Van Gelder[4], E.A.C. Wiemer[1], G.T.J. Van der Horst[5], R.H.J. Mathijssen[1]. *[1]Erasmus MC Daniel den Hoed Cancer Center, Medical Oncology, Rotterdam, Netherlands; [2]TweeSteden Ziekenhuis, Internal Medicine, Tilburg, Netherlands; [3]Sint Franciscus Gasthuis, Internal Medicine, Rotterdam, Netherlands; [4]Erasmus MC, Hospital Pharmacy, Rotterdam, Netherlands; [5]Erasmus MC, Genetics, Rotterdam, Netherlands*

Background: The anti-oestrogen tamoxifen (Tam) is extensively metabolised, involving activation to endoxifen, and inactivation to conjugates, catalysed by cytochrome P450 iso-enzymes and phase II enzymes, respectively. Variability in pharmacokinetics (PK), which may contribute to variable clinical response, may be caused by *CYP2D6* polymorphisms, co-medication, but possibly also by the circadian clock. Due to daily variation in physiological functions, Tam PK may vary depending on time of administration. To investigate whether Tam shows circadian time-dependent PK, both a preclinical study in mice and a prospective clinical study were initiated.
Material and Methods: Tam PK was studied in mice, dosed at 6 different times at 4 hour intervals during the day. Mice were housed under a 12 h light-dark cycle and were given 4 mg Tam orally. PK measurements were based on 6 time points of blood collection (3 mice/time point). In patients on steady state Tam, a PK crossover study was performed. During two 24 h-periods, once after Tam dosing at 8 AM and once after dosing at 8 PM, for at least 4 weeks, blood samples were collected for PK measurements. Tam and its major metabolites were analysed by a validated LC-MS/MS method. Differences in PK between morning and evening administration were compared using a paired *t*-test.
Results: In mice, a 34% difference in Tam $AUC_{0-20\,h}$ was observed between 8 AM and 8 PM dosing, while the highest exposure was reached after dosing at midnight. Up till now, 12 patients completed both study periods. The area under the curves ($AUC_{0-12\,h}$) of Tam and its metabolites were higher after dosing at 8 AM compared to 8 PM ($p < 0.02$), with endoxifen $AUC_{0-12\,h}$ being 20% higher following dosing at 8 AM ($p = 0.006$). Peak concentrations (C_{max}) of Tam, ND-Tam and 4-OH-Tam, but not of endoxifen, were 18−27% higher ($p = 0.001$–0.03) and were reached earlier after dosing at 8 AM.
Conclusions: Both in mice and humans, circadian changes in Tam PK were observed. Differences in AUC, C_{max} and t_{max} between morning and evening dosing in patients are most probably due to variation in absorption and may be clinically relevant. Circadian variation in gastric emptying and gastrointestinal blood flow may be underlying mechanisms, although differences in metabolism are currently not excluded.
No conflict of interest.

2096 POSTER

Androgen receptor expression and outcomes in early breast cancer: A systematic review and meta-analysis

F.E. Vera-Badillo[1], A.J. Templeton[1], P. De Goveia[1], I. Diaz-Padilla[2], P.L. Bedard[1], M. Al-Mubarak[1], B. Seruga[3], I.F. Tannock[1], A. Ocana[4], E. Amir[1]. *[1]Princess Margaret Hospital, Division of Medical Oncology & Hematology, Toronto, Canada; [2]Centro Integral Oncologico Clara Campal, Division of Medical Oncology, Madrid, Spain; [3]Institute of Oncology Ljubljana, Sector of Medical Oncology, Ljubljana, Slovenia; [4]Albacete University Hospital, Medical Oncology Department and Translational Research Unit, Albacete, Spain*

Background: The androgen receptor (AR) is expressed frequently in breast cancer, but its prognostic significance is unclear. Preclinical data suggest that expression of AR may modify clinical outcomes in early breast cancer with an improved prognosis seen in estrogen-receptor (ER)-expressing tumors and a worse prognosis in ER-negative disease.
Methods: A systematic review of electronic databases was conducted to identify publications exploring the association between AR expression and both overall survival (OS) and disease free survival (DFS) in women diagnosed with early breast cancer. The odds ratio for OS and DFS at 5 years were calculated and then weighted and pooled in a meta-analysis using Mantel-Haenszel random-effect modeling.
Results: Nineteen studies involving 7693 women were included in our analysis. AR expression was documented in 58% of patients. ER-positive tumors were more likely to express the AR than ER-negative tumors (75% vs 31%, p for difference <0.001). AR expression was more common among progesterone receptor (PR) positive tumors than PR negative tumors (58% vs 42%, p for difference =0.001). There was a highly significant association between AR expression and low Ki-67 ($P < 0.001$). Overall, AR-expression was associated with improved OS and DFS irrespective of ER-expression. Odds ratio for OS and DFS were 0.45 (95% CI 0.31–0.64, $P < 0.001$) and 0.34 (95% CI= 0.20–0.57, $P < 0.001$) respectively. Co-expression of the ER did not influence these results (p-values for subgroup differences 0.79 and 0.75 for DFS and OS respectively). Sensitivity analysis removing of studies using radioimmunoassay or reverse-phase protein array rather than immunohistochemistry (IHC) did not affect either OS or DFS. Among studies utilizing IHC, there was no statistically significant difference for the 1% or 10% thresholds at either OS (p for difference =0.09) or DFS (p for difference =0.38). Only 2 studies reported the influence of AR-expression on HER2/neu-positive breast cancer. No apparent association was seen for either OS (OR=1.58, 95% CI =0.09–27.26, $P = 0.75$) or DFS (OR=0.92, 95% CI: 0.34–2.52, $P = 0.87$), but CI were wide and the possibility of an association in either direction cannot be excluded.
Conclusion: Expression of AR in women with breast cancer is associated with better DFS and OS irrespective of co-expression of ER.
No conflict of interest.

2097 POSTER

Biomarkers for predicting taxane efficacy in ER+/HER2− breast cancer patients: From in-vitro chemosensitivity screening to clinical validation in the GEICAM/ 9906 trial

A. Rodriguez-Lescure[1], J.C. Brase[2], M. Schmidt[3], M. Gehrmann[4], A. Ruiz[5], M. Ruiz Borrego[6], B. Munarriz[7], C.A. Rodriguez[8], L. Calvo[9], M. Martin[10]. *[1]Hospital General Universitario de Elche, Elche (Alicante), Spain; [2]Sividon Diagnostics GmbH, Sividon Diagnostics GmbH, Köln, Germany; [3]University of Gynecology and Obstetrics, University of Mainz, Mainz, Germany; [4]Bayer Technology Services GmbH, Bayer Technology Services GmbH, Leverkusen, Germany; [5]Fundación Instituto Valenciano de Oncologia, Medical Oncology Department, Valencia, Spain; [6]Hospital Universitario Virgen del Rocio, Medical Oncology Department, Sevilla, Spain; [7]Hospital Universitario La Fe, Medical Oncology Department, Valencia, Spain; [8]Hospital Universitario de Salamanca, Medical Oncology Department, Salamanca, Spain; [9]Complejo Hospital Universitario de A Coruña, Medical Oncology Department, A Coruña, Spain; [10]Instituto de Investigacion Sanitaria Gregorio Marañon, Universidad Complutense, Medical Oncology Department*

Background: Taxanes are among the most active agents for breast cancer (BC) patients, but the benefit of taxane-based treatment has to be balanced against side-effects. Therefore, there is a great need for novel predictive markers. Here we present the clinical validation of marker genes identified in an *in-vitro* chemosensitivity study, in order to select the ER+/HER2− BC patients who have a benefit from the inclusion of a taxane in the chemotherapy regimen.
Material and Methods: Tumor cells from 29 ER+/HER2− BC samples were incubated *in-vitro* with Paclitaxel (P), 5-Fluorouracil (F) and Epirubicin (E). An area under the dose-response curve (AUC) was determined for all tumor samples and all agents, respectively. RNA was extracted from the same tissue specimens and used for gene expression profiling. Promising predictive markers from the *in-vitro* chemosensitivity study were validated in 555 node-positive ER+/HER2− BC patients from the GEICAM/ 9906 trial; including patients that were either treated with F, E, and Cyclophosphamide (FEC) or with FEC followed by weekly P (FEC-P). Distant metastasis rates were estimated using the Kaplan–Meier method.
Results: *In-vitro* chemosensitivity data were used to calculate a taxane-response score (higher likelihood of P benefit in comparison to F and E) in ER+/HER2− BC patients. Gene expression levels from the microarray data were correlated with the taxane-response score and two genes − S100P and PCSK6 − were selected due to their significant correlation ($p < 0.05$). Since both genes exhibited an independent predictive information, a metagene was defined resulting in a better correlation (Pearson $r = 0.63$, $p < 0.05$). Validation of the metagene in the GEICAM/ 9906 trial demonstrated that tumors with a high metagene expression (>75% percentile) had a significant benefit from taxane-based treatment (log-rank $p < 0.003$, FEC vs. FEC-P − absolute risk reduction of distant metastasis: 27.3%), whereas there was no effect in the low-metagene group.
Conclusions: Single agent *in-vitro* chemosensitivity data can be validated in a clinical study. Additional studies are needed to validate the cut-offs levels for the predictive marker genes.
Conflict of interest: *Other substantive relationships: Dr. JC Brase is employed at Sividon Diagnostics GmbH. No conflict of interests to declare by rest of authors.*

2098 POSTER

TP53 mutation-regulated DNA repair genes mediate different sensitiveness to chemotherapy in ER+ and ER− breast tumors

G. Bottai[1], B.G. Gyorffy[2], T. Iwamoto[3], J. Lehmann-Che[4], G. Bianchini[5], N. Turner[6], C. Sotiriou[7], A. Di Leo[8], L. Pusztai[9], L. Santarpia[1]. *[1]Istituto Toscano Tumori, Translational Research Unit, Prato, Italy; [2]Semmelweis University Budapest Hungary, Pediatrics and Bioinformatics, Budapest, Hungary; [3]Okayama University Hospital, Breast and Endocrine Surgery, Okayama, Japan; [4]University Rene Diderot Paris 7 Saint Louis Hospital Assistance Publique Hôpitaux de Paris, Biochemistry and INSERM U944, Paris, France; [5]San Raffaele − Scientific Institute, Oncology, Milan, Italy; [6]The Breakthrough Breast Cancer Research Center Institute of Cancer Research, Oncology, London, United Kingdom; [7]Institut Jules Bordet and Université Libre de Bruxelles, Breast Cancer Translational Unit, Bruxelles, Belgium; [8]Hospital of Prato − Istituto Toscano Tumori, Medical Oncology Unit, Prato, Italy; [9]Yale Cancer Center, Medical Oncology, New Haven, Italy*

Background: Breast cancers molecular subtypes carry specific *TP53* mutations that can influence gene expression and clinical outcomes. Furthermore, TP53 has been shown to regulate important DNA repair pathways. In the present study we aimed to identify DNA repair gene signatures driven by *TP53* mutations and to assess their clinical relevance in ER-positive (ER+) and ER-negative (ER-) breast cancers (BC).
Methods: Publicly gene expression data analyzed with Affymetrix technology from 5 independent BC datasets (ER+ n = 511, and ER− n = 184) with known *TP53* status were used. The raw array data was normalized in the R environment using the affy Bioconductor package. In the discovery cohort, ROC analysis was performed for each gene separately and the genes were ranked by AUC values. Kaplan–Meier analysis was performed by KM-plotter software(1) using 635 neoadjuvant taxanes and anthracyclines-based chemotherapy treated patients. Statistical significance was set at $p < 0.01$. Pearson correlations and GSEA analyses were assessed in each molecular BC subtype. siRNAs were performed for the top 12 DNA repair genes and sensitivity for different treatments was tested in several BC cell lines.
Results: *TP53* mutations, particularly deletions/nonsense and frame shift mutations were more frequent in ER− tumors. *TP53* mutations types did not affect prognostic values. Importantly, *TP53* mutations (deletions/nonsense > frameshift > missense) were associated with a significant higher number of deregulated DNA repair genes particularly in ER− tumors (*P <0.001*). Specific genes were able to categorize patients with high and low risk of relapse in ER+ tumors only. The most significant TP53-mutated regulated within ER+ were: *TPX2* (0.803) *CENPA* (0.801), *AURKA* (0.800), and *RRM2* (0.79), and among ER-: *MSH2* (0.73), *DEK* (0.73), *RAD51AP1* (0.73), *MCM2* (0.72), *ASPM* (0.72). All of the top TP53-regulated genes correlated with survival. However, only genes within the ER+ tumors were associated with shorter survival in neoadjuvant-treated BC patients. siRNAs for TPX2 and DEK showed increased sensitivity of BC cells to HDAC and KSP inhibitors.
Discussion: We identified different *TP53*-mutation driven DNA repair genes in ER+ and ER− breast tumors. Deletions/nonsense mutations were associated with a higher frequency of deregulated DNA repair genes particularly in the ER− tumors. Specific *TP53*-mutated regulated DNA repair genes correlates with different prognosis and with different sensitivity to selected pharmacological treatments.
No conflict of interest.

2099 POSTER

The role of interleukin-8 (IL-8), matrix metalloproteinase −2 and −9 (MMP-2 and MMP-9) in breast cancer progression

J. Milovanovic[1], N. Todorovic-Rakovic[1], Z. Abu Rabi[1]. *[1]Insitute of Oncology and Radiology, Experimental Oncology, Belgrade, Serbia*

Background: IL-8 is a chemokine that is involved in breast cancer progression by multiple mechanisms, including attracting inflammatory cells that produce growth factors, angiogenic factors and proteinases such as MMP-2 and MMP-9. The aim of the study was to investigate the relations between IL-8/MMP-2/MMP-9 and other prognostic variables in lymph node-negative (N0) untreated breast cancer patients, with emphasis on their relation to steroid receptor status, and to determine the prognostic value of these potential biomarkers in terms of relapse free survival (RFS).
Material and Methods: The study included 135 N0 untreated breast cancer patients with known clinicopathological parameters. The median follow-up time was 111 months. IL-8, MMP-2 and MMP-9 levels were determined by ELISA in primary tumour tissue lysates.
Results: There were no significant relations between IL-8/MMP-2/MMP-9 expression and available clinicopathological parameters (patient's age, menopausal status, tumour size and tumour grade), except for MMP-9 expression being significantly higher in patients with invasive ductal carcinoma as well as in patients with higher levels of IL-8 according to median IL-8 level (M = 102.27 pg/mg, Mann-Whitney rank sum test, $p = 0.004$ and $p < 0.001$, respectively). ER− patients had higher levels of both IL-8 and MMP-9 (Mann-Whitney rank sum test, $p = 0.006$ and $p = 0.04$, respectively) compared to ER+ patients, but PR+ patients had higher levels of MMP-2 than PR− patients ($p = 0.03$). There was a significant negative correlation between ER and IL-8 expression (Spearman rank order test, $p = 0.02$) and significant positive correlation between IL-8 and MMP-9, as well as between PR and MMP-2 expression ($p < 0.001$ and $p = 0.05$, respectively). Among investigated biomarkers, only IL-8 had a statistically significant prognostic value in terms of RFS (Log rank, $p < 0.001$). Patients with IL-8 levels higher than median value had worse prognosis.
Conclusions: Expression of IL-8 and consequently expression of MMP-9/MMP-2 could be hormonally regulated in breast cancer. However, different expression of MMP-2 and MMP-9 regarding differential hormonal receptor expression, indicate distinct mechanisms of their regulation. Besides being a marker of more aggressive, ER− breast cancer phenotype, IL-8 seems to be a strong and independent unfavourable prognostic parameter in N0 breast cancer. Such patients with higher levels of IL-8 should be treated with adjuvant, especially IL-8 targeted therapy.
No conflict of interest.

2100 POSTER

Serum vascular endothelial growth factor (VEGF) in women with stage I−II breast cancer

F. Lumachi[1], D.A. Santeufemia[2], G.M. Fadda[3], S. Tumolo[4], G. Lo Re[4], G. Capobianco[5], G.B. Chiara[6], S.M.M. Basso[6]. *[1]University of Padua School of Medicine, Department of Surgery Oncology & Gastroenterology, Padova, Italy; [2]S. Maria degli Angeli Hospital, Medical Oncology, Poerdenone, Italy; [3]University of Sassari, Medical Oncology, Sassari, Italy; [4]S. Maria degli Angeli Hospital, Medical Oncology, Pordenone, Italy; [5]University of Sassari, Gynecologic and Obstetric Clinic, Sassari, Italy; [6]S. Maria degli Angeli Hospital, Surgery 1, Pordenone, Italy*

Background: In patients with breast cancer (BC) a number of prognostic and predictive factors have been reported including age, staging, hormone receptor status, and human epidermal growth factor 2 (HER2) and Ki-67 overexpression. Ki-67 is a nuclear protein tightly linked to the cell cycle and a marker of cell proliferation found in several epithelial malignancies, including BC. Angiogenesis is essential for the growth of tumor and spread of metastases, and cancer cells overexpressing cyclooxygenase-2 (COX-2), an inducible enzyme involved in prostaglandin biosynthesis, produce angiogenetic factors, such as vascular endothelial growth factor (VEGF). It has also been shown that inhibition of COX-2 leads to inhibition of angiogenesis in cancer tissue, and that elevated serum VEGF can be considered a negative prognostic factor in patients with cancer. The aim of this study was to analyze the predictive value of VEGF and Ki-67 in patients with invasive BC.
Material and Methods: Data from a group of 59 women (median age 60 years, range 32−68 years) with confirmed stage I−II BC who underwent curative surgery were reviewed. For evaluation of the preoperative serum VEGF values commercially available quantitative enzyme-linked immunosorbent sandwich assay (ELISA) kit for human VEGF 165 was used. All measurements were performed in twice. Ki-67 immunohistochemistry using the MIB-1 antibody was performed on sections cut from archival formalin-fixed, paraffin-embedded specimens. Pearson's correlation coefficient (R) calculation was used to evaluate the relationship between pairs of variables, and the 95% confidence interval (95% CI) was calculated, when appropriate.
Results: At 5-year follow-up, 51 (96.5%) patients were still alive, while 11 (18.6%) experienced recurrence of their disease. The 3- and 5-year survival probability estimates were 0.95 (95% CI 0.85–0.99) and 0.81 (95% CI 0.68–0.90), respectively. As expected, there was a significant ($p < 0.01$) inverse relationship between MIB-1 rate and disease-free survival (DFS), while no correlation (p=NS) was found between serum VEGF and survival or DFS.
Conclusions: Although plasma VEGF level has a clinical significance, its measurement was unlikely to provide clinically useful prognostic information, in our experience, for patients with early BC.
No conflict of interest.

2101 POSTER

Clinical prognostic value of HLA-E and HLA-G expression in early breast cancer

I. Kolyadina[1], P.J.K. Kuppen[2], C.J.H. Van de Velde[2], G.J. Liefers[2], N.G. Dekker-Ensink[2], E. Bastiaannet[2], B.E.M. Prinse[2], C.C. Engels[2], A. Sajet[2], I.V. Poddubnaya[1]. [1]*Russian Cancer Research Center of Russian Academy of Medical Science, Oncology Department, Moscow, Russian Federation;* [2]*Leiden University Medical Center, Dept. of Surgery, Leiden, Netherlands*

Background: The immune system affects growth of tumors, including breast cancer. We studied the clinical prognostic value of the expression level of non-classical HLA class I, E and G alleles in early breast cancer.
Material and Methods: In our study we included tumors from 350 patients with early breast cancer (BC) (cancer *in situ*: 35 cases, 10%; T1N0M0 stage: 315 cases, 90%) treated in Russia between 1985 and 2009 (RCRC, RMAPE, Moscow). Median age of patients included was 53 years (range: 26−88 years). Patients had radical surgery (mastectomy: 161 cases, 46%; breast-conserving surgery: 189 cases, 54%) and on recommendation also adjuvant treatment (radiotherapy- 180 cases, 51.4% or/and systemic therapy- 225 cases, 64.3%). Median time of follow-up 72 months (range: 12–216 months). BC progression was seen in 85 patients (24.2%), with median time to progression being 33 months (range: 7–168); 9.1% presented with local recurrence; 2.3% with regional recurrence; and 12.9% with distant recurrence. During follow-up 54 patients died: 43 patients (12.2%) from breast cancer and 11 (3.1%) from any other reason. A Tissue Micro Array (TMA), with triplicate 1 mm tumor tissue punches of all patients was constructed. Subsequently, sections were immunohistochemically stained for HLA-E and HLA-G. Expression was quantified for HLA-E in 334 cases, in 342 cases for HLA-G.
Results: HLA-E expression was absent in only 4 tumors (1.2%) and present in 330 tumors (98.8%), median rate of expression of HLA-E (percentage of positive tumor cells within a sample) was 90% (range 0–100%). We divided patients into: low expression (HLA-E*low*): 0−90% positive tumor cells, 152 cases (45.5%); and high expression (HLA-E*high*): >90% positive tumor cells, 182 cases (54.5%). HLA-G expression was absent in most tumors (225, 65.8%). 117 tumors (34.2%) expressed HLA-G (1−90% positive tumor cells per patient). Expression of HLA-E and G did not correlate with progression of BC or survival time for the whole group. In the invasive cancer patients a correlation between high expression HLA-E and progression of BC was seen ($p = 0.05$). Furthermore, combined HLA-E*low*/-G*negative* significantly ($p < 0.05$) correlated with a favorable clinical prognosis (16.3% relapses *vs* >25% in all other combinations).
Conclusion: We conclude that both HLA-E and G expression have clinical prognostic value in stage I tumors, suggesting an involvement of the immune system in counteracting tumor development already in very early stages of BC.
No conflict of interest.

2102 POSTER

Expression levels of HER2−2 dimer in proximity ligation assays is associated with trastuzumab-sensitivity in HER2-positive breast cancer

H. Shigematsu[1], T. Kadoya[1], M. Ohara[2], A. Emi[1], N. Masumoto[1], T. Kataoka[1], M. Oda[3], K. Arihiro[3], M. Okada[1]. [1]*Hiroshima University Hospital, Breast Surgery, Hiroshima, Japan;* [2]*Hiroshima Prefectural Hospital, General Surgery, Hiroshima, Japan;* [3]*Hiroshima University Hospital, Pathology, Hiroshima, Japan*

Background: Expression of HER2-containing dimer could be a reliable predictive factor of HER2-targeting antibody trastuzumab in HER2-positive breast cancer. We investigated the association between expression of HER2-containing dimer and response to trastuzumab in HER2-positive breast cancer.
Method: The expression levels of HER2-containing dimer were evaluated in series of HER2-positive breast cancer cell lines. We also evaluated the association between expression of HER2-containing dimer and trastuzumab-sensitivity in breast cancer patients who underwent trastuzumab-containing neoadjuvant chemotherapy. HER2-containing dimer was evaluated by proximity ligation assays (Duolink in situ, Olink®).
Results: There were higher expression levels of HER2−2 dimer in trastuzumab-sensitive cell lines compared to the resistant cell lines (sensitive vs. resistant, 65 vs. 15, $p<0.01$). In acquired trastuzumab-resistant model by long-term exposure of trastuzumab, significant decrease in expression level of HER2−2 dimer was recognized irrespective of maintain similar levels of HER2-receptor. In a cohort of 23 HER2-positive breast cancer patients treated with trastuzumab-containing neoadjuvant chemotherapy, high HER2−2 dimer expression cohort showed significantly higher rate of quasi-pathological complete response compared with low HER2−2 dimer expression cohort (high vs. low, 12/16, 75% vs. 1/7, 14%, $p = 0.006$).
Conclusion: Expression level of HER2−2 dimer by proximity ligation assays can be a reliable predictive marker of trastuzumab-sensitivity in HER2-positive breast cancer in vitro and vivo. Further examination is warranted in larger population, especially from prospective randomized clinical trials.

2103 POSTER

The impact of baseline and genetic parameters on progression free survival and overall survival in breast cancer patients receiving neoadjuvant or adjuvant chemotherapy with fluorouracil, epirubicin and cyclophosphamide

A.M. Pfeil[1], C. Vulsteke[2], M. Schwenkglenks[1], R. Paridaens[3], A.S. Dieudonné[4], R. Pettengell[5], S. Hatse[3], P. Neven[4], D. Lambrechts[6], H. Wildiers[3]. [1]*University of Basel, Institute of Pharmaceutical Medicine (ECPM), Basel, Switzerland;* [2]*Catholic University of Leuven, General Medical Oncology, Leuven, Belgium;* [3]*Catholic University Leuven, General Medical Oncology, Leuven, Belgium;* [4]*Catholic University Leuven, Oncology, Leuven, Belgium;* [5]*St George's University of London, Cellular and Molecular Medicine, London, United Kingdom;* [6]*Catholic University Leuven, Translational Genetics, Leuven, Belgium*

Background: Several studies assessed the influence of genetic variability on outcome in breast cancer patients, but most studies were small or were limited to a few genes only. We assessed the impact of a wide range of patient-, tumor- and chemotherapy-related factors on progression-free survival (PFS) and overall survival (OS) in patients receiving fluorouracil, epirubicin and cyclophosphamide (FEC).
Methods: Female patients with early breast cancer receiving neoadjuvant or adjuvant chemotherapy with 6 cycles FEC were eligible. Patient-related factors (age at diagnosis, body mass index, body surface area and germ line genetic polymorphisms), chemotherapy-related factors (cycles received and growth factor use), baseline biochemical variables (white blood cell count, absolute neutrophil count, platelets, aspartate aminotransferase, alanine aminotransferase, total bilirubin and creatinine), tumor-related factors (stage and subtype) and severe toxicity occurrence (febrile neutropenia) were assessed (missing data <10%). The germ line genetic polymorphisms were selected based on our recent publication describing the impact of genetic variability on toxicity of FEC (Vulsteke et al, Ann Oncol. 2013 Feb 7). Univariate survival analysis of OS and PFS were performed.
Results: Among 462 patients planned to receive 6 cycles of FEC, 66 (14.3%) developed distant metastasis, 24 (5.2%) had a locoregional relapse and 44 (9.5%) died during a mean follow-up of 6.3 years. The median age was 50 years (range: 23−72 years) and 24 (5%) of the 462 patients received neoadjuvant chemotherapy. In the univariate analysis, patients with febrile neutropenia had a significantly better OS ($p = 0.03$) and patients with increasing tumor stage had a worse OS ($p = 0.002$). Univariate significant associations with a worse PFS were: higher tumor stage ($p = 0.0020$), less FEC cycles received ($p = 0.02$), higher white blood cell count ($p = 0.03$), no growth factor use ($p = 0.04$), HER2like and triple negative subtype ($p = 0.01$), C-allele carriers of rs1138272 in the GSTP1 gene ($p = 0.03$) and T-allele carriers of rs4673 in the MRP1 gene ($p = 0.01$). On the CYP2C9

gene, carriers of the homozygous C-alleles of rs1057910 were significantly associated with a worse OS and PFS ($p < 0.0001$).
Conclusions: Tumor-related factors but also genetic variability, baseline biochemical variables and chemotherapy-related factors significantly impacted on OS and PFS in a large cohort of early breast cancer patients treated with FEC only. A multivariate analysis of these putative predictive factors is now ongoing and the findings will be presented at the meeting.
No conflict of interest.

2104 POSTER

CHD1L protein is overexpressed and a marker for aggressive tumor biology in human breast cancer

J. Wu[1], L. Zhu[1], X.C. Fei[2], X.S. Chen[1], O. Huang[1], J.R. He[1], W.G. Chen[1], Y.F. Li[1], K.W. Shen[1]. *[1]Ruijin Hospital Shanghai Jiaotong University School of Medicine, Comprehensive Breast Health Center, Shanghai, China; [2]Ruijin Hospital Shanghai Jiaotong University School of Medicine, Department of Pathology, Shanghai, China*

Background: The chromodomain helicase/adenosine triphosphatase DNA binding protein 1-like gene (CHD1L) is a recently identified oncogene localized at 1q21. Overexpression of CHD1L protein in primary hepatocellular carcinoma is correlated with enhanced apoptosis inhibition, and could probably lead to reduced chemosensitivity and shortened patient survival. However, CHD1L protein status in primary breast cancer and its clinical significance remains obscure.
Material and Methods: In this study, immunohistochemistry (IHC) for CHD1L was performed on a tissue microarray (TMA) containing 179 primary invasive breast cancer. CHD1L status was determined by a scoring system using both the proportion score and the intensity score. Clinicopathologic features of the breast cancer patients were collected and compared between different CHD1L status.
Results: CHD1L overexpression was observed in 87 of the 179 breast cancers (48.6%). CHD1L overexpression was associated with a younger age ($P = 0.011$), higher grade ($P = 0.004$) and HER2 positive status ($P = 0.037$). No other clinicopathologic features were significantly correlated with CHD1L expression(Table 1).
Conclusions: CHD1L overexpression is more significantly associated with aggressive tumor biology rather than large tumor burden in breast cancer. The prognostic significance of CHD1L expression needs to be further studied.
No conflict of interest.

Immunogenicity of balugrastim and pegfilgrastim in breast cancer patients: An integrated analysis from phase I, II, and III studies

L. Pukac[1], S. Clark[1], N. Bukreyeva[1], S. Barash[2], A. Buchner[3], L. Adar[4], N. Avisar[4], P. Liu[1]. *[1]Teva Biopharmaceuticals USA, Global Bioassays and Technology, Washington DC, USA; [2]Teva Biopharmaceuticals USA, Global Bioassays and Technology, Rockville, USA; [3]Teva Ratiopharm, Teva Ratiopharm, Ulm, Germany; [4]Teva Pharmaceuticals Inc., Teva Pharmaceuticals Inc., Netanya, Israel*

Background: Balugrastim is a once-per-cycle, fixed-dose protein composed of human serum albumin (HSA) and granulocyte-colony stimulating factor (G-CSF) under review for the prevention of severe neutropenia in cancer patients receiving chemotherapy (CTx). Like any protein-based therapeutic, balugrastim may elicit an anti-drug antibody (ADA) response that could affect drug safety and efficacy. The immunogenicity of balugrastim versus pegfilgrastim and the impact of ADAs on the pharmacokinetics (PK), clinical efficacy, and safety of balugrastim were assessed in patients with breast cancer receiving CTx.
Methods: Patients received a subcutaneous injection of balugrastim or pegfilgrastim 6 mg on Day 2 of each CTx cycle. Balugrastim doses were: 50, 150, 300, or 450 μg/kg (Phase I); 30, 40, or 50 mg (Phase II); or 40 mg (Phase III). Serum samples for analysis of antibodies to balugrastim were obtained before dosing of balugrastim for each CTx cycle and at the end of the study (15−30 days after the last dose). Follow-up samples were collected 6 and 12 months after the last dose for the Phase II study and 4 and 10 months after last dose for the Phase III study. Samples were screened for antibodies specific to each study drug using ELISA assays. ADAs were confirmed using an immunocompetition approach and analyzed for titers and neutralizing activity in a cell-based assay. Antibodies to human albumin were also assessed using a separate ELISA with enhanced tolerance for serum albumin.
Results: A total of 764 patients from three clinical studies were tested for ADAs to balugrastim (n = 502) or pegfilgrastim (n = 262). Two patients were observed to have positive ADA responses to pegfilgrastim and three were observed to have positive ADA responses to balugrastim. All positive ADA samples had low antibody titers, and no neutralizing activity was observed in the cell-based assay. Antibodies to human albumin related to balugrastim administration were detected in seven patients at only one time point in each patient. Serum ADA status was not observed to correlate with the PK, clinical safety, or efficacy of balugrastim.
Conclusions: A low immunogenicity incidence was observed in the 502 breast cancer patients treated with balugrastim. All positive ADA responses had low antibody titers and lack of neutralizing activity for balugrastim. The incidences of confirmed positive anti-balugrastim or anti-pegfilgrastim binding antibodies were comparable between treatment groups.

2106 POSTER

Frequency of triple-negative breast cancer in women with different genotypic variants in BRCA, TP53

K.V. Sytenkova[1], I.V. Kolyadina[1], I.V. Poddubnaya[1], L.N. Lyubchenko[2]. *[1]Russian Medical Academy for Postgraduate Education RF, Oncology, Moscow, Russian Federation; [2]N.N. Blokhin Russian Cancer Research Center RAMS, Oncogenetics Laboratory, Moscow, Russian Federation*

Background: Triple-negative breast cancer (TNBC) is a tumor characterized by lack of estrogen receptor, progesterone receptor, and HER2/neu. Frequency of TNBC is about 15% of all invasive breast cancers. Triple-negative breast cancer is associated with the presence of a germline *BRCA*-mutations and poor prognosis. The purpose of this study was to analyze the frequency of TNBC in women with polymorphisms and mutations in *BRCA* and *TP53* genes.
Material and Methods: At the first stage *BRCA1*, *BRCA2*, *TP53* genes from 242 women with breast cancer were scanned for mutations and polymorphisms.
242 women with breast cancer enrolled in this study were divided: 184 women (76%) with hereditary breast cancer, associated with allelic variants in *BRCA1/2* [haplotype B (IVS1–103T/C, IVS1–115T/C, IVS8−58delT, D693N, S694S, L771L, P871L, E1038G, K1183R, S1436S, IVS14−63C/G, S1613G) − 24.8% (n = 60), Q356R − 5.4% (n = 13), *BRCA1*-mutations − 23.5% (n = 57), N372H − 8.3% (n = 20)], *TP53* [R72P − 4.5% (n = 11), In3dup16−4.1% (n = 10)] genes and 58 cases (24%) with sporadic breast cancer (wt*BRCA*/*TP53*) were included in control group.
Results: Triple-negative breast cancer in women with allelic variants was identified in 7.7% − 49.1% cases. Multiple studies have indicated that

triple-negative breast cancers in younger women are frequently *BRCA1*-related. We have also shown that TNBC is statistically-valid presented in women with *BRCA*-mutation − 49.1% compared to other breast cancers associated with or without allelic variants ($p < 0.05$). Less frequently TNBC was observed in women with haplotype B (*BRCA1*) − 18.3% and with missense variant R72P (*TP53*) − 18.2%.
Another fascinating fact is the detection of TNBC in patients with wt*BRCA*/*TP53* − 15.5% cases. TNBC was extremely rare indicated in women with polymorphism Int3dup16 (*TP53*) − 10% and with missense variant Q356R (*BRCA1*) − 7.7%. There is no one case of TNBC in women with missense variant N372H in *BRCA2*.
Conclusions: The study demonstrated different frequency of triple-negative breast cancer depending on *BRCA*- and *TP53*-genotype; TNBC is statistically-valid presented in women with germline mutation in *BRCA1*.
No conflict of interest.

Is there a correlation between CDKN1A and CDKN1B gene polymorphisms and Turkish breast cancer patients?

G. Gokoz Dogu[1], A. Kargi[2], S. Turgut[3], M. Tunç Ata[3], C. Ayada[4], R. Akcilar[4], B. Yapar Taskoylu[1], G. Demiray[1], A. Yaren[1], A. Ergin[5]. *[1]School of Medicine University of Pamukkale, Department of Internal Medicine Division of Medical Oncology, Denizli, Turkey; [2]Medstar Hospital, Clinic of Medical Oncology, Antalya, Turkey; [3]School of Medicine University of Pamukkale, Department of Physiology, Denizli, Turkey; [4]University of Dumlupinar Faculty of Medicine, Department of Physiology, Kutahya, Turkey; [5]School of Medicine University of Pamukkale, Department of Public Health, Denizli, Turkey*

Background: We assessed whether C120T in CDKN1A; C279T and Gly109Val in CDKN1B gene polymorphisms predicted clinical outcome in breast cancer patients.
Material and Methods: DNA was isolated from peripheral blood by standard phenol/chloroform extraction method for genotyping. The data were statistically analysed using SPSS software version 17.0 for Windows. Statistical significance of the observed genotype frequencies was evaluated according to Hardy–Weinberg rule.
Results: A total of 73 breast cancer patients with performance status of 0−2 were enrolled in this study. We determined the Ser31Arg and C120T in CDKN1A; C279T and Gly109Val in CDKN1B single nucleotide gene polymorphisms. Median age was 49 years (range 25−80 years) and all patients were female. Anthracycline or anthracycline plus taxane based chemotherapy were given At diagnosis lymph node involvement was detected in 41 patients (56.2%) and in 27 (37%) of the patients no involvement was detected. Her-2 positivity was recorded in 35 (47.9%) patients and negativity in 35 (47.9%) patients. Hormone reseptor positivity was found in 35 (47.9%) of the patients. We found polymorphisms of Ser31Arg in CDKN1A gene AC, AA, CC genotype and C,A allele frequencies in breast cancer patients as 46.6%, 35.6%, 17.8% and 36.7%, 63.3%; for C120T in CDKN1A gene, CC, CT, TT genotype and C, T allele frequencies as 71.2%, 27.4%, 1.4%, 84.9%, 15.1%; for C279T in CDKN1B gene CC, CT, TT genotype and C,T allele frequencies as 57.5%, 32.9%, 9.6%, 74.0%, 26.0%; for Gly109Val polymorphism in CDKN1B gene GT,TT,GG genotype and T,G allele frequencies as 47.9%, 45.2%, 6.8%, 69.2%, 30.8%, respectively. Patients with polymorphism of Ser31Arg in CDKN1A gene AA genotype had a longer survival (140.94 $\pm$12.57 months, 95% CI 116.32–165.56) than all of the other genotypes. However, this difference is not statistically significant ($p = 0.530$). We didn't find any significant correlation between overall survival and Ser31Arg and C120T in CDKN1A; C279T and Gly109Val in CDKN1B genotypes ($p = 0.411$, $p = 0.942$, $p = 0.754$, $p = 0.325$ respectively). Cox regression analysis for overall survival showed that only exist of metastasis was statistically significant (HR = 3.087, 95% CI=0.009–0.238, $p < 0.001$); it was the most important prognostic factor. The frequency of genotypes in these genes in patients did not show a significant deviation from Hardy–Weinberg equilibrium.
Conclusions: We could not find any significant association between the genotypes and clinicopathologic parameters. Further large and functional studies are needed to explore these gene polymorphisms in Turkish population.
No conflict of interest.

2108 POSTER

The significance of urokinase system in postmenopausal breast cancer patients

Z. Abu Rabi[1], N. Todorovic-Rakovic[1], M. Markicevic[1], L.J. Stamatovic[1], T. Vujasinovic[1], D. Nikolic-Vukosavljevic[1]. *[1]Institute for Oncology & Radiology, Division of Experimental Oncology, Belgrade, Serbia*

Background: Due to heterogeneous nature of breast cancer, individual adjuvant therapy is not successful in all patients. For that reason 30% of all patients with early-stage breast cancer will develop metastasis. Urokinase system has a central role in the process of migration, invasion, extracellular turnover and proliferation of malignant cells.
Material and Methods: Our analysis included 49 patients with histologically verified primary breast cancer. All of the investigated patients were postmenopausal women who received adjuvant tamoxifen therapy according to protocols at the time of diagnosis. At time of primary therapy, no patients had any clinical evidence of distant metastasis. The course of disease was followed for 30 months or until the recurrence of disease (emergence of distant metastasis).
Results: We determined cut off points by a method of minimal p values. Cut off value for PAI-1 was determined at 4.5 ng/mg. A strong trend for uPA was obtained at 0.26 ng/mg. Analysis of disease free intervals (DFI) probabilities showed that patients with high concentration of uPA or low concentration of PAI-1 in their tumors, have much higher chance of developing distant metastasis in the period of 30 months after the surgery. Analysis of DFI probabilities for quantitative values of ER and PR showed a cut off value of 5 fmol/mg in the case of both molecular biomarkers. Patients with high concentration of PR among uPA+ had better DFI, and patients with low uPA concentration in the PR- had a higher chance of recurrence. In the subgroup of PAI-1+ patients, those with ER− or pT2 tumors had a worst prognosis compared with ER+ and pT1. A strong positive correlation was found between ER and PR ($r = 0.6$, $p=<0.001$) and uPA and PAI-1 ($r = 0.35$, $p = 0.02$).
Conclusions: uPA and PAI-1 are significant predictive factors in the period of the first 30 months after surgical treatment. Both ER and PR were confirmed as predictive markers in regard to tamoxifen therapy. These markers, combined with other clinicopathological parameters, revealed subgroups of patients with increased risk of early metastasis occurrence.
No conflict of interest.

2110 POSTER

Prognostic value of tumor infiltrating lymphocytes (TILs) on residual disease after primary chemotherapy for triple-negative breast cancer (TNBC) patients

M.V. Dieci[1], C. Criscitiello[2], V. Guarneri[3], P.F. Conte[3], A. Goubar[1], C. Charpy[4], G. Viale[5], S. Delaloge[6], G. Curigliano[2], F. André[7]. *[1]Institut Gustave Roussy, INSERM U981, Villejuif, France; [2]European Institute of Oncology, Division of Medical Oncology Department of Medicine, Milano, Italy; [3]University of Padova istituto Oncologico Veneto IRCCS, Division of Medical Oncology 2, Padova, Italy; [4]Institut Gustave Roussy, Departement de Bio-pathologie Medicale, Villejuif, France; [5]European Institute of Oncology, Division of Pathology, Milano, Italy; [6]Institut Gustave Roussy, Department of Medical Oncology, Villejuif, France; [7]Institut Gustave Roussy, INSERM U981 Department of Medical Oncology, Villejuif, France*

Introduction: Patients (pts) with TNBC not achieving a pathological complete response (pCR) after neoadjuvant chemotherapy (NACT) show a poor prognosis. Previous data suggest that chemotherapy induces immune response and that TILs on primary tumor are associated with prognosis. Aim of the present study is to investigate the prognostic value of TILs on residual disease after NACT for TNBC pts not achieving pCR.
Methods: HES slides from surgical specimens of 308 TNBC pts without pCR after NACT were retrieved from 3 centers (European Institute of Oncology, Institut Gustave Roussy, Modena University Hospital). Samples were evaluated for the % of intratumoral (IT) and stromal (ST) TILs adopting Denkert et al's methods (J Clin Oncol, 2010). Samples were classified as high-TILs if IT and/or ST >60%. Overall survival (OS) was defined as the delay between BC surgery and death/last follow up (FU) and disease-free survival (DFS) as the delay between BC surgery and relapse (local/distant whatever occurred first) or death/last FU. Those factors significantly correlated with OS in univariate analysis were included in a multivariate model.
Results: 291 out of 308 pts resulted evaluable for at least one TIL variable and were included in the analysis. Median age was 48 yrs. Median FU was 5.7 yrs. 44% and 49% of the pts received anthra/tax- and anthra-based NACT, respectively. Among the latter, 38% received adjuvant taxanes. IT and ST values were correlated (Spearman's coefficient 0.72). Both IT and ST as continuous variables were associated with OS (23% and 21% reduction in death risk for a 10% increase in IT and ST, respectively;

p < 0.0001). 9.6% of cases were classified as high-TIL. Both DFS and OS were significantly better for high-TIL pts vs low-TIL pts (5 yrs-DFS rate 84% vs 46%, HR 3.64 95% CI 1.49–8.89, log-rank p = 0.002; 5 yrs-OS rate 90% vs 56%, HR 5.02 95% CI 1.59–15.80, log-rank p = 0.002). TIL as continuous variable (defined by considering the highest value between IT and ST for each case) was still significantly associated with both DFS and OS in the multivariate analysis adjusted on clinical stage at diagnosis, node status and tumor size after NACT (p = 0.02).
Conclusion: These data suggest that high-TIL on residual disease predict good outcome for TNBC pts. TIL may be a useful tool to stratify pts at different outcome after NACT in addition to pCR and could help in guiding clinical decisions. This study feeds the hypothesis that chemotherapy can induce immune response.

Laparoscopic versus open surgery for rectal cancer: Short-term outcomes of a multicentre, open label, randomised controlled trial

M. Van der Pas[1], G. Abis[2], E. Haglind[3], M. Cuesta[2], A. Fürst[4], A. Lacy[5], W. Hop[6], H. Bonjer[2]. *[1]Maastricht University Medical Centre, Maastricht, Netherlands; [2]VU University Medical Center, Surgery, Amsterdam, Netherlands; [3]Sahlgrenska Universitetssjukhuset, Surgery, Göteborg, Sweden; [4]Caritas Krankenhaus St Josef, Surgery, Regensburg, Germany; [5]Hospital Clinic I Provincial de Barcelona, Surgery, Barcelona, Spain; [6]Erasmus University Medical Centre, Surgery, Rotterdam, Netherlands*

Background: Laparoscopic surgery is considered an alternative to open surgery in patients with rectal cancer, but no sufficiently powered trial has unequivocally demonstrated oncological safety of laparoscopic resection of rectal cancer.
Materials and Methods: A non-inferiority phase III trial was undertaken at 30 centres worldwide. In total, 1103 patients with rectal carcinoma within 15 cm from the anal verge were randomly assigned to either open or laparoscopic surgery in a 1:2 ratio. Clinical and pathology variables were recorded.
Results: 1044 patients were eligible for analyses, 739 patients were assigned to laparoscopic surgery and 345 to open surgery. Laparoscopic surgery was associated with less blood loss (median 200 mL vs 400 mL after open surgery), but lasted 52 minutes longer (both p < 0.0001). Furthermore, laparoscopic approach was followed by earlier restoration of bowel function (p < 0.0001) and shorter hospital stay by 1 day for both. Hospital stay was 8 days after laparoscopic and 9.0 days after open surgery (p = 0.036). Macroscopically completeness of the resection was not significantly different between both groups (88% vs 92% for laparoscopic and open surgery, p = 0.250). In both groups a positive circumferential margin was noted in 10% (p = 0.850). 278 patients (40%) in the laparoscopic group had complications compared with 128 patients (37%) in the open group, (p = 0.424,). Mortality rates, 1.1% in the laparoscopic group and 1.7% in the open group were comparable in both arms, p = 0.409.
Conclusion: Short-term results show that Laparoscopic surgery for rectal cancer is similar to open surgery regarding safety and radicality of surgery while recovery after laparoscopic surgery was improved.
No conflict of interest.

Intensified follow-up in colorectal cancer patients using frequent carcino-embryonic antigen (CEA) measurements and CEA-triggered imaging

C. Verberne[1], P.M. Doornbos[2], I. Grossmann[1], G.H. De Bock[2], T. Wiggers[1]. *[1]Groningen University Hospital, Surgery, Groningen, Netherlands; [2]Groningen University Hospital, Epidemiology, Groningen, Netherlands*

Background: For colorectal cancer (CRC), there is need for an evidence-based follow-up schedule defining frequency of blood tests and imaging to detect recurrent disease as early as possible. The trial CEA Watch assesses the value of frequent CEA measurements and CEA-triggered imaging in detecting recurrent disease in CRC patients and aims to increase the rate of curable recurrences amongst all detected recurrences from 10 % to 25%.
Methods: This was a randomized-controlled multicenter prospective study using a stepped wedge cluster design. From October 2010 and on, 11 hospitals in the Netherlands were timed to change their follow-up care as usual into an intensified follow-up schedule for all patients in follow-up after non-metastasized CRC operated from January 2007. The moment of the follow-up switch was randomized per cluster. The inclusion has been stopped October 2013 and the study is in progress.
The intervention protocol consisted of CEA measurements every 2 months, with repetition of the CEA measurement after 1 month in case of a 20% rise and imaging in case of 2 subsequent rises. A sample size calculation was performed and 1600 patients were needed given a recurrence rate of 25%.
Results: 3223 patients were included; 243 recurrences were detected (7.5%), 104 (43%) recurrences were found while the patient participated in the control follow-up and 139 (57%) recurrences in the intervention follow-up. In total, 90 (37.0%) of the found recurrences could be treated with curative intent. The time between the operation and diagnosis of recurrent disease was the same amongst groups. The curability of detected recurrences was significantly higher for the intervention protocol than for the control protocol (42% v 30%, p = 0.04).
Conclusions: The CEA watch protocol detects recurrent disease after colorectal cancer in a phase that a significantly higher proportion of recurrences can be treated with curative intent.
Trial sponsor: The Netherlands Organisation for Health Research and Development.
Trial Registry Number 2182.
Participating hospitals: Medisch Spectrum Leeuwarden, Medisch Spectrum Twente, Nij Smellinghe Drachten, Albert Schweitzer Dordrecht, Martini Hospital Groningen, Jeroen Bosch Hospital Den Bosch, Catharina Hospital Eindhoven, Meander Amersfoort, Gelre Apeldoorn, Medisch Centrum Haaglanden, and Elisabeth Hospital Tilburg

Differences in circumferential resection margin involvement after abdominoperineal excision and low anterior resection no longer significant

N. Van Leersum[1], I. Martijnse[2], M. Dulk[3], N.E. Kolfschoten[3], S. Le Cessie[4], C.J. Van de Velde[3], R.A.E.M. Tollenaar[3], M.W.J.M. Wouters[5], H.J.T. Rutten[2]. *[1]Leiden University Medical Center, Surgery, Leiden, Netherlands; [2]Catharina Hospital, Surgery, Eindhoven, Netherlands; [3]Leiden University Medical Centre, Surgery, Leiden, Netherlands; [4]Leiden University Medical Centre, Epidemiology, Leiden, Netherlands; [5]Antoni van Leeuwenhoek Hospital, Surgery, Amsterdam, Netherlands*

Introduction: The oncologic inferiority of the APE technique in comparison with LAR has been widely reported in literature. However, due to large evolvement in rectal cancer care, outcomes after APE may have improved since.The aim of this study was to evaluate whether the abdominoperineal excision (APE) is associated with an increased risk of circumferential resection margin involvement (CRM) after rectal cancer surgery in comparison with low anterior resection (LAR).
Material and Methods: The population-based dataset of the Dutch Surgical Colorectal Audit (DSCA) was used selecting 5017 patients with primary rectal cancer undergoing surgery in 2010–2011. Propensity scores were calculated for the likelihood of performing an APE given relevant patient- and tumour characteristics, and used in the multivariate analysis of CRM involvement.
Results: A LAR was performed in 2969 patients (71%), an APE in 1245 patients (29%). After LAR, a deviating ostomy was constructed in 68% of patients. Factors associated with the performance of an APE were male gender, advanced cT stage, and tumours close to the anal verge (0−3 cm). The APE was associated with a slight, non-significant, increased risk of CRM involvement [OR 1.33; CI 0.93–1.90]. Absolute percentages of CRM involvement were 8 and 12 percent after LAR and APE respectively. In subgroup analysis, advanced rectal tumours (cT3,4) were associated to a higher risk of CRM involvement after APE (OR 1.61; CI 1.05–1.90), whereas smaller tumours (cT1,2) were not [OR 0.62, CI 0.27–1.40].
Conclusion: The results suggest that on a national level the APE procedure itself is not a strong predictor anymore for CRM involvement after rectal cancer surgery. However, in advanced tumours, results after APE are inferior to LAR.
No conflict of interest.

Preoperative radiotherapy with a simultaneous integrated boost compared to chemoradiotherapy for T3−4 rectal cancer: Interim analysis of a multicentric randomized trial

B. Engels[1], A. De Paoli[2], N. Platteaux[1], G. Cattari[3], S. Vagge[4], E. Garibaldi[3], D. Norkus[5], G. Tabaro[2], H. Versmessen[1], M. De Ridder[1]. *[1]UZ Brussel, Radiotherapy, Brussel, Belgium; [2]National Cancer Institute Aviano, Radiation Oncology, Aviano, Italy; [3]IRCC Candiolo, Radiation Oncology, Candiolo, Italy; [4]IRCCS San Martino-IST Genoa, Radiation Oncology, Genoa, Italy; [5]Institue of Oncology Vilnius University, Radiotherapy, Vilnius, Lithuania*

Background: The addition of chemotherapy to preoperative radiotherapy (RT) has been established as the standard of care for patients with cT3−4 rectal cancer. As an alternative strategy, we reported previously in a phase II study a limited toxicity and high 5-year local control rate with preoperative image-guided and intensity-modulated RT (IG-IMRT) with a simultaneous integrated boost (SIB), without concomitant chemotherapy. Here, we compared this strategy to chemoRT in a multicentric randomized trial (NCT 01224392).
Methods: cT3−4 rectal cancer patients were randomly assigned to receive either preoperative IG-IMRT (46 Gy in 23 fractions of 2 Gy) with a SIB to the rectal tumor up to a total dose of 55.2 Gy (boost-arm) or preoperative IG-IMRT (46 Gy in 23 fractions of 2 Gy) plus capecitabine (825 mg/m^2 twice daily) (chemo-arm). Surgery was performed 6−8 weeks after completion of preoperative treatment. Metabolic tumor activity reduction, assessed by comparing the maximal standardized uptake value (SUV_{max}) on sequential 18-fluorodeoxyglucose positron emission tomography (FDG-PET), was the primary endpoint. Acute side effects were scored using the National Cancer Institute Common Terminology Criteria for Adverse Events version 3.0.
Results: Eighty patients were randomly assigned to the boost-arm (n = 37) or chemo-arm (n = 43). Acute grade 3 toxicity occurred in 3% of the patients in the boost-arm compared to 7% in the chemo-arm (p = 0.37). No acute grade 4 toxicities were observed. Acute grade 2 enteritis was significantly lower in the boost-arm (22% vs 44%; p = 0.03). Surgery was performed in 95% of patients in both arms. The R0 resection rate was 97% and 98% for patients in the boost- and chemo-arm, respectively. Pathologic complete response rate (ypCR, Dworak grade 4) was 12% in the boost-arm compared to 24% in the chemo-arm (p = 0.15). Dworak regression grade 3−4 was not different between both arms (45% vs 46%, p = 0.56). The mean fractional change in SUV_{max} at 5 weeks after completion of preoperative RT as compared to baseline was − 49.0% $\pm$ 20.8% and − 50.9% $\pm$ 27.6% for patients in the boost-arm and chemo-arm, respectively (p = 0.40).
Conclusions: The implementation of preoperative IG-IMRT resulted in limited acute grade $\geqslant$3 toxicity in both arms. As compared to chemoRT, patients receiving a boost experienced less acute grade 2 enteritis. In terms of downstaging, impressive rates of major histomorphologic regression (Dworak grade 3−4) were recorded in both treatment arms, with a higher ypCR rate for patients receiving chemoRT. No differences in metabolic response were observed.
No conflict of interest.

Health-related quality of life of patients 14 years after short-term preoperative radiotherapy and total mesorectal excision for rectal cancer: Report of a multicenter randomized trial

L.M. Wiltink[1], T.Y.T. Chen[2], R.A. Nout[1], E. Meershoek-Klein Kranenbarg[3], S. Laurberg[2], C.J.H. Van de Velde[4], C.A.M. Marijnen[1]. *[1]Leiden University Medical Center, Radiotherapy, Leiden, Netherlands; [2]Aarhus University Hospital, Surgery P, Aarhus, Denmark; [3]Leiden University Medical Center, Surgical Datacenter, Leiden, Netherlands; [4]Leiden University Medical Center, Surgery, Leiden, Netherlands*

Background: Local recurrence is a major problem in rectal cancer treatment. Preoperative short-term radiotherapy (PRT) has shown to improve local control but not survival in combination with total mesorectal excision (TME). Therefore, we assessed the very long-term health-related quality of life (HRQL) of patients treated in the TME trial still alive more than 10 years after diagnosis.
Material and Methods: In the TME trial (1996–1999) 1530 Dutch patients with rectal cancer were treated with TME and randomly assigned to PRT (5 x 5 Gy). In 2012 HRQL was evaluated in all surviving patients (n = 583) using a questionnaire combining EORTC QLQ-C30, EORTC QLQ-CR29 and additional questions. To correct for multiple testing, a p-value of 0.01 was considered statistically significant.
Results: Results were obtained from 478 patients (response rate 82%), with a median follow up of 14.6 years (range: 12.5–16.6). Overall, no significant differences could be detected in global HRQL and functioning scores between the two treatment arms (table 1). For individual symptoms however, irradiated patients reported significantly more bowel dysfunction and increased use of incontinence material. In addition, irradiated male patients more often reported erectile dysfunction. Urinary function however, was not different between the two groups.

Table 1. Overview of prominent results

	Mean score		*P*
	PRT (N = 241)	TME (N = 237)	
Physical functioning	77.4	80.9	0.08
Role functioning	79.4	81.4	0.30
Emotional functioning	86.1	85.8	0.35
Cognitive functioning	83.3	84.0	0.33
Social functioning	86.8	87.7	0.59
Global health status	77.2	78.5	0.16
Stool frequency	26.3	19.4	<0.01
Faecal leakage	22.5	10.1	<0.001
Frequency of use of pads for faecal leakage	56.4	38.4	<0.001
Involuntary urine loss	41.8	41.3	0.88
Frequency of use of pads for urine loss	46.5	44.1	0.73
Sexually active	38.0	41.3	0.08
Difficulty getting or maintaining an erection	79.3	66.8	<0.01

PRT, preoperative short-term radiotherapy; TME, total mesorectal excision.

Conclusions: Long-term HRQL evaluation shows that short-term PRT is still associated with increased bowel dysfunction and increased erectile dysfunction 14 years after diagnosis. However, PRT does not affect global HRQL and functioning (EORTC QLQ-C30). To facilitate shared decision making, these long-term results should be discussed with newly diagnosed patients before start of treatment.
Supported by the Dutch Cancer Society (CKVO 95−04) and the Dutch National Health Council (OWG 97/026).

Phase III trial of treatment duration for oral uracil and tegafur/ leucovorin adjuvant chemotherapy for patients (pts) with stage IIB/III colon cancer: Final results of JFMC33–0502

S. Sadahiro[1], T. Tsuchiya[2], K. Sasaki[3], K. Kondo[4], K. Katsumata[5], G. Nishimura[6], Y. Kakeji[7], H. Baba[8], S. Kodaira[9], S. Saji[10]. *[1]Tokai University, Gastrointestinal Surgery, Isehara, Japan; [2]Sendai City Medical Center, Gastrointestinal Surgery, Sendai, Japan; [3]Otaru Ekisaikai Hospital, Gastrointestinal Surgery, Otaru, Japan; [4]National Hospital Organization Nagoya Medical Hospital, Gastrointestinal Surgery, Nagoya, Japan; [5]Tokyo Medical University, Gastrointestinal Surgery, Tokyo, Japan; [6]Japanese Red Cross Kanazawa Hospital, Gastrointestinal Surgery, Kanazawa, Japan; [7]Kobe University, Gastrointestinal Surgery, Kobe, Japan; [8]Kumamoto University, Gastrointestinal Surgery, Kumamoto, Japan; [9]Nerima General Hospital, Surgery, Tokyo, Japan; [10]Japanese Foundation for Multidisciplinary Treatment of Cancer, Surgery, Tokyo, Japan*

Background: JFMC33–0502 study (Kondo et al. ESMO 2012, Abstract 552) seemed to offer no significant superiority of 18 months treatment of oral UFT/LV adjuvant chemotherapy to 6 months treatment with respect to the primary endpoint of disease free survival (DFS) in patients with stage IIB/III colon cancer at the interim analysis. Here, we report the final results of this study.
Material and Methods: Patients with curatively resected stage IIB/III colon cancer (PS, 0 to 1; age, 20 to 75 years; no other therapy) were randomly assigned to receive UFT (300 mg/m^2/day)/LV (75 mg/day) for 28 out of 35 days for 6 months (Control (C) arm) or for 5 consecutive days per week for 18 months (Study (S) arm). The primary endpoint was the DFS, and the secondary endpoints were overall survival (OS) and safety. Patient information was fixed in February 2013.
Results: At the time of this final analysis, median follow-up was 61 months with 334 DFS events out of 1060 pts. The 5-year DFS for the primary endpoint was 69% in the S arm and 69% in the C arm. The 5-year OS was 85% in the S arm and 85% in the C arm. The 5-year DFS for the patients with stage IIB, III disease were 79%, 67% in the S arm and 80%, 67% in the C arm, respectively. In toxicity for 6 months, S arm was more feasible than C arm with respect to symptom.
Conclusion: Superiority of prolonging the treatment duration of adjuvant chemotherapy was not demonstrated in Japanese patients with stage IIB/III colon cancer. DFS and OS in both arms were compatible with those of FOLFOX treatment previously reported in MOSAIC and NSABP C-08 trials after follow-up. UFT/LV for 6 months had low recurrence rate and less toxic chemotherapy for patients with stage IIB/III colon cancer.
No conflict of interest.

2155A ORAL

Preoperative chemoradiotherapy and postoperative chemotherapy with capecitabine and oxaliplatin versus capecitabine alone in locally advanced rectal cancer: Response to the local treatment after chemoradiation and surgery as secondary endpoint

Leuven − Campus Gasthuisberg, Internal Medicine, Leuven, Belgium*

Background: The PETACC-6 trial investigates whether the addition of oxaliplatin to preoperative oral fluoropyrimidine-based chemoradiation (CRT) followed by postoperative adjuvant fluoropyrimidine-based chemotherapy (CT) improves disease-free survival (DFS) in locally advanced rectal cancer. We report on pathological staging and sphincter preservation following preoperative CRT.
Methods: Between 11/2008 and 09/2011, patients with rectal cancer within 12 cm from the anal verge, T3/4 and/or node-positive, with no evidence of metastatic disease and considered either resectable at the time of entry or expected to become resectable, were randomly assigned to receive 5 weeks of preoperative CRT (45 Gy in 25 fractions with an optional boost to a total dose of 50.4 Gy) with capecitabine (825 mg/m^2 twice daily), followed by 6 cycles of adjuvant CT with capecitabine (1000 mg/m^2 twice daily/days 1−15 every three weeks) (arm 1) or to receive the same regimen with the addition of oxaliplatin before (50 mg/m^2/days 1, 8, 15, 22, 29) and after surgery (130 mg/m^2/day 1, every three weeks) (arm 2). Pathological down-staging (ypT0−2N0) rate, complete remission (ypT0N0) rate and tumor regression grade according to Dworak were secondary endpoints. The assessment was based on the review of the specimen and scoring by the local pathologist. Patients not operated or not resected were scored as failures (intent-to-treat analysis).
Results: 1094 patients were randomized (547 in each arm). 98% and 92% of patients respectively, received at least 45 Gy of preoperative RT in arms 1 and 2. More than 90% of full dose concurrent CT was delivered in 91% and 63% of patients in arm 1 and arm 2 respectively. R0 resection rate was 92.0% in arm 1 and 86.3% in arm 2. The ypT0N0 rate was equal in both arms with 11.3% in arm 1 and 13.3% in arm 2 (p = 0.31). There was no difference in pathological down-staging rate (43.5% in arm 1 vs. 41.5% in arm 2). In arm 2, the tumor regression according to Dworak was minimal in 13.7% of patients, moderate in 35.5%, good in 20.5% and total in 13.5%. In arm 1, the percentages were 19%, 36.2%, 19.4% and 12.4% respectively. The anal sphincter was preserved in 70% vs. 65% (p = 0.09) in arms 1 and 2. Definitive numbers will be presented at the congress.
Conclusions: The addition of oxaliplatin to preoperative fluoropyrimidine-based CRT led to decreased treatment compliance and did not result in any improvement in tumour down staging or in anal sphincter preservation.

Effects of regorafenib therapy on health-related quality of life in patients with metastatic colorectal cancer in the phase III CORRECT study

S. Siena[1], A. Grothey[2], A. Sobrero[3], A. Falcone[4], M. Ychou[5], H.J. Lenz[6], T. Yoshino[7], F. Cihon[8], V. Pawar[9], E. Van Cutsem[10]. *[1]Ospedale Niguarda Ca' Granda, Milan, Italy; [2]Mayo Clinic, Department of Oncology, Rochester, USA; [3]Ospedale San Martino, Medical Oncology, Genova, Italy; [4]University of Pisa, Department of Translational Research and New Technologies in Medicine, Pisa, Italy; [5]ICM − Val d'Aurelle, Oncology, Montpellier, France; [6]VSC/Norris Comprehensive Cancer Centre, Division of Medical Oncology, Los Angeles, USA; [7]National Cancer Center Hospital East, Department of Gastroenterology and Gastrointestinal Oncology, Chiba, Japan; [8]Bayer HealthCare Pharmaceuticals, Global Biostatistics, Montville, USA; [9]Bayer HealthCare Pharmaceuticals, Global HEOR Specialty Medicine, Montville, USA; [10]University Hospitals Leuven, Digestive Oncology, Leuven, Belgium*

Background: In the phase III CORRECT trial (NCT01103323), the multikinase inhibitor regorafenib (REG) showed significant improvement in overall survival and progression-free survival *vs* placebo (P) in patients (pts) with metastatic colorectal cancer (mCRC) whose disease had progressed on other standard therapies. The most frequent grade 3 adverse events (AEs) seen with REG were hand–foot skin reaction (HFSR), fatigue, diarrhea, hypertension, and rash. We examined the impact of REG efficacy and tolerability on quality of life (QoL).
Materials and Methods: CORRECT was an international multicenter, randomized, placebo-controlled trial sponsored by Bayer HealthCare. Adults with mCRC progressing after all standard therapies were randomized 2:1 to receive REG 160 mg (n = 505) or P (n = 255) once daily for the first 3 weeks of each 4-week cycle. Prespecified QoL analyses were undertaken using the European Organisation for the Research and Treatment of Cancer QoL questionnaire (EORTC QLQ-C30) and the EuroQol-five dimension health utility index (EQ-5D). QoL outcomes were expressed as time-adjusted area under the curve (AUC) to allow descriptive evaluations of QoL in the REG and P groups across the entire treatment period. Individual domains were compared using descriptive statistics.
Results: Overall, changes in QoL were similar in the REG and P groups: difference in least-squares (LS) mean time-adjusted AUC of EORTC QLQ-C30 score: −1.19 (95% confidence interval [CI] −3.13 to 0.75); differences in LS mean time-adjusted AUC for EQ-5D index and visual analog scale (VAS) scores: 0.00 (95% CI −0.03 to 0.03) and −1.21 (−3.04 to 0.61), respectively. Changes from baseline did not differ between Reg and P on most of the 15 domains assessed in the EORTC QLQ-C30. Change from baseline on the role functioning scale was similar overall in both groups, although scores appear to differ between REG and P at cycles 3 and 4 for the diarrhea subscale and at cycle 4 for the social functioning subscale.
Conclusion: No substantial differences in overall change in QoL were seen between REG-treated pts and P recipients. Role functioning may be impaired by AEs, but remained similar in both groups; management of AEs with dose modifications may improve role functioning and diarrhea in REG-treated pts.

LS mean time-adjusted AUC (95% CI)	P	REG
EORTC QLQ-C30	58.13 (55.72–60.53)	56.93 (54.79–59.08)
EQ-5D index	0.67 (0.64–0.70)	0.67 (0.64–0.70)
EQ-5D VAS	61.84 (59.59–64.09)	60.62 (58.62–62.63)

Enteral nutrition and prevention of anastomotic leakage: A possible role for conditional essential amino acids? Results of a randomized clinical trial

K.W.Y. Van Barneveld[1], P.G. Boelens[2], F.F.B.M. Heesakkers[3], M.D. Luyer[3], J.A. Bakker[4], H.J.T. Rutten[3], N.D. Bouvy[1]. [1]*Maastricht University Medical Centre, Surgery, Maastricht, Netherlands;* [2]*LUMC, Surgery, Leiden, Netherlands;* [3]*Catharina Hospital, Surgery, Eindhoven, Netherlands;* [4]*LUMC, Clinical Chemistry, Leiden, Netherlands*

Background: Early enteral nutrition after abdominal surgery decreases infectious complications and mortality. Amino acids play an important role as metabolic fuel for rapidly dividing cells. Low plasma L-glutamine concentrations for example, represent poor prognosis in ICU-patients. Furthermore, it has been established that the route of feeding (enteral vs. parenteral) has implications for the metabolism of amino acids.
Methods: A total of 123 patients with rectal carcinoma were included in this prospective randomised controlled trial. Preoperatively, patients were randomised into two groups: early postoperative enteral feeding through a nasojejunal tube (EEN, n = 61) or parenteral feeding through a jugular vein catheter (EPN, n = 62). 8 hours after the surgical procedure feeding was started in hemodynamically stable patients. Both groups were stimulated to normal oral diet. Parenteral feeding was chosen as a control to ensure caloric equivalence between both groups. Blood samples were collected preoperatively and at POD +1 and +5. Plasma L-glutamine, L-citrulline and L-arginine levels were analysed using a validated UPLC-tandem mass spectrometric method.
Results: Baseline amino acid levels were comparable for both groups. Directly after rectal surgery, a decrease in all amino acid concentrations was seen. Plasma L-glutamine levels were higher in the EPN group compared to the EEN group both on postoperative day 1 (401.6 μmol/l ± 94.3 vs. 351.4±123, p = 0.013) and day 5 (441.6 μmol/l ± 119.7 vs. 395.5±110.7, p = 0.006). L-citrulline levels did not differ. L-arginine levels were significantly elevated in the EPN group compared to the EEN group at both day 1 (51.5 μmol/l ± 15.3 vs. 40.4±13.7, p = 0.008) and day 5 (77.4 μmol/l ± 27.7 vs. 61.6±21, p = 0.008). Because the EEN group showed a significantly lower number of anastomotic leakages (n = 1) compared to the EPN group (n = 9, $p = 0.009$), plasma amino acid levels were correlated with infectious complications. An inverse relation between the amino acid levels at day 5 and the occurrence of infectious complications was found. Moreover, the longer the surgical duration, the more blood loss was observed both inversely related to plasma L-citrulline and L-arginine on day 1.
Conclusion: Directly after major rectal surgery a strong decrease in plasma amino acid concentrations occurs. After early feeding plasma concentrations increase in both groups. Lower plasma L-glutamine and L-arginine levels were associated with characteristics of major surgery, e.g. longer duration of surgery, more blood loss and more infectious complications. Early parenteral feeding was associated with higher plasma glutamine, citrulline and arginine concentrations. We previously showed that enteral nutrition resulted in less anastomotic leakage, infectious complications and a shorter hospital stay than parenteral nutrition. Therefore, we hypothesized that plasma glutamine and arginine concentrations do not provide the explanation of the beneficial effect of enteral feeding on the intestinal anastomosis or infectious complications.

The impact of young age on survival in patients with metastatic colorectal cancer: Analysis from the ARCAD Clinical Trials Program

C. Lieu[1], L. Renfro[2], A. De Gramont[3], T.S. Maughan[4], M.T. Seymour[5], L. Saltz[6], R.M. Goldberg[7], D. Sargent[2], S.G. Eckhardt[1], C. Eng[8]. [1]*University of Colorado, Division of Medical Oncology, Aurora CO, USA;* [2]*Mayo Clinic, Division of Biomedical Statistics and Informatics, Rochester MN, USA;* [3]*Saint-Antoine Hospital, Division of Medical Oncology, Paris, France;* [4]*University of Oxford, Department of Oncology, Oxford, United Kingdom;* [5]*University of Leeds, Section of Oncology and Clinical Research, Leeds, United Kingdom;* [6]*Memorial Sloan-Kettering Cancer Center, Department of Gastrointestinal Cancer, New York NY, USA;* [7]*Ohio State University, Division of Medical Oncology, Columbus OH, USA;* [8]*The University of Texas MD Anderson Cancer Center, Department of Gastrointestinal Medical Oncology, Houston TX, USA*

Background: The median age of diagnosis of colorectal cancer (CRC) is 69 years. Patients younger than 50 years of age comprise 4.6% of the total incidence of CRC, but the incidence of CRC in the younger population is increasing. Only 5−7% of young-onset CRC cases are attributable to hereditary factors, and young patients with CRC present more commonly with stage III or IV disease. The purpose of this study is to assess whether age is prognostic for overall survival (OS) and progression-free survival (PFS) in patients with metastatic CRC. Previous investigations have treated age as dichotomized (e.g., <40 vs. >=40) and thus directly compared two groups representing broad pooled risk. Here, to obtain a better picture of the age-response relationship, we identify whether and how risk changes as a continuous (rather than categorized) function of age.
Materials and Methods: We analyzed data from the ARCAD Foundation CRC database which included 20,326 patients from 23 frontline phase III clinical trials, including trials with biologic agents. Endpoints included OS and PFS; primary covariates included age, sex, and performance status (PS). Cox proportional hazards models stratified by treatment arm within study were used to model primary age effects, as well as interactions with and/or adjustments for sex and PS. Patients without events by 1 year were right-censored. Non-linearity of age on the log relative hazard of PFS and OS was modeled using restricted cubic splines.
Results: 19,900 patients were evaluable for OS and PFS, of which 695 (3%) were younger than 40 years old. Age was prognostic for both OS ($p < 0.0001$) and PFS ($p < 0.0001$) with U-shaped risk for each endpoint; i.e., the highest risk of OS and PFS was evident in the youngest and oldest patients, while 57-year-olds and 61-year olds demonstrated the lowest risk of OS and PFS, respectively. Relative to these ages, the youngest CRC patients experienced 30% increased risk of death and 28% increased risk of progression or death (PFS) during the follow-up period. In contrast, the oldest CRC patients experienced a 72% increased risk of death and 19% increased risk of progression or death (PFS) in the follow-up period. Poor PS was significantly associated with decreased survival in younger patients but not older patients (interaction $p = 0.0001$). Sex was statistically but not clinically significant as an adjustment variable in these models.
Conclusions: Young age is associated with poorer OS and PFS in treated patients with metastatic CRC. Poor PS is also significantly associated with decreased survival in younger patients, though PS assessment may be subject to bias. Young patients with metastatic CRC represent a high-risk population for treatment failure and further studies identifying biological differences are warranted.

Updated efficacy/safety findings from a randomized, phase 2 study of bevacizumab plus mFOLFOX6 or FOLFOXIRI in patients with initially unresectable liver metastases from colorectal cancer (OLIVIA study)

J. Bridgewater[1], R. Adam[2], I. Chau[3], P. García Alfonso[4], M. Rivoire[5], S. Lasserre[6], M. Loeffler[7], T. Gruenberger[8]. [1]*University College London Cancer Institute, London, United Kingdom;* [2]*AP-HP Hôpital Paul Brousse Université Paris-Sud, Surgical Oncology, Villejuif, France;* [3]*The Royal Marsden NHS Foundation, Medical Oncology, Sutton, United Kingdom;* [4]*Hospital General Universitario Gregorio Marañón, Medical Oncology, Madrid, Spain;* [5]*Léon Bérard Cancer Center, Surgery, Lyon, France;* [6]*F. Hoffmann-La Roche Ltd, Statistics, Basel, Switzerland;* [7]*F. Hoffmann-La Roche Ltd, Medical, Basel, Switzerland;* [8]*Medical University Hospital, Surgical Oncology, Vienna, Austria*

Background: For patients with borderline resectable colorectal cancer liver-only metastases (CLMs), chemotherapy may downsize metastases and facilitate secondary resection. Intensified chemotherapy or the addition of a targeted agent may improve resection rates, but the optimal regimen remains undefined. OLIVIA aimed to determine if adding irinotecan to FOLFOX in combination with bevacizumab improved resection rates in patients with unresectable CLMs.
Material and Methods: OLIVIA was a multinational open-label phase 2 study in which patients with unresectable CLMs were randomized to bevacizumab (BEV) + mFOLFOX6 or FOLFOXIRI q2w. Unresectability was defined as ⩾1 of the following: no possibility of upfront R0/R1 resection of all hepatic lesions; <30% estimated residual liver after resection; or disease in contact with major vessels of the remnant liver. Resectability was assessed by interdisciplinary review. The primary endpoint was overall resection rate (R0/R1/R2). ClinicalTrials.gov identifier: NCT00778102.
Results: From 10/2008 to 12/2011, 80 patients were randomized to mFOLFOX6-BEV (n = 39) or FOLFOXIRI-BEV (n = 41). Patients were male (46% vs 71%), age ⩾60 y (36% vs 63%), with metastatic (82% vs 73%) or locoregional (18% vs 27%) disease in the mFOLFOX6-BEV and FOLFOXIRI-BEV arms, respectively. Efficacy outcomes are shown in the table. By 31 July 2012, 8 and 3 patients in the mFOLFOX6-BEV and FOLFOXIRI-BEV groups, respectively, had died. Follow-up is ongoing. Grade ⩾3 adverse events occurred in 84% and 95% of patients receiving mFOLFOX6-BEV and FOLFOXIRI-BEV, respectively, and included neutropenia (35% vs 48%; febrile, 8% vs 13%) and diarrhoea (14% vs 28%).

Table (abstract 2159).

Endpoint	mFOLFOX6-BEV (n = 39)	FOLFOXIRI-BEV (n = 41)	Difference	*P*
Resection R0/1/2 rate, % (95% CI)	48.7 (32.4–65.2)	61.0 (44.5–75.8)	12.3 (−11.0–35.5)	0.271
Histopathological response rate, n (%)*	7/14 (50)	10/20 (50)	0	1.0
Radiological response rate, % (95% CI)	61.5 (44.6–76.6)	80.5 (65.1–91.2)	18.9 (−2.1–40.0)	0.061
Median progression-free survival, mo (95% CI)†	12.0 (9.5–14.1)	18.8 (12.4–21.0)	–	0.0009
R0/R1	13.6 (9.8–15.9)	21.0 (16.0–31.8)	–	–
R2/other outcome	10.3 (7.4–12.4)	12.4 (8.5–19.6)	–	–

*Complete or major response (Blazer et al. JCO 2008); †Updated analysis (15 March 2013).

Conclusions: FOLFOXIRI-BEV was associated with higher resection and response rates and prolonged progression-free survival compared with mFOLFOX6-BEV in patients with initially unresectable CLMs. FOLFOXIRI-BEV should be evaluated further in this setting.

Prognostic impact of specific KRAS mutations in codon 12 and 13 in 2,165 BRAF-wildtype colon cancers: results from NCCTG (Alliance) trial N0147

H.H. Yoon[1], D. Tougeron[2], M.R. Mahoney[3], Q. Shi[3], G.D. Nelson[3], S.G. Nair[4], D.J. Sargent[3], S.N. Thibodeau[5], F.A. Sinicrope[2], S.R. Alberts[1]. *[1]Mayo Clinic, Medical Oncology, Rochester Minnesota, USA; [2]Mayo Clinic, Gastroenterology & Hepatology, Rochester Minnesota, USA; [3]Mayo Clinic, Alliance Statistics and Data Center, Rochester Minnesota, USA; [4]Lehigh Valley Hospital, Medical Oncology, Allentown PA, USA; [5]Mayo Clinic, Laboratory Medicine and Pathology, Rochester Minnesota, USA*

Background: Studies suggest that specific mutations in *KRAS* may differentially impact prognosis of colorectal cancer patients, but prior patient populations have been heterogeneous by disease stage and therapies received, and results have been inconsistent. We examined the prognostic impact of specific *KRAS* mutations in stage 3 colon cancer patients receiving FOLFOX alone or combined with cetuximab as adjuvant therapy in a phase 3 clinical trial. Analysis was focused on *BRAF*-wildtype tumors, given that $BRAF^{V600E}$ mutation was associated with poor prognosis in this cohort, and *BRAF* and *KRAS* mutations are mutually exclusive.

Material and Methods: *KRAS* mutations in codon 12 (6 mutations: G12A, G12R, G12D, G12C, G12S and G12V) and codon 13 (1 mutation: G13D) were examined in 2,165 colon adenocarcinomas found to carry wildtype *BRAF* from an adjuvant study, NCCTG N0147. *KRAS* was analyzed using the DxS mutation test kit (Manchester, UK) in a CLIA-certified laboratory. Given the lack of an interaction between *KRAS* status and treatment (P>.30), treatment arms were pooled for analysis. The primary endpoint, disease-free survival (DFS), was evaluated by hazard ratios (HR) using Cox models.

Results: Compared to patient tumors with wildtype copies of *KRAS* and *BRAF*, those with *KRAS* mutations in either codon 12 or 13 experienced significantly shorter DFS (Table). In multivariate analysis, 4 (G12R, G12D, G12S and G13D) of the 7 *KRAS* mutations, including those in codon 13, were significantly associated with shorter DFS as compared to *KRAS*-wildtype cancers (P < 0.5). Compared to *KRAS* wildtype, codon 12 and 13 mutations were each associated with right-sided (*v* left) tumor site (P < 0.001).

Conclusions: In a clinical trial population, we demonstrate for the first time that *KRAS* mutations in either codon 12 or 13 are associated with inferior disease-free survival in patients with stage 3 *BRAF*-wildtype colon cancer receiving FOLFOX as adjuvant therapy.

No conflict of interest.

Evaluation of PIK3CA mutation as a predictor of benefit from NSAID therapy in colorectal cancer

D. Church[1], E. Domingo[2], O. Sieber[3], R. Ramamoorthy[4], B. Davidson[4], D.J. Kerr[5], R. Midgley[5], I.P.M. Tomlinson[6]. *[1]Oxford Cancer Centre University of Oxford, Medical Oncology, Oxford, United Kingdom; [2]Wellcome Trust Centre for Human Genetics University of Oxford, Molecular and Population Genetics, Oxford, United Kingdom; [3]Ludwig Institute for Cancer Research, Ludwig Colon Cancer Initiative Laboratory, Melbourne, Australia; [4]University College London Royal Free Hospital, Division of Surgery and Interventional Science, London, United Kingdom; [5]Oxford Cancer Centre Churchill Hospital, Medical Oncology, Oxford, United Kingdom; [6]The Wellcome Trust Centre for Human Genetics University of Oxford, Molecular and Population Genetics Laboratory, Oxford, United Kingdom*

Background: Aspirin and other NSAIDs protect against colorectal cancer (CRC) and are associated with reduced disease recurrence and improved outcome following primary treatment. However, toxicities of NSAIDs have limited their use as antineoplastic therapy. Recent data have suggested that the benefit of aspirin after CRC diagnosis is limited to patients with *PIK3CA*-mutant cancers. We sought to determine the predictive utility of *PIK3CA* mutation for benefit from both COX-2 inhibition and aspirin.

Material and Methods: We performed molecular analysis of tumours from 896 participants in VICTOR, a large randomized trial comparing rofecoxib with placebo following primary CRC resection. We compared relapse-free survival (RFS) and overall survival (OS) between rofecoxib therapy and placebo, and between the use and non-use of low-dose aspirin, according to tumour *PIK3CA* mutation status.

Results: We found no evidence of a greater benefit from rofecoxib treatment compared to placebo in patients whose tumour had *PIK3CA* mutation (multivariate adjusted hazard ratio [HR]; 1.2, 95% CI 0.53–2.72; $P = 0.66$; $P_{INTERACTION}=0.47$), compared with *PIK3CA* wild-type cancers (HR 0.87; 95% CI 0.64–1.16; $P = 0.34$). In contrast, regular aspirin use after CRC diagnosis was associated with a reduced rate of CRC recurrence in patients with *PIK3CA*-mutant cancers (HR 0.11; 95% CI 0.001 to 0.832; $P = 0.027$; $P_{INTERACTION}=0.024$), but not in cases lacking tumour *PIK3CA* mutation (HR 0.92; 95% CI 0.60–1.42; $P = 0.71$).

Conclusion: Although tumour *PIK3CA* mutation does not predict benefit from rofecoxib treatment, it merits further evaluation as a predictive biomarker for aspirin therapy. Our findings are concordant with recent data, and support the prospective investigation of adjuvant aspirin in *PIK3CA*-mutant CRC.

Background: Bevacizumab (bev)-based therapy has demonstrated clinical efficacy for the neoadjuvant treatment of patients with CLLM. There are no data concerning the benefit of bev maintenance therapy after induction with bev-based therapy for patients who underwent R0 liver resection.
Methods: Untreated metastatic pts with histologically confirmed colorectal cancer with liver-limited mets were treated before surgery with the combination therapy mFOLFOX-6/bev for 5 cycle followed by one cycle of mFOLFOX6 alone (without bev). Postoperative chemotherapy + bev was restarted 5 weeks after surgery: patients were treated with the combination therapy mFOLFOX-6 + bevacizumab for additional 6 cycles. Immediately at the end of the post-operative phase, patients were treated with bev alone for 52 weeks (1 year). We report here an IA for the first 26 out of pre-planned 77 pts. Pts received oxaliplatin 85 mg/m^2 by intravenous infusion (i.v) on day1, i.v. LV 200 mg/m^2 on day 1, followed by 5-FU 2,400 mg/m^2, by continuous infusion over 46 hours + bev 5 mg/kg i.v on day 1 q2w. Eligibility criteria included adequate organ function and ECOG PS 0−1. All pts were candidates for neoadjuvant therapy and categorized according to the following surgical criteria: i) unresectable CLLM, ii) borderline resectable CLLM, where R0 surgery cannot be guaranteed iii) 'high risk' resectable CLLM based on number and mets size. Primary endpoint was ORR.
Results: According to ITT analysis, 26 out of 27 enrolled pts were assessable for ORR. Pts characteristics were: sex 18M/8F, median age 64.5 years [37−77], PS 0/1: 23/3. Site of primary tumor: rectum 2, colon 24. Synchronous/metachronous metastases: 24/2. Unresectable 14, borderline resectable 6, 'high risk' resectable 6. ORR was 16 responders (61.5%,all PR) and 10 non-responders [38.5%: 7 SD (26.9%) and 3 withdrawals], respectively. Fourteeen (53.8%) underwent R0 liver resection. Grade 3 related AEs (%) were: neutropenia 1 (3.8%) [and 2 G4 (7.6%)], myocardial infarction 1 (3.8%), fatigue 2 (7.6%), proteinuria 1 (3.8%), hypertransaminasemia 1 (3.8%).
Conclusions: IA results show high RR of mFOLFOX6/bev in CLLM treatment, resulting in high rate of R0 liver resection with good safety profile. Data should be confirmed and the role of bev maintenance elucidated with trial final results.
Conflict of interest: *Corporate-sponsored research: ROCHE*

2163 POSTER DISCUSSION

Endoscopy-based follow-up of clinical complete responders after chemoradiation for rectal cancer during a non-operative 'wait-and-see' policy

L.A. Heijnen[1], M. Maas[2], M.H. Martens[1], D.M.J. Lambregts[2], E. Van Drie[2], L.P.S. Stassen[3], S.O. Breukink[3], J.W.A. Leijtens[4], R.G.H. Beets-Tan[2], G.L. Beets[3]. [1]*Maastricht University Medical Centre, Radiology/Surgery, Maastricht, Netherlands;* [2]*Maastricht University Medical Centre, Radiology, Maastricht, Netherlands;* [3]*Maastricht University Medical Centre, Surgery, Maastricht, Netherlands;* [4]*Laurentius Ziekenhuis Roermond, Surgery, Roermond, Netherlands*

Background: The standard treatment for locally advanced rectal cancer is chemoradiation (CRT) followed by surgery. In 15−25% of the patients CRT leads to a complete tumour response (CR), which has excellent long-term outcome. When accurately selected, these patients may also opt for a non-operative treatment ('wait-and-see'). Adequate monitoring then becomes crucial to ensure a persistent complete response and to detect any potential recurrence as early as possible. Aim of this prospective cohort study was to describe the rectal wall morphology on endoscopy during the follow-up of patients with a clinical complete response who are treated with a 'wait-and-see' policy.
Materials and Methods: 44 patients with a clinical suggestion of CR were included. The criteria for CR on endoscopy were [1] white scar with telangiectasia and/or [2] small superficial ulcer, strengthened by negative biopsies. Follow-up consisted of 3-monthly (first two years) to 6-monthly (>2 years) endoscopy, which served as the standard of reference, in addition to MRI, CEA, and CT of thorax&abdomen.
Results: Mean follow-up was 27 months (range 2−91). At the moment of inclusion endoscopy showed a white scar with telangiectasia in 38/44 patients, which persisted during follow-up. In 6/44 patients a small superficial ulcer was observed, which changed into a white scar with telangiectasia after three months for 4/6 patients. The remaining 2 developed a local recurrence within two years. For patient 1 the ulcer disappeared during follow-up but no typical white scar was observed. After 23 months a bulge was observed, which was proven to be recurrent adenocarcinoma by biopsy. For patient 2 the recurrence was already observed after three months, suggesting an incomplete response at the time of selection. Both patients were treated with salvage surgery.
Conclusion: In a 'wait-and-see' policy for patients with a complete response after chemoradiation for rectal cancer, endoscopy can be used as a standard of reference to monitor the local status. An endoscopic complete response is observed as a white scar with telangiectasia. A small superficial ulcer after chemoradiation deserves attention and close follow-up with short intervals.
No conflict of interest.

2164 POSTER DISCUSSION

Primary tumour lymph node status is associated with survival after cytoreductive surgery and hyperthermic intraperitoneal chemotherapy for colorectal peritoneal carcinomatosis

A.M. Mehta[1], A.M.J. Kuijpers[1], A.G.J. Aalbers[1], I.H. De Hingh[2], B. Van Ramshorst[3], R.J. Van Ginkel[4], A.J. Bremers[5], E.A. Te Velde[6], V.J. Verwaal[1]. [1]*Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Department of Surgical Oncology, Amsterdam, Netherlands;* [2]*Catharina Hospital, Department of Surgery, Eindhoven, Netherlands;* [3]*St Antonius Hospital, Department of Surgery, Nieuwegein, Netherlands;* [4]*University Medical Center Groningen, Department of Surgical Oncology, Groningen, Netherlands;* [5]*University Medical Center Radboud, Department of Surgical Oncology, Nijmegen, Netherlands;* [6]*VU Medical Center, Department of Surgical Oncology, Amsterdam, Netherlands*

Background: This study evaluated the association of primary tumour nodal status with outcome after CytoReductive Surgery (CRS) combined with Hyperthermic IntraPEritoneal Chemotherapy (HIPEC) for peritoneal metastases of colorectal origin in the Netherlands.
Patients and Methods: A multi-institutional database of patients treated by the Dutch CRS-HIPEC protocol for peritoneal carcinomatosis (PC) from colorectal cancer was established. Patient, tumour and treatment characteristics were prospectively obtained. The primary end point was overall survival (OS). Secondary end points were surgical outcome and disease-free survival (DFS).
Results: Of 660 patients treated for colorectal PC, extent of nodal involvement of the primary tumour was known in 557 patients. 365 patients (55%) had lymph node metastases at the time of the primary tumour.
Lymph node positivity was significantly associated with increased intraperitoneal tumorload ($P = 0.03$) at the time of CRS-HIPEC but not with completeness of macroscopic cytoreduction.
Median OS was 44 (95% confidence interval (CI): 30−58) months for node-negative patients and 28 (95% CI: 25−31) months for node-positive patients. 5-year OS rates differed significantly between node-negative and node-positive patients (41% versus 24%; $P = 0.001$). Median DFS was 20 (95% CI: 14−26) months for node-negatives and 14 (95% CI: 12−16) months for node-positives. 5-year DFS rates also differed significantly between node-negative and node-positive patients (26% versus 13%; $P = 0.003$). In multivariate analysis, lymph node positivity was shown to be an independent predictor of decreased OS (HR 1.5; 95% CI: 1.0−2.0; $P = 0.03$) and decreased DFS (HR 1.5; 95% CI: 1.1−2.0; $P = 0.01$).
Patterns of recurrence after CRS-HIPEC did not differ significantly between node-negatives and node-positives, with intraperitoneal recurrences occurring in 55% and 53%, respectively ($P > 0.05$).
Conclusion: This study shows that survival of patients with colorectal peritoneal carcinomatosis following CRS-HIPEC is significantly and independently determined by the nodal status of the primary tumour. Moreover, in patients with peritoneal carcinomatosis lymph node positivity does not lead to an increased tendency to develop systemic recurrences (as is the case in primary colorectal carcinoma); this would suggest that the biological behaviour of peritoneal metastases is significantly different from primary colorectal cancer.
No conflict of interest.

Table (abstract 2165).

Barrier	Solution
Mutation analysis and genetic counselling is not feasible in all colorectal cancer patients	Select patients based on IHC
Using IHC, most identified cases are sporadic and caused by methylation of *MLH1*	Perform *MLH1* promoter methylation analysis
Molecular screening does not identify mutations with retained protein expression, hereditary *MLH1* methylation or other hereditary syndromes	Molecular screening is a supplement to family history
Several Lynch Syndrome patients do not have a significant family history or are older than 50 years	
− Screening strategy has to be simple	Screen all patients independently of age or other criteria
Primary tumor is often not resected or not representative – stage IV – preoperative radiotherapy and/or chemotherapy	Encourage IHC on biopsies
Screening result should be ready along with the final diagnosis and staging	– Close collaboration between pathology and genetic laboratory – Fast methylation analysis
Interpretation of IHC and methylation is a specialist task	The pathologist should be the driving force and should interpret and report the results to the clinicians
In daily clinic deviations and exceptions from standard care are common	Develop guidelines, establish databases, perform quality control, and give feed-back

2165 POSTER DISCUSSION

Barriers to population based screening for Lynch Syndrome in colorectal cancer and how to overcome them

L.H. Jensen[1], A. Bojesen[1], L. Byriel[1], K.U. Hansen[2], T.P. Hansen[3], M. Hardt-Madsen[4], C. Ladefoged[5], J. Lindebjerg[1], L.B. Ousager[6], I. Bernstein[7]. [1]*Vejle Hospital, Danish Colorectal Cancer Group South, Vejle, Denmark;* [2]*Esbjerg Hospital, Pathology, Esbjerg, Denmark;* [3]*Odense University Hospital, Pathology, Odense, Denmark;* [4]*Svendborg Hospital, Pathology, Svendborg, Denmark;* [5]*Sønderborg Hospital, Pathology, Sønderborg, Denmark;* [6]*Odense University Hospital, Clinical Genetics, Odense, Denmark;* [7]*Hvidovre Hospital, HNPCC Register, Hvidovre, Denmark*

Background: Lynch Syndrome is caused by germline mutation in the mismatch repair genes *MLH1*, *PMS2*, *MSH2*, or *MSH6*. Patients with Lynch Syndrome and their families must receive genetic counselling in order to identify all relatives at risk and to undergo surveillance for new cancers. We have established a true population based molecular screening for Lynch Syndrome in colorectal cancer patients and present here the challenges that must be met should the screening be efficient in daily clinic.
Materials and Methods: Patients diagnosed with colorectal cancer in a geographically defined area of 1,200,000 inhabitants were included during two years. Immunohistochemistry (IHC) was performed for pMLH1, pPMS2, pMSH2, and pMSH6 followed by *MLH1* promoter methylation analysis in cases with loss of pMLH1. Genetic counselling was indicated if any of the mismatch repair proteins were not expressed, but not if pMLH1 negative cases had *MHL1* methylation. Reminders were sent every 3−6 months if data was not reported to the national pathology database. 2,120 patients have been included and data is now available for 1932. Screening was positive in 54 patients.
Results: See the table.
Conclusion: Population based screening for possible Lynch Syndrome was positive in 54 of 1932 patients (2.8%). During the study, important barriers were identified and we suggest solutions that proved to work in daily clinic.
No conflict of interest.

2166 POSTER DISCUSSION

Updated results including quality of life of the phase III CAIRO3 study of the Dutch Colorectal Cancer Group (DCCG): Maintenance treatment with capecitabine and bevacizumab versus observation after induction treatment with chemotherapy and bevacizumab in metastatic colorectal cancer (mCRC)

C.J.A. Punt[1], L.H.J. Simkens[2], A. May[3], L. Mol[4], A.H. Honkoop[5], C.J. Rodenburg[6], P.J.C. Zoon[7], P. Schiphorst[8], H. Van Tinteren[9], M. Koopman[3]. [1]*Academic Medical Amsterdam, Medical Oncology, Amsterdam, Netherlands;* [2]*Academic Medical Center Amsterdam, Medical Oncology, Amsterdam, Netherlands;* [3]*University Medical Center Utrecht, Medical Oncology, Utrecht, Netherlands;* [4]*Comprehensive Cancer Centre the Netherlands (IKNL), Trial office, Amsterdam, Netherlands;* [5]*Isala kliniek, Medical Oncology, Zwolle, Netherlands;* [6]*Meander Medical Center, Medical Oncology, Amersfoort, Netherlands;* [7]*St Jansdal Hospital, Medical Oncology, Harderwijk, Netherlands;* [8]*Koningin Beatrix Hospital, Medical Oncology, Winterswijk, Netherlands;* [9]*The Netherlands Cancer Institute, Statistics, Amsterdam, Netherlands*

Background: The optimal duration of chemotherapy and bevacizumab in mCRC is not well established. The CAIRO3 study investigated the efficacy of maintenance treatment with capecitabine plus bevacizumab versus observation in mCRC patients (pts) not progressing during induction treatment with capecitabine, oxaliplatin and bevacizumab (CAPOX-B).
Material and Methods: Previously untreated mCRC pts, PS 0−1, with stable disease or better after 6 cycles of CAPOX-B, not eligible for metastasectomy and eligible for future treatment with oxaliplatin, were randomized between observation (arm A) or maintenance treatment with capecitabine 625 mg/m^2 bid daily continuously and bevacizumab 7.5 mg/kg iv q 3 weeks (arm B). Upon first progression (PFS1), pts in both arms were treated with CAPOX-B until second progression (PFS2, primary endpoint). For pts not able to receive CAPOX-B upon PFS1, PFS2 was considered equal to PFS1. Secondary endpoints were overall survival (OS) and time to second progression (TTP2), which was defined as the time to progression or death on any treatment following PFS1. All endpoints were calculated from the time of randomization. This trial is registered with ClinicalTrials.gov with the number NCT00442637.
Results: A total of 558 pts were randomized. Median follow-up is 39 months. The median number of maintenance cycles in arm B was 9 (range 1−54). The median PFS1 in arm A vs B was 4.1 vs 8.5 months (HR 0.44, 95% CI 0.37–0.53, $p < 0.0001$). Upon PFS1, 75% of pts received CAPOX-B in arm A and 47% in arm B. The median PFS2 was 10.5 vs 11.5 months (HR 0.81, 95% CI 0.67–0.98, $p = 0.03$). The median TTP2 and OS in arm A vs B were 14.1 vs 18.7 months (HR 0.67, 95% CI 0.56–0.82, $p < 0.0001$), and 18.0 vs 21.7 months (HR 0.87, 95% CI 0.71–1.06, $p = 0.16$), respectively. The overall quality of life (QoL) was not significantly different between the 2 treatment arms.
Conclusions: Maintenance treatment with capecitabine plus bevacizumab after 6 cycles CAPOX-B significantly prolonged PFS2. The small absolute difference in PFS2 may be due to the low percentage of pts in arm B that received CAPOX-B following PFS1. Maintenance treatment also significantly prolonged PFS1 and TTP2. The observed benefit in median OS was not statistically significant. Our data support the use of maintenance treatment with chemotherapy plus bevacizumab until progression or unacceptable toxicity. Subset analyses will be presented.
No conflict of interest.

2167 POSTER DISCUSSION

The SOFT study: A randomized phase III trial of S-1/oxaliplatin (SOX) plus bevacizumab versus 5-FU/l-LV/oxaliplatin (mFOLFOX6) plus bevacizmab in patients with metastatic colorectal cancer [SOFT Study Group]

H. Matsumoto[1], Y. Yamada[2], D. Takahari[3], H. Baba[4], K. Yoshida[5], Y. Komatsu[6], T. Satoh[7], K. Muro[3], Y. Shimada[2], K. Sugihara[8]. [1]*Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Department of Surgery, Tokyo, Japan;* [2]*National Cancer Center Hospital, Gastrointestinal Oncology Division, Tokyo, Japan;* [3]*Aichi Cancer Center Hospital, Department of Clinical Oncology, Nagoya, Japan;* [4]*Kumamoto University, Department of Gastroenterological Surgery, Kumamoto, Japan;* [5]*Gifu University School of Medicine, Department of Surgical Oncology, Gifu, Japan;* [6]*Hokkaido University Hospital, Department of Cancer Center, Sapporo, Japan;* [7]*Osaka University, Department of Frontier Science for Cancer and Chemotherapy, Osaka, Japan;* [8]*Tokyo Medical and Dental University Graduate School, Department of Surgical Oncology, Tokyo, Japan*

Background: Several studies of oxaliplatin plus S-1 combination therapy (SOX) conducted in Asia have shown promising efficacy and safety for metastatic colorectal cancer (mCRC), suggesting the potential to replace mFOLFOX6. The SOFT study (JapicCTI-090699) is a randomized

phase III trial designed to evaluate non-inferiority of SOX plus bevacizmab (SOX+Bev) to mFOLFOX6 plus bevacizmab (mFOLFOX6+Bev) for patients (pts) with mCRC.
Methods: Chemotherapy-naive pts with mCRC, an ECOG PS of 0−1, and adequate organ functions were randomly assigned to receive either mFOLFOX6+Bev (5 mg/kg of bevacizumab, followed by 200 mg/m^2 of *l*-leucovorin given simultaneously with 85 mg/m^2 of oxaliplatin, followed by a 400 mg/m^2 bolus of 5-FU on day 1 and then 2,400 mg/m^2 of 5-FU over 46 h, every 2 weeks) or SOX+Bev (7.5 mg/kg of bevacizumab, 130 mg/m^2 of oxaliplatin on day 1, and 40−60 mg of S-1 twice daily for 2 weeks, followed by a 1-week rest). The primary endpoint was PFS. A sample size of 225 pts per group was estimated to be necessary based on a median PFS of 10.0 months in each group and an 80% power to demonstrate non-inferiority of SOX+Bev with a 2.5-month margin (hazard ratio, HR = 1.33) and a 2-sided alpha of 0.05.
Results: A total of 512 pts were enrolled from February 2009 to March 2011. Data were analyzed after confirming >388 events as planned. Demographic factors were well balanced. The median PFS was 11.5 months (95% CI: 10.7–13.2) for mFOLFOX6+Bev and 11.7 months (95% CI: 10.7–12.9) for SOX+Bev. The adjusted HR for PFS was 1.043 (95% CI: 0.860–1.266), and the p value for non-inferiority was 0.0139. RR was 62.7% for mFOLFOX6+Bev and 61.5% for SOX+Bev. A waterfall plot analysis to investigate tumor shrinkage of target lesions disclosed that the response rates of target lesions at 8 weeks and 16 weeks and the maximum tumor response rate were 42.9%, 63.5% and 71.7% for mFOLFOX6+Bev and 40.3%, 58.8% and 72.3% for SOX+Bev, respectively. Grade >3 adverse events (%) with mFOLFOX6+Bev/SOX+Bev were leukopenia (8.4/2.4), neutropenia (33.7/8.8), anorexia (1.2/5.2) and diarrhea (2.8/9.2).
Conclusions: Consistent with the primary and secondary endpoints, the findings of a waterfall plot analysis support our conclusion that SOX+Bev was evaluated to be non-inferior to mFOLFOX6+Bev and could be one of the 1st line chemotherapies for mCRC pts.

2168 POSTER DISCUSSION

Updated survival analysis of EXPERT-C, a randomized phase II trial of neoadjuvant capecitabine and oxaliplatin (CAPOX) and chemoradiotherapy (CRT) with or without cetuximab in MRI-defined high risk rectal cancer patients

F. Sclafani[1], D. Cunningham[1], J. Tabernero[2], B. Glimelius[3], A. Cervantes[4], C. Peckitt[1], D. Tait[1], G. Brown[1], D. Gonzalez De Castro[1], I. Chau[1].
[1]The Royal Marsden, Department of Medicine, Sutton Surrey London, United Kingdom; [2]Vall d'Hebron University Hospital, Medical Oncology Department, Barcelona, Spain; [3]Akademiska Sjukhuset Uppsala, Department of Radiology Oncology and Radiation Science, Uppsala, Sweden; [4]Institute of Health Research Hospital Clinic of Valencia, Department of Hematology and Medical Oncology, Valencia, Spain

Background: EXPERT-C was a multicentre, randomised phase II trial of neoadjuvant CAPOX and CRT ± cetuximab in patients with MRI defined high-risk rectal cancer patients. We have shown previously that the addition of cetuximab did not result in a significant improvement in complete response (CR) and progression-free survival (PFS). However, in the initial analysis, a statistically significant overall survival (OS) benefit was observed in the group of KRAS/BRAF wild type (WT) patients. Here, we report the survival outcomes with extended follow-up.
Material and Methods: Between October 2005 and July 2008, 164 eligible patients were randomly assigned to 4 cycles of CAPOX followed by capecitabine CRT, surgery, and 4 cycles of adjuvant CAPOX (n = 81) or the same regimen plus weekly cetuximab (CAPOX-C, n = 83). The primary endpoint was CR in KRAS/BRAF WT patients (n = 90). PFS and OS in KRAS/BRAF WT and overall populations were secondary endpoints and estimated by using the Kaplan–Meier method.
Results: After a median follow-up of 63.1 months (95% CI: 61.0–65.3) 52 events were observed, 28 in the CAPOX arm and 24 in the CAPOX-C arm. In the KRAS/BRAF WT group, the 5-year PFS rates were 67.8% (95% CI: 53.9–81.7) and 80.0% (95% CI: 68.2–91.8) for CAPOX and CAPOX-C, respectively (p = 0.21). No difference in local and distant relapse rates between the two arms was found. The 5-year OS rates were 72.3% (95% CI: 59.0–85.6) and 84.3% (95% CI: 73.5–95.1) (p = 0.20). In the entire population, the 5-year PFS rates were 64.8% (95% CI: 54.2–75.4) and 72.0% (95% CI: 62.2–81.8) for CAPOX and CAPOX-C, respectively (p = 0.36). The 5-year OS rates were 68.5% (95% CI: 58.3–78.7) and 77.8% (95% CI: 68.8–86.8) (p = 0.13). Irrespective of the treatment received, pathologic CR (pCR) was associated with a significant improvement in relapse-free survival (92.6% vs 73.7%, p = 0.04) and OS (96.3% vs 77.3%, p = 0.02).
Conclusions: Neoadjuvant chemotherapy before standard CRT was associated with promising long-term outcomes in high-risk rectal cancer patients. Based on the absence of improvement in any of the study endpoints, cetuximab did not appear to be the optimal companion targeted agent to further increase the efficacy of this strategy. pCR was demonstrated to be a reliable surrogate end point for rectal cancer trials even in the context of intensified pre-operative regimens including induction chemotherapy.

2169 POSTER DISCUSSION

Feasibility results from a multi institutional randomized phase II study for patients with rectal cancer at risks for systemic disease: The KIR study

T. Vuong[1], T. Niazi[1], P. Kavan[2], E. Ferland[3], C.A. Vasilevsky[4], N. Nguyen[5], S. Desgroseilliers[6], A.G. Martin[7], C. Richard[8], G. Batist[9].
[1]McGill University, Radiation Oncology, Montréal, Canada; [2]McGill University, Medical Oncology, Montréal, Canada; [3]Pierre Boucher Hospital, Medical Oncology, Longueil, Canada; [4]McGill University, Colo-rectal Surgery, Montreal, Canada; [5]Sherbrooke University, Medical Oncology, Longueil, Canada; [6]Pierre Boucher Hospital, General Surgery, Longueil, Canada; [7]Laval University, Radiation Oncology, Quebec, Canada; [8]Montreal University, Colorectal Surgery, Montreal, Canada; [9]McGill University, Medical Oncology, Montreal, Canada

Background: Patients (pts) with rectal cancer at high risks for metastases are well identified at presentation with magnetic resonance imaging (MRI) using circumferential radial margins (CRM), features of extra mural venous invasion (EMVI) or qualitative nodal morphological changes (N+). In North America, the standard of care for locally advanced rectal cancer is neoadjuvant chemo-radiation therapy (CRT) prior to total mesorectal surgery (TME) followed by adjuvant chemotherapy(CT). This results in a median time of 4.5−5.5 months from the start of local therapy to the start of systemic treatment. The present study is proposing to evaluate a modified strategy to shorten the local disease treatment time to 2.5−3.5 months to allow for optimization of CT with FOLFOX chemotherapy (CT) given either in neoadjuvant or adjuvant setting.
Material and Methods: The primary endpoint is patient compliance to CT. Based on a reported compliance rate to adjuvant CT of 60 % after neoadjuvant radiation, a sample size of 180 pts was determined to allow the detection of an 85% compliance rate using one-sided binomial test and a significance level of 5% with a power of 90%. The pts were randomized using a 2:1 ratio. Image guided high dose rate endorectal brachytherapy (HDREBT) was used to deliver 26 Gy in 4 fractions either after 6 cycles of FOLFOX CT (arm A) and before TME or upfront to TME and 12 cycles of adjuvant FOLFOX (arm B).
Results: From 2010–2012, 70 out of the planned 180 pts were recruited with 47 pts treated in arm A and 23 pts in arm B. All pts underwent TME as planned. In arm A, MRI was repeated after CT in 37/41 pts that completed their treatment. The radiological rate of complete response, excellent response (>50%), partial response (⩽50%), minimal to no response and tumor progression were respectively: 8.1%, 37.8%, 27.3%, 13.5%, and13.5%. HDREBT was feasible in all pts but one pt. decided to have external beam RT. There was no significant difference in the rate of post-operative complications between the two arms and the preliminary results showed CT compliance rate of 94% for arm A compared to 50% in arm B.
Conclusion: The safety of this study design is confirmed and the study is now being activated across the province. This is also the first multi-institutional study using HDREBT as a neoadjuvant RT modality for rectal cancer, which confirms the feasibility and applicability of HDREBT in multi-centric trial.

2170 POSTER DISCUSSION

A comparison of the outcome of rectal cancer patients treated with high dose rate endorectal brachytherapy, short-course radiotherapy, or chemoradiation

C.B.M. Van den Broek[1], T.A. Vermeer[2], T. Vuong[3], E. Bastiaannet[4], L. Azoulay[5], O.M. Dekkers[6], T. Niazi[3], H.A. Van den Berg[7], H.J.T. Rutten[8], C.J.H. Van den Velde[1]. *[1]Leiden University Medical Center, Surgery, Leiden, Netherlands; [2]Catharina Hospital Eindhoven, Surgery, Eindhoven, Netherlands; [3]Jewish General Hospital McGill University, Radiation Oncology, Montréal, Canada; [4]Leiden University Medical Center, Surgery & Gerontology and Geriatrics, Leiden, Netherlands; [5]McGill University & Lady Davis Institute, Oncology & Centre for Clinical Epidemiology, Montréal, Canada; [6]Leiden University Medical Center, Epidemiology, Leiden, Netherlands; [7]Catharina Hospital Eindhoven, Radiotherapy, Eindhoven, Netherlands; [8]Catharina Hospital Eindhoven & Research Institute Growth and Development at Maastricht University Medical Center, Surgery, Eindhoven & Maastricht, Netherlands*

Background: Short course external beam radiotherapy decreases local recurrences in patients with rectal cancer. However, improvements should be weighed against treatment-related morbidity since there might be other preoperative options with fewer side effects, for example high dose rate endorectal brachytherapy (HDREBT). The current study compared overall survival, local recurrence and cancer specific mortality in rectal cancer patients treated with either preoperative short course radiotherapy or chemoradiotherapy (CRT) in The Netherlands and HDREBT in Canada.
Material and Methods: In total, 134 Dutch T3 rectal cancer patients treated with either preoperative 5x5 Gy radiotherapy (n = 52) or CRT (n = 82), and 141 T3 rectal cancer patients from Canada treated with preoperative HDREBT (26 Gy over 4 days) were included. Cox proportional hazard models were used to estimate hazard ratios along with 95% confidence intervals (CIs) adjusted for potential confounders. Primary endpoint was overall survival, secondary endpoints were local recurrence, regardless the status of systemic disease and cancer specific mortality.
Results: No differences in local recurrence and cancer specific mortality at five years were found between The Netherlands and Canada (5/134 versus 2/141, and 6/134 versus 4/141, respectively). A statistically significant reduction in the 5-year overall survival was observed with patients from Canada, compared to patients from The Netherlands, after adjustment for potential confounders (HR 0.42, 95% CIs 0.20–0.90, p = 0.03).
Conclusions: In the current study, no significant differences in local recurrence and cancer specific mortality were observed. Overall survival, on the other hand, was superior in Canada, possibly due to lower treatment-related toxicities. A previous study has shown that postoperative complications did not vary between short course radiotherapy and HDREBT. These findings could have profound clinical implications and should therefore be formally tested in a randomized controlled trial.
No conflict of interest.

2171 POSTER DISCUSSION

Stereotactic radiotherapy for oligometastatic cancer: a predictive model for survival

T. De Vin[1], B. Engels[1], T. Gevaert[1], G. Storme[1], M. De Ridder[1]. *[1]UZ Brussel, Radiotherapy, Jette, Belgium*

Background: Stereotactic body radiotherapy (SBRT) is a safe and locally effective treatment for patients with inoperable oligometastases. The challenge remains identifying subsets of patients that benefit in terms of overall survival (OS).
Methods: Between 2005 and 2011, 309 patients with $\leqslant$5 metastases were treated by SBRT (n = 209) and/or by intracranial stereotactic radiosurgery (n = 107). We analyzed OS and performed a risk factor analysis.
Results: The median survival of all patients was 24 months. The 3-year, 4-year and 5-year OS rates were 32%, 25% and 19% respectively. The following 4 risk factors were independently associated with impaired OS: non-adenocarcinoma histology (p < 0.01), intra-cranial metastases (p < 0.01), synchronous metastatic disease (p < 0.01) and male gender (p = 0.02). Patients with 0, 1 and 2 risk factors displayed a median survival (95% CI) of 40 (24−63), 29 (23−35) and 23 (16−29) months respectively and are defined as patients with good prognosis. Patients with 3 and 4 risk factors had a median survival of 9 (6−11) and 4(1−7) months only and are defined as bad prognostic patients.
Conclusions: We identified subsets of oligometastatic cancer patients with good prognosis after stereotactic radiotherapy. These patients are candidates for inclusion in prospective randomized trials for defining the role of SBRT in the management of oligometastases.
No conflict of interest.

2172 POSTER DISCUSSION

Urinary dysfunction after mesorectal excision with and without lateral lymph node dissection for clinical stage II or stage III lower rectal cancer (JCOG0212)

A. Kobayashi[1], S. Fujita[2], J. Mizusawa[3], N. Saito[1], Y. Kinugasa[4], Y. Kanemitsu[5], M. Ohue[6], S. Fujii[7], H. Kimura[8], Y. Moriya[2]. *[1]National Cancer Center Hospital East, Surgery, Kashiwa Chiba, Japan; [2]National Cancer Center Hospital, Surgery, Tokyo, Japan; [3]JCOG Data Center, Multi-institutional Clinical Trial Support Center, Tokyo, Japan; [4]Shizuoka Cancer Center, Surgery, Shizuoka, Japan; [5]Aichi Cancer Center, Surgery, Nagoya, Japan; [6]Osaka Medical Center and Cardiovascular Disease, Surgery, Osaka, Japan; [7]Yokohama City University Medical Center, Surgery, Yokohama, Japan; [8]Okayama Saiseikai General Hospital, Surgery, Okayama, Japan*

Background: Postoperative urinary dysfunction is recognized as a major complication of rectal cancer surgery. A randomized controlled trial was performed at 33 major hospitals in Japan to confirm the non-inferiority of mesorectal excision (ME) in relapse-free survival compared to ME with lateral lymph node dissection (LLND) (JCOG0212). The primary analysis is planned for 2015. Urinary dysfunction after surgery was investigated as secondary endpoint in this study.
Methods: Eligibility criteria included histologically proven rectal cancer of clinical stage II/III, with the main lesion located in the rectum with the lower margin below the peritoneal reflex, no lateral pelvic lymph node enlargement, PS of 0 or 1, patient age 20−75 years, and no past history of chemotherapy, pelvic surgery or radiation. After surgeons had confirmed R0 resection by ME, patients were randomized intraoperatively to ME alone or ME with LLND. Pelvic autonomic nerves were preserved as much as possible in both arms. The residual urine volume was measured 3 times as a general rule during postoperative 10−14 days in this protocol. Urinary dysfunction was defined that there was residual urine of 50 ml or more even once. Missing measurements of urine volume were counted as dysfunction. Risk factors, including LLND, demographics, tumor location, type of surgery, operative time and blood loss, were investigated by univariable and multivariable analysis.
Results: Urinary dysfunction in the ME alone group and the ME with LLND group were observed in 57.7% (202/350 pts; 95% CI, 52.4–63.0%; 76 pts with missing data) and 59.0% (207/351 pts; 95% CI, 53.6–64.2%; 74 pts with missing data), respectively (P = 0.76). In the univaliable analysis, tumor center located below the peritoneal reflection (P = 0.01) and blood loss $\geqslant$500 mL (P = 0.004) were increased risk of urinary dysfunction. In multivariable regression analysis, only blood loss remained associated with urinary dysfunction (relative risk 1.25, P = 0.04).
Conclusion: The ME alone did not show significant decrease of urinary dysfunction. Urinary dysfunction was associated with tumor location and blood loss.
No conflict of interest.

2173 POSTER DISCUSSION

Sexual dysfunction after rectal cancer surgery − the results from a prospective randomized trial comparing mesorectal excision with and without lateral lymph node dissection for clinical stage II or stage III lower rectal cancer: Japan Clinical Oncology Group Study JCOG0212

S. Saito[1], S. Fujita[2], J. Mizusawa[3], N. Saito[4], Y. Kinugasa[5], Y. Akazai[6], S. Fujii[7], Y. Kanemitsu[8], T. Akasu[2], Y. Moriya[2]. *[1]Saiseikai Yokohamashi Nanbu Hospital, Surgery, Yokohama, Japan; [2]National Cancer Center Hospital, Colorectal Surgery, Tokyo, Japan; [3]National Cancer Center, JCOG Data Center Multi-institutional Clinical Trial Support Center, Tokyo, Japan; [4]National Cancer Center Hospital East, Surgery, Kashiwa, Japan; [5]Shizuoka Cancer Center Hospital, Colorectal Surgery, Shizuoka, Japan; [6]Okayama Saiseikai General Hospital, Surgery, Okayama, Japan; [7]Yokohama City University Medical Center, Surgery, Yokohama, Japan; [8]Aichi Cancer Center Hospital, Surgery, Nagoya, Japan*

Background: Sexual dysfunction is one of potential complications of rectal cancer surgery. Generally, the proportion of the sexual dysfunction after mesorectal excision (ME) with lateral lymph node dissection (LLND) is deemed higher than ME alone. A randomized controlled trial was performed at 33 major hospitals in Japan to confirm the non-inferiority of ME in relapse-free survival compared to ME with LLND (JCOG0212). General postoperative complications were reported previously (Fujita et al., Lancet Oncol 2012). The primary analysis is planned for 2015. Sexual dysfunction after surgery was investigated as a secondary endpoint in this study.
Material and Methods: Patients (Pts) with clinical stage II/III lower rectal cancer were randomized intra-operatively to ME alone or ME with LLND both preserving all autonomic nerves. Questions on sexual function

were asked for men before surgery and 1 year after surgery, using the Japanese version of the abridged five-item version of the International Index of Erectile Function (IIEF-5). Sexual dysfunction was defined as IIEF-5 score of 21 or less, because no ED score is defined as 22−25 in IIEF-5. Proportion of sexual dysfunction was defined as pts having sexual dysfunction after surgery among no ED pts before surgery. Pts, whose sexual function was not evaluated postoperatively because of their death or other reasons, were included in the numerator of sexual dysfunction. For no ED or mild ED (IIEF-5 score: 17−21) pts before surgery, we analyzed the impact of LLND, age, tumor location, surgery type, operative time and blood loss on erectile function by IIEF-5 score difference between pre- and post-surgery.

Results: A total of 701 pts were randomized and 472 male pts were included in the present analysis. Among them, preoperative questionnaire were collected in 413 pts (87.5%). Both preoperative and postoperative questionnaires were collected in 343 patients (72.7%). Proportion of sexual dysfunction in the ME with LLND group and the ME alone group were observed in 79.3% (23/29; 95% CI, 60.3–92.0%; 5 pts were not evaluated after surgery) and 68.0% (17/25; 95% CI, 46.5–85.1%; 4 pts were not evaluated after surgery), respectively (P = 0.37). Postoperative score was decreased compared to preoperative score in both ME with LLND group (median (range); pre, 20 (17−25) vs. post, 13 (1−25); *P* <0.0001) and ME alone group (pre, 20 (17−25) vs. post, 16 (1−25); *P* <0.0001). Score difference was not statistically higher in ME with LLND group than in ME alone group (P = 0.10). In score difference, only age 56 or older was a risk factor for sexual dysfunction after surgery in multivariate analysis (P = 0.024).

Conclusion: LLND did not increase sexual dysfunction after rectal cancer surgery. Sexual dysfunction was associated with age.

No conflict of interest.

2174 POSTER DISCUSSION

Bowel function 14 years after sphincter-preserving total mesorectal excision for rectal cancer: Report of a multicentre randomised trial

T.Y.T. Chen[1], L.M. Wiltink[2], R.A. Nout[2], E. Meershoek-Klein Kranenbarg[3], S. Laurberg[1], C.A.M. Marijnen[2], C.J.H. Van de Velde[4]. *[1]Aarhus University Hospital, Department of Surgery P, Aarhus, Denmark; [2]Leiden University Medical Center, Department of Radiotherapy, Leiden, Netherlands; [3]Leiden University Medical Center, Surgical Datacenter, Leiden, Netherlands; [4]Leiden University Medical Center, Department of Surgery, Leiden, Netherlands*

Background: Bowel dysfunction is an important adverse outcome of sphincter-preserving surgery for rectal cancer, and the accuracy of its assessment is determined by the evaluation instrument and setting. Consequently, we investigated very long-term bowel function after sphincter-preserving treatment for rectal cancer using a standardised scoring system, and examined the association of bowel dysfunction with health-related quality of life (HRQL), in the setting of a randomised trial.

Material and Methods: In the TME trial (1996–1999), 1530 Dutch patients with resectable rectal cancer received total mesorectal excision (TME) and were randomly assigned to 5x5 Gy preoperative short-course radiotherapy (PRT). In 2012, a questionnaire was sent to all surviving non-stoma patients (n = 297), comprising the Low Anterior Resection Syndrome Score (LARS score), the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core (EORTC QLQ-C30) and Colorectal Module (EORTC QLQ-CR29). The LARS score has been validated extensively, and the score range is split into 'No LARS', 'Minor LARS', and 'Major LARS' categories in ascending severity of bowel dysfunction. Potential risk factors for Major LARS were tested by logistic regression. HRQL was compared between LARS score categories. To correct for multiple testing, statistical significance was set at p < 0.01. Ethics approval was obtained and patients gave informed consent.

Results: A response rate of 81% was achieved, with 242 patients participating (49% PRT+TME, 51% TME, patient characteristics comparable). The median time since treatment was 14.6 years (range 12.6–16.6) and the median age at follow-up was 75 years (range 39−95). Nearly half (46%) of all patients experienced Major LARS. PRT (odds ratio 2.6) and age ⩽75 at follow-up (odds ratio 2.3) increased the risk of Major LARS. In contrast, gender, distance of tumour from anal verge, time since treatment, and comorbid diabetes did not alter the risk of Major LARS. Patients with Major LARS were worse off in most of the HRQL domains measured by the EORTC QLQ-C30 and the EORTC QLQ-CR29.

Table: Selected HRQL results

	Mean score Major LARS	Mean score Minor/No LARS	p
Global health status*	73.4	80.3	<0.01
Role functioning*	79.0	85.5	<0.01
Emotional functioning*	81.8	87.5	<0.01
Cognitive functioning*	80.9	87.7	<0.01
Social functioning*	83.3	91.2	<0.01
Fatigue†	27.0	18.6	<0.01
Constipation†	20.8	12.1	<0.01
Diarrhoea†	24.8	4.6	<0.01
Stool frequency†	34.1	13.8	<0.01
Flatulence†	46.3	23.2	<0.01
Faecal incontinence†	27.5	7.6	<0.01

*Higher score = better HRQL; †Higher score = worse HRQL.

Conclusions: A substantial proportion of patients endure severe long-term bowel dysfunction after sphincter-preserving TME. Although surgery is probably the main contributing factor to Major LARS, PRT and age ⩽75 pose additional risks. Major LARS is associated with reduced HRQL. Patients should be well informed of these late complications prior to treatment.

Supported by the Dutch Cancer Society (CKVO 95−04) and the Dutch National Health Council (OWG 97/026).

No conflict of interest.

2175 POSTER DISCUSSION

Two-stage hepatectomy for non resectable colorectal cancer liver metastases: Results of the first prospective multicenter study

M. Rivoire[1], A. Dupré[1], S. Evrard[2], A. Ayav[3], F. Marchal[4], E. Buc[5], G. Passot[6], J.R. Delpero[7], F. Quenet[8], S. Chabaud[9]. *[1]Léon Bérard Cancer Center, Surgical Oncology, Lyon, France; [2]Bergonié Institute, Surgical Oncology, Bordeaux, France; [3]Nancy University Hospital, Hepato-biliary Surgery, Nancy, France; [4]Alexis Vautrin Cancer Center, Surgical Oncology, Nancy, France; [5]D'Estaing University Hospital, Hepato-biliary Surgery, Clermont-Ferrand, France; [6]Lyon-Sud University Hospital, Digestive Surgery, Lyon, France; [7]Paoli-Calmettes Institute, Surgical Oncology, Marseille, France; [8]Val D'Aurelle Cancer Center, Surgical Oncology, Montpellier, France; [9]Léon Bérard Cancer Center, Biostatistics, Lyon, France*

Background: Two-stage hepatectomy (TSH) may achieve long-term survival in selected patients whose liver metastases cannot be removed in a single procedure. There are encouraging preliminary results from retrospective, single-center studies, but this approach has not previously been prospectively assessed in a multicenter trial.

Material and Methods: In the SEPRA-C2T study (clinicaltrial.gov NCT01262417) undertaken between July 2008 and March 2010, a prospective cohort of patients with non resectable colorectal liver metastases (CRCm) who were candidates for TSH were enrolled from 8 French centers. Data were obtained on preoperative treatment, the nature of the first and second hepatectomies, and short and long term outcome.

Results: 54 patients, aged 60±9 years, had an initial hepatectomy. 93% of non resectable CRCm were synchronous (number 6.2±4, maximum diameter 5.4±2.8 cm). All patients had had induction chemotherapy (9±4 cycles). First hepatectomy was mostly minor and associated with ablation in 46% of patients and primary tumor resection in 57%. 56% of patients had portal vein embolization. There were no deaths. 44% of patients had at least 1 postoperative complication, severe in 11% (bilioma requiring percutaneous radiological drainage in 4 patients and intensive care unit hospitalization in 2 patients − after reoperation for a colorectal anastomosis fistula in 1 case and after cardiac failure in the other). Median hospital stay after first hepatectomy was 13 days (4−64). 41 patients (76%) had the second hepatectomy after a median interval of 2.5 months (0.9−9) and 2 cycles of chemotherapy (1−13). The second hepatectomy was a major resection in 76% of patients. There were no postoperative deaths. 32% of patients had at least one complication, severe in 10%. 2 biliomas required percutaneous drainage and there were 2 reoperations, for a postoperative occlusion and an intra-abdominal abscess. Median hospital stay was 10 days (5−28). At median follow-up of 45 months, 4 year overall survival is 62% and 4 year progression free survival 17% (intent to treat analysis).

Conclusions: This is the first prospective, multicenter study to confirm the feasibility of TSH in patients with initially non-resectable CRCm. It provides encouraging evidence of long term survival.
This trial was funded by the French NCI (under PHRC grant 2007-A00987−46).
No conflict of interest.

2176 POSTER DISCUSSION

Anastomotic leakage following low anterior resection in the Netherlands: Analyses from the Dutch Surgical Colorectal Audit (DSCA)

S. Malm[1], H.S. Snijders[2], P.A. Neijenhuis[1], H.M. Kroon[1]. *[1]Rijnland Hospital, Surgery, Leiderdorp, Netherlands; [2]LUMC, Surgery, Leiden, Netherlands*

Background: Anastomotic leakage (AL) is a severe complication following a low anterior resection (LAR) for rectal cancer. In the current study we analyzed the incidence of AL and its mortality following a LAR, using data from the Dutch Surgical Colorectal Audit (DSCA). Finally, we tried to indentify risk factors for AL.
Methods: All patients in the Netherlands who underwent a LAR with the construction of a primary anastomosis between January 2009 and January 2013, registered in the DSCA, were included in this study. Univariate and multivariate analyses were performed to indentify the risk factors of 'mild' AL (not requiring surgical intervention) and 'severe' AL (requiring surgical intervention).
Results: A total of 4170 patients underwent a LAR with a primary anastomosis. In 409 cases (9.8%) AL was reported of whom 256 (62.6%) had 'severe' AL. The overall 30-day mortality rate was 1.5% (n = 64). In 20 patients (5% of those with AL) AL was the cause of death in 14 patients suffering from 'severe' AL compared to 6 suffering from 'mild' AL ($p < 0.001$). Multivariate analysis showed that patients in whom a diverting ileostoma was constructed (n = 2752) had a decreased risk of developing 'severe' AL (OR=0.26; CI 0.20–0.35) while more 'mild' AL was observed in this group (OR=1.69; CI 1.06–2.68). A laparoscopic procedure showed significantly less 'mild' AL (OR=0.66; CI 0.46–0.94) and a trend towards less 'severe' AL (OR = 0.85; CI 0.65–1.11). Male gender was a risk factor for developing 'severe' AL (OR=1.71; CI 1.27–2.30) and patients who received neo-adjuvant radiotherapy or chemo-radiation showed a higher risk of developing 'mild' AL (OR = 2.60; CI 1.22–5.52 and OR = 2.38; CI 1.08–5.24). Patients who had an anastomosis constructed less than 7 cm from the anal ring developed significantly more 'severe' AL (OR = 1.84; CI 1.34–2.51).
Conclusion: The data from the DSCA show that AL following a LAR occurs in 9.8% of the patients. In the majority of cases AL is 'severe', requiring surgical intervention. The mortality rate of AL is 5%. The increased risk to develop 'mild' AL after the construction of a diverting ileostoma is most likely caused by patient selection in a way that those prone to develop AL receive an ileostoma, decreasing the risk of a 'severe' AL. Patients selected for laparoscopic surgery have a lower chance to develop AL while male gender, neo-adjuvant therapies and a distal anastomosis increase this risk.
No conflict of interest.

2177 POSTER DISCUSSION

Failure-to-rescue after colorectal cancer surgery and the association with three structural hospital factors

D. Henneman[1], N.J. Van Leersum[2], M. Ten Berge[2], H.S. Snijders[2], M. Fiocco[3], T. Wiggers[4], R.A.E.M. Tollenaar[2], M.W.J.M. Wouters[5]. *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Leids Universitair Medisch Centrum, Surgery, Leiden, Netherlands; [3]Leids Universitair Medisch Centrum, Medical Statistics, Leiden, Netherlands; [4]Universitair Medisch Centrum Groningen, Surgery, Groningen, Netherlands; [5]Nederlands Kanker Instituut- Antoni van Leeuwenhoek ziekenhuis, Surgical Oncology, Amsterdam, Netherlands*

Objective: To evaluate the association between structural hospital characteristics and failure-to-rescue after colorectal cancer surgery.
Background: There is a growing body of evidence suggesting a large hospital variation concerning mortality rates in patients with a severe complication (failure-to-rescue) in colorectal cancer surgery. Which structural hospital factors are associated with better failure-to-rescue rates remains largely unclear.
Methods: All patients undergoing colorectal cancer surgery and registered in the Dutch Surgical Colorectal Audit (DSCA) from 2009 through 2011 by 92 Dutch hospitals were analysed. Univariate and multivariate logistic regression models including casemix, hospital volume, teaching status and different levels of ICU facilities were used to analyse risk-adjusted FTR rates.
Results: 25591 patients from 92 hospitals were included. The failure-to-rescue rate ranged between 0 and 39%. In univariate analysis, FTR rates were lower in patients operated in high hospital volume hospitals (13% in hospitals operating >200 patients/year versus 18% in hospitals performing $\leqslant$200 colorectal resections/year), teaching status (12% in academic hospitals, versus 17% in teaching hospitals and 21% in non-teaching hospitals) and high level of ICU facilities (16% in highest level 3 versus 21% in lowest level 1 ICU hospitals). Only the higher levels of ICU facilities (2 or 3 compared to level 1) were independently associated with lower failure-to-rescue rates (OR 0.72 (95% CI 0.65–0.88) in multivariate analysis.
Discussion: Hospital type and annual hospital volume were not independently associated with failure-to-rescue rates in colorectal cancer surgery. Instead, the lowest level of ICU facilities was independently associated with higher rates. This suggests that a more advanced ICU may be an important factor that contributes to better failure-to-rescue rates, although individual hospitals perform well with lower ICU levels.
No conflict of interest.

2178 POSTER DISCUSSION

Chemotherapy plus cetuximab as conversion therapy for patients with initially unresectable colorectal cancer liver metastases

E. Van Cutsem[1], G. Folprecht[2], C. Bokemeyer[3], J. Xu[4], R. Esser[5], R. Adam[6]. *[1]University Hospital Gasthuisberg, Digestive Oncology Unit, Leuven, Belgium; [2]University Hospital Carl Gustav Carus, Dresden, Germany; [3]University Medical Centre Hamburg-Eppendorf, Hamburg, Germany; [4]Zhongshan Hospital, Fudan University Medical Center, Shanghai, China; [5]Merck KGaA, Darmstadt, Germany; [6]AP-HP Hôpital Paul Brousse University Paris-Sud, Villejuf, France*

Background: ~85% of patients (pts) with metastatic colorectal cancer (mCRC) present with liver disease that is initially unresectable. First-line chemotherapy (CT) can render such lesions resectable in certain pts, providing the best chance of long-term survival and in some cases even cure. The aim of this review was to evaluate the data from published studies in mCRC to assess whether addition of cetuximab to first-line CT increased the conversion rate of *KRAS* wild-type (wt), liver-limited metastatic disease from initially unresectable to resectable.
Material and Methods: Electronic searches of literature databases were carried out to identify publications describing resection rates for pts with *KRAS* wt mCRC receiving CT ± cetuximab. Results were checked for relevance regarding the inclusion of data related to liver-limited disease (LLD).
Results: Excluding reviews and case reports, 17 publications were identified that described the results of 14 different studies or observational cohorts. Of these, four randomized controlled trials reported resection rates for LLD in pts with *KRAS* wt mCRC in CT + cetuximab compared with CT alone treatment groups (Table). In three of these trials, R0 resection rates were markedly higher in the CT + cetuximab group for pts with *KRAS* wt tumors. In the fourth study (COIN), resection rates were similar between treatment groups, although data were not reported for oral and infusional fluoropyrimidine subgroups. Only one trial, carried out in Chinese pts, was specifically designed to assess the rate of resectability of *KRAS* wt synchronous LLD. In this, the R0 resection rate in the CT + cetuximab group was significantly higher than in the CT alone group (25.7% vs 7.4%; $p = 0.004$). PFS and OS were also longer in pts in the CT + cetuximab group (HR 0.60, $p = 0.004$ and HR 0.54, $p = 0.013$, respectively).
Conclusions: Data from randomized trials in mCRC confirm that the addition of cetuximab to first-line infusional 5-fluoropyrimidine-based CT regimens improves the rate of R0 resection of initially unresectable *KRAS* wt LLD and prolongs PFS and OS when compared with the corresponding CT regimen alone.

ONCO-Predict-II: A deep sequencing test predicting outcome in patients with colorectal cancer of stage II based on mutations signatures in driver genes

A. Rosenthal[1], K. Stecker[1], P. Pechanska[1], B. Hinzmann[1], S. Klaßen[1], H.P. Adams[1], K. Ridwelski[2], F. Marusch[3], M. Pross[4], R. Mantke[5].
[1]Signature Diagnostics AG, Potsdam, Germany; [2]Klinikum Magdeburg, Klinik für Allgemein- und Viszeralchirurgie, Magdeburg, Germany; [3]Ernst von Bergmann Klinikum Potsdam, Klinik für Allgemein- und Viszeralchirurgie, Potsdam, Germany; [4]DRK Kliniken Köpenick, Klinik für Chirurgie, Potsdam, Germany; [5]Klinikum Brandenburg, Klinik für Allgemein- und Viszeralchirurgie, Brandenburg, Germany

Background: Approximately 20% of patients (pts) with colorectal cancer of stage II will progress within 2−3 years after surgery while 80% of patients are cured by surgical resection. Assignment of patients with colorectal cancer of UICC stage II to adjuvant chemotherapy remains controversial. Pathological parameters (pT4, L+, V+) are poor predictors of the recurrence risk. Several RNA expression signatures (Oncotype Dx Colon Cancer Assay, ColonPrint, Predictor C) have been develeped, but their clinical performance is limited.
Methods: Patients with colorectal cancer of UICC stage II were selected from the observational prospective, multicenter MSKK study. Since 2005 more than 7.200 patients with colorectal cancer of all four UICC stages have been recruited by investigtors of 40 hospitals in Germany. Deep sequencing of 37 well known cancer genes using Illumina technology (MiSeq) was employed using a custom cancer panel of 120 amlicons. Only high quality missense and nonsense mutations were used for further analysis. Boolean Algebra was used to analyse the mutations, to generate truth values for each of the cancer genes and to connect cancer genes with Boolean functions including conjunction (AND), negation of conjunction (NAND), disjunction (OR), negation of disjunction (NOR), equivalence (EQV), exclusive disjunction (XOR), material implication (IMP) negation of material implication (NIMP).
Results: Altogether 173 pts fulfilled all the inclusion criteria, 61 females, 112 males, 87 were younger than 68 yrs, 86 were older, 31 pts had a rectum tumor, 142 a colon tumor. pT3 tumors were diagnosed in 153 pts, and pT4 tumors in 20 pts. L+ was seen in 37 tumors, V+ in 13 tumors. 41 pts received adjuvant therapy. 94 pts were progression free at 3 years, 12 were diagnsoed with local recurrence, 27 with secondary malignancy, and 40 pts were diagnosed with metastatic disease at 3 years. 497 missense and nonsense mutations were identified in approx. 13 driver genes. We then used these missense and nonsense variations in a double nested bootstrap to predict progression of disease events in a prospective fashion and to receive second order unbiased estimates of the performance characteristics.
From missense and nonsense mutations in 13 driver genes we found TP53 to have the largest impact followed by BRAF. The Boolean function !TP53 Eqv !BRAF reads as follows: 'pts who have neither missense or nonsense mutations in TP53 and BRAF, or pts who have missense and nonsense mutations in TP53 and BRAF have the highest likelihood of developing metastatic disease'. !TP53 EQV !BRAF has a sensitivity of 0.74, a specificity of 0.65, a positive predictive value of 0.48, a negative predictive value of 0.86 and an area under the receiver operating curve (AROC) of 0.69. A second signature !TP53 EQv !BRAF OR SMAD4 OR ATM OR KRAS leads to an increase of the sensitivity to 0.89, however on the expense of the specificity of 0.39.
Conclusion: Here we show that the aggregation of somatic mutations in well known cancer genes using Boolean algebra leads to signatures with clinical utility in UICC stage II colorectal cancer that outperform clinical marker. Our signature based on deep sequencing of FFPE tissue is more robust than any of the RNA expression signatures.

2180 POSTER DISCUSSION

Assessing tumor response beyond RECIST criteria: early tumor shrinkage (ETS) and deepness of response (DpR) in phase III TRIBE trial by the GONO group

C. Cremolini[1], F. Loupakis[1], C. Antoniotti[1], F. Bergamo[2], G. Tonini[3], A. Buonadonna[4], C. Valsuani[5], S. Chiara[6], S. Lucchesi[7], A. Falcone[1].
[1]Ospedale Santa Chiara, U.O. Oncologia Medica 2, Pisa, Italy; [2]Istituto Oncologico Veneto − IRCCS, Oncologia Medica 1, Padua, Italy; [3]Università Campus Bio-Medico, Oncologia Medica, Rome, Italy; [4]Istituto Nazionale Tumori, Oncologia Medica, Aviano, Italy; [5]Ospedale Versilia, Oncologia Medica, Viareggio, Italy; [6]National Cancer Institute, Medical Oncology Unit, Genoa, Italy; [7]USL 5 Pontedera, Oncologia Medica, Pontedera, Italy

Background: TRIBE trial demonstrated that first-line FOLFOXIRI plus bevacizumab (bev) provides a significant improvement in PFS and objective response rate (ORR), compared to FOLFIRI plus bev. Recent experiences evidenced that both the ETS and the DpR may implement the RECIST assessment of tumor response and correlate with survival.
Material and Methods: ETS was defined as the relative change in the sum of the longest diameters of RECIST target lesions at week 8 compared to baseline. A 20% decrease was adopted as cut-off value to discriminate early responders and non responders. DpR was defined as the relative change in the sum of the longest diameters of RECIST target lesions at the nadir in the absence of new lesions or progression of non-target lesions. compared to baseline. The median value was adopted as cut-off.
Results: Out of 508 randomized patients, 443 patients were evaluable for ETS. 142 (64%) out of 221 patients in the FOLFOXIRI plus bev arm achieved early response, compared to 114 (51%) out of 222 patients in the FOLFIRI plus bev arm ($p = 0.006$). A mean ETS of 30.2% was reported in the experimental arm compared to 21.4% in the control arm ($p = 0.0001$). In the global population, early responders achieved significantly longer PFS (median PFS: 12.7 months vs 10 months, HR: 0.66 [0.52–0.80], $p < 0.0001$). A significant correlation of ETS as a continuous variable with PFS was also observed (HR: 0.982 [0.977–0.987], $p < 0.0001$). 484 patients were evaluable for DpR. A mean DpR of 41.1% was reported in the FOLFOXIRI plus bev arm compared to 32.9% in the FOLFIRI plus bev arm ($p = 0.003$). Median time to DpR was 4.3 and 3.9 months in the experimental and control arm, respectively. In the global population, patients achieving a DpR higher than the median value achieved significantly longer PFS (median PFS: 13.1 months vs 9.3 months, HR: 0.61 [0.49–0.73], $p < 0.0001$). A significant correlation of DpR as a continuous variable with PFS was observed (HR: 0.983 [0.979–0.986], $p < 0.0001$).
Conclusions: FOLFOXIRI plus bev allows to achieve a better rate of early response and an higher extent of DpR compared to FOLFIRI plus bev. As previously suggested, both ETS and DpR are significantly related to PFS. Correlations with OS will be presented.
No conflict of interest.

2181 POSTER DISCUSSION

Towards the molecular structure of colorectal liver metastasis: ultra-deep sequencing of matched pairs of resected liver mets and primary tumors in 94 patients with metastatic colorectal cancer

A. Rosenthal[1], S. Klaßen[1], P. Pechanska[1], H.P. Adams[1], R. Pauli[2], C. Radke[3], K. Hellwig[4], H. Kosmehl[5], F. Lippek[6], G. Niedobitek[7].
[1]Signature Diagnostics AG, Potsdam, Germany; [2]Klinikum Brandenburg, Institut für Pathologie, Brandenburg, Germany; [3]DRK Kliniken Berlin Westend, Institut für Pathologie, Berlin, Germany; [4]Klinikum Magdeburg, Institut für Pathologie, Magdeburg, Germany; [5]Helios Klinikum Erfurt, Institut für Pathologie, Erfurt, Germany; [6]Ruppiner Klinikum Neuruppin, Institut für Pathologie, Neuruppin, Germany; [7]Sana Klinikum Berlin, Institut für Pathologie, Berlin, Germany

Background: In colorectal cancer (CRC) metastasis occurs predominantly in the liver. Patients (pts) die from metastasis and not from the primary tumor. While exome sequencing data from more than 200 patients with CRC are in the public domain little is known about the somatic mutation structure of liver metastasis. We attempted ultra-deep sequencing of resected liver metastases and their matched primary CRC tumors in 94 pts with metastatic colorectal cancer in order to identify molecular differences between liver mets and primary tumors.
Materials and Methods: Pts with metastatic CRC ($N = 1400$) originated from our prospective, multicenter MSKK study with 40 hospitals in Germany. We identified 233 pts (16%) with liver mets tissue in our MSKK tumor bank. After pathological review 178 pts had matched pairs of liver mets tissue and primary tumor tissue of sufficient size and quality and were accepted for the study. Macro-dissection was performed for all liver mets and primary tumor tissue. Specimens were only accepted for further

analysis if they had more than 15% tumor content. DNA was isolated and quality controlled for size using a LINE RT-PCR assay. Ultra-deep sequencing was performed on a MiSeq sequencer (Illumina) using a custom panel of 37 driver genes (represented in 120 amplicons) known to be mutated in CRC.
Results: We sequenced liver mets and matched primary tumor tissus of 94 pts with metastatic CRC. Sequence data of both FFPE (liver mets) and fresh frozen tissue (matched primary tumor) was of high quality allowing reliable mutation detection in all 94 matched pairs (188 mets/primary specimens). The average coverage was 5.000fold per base pair. Among the 94 pairs we identified significant differences in the mutation pattern between primary tumor and liver metastasis in 22 pts (22.3%). In 10 pts the liver mets displayed one or several actionable mutations that were not present in the primary tumor. In a further 7 pts, the primary tumor showed actionable mutations which did not exist in the matched liver mets. In three pts we found new actionable mutations in the liver mets but also mutations in the primary tumor which were not found in the mets: case 1: PIK3CA E545K in liver mets, TP53 C275F in primary, case 2: KIT M541L, APC Q1378X, and TP53 R196X in liver mets, TP53 R175H in primary, case 3: SMAD4 S343L and APC P1453L in liver mets, KRAS G12A in primary. In one case with two liver mets we found differences between the two mets and the primary specimen (mets 2: KRAS G13D und TP53 R175H; mets 1: KRAS G13D and TP53 E286K; primary tumor: KRAS G13D and TP53 E286K.
Conclusion: Deep sequencing of 36 driver genes revealed significant differences in the somatic mutation pattern in 22% of patients with liver mets and matched primary tumors. For these patients knowledge of the additional mutations in the liver mets might change the therapy. In the majority of cases other molecular features like copy number variations or mutations outside the known colorectal cancer driver genes might be responsible for altered signaling in liver mets with respect to their parent tumors.

Somatic variations in onco-genes relate to time-to-progression and survival in patients with colorectal cancer UICC stage III undergoing standard-chemotherapy

H. Adams[1], F. Marusch[2], M. Pross[3], R. Mantke[4], R. Koll[5], D. Nürnberg[6], K. Ridwelski[7], T. Manger[8], H. Engelhardt[9], A. Rosenthal[1]. [1]*Signature Diagnostics AG, Potsdam, Germany;* [2]*Klinikum Ernst von Bergmann gGmbH, Chirurgische Klinik − Allgemein- und Viszeralchirurgie, Potsdam, Germany;* [3]*DRK Kliniken Berlin Köpenick, Klinik für Chirurgie, Berlin, Germany;* [4]*Städtisches Klinikum Brandenburg GmbH, Klinik für Allgemein- und Viszeralchirurgie, Brandenburg an der Havel, Germany;* [5]*Klinikum Uckermark GmbH, Klinik für Allgemein- und Viszeralchirurgie, Schwedt, Germany;* [6]*Ruppiner Kliniken GmbH, Medizinische Klinik B, Neuruppin, Germany;* [7]*Klinikum Magdeburg, Klinik für Allgemein- und Viszeralchirurgie, Magdeburg, Germany;* [8]*SRH Wald-Klinikum Gera gGmbH, Klinik für Allgemeine- Viszerale und Kinderchirurgie, Gera, Germany;* [9]*Helios Klinikum Bad Saarow, Klinik für Allgemein- Viszeral- und Thoraxchirurgie, Bad Saarow, Germany*

Background: In colorectal cancer UICC-stage III current guidelines recommend chemotherapy for all patients (pts). Yet, many factors like co-morbidity, clinical performance, age, patient and family preferences influence decision making regarding chemotherapy. We investigated whether somatic variations in well-known onco-genes in the tumor might relate to time-to-progression (TTP) and overall survival (OS).
Materials and Methods: From the multi-center, prospective, diagnostic study 'Molecular Signatures in Colorectal Cancer' we selected pts using the inclusion criteria: 1) clinical UICC stage III, 2) no neo-adjuvant therapy, 3) R0 resection, 4) chemotherapy with either 5-Fluoruracil(5-FU) (5-FU+/− Leucovorin or Capecitabine) or 5-FU plus Oxaliplatin, 5) minimum observation time 2 years since diagnosis, 6) tumor specimen (fresh-frozen or FFPE) passing pathological quality control available, 7) new generation sequencing using Illumina technology (37 genes, 120 amplicons, average coverage per base >2000) of extracted DNA successful. We then used missense and nonsense variations in a double nested bootstrap to predict progression of disease events in a prospective fashion and to receive second order unbiased estimates of the performance characteristics. Lastly, we checked whether these predictions hold retrospectively within prognostic subgroups using survival analysis, in particular the log-rank test.
Results: Altogether 218 pts (111 female, 107 male), median age of 67 years (range 26−86 years) fulfilled all inclusion criteria. Baseline and tumor characteristics were typical for UICC stage III patients; 95 pts received 5-FU-based therapy and 123 FOLFOX/CAPOX therapy. Only 6 pts with rectum tumors received FOLFOX/CAPOX. The genes with 5 or more missense/nonsense variations were [gene symbol (Count)]: TP53 (158), APC (91), KRAS (88), KDR (74), PIK3CA (36), KIT (30), BRAF (26), SMAD4 (23), FBXW7 (21), MET (19), ATM (14), NRAS (8), JAK3 (7), and PTEN (5). A prediction scheme based on SMAD4, FBXW7, JAK3, APC, ATM, and BRAF missense variations achieves significant progression-free and overall survival discrimination in all clinical subgroups. Log-rank test p-values for overall survival time difference were: colon (0.00221), rectum (0.02156), UICC stage IIIB (0.00094), UICC stage IIIC (0.01192), N1 (0.00306), N2 (0.04424).
Conclusions: Our results show that UICC-stage III patients can be stratified into those likely to progress and those at low risk for progression of disease event. Since these data were generated in a multi-center prospective study recruiting more than 7000 patients, we expect that the results will be generalizable.

2183 POSTER DISCUSSION

COX-2 expression influences the prognostic effect of aspirin use after diagnosis in colon cancer patients

M.S. Reimers[1], E. Bastiaannet[2], R. Van Eijk[3], R.L.P. Van Vlierberghe[1], V.E.P. Lemmens[4], M.P.P. Van Herk-Sukel[5], T. Van Wezel[3], P.J.K. Kuppen[1], C.J.H. Van de Velde[1], G.J. Liefers[1]. [1]*Leiden University Medical Center, Surgery, Leiden, Netherlands;* [2]*Leiden University Medical Center, Surgery and Gerontology & Geriatrics, Leiden, Netherlands;* [3]*Leiden University Medical Center, Pathology, Leiden, Netherlands;* [4]*The Netherlands Eindhoven Cancer Registry, Comprehensive Cancer Centre South (IKZ), Eindhoven, Netherlands;* [5]*Pharmo, Institute for Drug Outcomes Research, Utrecht, Netherlands*

Background: Previous studies showed that aspirin use after diagnosis was associated with a survival advantage in colon cancer patients. Use of other Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) is however not associated with a worse survival. The reasons for this phenomenon remain unclear, but might be related to selective inhibition of cyclooxygenase-2 (COX-2). Approximately 70% of all colon cancers express COX-2, which is related to tumorigenesis and might therefore influence the effect of aspirin and NSAID on prognosis.
Material and Methods: The study population consisted of 999 patients diagnosed with colon cancer, registered in the Eindhoven Cancer Registry (ECR) between 1998 and 2007, linked to dispensings of aspirin and NSAIDs registered in the community pharmacy database of the PHARMO record linkage system. A tissue micro array (TMA) was constructed. TMA slides were immunohistochemically stained for COX-2 expression and scored for intensity of the staining. Survival was analyzed with user status as a time-dependent covariate. Multivariate Poisson regression survival models were used to study the effect of aspirin on Overall Survival (OS) and Distant Recurrence Free Survival (DRFS) and were further stratified for COX-2 expression.
Results: Aspirin use after diagnosis was associated with a better OS (HR 0.48, CI 0.22–1.03, $p = 0.05$). NSAID use was associated with a worse survival (HR 1.62, CI 1.18–2.23, $p = 0.004$). 61 patients (44.9%) with aspirin or NSAID use after diagnosis showed weak COX-2 tumor staining and 75 patients (55.1%) showed strong COX-2 staining. Interestingly, after stratification for COX-2 expression, only frequent aspirin use ($\geqslant$5 prescriptions) remained significantly associated with a better OS and DRFS in patients with strong expression of COX-2 (adjusted HR 0.32, CI 0.11–0.97, $p = 0.04$ and adjusted HR 0.32, CI 0.11–0.97, $p = 0.04$). This effect on OS was larger in older colon cancer patients (adjusted HR 0.05, CI 0.01–0.46, $p = 0.008$). After stratification for COX-2 expression, patients with NSAID use showed a worse OS in patients with both high and low expression of COX-2.
Conclusions: Frequent aspirin use is associated with a better OS and DRFS in patients with high COX-2 expression in their tumor sections, especially in older colon cancer patients. COX-2 might therefore play an important role in the effect of aspirin. Currently, COX-1 and PIK3CA are investigated for their role in this phenomenon.

2184 POSTER DISCUSSION

Prospective multi-center study of the impact of Oncotype® DX Colon Cancer Assay results on treatment recommendations in stage II colon cancer patients

G. Srivastava[1], L.A. Renfro[1], R.J. Behrens[2], M. Lopatin[3], C. Chao[3], G.S. Soori[4], S.R. Dakhil[5], G. Kim[6], M. Lee[3], S.R. Alberts[1]. *[1]Mayo Clinic, Medical Oncology, Rochester Minnesota, USA; [2]Medical Oncology and Hematology Associates, Oncology, Des Moines IA, USA; [3]Genomic Health Inc, Genomic Health Inc, Red Wood City CA, USA; [4]Alegent Bergan Mercy Cancer Center, Oncology, Omaha NE, USA; [5]Cancer Center of Kansas, Oncology, Wichita KS, USA; [6]Mayo Clinic, Medical Oncology, Jacksonville FL, USA*

Background: The Onco*type* DX Colon Cancer Recurrence Score® assay is a clinically-validated predictor of recurrence risk in stage II colon cancer patients. This prospective study evaluated the impact of Recurrence Score results on physician recommendations regarding adjuvant chemotherapy in T3, Mismatch Repair-proficient (MMR-P) stage II colon cancer patients.
Patients and Methods: Stage IIA colon cancer patients were enrolled in 17 centers. Patient tumour specimens were assessed by the Recurrence Score test (quantitative RT-PCR) and MMR (IHC). For each patient, the physician's recommended post-operative treatment plan of observation, fluoropyrimidine monotherapy, or combination therapy with oxaliplatin was recorded before and after the Recurrence Score and MMR results were provided.
Results: Of 221 enrolled patients, 141 patients had T3 MMR-P tumours and were eligible for the primary analysis. Treatment recommendations changed for 63 (45%, 95% CI 36%-53%) of these 141 T3 MMR-P patients, with intensity decreasing for 47 (33%) and increasing for 16 (11%). Recommendations for chemotherapy decreased from 73 (52%) to 42 (30%) patients, following review of Recurrence Score results by physician and patient. Increased treatment intensity was more often observed at higher Recurrence Score values and decreased intensity at lower values ($p = 0.011$).
Conclusion: Compared to traditional clinicopathological assessment, incorporation of the Recurrence Score result into clinical decision-making was associated with treatment recommendation changes for 45% of T3 MMR-P stage II colon cancer patients in this prospective multi-center study. Use of the Recurrence Score assay may lead to overall reduction in adjuvant chemotherapy use in this subgroup of stage II colon cancer patients.

Tissue proteinase levels and 10 year survival in colorectal cancer

L. Baker[1], N. Robinson[1], M.A. Tabaqchali[1], D.J. Leaper[1]. *[1]University Hospital of North Tees, Professorial Unit of Surgery, Stockton on Tees, United Kingdom*

Background: Proteinases and their inhibitors are involved in tumour invasion and metastasis. The levels of matrix metalloproteinase (MMP) and plasminogen activator (PA) system components were determined in paired colorectal tumour and normal tissue samples and correlated with the tumour pathology and ten year survival.
Material and Methods: MMP and PAS expression was determined in 101 paired tissue samples from colorectal cancer patients by ELISAs; MMPs-1, 2, −3 and −9 and the tissue inhibitors, TIMPs −1 and −2, urokinase and tissue type PA (uPA and tPA), the PA inhibitors, PAI-1 and −2 and the receptor for uPA, uPAR. Tissue levels were correlated with tumour pathology; Dukes stage, differentiation, tumour depth, vascular and lymphatic invasion ($P<0.05$, Spearman's correlation) and ten year survival analysis was performed ($p < 0.05$ Kaplan Meier). The study had ethics approval.
Results: The levels of all studied MMPs, uPA, uPAR, TIMP-1 and PAIs were significantly greater in colorectal tumour tissue than normal mucosa ($P<0.05$ Mann Whitney) e.g. PAI-1: tumour, median 14.9(range, 0.2–80.2)ng/mg total protein; normal, 2.1(0.1–65.0). However tPA levels were significantly greater in normal mucosa.
Tumour levels of MMPs, uPA, uPAR and PAI-1 significantly correlated with Dukes' stage e.g. MMP-1: Adenoma, 0.9(0.2−6.8); Dukes A, 4.7(0.1–23.0); Dukes B, 11.9(0.6–86.9); Dukes D, 16.3(0.3–30.8). PAI-1 and uPA tumour levels also significantly correlated with lymphatic invasion, TIMP-1 and PAI-1 with tumour depth and PAI-2 with vascular invasion.
The proportion of active MMP-2 and MMP-9 in tumour tissue significantly correlated to both disease free and overall ten year survival, with patients with higher levels of these factors having poorer survival.
Conclusions: Tumour levels of proteinases and inhibitors from both the MMP and PA proteinase systems correlated with tumour pathology. However, only active MMP-2 and MMP-9 levels correlated with disease-free and overall ten year survival.
No conflict of interest.

2186 POSTER

Biomarkers of resistance to anti-EGFR in wild type KRAS/BRAF colorectal cancer cell lines

S. Sree Kumar[1], T. Price[2], J. Hardingham[1]. *[1]The Queen Elizabeth Hospital, Haematology-Oncology, Adelaide, Australia; [2]The Queen Elizabeth Hospital, Medical-Oncology Unit, Adelaide, Australia*

Background: Treatment of metastatic colorectal cancer (mCRC) with targeted therapies such as monoclonal antibody (mAb) inhibiting the epidermal growth factor receptor (EGFR) offer promise in improving patient outcomes. However, a high proportion of CRC patients who receive mAb show resistance to such therapy. Biomarkers such as mutant KRAS, BRAF and NRAS predict resistance to anti-EGFR therapy in only a proportion of patients and we hypothesise that other biomarkers for resistance to EGFR-targeted therapies exist. We aimed to identify resistant and sensitive wild type (WT) KRAS/BRAF CRC cell lines to anti-EGFR treatment, to identify candidate biomarkers in resistant CRC cell lines, to validate these findings using qRT-PCR and to use siRNA to knockdown one or more of these biomarkers overexpressed in the resistant cell lines. We hypothesise that knockdown of such biomarkers in the resistant cell lines will restore sensitivity.
Materials and Methods: Six WT KRAS/BRAF CRC cell lines were tested for resistance/sensitivity to anti-EGFR treatment and proliferation determined using the Promega CellTiter 96® AQueous Assay kit, with proliferation rate >50% deemed resistant and <50% deemed sensitive (Jhawer *et al.* 2008). Biomarker expression in the cell lines was determined using Qiagen RT-Profiler Array Human EGF/PDGF pathway kit and validated using qRT-PCR. siRNA was performed to knockdown HBEGF in the resistant cell line SNUC1. siRNA concentration was optimised using 10 nm/well, 50 nm/well and 100 nm/well, and transfection reagent was used at 0.2 μL/well, 0.5 μL/well and 1 μL/well concentrations. qRTPCR was performed to confirm knockdown and determine optimum concentrations for both reagents.
Results: SW48, COLO-320DM and SNU-C1 were resistant to anti-EGFR treatment, with 59.1%, 68.25% and 83.8% proliferation respectively while LIM1215, CaCo2 and SW948 were sensitive to the treatment with 18.6%, 41.9% and 36.8% proliferation respectively ($P = 0.0003$). Following RT-Profiler Array, 3 upregulated genes were chosen as candidate biomarkers of resistance based on a number of criteria; number of occurrences in all combinations of resistance vs sensitive cell lines, fold change more than 3 and statistical significance and this correlated with qRT-PCR results. EGR1 (early growth response protein 1) was upregulated in the resistant cell line SW48 by 28-fold, AKT3 (protein kinase B gamma) was upregulated in COLO-320DM by 31.3-fold and HBEGF (heparin-binding epidermal growth factor-like growth factor) was upregulated in SNUC1 by 22.6-fold. siRNA knockdown of HBEGF by 73% was achieved in SNUC1 (by qRT-PCR), at 10 nm/well for siRNA and 0.2 μL/well transfection reagent, compared to the negative control sequence (7%) used in the same conditions.
Conclusion: Three biomarkers up-regulated in the resistant cell lines have been identified and these may have a role in causing resistance to anti-EGFR treatment. They may emerge as biomarkers of resistance and be predictive of patients' response to anti-EGFR therapy.
No conflict of interest.

miR-126 and miR-20b are under-expressed in colorectal tumors

T. Yamaguchi[1], T. Iijima[2], R. Wakaume[2], H. Matsumoto[1], D. Nakano[1], Y. Nakayama[1], K. Takahashi[1], M. Miyaki[2]. *[1]Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Department of Surgery, Tokyo, Japan; [2]Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Hereditary Tumor Research Project, Tokyo, Japan*

Background: MicroRNAs (miRNAs), member of a family of short nucleotide non-coding RNAs, play important roles in cell proliferation, differentiation, apoptosis, and development. MiR-126 regulates angiogenic

signaling and vascular integrity, and suppresses the neoplastic cell growth by targeting PI3K signaling in colon cancers. MiR-20b regulates VEGF expression mediated by HIF-1α, and affects cell proliferation. The aim of this study is to clarify significance of miR-126 and miR-20b in colorectal carcinogenesis.
Materials: Colorectal tumors and corresponding normal tissues obtained after informed consent from 2008 to 2011. In all, 58 FAP tumors, 16 Lynch syndrome tumors, and 62 sporadic colorectal tumors, including 38 MSS tumors, and 23 MSI-H tumors, were analyzed for miRNA expression in this study.
Results: Expression levels of miR-126 and miR-20b in colorectal tumors were lower than those in normal mucosa. Frequency of miR-126 down-regulation was 100.0% in FAP adenoma, 87.5% in FAP intramucosal carcinoma, 88.9% in invasive carcinoma, 86.7% in Lynch syndrome, 70.0% in MSS tumor, and 75.0% in MSI-H tumor, respectively. Frequency of miR-20b down-regulation was 64.0% in FAP adenoma, 50.0% in FAP intramucosal carcinoma, 73.3% in invasive carcinoma, 62.5% in Lynch syndrome, 79.5% in MSS tumor, and 91.3% in MSI-H tumor, respectively.
Conclusion: The under-expression of miR-126 and miR-20b were observed in various types of colorectal cancer, and the current study supports that the under-expressions of miR-126 and miR-20b occur in the early event of colorectal carcinogenesis.
No conflict of interest.

2188 POSTER

Dual blockade of IGF-IR and EGFR sensitizes colorectal cancer cells to 5-FU-based radiochemotherapy in vitro and in vivo

S. Kaulfuß[1], R. Oberthür[1], J. Meyer[1], H. Seemann[1], L.C. Conradi[2], M. Rave-Fränk[3], J.G. Scharf[4], P. Burfeind[1]. *[1]University Medical Center Goettingen, Institute of Human Genetics, Goettingen, Germany; [2]University Medical Center Goettingen, Department of General and Visceral Surgery, Goettingen, Germany; [3]University Medical Center Goettingen, Department of Radiotherapy, Goettingen, Germany; [4]HELIOS Klinikum Erfurt GmbH, 2nd Department of Internal Medicine, Erfurt, Germany*

Background: Receptor tyrosine kinases (RTKs) are known to be key players in the development of colorectal cancer (CRC). We hypothesize that the simultaneous inhibition of the RTKs insulin-like growth factor receptor (IGF-IR) and epidermal growth factor receptor (EGFR) increases efficiency of the 5-Fluorouracil-based radiochemotherapy (RCT) of CRC in non-responder patients.
Methods: Colony formation assays and xenograft models were used to study sensitization and therapy effects after RCT in combination with the inhibition of IGF-IR (AEW-541) and EGFR (erlotinib) *in vitro* and *in vivo*. To identify the molecular mechanisms of the success of the additional RTK inhibition western blot, immunofluorescence, live/dead and caspase activation assays were performed to unravel DNA damage repair and induction of apoptosis; cell cycle distribution was analysed by flow cytometry. Furthermore, proximity ligation assays were applied to study interaction of IGF-IR and EGFR during RCT treatment.
Results: Simultaneous inhibition of IGF-IR and EGFR results in a sensitization of CRC cells (DLD-1, SW837 and Caco-2) to RCT regardless of their responder state to RCT. In addition, dual blockade of both receptors in CRC cells enhanced the therapy success in the SW837 xenograft model. To identify the molecular mechanisms underlying this sensitization of CRC cells we analysed the DNA repair mechanisms, apoptosis and cell cycle distribution. Phospho-H2AX staining as a marker for double strand breaks revealed impairment of DNA repair in single inhibitor treatments 24 h after RCT and even more pronounced effects were observed when both receptors were inhibited simultaneously. Moreover, DLD-1 cells showed a cell cycle arrest in G2, mediated by cyclin B1, whereas induction of apoptosis was observed in SW837 and Caco-2 cells. Furthermore, we could show using proximity ligation and co-immunoprecipitation assays that IGF-IR and EGFR form heterodimers in CRC cells in a ligand-dependent manner. During RCT this heterodimerization of IGF-IR and EGFR is disturbed.
Conclusion: Taken together, these results indicate a role of RTKs EGFR and IGF-IR in sensitization of CRC cells to RCT. Dual inhibition of both RTKs EGFR and IGF-IR might represent a promising new approach for patients with rectal cancer not responding to a combined RCT.
No conflict of interest.

2189 POSTER

KRAS G13D mutations associated with sensitivity to cetuximab or panitumumab treatment in colorectal cancer cell lines

S. Sree Kumar[1], T. Price[2], O. Mohyieldin[3], M. Borg[4], A. Townsend[2], J. Hardingham[1]. *[1]The Queen Elizabeth Hospital, Haematology-Oncology, Adelaide, Australia; [2]The Queen Elizabeth Hospital, Medical-Oncology Unit, Adelaide, Australia; [3]Royal College of Surgeons in Ireland, School of Medicine Bahrain Campus, Al-Sayh, Bahrain; [4]University of Adelaide, School of Medicine, Adelaide, Australia*

Background: The treatment of metastatic colorectal cancer (mCRC) has improved over recent years, with targeted therapies providing additional benefit. One such target that has emerged for mCRC treatment is the epidermal growth factor receptor (EGFR). It is well accepted that a mutation in codon 12 or 13 in *KRAS,* downstream of the EGFR, evokes constitutive activation of the RAS/RAF/MAPK signalling pathway, and that this correlates with resistance to anti-EGFR monoclonal antibody therapies. However, a retrospective study reported that a proportion of patients with KRAS G13D mutation respond better to cetuximab (Cmab) compared to patients with other KRAS mutation. A similar analysis for panitumumab (Pmab) was not as conclusive. We aimed to determine the sensitivity of colorectal cancer cell lines to Cmab or Pmab treatment, and investigate the correlation of the KRAS mutational status of the colorectal cancer cell lines to the responsiveness to Cmab or Pmab.
Materials and Methods: To determine the responsiveness of CRC cell lines to Cmab or Pmab, proliferation assays were conducted using the MTS colorimetric assay with the Promega CellTiter 96® AQueous Assay kit.
Results: Following treatment with Cmab or Pmab at the optimum concentration of 8 μg, SW480 with KRAS G12V mutation had the highest proliferation rate for Cmab at 72.3% and for Pmab at 71.4%, showing resistance to both treatments. LIM1215, a KRAS WT and BRAF WT cell line, had the lowest proliferation rate for Cmab at 29.3% and Pmab at 29%, showing greatest sensitivity to both treatments. HCT-116, LoVo and T84, all with KRAS G13D mutation and BRAF WT showed intermediate sensitivity to Cmab and Pmab. In the Cmab treatment group, HCT-116 showed highest sensitivity at 44.5% proliferation, followed by T84 at 55.2% and LoVo at 60.6%. In the Pmab treatment group, LoVo showed highest sensitivity at 40.4% proliferation, followed by T84 at 45.4% and HCT-116 at 48.3%. However, there was no significant difference noted overall between sensitivity of KRAS G13D mutated cell lines to Pmab vs Cmab (44.7% vs 53.7%), differing from that reported in the clinic.
Conclusion: The specific KRAS mutation determines the responsiveness to anti-EGFR monoclonal antibody treatment and confirms clinical observations for Cmab, but the difference of efficacy between Pmab and Cmab was not confirmed.
Conflict of interest: *Advisory board: Merck and Amgen*

2190 POSTER

Protein kinase CK2 enhances colorectal cancer malignancy by upregulating the expression of cyclooxygenase-2 through the canonical Wnt signaling pathway

E. Silva[1], R. Yefi[1], P. Cabello[1], I. Niechi[1], R. Armisen[2], C. Fernandez[3], A. Quest[2], J.C. Tapia[1]. *[1]University of Chile, Cell Transformation Laboratory − ICBM − Faculty of Medicine, Santiago, Chile; [2]University of Chile, ICBM − Faculty of Medicine, Santiago, Chile; [3]University of Chile, Department of Anatomopathology − HCUCH − Faculty of Medicine, Santiago, Chile*

Background: Protein kinase CK2 is abnormally elevated in a wide variety of cancers. The concept that cancer cells are become 'addicted to CK2' in order to create a cellular environment favorable to neoplasia has recently emerged. Regarding to this, CK2 promotes an elevated activity of β-catenin at the canonical Wnt signaling pathway. Aberrant activation of this pathway leads to an increased expression of genes, including survivin and cyclooxygenase-2 (COX-2), which are linked to cancer development and progression. Also, COX-2's metabolite prostaglandin E2 (PGE2) has been demonstrated to be involved in progression and metastasis of colon and breast cancers. However, if CK2 regulates the COX-2-dependent production of PGE2 and this is functionally related with colon cancer cell viability and invasion has not been studied.
Methods: Changes in COX-2, β-catenin and survivin expression were analyzed by RT-PCR and western blot in colon (HT29-ATCC, HT29-US, DLD-1) and breast (ZR-75) cancer cells. CK2 activity was specifically inibited with TBB or DMAT, while COX-2 activity was inhibited with SC-791 or celecoxib. Proliferation and apoptosis were determined by the MTS® and Caspase-Glo® assays, respectively. Cell invasion was evaluated with

a matrigel-based assay®. The effects of PGE2 on proliferation, apoptosis and cell invasion were investigated.
Results: Elevated COX-2 expression and activity were detected in colon and breast cancer cells. Inhibition of both CK2 and COX-2 significantly down-regulated cell viability, as observed by decreased proliferation and increased apoptosis. CK2 inhibition also correlated with decreased mRNA and protein levels of COX-2. However, supply of PGE2 did revert the CK2's inhibitor-induced loss of COX-2 expression, augmenting proliferation and invasiveness, as well as decreasing apoptosis.
Conclusions: Our results identify the CK2/COX-2/PGE2 axis like relevant for colon and breast cancer malignancy. Moreover, they point to CK2 as a potentially interesting pharmacological target in colon and breast cancer treatment. Supported by grants from ICGEB (CRP/CHI10−01) and FONDECYT (11070116, 1120132).

2191 POSTER

Simvastatin induces KRAS translocation in KRAS mutant colorectal cancer cells and may influence the susceptibility to anti-EGFR therapy

L. Krens[1], C.M.C. Pullen[1], R.F. Baak-Pablo[1], H.J. Guchelaar[1], R.J.H.M. Straaten van der[1]. [1]*Leiden University Medical Center, Clinical pharmacy and Toxicology, Leiden, Netherlands*

Background: *KRAS* mutation status in colorectal cancer is leading for the use of EGFR antibodies, such as cetuximab. KRAS is activated by post-translational modification (prenylation) by binding C15 and C17 fatty acid chains. As a consequence KRAS becomes more lipophilic and associates with the membrane to exert its function. Statins inhibit the synthesis of these C15 and C17 chains. Statins may therefore have the potential to influence the KRAS mutant phenotype. Previous experiments have shown that *KRAS* mutant cells could be sensitized to anti-EGFR therapy using simvastatin.
This study sought to determine the mechanism of sensitisation by simvastatin in *KRAS* mutant CRC cells. We hypothesise that by inhibiting the prenylation, KRAS will not associate with the inner-membrane and KRAS will be less active, making *KRAS* mutant cells more susceptible to anti-EGFR therapy.
Material and Methods: LoVo (*KRAS mutant* G13D) and SW48 (*KRAS* wildtype) CRC cells were seeded in NuncTM glass 8-chamber slides at density of 20,000 cells/well and cultured for 24 hours. After 24 hours, medium was replaced with medium with or without simvastatin (2μM) and cultured for another 24 hours. Cells were fixated with 2% PFA, permeabilized using 0.1% Saponin + 2% PFA, incubated with KRAS mouse anti-human antibody and incubated with Alexa 488 goat anti-mouse antibody. Vectashield-Dapi was used to stain the nucleus.
Results: Confocal microscopy showed that KRAS is associated with the membrane in both wildtype and mutant CRC cells. In wildtype *KRAS* cells, we observed that KRAS is also localized in the cytoplasm. After incubation with simvastatin, in *KRAS* mutant Lovo cells, KRAS translocates from the membrane to the cytoplasm.
Conclusions: Simvastatin induces translocation of KRAS from the membrane to the cytoplasm in *KRAS* mutant cells and therefore may sensitize *KRAS* mutant CRC cells to anti-EGFR therapy.
No conflict of interest.

2192 POSTER

Blockade of PDGFR family together with SRC leads to diminished proliferation of CRC cells

S. Kaulfuß[1], H. Seemann[1], R. Kampe[1], J. Meyer[1], B. König[1], R. Dressel[2], J.G. Scharf[3], P. Burfeind[1]. [1]*University Medical Center Goettingen, Institute of Human Genetics, Goettingen, Germany;* [2]*University Medical Center Goettingen, Department of Molecular Immunology, Goettingen, Germany;* [3]*HELIOS Klinikum Erfurt GmbH, 2nd Department of Internal Medicine, Erfurt, Germany*

Background: Among the family of receptor tyrosine kinases (RTKs) the platelet-derived growth factor receptor (PDGFR) has attracted increasing attention as potential target of anti-tumor therapy in colorectal cancer (CRC).
Methods and Results: Varying expression of the PDGFRβ was demonstrated in CRC cell lines. SW480 cells showing the highest PDGFRβ expression were used for receptor down-regulation by siRNA and by the pharmacological inhibitor of PDGFRβ Ki11502. Blockade of PDGFRβ using both approaches led to a moderate inhibition of cell proliferation and diminished the PDGF-BB-induced phosphorylation of the downstream signaling pathway AKT. Surprisingly, incubation with Ki11502 resulted in an arrest of SW480 cells in the G2 phase of the cell cycle, whereas the siRNA approach did not. To address this difference, we analyzed proliferation and cell cycle distribution in DLD-1 and Caco-2 cells either with down-regulated PDGFRβ expression or after Ki11502 treatment. Whereas DLD-1 cells (high c-KIT expression) showed a strong decrease of proliferation after treatment with Ki11502, this effect was not observed in the siRNA approach. Caco-2 cells (no c-KIT expression) did not respond at all. Hence, we reduced expression of c-KIT in SW480 and DLD-1 cells, but proliferation studies could not prove the involvement of c-KIT inactivation during Ki11502 treatment.
To identify the underlying cause of effectiveness of Ki11502 in CRC cell lines we applied a RTK activation antibody array on SW480 cells treated with siRNAs against c-KIT, PDGFRβ or both and two concentrations of Ki11502. This analysis revealed that SRC kinase is inactivated after Ki11502 treatment, but not after the siRNA approach. Further studies using the SRC-specific inhibitor PP2 showed that SRC inhibition upon treatment with the inhibitor Ki11502 is responsible for the observed effects of Ki11502 in SW480 CRC cells.
Conclusion: In summary our results demonstrate, that inhibition of PDGFRβ alone using siRNA has only moderate cellular effects in CRC cell lines, instead, multi-target inhibition of PDGFRβ, c-KIT and SRC, e.g. using Ki11502, represent a promising therapeutic intervention for the treatment of CRC.
No conflict of interest.

2194 POSTER

Kiss-1 suppresses the motility of colorectal cancer cells via the ERK pathway and aberrant expression of Kiss-1 and its receptor (Kiss-1R) in patients with colorectal cancer

K. Ji[1], W. Jiang[1]. [1]*Cardiff University, Metastasis & Angiogenesis Research Group Cardiff University School of Medicine, Cardiff, United Kingdom*

Background: The metastatic process involves impairment of cell-cell adhesion in neoplastic epithelia, invasion into adjacent tissues and dissemination of cancer cells through the lymphatic and haematogenous routes. During the process, metastasis suppressor genes play pivotal roles. However, classical metastasis suppressor genes are limited in both numbers and to the knowledge of their mode of actions. Kiss-1 and its receptor (Kiss-1R) have been suggested as a novel pair of metastasis suppressors in several human solid tumours. However, the role of Kiss-1 and Kiss-1R in colorectal cancer remains largely unknown. Therefore, the aim of this study was to investigate the role and signal transduction of Kiss-1 and its receptor in colorectal cancer.
Material and Methods: Colorectal cancer cell lines (HT115, HRT18, RKO and Caco-2) were screened for the mRNA expression levels of Kiss-1 and Kiss-1R using PCR analysis. Sublines of cancer cells with differential expression of Kiss-1 and Kiss-1R were created, using ribozyme transgenes to respectively knock down the expression of Kiss-1 and Kiss-1R. The influence of Kiss-1 and Kiss-1R on the biological functions of cancer cells was evaluated using *in vitro* function assays and ECIS assay. A cohort of human colorectal cancer tissues (n = 171) were investigated Kiss-1 and Kiss-1R expression. The expression levels of both molecules were correlated with the clinical and pathological and outcome results of the patients.
Results: Over-expression of Kiss-1 suppressed the *in vitro* invasion and migration of colorectal cancer cells. Exogenous Kiss-1 (Kisspeptin-10) decreased cellular migration of colorectal cancer cells, an action required ERK signalling as shown in an ECIS based cellular model. In human colorectal cancer tissues, levels of message expression of Kiss-1 had a negative correlation with Dukes staging, TNM staging, tumour size and lymph node involvement. Kiss-1R expression was significantly decreased in tumour tissues compared with adjacent normal tissues ($p<0.00001$). In contrast, the increased expression of Kiss-1R had positive correlation with colorectal incidence ($p = 0.0207$). In addition, it was observed that patients with high level of Kiss-1R had significantly shorter overall and disease free survival time than those with low level was observed ($p = 0.011$ and $p = 0.033$, respectively).
Conclusions: It is concluded that Kiss-1 plays a pivotal tumour suppressor role in colorectal cancer through the inhibiting of the motility of colorectal cancer cells, a process requiring the participation of the ERK pathway. Together with the aberrant expression of Kiss-1 and Kiss-1R in patients with colorectal cancer, it is suggested that the Kiss-1 complex is a potential tumour suppressor with prognostic value in patients with colorectal cancer.
No conflict of interest.

2195 POSTER

Genetic variants in DNA repair genes and survival in colorectal cancer patients treated with oxaliplatin combination chemotherapy

E.J. Kap[1], P. Seibold[1], K. Buck[2], A. Benner[3], M. Hoffmeister[4], H. Brenner[4], C.M. Ulrich[2], B. Burwinkel[5], J. Chang-Claude[1]. *[1]German Cancer Research Center, Division of Cancer Epidemiology, Heidelberg, Germany; [2]National Center for Tumor Diseases, Division of Preventive Oncology, Heidelberg, Germany; [3]German Cancer Research Center, Division of Biostatistics, Heidelberg, Germany; [4]German Cancer Research Center, Division of Clinical Epidemiology and Aging Research, Heidelberg, Germany; [5]University of Heidelberg, Division of Molecular Biology of Breast Cancer, Heidelberg, Germany*

Background: Oxaliplatin has become one of the main chemotherapeutic agents for the treatment of colorectal cancer (CRC). The platinum agent causes DNA adducts and crosslinks, which forces the (tumor) cell to go into apoptosis. The Nucleotide Excision Repair (NER) pathway and the Double Strand Break Repair (DSBR) pathway are involved in the repair of damage caused by oxaliplatin treatment. Genetic variants in these genes may therefore influence survival in CRC patients. Only a limited number of genetic variants in these genes have been investigated so far and therefore we assessed the association between 321 genetic variants in 52 genes of the NER and DSBR pathways and overall survival (OS) in CRC patients who received oxaliplatin chemotherapy and assessed differential effects compared to patients with other chemotherapeutics.
Material and Methods: We included 620 CRC patients diagnosed between 01.01.2003 and 31.12.2007 and recruited in a German population-based study (DACHS), who received adjuvant chemotherapy (223 patients with oxaliplatin treatment) and had complete follow-up for 3 to 5 years. Detailed epidemiological, clinical and therapy data were collected using questionnaires and clinical/pathological records. Genotyping was conducted using the Illumina GoldenGate assay. Genetic main effect analysis was performed using component-wise Cox regression models, adjusting for age, sex, UICC stage, cancer site and BMI. The Benjamini & Hochberg False Discovery Rate (FDR) was used to correct for multiple comparisons. Effect modification by oxaliplatin treatment was assessed using a multiplicative interaction term.
Results: Median follow-up time in patients receiving oxaliplatin was 3.0 years after which 107 patients were deceased. In patients who received oxaliplatin, 15 SNPs were nominally significantly associated with overall survival (OS). Six SNPs in 6 genes showed some evidence of differential association with OS according to oxaliplatin treatment (nominal p for heterogeneity <0.01). Of these SNPs, only rs11574214 in the Werner syndrome ATP-dependent helicase (*WRN)* gene showed to be a marginally predictive marker for outcome after oxaliplatin treatment after correction for multiple testing (adjusted p for heterogeneity =0.07).
Conclusion: Our data suggest that genetic variants in the *WRN* gene may be predictive markers for oxaliplatin treatment; however, more research is warranted to confirm these results.
No conflict of interest.

2196 POSTER

Elevated frequency but decreased absolute count of regulatory T lymphocytes in rectal cancer patients undergoing therapy

B. Bencsikova[1], K. Greplova[2], L. Zdrazilova-Dubska[3]. *[1]Masaryk Memorial Cancer Institute, Department of Complex Oncology Care, Brno, Czech Republic; [2]Masaryk Memorial Cancer Institute, Department of Laboratory Medicine/ Regional Centre for Applied Molecular Oncology, Brno, Czech Republic; [3]Masaryk Memorial Cancer Institute, Department of Laboratory Medicine/Department of Pharmacology − ACIU Medical Faculty Masaryk University/Regional Centre for Applied Molecular Oncology Masaryk Memorial Cancer Institute, Brno, Czech Republic*

Introduction: T-regulatory cells (Tregs) are a specialized subpopulation of T cells that suppress the activation, expansion, and function of other T cells. Tregs inhibit and eradicate cytotoxic T-lymphocytes and T-helper lymphocytes. In colorectal cancer, they are up to 80% of the population of tumor-infiltrating lymphocytes and their number in tumor has been reported to correlate with worse outcome.
Materials and Methods: Peripheral blood was sampled into K_3EDTA anticoagulant and CBC and Tregs were measured within 3 hours from blood withdrawal. Tregs were detected as CD3-FITC(+), CD127-PE(low/-), CD25-PC5(+) and CD4-PC7(+) cells using flow cytometry. Tregs were evaluated in samples from reference population (51 men, 51 women) and from patients with rectal tumors (102 men, 43 women) as frequency (% from lymphocytes) and absolute count (cell/microL).
Results: In reference population, the median of absolute Treg count was 39.2 cells/microL (**interquartile range IR:** 28.8 to 53.5 cells/microL) and median of Treg frequence was 4.9% (**IR:** 3.9 to 6.4%). We have not observed either difference in Tregs level between men and women or age-dependence. In cancer patient group, median of absolute Treg count was 21.1 cells/microL (**IR:** 15.3 to 29.3 cells/microL) and median of Treg frequence was 6.3% (IR: 3.9 to 8.5%). Comparing both, absolute count and percentage, we found statistically significant difference between reference and cancer population. Interestingly however lower absolute Tregs and increased percentage of Tregs in rectal cancer patients. Higher proportion of Tregs is likely result of lower lymphocyte count in patients undergoing anticancer therapy (1.21 x 10^9/L vs 1.81 x 10^9/L in reference population).
Conclusion: The elevated levels of circulating Tregs have been reported as a negative prognostic factor for various cancers. Here we show that Treg absolute count and frequency are not interchangeable and that Treg count but not their frequency is stable within one cancer patients. In conclusion, we evaluated peripheral blood Tregs as a potential marker of disease and prognostic factor, which is relatively easy to measure, and discuss our findings.

2197 POSTER

The gp130/Jak/Stat3 pathway is required for Wnt induced regeneration and tumorigenesis in the mouse intestine

M. Buchert[1], T.J. Phesse[1], E.C. Stuart[1], M. Ernst[1]. *[1]The Walter and Eliza Halll Institute of Medical Research, Cell Signaling and Cell Death, Parkville, Australia*

Background: The majority of sporadic and familial colorectal cancers (CRC) arise from mutations in the tumor suppressor gene *APC* leading to uncontrolled activation of the canonical WNT signalling pathway. Meanwhile, WNT mediated regulation of intestinal stem cells (ISCs) is critical for epithelial regeneration and homeostasis. Thus far, however, therapeutic targeting of the WNT pathway has proven difficult in human disease.
Material and Methods: We use mouse models of inherited and sporadic CRC to genetically and pharmacologically target the cytokine-dependent gp130/Jak/Stat3 pathway. Furthermore, we assay the growth of human CRC cell lines *in vitro* and *in vivo* under conditions that interfere with gp130/Jak/Stat3 signalling.
Results: We show that excessive gp130/Jak/Stat3 signalling promotes WNT-pathway dependent regeneration of the intestinal epithelium after injury and exacerbates intestinal tumorigenesis in mouse models of spontaneous or inherited CRC, and arising from mutant *APC*. Conversely, genetic restriction of the gp130/Jak/Stat3 pathway inhibits intestinal regeneration and suppresses tumor growth despite persistent excessive WNT signalling. Additionally, therapeutic administration of a small molecule Jak kinase inhibitor potently blocked *de novo* tumor formation and restricted the growth of already existing lesions in mouse models of spontaneous and inherited CRC. Moreover, this inhibitor also blocked the growth of human CRC cell lines with *APC* mutations in soft agar colony assays and as xenografts in nude mice, but had no effect on the growth of isogenic CRC cell counterparts that expressed wild type *APC*. These results suggest that gp130/Jak/Stat3 pathway is only rate limiting for the proliferative responses elicited during conditions of excessive WNT signalling. We identify Stat3-dependent Bmi1 induction and the resulting repression of p16 and p21 as the mechanism by which the gp130/Jak/Stat3 pathway modulates the cellular response to excessive WNT signalling.
Conclusions: We propose that the gp130/Jak/Stat3 pathway is rate-limiting selectively for the growth of *APC* mutant tumors, and this pathway therefore provides a readily exploitable target for the therapeutic treatment of CRC.

Is there a synergistic effect between ascorbic acid and conventional chemotherapy in the treatment of colorectal carcinoma?

C.R. Marques[1], A.S. Pires[2], J.C. Encarnação[2], T.J. Gonçalves[2], A.C. Mamede[3], J. Casalta-Lopes[2], A.C. Gonçalves[4], A.M. Abrantes[5], A.B. Sarmento-Ribeiro[4], M.F. Botelho[5]. *[1]Life Sciences Department, Faculty of Science and Technology of University of Coimbra, Coimbra, Portugal; [2]Biophysics Unit − IBILI, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [3]CICS-UBI − Health Sciences Research Centre, University of Beira Interior, Covilhã, Portugal; [4]Applied Molecular Biology Unit − CIMAGO, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [5]Biophysics Unit − IBILI − CIMAGO, Faculty of Medicine of University of Coimbra, Coimbra, Portugal*

Background: Colorectal cancer (CRC) is a major health problem with more than one million new cases diagnosed worldwide every year.

Ascorbic acid (AA), the reduced form of vitamin C works as a pro-oxidant at pharmacological concentrations, promoting the formation of reactive oxygen species which can induce cancer cell death. It has been proved that AA doesn't protect cancer cells from chemotherapy but plays a protective role in normal cells. At the same time AA can enhance tumor growth inhibitory effect conferred by usual therapies regardless tumor type. Giving the positive feedback in turn of the use of AA with chemotherapy, the aim of this study is to evaluate the therapeutic potential of AA in combination with 5-Fluorouracil (5FU) in human CRC cell lines.
Methods: WiDr, C2BBe1 and LS1034 (multidrug resistant) cell lines were cultured in appropriate culture medium and incubated in absence and with different concentrations of AA and 5FU alone or in combination during different periods of time. The half maximal inhibitory concentration (IC50), as well as the interaction index were calculated after 48, 72 and 96 hours by sulphorhodamine B (SRB) assay. To evaluate cell survival clonogenic assays were done, the number of colonies was counted, being plate efficiency and survival factor determined. To evaluate cell viability and types of cell death, flow cytometry was performed, using annexin V and propidium iodide double staining.
Results: Results obtained with SRB showed an anti-proliferative effect induced by AA in all cell lines in a dose and cell line-dependent way (r^2>0.90). C2BBe1 cells revealed to be the most sensitive to AA (IC50=0.82mM) comparing to WiDr (IC50=5.9mM) and LS1034 cells (IC50=5.37mM). Clonogenic assays revealed that, as the concentration of AA increases, survival factor decreases. AA also induces a cytotoxic effect when present in higher concentrations. When in combination, we reached an addictive effect at 72 hours of incubation for C2BBe1 and LS1034 and a synergistic effect at 96 hours in all cell lines, more evident in LS1034. Clonogenic assays corroborate these results.
Conclusions: Our study allowed us to verify the existence of synergism between AA and 5FU as the combination of these drugs induced an anti-proliferative effect and a decrease in cell survival more relevant than that obtained with compounds alone that probably affect somehow LS1034 resistance. The data obtained could contribute to the development of a promising therapy in CRC with reduced doses of conventional chemotherapeutic drugs and consequently, a decrease in secondary effects.
No conflict of interest.

2199 POSTER

Ascorbic acid and colon carcinoma: correlation between uptake and cytotoxic effect

A.R. Almeida[1], A.S. Pires[2], C.R. Marques[1], A.C. Mamede[3], J. Casalta-Lopes[2], A.M. Abrantes[4], A.B. Sarmento-Ribeiro[5], M.F. Botelho[4]. *[1]Life Sciences Department, Faculty of Science and Technology of University of Coimbra, Coimbra, Portugal; [2]Biophysics Unit − IBILI, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [3]CICS-UBI − Health Sciences Research Centre, University of Beira Interior, Covilhã, Portugal; [4]Biophysics Unit − IBILI − CIMAGO, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [5]Applied Molecular Biology Unit − CIMAGO, Faculty of Medicine of University of Coimbra, Coimbra, Portugal*

Background: Ascorbic acid (AA), the reduced form of vitamin-C, has a double action: antioxidant and pro-oxidant. AA is a powerful antioxidant, since it can neutralize free radicals, constituting a powerful anticancer mechanism. As a pro-oxidant, AA promotes the formation of reactive oxygen species (ROS) such as hydrogen peroxide (H_2O_2), which endanger the cell viability. Another feature shown in tumor cells is the reduction of ROS-detoxification machinery, such as catalase, compared with normal cells. Thus, the increased production of H_2O_2 coupled with deficiency of catalase activity and presence of transition metals may result in the selective cytotoxicity of vitamin-C. The aim of this work is to correlate the metabolism of vitamin-C with the cytotoxic effect on colon carcinoma cells.
Material and Methods: The cell lines used were LS1034 and C2BBe1. Both cell lines were incubated in absence and with different concentrations of AA. The half maximal inhibitory response (IC50) was calculated after 24, 48, 72 and 96 hours by sulphorhodamine B (SRB) assay. To complement, clonogenic assays were performed to evaluate cell survival. To study the uptake of vitamin-C by the cells it was used a radionuclide (^{99m}Tc) to label the reduced form of vitamin-C obtaining ^{99m}Tc-AA, with a previously described method. The respective quality control was done by HPLC in order to determine the labeling efficiency. Cell suspensions were incubated with ^{99m}Tc-AA (25 μCi/ml) and uptake studies were conducted.
Results: Our results obtained with SRB showed that AA induces a decrease in cell proliferation in both cell lines, in a dose-dependent way (r^2>0.91). The clonogenic assays revealed that, as the concentration of AA increases, the survival factor decreases. These facts were much more evident in C2BBe1 cells (IC50<0.95mM) comparing to LS1034 cells (IC50>4.33mM). The percentage of uptake of ^{99m}Tc-AA is higher than the uptake of sodium pertechnetate ($^{99m}TcO_4Na$) in both cell lines. The radiolabeling efficiency was 97.5%±2.28%, determined by graphic integration and normalization of the peaks by HPLC. Preliminary results showed that ^{99m}Tc-AA uptake is higher in C2BBe1 (around 6%) and lower in LS1034 cells (not exceeding 1.06%).
Conclusions: Our study suggests that AA induces an anti-proliferative effect and decreases cell survival. The higher uptake and the higher sensitivity of C2BBe1 cells to AA, lead to a possible correlation between the cytotoxic effects and the uptake of AA by cells.
No conflict of interest.

2200 POSTER

Circulating tumor cells (CTCs) as a surrogate biomarker of DFS in patients (pts) with liver-only (L) metastases of colorectal cancer (LM-CRC)

L. Teijeira[1], A. Viudez[2], M.L. Antelo[3], S. Zalba[3], I. Hernández[2], J. Herrera[4], A. Tarifa[4], C. Zazpe[4], R. Vera[2]. *[1]Complejo Hospitalario de Navarra, Pamplona (Navarra), Spain; [2]Complejo Hospitalario de Navarra, Medical Oncology, Pamplona (Navarra), Spain; [3]Complejo Hospitalario de Navarra, Hematology, Pamplona (Navarra), Spain; [4]Complejo Hospitalario de Navarra, Surgery, Pamplona (Navarra), Spain*

Background: The role of CTCs in pts with LM-CRC metastases has been little explored. The purpose of this study was to quantify CTCs during radical liver surgery (LS) in pts with LM-CRC and to demonstrate the role of CTCs in pts behavior.
Methods: 7.5 ml of blood were drawn in CellSave tubes. CTCs were enumerated before, just performed and 3 months after radical LS. CTCs were immunomagnetically separated and fluorescently labeled using the CellSearch System (Veridex/Immunicon Corp.).
Results: From February 2009 to March 2013 the samples of 48 pts were analyzed. Pts characteristics were as follows: median age was 64 (45−79) with 68% men. K-ras status was wild-type in 56%; 55% received neoadjuvant treatment, (95% with fluoropirimidines-based) and 70% received adjuvant treatment. Among 29 pts, best response rates were 69% PR and 31% SD. In 75% of cases, limited LS were done (R0:77%). Of the 25 pts analysed, pCR were observed in 2 (8%) with 11 other pts (44%) with major pathological response. With a median of follow-up of 26 months, progression disease occurred in 25 pts (46.3%), and 8 died (14.8%).
Median CTCs was 0 before (0−2: 82.5%; ⩾3: 17.5%) and just performed (0−2: 70.7%; ⩾3: 29.3%) increasing in 12% the group of CTCs ⩾3 after surgery. Median of DFS was 27 months (95% CI: 19.05–34.95), with DFS for pts with post-surgery CTCs 0−2 and CTCs ⩾3 group of 31 and 20 months, respectively (p = 0.038). There are no difference in overall survival in any group. In t he multivariate analysis post-surgery CTCs proves to be an independent predictor of outcome for DFS in our study (HR: 0.31, 95% CI: 0.10–0.96).
Conclusion: Based on our results, CTCs level analyzed just performed LS in pts with LM-CRC could be a useful independent predictor of DFS in this scenario, although more prospective studies are needed to confirm our results.

2201 POSTER

Aflibercept inhibits tumor growth more effectively than bevacizumab in patient-derived xenograft (PDX) models of colorectal cancer

M. Chiron[1], R.G. Bagley[2], J.R. Pollard[3], C. Henry[4], P.K. Mankoo[3], L. Vincent[5], C. Geslin[4], Z. Amalou[6], N. Baltes[6], D.A. Bergstrom[3]. *[1]Sanofi Oncology, Translational and Experimental Medicine, Vitry sur Seine, France; [2]Sanofi Oncology, Clinical Development, Cambridge, USA; [3]Sanofi Oncology, Translational and Experimental Medicine, Cambridge, USA; [4]Sanofi Oncology, Oncology, Vitry sur Seine, France; [5]Sanofi Oncology, Pharmacology, Vitry sur Seine, France; [6]Oncotest GmbH, Project Management, Freiburg, Germany*

Background: Aflibercept (afl) is a potent new multiple angiogenic factor trap that prevents not only VEGF-A but also VEGF-B and PlGF from activating their native receptors. Based on the overall survival benefit demonstrated in the phase 3 VELOUR trial, afl + FOLFIRI was approved for patients with metastatic colorectal cancer (mCRC) who had failed a prior oxaliplatin-containing regimen. In preclinical studies, afl inhibits VEGFR signaling more potently and blocks cell migration more effectively than bevacizumab (bev). Here, the efficacy of afl and bev were compared in 48 PDX CRC models. PDX models may better represent histology and genetic heterogeneity of human cancer than xenografts derived from cancer cell lines.

Methods: CRC adenocarcinoma tumors from primary or metastatic sites were engrafted and passaged subcutaneously (SC) into NMRI nude mice, creating 48 PDX models. Expression of mouse (m) and human (h) VEGF-A (mVEGF-A, hVEGF-A) and PlGF (mPlGF, hPlGF) in untreated tumors was measured by ELISA and Luminex. Tumor-bearing mice were dosed with afl, bev, or placebo (8 mice/treatment group/model) 2x/wk for 3 wks and SC tumor measurements recorded 2x/wk. Activity was expressed as the relative change in tumor volume between treatment (dT) and control (dC) at 3 wks. A dT/dC value of <10% (>90% inhibition) was scored as activity. Partial tumor regression was defined by $\geqslant$50% reduction in tumor size from baseline.
Results: Afl inhibited tumor growth in more PDX models than did bev (43/48 vs 7/48; Table). The 5 models insensitive to afl were also resistant to bev. Partial tumor regression occurred in 16/48 models treated with afl and in only 3/48 models treated with bev. Tumor levels of hVEGF-A (776–56,039 pg/mg total protein) were ~16- to 1,777-fold greater than mVEGF-A (8–159 pg/mg total protein) in PDX models. Tumor levels of mPlGF (104–1,837 pg/mg total protein) were higher than hPlGF (0–543 pg/mg total protein) in 47/48 models.

Table: Antitumor response to afl and bev in 48 PDX CRC models

	Afl	Bev
Tumor growth inhibition	43/48	7/48
Partial tumor regression	16/48	3/48

Conclusions: Afl demonstrated greater and more consistent antitumor activity than did bev in PDX models of metastatic and primary CRC. Tumor cells were the major source of VEGF, whereas PlGF was primarily produced by the tumor stroma. Tumor levels of hVEGF-A were much greater than mVEGF-A; thus, the inability of bev to bind to mVEGF-A does not explain the enhanced relative activity of afl.

Investigation of miR-504 expression in colorectal and breast cancer

N. Hogan[1], S. Khan[1], Q. Huong[1], C. Brogham[1], M.R. Joyce[1], M.J. Kerin[1], R.M. Dwyer[1]. [1]*Clinical Science Institute, Discipline of Surgery, Galway, Ireland*

Background: MicroRNAs are a group of short non-coding RNAs which regulate gene expression at a post transcriptional level. The discovery that MicroRNAs(miRs) are differentially expressed in cancer has added a new dimension to investigation of novel diagnostic and therapeutic strategies for a number of cancers. miR-504 has recently been implicated in regulation of the *p53* tumour suppressor, which plays a central role in development of many cancers. However, miR-504 expression in patient samples has not previously been reported. This study aimed to investigate miR-504 expression at both the circulating and tissue level in patients with colorectal or breast cancer.
Materials and Methods: Following informed consent, tissue was harvested from patients with breast or colorectal cancer. RNA was extracted from colorectal tissue (n = 20 tumour, n = 13 tumour associated normal), breast tissue (n = 43 tumour, n = 20 normal), whole blood from patients with breast cancer (n = 20), blood from patients with colorectal cancer (n = 23) and blood from healthy controls (n = 23). RNA was reverse transcribed and relative levels of miR-504 in the tissue and circulation quantified by RQ-PCR.
Results: In breast tissue, significantly lower expression of miR-504 was observed in cancers (Mean$\pm$SEM; 1.766$\pm$0.096 $\log_{10}$ Relative Quantity (RQ)) in comparison with normal breast samples (2.935$\pm$0.202 $\log_{10}$RQ, p<0.001). Samples were further analysed according to patient clinico-pathological details. Within the breast cancer cohort, no significant difference was observed across epithelial subtype (p = 0.347), tumour grade (p = 0.38) or disease stage (p=0.20). In contrast to the differential expression observed in breast cancer, in colorectal cancer tissue no significant difference was observed (2.99$\pm$0.33 $\log_{10}$RQ) when compared with tumour associated normals (2.73$\pm$0.30 $\log_{10}$RQ). At a circulating level, no change in miR-504 expression was observed in colon cancer, breast cancer or healthy controls.
Conclusions: This is the first study to examine miR-504 expression in patient samples. The data herein shows miR-504 to be dysregulated in breast tumour tissue but not in colorectal cancer tissue. Combined with the absence of dysregulation in the circulation, this highlights the potential importance of miR-504 in the breast tumour microenvironment.
No conflict of interest.

2203 POSTER

From monoclonal tumor cell arises an identical colon adenocarcinoma?

D.G. Priolli[1], N.P. Martinez[1], A.M. Abrantes[2], A.C. Gonçalves[3], M. Laranjo[2], C.O. Lopes[4], J.A. Pereira[1], A.B. Sarmento[3], S. Neves[3], M.F. Botelho[2]. [1]*Sao Francisco University, Postgraduate Program in Health Science, Bragança Paulista, Brazil;* [2]*University of Coimbra, Biophysics Unit − IBILI, Coimbra, Portugal;* [3]*University of Coimbra, ibili, Coimbra, Portugal;* [4]*Sao Francisco University, Scientic Iniciation Program, Bragança Paulista, Brazil*

Background: The study aims to identify differences between left and right colon adenocarcinomas of identical clonal origin in orthotopic animal models of human cancer and contribute towards a better understanding of extracellular environment influence on MMP2, p53 and beta-Catenin expression as an important factor in the development of tumor phenotype characteristics.
Material and Methods: In the orthotopic model of right colon tumor the animals (a *Rat* without a thymus) were submitted to a cecostomy (n = 10), while for the left colon model a distal mucous fistula (n = 13) in the descending colon was used. Cultivated human colon adenocarcima cells (CCL-218) were inoculated into the sub-mucosa via the models' cecos-tomies and distal fistulas. Conventional e*x vivo* anatomic pathology studies (HE) were conducted, as well as gene expression analysis (RT-PCR) for beta-Catenin, p53, MMP2 and immunohistochemical examination for p53 and beta-Catenin expression. Statistical analysis adopted a significance value of 5% as the criterion for rejecting the hypothesis of nullity and was conducted using central tendency, variance analysis and the Livak delta-delta-CT methods for determining gene expression.
Results: In the left colon 100% of the tumors exhibited infiltrative ulceration while in the right colon tumor growth was predominantly exophytic (67%). Tumor growth in the left colon was undifferentiated (100%) and moderately differentiated in the right colon (83%). RT-PCR gene expression analysis revealed there was greater MMP2, p53 and beta-Catenin expression in right colon tumors compared to left colon tumors and the p53 and beta-Catenin expressions for those locations were confirmed by immunohistochemical means.
Conclusion: Human adenocarcinomas of the left and right colons developed in animal models have distinct characteristics even when their clonal origin is identical. Micro-environmental action modifies p53, beta-Catenin, and MMP2 expression in animal colon models leading to differentiated phenotype characteristics, even when their origin is monoclonal.

Increased activation and migration potential of dendritic cell in patients with colorectal cancer − the implication and future of cancer immunotherapy

G. Lee[1], G. Malietzis[1], N. Yassin[1], E. Mann[1], D. Bernardo[1], R.K. Phillips[2], S.K. Clark[2], S.C. Knight[1], H.O. Al-Hassi[1]. [1]*Antigen Presentation Research Group Imperial College London, Department of Medicine, London, United Kingdom;* [2]*St Mark's Hospital, Department of Colorectal Surgery, London, United Kingdom*

Background: Dendritic cells (DC) are antigen presenting cells that migrate to lymphoid tissues to initiate a cytotoxic or tolerogenic immune response to tumour antigens. CD40 is a co-stimulatory molecule and a marker for DC activation. Increased expression of CD40 on DCs can be associated with maturation and enhanced cytokine production against tumour cells. Activation of DC is accompanied by up regulation of the lymph node migration marker C-chemokine receptor7 (CCR7). However, DC in cancer are unable to elicit effective immune responses against tumour cells. Previous studies on DC in colorectal cancer (CRC) were on cell lines and animal models. We aimed to determine the phenotype and activation status of systemic DC in CRC patients.
Materials and Methods: Peripheral blood mononuclear cells were obtained from CRC patients before any surgical intervention (n = 19). Blood from age and sex-matched healthy controls (n = 19) was also collected. DC identified as HLA-DR positive and lineage(anti-CD3, CD14, CD16, CD19, CD34 and CD56) negative cells. DC were further classified as CD11c+ myeloid (mDC) or CD11c- putative plasmacytoid. CD40, CD80, CD86 and CCR7 expression was determined on DC by flow-cytometry.
Results: In CRC the expression of CD40 was significantly higher on all DC (27.76% $\pm$2.790 vs 17.37%$\pm$ 3.306, p = 0.0215) compared to control. This increase was driven by the mDC subset, which was significantly increased in CRC (30.81%$\pm$4.480 vs 18.84%$\pm$2.391, p = 0.0240). There was also a increased CCR7 expression on all DC from CRC compared with control. This increase was a statistically significant on mDC in CRC

(33.33%±3.971) compared with control (15.15%±2.269), (p = 0.0003). There were no differences in CD80 and CD86 expression between groups.
Conclusion: DC in CRC patients are activated and their potential capacity to migrate to lymph nodes is increased. This increase in CCR7 expression suggests a role for DC in the metastasis of CRC. Our results are contrary to previous studies on monocyte-derived DC, which showed reduced CD40 expression. Hence, results should be interpreted with caution when using such cytokine stimulated DC as they do not resemble those normally present in blood.
Activated DC may stimulate either immunogenic or suppressive responses upon migration to lymph nodes. Therefore, further studies are warranted to investigate which immune response DC in CRC are inducing, which is an important step towards creating more suitable anti-tumour vaccines.

2205 POSTER

rs28381943 and rs2032586 SNPs of ABCB1 gene may be the reason of mRNA stabilisation which may lead to gene overexpression in gastrointestinal cancers

M. Mansoori[1], M. Shahbazi[2]. [1]*Cellular and Molecular Medicine Research Center, Gorgan, Iran;* [2]*Cellular and Molecular Medicine Research Center, Research Center, Gorgan, Iran*

Background: One of the major mechanisms for drug resistance is associated with altered anticancer drug transport, mediated by human-adenosine triphosphate binding cassette (ABC) transporter superfamily proteins. The overexpression of MDR1 (Multi Drug Resistance 1) by multidrug-resistant cancer cells is a serious impediment to chemotherapy. In our study we have studied the possibility that the mechanism of MDR1 overexpression is caused by structural single-nucleotide polymorphisms (SNPs).
Materials and Methods: A total of 101 MDR1 cases and 100 controls were genotyped with SSP-PCR (Sequence Specific Primer). Gene expression was evaluated for 70 MDR1 cases and 54 controls by Real Time PCR. The correlation between the two groups was based on secondary structures of RNA were predicted by bioinformatics tool (Rn) (Vienna RNA Fold Server).
Results: The results of genotyping showed that among 3 studied SNPs, rs28381943 and rs2032586 have significant difference between MDR1 cases and control group but there were no differences in the two groups for C3435T. The results of Real Time PCR showed overexpression of ABCB1 when we compared our data with each of the genotypes in average mode. Prediction of secondary structures in the existence of 2 related SNPs (rs28381943 and rs2032586) showed that the amount of ΔG for original mRNA is higher than the amount of ΔG for the two mentioned SNPs.
Conclusions: We have observed that 2 of our studied SNPs (rs283821943 and rs2032586) may affect the overexpression of MDR1 gene, and the observed overexpression may be due to mRNA stability while this was not the case for C3435T.
No conflict of interest.

2206 POSTER

TRP genes family expression in colorectal cancer and its relationship with prognostic factors

M. Kalender[1], Y. Sozucan[1], I. Sari[2], A. Suner[1], S. Oztuzcu[3], I. Bozgeyik[3], B. Cengiz[4], Y. Igci[3], O. Balakan[5], C. Camci[1]. [1]*Gaziantep University, Medical Oncology, Gaziantep, Turkey;* [2]*Gaziantep University, Pathology, Gaziantep, Turkey;* [3]*Gaziantep University, Medical Biology, Gaziantep, Turkey;* [4]*Gaziantep University, Physiology, Gaziantep, Turkey;* [5]*Sutcu Imam University, Medical Oncology, Kahramanmaras, Turkey*

Background: Colorectal cancer (CC) is the most common cancer of the gastrointestinal tract. Different factors are effective in the development of CC. With the discovery of that TRP (transient receptor potential) genes family is an important component of calcium channel, about 30 members of the family of TRP ion channel in mammals have been determined up to the present. TRP channels are associated with many pathological conditions like cancer, neurodegenerative and cardiovascular diseases as well as the physiological significance of them. The aim of this study is to investigate TRPM, TRPV and TRPC gene expression levels in tumor tissues of CC patients and to analyze the relationship of expression in tumor tissue of colorectal cancer with other known prognostic factors.
Material and Methods: In this study, 93 CC patients whose follow-up and treatment realized in Medical Oncology Department of Gaziantep University Medical Faculty Hospital were analyzed retrospectively. Level of TRP gene expression in paraffin blocks of normal and cancerous colorectal tissue samples of 93 patients were studied at the level of mRNA with Real-time PCR.
Results: According to Real-time PCR results realized to determine levels of mRNAs obtained from normal and cancerous colorectal tissues of 37 female and 56 male patients diagnosed with colorectal cancer, expressions of TRPV3, TRPV4, TRPV5, TRPM4 and TRPC6 genes in tumor tissue were detected lower when compared to normal tissue (p < 0.05). When expression levels of other TRP genes in tissues were compared, any significant difference wasn't found (p > 0.05). There was no meaningful difference between prognostic factors and gene expressions of tumor tissues statistically (p > 0.05).
Conclusions: Expression of many proteins in cancer cells compared to normal cells increases or decreases. In CC, TRPV3, TRPV4, TRPV5, TRPM4 and TRPC6 genes of which expression in cancerous tissue decreases may be thought as potential genes contributing to tumorigenesis. To verify this hypothesis, it should be supported with further studies.
No conflict of interest.

2207 POSTER

MicroRNA-124 suppresses colorectal tumor progression via targeting KITENIN, a metastasis-enhancing protein

S.Y. Park[1], S. Yoon[1], J.A. Bae[1], Y.E. Joo[2], I.J. Chung[3], H. Kim[4], K.K. Kim[1]. Background: MicroRNAs (miRNAs) are increasingly implicated in modulating the progression of various cancers. Although there is emerging evidences that some miRNAs can function as oncogenes or tumour suppressors, the regulation of colorectal cancer (CRC) progression by miRNA is not fully understood. Several lines of reports demonstrated the potential tumor suppressor role of miR-124, however, it remains unclear which target genes are responsible for the role of miR-124 on progression of CRC and whether miR-124 plays a certain role in the suppression of colorectal tumorigenesis. KITENIN (KAI1 C-terminal interacting tetraspanin) acts as a major component of functional KITENIN complex promoting CRC cell invasiveness. We previously reported that KITENIN is highly expressed in sporadic human CRC tissues, however, the underlying regulation mechanisms of aberrant expression are not clearly understood.
Methods: We tried to identify which miRNAs modulate the expression of KITENIN, using luciferase assay and with computational prediction of miRNA targeting KITENIN.
Results: We here identified several miRNAs and one of them is miR-124. miR-124 negatively regulated KITENIN expression through binding to the 3'-untranslated region of KITENIN. We further examined whether increased expression of miR-124 affects colorectal tumor progression through targeting KITENIN. Forced expression of miR-124 was found to suppress the migration and invasiveness of various CRC cells. Overexpressed miR-124 also inhibited tumor growth in a mouse xenograft model.
Conclusions: These findings provide the experimental evidence to a possible therapeutic effect of miR-124 on suppressing colorectal tumor progression.

2208 POSTER

mTOR activity and mTOR inhibitor sensitivity of colon carcinoma cells and their relation to mTOR complexes

A. Mark[1], T.B. Sticz[1], A. Molnar[1], M. Hajdu[1], N. Nagy[1], L. Kopper[1], A. Sebestyen[2]. [1]*Semmelweis University, 1st Department of Pathology and Experimental Cancer Research, Budapest, Hungary;* [2]*Hungarian Academy of Sciences and Semmelweis University, Tumor Progression Group and 1st Department of Pathology and Experimental Cancer Research, Budapest, Hungary*

The constellation of features of PI3K/AKT/mTOR signalling − critical cellular functions (growth and survival), prevalent oncogenic genetic aberrations, consequent therapeutic resistance and its potential reversal − have made the inhibition of this pathway an attractive target for anticancer strategies. The activation of mTOR is associated with growth and progression of a number of cancers, including colorectal cancer. The active form of mTOR kinase exists in two funcionally different complexes (mTORC1 and mTORC2).
We investigated the effect of different mTOR inhibitors (mTORI) on several colon carcinoma cell lines in relation to mTOR complex activity. The in vitro effects on proliferation and apoptosis were monitored by Alamar blue assay and flow cytometry. The expression and activity of mTOR signaling related proteins were studied by immunocytochemistry using Duolink technique and Western-blotting. p-mTOR, p-S6, Raptor and Rictor expression was also analysed by immunohistochemistry (IHC) in more than 100 human

colon carcinoma samples in order to find correlation between clinical and experimental data.
mTOR activity, and C1 and C2 mTOR complex activity was altered in different colon carcinoma cells. mTOR inhibitor (rapamycin, PP-242, NVP-BEZ235) sensitivity correlated to the Rictor to Raptor ratio. Rapamycin alone was less effective in cells with high Rictor expression, as well as in combination with EGFR inhibitors (gefitinib, erbitux). More than 70% of human tumor samples displayed high mTOR activity. Rictor and Raptor IHC showed Rictor overexpression (element of mTORC2) in about 50%, and Raptor overexpression (mTORC1) in 13% of the cases; Rictor and Raptor expression was equal in the remainder of the cases. Low mTOR activity was related to good prognosis. Patients with high mTOR activity and Rictor overexpression had the worst prognosis during 5 year follow up. The majority of colorectal carcinomas have characteristic high mTOR activity, especially in patients with poor prognosis. Targeting mTOR activity may be an additional therapeutical option in these cases. Moreover, we suggest that the evaluation of mTORC1 and C2 related activity in colon carcinomas may help identify patients suitable for adequate mTORI therapy, who can expect longer survival or potential cure with conventional mTORI therapy, and warn if dual inhibitors are required in order to provide therapeutical benefit.

2209 POSTER

Activation and maturation status of dendritic cells is altered in post-operative colorectal cancer patients

H.O. Al-Hassi[1], G. Lee[1], G. Malietzis[1], N. Yassin[1], E. Mann[1], D. Bernardo[1], R.K. Phillips[2], S.K. Clark[2], S.C. Knight[1]. *[1]Antigen Presentation Research Group Imperial College London, Department of Medicine, London, United Kingdom; [2]St Mark's Hospital, Department of Colorectal Surgery, London, United Kingdom*

Background: Dendritic cells (DC) are antigen presenting cells that promote a cytotoxic or tolerogenic immune response against tumour antigens upon migration to lymph nodes. CD40 is a co-stimulatory molecule and a marker for DC activation. Immunoglobulin-like transcript 3 (ILT3) is an inhibitory receptor expressed on DC and negatively regulates their activation. Activation of DC is accompanied by up regulation of the lymph node migration marker C-chemokine receptor7 (CCR7). Previous studies have shown that tumour cells and microenvironment have both direct and indirect effects on the ability for DC to promote cancer specific cytotoxic immune response. However, little is known about the activation and phenotype status of systemic DC in postoperative colorectal patients. We aimed to determine changes in systemic DC phenotype after a curative resection of CRC.
Material and Methods: Blood samples were obtained from 7 CRC patients pre-operatively and 4 to 6 weeks after operation, prior to chemo or radiotherapy. All patients had same tumour staging and no significant medical co-morbidity. Peripheral blood mononuclear cells were separated and DC identified as HLA-DR positive and lineage cocktail (anti-CD3, CD14, CD16, CD19, CD34 and CD56) negative cells. DC were further classified as CD11c+ myeloid (mDC) or CD11c- putative plasmacytoid (pDC). CD40, CCR-7 and ILT3 expression was determined on DC by flow cytometry. Results are the mean $\pm$SED. Paired student *t* test was used for comparison and $p < 0.05$ was considered as significant.
Results: CD40 expression was decreased on mDC and pDC post-operatively from $26.32\pm5.787\%$ to $14.88\pm6.024\%$ ($p = 0.0393$). ILT3 expression increased post-operatively from $45.32\pm9.621\%$ to $72.04\pm7.336\%$ ($p = 0.004$). There were no significant differences in CCR7 expression on DC between pre and post-operation.
Conclusion: We have demonstrated that removal of colorectal tumour alters the phenotype of DC resulting in systemic DC becoming less activated and more immature. Postoperative immunosuppression increases the recurrence and adversely affects the prognosis of cancer patients. Our findings suggest that these changes in CD40 and ILT3 expression may contribute to the general postoperative immunosuppression. Hence, immunotherapy targeting the activation of DC immediately after operation could be a potential tool in the treatment of colorectal cancer.

Influence of sodium butyrate on 18F-FDG uptake in two colon cancer cell lines

T.J. Gonçalves[1], A.S. Pires[1], J.C. Encarnação[1], C.R. Marques[2], J. Casalta-Lopes[1], A.M. Abrantes[3], M.F. Botelho[3]. *[1]Biophysics Unit − IBILI, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [2]Life Sciences Department, Faculty of Science and Technology of University of Coimbra, Coimbra, Portugal; [3]Biophysics Unit − IBILI − CIMAGO, Faculty of Medicine of University of Coimbra, Coimbra, Portugal*

Background: Butyrate is a short chain fatty acid (SCFA) and it's produced by decomposition of dietary fiber by intestine's bacteria, being the main energy source of colonocytes. It is related with colon cancer mostly because of its capacity to inhibit histone deacetylases (HDAC), and inducing apoptosis and differentiation in contrast to normal cells. Some studies suggest that the Warburg effect may explain why the cancer cells use preferentially glucose rather than other energy sources, inducing butyrate accumulation in the tumor cells. Other studies also suggest that butyrate can be used by tumor cells as energy source when glucose levels are reduced. The aim of this study is to evaluate if butyrate interferes with uptake of the radiolabeled glucose analogue (^{18}F-FDG) and the increased glycolysis in colorectal cancer cells.
Methods: WiDr and C2BBe1 cell lines were cultured in DMEM with low glucose content (5mM). To perform the uptake studies, cells were incubated with or without butyrate, 3mM for WiDr cells and 15mM for C2BBe1 cells (values chosen taking into account the respective IC_{50}) during 1 and 4 hours, before the incubation with ^{18}F-FDG (25 μCi/ml). At 5, 30, 60, 90, and 120 minutes, duplicate samples of 200 μl of cell suspension were collected for eppendorfs with iced phosphate buffer solution (PBS). The samples were centrifuged at 10000rpm for 60 seconds, separating the pellet from the supernatant. In order to calculate the ^{18}F-FDG uptake percentage, radioactivity of both fractions was measured in a well-type gamma counter, in counts per minute (CPM).
Results: ^{18}F-FDG uptake is greater in WiDr cells than in C2BBe1 cells, being the uptake at 120 minutes of $6.91\%\pm0.15\%$ and $5.05\%\pm0.15\%$, respectively. In both cell lines, we observed that incubation with butyrate decreases the ^{18}F-FDG uptake. This difference was more pronounced in WiDr cell line however, in C2BBe1 cells there seems to be a trend for a decrease in tracer uptake with increasing exposure time to butyrate.
Conclusions: Our study suggests that butyrate can reduce the ^{18}F-FDG uptake and may interfere with the Warburg effect which influences the agressiveness of the tumor. This also suggests that butyrate can act in cancer cells in an advanced phase of development, and could contribute to the understanding of the importance of our diet in advanced tumor stages.

2211 POSTER

Pharmacogenetic analysis of tegafur-uracil (UFT) plus leucovorin (LV) with preoperative chemoradiation for locally advanced rectal cancer (LARC)

S.Y. Kim[1], H.M. Kim[1], J.Y. Baek[1], J.H. Oh[1], S.C. Park[1], D.Y. Kim[1], H.J. Chang[1], S.Y. Kong[1]. *[1]Research Institute and Hospital National Cancer Center, Center for Colorectal Cancer, Goyang Gyeonggi, South Korea*

Background: Tegafur-uracil (UFT) is one of oral fluoropyrimidines and has shown its efficacy on colorectal cancer. Various doses (300–400 mg/m^2/day) of UFT have been tried for preoperative chemoradiation (preop CRT) of locally advanced rectal cancer (LARC). This study aims to evaluate efficacy of higher dose (400 mg/m^2) of UFT plus leucovorin (LV) with preop CRT and to explore the impact of germline polymorphisms concerning metabolism and transmembrane transport of tegafur on clinical outcome.
Materials and Methods: A total of 88 patients (pts) with MRI-defined cT3 or cT4 were enrolled to this phase II trial and were given UFT 400 mg/m^2/day and LV 90 mg/m^2/day for 5 days a week during preop CRT (50.4 Gy/28 fractions). Genomic DNA was extracted from peripheral blood, where genotyping was done for CYP2A6 (*4, *7, *9 and *10), OPRT G638C, and three genotypes of ABCB1 as C1236T, C3435T, and G2677T.
Results: One pt refused surgery after preop CRT and 87 who underwent curative surgery were analyzed for efficacy outcome; circumferential margin was positive ($\leqslant$1 mm) in 12 (13.8%) and pathologic complete response (pCR) was noted in 10 pts (11.5%). For all treated 88 pts, toxicities $\geqslant$ grade 2 included diarrhea (14, 15.9%), abdominal pain (9, 10.2%) anemia (9, 10.2%) neutropenia (6, 6.8%) and stomatitis (6, 6.8%). Pts with OPRT 638 CC genotype experienced significantly more frequent grade 2−3 diarrhea and any adverse events (AE) $\geqslant$ grade 3 when adjusted to age, sex, and performance status (table). There was a tendency of increasing pCR rate according to number of variant allele: GG genotype (2/41, 4.9%),

GC genotype (6/38, 15.8%) and CC genotype (2/8, 25%) (p for trend = 0.05). Polymorphisms in CYP2A6 and ABCB1 had no clinical correlation with outcome from UFT/LV-based preop CRT.

Conclusions: Preop CRT with UFT 400 mg/m^2/day with LV was feasible and safe. OPRT 638 CC genotype might be a candidate biomarker predicting toxicity and pathologic response in pts receiving UFT/LV-based preop CRT for LARC.

No conflict of interest.

Toxicity and genotype	Odds ratio	95% Confidence interval	P value
Diarrhea ⩾grade 2			
OPRT 638 GG (n = 41)	1		
OPRT 638 GC (n = 39)	1.96	0.42–9.06	0.389
OPRT 638 CC (n = 8)	10.76	1.50–77.40	0.018
Any AE ⩾ grade 3			
OPRT 638 GG (n = 41)	1		
OPRT 638 GC (n = 39)	0.97	0.28–3.40	0.962
OPRT 638 CC (n = 8)	10.20	1.44–72.13	0.020

2212 POSTER

Outcome in patients with locally recurrent rectal cancer after TME with and without neoadjuvant radiotherapy for the primary rectal tumor

W.J. Alberda[1], C. Verhoef[1], J.J. Nuyttens[2], J. Rothbarth[3], J.H.W. De Wilt[4], J.W.A. Burger[1]. *[1]Erasmus MC − Cancer Institute, Surgical Oncology, Rotterdam, Netherlands; [2]Erasmus MC − Cancer Institute, Radiotherapy, Rotterdam, Netherlands; [3]Erasmus MC − Cancer Institute, Surgical Oncology, Rotterdam, Netherlands; [4]Radboud University Nijmegen Medical Center, Surgical Oncology, Rotterdam, Netherlands*

Background: The application of neoadjuvant radiotherapy (nRTx) for rectal cancer became widespread after the Dutch TME trial demonstrated that nRTx followed by total mesorectal excision (TME) reduces local recurrence rates. However, this widespread use of nRTx followed by TME introduced the problem of treating locally recurrent rectal cancer (LRRC) after nRTx and TME. Primary tumor resection by TME may lead to recurrences that are not limited to the anatomical compartment lined by the visceral rectal fascia and when neoadjuvant radiotherapy was administered for the primary tumor, the radiation dose for the treatment of LRRC is limited. These factors render radical resection of these local recurrences more demanding than resection in patients who did not receive nRTx or TME for their primary tumor. However, few data exist on the outcome of the surgical treatment of this specific 'type' of LRRC and the influence of nRTx for the primary tumor on the outcome is unclear.

Methods: All patients treated for LRRC between January 1996 and July 2012 were retrospectively analyzed. The outcome of the surgical treatment of LRRC in patients who received nRTx and TME for the primary tumor was compared with the outcome of patients who had TME without nRTx for the primary tumor.

Results: During this period, 139 patients underwent surgery for LRRC; 93 of these patients underwent curative resection of LRRC after TME for the primary tumor. Twenty-eight patients received nRTx for the primary tumor, while 65 patients did not receive nRTx for the primary tumor. Both groups were comparable with respect to the baseline and demographic characteristics. There were no significant differences in the number of incomplete resections or peri-operative morbidities. Although, there tend to be more R1-resections in patients treated with nRTx for the primary tumor (64% versus 46%, p = 0.11). There was no significant difference in 5-year overall survival (43% vs. 28%, p = 0.81), recurrence-free survival (48% vs. 55%, p = 0.50) and disease-free survival (40% vs. 27%, p = 0.59). A significant difference in distant metastasis-free survival was found in favor of patients who received nRTx for the primary tumor (66 vs. 39%, p = 0.05).

Conclusion: Surgical treatment of resectable LRRC after nRTx and TME for the primary tumor is feasible and can result in sustained local control and overall survival. Patients who received nRTx for the primary tumor do not have a poorer outcome than patients who did not.

No conflict of interest.

2213 POSTER

Patterns of recurrence following complete cytoreductive surgery and hyperthermic intraperitoneal chemotherapy in patients with peritoneal carcinomatosis of colorectal cancer

H.J. Braam[1], D. Boerma[1], M.J. Wiezer[1], B. Van Ramshorst[1]. *[1]St. Antonius Hospital, Surgery, Nieuwegein, Netherlands*

Background: Cytoreductive surgery (CRS) combined with hyperthermic intraperitoneal chemotherapy (HIPEC) has an established role in the multidisciplinary treatment of metastasized colorectal cancer. In selected patients long term survival is achieved in 40%. Nonetheless, many patients suffer from recurrence after CRS+HIPEC. The aim of the study was to describe the recurrence pattern following CRS+HIPEC, including anatomical location, treatment and outcome.

Methods: A prospective database of all patients treated with CRS+HIPEC between April 2005 and March 2013 was retrospectively analyzed with special interest in the following parameters: disease recurrence and location, interval between HIPEC and recurrence, treatment, and survival. Survival and the prognostic value of several clinical and histopathological parameters was calculated using Kaplan–Meier method and Cox Regression.

Results: In total 139 patients with colorectal cancer (no PMP or appendiceal cancer) and peritoneal carcinomatosis were treated with complete CRS (i.e., no residual macroscopic disease) and HIPEC. After a median follow-up of 21.4 months, 74 patients (53%) had reported recurrence. The median interval between HIPEC and recurrence was 12.4 months (range 3−54). 33 patients (45%) developed isolated peritoneal recurrence, 20 patients (27%) isolated distant metastases and 21 patients (28%) peritoneal recurrence combined with distant metastases. Of these patients 26 were treated surgically with curative intent. Pulmonary metastasectomy was performed in 7/10 patients with isolated pulmonary recurrence, partial liver resection in 5/9 patients with isolated liver recurrence, repeat cytoreductive surgery with or without HIPEC in 14/33 patients with isolated peritoneal recurrence, and in one patient with distant and peritoneal recurrence a pulmonary metastasectomy and a repeat CRS+HIPEC procedure was performed. The overall survival was significantly longer in patients with resection of recurrence vs. no resection with a median overall survival of 11 months vs. 43 months after diagnosis of disease recurrence (P<0.001). Additionally, a longer interval between HIPEC and recurrence was significantly related to a improved overall survival after disease recurrence (P<0.001). Other clinical and histological parameters were not significantly related to survival.

Conclusion: Disease recurrence after cytoreductive surgery and HIPEC is common, however, surgery in a selected patient group may be beneficial and result in long-term survival.

No conflict of interest.

2214 POSTER

Clinical complete response after neoadjuvant chemoradiotherapy (nCRT) of rectal cancer: A key end point to increase conservative treatment − findings from the ACCORD12 randomized trial

K. Benezery[1], E. Chamorey[2], E. Francois[3], J. Doyen[4], S. Gourgou-Bourgade[5], J.P. Gérard[6]. *[1]Centre Antoine Lacassagne, Radiotherapy, Nice Cedex 2, France; [2]Centre Antoine Lacassagne, Statistic, Nice Cedex 2, France; [3]Centre Antoine Lacassagne, Oncology, Nice Cedex 2, France; [4]Centre Antoine Lacassagne, Oncologist Radiotherapy, Nice, France; [5]Val D'aurelle, Statistic, Montpellier, France; [6]Centre Antoine Lacassagne, Radiotherapy, Nice, France*

Background: During the ACCORD12 randomized trial, a specific evaluation of the clinical tumor response of the rectal cancer following nCRT was performed before surgery. The correlation of this end point with patient characteristics and treatment outcomes is reported.

Material and Method: Between 2005 and 2008 a randomized trial comparing 2 different regimens of nCRT (cap45: capecitabine + 45 Gy/5w vs capox50: capecitabine + 50 Gy/5w + oxaliplatine) included 598 patients. A careful evaluation of the clinical response of the tumor was planned 5 weeks after the end of CRT just before surgery. Rectoscopy and digital rectal examination (DRE) was used to establish a specific score of clinical response adapted from the RECIST criteria: Clinical complete response: no visible or palpable tumor, supple rectal wall (cCR); partial response (PR), stable disease (ST), progressive disease (PROG). This score was correlated with patients characteristics, type of surgery, pathological response and 3-year clinical outcome.

	cCR (16 pts)	PR (137 pts)	ST + PG (48 pts)
Sphincter. Saving Surgery	13* (87 %)	105 (76 %)	33 (68 %)
yp CR (pTo)	11 (73 %)	21 (15 %)	6 (12 %)
CRM R1	0 (0 %)	4 (3 %)	4 (9 %)
DFS 3 y	87.5%	77.6%	65%

*11 Ant. Resection; 2 local excision; + one patient watch and wait only.

Results: Clinical response was evaluable in 201 patients. Score was as follow: cCR: 8%, PR: 68%, ST + PROG: 24%, PROG: 4%. There was a trend toward more cCR in the capox 50 arm (9.3% vs 6.7%). When analysed for the whole cohort of 201 patients, cCR was associated with early T stage (T2: 28% vs T3−4: 6%). cCR was associated with sphincter saving surgery, ypCR, CRM R1, disease free survival (table). In 3 patients with cCR a rectal preservation was possible (2 local exicision-one watch and wait strategy) with the 3 patients alive and well between 3 and 5 years follow up.

Conclusion: cCR appears as a very important end point after neoadjuvant treatment of rectal cancer. It is correlated with increased pCR, negative CRM, 3 year DFS and it is probably influencing the chance of a sphincter saving procedure. Rectoscopy and DRE should be performed after neoadjuvant CRT to evaluate the tumor response and adapt the surgical technique.
No conflict of interest.

2215 POSTER

What about the young rectal cancer patient?

R.G. Orsini[1], R. Verhoeven[2], V.E.P.P. Lemmens[2], L.N. Van Steenbergen[2], G.A.P. Nieuwenhuijzen[1], I.H.J.T. De Hingh[1], H.J.T. Rutten[1].
[1]Catharina Hospital, Department of Surgery, Eindhoven, Netherlands; [2]Comprehensive Cancer Center South (CCCS), Eindhoven Cancer Registry, Eindhoven, Netherlands

Background: Multiple studies have shown a rising incidence of young patients with rectal cancer. These patients often present with more advanced stage of disease and different tumor characteristics, resulting in possibly worse oncological outcome. However, studies with an interest in tumor characteristics and outcome of young rectal cancer patients are scarce.
Methods: For this study population based data of the Netherlands Cancer Registry (NCR) were used. Patients with rectal or rectosigmoid cancer diagnosed between 1989 until 2009 were included. Younger patients (⩽40 years) were compared to middle aged patients (41−70 years) with respect to tumor characteristics, treatment and outcome. Patients older than 70 years were excluded from this analysis.
Results: A total of 37,639 patients were included (⩽40 years n = 1146). The young presented more often with pT4 stage (6.0% vs. 5.1%), and less often pT3 (46.3% vs. 47.2%) and pT1−2 stage (30.9% vs. 33.9%) compared to middle aged patients (p = 0.04). Younger patients presented more often with pN1 (23.3% vs. 16.9%) and pN2 stage (22.1% and 11.8% p < 0.001) and more often with metastatic disease at presentation (22.8% vs. 19.2% p = 0.003). Tumour histology of younger patients was less often an adenocarcinoma (82.1 vs. 88.0%) but more frequently mucinous type carcinomas (10.4% vs. 8.8%), signetcell carcinomas (2.5% vs. 0.6%) and carcinoid tumors (2.5% vs. 0.3) (p < 0.001). In the young the histopathological grade of differentiation was more often poorly differentiated (G3) but less often moderately differentiated (G2) (p = 0.001). The young were more often treated with radiotherapy (51.7% vs. 38.4% p = 0.028) or chemotherapy (48.5% vs. 24.7% p < 0.001) but received less curative rectal surgery (77.0% vs. 82.7% p < 0.001). The overall 5-year survival rate was better for younger patients (57% vs. 53% p < 0.001) and survival of both young and middle-aged patients improved significantly over time. Also stage-specific survival was better for younger patients, except for stage IV rectal cancer.
Conclusions: This study shows that the overall survival of younger patients is the same as in older patients and have improved over time, despite the fact that younger patients present with more aggressive tumors and higher disease state. The standard treatment for younger patients seems therefore appropriate. As earlier detection might be more effective than more aggressive treatment, we have to focus on improving awareness amongst (primary) health-care providers.
No conflict of interest.

2216 POSTER

Overall survival, resection of liver metastases and response to treatment in patients with initially unresectable colorectal liver metastases and following treatment with FOLFOX/cetuximab or FOLFIRI/cetuximab (CELIM-study)

C. Köhne[1], T. Gruenberger[2], W.O. Bechstein[3], H.R. Raab[4], F. Lordick[5], J.T. Hartmann[6], H. Lang[7], J. Weitz[8], J. Stoehlmacher-Williams[9], G. Folprecht[10]. *[1]Klinikum Oldenburg, Klinik für Onkologie, Oldenburg, Germany; [2]University Hospital Vienna, Dpt Hepatobiliary Surgery, Vienna, Austria; [3]University Hospital Frankfurt, Surgical Dpt, Frankfurt, Germany; [4]Klinikum Oldenburg, Surgical Dpt, Oldenburg, Germany; [5]University Hospital Leipzig, University Cancer Center, Leipzig, Germany; [6]University Kiel, Oncology, Kiel, Germany; [7]University Hospital Mainz, Surgical Dpt, Mainz, Germany; [8]University Hospital Dresden, Surgical Dept, Dresden, Germany; [9]University Hospital Dresden, Medical Dpt I, Dresden, Germany; [10]University Hospital Dresden, University Cancer Center/Medical Dpt I, Dresden, Germany*

Background: Initially unresectable CRC liver metastases can potentially be resected following active medical treatment. Cetuximab plus chemotherapy has been shown to increase the rates of tumor response and resection of liver metastases (Van Cutsem et al., JCO 2011).
Methods: Patients (pts) with technically non-resectable and/or with >4 liver metastases were randomized to receive FOLFOX/cetuximab (arm A) or FOLFIRI/cetuximab (arm B). Resectability was evaluated every 2 months. Liver resection was offered to those patients who became resectable. K-ras and b-raf status were evaluated retrospectively. A blinded surgical review was performed to analyze resectability according to imaging criteria. Data on tumor response and resection were reported earlier (Folprecht et al, Lancet Oncol 2010, NCT00153998). Overall and progression free survival were analyzed in December 2012.
Results: Between Dec 2004 and March 2008, 56 pts were randomized to arm A, 55 to arm B. For the current analysis, 109 pts were evaluable for overall survival (OS), and 106 patients for PFS. The median OS was 35.7 [95% CI: 27.2–44.2] months (arm A: 35.8 [28.1–43.6], arm B: 29.0 [16.0–41.9], HR 1.03 [0.66–1.61], p = 0.9). The median PFS was 10.8 [9.3–12.2] months (Arm A: 11.2 [7.2–15.3], Arm B: 10.5 [8.9–12.2], HR 1.18 [0.79–1.74], p = 0.4). Patients with R0 resection had a better OS (median: 53.9 [35.9–71.9] vs. 27.3 [21.1–33.4] mo, p = 0.002) and PFS (median 15.4 [11.4–19.5] vs. 8.9 [6.7–11.1] mo, p < 0.001) than patients without R0 resection. The trend to a longer OS with R0 resection was confirmed in the subgroup of patients who achieved a PR/CR (median 54.6 [29.2–79.9] vs. 41.6 [31.0–52.3], n.s.). The 5 year survival in all R0 resected patients is 46.2%.
Resectability according to the surgical imaging review after treatment (HR 0.50 [0.29–0.85]) had a significant influence on overall survival, in contrast to baseline imaging (HR 0.77 [0.42–1.41]). In a multivariate analysis, k-ras status at baseline, response to treatment and R status were significant factors for overall survival.
Conclusions: This study confirmed a favourable long term survival of selected patients with initially 'non-resectable' CRC liver metastases treated in a multidisciplinary approach and the influence of both, efficacy of systemic treatment and resection of liver metastases.

2217 POSTER

Prognosis and value of adjuvant chemotherapy in stage III mucinous colorectal carcinoma

N. Hugen[1], R.H.A. Verhoeven[2], S.A. Radema[3], I.H.J.T. De Hingh[4], J.F.M. Pruijt[5], I.D. Nagtegaal[6], V.E.P.P. Lemmens[7], J.H.W. De Wilt[1].
[1]Radboud University Nijmegen Medical Centre, Department of Surgery, Nijmegen, Netherlands; [2]Comprehensive Cancer Centre South, Eindhoven Cancer Registry, Eindhoven, Netherlands; [3]Radboud University Nijmegen Medical Centre, Department of Oncology, Nijmegen, Netherlands; [4]Catharina Hospital Eindhoven, Department of Surgery, Eindhoven, Netherlands; [5]Jeroen Bosch Hospital, Department of Internal Medicine, 's-Hertogenbosch, Netherlands; [6]Radboud University Nijmegen Medical Centre, Department of Pathology, Nijmegen, Netherlands; [7]Erasmus MC University Medical Centre, Department of Public Health, Rotterdam, Netherlands

Background: Colorectal mucinous adenocarcinoma (MC) is reported in 10−15% of cases with colorectal cancer and has been associated with impaired prognosis compared to non-mucinous adenocarcinoma (NMC). Response to palliative chemotherapy is poor in advanced disease, but the benefit of adjuvant chemotherapeutic treatment has never been assessed in large patient groups. This study analyses overall survival of mucinous colorectal cancer patients and efficacy of adjuvant chemotherapy in terms of survival in patients following radical resection for mucinous colon cancer.
Patients and Methods: This population-based study involved 27,251 unselected patients diagnosed with colorectal carcinoma between 1990 and 2010. Clinicopathologic data was recorded prospectively and included additional variables concerning comorbidity and socio-economic status. A meta-analysis of published data for MC patients treated with palliative and adjuvant chemotherapy was conducted.
Results: MCs were found in 12.3% (N = 3,052) of colorectal tumours with a different distribution compared to NMC, with only 24.4% located in the rectum and 54.3% in the proximal colon (P<0.0001). NMCs were more often classified as stage I disease (P<0.0001). After adjustments for covariates, mucinous histology was associated with a higher risk of death only when located in the rectum (HR 1.28; 95% CI 1.17–1.40). Multivariate regression analysis showed a similar response to adjuvant chemotherapy for stage III MC and NMC patients. A meta-analysis demonstrated a poorer response to chemotherapy in the palliative setting (HR 1.67; 95% CI 1.39–2.00), but not in the adjuvant setting.
Conclusions: Based on its histological appearance and its clinico-pathologic features MC may be considered a distinct entity with a

predominant right sided location. Mucinous histology has no impact on prognosis, except when the tumour is located in the rectum. Despite lower response to palliative chemotherapy in MC, there is no difference in the efficacy of chemotherapy between MC and NMC in the adjuvant setting. Therefore, current adjuvant treatment recommendations should not take histology into account.
No conflict of interest.

2218 POSTER

Accurate identification of complete responders after CRT for rectal cancer with endoscopy and MRI

L.A. Heijnen[1], M. Maas[2], D.M.J. Lambregts[2], M.H. Martens[1], E. Van Drie[2], L.P.S. Stassen[3], S.O. Breukink[3], J.W.A. Leijtens[4], G.L. Beets[3], R.G.H. Beets-Tan[2]. *[1]Maastricht University Medical Centre, Radiology/Surgery, Maastricht, Netherlands; [2]Maastricht University Medical Centre, Radiology, Maastricht, Netherlands; [3]Maastricht University Medical Centre, Surgery, Maastricht, Netherlands; [4]Laurentius Hospital, Surgery, Roermond, Netherlands*

Background: Chemoradiotherapy (CRT) for rectal cancer leads to complete tumour response (CR) in up to 15−25%. Accurate identification of a CR is necessary when less invasive treatment is considered (i.e. local excision or wait-and-see policy). Standard imaging consisting of T2-weighted (T2W) MRI and endoscopic ultrasound (EUS) cannot accurately identify a CR. Aim was to evaluate the accuracy of [1] endoscopy and [2] MRI including diffusion weighted imaging (DWI) for identification of a CR and compare it to standard MRI.
Materials and Methods: 49 patients who underwent CRT followed by response evaluation (standard MRI including DWI and endoscopy) 8 weeks after completion of CRT, were retrospectively included. One experienced reader scored [1] the standard T2W images followed by [2] the MR images including DWI. A second reader scored the endoscopy images. Readers were blinded for histology and each other's results. Scoring was performed with a confidence level score (0=definitely residual tumour, 4=definitely CR) and results were compared with histology (CR vs non-CR).
Results: Of the 49 patients, 31 had residual tumour and 18 had a CR. The AUCs for standard MRI, standard MRI + DWI, and endoscopy were 0.71, 0.78, and 0.88 respectively. Corresponding sensitivities and specificities were 39% and 87% for T2W-MRI, 39% and 93% for T2W+DWI, and 67% and 97% for endoscopy. When a combination of standard MRI + DWI with endoscopy was used the highest accuracy was reached: 0.91.
Conclusion: Endoscopy is more accurate in identifying a CR after CRT than standard MRI (+/−DWI). With a higher sensitivity, endoscopy corrects for understaging of a CR with MRI. MRI remains crucial to evaluate the presence of any extramural residual tumour and/or involved nodes. A combination of endoscopy and MRI+DWI is therefore recommendable to identify patients with a CR after CRT, making less invasive treatments after CRT feasible.
No conflict of interest.

2219 POSTER

Predictors of response and prognosis in patients with rectal adenocarcinoma who received preoperative chemoradiotherapy [CRT]: Biopsy specimens obtained one week after starting CRT are reliable factors

T. Suzuki[1], S. Sadahiro[1], A. Tanaka[1], K. Okada[1], G. Saito[1], A. Kamijo[1], S. Kawada[2], T. Akiba[2]. *[1]Tokai University, Surgery, Isehara, Japan; [2]Tokai University, Radiology, Isehara, Japan*

Background: Preoperative chemoradiotherapy (CRT) for locally advanced rectal adenocarcinoma significantly reduced local recurrence. Patients with a marked histological response to CRT have been reported to reveal good oncologic outcomes. We tested the hypothesis that biopsy specimens obtained soon after the start of CRT can be used as predictive factors.
Subjects and Methods: The study group comprised 119 patients with cT3/T4, Nx, M0 or cT2, N+, M0 adenocarcinoma of the middle or lower rectum who received preoperative CRT from 2000 through 2012. Preoperative radiotherapy in a dose of 40 to 45 Gy was combined with oral uracil/tegafur (UFT) or S-1 chemotherapy. Surgery was performed 6 to 8 weeks after the completion of radiotherapy. We evaluated histologic findings on hematoxylin and eosin(H-E) staining and immunohistochemical expressions of Ki67, p53, p21, and apoptosis in biopsy specimens obtained one week after starting CRT. These findings were contrasted with the histologic response, the degree of tumor shrinkage and prognosis. Tumor Regression Grade 1 and 2 were defined as marked histologic regression.
Results: Twenty-one patients (17.6%) had a pathological complete response. The rates of histologic marked regression were as follows: 64% in patients with moderate changes and 20% in those with mild changes on H-E stained biopsy specimens; 61% in apoptosis-positive patients and 34% in apoptosis-negative patients; and 52% in p21-positive patients and 27% in p21-negative patients. Histologic marked regression rates were significantly higher in positive cases ($p < 0.01$, $p < 0.01$, and $p < 0.01$, respectively).
Tumor shrinkage rates from MRI volumetry were 77± 15% in patients with moderate changes on H-E stained specimens and 67±18% in those with mild changes. ($p < 0.01$) Tumor shrinkage rates were significantly larger in patients with apoptosis positive and with p21 positive expression as compared to those with apoptosis negative and with p21 negative expression, respectively.($p < 0.01$, $p = 0.05$) In 89 patients who received surgery until March 2011 (median follow-up, 44 months), the rates of recurrence-free survival and overall survival at 5 years were 83% and 98% in patients with moderate changes on H-E stained specimens, respectively, as compared with 62% and 85% in patients with mild changes. Patients with moderate changes on H-E stained specimens had better recurrence-free and overall survivals than those with mild changes ($p = 0.04$ and $p = 0.04$, respectively).
Conclusions: In patients with locally advanced rectal adenocarcinoma, histological changes on H-E stained biopsy specimens obtained one week after starting CRT are reliable predictors of response, equivalent to apoptosis and p21 expression on immunohistochemical staining. Histologic changes on H-E stained specimens are related to recurrence-free and overall survivals.
No conflict of interest.

2220 POSTER

Impact of neoadjuvant chemoradiotherapy on long-term results and sphincter sparing rate in distal rectal carcer patients

A. Rasulov[1], Z. Mamedli[1], Y. Sheligyn[2], S. Zhdankina[2], A. Boiko[3], I. Droshneva[3]. *[1]N.N. Blokhin Russian Research Cancer Center, Colorectal Cancer, Moscow, Russian Federation; [2]State Research Center of Coloproctology, Colorectal Cancer, Moscow, Russian Federation; [3]Moscow Herzen Research Oncology Institute, Radiotherapy, Moscow, Russian Federation*

Background: Tumor downstaging influenced by preoperative chemoradiotherapy (CRT) might result in higher sphincter preservation rate for low rectal cancer (LRC).
Material and Methods: Between 2006 and 2009, 321 patients with T3−4N0−2 or T2N0−2 adenocarcinoma located in low rectum (below 6 cm), enrolled into the study. 176 received preoperative CRT with total dose 50 Gy, Cisplatin, 5-FU followed by surgery after 5−6 weeks and 145 underwent surgery alone. Chemotherapy scheme was as follows: 5 days prolonged iv infusion 5-FU 350 mg/m^2, next 3 days − Cisplatin 30 mg iv single dose, concurrently with external beam radiation: single dose 4 Gy and followed by dynamic fractionation − daily dose 2.5 Gy divided in 2 fractions up to total dose of 50 Gy. Surgery was performed 5−6 weeks after completion of CRT. All patients had adjuvant chemotherapy (Xelox).
Results: Tumor downstaging was revealed in 66.4% of irradiated patients. Complete and near complete tumor regression according Mandard classification registered in 35.4% (11.4% and 24%, respectively). Average distance from anal verge to tumor increased from 5.0±2.3 up to 5.7±2.1 cm for all RC and from 3.8 to 4.4±1.1 cm for LRC due to regression.
There was increase of sphincter-saving surgery (SSS) rate (57.6% vs 13.2%, $p < 0.0001$) including partial sphincter resection for LRC after CRT compare to surgery. Distal margin was negative in all cases. Postoperative complications developed in 27.6% of irradiated patients and 20.1% after surgery alone ($p > 0.05$). With follow-up median 26 months (3−72) local recurrences developed in 2.4% and 11.4% ($p = 0.0031$), metastases − in 12.2% and 12.1% ($p = 1.0$) and 5-years disease free survival rate was − 75.8% and 57.6% in CRT and surgery ($p = 0.09$) groups, respectively.
Conclusion: Preoperative CRT results in increase of SSS rate for LRC and reduction of local recurrence.
No conflict of interest.

2221 POSTER

Nutrient patterns: a first application to colorectal cancer in the EPIC Study

H. Freisling[1], A. Moskal[1], P. Ferrari[1], G. Byrnes[1], P.T. Pisa[1], N. Slimani[1], for the EPIC Group[1]. *[1]International Agency for Research on Cancer, Lyon, France*

Background: Potential benefits of a diet are likely to be due to a combination of nutrients rather than nutrients in isolation. The aim of this study was to investigate associations between nutrient patterns and risk of colon and rectal cancers within a prospective cohort study.
Material and Methods: The present analysis includes 477,312 subjects (~70% women) aged between 25 and 70 years who were recruited between 1992 and 2000 in 23 centers from 10 European countries

participating in the European Prospective Investigation into Cancer and Nutrition (EPIC) study. The intakes of 23 nutrients were estimated from country-specific baseline dietary questionnaires using the harmonized EPIC Nutrient DataBase (ENDB). Nutrient patterns were derived from Principle Component Analysis (PCA) of log-transformed nutrient densities (excluding alcohol) across all centers adjusting for non-alcohol energy intake. The relationship between each of the retained nutrient patterns (PC scores) and cancer risk was examined for colon and rectal cancers combined and separately, and also by sex. The hazard ratios to develop colon or rectal cancer (and associated 95% CI) were calculated for each PC score using Cox proportional hazard regression and adjusting for a number of relevant confounders.
Results: The first 4 nutrient patterns identified were retained. They explained 67% of the total variance and reflected the following nutrient patterns: (PC1) Animal vs. plant nutrients; (PC2) Vitamins and minerals; (PC3) Non-dairy-vitamin D; and (PC4) Dairy and soy driven nutrients. After adjustments, the HR (per SD of the population) of the association between colorectal cancer and PC2 was 0.92 for men (95% CI: 0.86, 0.98) and 0.95 for women (95% CI: 0.91, 1.00). The HR for PC4 were 0.94 (95% CI: 0.84, 1.04) for men and 0.91 (95% CI: 0.83, 0.99) for women. Similar inverse associations were found with colon cancer, but not with rectal cancer. PC1 and PC3 were not associated with risk of colon or rectal cancer.
Conclusions: A nutrient pattern high in vitamins and minerals appears to be associated with a decreased risk of colorectal cancer in men, while in women similar associations were found for a pattern driven by dairy and soy. Sub-group analyses by anatomical sub-site showed the associations to be driven by the colon.
Acknowledgements: We acknowledge the contribution of all EPIC colleagues to the study and funding by the EC, the Fondation de France and other national funding organizations.
No conflict of interest.

2222 POSTER

Diminishing differences in treatment between colorectal cancer patients with and without diabetes: A population-based study

M. Zanders[1], L. Van Steenbergen[1], H. Haak[2], H. Rutten[3], J. Pruijt[4], P. Poortmans[5], V. Lemmens[1], L. Van de Poll-Franse[1]. *[1]Eindhoven Cancer Registry, Research, Eindhoven, Netherlands; [2]Maxima Medical Centre, Internal Medicine, Veldhoven/Eindhoven, Netherlands; [3]Catharina Hospital, Surgery, Eindhoven, Netherlands; [4]Jeroen Bosch Hospital, Internal Medicine, 's-Hertogenbosch, Netherlands; [5]Institute Verbeeten, Radiation Oncology, Tilburg, Netherlands*

Background: Cancer patients with diabetes are less likely to be treated according to guidelines. We assessed changes in patient-, tumour-, and treatment- related variables in colorectal cancer patients with and without diabetes, thereby evaluating the implementation of national treatment guidelines.
Methods: All 17,170 cases of primary colorectal cancer between 1995 and 2010 in the South-Eastern Netherlands were included. The Cochrane-Armitage test and logistic regression analysis were used to analyse trends.
Results: 11,893 patients were diagnosed with colon cancer and 5,277 with rectal cancer, of whom 1,711 (14%) and 609 (12%), respectively, had diabetes at the time of cancer diagnosis. Colorectal cancer patients with diabetes compared to those without were about 5 years older and more often diagnosed with proximal colon tumours (60% vs. 54%, $p < 0.0001$). Chemotherapy administration significantly increased in stage III colon cancer patients with and without diabetes (from 17% in 1995–1998 to 52% in 2007–2010, 36% to 64%, respectively, $p < 0.0001$). However, even in the most recent period and after adjusting for the co-variables age, gender, year of diagnosis, and specific comorbidities, stage III colon cancer patients with diabetes received adjuvant chemotherapy less frequently than those without (OR: 0.8 (95% CI 0.6−1.0) $p = 0.04$). The proportion of stage II/III rectal cancer patients with and without diabetes who underwent radiotherapy was similar in recent years (91% vs. 87%). Furthermore, stage IV rectal cancer patients with diabetes received chemotherapy less frequently and received radiotherapy more often compared to patients without diabetes.
Conclusions: Although colorectal cancer patients with diabetes receive chemotherapy less often, differences in treatment between colorectal cancer patients with and without diabetes are decreasing. A growing knowledge of colorectal cancer care is probably shifting the approach in diabetic individuals towards more aggressive treatment. In future studies, we will investigate the influence of this more aggressive treatment on outcomes in colorectal cancer patients with diabetes.
No conflict of interest.

2223 POSTER

Phase I/II study of capecitabine, oxaliplatin, irinotecan and cetuximab (COI-E regimen) as perioperative treatment of high-risk or borderline resectable colorectal cancer liver metastases (CLM)

F. Pietrantonio[1], J. Coppa[2], F. De Braud[1], V. Mazzaferro[2], P. Biondani[1], F. Perrone[3], A. Gevorgyan[1], K.F. Dotti[1], C. Cotsoglou[2], M. Di Bartolomeo[2]. *[1]Fondazione IRCCS Istituto Nazionale Tumori, Medical Oncology Department, Milano, Italy; [2]Fondazione IRCCS Istituto Nazionale Tumori, Gastro-Intestinal Surgery Liver Transplantation and Hepatology, Milano, Italy; [3]Fondazione IRCCS Istituto Nazionale Tumori, Pathology & Molecular Oncology Department, Milano, Italy*

Background: Perioperative treatment of CLM may increase R0 resection, convert borderline resectable disease to curative surgery and improve survival.
Materials and Methods: This phase I/II study aimed to determine the safety and activity of capecitabine, oxaliplatin and irinotecan plus cetuximab (COI-E regimen) as perioperative treatment in pts with contraindication for upfront resection of CLM. Six pts received as first dose level: irinotecan (180 mg/mq) and cetuximab (500 mg/mq) on day 1, oxaliplatin (85 mg/m^2) on day 2 and capecitabine (1000 mg/m^2 orally twice daily) on days 2−6; four biweekly cycles were administered both pre- and post-operatively. Since this was the recommended phase II dose (RP2D), 30 additional pts were enrolled from November 2008. In June 2009, the protocol was amended to enrol only KRAS exons 2−4 wild type. Main inclusion criteria: primary tumour resected; no extraepatic disease; borderline liver resectability with portal vein embolization or two stage epatectomy, involvement of >1 hepatic vein or >4 liver segments; and/or at least one adverse prognostic factor: >4 metastases; CEA >200; synchronous metastases. Primary endpoint: response rate (RR); secondary: R0 resection; safety; pathological response; relapse-free survival (RFS) and overall survival (OS).
Results: The RP2D was identified at the first level, due to occurring of G3 diarrhoea in 1/6 pts. Overall, 36 pts enrolled and 35 evaluable for response. RR was 86% (all PR), with 4 (11%) SD and 1 (3%) PD. Surgery with curative intent was performed in 33 pts (3 awaiting surgery) and R0 resection was achieved in 26 (79%), in addition with radiofrequency ablation in 2. Pts characteristics: M/F: 23/13, median age 58 yrs (range 35−72), synchronous CLM 28/36 (78%), number of CLM 1/2−4/>4 in 15 (42%)/14 (39%)/7 (19%), KRAS mutation 8/36 (22%), N+ hilar nodes 1/33 (3%), N+ at primary 25/36 (69%), CEA >200 2/36 (6%), extrahepatic disease 5/33 (15%: 2 extraregional nodes, 2 peritoneal carcinosis, 1 second primary). At a median follow up of 40 months, median RFS was 12.3 mos. OS and safety data will be presented at the Meeting.
Conclusions: Biweekly COI-E is feasible and active. The regimen is well suited for liver downstaging in KRAS wild type CLM before curative surgery.
No conflict of interest.

2224 POSTER

Similar survival outcome of locally advanced proximal and distal rectal cancer for patients treated in a specialized cancer center

M. Rijpkema[1], L. Dewit[2], A. Aalbers[1], H. Boot[3], A. Cats[3], M. Lopez Yurda[4], V. Verwaal[1]. *[1]The Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital (NKI-AVL), Surgical Oncology, Amsterdam, Netherlands; [2]The Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital (NKI-AVL), Radiotherapy, Amsterdam, Netherlands; [3]The Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital (NKI-AVL), Oncological Gastroenterology, Amsterdam, Netherlands; [4]The Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital (NKI-AVL), Statistics, Amsterdam, Netherlands*

Background: Distal rectal cancer (DRC) that requires an abdominoperineal resection (APR), remained largely out of focus in the implementation of total mesorectal excision (TME) which improved outcome for patients with rectal cancer. DRC still has a worse prognosis compared to proximal rectal cancer (PRC), due to a high percentage of positive circumferential resection margins (CRM), resulting in a higher local recurrence rate and worse survival outcome. In this study we investigate whether the outcome of DRC can be brought to a similar level as PRC when the treatment is performed in a specialized cancer center.
Materials and Methods: Patients with advanced (T3 and T4) primary PRC and DRC treated between 1−1–2005 and 31−12–2010 in the Netherlands Cancer Institute, were analyzed for CRM involvement and survival outcome. A tumor located 5 cm or less from the anal verge was considered to be DRC, whereas higher situated tumors were considered to be PRC. Patients received preoperative (chemo)radiotherapy, except those who previously had radiotherapy of the pelvis, and had surgery. Data were collected on operative details, histological results, postoperative morbidity and mortality and long-term outcomes. Determinants of recurrence and survival were

examined using Kaplan–Meier survival curves and Cox regression analysis. Patients with distant metastasis at time of surgery were excluded from analysis for disease free survival.
Results: 102 patients with advanced PRC and 92 patients with advanced DRC were included. Median follow-up time was 37 months. After surgery CRM involvement was observed in 14/93 (15.1%) of the patients with PRC and in 16/87 (18.4%) of the patients with DRC (P = 0.501). The 3- and 5-year overall survival rates were 71% and 68% for PRC versus 78% and 67% for DRC (P = 0.600), the 3- and 5-year disease free survival rates were 70% and 57% for PRC and 67% and 55% for DRC (P = 0.426). Both the univariate and multivariate regression analyses on overall survival showed no difference between proximal and distal rectal cancer (P = 0.600 and P = 0.344).
Conclusion: Treatment in a specialized cancer center can reduce CRM involvement and recurrence rates for advanced distal rectal cancer, with improvement of survival outcomes similar to that of advanced proximal rectal cancer.
No conflict of interest.

2225 POSTER

The level of carcinoembryonic antigen (CEA) influences the pathological complete response after preoperative chemoradiotherapy in locally advanced rectal cancer

G.E. Trejo Duran[1], G. Calderillo Ruiz[2], C. Diaz Romero[2], J. Zamora Varaona[1], M.I. Palma Valle[2], N.P. Alvarez Aguila[1], J.M. Flores Castro[1], H.N. Lopez Basave[3]. *[1]INCAN, Radiotherapy, Mexico DF, Mexico; [2]INCAN, Medical Oncology, Mexico DF, Mexico; [3]INCAN, Surgical Oncology, Mexico DF, Mexico*

Background: The ACE level after treatment is independent adverse factor in advanced colorectal cancer. We investigated the meaning of ACE as a predictor of pathologic complete response in patients with rectal cancer who receive preoperative chemoradiotherapy.
Material and Methods: In this retrospective analysis of patients treated from May 2005 to October 2012, included 253 patients with locally advanced rectal cancer with a mean age of 55 years (range 18−90), 57% male and 43% female, located in lower third in 58% (n = 147) medium 31% (n = 78) and superior in 11% (n = 27), with a medium length of 6 cm tumor. ACE level was determined in 237 and were <10 ng/dl in 154 cases (65%) and >10 ng/dl in 83 cases (35%). All patients received preoperative treatment with concomitant chemoradiotherapy and subsequently measured with endoscopy and biopsy followed by radical surgery (in 53%).
Results: The results are presented in the table.

	ACE 0−10 ng/dl	ACE >10 ng/dl
Number	154	83
Radical surgery	82 (53%)	44 (53%)
Pathologic complete response (with radical surgery)	23/82 (28%)	7/44 (16%)
Palliative surgical	6 (4%)	9 (11%)
Progression at QT-RT	11 (7%)	10 (12%)
No acept radical treatment, post-QT-RT*	45 (29%)	17 (20%)
Complete response with biopsy, without radical surgery*	39/45 (87%)	11/17 (65%)

Conclusions: In patients with rectal cancer who receive neoadjuvant concomitant QT-RT, ACE level pretreatment above 10 ng/ml may be a predictor of pathologic complete response. However, it requires a long-term monitoring and multivariate analysis.
No conflict of interest.

2226 POSTER

Long term outcome of pathological complete response patients after neoadiuvant therapy for locally advanced rectal cancer: Monoistitutional prospetictive trial

A. Tamburini[1], E. Orsenigo[1], S. Di Palo[1], M. Ronzoni[2], C. Staudacher[1]. *[1]University Vita-Salute San Raffaele, Gastrointestinal Surgery, Milan, Italy; [2]San Raffaele Hospital, Medical Oncology, Milan, Italy*

Background: In the European randomized trials of neoadjuvant CRT the rate of complete response ranged from 11−16% and was significantly greater that for neoadjuvant radiotherapy alone. A favorable prognosis was observed for complete pathologic response after preoperative therapy in patients with locally advanced rectal cancer. The aim of our analysis was verify whether yPCR predicts a favorable outcome.
Patients and Methods: 370 patients with locally advanced low and mid rectal cancer underwent neoadjuvant chemoradiation at the Surgical Department of University Vita-Salute San Raffaele of Milan from January 1998 to December 2011. All patients were identified from our prospective Rectal Database. Eligibility criteria included locally advanced rectal cancer with no evidence of distant metastases at the time of the diagnosis and evidence of ypCR after the neoadjuvant treatment. All patients received the same neoadjuvant treatment with 5-FU and Oxaliplatin. After a median interval of 10 weeks after complatation of neoadjuvant treatment patients underwent a radical resection according to the principles of TME. Standard pathological tumour staging of resected specimen was performed according the AJCC Cancer staging Manual (7th edition) The pCR was defined by no evidence of viable tumour cell on pathologic analysis. Local recurrence was defined as clinical, radiological or pathological evidence of tumour in any other site. The time to last follow up, local recurrence, or death was measured from the time of radical resection. Statistical analysis was performed using SPSS (version 15.0; SPSS Inc Chicago, IL) Recurrence free survival and overall survival were estimated using the Kaplan Meier method, and differences between survival curves were determinated by using the long rank test. A P value of <0.05 was considered statistically significant.
Results: 61 patients had a complete response and 107 patients were not responders. Sphincher preserervation, anteroposterior resection and endoscopic surgery were performed in 57 patients (97.2%). five patients with complete no had surgical procedure. Mean number of examinated lymphnodes was 11.83±8.7. Median follow up was 60 months. In pCR patients no locoregional recurrence occured and distant metastase occured in 4 patients (6.5%). In the no responder group we found 21 (12.7%) local recurrence and 62 (57.9%) patients developped distant metastases The pCR group 5-years overall and disease free survival were 96.6% and 91.4% rispectively.
Conclusions: The improved patological outcome in patients with rectal cancer who achieve a pCR appears related to their significantly decreased rate of distant failure when compared with no down staging patients. To further improve the oncological outcomes and sphincter preservation rates in patients with locally advanced rectal cancer, the molecular mechanism governing the rectal cancer response to preoperative CRT need to be explored.
No conflict of interest.

2227 POSTER

Bevacizumab related complications in rectal cancer patients after neoadjuvant chemoradiotherapy and surgery

C. De la Fouchardière[1], O. Derbel[2], M.H. Laidet[1], F. Desseigne[1], P. Guibert[1], P. Méeus[3], P. Peyrat[3], A.I. Lemaistre[4], I. Martel-Lafay[5], M. Rivoire[6]. *[1]Centre Léon Bérard, Departement Oncologie Medicale, Lyon, France; [2]Madame Olfa Miled Derbel, Departement Oncologie Medicale, Lyon, France; [3]Centre Léon Bérard, Departement De Chirurgie, Lyon, France; [4]Centre Léon Bérard, Departement d'Anatomo Pathologie, Lyon, France; [5]Centre Léon Bérard, Departement de Radiotherapie, Lyon, France; [6]Centre Léon Bérard, Departement de Chirurgie, Lyon, France*

Background: Bevacizumab was the first angiogenesis inhibitor approved for the first-line treatment of metastatic colorectal cancer in combination with intravenous fluorouracil-based chemotherapy. Clinical trial data have indicated that bevacizumab can induce complications. However, published informations regarding the safety of this treatment, especially for patients with rectal cancer already treated by radiotherapy and surgery are still limited.
Methods and Materials: We performed a retrospective evaluation of bevacizumab-associated adverse events from our institutional database. Medical records of these patients were examined for reports of clinicopathological factors, treatment and the safety profile, particularly the targeted adverse events such as proteinuria, bowel perforation, hypertension, fistlae, thromboembolism and bleeding.
Results: Records of patients treated for metastatic rectal cancer from january 2009 to December 2012 were reviewed. One hundred and six patients were identified with a median age of 61 years (range 25−85). Forty six patients (43%) had synchronous metastatis at initial diagnosis. Eighty patients (75%) received preoperative radiochemotherapy, 67 (63%) were operated after neo-adjuvant treatment. Ninety six patients (90%) were treated for metastatic or locally advanced disease with 5-FU, leucovorin regimen associated to irinotecan (FOLFIRI) or oxaliplatin (FOLFOX). Bevacizumab was associated to chemotherapy in 60 patients (62%). On average, bevacizumab was initiated 8 months after the initial operation; complications occurred 12 months after starting bevacizumab. The most common bevacizumab-related toxicity was fistulae formation in 9 patients (15%) followed by venous thromboembolic (VTE) events in 6 patients (10%). Fistulae were most commonly recto-vesical or recto-vaginal and were managed surgically in 61% of patients. No fistulae occurred in patients treated with chemotherapy alone.
Conclusions: Treatment with bevacizumab does not significantly increase thromboembolic toxicity compared to standard salvage chemotherapy. However, anti-angiogenic effect of bevacizumab may potentialise fistulae

occurrence in patients with rectal cancer already treated by chemoradiotherapy and surgery.
No conflict of interest.

2228 POSTER

Hyperthermic intraperitoneal chemotherapy during primary tumor resection in colorectal cancer limits extent of bowel resection compared to a two-stage treatment

H.J. Braam[1], D. Boerma[1], M.J. Wiezer[1], B. Van Ramshorst[1].
[1]*St. Antonius Ziekenhuis, Surgery, Nieuwegein, Netherlands*

Introduction: Cytoreductive surgery (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC) is increasingly applied as a standard treatment in patients with synchronous peritoneal carcinomatosis (PC) from colorectal cancer (CRC). Synchronous PC is often diagnosed at laparoscopy or laparotomy scheduled to resect the primary tumor. CRS and HIPEC is a complex multimodality procedure, which is generally performed in specialized referral centers after prior resection. This study compares the clinical outcome of CRS and HIPEC procedures in CRC patients with synchronous PC in whom the primary tumor was previously resected to patients in which the primary tumor was resected in the same procedure as the CRS and HIPEC.
Methods: In total 72 patients (44 males; median age 60 years) with synchronous PC from CRC who underwent CRS and HIPEC between march 2005 and January 2012 were analyzed. Relevant clinicopathologic data were retrospectively retrieved from a prospective database with special interest in bowel continuity, ostomy formation and postoperative complications.
Results: In twenty patients (27.8%) the primary tumor was resected at the HIPEC procedure; fifteen of these patients had non-resective prior surgery, e.g. formation of a deviating ostomy. In the other 52 patients (72.2%) the primary tumor was resected prior to the CRS+HIPEC, with the creation of 37 anastomoses (71.1%). During CRS and HIPEC 22 (59.5%) of these anastomoses were resected. In 12 (54.5%) histopathological assessment of the anastomoses revealed malignancy. The median duration between the first operation and HIPEC procedure was 37 days (range 8−85) in patients with non-resective preceding surgery, which was significantly shorter ($P<0.001$) compared to patients whom already underwent a resection; median 93 days (range 42–175). Complication rates and long-term results were not statistically different between both groups. Anastomotic leakage rates seemed higher in patients with a resection of a previous anastomosis compared to the rest of the patients (31.8% vs. 14.7%). Twenty patients ended with a colostomy after CRS and HIPEC, 10 of these patients had complete bowel continuity after previous resection.
Conclusion: Referral before resecting the primary tumor may prevent extended bowel resections and permanent colostomy. Therefore, it is important to consider CRS and HIPEC in patients with synchronous PC from CRC.
No conflict of interest.

2229 POSTER

Synchronised chemoradiation and systemic chemotherapy for patients presenting with simultaneously primary and metastatic rectal cancer

P. Cooray[1], J. McKendrick[1], S.W. Wong[1], C. Ngan[2], K. Palaniappan[3], C. Moldovan[1], S. Chander[4], M. Michael[5], M. Steel[6], S. Ngan[4]. [1]*Box Hill Hospital, Oncology, Box Hill, Australia;* [2]*University of Melbourne, Faculty of Medicine, Parkville, Australia;* [3]*Monash University, Faculty of Medicine, Clayton, Australia;* [4]*Peter MacCallum Cancer Centre, Radiation Oncology, East Melbourne, Australia;* [5]*Peter MacCallum Cancer Centre, Medical Oncology, East Melbourne, Australia;* [6]*Box Hill Hospital, Surgery, Box Hill, Australia*

Background: Chemotherapy used during chemoradiation is adequate for radiosensitisation but suboptimal for systemic control. The aim of this study was to evaluate tolerability, and local and systemic benefits of a new treatment regimen delivering intensive chemotherapy and radical radiotherapy in a synchronised manner to achieve optimum systemic and local control concurrently.
Materials and Methods: This study reviewed our experience in treating patients presenting with untreated simultaneous symptomatic primary and metastatic rectal cancer. The protocol regimen was 12 weeks long. FOLFOX chemotherapy (oxaliplatin 100 mg/m^2 day 1, leucovorin 200 mg/m^2 day 1, 5-FU 400 mg/m^2 bolus day 1, then continuous infusion 2.4 g/m^2 over 46 hours) was given in week 1, 6, and 11. Pelvic radiotherapy (25.2 Gy in 3 weeks in 1.8 Gy/fr with concurrent oxaliplatin 85 mg/m^2 day 1 and 5-FU continuous infusion 200 mg/m^2/day) was given in week 3−5, and week 8−10. In total, patients received, in 12 weeks, 3 courses of FOLFOX and pelvic radiation 50.4 Gy with concurrent oxaplatin and 5-FU.
Results: Thirty-eight patients were treated in this study. The mean age was 63 (range 33−84) years. 63% were male. Liver, lung, extrapelvic nodes and other metastases were present in 74%, 26%, 13% and 11% of patients, respectively. 37% of patients had more than one site of metastatic disease. Thirty-five patients (92%) completed the 12-week treatment regimen. 95% patients received the planned radiation dose. 92% of patients receiving at least 75% of the oxaliplatin dose; 95% receiving $\geqslant$75% 5-FU. Worst-grade neutropenia were G1 21%, G2 13%, G3 29%, and G4 18%. PET metabolic response (CR+PR) rate was available for 34 patients. Metabolic CR+PR rate for rectal primary was 100%. Overall metabolic CR+PR rate for metastatic disease was 76% (CR 44%). Median survival was 21.5 months. For surviving patients (n = 15), median follow-up was 30 (range 18−57) months. Five patients had resection of primary and liver metastases: 4 remaining alive at the time of this analysis.
There were 11 patients $\geqslant$70 and 27 patients <70 years old: radiation completion rates 91% and 96% respectively; 82% and 96% of patients received $\geqslant$75% of the planned oxaliplatin dose respectively; 91% and 96% of patients received $\geqslant$75% of the planned 5-FU dose respectively.
Conclusions: This regimen provides good local treatment without compromising systemic therapy in patients presenting with rectal cancer and synchronous metastasis. Toxicity and efficacy compare favorably with other regimens. Although oxaliplatin dose reduction is more common in over 70 years group, overall tolerability in elderly patient is satisfactory. This strategy is the subject of an ongoing phase II clinical trial (CHROME B) with the addition of bevacizumab.
No conflict of interest.

2230 POSTER

CRAB trial: Long-term results from a prospective phase II study evaluating neoadjuvant capecitabine, radiotherapy (RT) and revacizumab in locally advanced rectal cancer

V. Velenik[1], J. Ocvirk[2], M. Music[3], M. Bracko[4], F. Anderluh[1], I. Oblak[1], I. Edhemovic[5], E. Brecelj[5], M. Kropivnik[3], M. Omejc[6]. [1]*Institute of Oncology, Radiotherapy, Ljubljana, Slovenia;* [2]*Institute of Oncology, Medical Oncology, Ljubljana, Slovenia;* [3]*Institute of Oncology, Radiology, Ljubljana, Slovenia;* [4]*University Clinical Center, Pathology, Ljubljana, Slovenia;* [5]*Institute of Oncology, Surgery, Ljubljana, Slovenia;* [6]*University Clinical Center, Surgery, Ljubljana, Slovenia*

Background: This study evaluated the impact of addition of bevacizumab to concurrent capecitabine based chemoradiotherapy (CRT) in locally advanced rectal cancer (LARC) on pathological complete response (pCR) as primary endpoint and on local control and survival parameters as secondary endpoints.
Methods: Enrolled patients (pts) with MRI-confirmed stage II/III rectal cancer were treated with an infusion of Bev (5 mg/kg) 2 weeks prior to neoadjuvant CRT, followed by Bev 5 mg/m^2 on week 3, 5, 7 and capecitabine 825 mg/m^2 bid including weekends during RT. RT was administered at 50.4 Gy (25$\times$1.8 Gy with boost 3$\times$1.8 Gy, 3D conformal technique), starting on week 3. Total mesorectal excision was scheduled 6−8 weeks after completion of CRT. Four to six cycles of adjuvant capecitabine chemotherapy were recommanded.
Results: Sixty pts were eligible for analysis. Median age was 60 (range: 31−79) years, 64% of pts were male. Twelve pts (20%) presented with stage II and all other with stage III of disease. In 28 patients (46.6%) the tumour invaded the mesorectal fascia. Radical resection was achieved in 58 pts (96.6%). TRG 4 (pCR) was recorded in 5 pts (13.3%) and TRG 3 in 6 pts (15%). Fifty patients (83.3%) received capecitabine postoperatively. Perioperative adverse events (within 30 days after surgery) were recorded in thirty-eight pts (62.3%): delayed wound healing (n = 18, 30%), infection/abscess (n = 12, 20%) and anastomotic leak (n = 7, 11.7%). Six pts required surgical reintervention for leak (n = 3), abdominal abscess (N = 2) and pnevmothorax (n = 1). With longer follow-up, the rate of adverse events was 41.6% (n = 25) and most commonly due to delayed wound healing (n = 9, 15%), followed by rectovaginal or uretro perineal fistula (n = 4, 6.7%), anastomotic leak (n = 2, 3.3%) and intestinal necrosis (n = 2, 3.3%). Six pts (10.0%) required re-operation. Median follow-up was 38 months (8−49). The 3-y overall survuval, recurrence-free survival, disease-free survival and local control were 80.9%, 80.7%, 74.1% and 94.4%, respectively.
Conclusions: This updated long-term analysis indicated that combination neoadjuvant CRT with bevacizumab in LARC resulted in good pathological responses, impressive rate of radical resections and excellent local control. Other long-term efficacy results are promising, safety profile is manageable, but with caution to higher incidence of post-operative complications.
No conflict of interest.

2231 POSTER

Preoperative neutrophil to lymphocyte ratio independently predicts failure to proceed with adjuvant chemotherapy in stage III colorectal cancer

G. Malietzis[1], M. Giacometti[1], G.H. Lee[1], R.H. Kennedy[1], R. Glynne-Jones[2], N. Anyamene[2], O. Aziz[1], J.T. Jenkins[1]. *[1]St Mark's Hospital, Colorectal Surgery, Harrow Middlesex, United Kingdom; [2]Mount Vernon Hospital, Mount Vernon Cancer Centre, Northwood, United Kingdom*

Background: The role of adjuvant chemotherapy [AC] is established in stage III colorectal cancer but a significant proportion do not proceed with therapy after colorectal resection. Preoperative neutrophil to lymphocyte ratio (NLR) has been found to be an independent negative prognostic outcome marker in patients with colorectal cancer (CRC). In an era of increasingly personalised cancer treatment, we assessed whether NLR might determine the likelihood of proceeding with adjuvant therapy.
Materials and Methods: All patients diagnosed with stage III CRC undergoing curative elective resection from 2006 to 2011 were assessed from a prospective database. Demographics, operative factors and postoperative outcomes were recorded. Data fields were complete for all patients in the study. Univariate analysis determined predictors of failure to initiate AC that were then submitted to multivariate analysis to determine independent predictors. Factors including sex, age, operation type (laparoscopic versus open), 30-day major morbidity [Clavien-Dindo (CD)$\geqslant$3], Enhanced Recovery protocol, TNM stage, ratio of positive lymph nodes, vascular invasion, tumour site, Charlson morbidity score, preoperative albumin and preoperative NLR were assessed. Emergency presentations and operations were excluded.
Results: 271 patients were analysed. Median age of 68.5 years [IQR, 57.25–77.00]. 177 patients (57%) were male. Multivariate regression analysis identified NLR>3 (OR 0.42, (95% CI 0.23–0.78) P = 0.006) and age $\geqslant$65 years (OR 0.13, (95% CI 0.06–0.26); P<0.001) as independent prognostic factors for failure to proceed with AC. NLR>3.0 was significantly associated with age, higher T and N stage and a low pre-operative albumin level.
Conclusions: In this prospective cohort study, preoperative NLR>3.0 and age were independent predictors of failure to proceed to adjuvant chemotherapy: NLR>3.0 was related to >50% reduction in the likelihood of starting therapy. Preoperative NLR may assist clinicians where individual risks need to be considered before initiating adjuvant therapy, particularly in older patients.
No conflict of interest.

2232 POSTER

Neoadjuvant treatment responses as a tumor necrosis grade for patients with rectal cancer

B. Shim[1], J.H. Jung[2], H.M. Cho[3], H.J. Kim[3], S.W. Kim[4], J.H. Lee[4]. *[1]St. Vincent's Hospital, Medical Oncology, Suwon, South Korea; [2]St. Vincent's Hospital, Pathology, Suwon, South Korea; [3]St. Vincent's Hospital, General Surgery, Suwon, South Korea; [4]St. Vincent's Hospital, Radiation Oncology, Suwon, South Korea*

Background: Neoadjuvant chemoradiotherapy for rectal cancer results in prevention of local recurrence and may achieve sphincter conserving surgery. Association between pathologic response evaluated after radical tumor resection and patient prognosis was well established. The object of this study was to assess the association between the degree of tumor necrosis after chemoradiotherapy and oncologic outcomes.
Patients and Methods: In all, 225 patients with locally advanced rectal cancer (stage II and III by endorectal ultrasonography, CT and MRI) had 50.4 Gy over 5.5 weeks, plus 5-fluorouracil and leucovorin and surgery was performed at 7 to 10 weeks after completion of all therapies. Pathologic tissue necrosis after chemoradiotherapy was reviewed and scored as follows: Grade 0, no response; Grade 1, necrosis or disappearance of tumor cells less than 2/3; Grade 2, necrosis or disappearance of tumor cells more than 2/3; and Grade 3, no viable cells (ypCR). Correlation analysis was performed using Pearson's Chi square or Fisher's exact test, as appropriate. Recurrence-free survival and overall survival were calculated using the Kaplan–Meier method.
Results: This study included cStage II (101 patients) and cStage III (124 patients) rectal cancer patients, and down stage rate was 57.3% and pCR was 16.9%. The pathologic tumor response (pStage 0 v I v II v III) was associated with 5-year RFS (97.4% v 81.5% v 76.6% v 50.0%; p < 0.001). The tumor necrosis (Grade 0 & 1 v 2 v 3) was associated with 5-year RFS (64.4% v 76.8 v 97.4%; p = 0.002).
Conclusions: The tumor necrosis to neoadjuvant chemoradiotherapy is a surrogate marker for recurrence and oncologic outcomes in rectal cancer patients treated with 5 flurouracil and leucovorin neo-adjuvant chemoradiotherapy.
No conflict of interest.

2233 POSTER

Synergistic antitumor interaction between valproic acid, capecitabine and radiotherapy in breast and colorectal cancer cells

E. Di Gennaro[1], B. Pecori[2], M. Terranova Barberio[1], S. Imbimbo[2], A. Zotti[1], F. Bruzzese[1], M.C. Piccirillo[1], A. Avallone[3], P. Muto[2], A. Budillon[1]. *[1]INT Fondazione Pascale, Research, Naples, Italy; [2]INT Fondazione Pascale, Radiotherapy, Naples, Italy; [3]INT Fondazione Pascale, Gastrointestinal Oncology, Naples, Italy*

Background: Capecitabine is a pro-drug designed to take advantage of the increased levels of thymidine phosphorylase (TP), a key enzyme for its conversion to 5-florouracil (5- FU), observed in tumors as opposed to normal tissues, potentially allowing for selective cytotoxicity. We have recently demonstrated that the histone deacetylase-inhibitor (HDAC-i) vorinostat induces synergistic antitumour effects in combination with capecitabine by up-regulating, in *vitro* and *in vivo*, in colorectal cancer cells but not in *ex vivo* treated peripheral blood lymphocytes, the mRNA and protein expression of TP (Di Gennaro, Brit J Cancer 2010). Multiple HDACis have been shown to modulate radiosensitivity in preclinical models including valproic acid (VPA). HDACi vorinostat has been recently safely combined with short-term pelvic palliative radiotherapy in gastrointestinal neoplasms including rectal cancers. Based on these data we studied the effects of capecitabine metabolite 5′-deoxy-5-fluorouridine (5′-DFUR) and VPA in combination with radiotherapy in colorectal and breast cancer cells.
Methods: We evaluated the antiproliferative/cytotoxic effects of 5′-DFUR, VPA and/or radiotherapy by sulforhodamine B colorimetric and clonogenic assays. Drugs synergistic interaction was determined by calcusyn software based on Chou and Talalay method. protein, Western blotting analysis of γH2AX and caspase-3 measured DNA damage and apoptosis, respectively. TP knockdown was performed using TP-shRNA.
Results: We demonstrated synergistic/additive antiproliferative and proapoptotic effects of 5′-DFUR in combination with several HDACi, including VPA, in both breast and colorectal cancer cells. TP knockdown experiments confirmed the crucial role of TP protein modulation in the synergism observed. Interestingly, TP protein induction was achieved also at low doses of VPA corresponding to a plasma level between 50 and 100 μg/ml, easily reached in patients treated with common anticonvulsant doses. Radiotherapy further potentiated the antiproliferative effects, DNA damage and apoptosis, induced by 5′-DFUR/VPA combination.
Conclusions: On these bases we recently launched a phase I/II clinical study (V-ShoRT-R3 trial) to explore whether the addition of both VPA and capecitabine to short-course radiotherapy before optimal radical surgery, might increase the pathologic complete tumor regression rate in low-moderate risk rectal cancer patients (EudraCT Number: 2012–002831−28).
No conflict of interest.

2234 POSTER

Pathologic response after long-course or hypo fractionated preoperative radiotherapy in combination with capecitabine versus 5-fluorouracil leucovorin in locally advanced rectal cancer: A retrospective review National Cancer Institute Mexico

G. Calderillo[1], M.C. Díaz Romero[2], I.M. Palma Valle[2], J. Zamora Varaona[2], E.G. Trejo Duran[3], N.P. Alvarez Aguila[3], J.M. Flores Castro[3], E.B. Ruiz Garcia[2]. *[1]INCAN, Mexico DF, Mexico; [2]INCAN, Oncology, Mexico DF, Mexico; [3]INCAN, Radiotherapy, Mexico DF, Mexico*

Background: Chemoradiotherapy neoadjuvant is standard treatment in Locally Advanced Rectal Cancer (LARC). Two schemes of preoperative radiotherapy are possible: long course (45–50.4 Gy/25fr) and short course (25 Gy/5fr) both are effective in tumor control; different chemotherapeutic agents concomitant improving local control. The aim of the review is to assess tumoral response in patients who underwent preoperative radiotherapy according two different protocols: long course of 45 Gy/25 fractions and hypofractionated (45 Gy/15fr) concomitant with capecitabine or 5-fluorouracil (5-FU) leucovorin.
Material and Methods: A total of 135 patients with LARC, who received treatment preoperative between 2005 and 2011, were analyzed and performed pathological response. 75 patients were treated with hypofractionated 45 Gy in 15 fractions for fifteen days and 60 received conventional radiotherapy (45 Gy/25fr), simultaneous treatment with 5-FU, leucovorin intravenous or capecitabine 850 mg/m^2 twice a day for fourteen days. Pathological Complete Response (pCR) including downstaging tumour (T)/nodal (N) after surgery.
Results: One hundred and thirty-five patients were identified, with a mean age 53 years, 58 female and 77 men. 25 (19%) patients underwent

colostomy by stenosis over 90%. 64 (47.5%) patients were treated with 5-FU and 71 (52.5%) with capecitabine, four cycles of chemotherapy was mean of treatment. The tumoral pathological complete response was observed in 31 (22.9%) of all patients, 14% vs 9% of the patients treated with hypofractionated and conventionally radiotherapy, the difference was not significant (p = 0.46). A pCR was shown in 13 patients of 5-FU with hypofractionated radiotherapy and 2 patients who received conventional radiotherapy. In the capecitabine group 6 of 31 patients with hypofractionated and 10 of long course (45 Gy/25fr) had a pCR. There was no significant difference in of pathologic complete response between patients who received capecitabine vs 5-FU (pCR: 12.8% vs. 11.1%; p = 0.87).

Conclusions: Preoperative short term radiotherapy and long courses provide local control in rectal cancer, with this retrospective results are according to literature than short-course irradiation appears to be a useful alternative to long-course. These regimes of radiotherapy and chemotherapy with oral or intravenous fluoropyrimidine show effect in the pathological tumor response. However, a prospective study is needed to obtain data on survival and relapse in our population.

No conflict of interest.

2235 POSTER

A prognostic value for lymph node harvest in patients with colorectal cancer?

D.A.M. Sloothaak[1], S. Grewal[1], M. Ooft[2], H. Doornewaard[2], P. Van Duijvendijk[1], P.J. Tanis[3], W.A. Bemelman[3], E.S. Van der Zaag[1], C.J. Buskens[3]. *[1]Gelre Ziekenhuizen Apeldoorn, Surgery, Apeldoorn, Netherlands; [2]Gelre Ziekenhuizen Apeldoorn, Pathology, Apeldoorn, Netherlands; [3]Academic Medical Center, Surgery, Amsterdam, Netherlands*

The prognosis of patients with colorectal cancer has been associated with the number of lymph nodes that is harvested for pathological staging. The general concept is that the accuray of nodal staging improves with increased lymph node harvest, which might influence oncological outcome. In this study we analyzed if the correlation between lymph node harvest and prognosis is confounded by lymph node size. Additionally we studied the contribution of very small lymph nodes to staging of patients with colon cancer.

Stage I/II colon cancer patients who underwent elective surgery between November 2005 and July 2009 were included from a prospective database from the Gelre Hospital, Apeldoorn, the Netherlands. Lymph node size was determined by long axis measurements on H&E stained slides. We used the Pearson test for the correlation between lymph node size and harvest. To calculate the odds ratio (OR; 95% CI) of metastatic involvement, five categories (<3 mm, 3−6 mm, 6−10 mm, 10−15 mm and >15 mm) were defined. The most common lymph node sizes were used to determine the reference value for logistic regression analyses.

We included 96 stage I/II (pN0) and 55 stage III (pN+) patients in this study. In the N0 patients, a total of 1485 lymph nodes was harvested (measurements were obtained for 92.9%). For N+ patients, a total of 763 lymph nodes was harvested (measurements were obtained for 90.2%). The majority of lymph node diameters ranged between 3 and 6 mm (61.7%). The mean lymph node count for N0 patients who developed recurrent disease was lower than in patients without any recurrence (13 vs. 16 respectively; ns). Concordantly, the mean lymph node size in patients who developed a recurrence was significantly lower than those without recurrence (3.5 mm vs. 4.2 mm respectively, p = 0.008). The Pearson test showed a significant correlation of 0.314 between lymph node size and lymph node count (p = 0.003).

Of all measured lymph nodes (n = 2043), 99 nodes contained a metastatic lesion. Compared to the reference category (3−6 mm) the odds of metastatic involvement was significantly lower for lymph nodes <3 mm (OR 0.5; 0.3−0.9), similar for lymph nodes of 6−10 mm (OR 1.5; 0.9−2.5) and significantly increased for lymph nodes of 10−15 mm or larger (OR 3.6; 1.5−8.1 and OR = 6.7; 2.5–17.8, respectively). Metastatic involvement in lymph nodes smaller than 3 mm was found in 9 (6.0%) patients, but was responsible for nodal upstaging in only two patients.

An increase in lymph node harvest does not necessarily result in more accurate staging. The success of lymph node harvest in patients with colorectal cancer with a favourable prognosis might merely be a result of the increased lymph node size. Moreover our study suggests that detection of very small lymph nodes is not likely to result in better staging. Not only the number of lymph nodes is important for staging, but selection of the relevant lymph nodes might be important for accuracy as well.

No conflict of interest.

2236 POSTER

Pathological complete response in colorectal cancer (CRC) patients with liver metastasis after preoperative chemotherapy

L. Calera[1], I. Pajares[1], P. Bueso[1], A. Anton Torres[1], R. Pazo[1], I. Trueba[2], R. Jaso[3], F. Rivera Herrero[4]. *[1]Hospital Miguel Servet, Medical Oncology, Zaragoza, Spain; [2]Hospital Txagorritxu, Radiotherapy, Vitoria, Spain; [3]Hospital Marques de Valdecilla, Internal Medicine, Vitoria, Spain; [4]Hospital Marques de Valdecilla, Medical Oncology, Vitoria, Spain*

Background: CRC is the second most common malignancy in Spain. Almost 50% of patients develop metastases, and the common sites of metastases are liver and lung. Advances in multimodal treatment have led to prolongation of survival in patients after resection of colorectal liver metastasis. The aim of this study was to evaluate the prognostic factor of pathological complete response in CRC patients with liver metastasis after preoperative chemotherapy.

Material and Methods: Between 2004–2010, 226 patients (pts) with CRC and liver limited disease were diagnosed in our institution. All patients were evaluated by multidisciplinary team and patients were subdivided in three groups according with recommendations from European Colorectal Metastases Treatment Group (Nordlinger, et al. Annals of Oncology 2009): a) Resectable liver metastases, b) Potentially resectable liver metastases, c) Unresectable and never likely to be resectable liver metastases. Pts classified as b were evaluated after neoadjuvant chemotherapy and those who achieved radiological response were proposed for surgery. We analyzed clinical characteristics of patients who achieved pathological complete response after neoadjuvant chemotherapy.

Results: Of 226 patients with CRC and liver metastases, 54 were clasificated as b (potencially resectable liver metastases), 31 were operated and seven achieved complete pathological response.5 pts (71%) are alive, after mean of follow up 4.8 years range 5.22 (3−8.2). Four pts are disease free and one patient develop liver recurrence.Two pts have died, one after disease recurrence and one after upper gastrointestinal bleeding.

Conclusions: This study has shown a good survival benefit in stage IV CRC when pathological complete response is achieved after preoperative chemotherapy.

No conflict of interest.

2237 POSTER

A retrospective study analysing the significance of a microscopically positive resection margin in the curative intent treatment of rectal adenocarcinoma

Z. Fekete[1], A. Muntean[2], A. Irimie[3], S. Hica[4], L. Resiga[5], N. Todor[6], V. Nagy[1]. *[1]Iuliu Hatieganu University of Medicine and Pharmacy, Department of Oncology, Cluj-Napoca, Romania; [2]Ion Chiricuta Institute of Oncology, Department of Radiotherapy 3, Cluj-Napoca, Romania; [3]Iuliu Hatieganu University of Medicine and Pharmacy, Department of Oncology, Cluj-Napoca, Romania; [4]Ion Chiricuta Institute of Oncology, Department of Surgery 1, Cluj-Napoca, Romania; [5]Ion Chiricuta Institute of Oncology, Department of Pathology, Cluj-Napoca, Romania; [6]Ion Chiricuta Institute of Oncology, Department of Epidemiology and Biostatistics, Cluj-Napoca, Romania*

Background: A positive microscopic margin (R1) after resection of rectal cancer is still challenging and management depends on prior radiotherapy and further possibility of surgery. There is no general consensus on the definition of R1 in rectal adenocarcinoma, no standard approach has been validated and data on these cases is scarce.

Material and Methods: We have reviewed all pathology data concerning resected specimens from patients with rectal or recto-sigmoid adenocarcinoma operated with curative intent at the Institute of Oncology 'Prof. Dr. Ion Chiricuta', Cluj, Romania between 2000–2011 (763 patients in 12 years) and pathology files of patients addressed from other institutions for adjuvant treatment (318 patients). We have included specimens obtained through anterior resection, Hartmann's procedure and abdomino-perineal resection, but have excluded transanal excision results and situations when R2/R1 was obtained at first intervention, but R0 was achieved after re-resection (56 patients). We have identified and analyzed a number of 30 R1-patients.

Results: With surgery only local relapse (LR) followed resection inevitably. Interestingly, when neoadjuvant chemoradiation was used, only 14.3% of patients presented LR after 2 years of minimum follow-up despite of an R1-resection. If radiotherapy was given (in conventional doses) after surgery, only 50% of patients were LR free at 2 years, or in other words only half were compensated for R1. Comparison of other risk factors with R0 cases is in progress.

Conclusions: R1 after primary surgery must be compensated by either re-resection or if not possible, by adjuvant chemoradiation; higher radiotherapy doses should be tested in a prospective study. Because it seems that R1 is difficult to compensate with adjuvant treatment, a good quality total

mesorectal excision (TME) should be always aimed for and the use of neoadjuvant chemoradiation should be employed whenever possible. In the case of R1 after neoadjuvant chemoradiation it is difficult to decide further treatment, because a large percentage of cases won't relapse despite a positive margin, probably due to the fact, that a minimum of 1 mm margin, although it is considered positive in the TNM staging system, would be safe in most cases or the cancer cells in question are not viable. A subclassification of R1 should be always reported.

Conflict of interest: *Other substantive relationships: This study was accomplished with the sponsorship of the European Social Found through the POSDRU project no. 107/1.5/S/78702.*

2238 POSTER

The influence of the treatment response on the impact of resection margin status after preoperative chemoradiotherapy in rectal cancer

J.H. Lee[1], E.K. Chie[1], K. Kim[1], S. Jeong[2], K.J. Park[2], G.H. Kang[3], S. Han[4], D. Oh[4], T. Kim[4], S.W. Ha[1]. *[1]Seoul National University Hospital, Radiation Oncology, Seoul, South Korea; [2]Seoul National University Hospital, Surgery, Seoul, South Korea; [3]Seoul National University Hospital, Pathology, Seoul, South Korea; [4]Seoul National University Hospital, Internal Medicine, Seoul, South Korea*

Background: Circumferential resection margin (CRM) and distal resection margin (DRM) have different impact on clinical outcomes after preoperative chemoradiotherapy (CRT) followed by surgery. Effect and adequate length of resection margin as well as impact of treatment response after preoperative CRT was evaluated.

Material and Methods: Total of 403 patients with locally advanced rectal cancer underwent preoperative CRT followed by total mesorectal excision between January 2004 and December 2010. After applying the criterion of margin less than 0.5 cm for CRM or less than 1 cm for DRM, 158 cases were included as a study cohort. All patients underwent conventionally fractionated radiation with radiation dose over 50 Gy and concurrent chemotherapy with 5-FU or capecitabine. Postoperative chemotherapy was administered to 146 patients (92.4%). Median follow-up duration was 44.9 months.

Results: The 5-year overall survival (OS), disease-free survival (DFS), locoregional relapse-free survival (LRFS), and distant metastasis-free survival (DMFS) were 83.3%, 75.6%, 86.3%, and 77.4% respectively. CRM of 1.5 mm and DRM of 7 mm were cutting points showing maximal difference using a maximally selected rank method. In univariate analysis, the shorter CRM was significantly related with worse clinical outcomes, whereas DRM was not. In multivariate analysis, CRM of 1.5 mm, ypT, ypN, and perineural invasion were prognosticators for all studied endpoints. CRM was not a significant prognostic factor for good responders, defined as patients with near total regression or T down-staging, which was found in 16.5% and 40.5% of the patients, respectively. However, poor responders demonstrated a significant difference according to the CRM status.

Conclusions: Close CRM, defined as 1.5 mm, was a significant prognosticator, but the impact was different for treatment response. Postoperative treatment strategy may be individualized based on this finding. However, findings from this study need to be validated with larger independent cohort.

No conflict of interest.

Table: Subgroup analysis according to response of preoperative treatment

	Good responders			Poor responders		
	CRM >1.5 mm 65 patients	CRM ⩽1.5 mm 10 patients	p†	CRM >1.5 mm 60 patients	CRM ⩽1.5 mm 23 patients	p†
5 yr OS	92.1	90.0	0.333	86.7	51.1	<0.001
5 yr DFS	86.4	90.9	0.989	77.8	34.2	<0.001
5 yr LRFS	93.4	100.0	0.529	87.0	59.9	0.001
5 yr DMFS	88.0	90.0	0.869	79.8	36.9	<0.001

*Values are percentages of patients; † log rank test. OS, overall survival; DFS, disease-free survival; LRFS, locoregional-free survival; DMFS, distant metastasis-free survival; CRM, circumferential resection margin.

2239 POSTER

Long term survival and prognostic factors in metastatic colorectal cancer patients treatment with preoperative transarterial chemoembolization (TACE)

I. Rebeko[1], V. Zharkov[2], V. Kokhnyuk[1], V. Dudarev[3], V. Akinfeyev[3], D. Dorosh[2]. *[1]N.N. Alexandrov National Cancer Centre of Belarus, Abdominal Oncological Department, Minsk, Belarus; [2]N.N. Alexandrov National Cancer Centre of Belarus, Thoracic Oncological Department, Minsk, Belarus; [3]N.N. Alexandrov National Cancer Centre of Belarus, Diagnostic Radiological Department, Minsk, Belarus*

Background: Hepatic resection (HR) is a main treatment option in liver colorectal (CR) metastases patient. The role of neoadjuvant therapy hasn't been estimated yet. The purpose of the study was to evaluate the long term survival and prognostic factors in CR liver metastases patients with treatment included preoperative TACE with oxaliplatin following HR.

Material and Methods: Prospective nonrandomized trial, including 66 synchronous and metachronous CR liver metastases patients, has been completed. HR has been performed in the group 1 (n = 40, average age − 59, 25 men, 15 women). TACE with 50–100 mg oxaliplatin following HR in 4−6 weeks was carried out in group 2 (n = 10, 58, 2/8). TACE with 30−50 mg doxorubicin following HR in 4−6 weeks was conducted in group 3 (n = 16, 56, 8/8). The TACE with oxaliplatin,age, stage, lymphatic nodes status, number of metastasis and metastasis average size, bloodless volume, postoperative complications, extended HR, metastatic index, extrahepatic metastasis or bilobar involvement have been evaluated with Cox regression analysis.

Results: The surveillance median has composed 37.1 months. Median, 5-year and 10-year recurrence-free survival (RFS) have amounted to 12.6 months and 23.1±6.7% in group 1. Median and 5-year RFS have amounted 36.7 months and 40.0±15.5% in group 2; 12.4 months and 6.3±6.1% in group 3, respectively (p = 0.017). RFS was higher in group 2 versus group 1 (p = 0.04) and group 3 (p = 0.003). Median, 5-year and 10-year overall survival (OS) have totalled 31.9 months and 31.7±7.5%, 25.6±7.2% in group 1. Median 5-year OS have made up 54.4 months and 50.0±15.8% in group 2; 29.5 months and 9.4±8.2% in group 3, respectively. Statistically significant differences of OS haven't been obtained (p = 0.08). TACE with oxaliplatin (HR 0.31 [95% CI 0.12–0.82] p = 0.004), lymphatic nodes status (HR 1.74 [95% CI 1.17–2.58] p = 0.006) and postoperative complications (HR 2.34 [95% CI 1.12–4.89] p = 0.02) have been independent prognostic factors on RFS. TACE with oxaliplatin and lymphatic nodes status have been independent prognostic factors on OS (HR 0.29 [95% CI 0.10–0.86] p = 0.03; HR 2.42 [95% CI 1.6−3.7] p = 0.0003 respectively).

Conclusions: Using TACE with oxaliplatin can improve RFS. Only TACE with oxaliplatin and lymphatic nodes status result as independent prognostic factors of RFS and OS in liver colorectal metastases patients.

No conflict of interest.

2240 POSTER

Correlation between KRAS mutational status and radiomorphologic features of colorectal cancer-related liver metastases (CLM)

N. Rozumna-Martynyuk[1], M.Y. Teo[1], M.S.N. Mohd Sharial[1], A. Jayaram[1], R.S. McDermott[1]. *[1]Adelaide & Meath Hospital Incorporating National Children's Hospital, Department of Medical Oncology, Dublin, Ireland*

Background: In patients with colorectal cancer with liver-only metastases, hepatic metastatectomy offers possibility for cure. KRAS mutation status in metastatic colorectal cancer (mCRC) is a predictive marker of response to anti-EGFR monoclonal antibodies. The addition of anti-EGFR therapy to first line chemotherapy significantly increases overall response rate. However, this gain in response rate did not translate proportionately to gains in rates of resection and conversion to resectable disease. While different EGFR mutations have been correlated with varying clinical phenotypes of metastatic disease in non-small cell lung cancer, no such observations have been made as yet in mCRC. The aim of this study was to examine the correlation between KRAS mutational status and radiomorphological appearance of colorectal cancer-related liver metastasis (CLM).

Methods: Patients with CLM and known KRAS status were identified from institutional database. CT scans at diagnosis of metastatic disease and at best response were evaluated to identify number of CLMs (solitary, 2−5, 6−10, >10), margins (sharp vs fuzzy as surrogate of infiltrative growth pattern) and contrast-enhancement (as surrogate for vascularity). Comparisons were made between patients with KRAS mutant (mt) and KRAS wild type (wt) with either t-test or Fisher's exact as appropriate.

Results: 68 patients were identified, with 29 mt and 39 wt, with 46 and 61 liver lesions in each groups respectively. Comparing wt to mt, number of CLM were comparable (solitary: 6 vs 8; 2−5: 9 vs 15; 6−10: 3 vs 4; >10: 11 vs 12; p = 0.615). Mean size of LM for mt group was 3.51 cm (95% CI 2.78–4.24) with no significant difference from mean size in wt of 3.48 cm (95% CI 2.75–4.22), p = 0.962. At best response, mean size was 2.28 cm (95% CI 1.73–2.83) for mt and 3.00 cm (95% CI 2.19–3.81) for wt (p = 0.141). 13.8% of mt had contrast-enhancement at baseline compared to 15.4% of wt (p = 0.732), while 10.5% of mt and 7.4% of wt had contrast-enhancement at best response (p = 0.645). For mt, 42.1% had infiltrative margins at baseline and 52.4% at best response (p = 0.746) while for wt, 51.9% had infiltrative margins at baseline and 70.4% at best response (p = 0.264).

Conclusion: Our data did not suggest radiomorphological differences amongst CLM due to KRAS mutational status. KRAS-related pathophysiology is unlikely to contribute to low rate of resection despite higher response rates in KRAS wild type.

No conflict of interest.

2241 POSTER

Neoadjuvant short-course versus long-course radiation for distal T3 rectal cancer

I. Shchepotin[1], O. Kolesnik[1], V. Ivankova[1], A. Beznosenko[1], M. Krotevich[1]. [1]*National Cancer Insitute, Kyiv, Ukraine*

Background: The two broad approaches to preoperative therapy for distal rectal cancer − short-course and long-course radiation. The outcomes of these approaches reported in nonrandomized trials are not comparable because patients selected for treatment with short-course radiotherapy included those with T1−3 disease. The aim of this study was to compare survival, local control, postoperative complications and anal sphincter preservation in the two treatment groups: short-course (sRT) versus long-course radiotherapy (lRT) as a neoadjuvant modality for the management of lower rectal cancer.
Materials and Methods: The study randomized 172 patients with T3N+/−M0 distal rectal cancer. Patients receive either neoadjuvant short-course radiotherapy (5 × 5 Gy) and surgery within 1−2 days (Group 1) or long-course radiotherapy (30 Gy in 15 fractions of 2 Gy) and surgery 4 weeks later (Group 2). The median follow-up of living patients was 38 (range 32−58) months.
Results: Complete response − 8.8%, partial response − 42.3% in Group 2. The actuarial 3-year overall survival was 67.9% in the Group 1 and 88.6% in the Group 2 ($P = 0.01$). Disease-free survival was 67.9% *versus* 84.2% per cent ($P = 0.001$), crude incidence of local recurrence was 8.8% *versus* 6.9% ($P = 0.170$) respectively. Anal sphincter preservation in Group 1 was 91%, compared with 67.5% in the 2nd group. Number of sphincter saving surgery for patients in Group 1 with initially planned abdominoperineal resection of the rectum increased by 2.7 times ($p < 0.005$). Postoperative complications such as anastomotic leak comparable in both groups (8.8 and 7.5%). Partial and complete tumor regression occurred in 41% of patients in Group 1. Local recurrences were observed in 9 (11.3%) patients in group 2, and 2 (2.5%) patients in Group 1 ($p < 0.005$).
Conclusion: Combined treatment of patients with distal rectal cancer (stage II−III) using neoadjuvant long-course radiotherapy radiotherapy of 30 Gy is safe and effective.
No conflict of interest.

2242 POSTER

Safety and adverse events of neoadjuvant short-course hyperfractionated accelerated radiotherapy (SC-HART) combined with chemotherapy for rectal cancer

H. Doi[1], N. Beppu[2], S. Odawara[1], Y. Takada[1], Y. Niwa[1], M. Fujiwara[1], H. Yanagi[2], N. Yamanaka[2], N. Kamikonya[1], S. Hirota[1]. [1]*Hyogo College of Medicine, Department of Radiology, Nishinomiya-City Hyogo, Japan;* [2]*Meiwa Hospital, Department of Surgery, Nishinomiya-City Hyogo, Japan*

Purpose: Neoadjuvant radiotherapy combined with chemotherapy followed by surgery has been adopted as the standard treatment for rectal cancer. However, the tolerability of neoadjuvant short-course hyperfractionated accelerated radiotherapy (SC-HART) is unclear. The purpose of this study was to examine the safety and feasibility of SC-HART combined with chemotherapy for lower rectal cancer.
Material and Methods: A total of 73 patients with lower rectal cancer was treated with SC-HART followed by radical surgery between March 2008 and May 2012, and were analyzed retrospectively in the present study. SC-HART was performed with a dose of 2.5 Gy twice daily, with an interval of at least 6 hours between fractions, up to a total dose of 25 Gy (25 Gy in 10 fractions for 5 days) combined with chemotherapy. Radical surgery was performed within three weeks following the end of the SC-HART. Adverse events were assessed in acute toxicity prior to surgery, perioperative complications, and late toxicity after surgery according to the CTCAE version 3.0. To analyze the predictive factors of treatment related complications, we examined age (<65 or ⩾65 years old), gender (male or female), tumor differentiation (tub2 or not), and the type of surgery (laparotomy or laparoscopic surgery).
Results: The median age was 65.0 (range: 39−85) years. The median follow-up term was 14.7 (range; 0−53) months. S-1 was administered with SC-HART in 65 pts (89.0%). Sixty-six patients (90.4%) had no apparent adverse events before surgery. One patient stopped chemotherapy because of grade 3 gastrointestinal toxicity (CTCAE v.3). The sphincter preservation rate was 94.5%. Downstaging rate was 38.4%, 67.1% and 65.8% in T stage, N stage, and stage grouping, respectively. Perioperative complications were observed in 20 patients (27.4%). Two different toxicities were recorded in each of five patients. However, there was no perioperative mortality. Late toxicity was observed in 23 patients (31.5%). Two different toxicities were recorded in each of four patients. There were no significant differences in acute toxicity, peripoerative complications and postoperative late toxicity according to grouping with age, gender, tumor differentiation, and the type of surgery. The disease-free survival rate and disease-specific survival rate was 80.8% and 98.6%.
Conclusions: SC-HART combined with chemotherapy for rectal cancer was well tolerated and produced good short-term outcomes. Age, gender, tumor differentiation, and the type of surgery seemed to have no apparent effects on toxicity of SC-HART. SC-HART therefore appeared to have a good feasibility for use in further clinical trials.
No conflict of interest.

Background: Today, much of the cancer treatment involves Surgical Oncology, Medical Oncology and Radiation Oncology with support from other related specialties remain very important in the multidisciplinary therapeutic decisions.
Material and Methods: On December 6, 2010, began with this multidisciplinary decision model in patients with esophageal cancer, stomach, small intestine, colon, rectum and anus. We reviewed all records of patients admitted to this model in December 2010 to November 2012 and we make a historical comparison with patients treated at the same hospital and doctors in 2009 (360 cases).
Results: 1090 patients were treated with gastrointestinal cancer (90 esophageal, 37 of the gastroesophageal junction, 362 stomach, 8 of small intestine, 535 colorectal, 21 anous and 37 excluded (19 without confirmation of malignancy and 18 with tumors in other locations). Gender was 622 men (57%) and 468 women (43%). Diabetics in 13.3% and hypertension essencial in 15.8%. History of another malignancy (prostate, breast and cervical cancer the most common) in 3.3%. In 796 (75.6%) cases received at least one cancer treatment and in 109 patients (10.4%) had the best medical support, seven cases (0.7%) died before the therapeutic decision and in 140 patients (13.3%) did not complete the studies requested or not accept the proposed treatment. The 60% of the patients (623 cases) received chemotherapy (QT) with a total of 3932 cycles with median of 6. In 40% (418 cases) received surgical procedures were serious complications in 61 (14.6%) and mortality of 1.7%.- The radiotherapy were received in 283 patients (the most of them in conjunction with QT).
Conclusions: With this model of multidisciplinary care has been reduced morbidity and mortality. Decreased the percentage of patients lost greater number of supports and Palliative Care.

	Year 2009	UFG 2011–2012
Cases	360	1053

2244 POSTER

Response to neoadjuvant chemoradiotherapy, ypT-stage and lymph node involvement in mid and low rectal cancer

A. Frunza[1], L.J. García Flórez[2], G. Gómez Álvarez[1], M.F. Fresno Forcelledo[3]. [1]*Hospital Universitario Central de Asturias, General Surgery, Oviedo, Spain;* [2]*Hospital San Agustín, General Surgery, Avilés, Spain;* [3]*Hospital Universitario Central de Asturias, Pathology, Oviedo, Spain*

Background: Tumour regression grading (TRG) is a predictive factor for local recurrence in rectal cancer. The correlation of TRG with overall survival is more controversial. Lymph node status after chemoradiation is one of the most important predictors of disease-free and long-term survival. The aim of this study was to determine the correlation between TRG and lymph node status after neoadjuvant chemoradiation in the resected surgical specimens.
Material and Methods: 130 patients with mid (58%) and low (42%) locally advanced rectal cancer treated with neoadjuvant chemoradiation and

radical surgery were included. 87 (67%) were males and 43 (33%) females. Mean age was 67.4 years. Preoperative staging by endorectal ultrasound and/or MRI was available in all patients. Neoadjuvant radiotherapy consisted of 5 weeks regimen of 45 (65%) or 50.4 Gy (35%). 5FU-based chemotherapy was administered in 88% of cases. Reviewed TRG using Mandard's scoring system was used and patients were categorised into 'responders' (TRG 1−2) and 'non responders' (TRG 3−4−5). Chi square and Spearman correlation tests were used to evaluate correlation between TN change, TRG and lymph node status.
Results: Pathologic complete response was observed in 19 patients (14.6%), T-downstaging in 63 (48.5%) and tumour progression only in one case. The mean number of retrieved lymph nodes was 9.4. Node involvement was T0−1: 9.4%, T2: 22.2%, T3−4: 43.7%. Tumor response (TRG) was: TRG1: 19 (14.6%); TRG2: 18 (13.9%); TRG3: 39 (30%); TRG4: 41 (31.5%); TRG5: 13 (10%). Preoperative staging showed N0 40.8%, N1 54.6% and N2 4.6%. Postoperative pathological evaluation of lymph node status showed no involvement in 68.5%, N1 22.3% and N2 9.2%. Responders were N0 89.2% and N positive 10.8%. Non responders were N0 60.2% and N positive 39.8% ($p < 0.001$).
Conclusions: Response to neoadjuvant therapy according to TRG and ypT-stage was associated with lymph node status (ypN). Patients with node involvement had less response to chemoradiation than those N negative.
No conflict of interest.

2245 POSTER

Pathological node stage is a strong prognostic factor for survival outcome in rectal cancer and might be useful as an indicator for adjuvant second-line chemotherapy

M. Rijpkema[1], L. Dewit[2], A. Aalbers[1], H. Boot[3], A. Cats[3], M. Lopez Yurda[4], V. Verwaal[1]. *[1]The Netherlands Cancer Institute − Antoni Van Leeuwenhoek Hospital (Nki-avl), Surgical Oncology, Amsterdam, Netherlands; [2]The Netherlands Cancer Institute − Antoni Van Leeuwenhoek Hospital (Nki-avl), Radiotherapy, Amsterdam, Netherlands; [3]The Netherlands Cancer Institute − Antoni Van Leeuwenhoek Hospital (Nki-avl), Oncological Gastroenterology, Amsterdam, Netherlands; [4]The Netherlands Cancer Institute − Antoni Van Leeuwenhoek Hospital (Nki-avl), Statistics, Amsterdam, Netherlands*

Background: Until now there is no solid evidence on the practice of adjuvant chemotherapy in the treatment of rectal cancer. Especially for the patients receiving preoperative chemoradiation, the utility of adjuvant chemotherapy remains unclear. To identify a subset of patients more likely to benefit from adjuvant chemotherapy we analyzed patients with primary rectal cancer on the first site of recurrence, disease-free survival and overall survival. A subgroup analysis was made for patients with positive lymph nodes.
Patients and Methods: In this study we analyzed 236 patients with primary rectal cancer, operated between January 2005 and December 2010 in the Netherlands cancer institute. Patients were treated with preoperative therapy followed by radical surgery. Patients with distant metastases at time of surgery were excluded for analysis. Determinants of recurrence and survival were examined using Kaplan–Meier survival curves and Cox regression analysis. Nodal stage of the tumor was set off against survival outcomes.
Results: After exclusion of patients with distant metastases, 185 patients remained eligible. At time of diagnosis positive lymph nodes were observed in 65.1% of these patients. After preoperative therapy the percentage of positive lymph nodes declined to 33.5%. Pathological node stage rather than clinical node stage influenced survival. When stratified for nodal stage, 3- and 5-year overall survival were 92% and 84% for pN0, 83% and 75% for pN1 and both 73% for pN2 ($P = 0.280$). 3- and 5-years disease free survival were respectively 83% and 73% for pN0, 77% and 72% for pN1 and 47% and 42% for pN2 ($P = 0.000$). Pathological node stage was prognostic for developing systemic disease ($P = 0.000$). In the multivariate analyses pathological node stage was an prognostic factor for both overall survival and disease free survival ($P = 0.046$ and $P = 0.002$).
Conclusion: Nodal stage, after preoperative therapy, is a strong prognostic factor for developing systemic disease, for disease free survival and overall survival. To further improve survival outcomes for rectal cancer, patients with positive lymph nodes after preoperative therapy might be considered for second-line adjuvant chemotherapy.
No conflict of interest.

2246 POSTER

Surgical management of synchronous colorectal liver metastasis

I. Shchepotin[1], O. Kolesnik[1], A. Lukashenko[1], V. Priymak[1], A. Burlaka[1]. *[1]National Cancer Institute in Ukraine, Abdominal Oncology, Kyiv, Ukraine*

Background: Surgical treatment remains the only method that improves overall 5-year survival. Aim of the study: to carry out comparative analysis of immediate and long-term outcomes of synchronous and staged surgical treatment of patients with synchronous colorectal liver metastasis.
Methods: We retrospectively analyzed medical records (2008–2012) of 98 consecutive patients with synchronously recognized primary carcinoma and hepatic metastases who underwent concurrent (40 patients, Groupe 1) or staged (58 patients, Groupe 2) colonic and hepatic resections performed at our institution.
Results: Concurrent and staged groups were similar in demographics, tumor grade, stage, preoperative comorbidity (cardiac and respiratory), characteristics of hepatic metastases and single vs. multiple lesions. No significant differences were observed between groups (concurrent vs. staged) in type of colon resection ($P = 0.5$) or hepatic resection ($P = 0.1$), overall operative duration (mean, 484 vs. 316 minutes), blood loss (mean, 340 vs. 250 ml), disease-free survival from date of hepatectomy (median, 11 vs. 11 months). Overall duration of hospitalization was significantly shorter for concurrent than for staged resection (mean, 23 vs. 10 days; $P < 0.001$). It is noticed, that in Group 1 of patients there is a bigger risk of development of postoperative complications (37 vs. 30%), 30 % from them were specific to a resection of a liver. Overall 3-year survival rate was shorter for concurrent than for staged resection (42 vs. 55%; ? = 0.22).
Conclusions: The analysis of our research highlights the need for a differentiated approach in the surgical treatment synchronous liver metastases from colorectal cancer. Synchronous resection is safe resection of liver segments $\leqslant 3$, provide the best results. Subsequent research should be directed towards study of prognosis factors and criteria for patients' selection for surgical treatment groups, assessment of economic effect, and patients' life quality.
No conflict of interest.

2247 POSTER

Short-course radiotherapy combined with systemic chemotherapy: Short-term results

Y.A. Barsukov[1], S.I. Tkachev[2], A.G. Perevoshikov[3], Z.Z. Mamedli[1], D.V. Kuzmichev[1], A.M. Pavlova[1], V.A. Aliev[1]. *[1]N.N. Blokhin Russian Research Cancer Center, Colorectal cancer, Moscow, Russian Federation; [2]N.N. Blokhin Russian Research Cancer Center, Radiation Oncology, Moscow, Russian Federation; [3]N.N. Blokhin Russian Research Cancer Center, Pathomorphology, Moscow, Russian Federation*

The aim of this study was to estimate toxicity and efficacy in term of tumour response range after short-course neoadjuvant chemoradiotherapy of rectal cancer with different fluorpyrimidines.
Materials and Methods: During January 2011 − April 2012 87 patients with T2−3N0−1M0 rectal cancer were included in a prospective randomized trial. All patients received short-course 5×5 Gy radiotherapy with local hyperthermia on days 3−5, local application of metronidazole 10 g/m^2 on days 3, 5. Local intraluminal hyperthermia has been performed on 'Yalik', 'Yachta-3' and 'Yachta-4' devices during 60 minutes with 41−45ºC. When intraluminal hypethermia has been technically impossible due to tumor stenosis, hyperthermia has been performed with 'Synchrotherm' device via percutaneous applicators. Patients were randomized in 3 groups: 28 patients additionally received 5-fluoruracil 425 mg/m^2 24-hours i.v. infusion on days 1−5 of radiotherpy, 29 patients received Capecitabine 2000 mg/m^2 per os on days 1−14 and 28 patients received Tegafur 800 mg/m^2 per os on days 1−21 starting from the first day of radiotherapy. Study endpoints were treatment toxicity according to NCI-CTC v.3.0 and tumor regression according to Dworak-Rodel scale.
Results: Treatment was generally well tolerated. In 5-FU group II−III degree gastrointestinal toxicity were 21.4% and 17.5% correspondingly. In Capectabine group II and III degree GI toxicity were observed in 17.2% and 10.3% respectively. In Tegafur group II−III degree of GI were in 7.7% and 15.4% respectively. Treatment was carried out according to plan in all patients. 1 patient in each investigated group developed grade II leucopenia. Grade III−IV tumor regression was observed in 32 % of the patients in 5-FU group, 56 % in Capecitabine group and 57 % in Tegafur group respectively.
Conclusion: Preliminary results show identical toxicity profile and tumor regression rates for investigated fluorpyrimidines. Oral fluorpyrimidines can be recommended due to simplicity of use and similar treatment outcome. But this results needs future studies.
No conflict of interest.

Incidence of complete pathological response after neoadjuvant chemoradiotherapy for locally advanced rectal cancer: A retrospective review in a tertiary care center in the UAE

M. Mahmoud[1], M. Jaloudi[2], S. Abdullah[3], S. Hasnain[4], J. Kanbar[2], A. Mohamed[1], H. ElSalhat[1]. *[1]Tawam John Hopkins Hospital, General Surgery, Al Ain, U.A.E.; [2]Tawam John Hopkins Hospital, Medical Oncology, Al Ain, U.A.E.; [3]UAE University Faculty of Medicine & Health Sciences, Histopathology, Al Ain, U.A.E.; [4]Tawam John Hopkins Hospital, Radiation Oncology, Al Ain, U.A.E.*

Background: Neoadjuvant chemoradiotherapy (nCRT) is the standard of care for treatment of locally advanced rectal cancer(LARC) followed by radical surgery. The benefits of nCRT were demonstrated in tumour downstaging, sphincter preservation, and decreased local recurrence. Complete pathological response (pCR) is now a recognised endpoint. New approaches for pCR patients are being proposed. The aim of this work is to assess the incidence of pCR in patients with LARC after nCRT and to determine if results are sufficient to consider a wait and see approach.
Materials and Methods: Between April 2010 and 2012, a retrospective chart review was conducted. All patients who received 50.4 Gy in 28 fractions with concomitant oral capecitabine over 5 weeks followed by radical surgery were included.
Results: Twenty-nine patients with LARC received nCRT. Mean age was 50 years (20−68). Mean tumour distance from the anal verge was 5 cm (0−12 cm). Mean duration from nCRT to surgery was 10 weeks (5−12 weeks). One patient (3.5%) was unresectable at operation. Twenty-seven (93%) had negative resection margins. One (3.5%) had a positive circumferential margin. Twelve (41.3%) had a Mandard tumour regression grade one, of whom: one (3.4%) had TisN0, two (6.8%) had ypT0N1 disease and nine (31%) had a pCR (ypT0N0). PreCRT staging in the pCR group included 9% Stage IIIA, 81.8% Stage IIIB, and 9% Stage IIIC. 18.1% (n = 2) of the pCR group required re-operation for postoperative complications compared with 24.1% (n = 7) in the incomplete responders. At a mean follow up of 14.5 months, none of the patients with pCR and 8.3% of the non-responders developed resectable metastatic disease. None developed local recurrence.
Conclusion: Our study demonstrates a high incidence of pCR with nCRT for LARC with a low incidence of metastatic disease, and no local recurrence. This is the first cohort reported from the UAE. Our pCR incidence compares favourably to that reported in the literature. Our findings indicate that it may be feasible to avoid surgery in some pCR patients. Further randomised prospective studies are needed to consider a non-operative approach in patients with clinical and imaging complete response.

2249 POSTER

Impact of timing of adjuvant chemotherapy on prognosis of colon cancer patients

S. Elsamany[1], A. Alzahrani[1], A. Alkashif[1], A. Abdelmonem[1], S. Elmorsy[2], H. El Taani[1]. *[1]King Abdullah Medical City, Oncology, Makkah, Saudi Arabia; [2]King Abdullah Medical City, Research, Makkah, Saudi Arabia*

Background: The impact of timing to start adjuvant chemotherapy (TTAC) after surgery was addressed by several studies with somewhat contradictory results. These studies were largely from a period prior to widespread use of oxaliplatin in adjuvant chemotherapy (AC). In addition to deficient reporting of AC completion and performance status (PS), new molecular factors such as K-ras status that may have prognostic relevance were not considered. The present study aims to assess the impact of TTAC on prognosis of colon cancer patients and to find particular subgroups of patients who may get benefit from early initiation of AC, if any.
Patients and Methods: A single center retrospective study where colon cancer patients who received AC were grouped into early and late TTAC groups taking 8 weeks as a cutoff and DFS of both groups were compared. Also, DFS according to different prognostic parameters [age, grade, stage, LN ratio, lymphovascular invasion (LVI), k-ras status] were compared in early and late TTAC groups to determine subgroups that may benefit from early start of AC.
Results: 81 patients with stage II and III colon cancer were screened. 17 patients were excluded (9 due to lack or incomplete course of AC, 8 had no recorded date of surgery). 64 patients with full course of AC were included (75% folfox/xelox, 25 % capecitabine FU/LV). These patients had no significant comorbidity (PS 0 or 1 in 69%, 2 in 31%). K-ras results of 38 patients were available (66% wild, 34% mutant). Different parameters were balanced in the two TTAC groups. DFS was significantly improved in early compared to late TTAC group (HR = 2.6, P = 0.04). In patients with stage II disease, early TTAC group had better DFS (HR = 6.0, P = 0.01) while no difference was found between early and late groups in stage III patients (HR = 1.1, P = 0.88). Similarly, early TTAC group had better DFS in patients with LN ratio <0.2 (HR = 4.6, P = 0.03) with no difference between the two groups in those with high LN ratio $\geqslant$0.2 (HR = 1.6, P = 0.46). No significant difference was found between early and late TTAC groups according to age, k-ras status, LVI or tumour grade.
Conclusion: Colon cancer patients treated with full course of AC (mostly folfox/xelox) with no significant comorbidity have improved DFS with shorter TTAC <8 weeks. Our data suggests that stage II disease and low LN ratio <0.2 are potential predictors of benefit from early start of AC.
No conflict of interest.

2250 POSTER

Role of immunohistochemistry in the treatment of patients with colorectal cancer complicated with abdominal carcinomatosis

S.N. Navruzov[1], S.B. Abdujapparov[1], M.S. Gildieva[2], B. Aloev[1], H.J. Islamov[1]. *[1]National Cancer Center of Uzbekistan, Coloproctology, Tashkent, Uzbekistan; [2]National Cancer Center of Uzbekistan, Laboratory of Immunogenetics, Tashkent, Uzbekistan*

Background: To study the particularities of protein p53 expression and proliferated cells of nucleus antigens (PCNA) in the development of carcinomatosis in patients with colorectal cancer and its effect on the efficiency of conducted methods of treatment.
Materials and Methods: In 36 patients with colorectal cancer complicated with abdominal carcinomatosis has been used complex approach to diagnostics and treatment with immunohistochemical studies. In all cases has been revealed the adenocarcinoma of various stages of differentiation. All patients received palliative colostomy whereupon systemic polychemotherapy has been carried out on FOLFOX scheme against a background of immune therapy and hyperglycaemia. Tumour tissue apoptosis has been studied after each course of chemotherapy.
Results: Study results of protein p53 expression in the colon epithelium, affected by cancer were shown positive result in the nucleus of cancer cells in 23 of 36 patients. The amount of p53-positive cancer cells in patients with adenocarcinoma on average was 48.1$\pm$0.71%. The expressed increase ($p < 0.05$) of the amount of p53 positive cancer cells was reported in patients with moderately differentiated form with elevation of stage of cancer malignancy. This explains the lower stage of sensitivity to conducted chemotherapy, in this group of patients the particular regress of tumour was observed only in 1 patient, stabilisation or process in 6, and the progress developed in 15 patients, whereas in patients with p53 negative reaction was shown the particular regress of tumour in 2 patients and stabilization was revealed in 9 and progress was in 1 patient. Study of PCNA expression in cancer cells showed that positive reaction was recorded in 26 of 36 examined patients. The amount of PCNA positive cells of adenocarcinoma on average was 52.4$\pm$3.3%. It has been noted the direct dependence between amount of PCNA − positive cells in cancer and stage of their malignancy. So, the average amount of such cells being at 1 stage of morphologic malignancy 37.4$\pm$1.6%, at 2–49.8$\pm$1.9% at 3–57.8$\pm$4.1%.
Conclusion: Consequently the colorectal cancer complicated with abdominal carcinomatosis is multifactorial pathology, stage of revealing and particularities of proliferate activity, the level of protein p53 expression and PCNA depends on morphologic stage of malignancy as well.
No conflict of interest.

2251 POSTER

Magnetic Resonance Imaging after neoadjuvant chemoradiaton therapy is a suitable device for evaluation of tumour response

L.B.M. Weerink[1], L.F.I.J. Oudenhoven[2], C.M. Gant[1], E.A. Kouwenhoven[1], I.F. Faneyte[1]. *[1]ZGT Almelo, Surgery, Almelo, Netherlands; [2]ZGT Almelo, Radiology, Almelo, Netherlands*

Background: Magnetic Resonance Imaging (MRI) after neoadjuvant chemoradiation therapy (CRT) in rectal carcinoma shows great, sometimes even complete, remission of the tumour. Based on this remission the planned operation could in some cases be changed. A less invasive, e.g. TEM procedure, or even 'wait and see' policy could be appropriated. Aim of this study is to analyse the accuracy of the MRI after CRT with regards to tumour response.
Material and Method: In 2011 to 2012 30 patients were treated with neoadjuvant CRT and were subsequently evaluated using MRI. From these patients data concerning T-stage, N-stage and CRM was recorded, derived from interpretations of preoperative MRI images and definitive pathology results.
Results: The sensitivity of MRI for classifying a stage T_3/T_4 tumour after CRT was 89.5% in our population, the positive predictive value (PPV) was 70.1%. The sensitivity for identifying a CRM <5 mm was 90.0% with a

negative predictive value (NPV) of 87.5%. In detecting malignant lymph nodes the sensitivity was 75.0% with a NPV of 80%.
In 4 patients we observed a morphological T4 tumour, but on diffusion weighted imaging (DWI) we found no tumour activity. The pathology results for these patients showed a complete remission of the carcinoma.
Conclusions: Our analysis showed that the MRI after chemoradiation therapy is an accurate device to determine local tumour evolvement, distance to the mesorectal fascia and the presence of malignant lymph nodes. With regards to the high sensitivity for detecting T3/4 tumours, small resection margins and presence of malignant lymph nodes the MRI after CRT is an important device in the perioperative diagnostic process. And therefore plays an important role in determining a treatment policy. The MRI after CRT is a suitable device to evaluate the tumour response. Based on its results a less invasive treatment for the rectal carcinoma or even a 'wait and see' policy could be appropriate.
No conflict of interest.

2252 POSTER

Patterns of metachronous metastases after curative treatment of colorectal cancer

Y.R.B.M. Van Gestel[1], I.H.J.T. De Hingh[2], M.P.P. Van Herk-Sukel[3], F.N. Van Erning[1], L. Beerepoot[4], J.H. Wijsman[5], G.D. Slooter[6], H.J.T. Rutten[2], G.J.M. Creemers[7], V.E.P.P. Lemmens[1]. *[1]Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands; [2]Catharina Hospital, Surgery, Eindhoven, Netherlands; [3]PHARMO Institute for Drug Outcomes Research, Research, Utrecht, Netherlands; [4]St. Elisabeth Hospital, Internal Medicine, Tilburg, Netherlands; [5]Amphia Hospital, Surgery, Breda, Netherlands; [6]Maxima Medical Centre, Surgery, Eindhoven, Netherlands; [7]Catharina Hospital, Internal Medicine, Eindhoven, Netherlands*

Background: Population-based data on patterns of metachronous metastases of colorectal cancer are scarce. This study aimed to provide information on timing, anatomical location, and risk factors of metachronous metastases based on a large consecutive series of non-selected patients.
Material and Methods: All patients operated with curative intent for colorectal cancer ($T_{any}N_{any}M_0$) between 2003 and 2008 in the Dutch Eindhoven Cancer Registry were included (n = 5671). By means of active follow-up by the Cancer Registry staff within ten hospitals, data on development of metastatic disease were collected for all patients. Median follow-up was 5.0 years.
Results: Of the 5671 colorectal cancer patients, 1042 (18%) were diagnosed with metachronous metastases. Most common affected sites were the liver (60%), lungs (39%), extra-regional lymph nodes (22%), and peritoneum (19%) (numbers include multiple organ involvement, e.g. liver and lungs in 19% of patients). 86% of all metastases was diagnosed within three years after the primary diagnosis and the median time to diagnosis was 17 months (interquartile range 10−29 months). Male gender (HR = 1.2, 95% CI 1.02–1.32), an advanced primary tumour stage (T4 vs. T3 HR = 1.6, 95% CI 1.33–1.92) and lymph node stage (N1 vs. N0 HR = 2.8, 95% CI 2.42–3.30 and N2 vs. N0 HR = 4.5, 95% CI 3.71–5.41), high-grade tumour differentiation (HR = 1.4, 95% CI 1.18–1.63), a positive resection margin (HR = 2.1, 95% CI 1.69–2.71), and primary tumours located in the rectum (HR = 1.4, 95% CI 1.14–1.78) were significantly associated with increased risk for developing metachronous metastases.
Conclusions: Almost one fifth of colorectal cancer patients who were free of metastases at initial diagnosis developed metachronous metastases during follow-up. Different patterns of metastatic spread were observed for colon and rectal cancer patients and differences in time to diagnosis were found for the affected sites. Knowledge on these patterns and risk factors for metachronous metastases may enhance tailor-made follow-up schemes leading to earlier detection of metastasized disease and increased curative treatment options.
No conflict of interest.

2253 POSTER

Aflibercept (afl) in combination with FOLFIRI for the 2nd-line treatment of patients (pts) with metastatic colorectal cancer (mCRC): Interim safety and quality-of-life (QoL) data from the Italian subgroup of the Aflibercept Safety and Quality-of-Life Program (ASQoP)

R. Bordonaro[1], A. Passardi[2], G. Fasola[3], L. Ciuffreda[4], M. Di Bartolomeo[5], S. Siena[6], F. Di Costanzo[7], G. Fornarini[8], S. Cordio[1], A. Sobrero[9]. *[1]ARNAS Garibaldi Catania, Oncology, Catania, Italy; [2]IRCCS − IRST (Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori), Medical Oncology, Meldola (FC), Italy; [3]University Hospital, Oncology, Udine, Italy; [4]A.O. Citta' Della Salute E Della Scienza Di Torino, S.C. Oncologia Medica 1, Torino, Italy; [5]Fondazione IRCCS Istituto Nazionale dei Tumori di Milano, Medical Oncology, Milan, Italy; [6]Ospedale Niguarda Ca' Granda Milano, Dipartimento di Ematologia ed Oncologia, Milano, Italy; [7]Azienda Ospedaliero-Universitaria Careggi, Oncology, Firenze, Italy; [8]IRCCS Azienda Ospedaliera Universitaria San Martino − IST- Istituto Nazionale per la Ricerca sul Cancro, Onco-hematology, Genova, Italy; [9]IRCCS San Martino, Medical Oncology, Genova, Italy*

Background: In the phase 3 VELOUR trial, afl+FOLFIRI (irinotecan, 5-FU, leucovorin) demonstrated a statistically significant overall survival benefit compared with FOLFIRI alone in mCRC pts previously treated with an oxaliplatin-containing regimen. The VELOUR trial supported the initiation of the multinational Aflibercept Safety and Quality-of-Life Program (ASQoP; NCT01571284) to collect additional safety and QoL data from mCRC pts. Interim data collected by Italian investigators are reported.
Methods: At the cut-off date, 48 pts (safety population) from 17 Italian sites had completed >1 cycle of afl+FOLFIRI. Treatment cycles were repeated q2wks up to disease progression, unacceptable toxicity, death, or investigator/pt decision. FOLFIRI starting dose and dose modifications were at the investigator's discretion. Safety was assessed at each cycle and up to 30 days after last drug administration. The EuroQol EQ-5D™, selected as a utility measure instrument, was self-administered within 3 days prior to first treatment and at the beginning of every odd treatment cycle. The EQ-5D population consists of pts completing the questionnaire at baseline and at least once postbaseline, and who received at least part of 1 treatment dose. The percentage of pts with grade 3/4 AEs in the safety population of the Italian subset of ASQoP was compared with that in VELOUR.
Results: Baseline demographic characteristics of the Italian ASQoP subset were similar to VELOUR. EQ-5D data from 26 pts were analyzed; 54% were male; median age 60 years; 88.5% had ECOG score of 0. Mean±SD utility index at baseline was 0.77±0.20 and remained unchanged at cycle 3 (0.78±0.26) in 24 evaluable pts. 50% of pts of the Italian ASQoP subset experienced >1 G3/4 AE vs 83.5% in VELOUR. G3/4 hypertension and diarrhea were 14.6% and 6.3%, respectively, vs 19.1% and 19.3% in VELOUR. G3 infections (SOC) occurred in 8.3% vs 12.3% in VELOUR. No fatal events were reported.
Conclusion: Enrollment in ASQoP has enabled collection of additional safety and QoL data for afl in mCRC pts. Preliminary health-related QoL data from the Italian subset suggest that treatment with afl does not result in decrements in QoL for patients treated with afl+FOLFIRI. These interim results support the favorable safety profile of afl+FOLFIRI and have identified no new safety signals. The incidence of AEs with the afl+FOLFIRI combination in the Italian subset of ASQoP is lower than in VELOUR and clinically manageable in practice.

2254 POSTER

Prospective investigation of association between UGT1A1 polymorphisms and irinotecan toxicity in Korean patients with advanced colorectal or gastric cancer treated with FOLFIRI regimen

K.P. Kim[1], T.W. Kim[1], Y.S. Hong[1], S.Y. Kim[2], S.R. Park[2], B.H. Nam[2], K.W. Lee[3], J.H. Kim[3], I.J. Chung[4], Y.S. Park[5]. *[1]Asan Medical Center, Oncology, Seoul, Korea; [2]National Cancer Center, Oncology, Seoul, Korea; [3]Seoul National University Bundang Hospital, Oncology, Seoul, Korea; [4]Chonnam National University Hwasun Hospital, Oncology, Seoul, Korea; [5]Samsung Medical Center, Oncology, Seoul, Korea*

Background: This was a prospective observational study to assess the association between UGT1A1 variants and irinotecan-related toxicities including neutropenia and diarrhea in patients with gastric and colorectal cancer in clinical practice.
Methods: Wild-type allele (wt) and mutant allele (mut) for UGT1A1 *6 and *28 were genotyped in colorectal and gastric cancer patients who received FOLFIRI as 1st or 2nd line palliative chemotherapy. Safety including Gr $\frac{3}{4}$

neutropenia, febrile neutropenia and diarrhea was evaluated for the first cycle of FOLFIRI treatment.
Results: A total of 1,575 patients (948 colorectal and 627 gastric cancers) were enrolled. Median age was 60 (range: 20−90). Genotype frequencies of wt/wt, wt/mut and mut/mut for UGT1A1*6 were 1011, 486, 65 and for *28 were 1204, 331, 25, respectively. Patients were grouped as 'defective genotype' if the patient had a mut/mut genotype for either UGT1A1*6 or *28 or a wt/mut for both *6 and *28; and the others were grouped as 'control genotype'. The dose of irinotecan was 180 mg/m^2 and 150 mg/m^2 in 63.5% (1,000/1,575) and 32.3% (509/1,545) of the patients. Grade $\geqslant 3$ neutropenia, febrile neutropenia and diarrhea were observed in 70.1% (1,105/1,575), 1.9% (30/1,575) and 1.3% (21/1,575) at the 1st cycle of FOLFIRI. On multivariate analysis, defective genotype, female gender, older age significantly increased the risk of Gr $\geqslant 3$ neutropenia ($P<0.0001$, $P = 0.0125$, $P = 0.0011$). These findings were consistent within subgroups according to cancer origin and line of chemotherapy. However, only defective genotype was significantly associated with febrile neutropenia ($P = 0.028$). No factor was associated with Gr $\geqslant 3$ diarrhea.
Conclusions: Our findings indicated that UGT1A1*6 and *28 genotyping is significantly associated with severe neutropenia and febrile neutropenia, but not severe diarrhea in a Korean population.
No conflict of interest.

2255 POSTER

Hepatic administration of drug-eluting beads loaded with Irinotecan in unresectable liver metastasis from colorectal cancer (LMCRC) refractory to systemic chemotherapy: Retrospective analysis McGill University Health Centre

M. Stutz[1], A. Hausvater[1], A. Mamo[1], D. Valenti[2], T. Cabrera[2], P. Metrakos[3], P. Chaudhury[4], G. Steacy[3], E. Garoufalis[5], P. Kavan[6].
[1]McGill University, Segal Cancer Center Jgh, Montreal, Canada; [2]McGill University, Radiology Mcgill University Health Center, Montreal, Canada; [3]McGill University, Hepatobiliary Surgery Mcgill University Health Center, Montreal, Canada; [4]McGill University, Radiology Mcgill University Health Center, Montreal, Canada; [5]McGill University, Oncology Mcgill University Health Center, Montreal, Canada; [6]McGill University Health Centre, Royal Victoria Hospital, Oncology

Background: Transarterial chemoembolization (TACE) has been investigated in patients with LMCRC. Limited experience and available data suggest that TACE can achieve disease stabilization or improvement even in heavily pretreated patients. Retrospective analysis of loco-regional chemotherapy using irinotecan-loaded drug eluting beads (DC beads) in real life setting was performed at McGill University Hospitals.
Methods: The analysis included patients with LMCRC, ECOG 0−1, who failed at least 2 lines of chemotherapy and received repeat embolizations with 2 ml of microspheres preloaded with 100 mg of Irinotecan (4 ml loaded with 200 mg of Irinotecan as a maximum single dose). Beads were delivered selectively into hepatic arteries and procedure repeated as per treating physician's discretion. All patients were treated according to standard hospital procedure for chemoembolization using prophylactic treatments against nausea and vomiting, infections, and upper quadrant right pain. Follow-up analyses were done using CT scans at 1−2 months after the procedure and then every 3 months or when clinically needed.The primary endpoint of this analysis was overall survival (OS) defined as the time from the last treatment with TACE to death. Survival data was analyzed by the Kaplan–Meier method. Secondary endpoints were safety using CTCAE version 4.0 and progression free survival (PFS).
Results: Twenty six patients were treated using Irinotecan drug eluting beads. No complications due to the procedure occurred. Patient's median age was 57 years (range 45−82 years), with 50% male vs 50% female. The median number of total treatments per patient was 3 (range of 1−5). With an average follow up of 1 year, the median OS was 5.4 months (95% CI; 1.1–22.7 months). The median PFS was 72 days (20–437 days) based on radiological assessments for all patients. The most reported post embolization events were: nausea (8/26); vomiting (6/26); right upper quadrant pain (12/26), fatigue (9/26) and increased transaminases (1/26 grade 3). Five out of 26 patients (19%) required hospitalization post-TACE treatment due to severe persistent pain.
Conclusion: Our data suggests that TACE with irinotecan-loaded drug eluting beads could be a palliative therapy for patients with LMCRC. Nevertheless, a randomized trial is needed in order to optimize the timing of the procedure for improved survival rate.
No conflict of interest.

2256 POSTER

A prognostic score based on tumour characteristics to predict survival of patients with metastatic colorectal cancer: Results from a prospective study

N. Marschner[1], A. Karcher[2], E. Ladda[3], M. Franzem[4], M. Jänicke[4].
[1]Praxis für Interdisziplinäre Onkologie & Hämatologie, Freiburg, Germany; [2]Onkologische Schwerpunktpraxis, Heidelberg, Germany; [3]Praxis für Innere Medizin, Neumarkt, Germany; [4]iOMEDICO, Freiburg, Germany

Background: Prognostic scores are useful to compare patients (pts) between different clinical studies. Several laboratory and clinical factors have been reported to affect survival of pts with metastatic colorectal cancer (mCRC). These results are based on data from clinical trials that generally exclude specific groups of pts, e.g. those with comorbidities. Here we present the development and validation of a prognostic score based on tumour characteristics of unselected pts treated in clinical practice.
Methods: Using the Tumour Registry Colorectal Cancer (TKK), we split data from pts at the start of 1st-line therapy in a learning (796 pts; 2006–2008) and validation sample (908 pts; 2009–2012). The TKK prospectively documents treatment of CRC pts by office-based oncologists in Germany. Pts receive standard treatments according to physician's choice.
Six prognostic factors were identified in the learning sample using univariate and multivariate analyses based on Cox proportional hazards regression. A score was proposed stratifying patients into three prognostic groups. The predictive performance was validated in the independent validation sample.
Results: Median follow-up of all pts was 44 months, median overall survival (OS) was 23 months (64% events). KRAS mutation status (mutated; hazard ratio [HR] 1.5, confidence interval [CI] 1.2−1.8) and number of metastatic sites at start of palliative therapy ($\geqslant 2$; HR 1.5, CI 1.2−1.9); tumour stage ($\geqslant 3$; HR 1.4, CI 1.1−1.9) and grading ($\geqslant$ G3; HR 1.3, CI 1.1−1.6) at primary diagnosis; and resectability ($\geqslant$ R1; HR 1.5, CI 1.2−1.8) and lymph node ratio ($\geqslant 0.4$, HR 1.3, CI 1.0−1.6) of primary tumour were identified as prognostic risk factors. Pts were stratified into three groups according to risk. Median OS was 31 months for pts with low risk (1−2 risk factors, 42 % of pts), 21 months for pts with intermediate risk (3 risk factors, 28 % of pts, HR 1.6) and 15 months for pts with poor risk (4−6 risk factors, 30 % of pts, HR 2.5). The difference in OS is statistically significant ($p < 0.02$, adjusted for multiplicity). Results were confirmed in the validation sample.
Conclusions: At the start of palliative treatment, pts with mCRC can be stratified into three risk groups based on six tumour characteristics, with superior OS for pts with low and intermediate risk. This score could significantly facilitate comparability of pts between clinical studies. The effectiveness of different treatments may be evaluated in the three risk groups.
No conflict of interest.

Genomic classifier (ColoPrint) predicts outcome and chemotherapy benefit in stage II and III colon cancer patients

S. Kopetz[1], Z.Q. Jiang[2], M.J. Overman[1], R. Rosenberg[3], R. Salazar[4], J. Tabernero[5], L. Stork-Sloots[6], I. Simon[7], G.J. Chang[8], D.M. Maru[9].
[1]University of Texas MD Anderson Cancer Center, Department of Gastrointestinal Medical Oncology, Houston, USA; [2]University of Texas MD Anderson Cancer Center, Department of Radiation Oncology, Houston, USA; [3]Kantonsspital Baden, Department of Surgery, Baden, Switzerland; [4]Institut Catala Oncologia − IDIBELL Hospitalet de Llobregat, Department of Medical Oncology, Barcelona, Spain; [5]Vall d'Hebron University Hospital, Department of Medical Oncology, Barcelona, Spain; [6]Agendia, Medical Affairs, Amsterdam, Netherlands; [7]Agendia, Research and Development, Amsterdam, Netherlands; [8]University of Texas MD Anderson Cancer Center, Department of Surgical Oncology, Houston, USA; [9]University of Texas MD Anderson Cancer Center, Pathology, Houston, USA

Background: Although benefit of chemotherapy in stage II and III colon cancer patients is significant, many patients might not need adjuvant chemotherapy because they have a good prognosis even without additional treatment. ColoPrint is a gene expression classifier that distinguish patients with low or high risk of disease relapse. It was developed using whole genome expression data and validated in independent validation studies (JCO 2011, Ann Surg 2013).
Material and Methods: ColoPrint was validated in stage II ($n = 96$) and III patients ($n = 95$) treated at the MD Anderson Cancer Center. Frozen tissue specimen, clinical parameters and follow-up data (median follow-up 64 months) were available. Stage II patients from this study were pooled with patients from previous studies ($n = 416$) and ColoPrint performance was compared to high risk factors described in the ESMO clinical consensus guidelines.

Results: In the MDACC patient cohort, ColoPrint classified 56% of stage II and III patients as being at Low Risk. The 3-yr Relapse-Free-Survival (RFS) was 91% for Low Risk and 78% for High Risk with a HR of 2.42 (p = 0.025). In uni-and multivariate analysis, ColoPrint and stage were the only significant factors to predict outcome. Low Risk ColoPrint patients had a good outcome independent of stage or chemotherapy treatment (91% 3-yr RFS for treated patients, 90% for untreated patients) while ColoPrint High Risk patients treated with adjuvant chemotherapy had 3-yr RFS of 84%, compared to 70% 3-year RFS in untreated patients (p = 0.037). In the pooled stage II dataset, ColoPrint identified 63% of patients as Low Risk with a 3-yr RFS of 93% while High Risk patients had a 3-year RFS of 82% with a HR of 2.7 (p = 0.001). In the univariate analysis, no clinical factor reached statistical significance. Using clinical high risk factors as described in the ESMO clinical consensus guidelines, 56% of patients were classified as low risk with a 3-yr RFS of 90% while high risk patients had a 3-yr RFS of 88% with a HR of 1.31 (p = 0.38).
In the subgroups of stage 2 patients with T3-MSS (n = 286) ColoPrint classified 57% as Low Risk with a 3-yr RFS of 94% for Low Risk and 81% for High Risk patients with a HR of 3.17 (p = 0.003). In the univariate analysis, no clinical factor reached statistical significance.
Conclusions: ColoPrint significantly improves prognostic accuracy, thereby facilitating the identification of patients at higher risk who might be considered for additional treatment.
Conflict of interest: *Other substantive relationships: L.Stork-Sloots and I. Simon are employees of Agendia*

2258 POSTER

Evaluation of erectile dysfunction risk factors in young male survivors of colorectal cancer

M. Sendur[1], S. Aksoy[2], S. Yaman[1], O. Yazici[1], N.Y. Ozdemir[1], D. Uncu[1], N. Zengin[1]. *[1]Ankara Numune Education and Research Hospital, Medical Oncology, Ankara, Turkey; [2]Hacettepe University Institute of Oncology, Medical Oncology, Ankara, Turkey*

Background: Improved long-term survival of colorectal patients who were treated with surgery and/or chemotherapy ± radiotherapy (RT) has led to increased awareness of long-term side effects, including effecting sexual life, which can ultimately affect quality of life in these patients. Due to the absolute risk factors of erectile dysfunction (ED) have not been defined in colorectal patients, the aim of this research is to identify severity and absolute risk factors of ED in male colorectal cancer survivors.
Patients and Methods: A total of 61 male survivors of colorectal cancer treated with surgery and/or chemotherapy ± RT were recruited from medical oncology outpatient clinics during routine follow-up visits in 2011–2012 were analyzed. Patients older than 55 years-old and erectile dysfunction history before diagnosis were excluded. Medical information of patients was obtained from medical charts.
Results: A total of 61 male colorectal cancer survivors were included in this study. The mean age of the study population was 44.3±7.5 and 47.6±6.7 (range, 18−55 years) at the time of diagnosis and intervention, respectively. According to the International Index of Erectile Function (IIEF) score, 83.6% of patients had some degree of ED. The severity of ED; 42.6% of patients have mild ED, whereas 16.4% and 24.6% have moderate and severe ED according to the IIEF score, respectively. In terms of age, moderate-severe ED was observed in 50.0% of patients ⩾40 years old, whereas 31.0% moderate-severe ED was observed in patients younger than 40 years old (P = 0.01). According to the tumor location; in rectal cancer patients compared to the colon cancer, moderate-severe ED was 67.8% and 18.2%, respectively (P = 0.01). In terms of the type of surgery; in APR patients, the moderate-severe ED was 66.7%, in LAR patients, the moderate-severe ED was 60.0%, whereas 17.2% moderate-severe ED was observed in non-APR, non-LAR patients (P = 0.02). At the time of intervention, stoma was found in 15 (24.6%) of patients. The moderate-severe ED was found in 80.0% of patients with stoma whereas moderate-severe ED was found in only 28.2% of patients without stoma (P = 0.003). The 37.7% of the survivors had treated with pelvic RT; the moderate and severe ED was observed in 69.6% of patients treated with pelvic RT, whereas moderate-severe ED was observed only in 23.7% of patients who treated without RT (P = 0.005). Also there was no significant correlation between smoking status, hypertension, diabetes mellitus, cardiovascular disease, stage of the tumor and ED. Also hormonal disturbances such as serum FSH, LH and testesterone levels did not affect the presence of ED and its severity.
Conclusion: Overall, 83.6% of the male survivors of colorectal cancer had some degree ED according to the IIEF. The risk factors of the ED was older age, tumor location, type of surgery, presence of stoma and RT. Clinicians should be aware of this risk factors to offer adequate treatment options and new treatment strategies are necessary to reduce further ED in colorectal cancer survivors.

Phase II trial of combined chemotherapy with irinotecan, S-1, and bevacizumab (IRIS/BV) in patients with metastatic colorectal cancer (mCRC): Hokkaido Gastrointestinal Cancer Study Group (HGCSG) tria l- comparison of the efficacy of KRAS status

S. Saitoh[1], S. Yuki[2], K. Harada[3], M. Nakamura[4], K. Hatanaka[5], T. Miyagishima[6], M. Kudo[7], N. Akakura[8], Y. Sakata[1], Y. Komatsu[9]. *[1]Misawa City Hospital, Medical Oncology, Misawa, Japan; [2]Hokkaido University Hospital, Gastroenterology and Hepatology, Sapporo, Japan; [3]Hokkaido University Hospital, Gastroenterology and Hepatorogy, Sapporo, Japan; [4]Sapporo City General Hospital, Gastroenterology, Sapporo, Japan; [5]Hakodate Municipall Hospital, Gastroenterology, Hakodate, Japan; [6]Kushiro Rosai Hospital, Internal Medicine, Kushiro, Japan; [7]Sapporo Hokuyu Hospital, Gastroenterology, Sapporo, Japan; [8]Sapporo Medical Center NTT EC, Gastroenterology, Sapporo, Japan; [9]Hokkaido University Hospital, Cancer Center, Sapporo, Japan*

Background: Mutations of the KRAS gene were identified as predictive markers in mCRC for anti-EGFR antibodies. Previously reported data suggest that the longer overall survival (OS) observed with bevacizumab (BV) treatment in mCRC is independent of alterations in the KRAS status. We analyzed the efficacy of BV combined irinotecan and S-1 (IRIS/BV) in mCRC relative to KRAS status.
Patients and Methods: In the retrospective analysis (n = 53) of patients who participated in the Phase II trial of IRIS/BV, additional statistical analyses were done with data from KRAS status. In this trial, eligible patients had to have mCRC with a confirmed diagnosis of adenocarcinoma, an age of >20 years, and no history of prior chemotherapy. S-1 40−60 mg twice daily p.o. was given on days 1−14 and irinotecan 100 mg/m^2 and bevacizumab 5 mg/kg i.v. were given on days 1 and 15 of a 28-day cycle. The Response Evaluation in Solid Tumors (RECIST) criteria version 1.0 was used to assess tumor response. The Kaplan–Meier method was used to determine Progression-free survival (PFS) and OS. Log- rank test was used to compare with mutant or wild-type KRAS in terms of PFS and OS. All statistical tests were performed using SPSS.
Results: The target number of 53 patients was enrolled as of March 2009. KRAS status was assessed in 43 patients (wild=27, mutant=16). Response rate was 63.0% with wild-type and 68.8% with mutant-type KRAS, that was not significant (p = 0.531). And median OS was 49.0 months with wild-type and 38.0 months with mutant-type KRAS, that was not significant (p = 0.906) as well.
Conclusions: IRIS/BV provides clinical benefit in patient with mCRC expressing either mutant or wild-type KRAS. This analysis has shown that the efficacy of IRIS/BV does not affect the KRAS mutational status and urgently requires further large-scale validation studies.

Aflibercept/FOLFIRI vs placebo/FOLRIRI in metastatic colorectal cancer: post-hoc analysis of survival by prior bevacizumab use subsequent to exclusion of patients who had recurrence during or within 6 months of completing adjuvant oxaliplatin-based therapy

E. Van Cutsem[1], D.R. Ferry[2], R. Lakomy[3], P. Bhargava[4], J. Prausova[5], G.A. Van Hazel[6], V.M. Moiseyenko[7], J. McKendrick[8], E. Boelle[9], T. Macarulla[10]. *[1]Leuven Cancer Institute, Digestive Oncology Unit, Leuven, Belgium; [2]New Cross Hospital, Oncology, Wolverhampton, United Kingdom; [3]Masaryk Memorial Cancer Institute, Medical Oncology, Brno, Czech Republic; [4]Sanofi, Research and Development, Cambridge, USA; [5]University Hospital Motol, Oncology, Prague, Czech Republic; [6]University of Western Australia, School of Medicine and Pharmacology, Perth, Australia; [7]Cancer Center, Chemotherapeutic, St. Petersburg, Russian Federation; [8]Box Hill Hospital, Medical Oncology, Melbourne, Australia; [9]Sanofi, Research and Development, Vitry sur seine, France; [10]Vall d'Hebron Hospital, Oncology, Barcelona, Spain*

Background: The phase 3 VELOUR trial (NCT00561470) showed that aflibercept + FOLFIRI (AF) significantly improved overall survival (OS) when compared with FOLFIRI + placebo (PBO). In VELOUR, 10% (124) of the patients (pts) in the ITT population had recurrence during or within 6 mos of completing adjuvant oxaliplatin-based therapy (ADJ-only). Exclusion of ADJ-only pts from the ITT population demonstrated

improvements in median OS in the AF arm. Analysis of the ITT population by prior bevacizumab (bev) treatment also demonstrated improved OS with AF in both the prior bev use and the no prior bev use groups. We report OS by prior bev treatment after exclusion of ADJ-only pts.
Methods: 186 pts in the AF and 187 in the PBO groups were stratified to prior bev while 426 in the AF and 427 in the PBO groups were stratified to no prior bev. Within the prior bev group, 9 pts in the AF and 8 in the PBO groups comprised the ADJ-only group. Of 853 pts stratified to the no prior bev group, 51 pts in the AF and 56 in the PBO comprised the ADJ-only group. Baseline characteristics and efficacy were determined for the ITT population excluding ADJ-only pts by prior bev treatment. OS and progression-free survival (PFS) are reported as median estimates using the Kaplan–Meier product limit and hazard ratios (HRs) with 95% confidence intervals (CIs) from Cox proportional hazard model.
Results: In this post-hoc analysis of the prior bev group, there were 177 pts in the AF and 179 in the PBO groups following exclusion of ADJ-only pts. We observed an improved median OS with AF vs PBO of 2.14 mos (13.80 vs 11.66); HR = 0.812 (95% CI, 0.634–1.042). Median PFS was 6.7 vs 3.9 mos for the AF group compared with PBO; HR = 0.645 (95% CI, 0.498–0.835). In the no prior bev group, there were 375 pts in the AF and 371 in the PBO groups following exclusion of ADJ-only pts. Median OS was improved with AF vs PBO by 1.31 mos (13.73 vs 12.42); HR = 0.766 (95% CI, 0.645–0.908). Median PFS was 6.9 vs 5.3 mos for the AF group compared with PBO; HR = 0.777 (95% CI, 0.655–0.921).
Conclusions: Excluding the ADJ-only pt population from the analysis of OS by prior bev use shows improvements over PBO in median OS and PFS in both the prior bev as well as the no prior bev treated groups. This post-hoc analysis reinforces the therapeutic benefit of AF in clinically relevant pt populations.
Conflict of interest: *Advisory board: Sanofi, AstraZeneca, Roche, Lilly, Pfizer Ns Bayer. Corporate-sponsored research: Velour study (Sanofi). Other substantive relationships: Full time Sanofi employee*

2261 POSTER

Can the yield of repeat colonoscopy be improved by SNPs at the TGFBR1, mix4 and CHR8 loci as risk markers for CRC?

G. Mahon[1], M. Pauly[1], B. Metzger[1], M. Dicato[1], A. Menzel[2], B. Weber[2].
[1]Centre Hospitalier de Luxembourg, Recherche sur le Cancer et Maladies du Sang, Luxembourg, Luxembourg; [2]Laboratoires Réunis, Recherche, Junglinster, Luxembourg

Background: Standard recommendations for screening for colorectal cancer (CRC) specify a colonoscopy about age 50 and if normal a repeat after 10 years. The yield of the follow-on colonoscopy in this setting is poor. There is a highly significant association between certain SNP variants at the TGFBR1 locus and CRC, and weaker associations between a mix4 or CHR8 variant and CRC (WCGIC 2012, abstract O-0027). We have suggested that TGFBR1 could potentially be useful to screen for CRC (ASCO 2013, abstract e14591). We now present the sensitivities and specificities of tests using various combinations of SNP variants and discuss the consequences for screening.
Materials and Methods: Tumour samples were obtained from 187 CRC patients and blood from 94 healthy control subjects, all Caucasian. After gDNA extraction, selected amplicons were amplified by PCR, followed by melting curve analysis. The SNP sites for TGFBR1 were rs334348, rs334349 and rs1591; (TGFBR1) mix4, rs7871490; and CHR8, rs7014346. Sensitivity was calculated as the ratio of test-positive cases to total cases, and specificity as the ratio of test-negative controls to total controls.
Results: For TGFBR1, contrasting homozygous variants (VV) versus heterozygotes plus homozygous normals (VN+NN) for CRC cases and controls, the sensitivity as found to be 42.8% and specificity 89.4%. Comparing TGFBR1 (VV+VN) with (NN) showed a sensitivity of 82.4% and specificity of 42.6%. Contrasting TGFBR1 and CHR8 variants (VV+VN) with (NN) showed a sensitivity of 95.2% and a specificity of 19.1%. Finally, comparing TGFBR1, CHR8 and mix4 variants (VV+VN) with (NN) gave a sensitivity of 98.9% and a specificity of 12.8%.
Conclusions: There is a trade-off between sensitivity and specificity depending on how the TGFBR1 heretozygotes are considered. When they are combined with the homozygous normals, sensitivity is low and specificity high; when combined with the homozygous variants the sensitivity is high and the specificity low. Sensitivity relates to the test's ability to identify positive results. Thus we conclude that the heterozygotes should be included with the homozygous variants in any eventual screening test. Including further loci (CHR8 and mix4) raises the sensitivity to a very high level but reduces specificity. Using a test to predict cancer risk would be cost-saving and much easier on patients and could possibly, in patients at risk, call for a colonoscopy sooner and more frequently while increasing yield. A prospective clinical trial to prove the cost-benefit is indispenbable.
No conflict of interest.

2262 POSTER

Updated overall survival (OS) analysis of novel predictive KRAS/NRAS mutations beyond KRAS exon 2 in PEAK: A 1st-line phase 2 study of FOLFOX6 plus panitumumab (pmab) or bevacizumab (bev) in metastatic colorectal cancer (mCRC)

M. Karthaus[1], L. Schwartzberg[2], F. Rivera[3], G. Fasola[4], J.L. Canon[5], H. Yu[6], K.S. Oliner[6], W.Y. Go[6]. *[1]Städtisches Klinikum München GmbH − Klinikum Neuperlach, München, Germany; [2]The West Clinic, Memphis, USA; [3]Hospital Universitario Marques de Valdecilla, Santander, Spain; [4]University Hospital S. Maria della Misericordia, Udine, Italy; [5]Grand Hôpital de Charleroi, Charleroi, Belgium; [6]Amgen Inc, Thousand Oaks, USA*

Background: From a prospective-retrospective analysis of this estimation study, PEAK showed trends towards improved progression-free survival (PFS) and OS in patients (pts) with wild-type (WT) *RAS* (exons 2, 3, 4 of *KRAS*/*NRAS*) mCRC tumors treated with pmab+FOLFOX6 relative to bev+FOLFOX6. Here we report updated results for the intent-to-treat set (ITT) and the novel *RAS* analyses.
Material and Methods: Pts randomized were required to have WT *KRAS* exon 2 mCRC (ITT). This analysis assessed the effect of pmab or bev+FOLFOX6 on PFS and OS in WT *RAS* mCRC. Bidirectional Sanger sequencing and SURVEYOR®/WAVE® analysis were independently conducted to detect mutations in *KRAS* exon 2 (codons 12/13), exon 3 (codons 59/61), exon 4 (codons 117/146); *NRAS* exon 2 (codons 12/13), exon 3 (codons 59/61), exon 4 (codons 117/146).
Results: 285 pts were randomized, 278 received treatment (tx). The *RAS* ascertainment rate was 80%. OS tx HRs (pmab:bev) for the WT *KRAS* exon 2 was 0.62 (95% CI:0.44–0.89), descriptive p-value=0.009. *RAS* analyses results are shown (Table).
Conclusions: From this updated analysis in pts with WT *RAS*, PFS and OS HR strongly favored pmab+FOLFOX6 relative to bev+FOLFOX6. In the WT *KRAS* exon 2, MT *RAS* group, a trend toward inferior PFS in the pmab+FOLFOX6 arm relative to the bev+FOLFOX6 arm was shown. OS tx HRs favored pmab+FOLFOX6 in pts with WT *KRAS* exon 2 (ITT) with 9.9 mos median difference. The safety profile for both arms was similar with previously reported studies with no new toxicities identified. These additional *RAS* mutations beyond *KRAS* exon 2 appear to be predictive for pmab tx effect.

Quality of life as prognostic factor of relative survival in elderly patients with colorectal cancer: A population-based study

E. Fournier[1], F. Rollot[2], A.S. Woronoff[1], V. Jooste[2], S. Normand[2], M. Mercier[3], A.M. Bouvier[2]. [1]*CHU Besancon, Doubs Cancer Registry, Besançon, France;* [2]*University of Bourgogne, Burgundy Digestive Cancer Registry Inserm U866, Dijon, France;* [3]*University of Franche-Comté, EA3181, Besançon, France*

Background: The aim of this study was to evaluate the prognostic value of baseline HR-QoL assessment on survival in a population-based cohort of elderly patients with newly diagnosed colorectal cancer (CRC).
Methods: All patients aged 65 and over, diagnosed with a new CRC and registered in the Digestive Cancer Registry of Burgundy between 2003 and 2005 were eligible. Four hundred and one patients were asked to complete EORTC Quality of life Questionnaire QLQ-C30 at inclusion, 3, 6 and 12 months after diagnosis. Spitzer Index (SI) was also completed by each patient's personal physician at the same time points. Relevant QLQ-C30 dimensions and SI were considered using dichotomized variables with the median cut-point. The analysis was firstly performed incident cases still alive one year after diagnosis and secondly among patients with baseline QoL assessments.
Uni- and multivariate regression analyses were performed using the Esteve model with the Dickman approach to evaluate prognosis factors for relative survival (RS). Conditional relative survival (CRS5=RS 5 yrs/RS 1 yr) was computed in order to assess survival according to study participation.
Results: One hundred fifty-six patients replied to baseline QoL questionnaire, 90 to other time-point and 155 did not participate to the study. Respondents to baseline QoL questionnaire were younger and more often treated with curative surgery than non-respondents.
Overall 5 year RS was 63% [57, 69]. In the analysis performed among the 328 patients still alive one year after diagnosis, a Charlson Index superior to 3 (CSR5 = 38% [25, 51]), an advanced tumor stage (CSR5 = 18% [10, 28]), non-response to the QLQ-C30 (CRS5 = 68% [61, 74] and a lower QoL (CRS5 = 49% [35, 64]) were significantly associated with lower survival.
Among the 156 patients with baseline QoL, role functioning was the only QoL dimension significantly predictive of relative survival in the multivariate analysis (HR = 4.3, $p < 0.001$). Advanced tumor stage (HR = 16.3, $p < 0.001$) was associated with lower survival.
Conclusions: Those results suggest that baseline QoL assessments are strong independent predictors of elderly colorectal cancer patients' survival. Moreover, even when focusing the analysis on patients still alive one year after diagnosis and thus avoiding selection bias, non-response to the cohort study is significantly associated to lower survival.
No conflict of interest.

2264 POSTER

Increased lymph node yield in colon cancer: No increase in overall node positivity rate except for pT1 stage

F.N. Van Erning[1], R.M.P.H. Crolla[2], H.J.T. Rutten[3], L.V. Beerepoot[4], J.H.J.M. Van Krieken[5], V.E.P.P. Lemmens[1]. [1]*Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands;* [2]*Amphia Hospital, Surgery, Breda, Netherlands;* [3]*Catharina Hospital, Surgery, Eindhoven, Netherlands;* [4]*St. Elisabeth Hospital, Internal Medicine, Tilburg, Netherlands;* [5]*University Medical Centre St. Radboud, Pathology, Nijmegen, Netherlands*

Background: Few data are available on the effect of increasing lymph node yield after resection for colon cancer on metastasis-positive node rates.
Patients and Methods: 9115 patients resected for stage I−III ($T_{any}N_{any}M0$) colon cancer diagnosed in the southern Netherlands between 2000 and 2010 were included. Trends in nodal evaluation and node positivity were analyzed. Multivariate logistic regressions were used to assess determinants of adequate nodal evaluation and node positivity. Adequate nodal evaluation was defined as $\geqslant$12 lymph nodes examined in accordance with the recommendation of the International Union Against Cancer. Cox regression was used to discriminate independent risk factors for death.
Results: Overall, the proportion adequate nodal evaluation increased from 13.2% in 2000–2002 to 55.5% in 2009–2010 ($p < 0.0001$), whereas the proportion node positivity remained unchanged (37.8%). In pT1 patients, proportion of node positivity increased from 5.1% to 12.1% ($p = 0.004$). Node-positive patients more often received adequate nodal evaluation (adjusted OR N+ versus N0 1.22; 95% CI 1.10–1.35). A more extensive nodal evaluation was associated with node positivity (adjusted OR $\geqslant$12LNs versus 1−8LNs 1.26; 95% CI 1.12–1.42). Elderly were less likely to have node-positive disease (adjusted OR 70−79 years versus <50 years 0.72; 95% CI 0.58–0.90). Risk of death was correlated with number of nodes evaluated for both node-negative patients (HR $\geqslant$12LNs versus 1−8LNs 0.64; 95% CI 0.56–0.72) and for node-positive patients (HR $\geqslant$12LNs versus 1−8LNs 0.61; 95% CI 0.54–0.69).
Conclusion: In patients with stage I−III colon cancer, the number of lymph nodes evaluated has significantly increased between 2000 and 2010, without an increase in the overall proportion of node positivity. However, we detected a higher proportion of patients with pT1 stage who had lymph node metastasis. This finding stresses the importance to keep striving for adequate nodal evaluation to avoid unjust withholdment of adjuvant treatment and prognostic information to individual patients.
No conflict of interest.

2265 POSTER

The individual and combined effects of colorectal cancer and diabetes on health-related quality of life and sexual functioning: 1+1=3?

P.A.J. Vissers[1], M.S.Y. Thong[1], F. Pouwer[1], B.L. Den Oudsten[1], G.A.P. Nieuwenhuijzen[2], L.V. Van de Poll-Franse[3]. [1]*Tilburg University, Medical Psychology and Clinical Psychology, Tilburg, Netherlands;* [2]*Catharina Hospital, Department of Surgery, Eindhoven, Netherlands;* [3]*Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands*

Background: This study compares persons without colorectal cancer and diabetes (CRC-DM-), persons with only diabetes (CRC-DM+), persons with only colorectal cancer (CRC+DM-), and persons with both colorectal cancer and diabetes (CRC+DM+) on Health-Related Quality of Life (HRQoL) and sexual functioning. In addition, the additive interaction effect of diabetes and colorectal cancer was tested.
Material and Methods: Persons older than 60 years who participated in a survey in 2010 among patients with colorectal cancer or among a normative Dutch population, were included. Having diabetes was self-reported. Both samples completed the EORTC-QLQ-C30 and four scales of the EORTC-QLQ-C38 to assess HRQoL and sexual functioning, respectively.
Results: Response rates among those aged 60 years or older were 85% and 73% for the normative population and colorectal cancer patients, respectively. In total 624 CRC-DM-, 78 CRC-DM+, 1726 CRC+DM-, and 328 CRC+DM+ persons were included in the analysis. No additive interaction effect of both diabetes and cancer was observed on any of the subscales of HRQoL, except for pain. Having colorectal cancer was associated with less optimal scores on all the HRQoL subscales, except global health and pain, while diabetes was mainly associated with less favorable scores on global health, physical functioning, fatigue and dyspnoea. However, all associations were not clinically relevant. Sexual dysfunction was mainly apparent among male CRC+DM+ persons. Erection problems were reported among 15% of CRC-DM-, 27% of CRC-DM+, 48% of CRC+DM- and 59% of CRC+DM+ persons (P-value <0.0001). After adjustments, CRC+DM- and CRC+DM+ persons were more likely to report erectile dysfunction compared to CRC-DM- persons with odds ratios of 4.7 and 6.5, respectively. Moreover, more CRC+DM+ persons reported ejaculation problems compared to CRC+DM- persons with 48% versus 39% respectively (P-value=0.04). After adjustments this effect remained significant with male CRC+DM+ persons being 1.6 times more likely to report ejaculation problems compared with CRC+DM- persons.
Conclusion: Colorectal cancer or its treatment but not diabetes seems to contribute to a decreased HRQoL and sexual functioning compared with the normative population. No additive interaction between diabetes and cancer was found, except for pain, thus having diabetes and cancer does not result in a worse HRQoL and sexual functioning than the sum of both individual effects.
No conflict of interest.

2266 POSTER

Reduced benefit of bevacizumab in patients with advanced colorectal cancer who continue to smoke

S. Imbevaro[1], P. Rescigno[1], M. Mazurek[1], A. Jirillo[1]. [1]*Istituto Oncologico Veneto IRCCS, Anticancer Drugs Evaluation Center, Padova, Italy*

Background: It is well known that cigarette smoking is the most important cause of lung cancer and other types of tumor. We set out to analyze the role of cigarette smoking in patients undergoing chemotherapy combined with bevacizumab at the Veneto Oncology Institute IRCCS /Istituto Oncologico Veneto/ in Padua (Italy) in order to see if the smoking continuation during chemotherapy treatments affects positive results.
Material and Methods: It is an observational retrospective monoistitutional analysis that covers 187 patients (59% male) undergoing chemotherapy in combination with bevacizumab for the treatment of colorectal cancer and included in the Onco-AIFA national register for monitoring of innovative anticancer drugs. The observation period begins in June 2006 and finishes in February 2012. From the Onco-AIFA register we obtained the personal data as well as the pathology and treatment details, while from hospital

discharge records and medical records we were able to acquire socio-demographic information and the number of health benefits.
The Kaplen-Meier method was used to analyze the OS (overall survival) and PFS (progression free survival).
Results: Among the information collected we concentrated on the data related to smoking and we found out that 55% of patients were non-smokers, 26% smokers and the remaining 19% ex-smokers.
We observed responses to treatment for 183 patients (98%): 5 complete response (3%), 51 partial response (27%), 93 stable disease (50%), 34 progressive disease (18%). The study revealed that being a smoker is a determinant of the OS of patients: in particular non-smokers showed a median survival of 25 months, ex-smokers of 20 and smokers of 17 ($p = 0.021$). The median PFS was calculated for 166 patients and it was 12 months for non-smokers, 10 ex-smokers and 7 smokers ($p = 0.036$).
Conclusions: Overall, smoking was significantly associated with shorter OS and PFS in patients with colorectal cancer. This is the first observation about chemotherapy combined with bevacizumab that in colorectal cancer the results can be influenced by smoking status.
Therefore, in addition to an increased risk, there is a reduced benefit in terms of clinical conditions and response since tabacco reduces the effects of anticancer chemotherapy.
No conflict of interest.

2267 POSTER

Factors determining hospital delay in an unrestricted population of colorectal cancer patients in the western part of The Netherlands

L.G.M. Van der Geest[1], M.A.G. Elferink[2], W.H. Steup[3], A.M.C. Witte[4], J.W.R. Nortier[5], R.A.E.M. Tollenaar[6], H. Struikmans[7]. [1]*Comprehensive Cancer Centre The Netherlands, Epidemiology, Leiden, Netherlands;* [2]*Comprehensive Cancer Centre The Netherlands, Epidemiology, Enschede, Netherlands;* [3]*Haga Hospital, Surgery, The Hague, Netherlands;* [4]*Diaconessenhuis, Internal Medicine, Leiden, Netherlands;* [5]*Leiden University Medical Centre, Clinical Oncology, Leiden, Netherlands;* [6]*Leiden University Medical Centre, Surgery, Leiden, Netherlands;* [7]*Medical Centre Haaglanden, Radiotherapy, Leiden, Netherlands*

Background: The aim of this study was to investigate factors determining pre- and in-hospital delay in an unrestricted population of colorectal cancer patients in the Western part of The Netherlands, in order to identify possibilities for shortening time intervals.
Methods: All patients with newly diagnosed colon (n = 2,146) and rectal carcinoma (n = 1,036) in the period 2006–2008 were included in analyses of in-hospital delay (interval between first hospital visit and first treatment >35 days). Patients in four hospitals (one third of all patients) were also available for analyses of pre-hospital delay (interval between enrolment and first hospital visit >7 days). Patient, tumour, treatment and process factors predicting pre- and in-hospital delay were examined in logistic regression models.
Results: Median pre-hospital time interval was 2 days (IQR: 0−16) for colon cancer patients (excluding emergency surgery: 4 days (0−18)), and 7 days (1−21) for rectal cancer patients. Median in-hospital time interval was 32 days (17−49) for colon (excluding emergency surgery: 36 days (23−52)) and 43 days (33−60) for rectal cancer patients. In multivariate analyses, lower tumour stage was independently associated with increased pre-hospital delay in colon cancer patients, and first hospital visit prior to histological confirmation of cancer was associated with decreased pre-hospital delay in colon and rectal cancer patients. Furthermore, higher age, more comorbidities and lower tumour stage were independently associated with increased in-hospital delay in colon cancer patients. Colon and rectal cancer patients with first hospital visit prior to histological confirmation of cancer, complete diagnostic assessment, or discussed in a multidisciplinary meeting had a higher probability of increased in-hospital delay. Finally, rectal cancer patients starting with chemotherapy had a lower probability of in-hospital delay compared to patients who underwent elective surgery or radiotherapy.
Conclusions: After adjustment for patient and tumour characteristics, guidelines-based diagnostic assessment (considered high quality of care) was associated with hospital delay. Residual variation between hospitals and less delay in patients starting with chemotherapy suggest that improvements in patient logistics are possible.
No conflict of interest.

2268 POSTER

The impact of toxicity and efficacy on quality of life in KRAS wild-type metastatic colorectal cancer patients treated with first-line chemotherapy plus cetuximab

K. Yamaguchi[1], M. Ando[2], A. Ooki[1], F. Beier[3], P. Von Hohnhorst[3], R. Esser[3], E. Van Cutsem[4]. [1]*Saitama Cancer Center, Saitama, Japan;* [2]*Nagoya University Graduate School of Medicine, Aichi, Japan;* [3]*Merck KGaA, Darmstadt, Germany;* [4]*University Hospital Gasthuisberg, Leuven, Belgium*

Background: Skin reactions are common side-effects of cetuximab treatment and may be a limiting factor for its use in many countries including Japan. In the CRYSTAL study adding cetuximab to first-line chemotherapy (CT) improved clinical outcome in patients (pts) with *KRAS* wild-type metastatic colorectal cancer without markedly impacting on quality of life (QoL). In the absence of clinical data in Japan the impact of treatment toxicities and efficacy (early tumor shrinkage [ETS] and response) on QoL was further investigated including additional criteria in the CRYSTAL study.
Material and Methods: QoL was assessed by the European Organization for Research and Treatment of Cancer QoL questionnaire core-30 (EORTC QLQ C-30) focusing on global health status (GHS)/QoL and social functioning (SF) scales at wks 8 and 32. Analyses assessed change from baseline QoL scores by toxicity (diarrhea, anorexia, nausea, vomiting, fatigue, mucositis, and skin reactions), baseline covariates and ETS (<20% vs $\geqslant$20% at wk 8 only) and tumor response at wks 8 and 32. Multivariate analyses were performed to explain changes in QoL scores.
Results: QoL was evaluable in 476 pts with at least one complete baseline EORTC QLQ C-30. In the multivariate analysis, in the CT + cetuximab arm 155 pts at wk 8 and 55 at wk 32 were used for GHS/QoL, and 154 pts at wk 8 and 55 at wk 32 were used for SF. In the CT arm, 157 pts at wk 8 and 59 at wk 32 were used for GHS/QoL, and 164 pts at wk 8 and 58 at wk 32 were used for SF. Skin reactions did not markedly ($p > 0.2$) impact on GHS/QoL or SF in either treatment arm at the selected timepoints. No clear pattern was observed for the other toxicities. For example, diarrhea significantly affected GHS/QoL at wk 8 in the CT arm ($p = 0.041$) and at wk 32 in the CT + cetuximab arm ($p = 0.022$), and SF at wk 8 in the CT arm ($p = 0.037$), but not at wk 32 in either treatment arm. ETS significantly impacted on GHS/QoL ($p = 0.041$) and on SF ($p = 0.078$) in the CT + cetuximab arm but not in the CT arm (GHS/QoL, $p = 0.14$ and SF, $p = 0.44$). GHS/QoL and SF at baseline had the most pronounced impact ($p < 0.01$) on corresponding QoL scores at wks 8 and 32. No clear pattern was observed for other baseline covariates.
Conclusions: This multivariate analysis confirmed that toxicity, particularly skin reactions, did not markedly impact on QoL in mCRC patients treated with first-line CT + cetuximab. QoL score at baseline and ETS affected GHS and SF scores in this treatment setting.

2269 POSTER

Efficacy of glutamine added to calcium/magnesium on oxaliplatin-induced peripheral sensory neuropathy in patients with colorectal cancer, a phase III study

B. Samson[1], P. Dube[2], N. Aucoin[3], R. Wierzbicki[4], J. Maroun[5], R. Letourneau[6], E. Chen[7], D. Charpentier[8], H. Grassin[9], P. Kavan[10]. [1]*CSSS Champlain Charles-Lemoyne, Oncology and Hematology, Greenfield Park QC, Canada;* [2]*Hopital Maisonneuve-Rosemont, Surgical Oncology, Montreal QC, Canada;* [3]*Hopital de la Cite-de-la-Sante, Oncology and Hematology, Laval QC, Canada;* [4]*RSM Durham Regional Cancer Centre, Oncology, Oshawa ON, Canada;* [5]*The Ottawa Hospital Cancer Centre, Oncology, Ottawa ON, Canada;* [6]*CHUM-Hopital St-Luc, Oncology, Montreal QC, Canada;* [7]*Princess Margaret Hospital, Oncology and Hematology, Toronto ON, Canada;* [8]*CHUM-Hopital Notre-Dame, Oncology and Hematology, Montreal QC, Canada;* [9]*Sanofi Canada, Oncology, Laval QC, Canada;* [10]*McGill University, Oncology, Montreal QC, Canada*

Background: Oxaliplatin (Ox)-based chemotherapy (OxCT) has significantly improved overall survival in patients with various settings of colorectal cancer (CRC). Peripheral sensory neuropathy (PSN) is the dose limiting toxicity leading to dose reduction or treatment discontinuation which may compromise efficacy and patients' quality of life. Calcium/magnesium (CaMg) significantly reduces PSN occurrence, dose reduction and treatment interruption without affecting OxCT efficacy in randomized trials. In a phase II randomized study, glutamine (Glu) reduced the incidence and severity of OxCT induced PSN.
Methods: A Canadian, multicenter, randomized, open-label, phase III clinical trial was initiated to assess the benefit of Glu when added to

CaMg on the occurrence of OxCT PSN in patients with CRC (NCI-CTCAE grade (G) 2−4). Secondary outcomes include cumulative dose of Ox at the occurrence of G 2−4 PSN and incidence of subsequent dose-reduction and dose-delay. A total of 200 Ox-naive patients with ECOG ⩽2 were treated in adjuvant or metastatic 1st-line setting (mCRC) with an OxCT (FOLFOX4, mFOLFOX6, XELOX). Both arms received OxCT with CaMg (1g Ca, 1g Mg IV before and after Ox) for 6 months with (arm A n = 103) or without (arm B n = 97) Glu with a 6-month follow-up. Glu was given as 30 g/d for 7 days starting 2 days before Ox.
Results: Baseline characteristics were balanced between the 2 groups. Most of the patients received OxCT in the adjuvant setting (71%), with either mFOLFOX6 (89%) or FOLFOX4 (11%). Patients with mCRC (29%) received either mFOLFOX6 (88%), FOLFOX4 (9%) or XELOX (3%). Occurrence of G 2−4 PSN and median time to 1st occurrence were not significantly different between the 2 arms (arm A: 36.9%, 177 days; arm B: 36.1%, 174 days, p > 0.5). No difference was observed in the median cumulative dose of Ox at 1st occurrence of G 2−4 PSN (arm A: 655 mg; arm B: 680 mg, p > 0.5) or in the median number of cycles (10 in both arms). No difference was seen in dose reduction rates (32% and 34%, p > 0.9) and in CT delay occurrences (11.7% and 9.3%, p > 0.5) due to G 2−4 PSN, in arm A and B respectively.
Conclusions: The addition of glutamine does not further enhance the benefit of CaMg in PSN prevention in CRC patients treated with oxaliplatin-based regimen. The benefit of CaMg is comparable to historical controls.

2270 POSTER

Effect of peri-operative high protein nutritional support on post-operative complications and costs of treatment in patients with colorectal cancer

V. Manásek[1], K. Bezdek[2], A. Foltys[3], K. Klos[4], J. Smitka[5], D. Nmehlík[6].
[1]Onkology and Radiotherapy Novy Jicin, Oncology, Novy Jicin, Czech Republic; [2]Onkology and Radiotherapy Novy Jicin, ICU, Novy Jicin, Czech Republic; [3]Faculty Hospital Ostrava, Surgery, Ostrava, Czech Republic; [4]Hospital Vítkovice, Surgery, Vítkovice, Czech Republic; [5]Nutricia a.s., Medical, Praha, Czech Republic; [6]RBP-ZP a.s., Health Policy, Ostrava, Czech Republic

Background: Purpose of the study was to investigate the impact of high protein oral nutrition supplement (ONS) on clinical and economical outcomes in patients with colorectal cancer (CRC).
Primary Objective of the study was to assess the effect of pre- a post-operative nutritional support on frequency of complications, rehospitalization rate and length of stay (LoS) independently of initial nutritional status of patients.
Secondary Objective was to assess the impact of nutrition support on costs of treatment.
Patients and Methods: Study group (SG; n 37) represented patients with CRC without distant metastases for whom radical surgery was indicated. Patients aged 18−80 years were included (mean age 64). Nutritional support represented daily application of 2 pieces of high protein ONS (Nutridrink Protein®, 600kcal, 40g of protein), performed 10 days before surgery and 2 weeks postoperatively, consumed between meals.
Control group (CG; n 106) created patients with the same inclusion criteria as SG with conventional nutritional support.
Parameters monitored: wound/anastomosis dehiscence, infection in wound, re-hospitalization related to basic diagnosis, nutritional risk before and after surgery (protocol of The Working Group on Nutritional Care in Oncology, The Czech Oncology Society), nutritional status (weight, BMI) before and 1 month after surgery, (LoS, ONS consumption, patients palatability, ONS benefits for the patients, costs of treatment (procedures, materials, drugs incl. antibiotics, total costs) during hospitalization and 6 months after surgery excluding chemo/radiotherapy.
Results: 37 patients in SG were compared with 106 patients in CG. There was significant decrease of BMI before and after surgery (mean BMI 24.6 versus 25.3, respectively, p = 0.014) and slow-down of loss of weight after surgery (mean 5.4% before, mean after surgery 2.5%, p = 0.055).
31 patients (86.1%) liked ONS product and 33 patients (91.7%) appraised its benefits.
SG showed 2.3× lower relative occurrence of wound dehiscence, 2.9× lower relative occurrence of anastomosis dehiscence, 2.1× lower relative occurrence of infection in wound and 1.8× lower relative risk of rehospitalization. Mean LoS in SG was 9.6±5.8 days, in CG 12±6.4 days. It was approved that longer LoS determine higher total costs of hospitalization in both groups of patients (p = 0.01).
All treatment expenses were significantly decreased in SG vs CG, including costs of antibiotics during hospitalization and 6 months after surgery as well (p = 0.01). Patients without complications had significantly lower costs of drugs (p = 0.02), including antibiotics (p = 0.01) vs patients with complications. Mean total costs per 1 day in hospital was reduced by 10% in SG compare to CG. Mean total costs per 1 day in hospital in patients without complications declined to 508.4 EUR, median 443.8 EUR, compared to the group of patients with complications (mean total costs 527.2 EUR, median 548.7 EUR).
Conclusion: Pre- and post-operative nutritional intervention with high protein ONS reduces occurrence of post-operative complications, LoS and significantly reduces costs of treatment during hospitalization and 6 months after surgery as well in patients with CRC regardless of initial nutritional status. Nutridrink Protein® was well tolerated with positive evaluation of its benefits by patients.
No conflict of interest.

2271 POSTER

Positron emission tomography (PET) interest in the follow-up of colorectal cancer stage II and III: PETCOLON study

S. Lavau-Denes[1], J. Monteil[2], X. Zasadny[3], M. Duluc[4], O. Mundler[5], D. Smith[6], E. Bullier[7], D. Pezet[8], F. Cachin[9], N. Tubiana-Mathieu[1].
[1]CHU Dupuytren, Medical Oncology, Limoges, France; [2]CHU Dupuytren, Nuclear Medicine, Limoges, France; [3]Clinic Chenieux, Radiotherapy, Limoges, France; [4]CHU la Timone, Gastro-enterology, Marseille, France; [5]CHU la Timone, Nuclear Medicine, Marseille, France; [6]CHU Saint André, Gastro-enterology, Bordeaux, France; [7]CHU Haut Lévèque, Nuclear Medicine, Bordeaux, France; [8]CHU, Surgery, Clermont-Ferrand, France; [9]CHU, Nuclear Medicine, Clermont-Ferrand, France

Background: Survival after relapse of the colorectal cancer depends on the possibility of curative action. To detect relapses earlier, we designed a phase III open-labelled, multicenter, randomised study to compare Positron Emission Tomography (PET) with 18 fluorodesoxyglucose (^{18}FDG) to conventional follow-up.
Material and Methods: Patients were aged 18 or more. All patients underwent curative surgery for colorectal cancer, and could have received an adjuvant treatment with chemo or radio-chemotherapy, regarding to initial staging. Patients with uncontrolled diabetes were excluded from the screening. Confirmed Stage II or III was mandatory, and initial assessment to find metastases was performed, using complete colonoscopy, liver ultrasound and Chest X-Ray (or chest and abdominal CT-scan). Patients were randomized no more than 3 months after surgery to either control arm (standard follow-up: carcinoembryonic (ACE) levels, US liver and chest X-Ray or CT Scan) or PET performed every 6 months, during 3 years. All PET were blindly reviewed by an independent committee including nuclear and oncologist practitioners.
Results: Fifteen centres in France participated. A total of 376 patients were randomized from March 2004 to January 2010: 203 males and 173 females. One hundred and eighty-four patients were included in control arm and 192 in PET arm. The mean age was 65 years old. There were 22% of rectal cancers. One hundred and ninety-four patients were stage III (52%). Two hundred and seventy-two received chemotherapy after surgery (72%).
Conclusion: The primary objective is the delay between surgery and detection of colorectal cancer relapse during the 3 years of follow-up. Some results will be available for the congress, especially about systematic review of PET.
No conflict of interest.

2272 POSTER

Patients' experience of pain and anxiety during high-dose-rate brachytherapy for rectal cancer

S. Neron[1], S. Perez[1], R. Benc[2], A. Bellman[1], Z. Rosberger[1], T. Vuong[2].
[1]Jewish General Hospital McGill University, Oncology, Montreal, Canada; [2]Jewish General Hospital McGill University, Radiation Oncology, Montreal, Canada

Background: Pain and anxiety has been reported as the primary concerns of patients with head and neck, gynecological and prostate cancer who undergo high-dose rate (HDR) brachytherapy. However, the medical literature provides virtually no data about the degree of these symptoms experienced by rectal cancer patients who undergo brachytherapy. We conducted a pilot study to examine rectal cancer patients' experience during brachytherapy, including the intensity and trajectory of anxiety and pain.
Methods: Rectal cancer patients (*N* = 25) who received brachytherapy treatment at a hospital in Montreal, Canada completed verbal analog scales

(VAS) for pain and anxiety at four specific time-points, on four procedure days.
Results: On all four days, prior to insertion of the applicator, patients reported moderate to severe anxiety. Pain significantly increased from when patients were lying on the table to immediately after insertion of the applicator, on all four days, $p < 0.001$. The insertion of the applicator was the most painful point of the procedure. Anxiety decreased below the baseline level after the applicator was removed. Pain, however, remained elevated even after removal. A subset of patients (12−32%) required additional conscious sedation. Despite additional pain medication, patients who received pain medication reported more frequently moderate/severe pain compared to those who did not, $p < 0.05$).
Conclusion: HDR rectal brachytherapy is well tolerated by majority of patients with rectal cancer. However, it is a stressful and painful procedure for at least some participants. The insertion of the applicator was found to be a point of maximal pain. For some, the pain medication was not completely successful at alleviating their pain, suggesting that perhaps additional psychosocial interventions may be needed, with particular emphasis on the time of insertion of the applicator as a target for these interventions.

2273 POSTER

Clinical significance of serum epiregulin level in prediction of clinical outcome and skin toxicity in KRAS wild-type metastatic colorectal cancer patients treated with anti-epidermal growth factor receptor antibodies

A. Kubo[1], N. Takahashi[2], Y. Yamada[2], K. Nagashima[3], S. Iwasa[2], Y. Honma[2], A. Takashima[2], K. Kato[2], T. Hamaguchi[2], Y. Shimada[2]. *[1]National Cancer Center Hospital, Pharmaceutical Service, Tokyo, Japan; [2]National Cancer Center Hospital, Gastrointestinal Oncology Division, Tokyo, Japan; [3]Josai University, Faculty of Pharmaceutical Science, Saitama, Japan*

Background: Binding of ligands such as EGF, TGF-alfa, and epiregulin to the epidermal growth factor receptor (EGFR) leads to activation of intracellular signal pathways, but the clinical effect of serum EGFR ligands on the treatment with anti-EGFR antibodies is uncertain. We conducted this study to evaluate the predictive roles of serum ligands in terms of prognosis and skin toxicity in the anti-EGFR antibody treatment of *KRAS* wild-type patients with metastatic colorectal cancer (mCRC).
Material and Methods: Between August 2008 and August 2011, serum samples stocked in the department of clinical laboratories in the National Cancer Center Hospital were obtained from *KRAS* wild-type patients who received anti-EGFR antibody treatment as third-line or subsequent chemotherapy. Main inclusion criteria were as follows: ECOG PS 0 to 2, refractory or intolerant to fluoropyrimidine, oxaliplatin, irinotecan as prior chemotherapy, adequate renal and liver functions. Serum concentrations of ligands were measured by enzyme-linked immunosorbent assay. Clinical outcome and skin toxicities (acneiform eruption and paronychia) were monitored during anti-EGFR antibody treatment from a database in our hospital.
Results: A total of 103 patients were enrolled to the present study. At the pre-treatment serum levels, patients with high levels of epiregulin had shorter progression-free survival (PFS) and overall survival (OS) compared to those with low levels of epiregulin (PFS, 6.6 months vs 4.9 months, HR = 0.618, $P = 0.016$; OS, 13.8 months vs 7.4 months, HR = 0.621, $P = 0.035$; log-rank test). Although there was no significant difference, a better response rate was observed in patients with low epiregulin compared to those in the high epiregulin group (40.4% vs 23.5%, $P = 0.091$). Eleven patients (11%) had no skin toxicity, and 92 (89%) patients had some skin toxicity during the treatment. The occurrence of skin toxicity was associated with lower pre-treatment concentration of serum epiregulin ($P = 0.031$). On the other hand, the concentration of serum EGF, TGF-alfa, etc. had no correlation with efficacy and skin toxicity of anti-EGFR antibody treatment.
Conclusions: Our study indicated that high levels of epiregulin at pre-treatment were associated with resistance to treatment with anti-EGFR antibodies and lesser skin toxicities in *KRAS* wild-type patients with mCRC.
No conflict of interest.

2274 POSTER

Peripheral immunosuppressive cell levels as predictive marker for the clinical outcome in stage IV colorectal carcinoma

A. Koutoulaki[1], Z. Zafeiriou[2], D. Skalidaki[1], D. Aggouraki[1], K.E. Vetsika[1], D. Mavroudis[2], V. Georgoulias[2], A. Kotsakis[2]. *[1]University of Crete, Laboratory of Tumor Cell Biology School of Medicine, Heraklion, Greece; [2]University General Hospital of Heraklion, Medical Oncology, Heraklion, Greece*

Background: Immune suppressive cells, Myeloid-Derived Suppressor Cells (MDSCs) and T Regulatory Cells (Tregs) have been identified as negative prognostic biomarkers in distinct solid tumors. In colorectal cancer (CRC), increased peripheral levels of MDSCs have been correlated to worse survival (Solito S *et al.*; Blood 2011). Although Tregs infiltrated in tumors have been associated with favourable clinical outcome (Salama P *et al.*; JCO 2009), their significance in peripheral blood remains unclear. The aim of the present study was to evaluate the role of these cells in the peripheral blood as a prognostic marker in CRC patients.
Methods: Blood sample was collected from 49 CRC naive patients (Stage IV) prior to 1st line treatment and 33 healthy donors. Flow cytometric analysis of MDSCs ($HLA\text{-}DR^{-}Lin^{-/low}CD33^{+}CD11b^{+}$) and Tregs ($CD3^{+}CD4^{+}CD25^{high}CD127^{low/-}FoxP3^{+}CD39^{+}$) was performed in fresh samples. MDSC and Treg levels of patients and normal controls were analyzed by using unpaired t-test. ROC analysis (area = 0.8539) was used to define high versus low MDSC levels, whereas the median value of Tregs in normal controls was used as a cut-off. Among patients that relapsed, Kaplan–Meier analysis was used to compare time to tumor progression (TTP) with high and low levels of MDSCs and Tregs.
Results: The median percentages of MDSCs and Tregs in patients were significantly increased compared to controls (Mann Whitney test: $p < 0.0001$; $p = 0.0111$, respectively). MDSCs were positively correlated to Treg levels (Spearman's $r^2 = +0.408$; $p = 0.048$). Patients with high levels of MDSCs at baseline, but not Tregs ($p = 0.7165$), relapsed earlier to those with low levels ($p = 0.0348$; 9.83 vs. 4.93 months, respectively).
Conclusions: CRC patients have elevated peripheral levels of immuno-suppressive cells. MDSCs seem to be an independent prognostic factor for TTP. The significance of the observed correlation of MDSCs with Tregs and the suppressive mechanisms of these cells will be further investigated. Updated survival data will be presented in an increased cohort of patients.
No conflict of interest.

2275 POSTER

Tumor genetic analysis of PRIME: KRAS, NRAS, and BRAF mutations as predictive biomarkers in patients with metastatic colorectal cancer (mCRC) receiving first-line treatment with panitumumab (pmab) + FOLFOX4

K. Oliner[1], J.Y. Douillard[2], S. Siena[3], J. Tabernero[4], R. Burkes[5], M. Barugel[6], Y. Humblet[7], A. Rong[8], R. Sidhu[9], S. Patterson[10]. *[1]Amgen Inc, Medical Sciences − IVD, Thousand Oaks CA, USA; [2]ICO Rene Gauducheau, Oncology, Nantes, France; [3]Ospedale Niguarda Ca' Granda, Dipartimento di Ematologia ed Oncologia, Milan, Italy; [4]Vall d'Hebron University Hospital, Vall d'Hebron Institute of Oncology, Barcelona, Spain; [5]Mount Sinai Hospital, Oncology, Toronto, Canada; [6]Hospital de Gastroenterología, Oncology, Buenos Aires, Argentina; [7]Universite Catholique de Louvain, Centre du Cancer, Brussels, Belgium; [8]Amgen Inc., Biostatistics, Thousand Oaks CA, USA; [9]Amgen Inc., Clinical Development, Thousand Oaks CA, USA; [10]Amgen Inc., Medical Sciences − IVD, Thousand Oaks CA, USA*

Background: The results from a phase 3 pmab monotherapy study suggested that patients with mutant (MT) *KRAS* or *NRAS* mCRC tumors beyond *KRAS* exon 2 may not respond to pmab treatment.
Methods: The primary objective of this prospectively defined retrospective analysis of PRIME was to evaluate the treatment effect of pmab + FOLFOX4 vs FOLFOX4 alone in patients with mCRC based on *RAS* (*KRAS* or *NRAS*) or *BRAF* mutation status. Eligibility was defined by baseline wild-type (WT) *KRAS* exon 2 tumor status from the primary analysis. To identify mutations in *KRAS exon 3, exon 4*; *NRAS exon 2*, *exon 3, exon 4*; and *BRAF exon 15,* 'gold standard' bidirectional Sanger sequencing and WAVE-based SURVEYOR® from Transgenomic were independently performed. An updated exploratory analysis of OS (when OS data was available for >80% of patients in both the WT and MT *KRAS* exon 2 subgroups), the most mature estimate in PRIME, was used in this analysis.
Results: The *RAS* ascertainment rate was 90% of enrolled patients. In patients with WT *RAS* mCRC, median OS improved by 5.6 months for patients receiving pmab + FOLFOX4 vs FOLFOX4 alone. The OS treatment hazard ratio (HR) was 0.77 (95% confidence interval [CI], 0.64–0.94; $p = 0.009$). 17% of patients (108/641) were WT *KRAS* exon 2/MT other

RAS. The OS treatment HR for this subgroup was 1.39 (95% CI, 0.91–2.13; p = 0.118). Treatment HRs for patients with WT or MT *BRAF* were inconsistent with a predictive biomarker (table). No new safety signals were identified.

Conclusions: This analysis of an exploratory, updated OS dataset suggests that the benefit:risk of pmab + FOLFOX4 treatment is increased by excluding additional patients with mutations in *RAS* beyond *KRAS* exon 2. In patients with WT *RAS* mCRC, an improved OS benefit (p = 0.009) was observed in the pmab + FOLFOX4 vs FOLFOX4 alone arm. Consistent with *KRAS* exon 2 mutations, inferior outcomes were observed in the WT *KRAS* exon 2/MT *RAS* subgroup in the pmab + FOLFOX4 arm. There was no evidence in this study that *BRAF* mutations had predictive value.

Background: In the phase 3 VELOUR trial, aflibercept + FOLFIRI (irinotecan, 5-FU, and leucovorin) demonstrated a statistically significant overall survival benefit compared with FOLFIRI alone in metastatic colorectal cancer (mCRC) patients (pts) previously treated with an oxaliplatin-containing regimen. Evidence from the VELOUR trial supported the initiation of the global Aflibercept Safety and Quality-of-Life (QoL) Program composed of 2 clinical studies (ASQoP [NCT01571284]; AFEQT [NCT01670721]) to capture utility values from QoL instruments and collect safety data from a target population similar to that in VELOUR in a real-life setting. We report early safety data from these ongoing studies.
Methods: ASQoP and AFEQT are single-arm, open-label trials evaluating safety and health-related QoL of aflibercept in mCRC pts previously treated with an oxaliplatin-containing regimen. Estimated total enrollment is ~1100 mCRC pts from ~180 global sites. Eligible pts receive aflibercept (4 mg/kg) q2wks on day 1 of each cycle followed by FOLFIRI up to disease progression, unacceptable toxicity, death, or investigator/patient decision. FOLFIRI starting dose and subsequent additional dose modifications are at the discretion of the treating physician. Safety assessments follow each cycle and continue until 30 days after last drug administration. The percentage of pts with grade 3/4 adverse events (G3/4 AEs) in the combined safety population of ASQoP and AFEQT are compared with that of VELOUR.
Results: At data cut-off, the safety population comprised 116 pts with at least 1 completed cycle of treatment. Baseline demographic characteristics were similar to those in VELOUR. At least 1 G3/4 AE was experienced by 54.3% of pts vs 83.5% in VELOUR. Most reported G3/4 AEs were G3. There were no reports of G4 hypertension or diarrhea. More data will be reported at the congress.

Grade 3/4 Adverse Event	Percentage of patients	
	ASQoP and AFEQT	VELOUR
Proteinuria	0.9	2.9
Stomatitis	3.4	12.8
Diarrhea	8.6	19.3
Infections	12.1	12.3
Hypertension	16.4	19.1

Conclusions: In VELOUR, AEs occurred early in treatment, were often a single occurrence, generally reversible, and consistent with AEs commonly seen by medical oncologists. Interim safety analysis from ASQoP and AFEQT has identified no new safety signals. The early interim analysis provides additional safety data and suggests a lower toxicity in this real-life setting.

2277 POSTER

Survival after resection of colorectal liver metastases: Is the primary nodal status still a prognostic factor?

M. Reitsma[1], W.J. Alberda[1], J. Rothbarth[1], D.J. Grünhagen[1], C. Verhoef[1].
[1]*Erasmus MC Daniel den Hoed, Surgical Ongology, Rotterdam, Netherlands*

Background: Several prognostic variables determine survival after resection of colorectal liver metastasis (CRLM). These prognostic factors are included in clinical risk scores (CRS), which are used to predict outcome. Fong's CRS (1999) is most widely used and validated. It includes lymph node status of the primary tumor as a prognostic factor. Since its introduction however, the use of adjuvant chemotherapy in node positive colon cancer patients has improved survival significantly. Furthermore, the TME (total mesorectal excision) technique and the use of neoadjuvant radiotherapy for rectal cancer has improved outcome in these patients. This study focuses on the impact of nodal positivity of the primary tumor after liver resection for CRLM.
Methods: Between January 2000 and December 2009, all consecutive patients who underwent curative liver resection for CRLM were prospectively included. Patients were excluded if no resection of the primary was performed, if therapy was with no curative intent or if nodal status of the primary tumor was unknown. Minimal follow up was 2 years. Survival of patients was analyzed by location of primary tumor (colon or rectum) and by lymph node status (Npos vs. Nneg) of the primary tumor.
Results: Of 446 consecutive liver resections, 429 patients met the inclusion criteria. In 246 patients a primary colon carcinoma (148 Npos, 98 Nneg) and in 183 a primary rectal carcinoma (99 Npos, 84 Nneg) was found. All patient- and tumor characteristics were comparable; only adjuvant chemotherapy was administered more in colon primaries (p < 0.0001). Median follow up was 37 months (0–145), in colon primaries 38 (0–131) and 36 months (0–145) in rectal primaries. The estimated 5-year survival after liver resection was 54% (colon) vs. 48% (rectum) respectively (p = 0.213). The estimated 5-year survival of primary colon carcinoma patients was comparable between Npos and Nneg patients (50% vs. 57%, p = 0.33). In rectal carcinoma patients it was 37% (Npos) vs. 59% (Nneg) (p = 0.003). Comparison between the colon and rectal node positive tumors also showed a significant difference (50% vs. 37% respectively, p = 0.04).
Conclusions: The present data show that nodal positivity of the rectal primary tumor is a prognostic factor for survival, but not in case of primary colon cancer. The more frequent use of adjuvant chemotherapy after resection of the primary in the group with colon cancer could be an explanation for this phenomenon.

Metachronous peritoneal carcinomatosis after curative treatment of colorectal cancer

Y.R.B.M. Van Gestel[1], I. Thomassen[1], V.E.P.P. Lemmens[1], J.F.M. Pruijt[2], M.P.P. Van Herk-Sukel[3], H.J.T. Rutten[4], G.J.M. Creemers[5], I.H.J.T. De Hingh[4]. *[1]Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands; [2]Jeroen Bosch Hospital, Internal Medicine, 's-Hertogenbosch, Netherlands; [3]PHARMO Institute for Drug Outcome Research, Research, Utrecht, Netherlands; [4]Catharina Hospital, Surgery, Eindhoven, Netherlands; [5]Catharina Hospital, Internal Medicine, Eindhoven, Netherlands*

Introduction: Population-based data on metachronous peritoneal carcinomatosis (PC) after curative resection of colorectal origin are scarce. The aim of this study was to investigate the incidence of and risk factors for developing metachronous PC from colorectal cancer as well as survival since diagnosis of PC.
Material and Methods: Data on metachronous metastases were collected between 2010 and 2011 for all patients diagnosed with M0 colorectal cancer between 2003 and 2008 in the Dutch Eindhoven Cancer Registry. Median follow-up was 5.0 years. Survival was defined as time from metastases diagnosis to death.
Results: During follow-up, 1042 (18%) patients were diagnosed with metastatic disease of whom 197 (19%) developed metachronous PC. The peritoneal surface was the only site of metastasis in 81 (41%) patients while 116 (59%) patients were diagnosed with both PC and metastases elsewhere. Median survival after diagnosis of PC was 6 months compared to 15 months for patients with distant metastases in other organs. Patients with an advanced primary tumour stage, positive lymph nodes at initial diagnosis, primary mucinous adenocarcinoma, positive resection margin and a primary tumour located in the colon were at increased risk of developing metachronous PC.
Conclusions: Approximately one fifth of initially M0 colorectal cancer patients who developed metastases during follow-up is diagnosed with PC. Prognosis of these patients is poor with a median survival of 6 months after PC diagnosis. Identifying patients at high risk for developing metachronous PC is important as it may contribute to more accurate patient information, tailor-made follow-up schemes, and more adequate treatment.

2279 POSTER

Risk of treatment-related mortality with bevacizumab treatment in advanced cancers

F. Roncolato[1], P. Ding[2], S. Lord[3], V. Gebski[3], C. Lee[3]. *[1]Prince of Wales Cancer Center, Randwick New South Wales, Australia; [2]Liverpool Hospital, Medical Oncology, Liverpool New South Wales, Australia; [3]NHMRC Clinical Trials Centre, Camperdown New South Wales, Australia*

Background: Treatment with combination bevacizumab and chemotherapy has been associated with improvement in progression-free survival (PFS) for many advanced cancers. A prior meta-analysis of a limited number of randomised controlled trials (RCTs) reported increased risk of bevacizumab treatment-related mortality (TRM). As bevacizumab is frequently administered as prolonged maintenance therapy following completion of standard course of chemotherapy, previous studies have not accounted for the differences in duration of drug exposure. We performed an updated meta-analysis to estimate the overall risk of bevacizumab treatment-related mortality accounting for differences in drug exposure.
Methods: RCTs comparing combination bevacizumab chemotherapy or targeted biological therapy vs chemotherapy or targeted biological therapy alone were included. We extracted data on TRM events, and computed pooled relative risks (RR) adjusted for treatment arm median PFS, expressed as the ratio of the mortality rates in the bevacizumab arm versus the control group. In trials with more than 2 bevacizumab containing arms, RR was estimated separately for each arm.
Results: A total of 16 282 patients with various advanced solid tumours from 24 RCTs were included. Combination bevacizumab chemotherapy or targeted biological therapy was not associated with a statistical significant increase of TRM after accounting for differences in duration of drug exposure (unadjusted RR 1.39, 95% CI 1.14−1.7; adjusted RR 1.09, 95% CI 0.89–1.33). TRM was significantly higher when bevacizumab was combined with platinum or taxane chemotherapy (unadjusted RR 1.53, 95% CI 1.19–1.97; adjusted RR 1.31, 95% CI 1.01–1.69). Higher (5.0 mg/kg per week; adjusted RR 1.30, 95% CI 0.97–1.74) or lower (2.5 mg/kg per week; adjusted RR 0.94, 95% CI 0.70–1.26) dose of bevacizumab were not significantly different (P = 0.13) and did not impact on TRM. TRM varied significantly according to different advanced cancers (P = 0.001), with higher risks observed for non-small cell lung (adjusted RR 1.46, 95% CI 0.96–2.24), pancreatic (adjusted RR 1.76, 95% CI 0.98–3.18), and ovarian (adjusted RR 1.75, 95% CI 0.91–3.38) cancers but lower risks observed for breast (adjusted RR 0.51, 95% CI 0.30–0.88), renal (adjusted RR 0.51, 95% CI 0.22–1.17), and colorectal (adjusted RR 0.97, 95% CI 0.61–1.53) cancers.
Conclusion: Combination bevacizumab chemotherapy or targeted biological therapy was not associated with an overall increase in TRM after accounting for prolonged bevacizumab exposure. The use of platinum or taxane chemotherapy with bevacizumab increased the risk of TRM. The increased risks of TRM also varied with different advanced cancers but not with different doses of bevacizumab.
No conflict of interest.

Utility assessment of health-related quality of life in 2nd-line metastatic colorectal cancer patients: interim analyses of the global Aflibercept Safety and HR-QoL Program

A. Sobrero[1], R. Bordonaro[2], S. Siena[3], L. Ciuffreda[4], A.L. Thomas[5], J. Taieb[6], G. Lledo[7], F. Joulain[9], D.R. Ferry[10]. *[1]IRCCS San Martino, Medical Oncology, Genova, Italy; [2]ARNAS Garibaldi Catania, Oncology, Catania, Italy; [3]Ospedale Niguarda Ca' Granda Milano, Dipartimento di Ematologia ed Oncologia, Milano, Italy; [4]A.O. Citta' Della Salute E Della Scienza Di Torino, SC. Oncologia Medica 1, Torino, Italy; [5]University of Leicester, Cancer Studies and Molecular Medicine, Leicester, United Kingdom; [6]APHP and Paris Descartes University, GI Oncology, Paris, France; [7]Hopital Jean Mermoz, Lyon, France; [8]Sanofi Oncology, Global Evidence & Value Development, Cambridge, USA; [9]Sanofi Research and Development, G-EVD, Chilly-Mazarin, France; [10]New Cross Hospital, Oncology, Wolverhampton, United Kingdom*

Background: In the phase 3 VELOUR trial, aflibercept + FOLFIRI provided a significant overall survival benefit compared with FOLFIRI alone in metastatic colorectal cancer (mCRC) patients previously treated with an oxaliplatin-containing regimen. Evidence from the VELOUR trial supported the initiation of the global Aflibercept Safety and Quality-of-Life (QoL) Program composed of 2 clinical studies (ASQoP [NCT01571284] and AFEQT [NCT01670721]) that capture utility values derived from QoL instruments and collect every-day safety data from a target population similar to that in VELOUR in a real-life setting. This analysis reports early interim data on QoL-based utility values from both the ASQoP and AFEQT studies.
Methods: Target recruitment in ASQoP is 900 patients across 150 multiple country investigational sites and 200 patients in AFEQT across sites in France. The EuroQol EQ-5D™ instrument was selected as the utility measure. The QoL population of the EQ-5D consists of all patients who completed the EQ-5D questionnaire at baseline and at least 1 assessment postbaseline, and who received at least part of 1 dose of study treatment. The EQ-5D instrument was self-administered at baseline within 3 days prior to first treatment administration and subsequently at the beginning of every odd cycle of treatment.
Results: At the data cut-off date, for the current analysis, EQ-5D data from 67 patients were analyzed; 56.7% were male; median age was 64 years (range 33 to 78 years); and 73.1% had Eastern Cooperative Oncology Group scores of 0. Mean (± SD) utility index at baseline was 0.77 (± 0.22). Utility index remained stable in 63 evaluable patients at cycle 3 and in the 30 evaluable patients at cycle 5, with a mean (± SD) change from baseline of +0.01 (± 0.24) and −0.02 (± 0.25), respectively.
Conclusion: Initial trends suggest that treatment with aflibercept does not result in decrements in QoL for 2nd-line mCRC patients. These results have important implications in advanced cancer settings, as patient-reported outcomes provide an informed perspective on the patient's health status and well-being.

2281 POSTER

HER-2 overexpression in colorectal cancer is associated with KRAS wildtype status − analysis of a large consecutive series

J. Quidde[1], F. Ehnert[1], A. Stein[1], C. Bokemeyer[1], T. Grob[2]. *[1]University Hospital Hamburg, Hubertus Wald Tumor Center − University Cancer Center Hamburg Department of Oncology Haematology, Hamburg, Germany; [2]University Hospital Hamburg, Department of Pathology, Hamburg, Germany*

Background: Despite current developments including monoclonal antibodies, fusion proteins and tyrosine kinase inhibitors survival of metastatic colorectal cancer (CRC) remains poor. Therefore, evaluation of new targets is a critical issue. Human Epidermal growth factor Receptor

2 (HER2) is a cell membrane surface-bound receptor tyrosine kinase, involved in signal transduction pathways leading to cell proliferation and differentiation (e.g. MAPK and PI3K/AKT pathways). HER2 overexpression and/or amplification occur in about 20% of patients with breast and gastric cancer. For this molecular subset of patients distinct molecular targeting drugs are available (e.g. trastuzumab, pertuzumab). Data on the prevalence of HER2 overexpression and/or amplification in CRC are conflicting, with positivity rates ranges from 0 to 83%. Moreover, higher rates have been reported in rectal cancer (up to 30%).
Material and Methods: The current analysis included 763 consecutive patients with colorectal cancer, which underwent surgery for primary tumor or metastatic disease. All malignant lesions were collected in the Department of Pathology and staged according to TNM system. Besides determination of KRAS mutational status, HER2 amplification was measured by fluorescent in situ hybridization (FISH) according to the guidelines for breast and gastric cancer (ratio HER2/CEP17 $\geqslant$2).
Results: The median age of the collective was 69.7 years (range 26.5–98.7 years). 335 were female and 428 male patients. Primary tumor (PT) site was colon in 548 patients (caecum to sigmoid colon) and rectum in 211 patients (including recto-sigmoid junction). 503 PTs were left-sided (66.27%). KRAS, analyzed in 753 tumors, was mutated in 38.6% (n = 291, male 151, female 140) of which 67.4% were left-sided. Out of 763 evaluable specimens14 (1.83%) showed HER2 gene amplification by FISH. Distribution of HER2 amplified CRC were 5 (35.7%) right sided and 9 (64.3%) left sided. HER2 amplified patients had a median age of 64.1 years; 3 were female and 11 were male. Concomitant KRAS mutation was noted only in one tumor (p = 0.006).
Conclusion: In colorectal cancer HER2 amplification occurs rarely, if screened by FISH analysis (about 2%). Activation of the MAPK pathway by KRAS mutation is rare in HER2 amplified CRC.
No conflict of interest.

2282 POSTER

Early tumour shrinkage has a favorable impact on clinical outcome in KRAS wild-type colorectal liver-limited metastases treated with cetuximab plus chemotherapy

L.C. Ye[1], Y.S. Zhong[1], Y. Wei[1], L. Ren[1], D.X. Zhu[1], J.W. Chen[1], W.J. Chang[1], Q. Lin[1], Q.Y. Feng[1], J.M. Xu[1]. *[1]Zhongshan Hospital Fudan University, General Surgery, Shanghai, China*

Background: Recently, early tumour shrinkage (ETS) was reported to predict outcome in metastatic colorectal cancer treated with cetuximab (cet). This study was to evaluate the impact of ETS on long-term outcome in patients (pts) with wild-type-KRAS unresectable colorectal liver-limited metastases (CLLM) receiving cet plus chemotherapy (CT, FOLFIRI or mFOLFOX6).
Material and Methods: 138 pts treated in a randomized controlled trial (70 in arm A received CT plus cet and 68 in arm B received CT alone) previously reported (Jianmin et al, ESMO 2012, abstract-557, ClinicalTrials.gov, number NCT01564810) were included into this analysis. ETS was defined as a reduction of $\geqslant$20% in the sum of the longest diameters of target lesions compared to baseline at the first evaluation (8 weeks). Outcome measures were progression-free survival (PFS) and overall survival (OS).
Results: 132 pts were available for evaluation, and ETS occurred more frequently in arm A than that in arm B (45/68 vs. 26/64, p = 0.003). Irrespective of treatment arm, pts achieved ETS were associated with longer OS (arm A: 38.0 vs. 18.7 months, p < 0.001; arm B 30.6 vs.17.7 months, p = 0.003) and PFS (arm A: 11.8 vs. 4.8 months, p < 0.001; arm B 8.0 vs. 4.6 months, p = 0.001) when compared to pts with no-ETS. Among pts with ETS, there were statistic difference between arm A and arm B in terms of PFS (11.8 vs. 8.0 months, p = 0.041) but not of OS (38.0 vs. 30.6 months, p = 0.30); the converted resection rates for liver metastases were 40.0% (18/45) in arm A and 19.2% (5/26) in arm B, which were not significantly different (p = 0.072). For pts without liver surgery, pts observed ETS also gained an increased survival benefit over those no-ETS in arm A with regards to OS (p = 0.01) and PFS (p < 0.001) though it was not full certified in arm B (OS: p = 0.054; PFS: p = 0.041). For pts in arm A, cet-induced skin toxicity correlated with the occurrence of ETS (p = 0.048). In addition, cox regression for OS using indicated a hazard ratio of 0.39 (95% CI 0.21–0.72, p = 0.003).
Conclusions: ETS $\geqslant$20% at 8 weeks may serve as a predictor of favourable outcome in pts with wild-type-KRAS CLLM receiving cet plus CT.
No conflict of interest.

2283 POSTER

Which treatment outcomes should be addressed in the pre-radiation consultation with rectal cancer patients? A Delphi consensus study among patients and radiation oncologists

M. Kunneman[1], A.H. Pieterse[1], A.M. Stiggelbout[1], C.A.M. Marijnen[2]. *[1]Leiden University Medical Centre, Medical Decision Making, Leiden, Netherlands; [2]Leiden University Medical Centre, Clinical Oncology, Leiden, Netherlands*

Background: Preoperative radiation (PRT) in rectal cancer is associated with several adverse effects, which should be balanced against the possible benefits for each individual patient. The Dutch national guidelines for the treatment of colorectal cancer states that clinicians need to 'thoroughly discuss the possible benefits and harms of radiation with the patient'. However, which treatment outcomes (benefits and side effects) should be addressed, is not specified and large variation exists in what radiation oncologists tell patients in clinical practice. Our aim was to reach consensus among experts on treatment outcomes to be addressed with new rectal cancer patients.
Material and Methods: An online three round Delphi study was conducted with two expert panels: one of 35 radiation oncologists and one of 31 rectal cancer patients. 37 possible treatment outcomes of radiation were shown, which were based on 45 taped pre-radiation consultations, complemented with outcomes from the literature. Prevalence and severity of outcomes were described. The panel members were asked to indicate whether the outcomes should be addressed in the consultation. Response categories were 1) Essential; 2) Desired; 3) Not necessary; and 4) Avoid. When $\geqslant$80% of the experts agreed on the answer category, it was considered that consensus was reached. Responses from the panels were analyzed separately and fed back in the next round. Radiation oncologists received feedback on patients' responses.
Results: In the first Delphi round, radiation oncologists reached consensus on three outcomes (Essential: infertility in women; menopause; Not necessary: altered appetite). Patients reached consensus on three other outcomes (Essential: infertility in men; prevention of pregnancy; erectile dysfunction). In the second round all outcomes except the three they agreed on were included in each panel. Final results will be presented.
Conclusions: For informed shared decision making, relevant information on benefits and side effects should be given along with a treatment recommendation. This study shows that there is lack of clarity on which treatment outcomes should at the minimum be addressed in the pre-radiation consultation with rectal cancer patients. Reaching consensus is a first step towards more standardized information provision, in which all patients receive information on the major benefits and side effects of PRT, supplemented with outcomes that might be of interest to the individual patient.
No conflict of interest.

2284 POSTER

Relation of response based on morphologic and RECIST criteria with pathologic response in patients with colorectal liver metastases undergoing neoadjuvant or conversion treatment with bevacizumab

P. García Alfonso[1], A. Muñoz Martin[1], M. Blanco Codesido[1], A.B. Rupérez Blanco[1], S. Custodio Cabello[1], M. Cavanagh Podesta[1], D. López-Trabada Ataz[1], M. Martín[1]. *[1]Hospital General Universitario Gregorio Marañón, Medical Oncology, Madrid, Spain*

Background: We aimed to assess efficacy of bevacizumab (BEV) as neoadjuvant or conversion treatment in patients with colorectal liver metastases (CLM) and the relation of the response based on morphologic and RECIST criteria with their outcome after surgery.
Material and Methods: Observational retrospective chart review in patients with CLM treated with neoadjuvant or conversion chemotherapy with BEV as first or second line treatment. Response determined using RECIST and computed tomography morphologic criteria was correlated with pathologic response and disease-free survival (DFS).
Results: 52 patients were evaluated: 78% had synchronic metastases; 10% had initially resectable metastases, 16% irresectable and 74% potentially resectable. 86% and 14% received first and second line BEV prior to surgery, respectively. Initially unresectable metastases become resectable in 86%. R0 was achieved by 88%. A complete pathologic response was seen in 9% and 57% achieved a major response. Median overall survival after surgery was 46 months. DFS after treatment initiation and after surgery was 17 and 9 months respectively. A trend to an extended DFS was seen in patients with complete/major pathologic response compared with those with minor response (18 vs. 15 months; p = 0.19). The relation of morphologic and RECIST response with pathologic response and DFS was analyzed in 25 patients. Partial response (PR) was achieved in 65%, and 31% and 4% had stable and progressive disease respectively.

An optimal morphologic response was reported in 32% and incomplete and no response by morphology was seen in 32% and 36% respectively. There was no difference in median DFS between patients with optimal morphologic response and those with incomplete or no morphologic response (6 vs. 11 months respectively; p = 0.09). Similarly, RECIST response (PR vs. no response) had not a significant association with DFS (18 vs. 17 months; p = 0.39). However, while a similar proportion of patients with morphologic optimal response (50%) and RECIST PR (69%) achieved a complete or major pathologic response (p = 0.28), a significant superior proportion of patients with morphologic incomplete or no response had minor pathologic response compared with RECIST non-responders (100% vs. 25%; p = 0.002).
Conclusions: Our preliminary findings suggest that suboptimal morphologic response to neoadjuvant or conversion treatment with BEV is significantly associated with poor pathologic response after resection of CLM. Nevertheless, a larger cohort will be needed to adequately evaluate morphologic response in this scenario.
No conflict of interest.

2285 POSTER

Changes in body weight during and after colorectal cancer treatment

S. Beijer[1], R. Van Lieshout[2], A. Adriaans[3], G. Vreugdenhil[4], G.D. Slooter[5], L.J.C. Van Warmerdam[6]. *[1]Comprehensive Cancer Centre South, Research Department, Eindhoven, Netherlands; [2]Maxima Medical Center Eindhoven/Veldhoven, Department of Dietetics, Veldhoven, Netherlands; [3]Comprehensive Cancer Center South, Research Department, Eindhoven, Netherlands; [4]Maxima Medical Center Eindhoven/Veldhoven, Department of Internal Medicine, Eindhoven/Veldhoven, Netherlands; [5]Maxima Medical Center Eindhoven/Veldhoven, Department of Surgery, Eindhoven/Veldhoven, Netherlands; [6]Catharina Hospital Eindhoven, Oncology Center, Eindhoven, Netherlands*

Background: In an earlier study [van Waalwijk MA et al. Journal of Comorbidity 2011;1:19−27] among stage III colon cancer patients, preliminary results showed significant weight gain over an unknown period in the group receiving adjuvant chemotherapy. The aim of this study was to investigate weight change in various phases of the treatment of stage II/III colorectal cancer patients receiving adjuvant chemotherapy.
Patients and Methods: All stage II/III colorectal cancer patients, diagnosed in the period 2007 to July 2011 and treated with surgery and adjuvant chemotherapy in the Maxima Medical Center Eindhoven/Veldhoven and the Catharina Hospital Eindhoven, were included. Information about body weight and chemotherapy was retrospectively collected from medical records. Patient, tumor and other treatment characteristics were retrieved from the Eindhoven Cancer Registry. Data were analysed using paired sample t-tests and multivariate linear regression analyses.
Results: 256 patients with a mean age of 64±11 years were included (56% male). 43% of the patients were overweight at diagnosis (BMI 25−30) and 13% were obese (BMI>30). In the period from diagnosis to minimal 6 months of follow-up, body weight decreased during surgery (−2.2±4.1 kg; p = 0.000; weight available in 112 patients); increased during adjuvant chemotherapy (+3.7±5.0 kg; p = 0.000; weight available in 43 patients) and further increased during the follow-up period (+2.2±7.5 kg; p = 0.008; weight available in 87 patients). For weight change per week the same trend was seen. In the total period from diagnosis to minimal 6 months of follow-up, 28% of the patients lost weight; 19% remained stable and 53% gained weight of which 27% gained more than 5 kg. Multivariate regression analysis showed that in the period from diagnosis to the end of chemotherapy as well as in the period from diagnosis to minimal 6 months of follow-up only the number of chemotherapy courses was independently associated with weight gain.
Conclusion: In patients with stage II/III colorectal cancer receiving adjuvant chemotherapy, weight gain occurs during and after chemotherapy after a decline in weight during surgery. Weight gain is related to the number of chemotherapy courses. To clarify the underlying mechanism and consequences of weight gain in stage II/III colorectal cancer patients receiving chemotherapy, more research is needed. Oncology care providers should inform these patients about the possibility of weight gain and promote a healthy life style.
No conflict of interest.

2286 POSTER

The efficacy of palonosetron/dexamethasone plus NK1 receptor antagonist (aprepitant) therapy for prevention of chemotherapy induced nausea and vomiting in colorectal cancer patients

Y. Ozaki[1], T. Horimatsu[2], A. Nozaki[3], S. Hasegawa[4], S. Matsumoto[5], Y. Sakai[4], M. Muto[2]. *[1]Kyoto University Graduate School of Medicine, Department of Gastroenterology and Hepatology, Kyoto, Japan; [2]Kyoto University Graduate School of Medicine, Department of Therapeutic Oncology, Kyoto, Japan; [3]Kyoto Min-iren Chuo Hospital, Division of Medical Oncology, Kyoto, Japan; [4]Kyoto University Graduate School of Medicine, Department of Surgery, Kyoto, Japan; [5]Kyoto University Graduate School of Medicine, Department of Clinical Oncology and Pharmacogenomics, Kyoto, Japan*

Background: All antiemetic guidelines for patients receiving anthracycline/cyclophosphamide (AC)-based moderately emetogenic chemotherapy (MEC) recommend the addition of aprepitant to a regimen of 5-HT3 receptor antagonist and dexamethasone to prevent chemotherapy induced nausea and vomiting (CINV). While recent study showed the efficacy of aprepitant in patients with a wide range of tumor types who received AC and non-AC-based MEC regimen, colorectal cancer (CRC) patients' specific efficacy has been unknown. To investigate the efficacy of addition of aprepitant in the standard MEC regimen in CRC patients, we conducted a multicenter randomized phase II study.
Material and Methods: From August 2011 to March 2013, 60 patients were enrolled and were randomly allocated to the standard regimen [palonosetron plus dexamethasone] or the aprepitant regimen [standard regimen + aprepitant]. Patients used diaries to report the time and data of nausea, vomiting, additional antiemetic use, and dietary intake situation from day1−7. The primary endpoint was the proportion of complete response: CR (no vomiting and no rescue medication). The secondary endpoints were the proportions of complete protection (CR and no nausea at least moderate), no vomiting, no rescue medication, no nausea, no nausea at least moderate, time to treatment failure (first vomiting or rescue treatment), and dietary intake situation.
Results: Fifteen patients were excluded because of insufficient diary and protocol violation. Finally, we analyzed 45 patients (26 male, 19 female) for this study. Twenty-one patients (47%) received the aprepitant treatment and 39 patients (87%) received oxaliplatin-based regimen. During the overall phase (day1−7), the proportion of CR was 68.4% in the aprepitant regimen, and 57.7% in the standard regimen (P = 0.543). During the delayed phase (day2−7), the proportion of CR was 73.7% in the aprepitant regimen, and 57.7% in the standard regimen (P = 0.351). The secondary endpoints did not differ significantly, and there were no notable differences in adverse events between the groups.
Conclusions: In the CRC patients receiving MEC, the addition of aprepitant to standard antiemetic regimen could not provide superior efficacy in preventing CINV in both the overall phase and the delayed phase in this small study. However, 16% increase of CR during the delayed phase in the aprepitant regimen compared to the standard regimen in the CRC patients should be verified by large scale randomized controlled study.

Pre-operative staging of rectal cancer: The diagnostic accuracy of magnetic resonance imaging in predicting nodal status

L. Connell[1], C. Stuart[2], N. Daly[1], B. Mehigan[3], J. Kennedy[1]. *[1]St James's Hospital, Medical Oncology, Dublin, Ireland; [2]St James's Hospital, Gastroenterology, Dublin, Ireland; [3]St James's Hospital, Colorectal Surgery, Dublin, Ireland*

Background: Rectal cancer is a common malignancy with high rates of local pelvic recurrence. Careful pre-operative staging is essential for planning optimal therapy in these patients(pts). Two important prognostic factors include the circumferential resection margin (CRM) and lymph node (LN) status. Magnetic resonance imaging (MRI) is increasingly being used as part of pre-operative staging due to its proven accuracy in determining the CRM. This enables the appropriate selection of pts for neoadjuvant therapy prior to curative surgical resection. The evaluation of nodal status remains problematic. We assessed our institution's experience of neoadjuvant therapy versus upfront surgery in stage I−III rectal cancer to ascertain the accuracy rates and clinical usefulness of MRI as a tool in the pre-operative evaluation of LN status.
Methods: We retrospectively reviewed a prospectively maintained database for all pts with a diagnosis of stage I−III rectal cancer from January 2006 to September 2012 in a specialist colorectal cancer centre. We extracted & analysed data with respect to preoperative MRI staging & definitive histopathological confirmation of LN status.

Results: A total of 210 pts were identified that had surgery for rectal cancer with curative intent. Of these, 112 pts received neoadjuvant therapy while 98 had upfront surgery.
Of those who proceeded directly to surgery, there were 41 females & 57 males. Average age in this sub-group was 73.4 years (range 33 −90). LN staging by MRI was accurate in 45.9% cases (n = 45). LN status could not be evaluated (Nx) in 15.3% (n = 15) on pathology & 2% (n = 2) radiologically. In 19.4% (n = 19) more advanced LN staging was apparent on histology while in 17.3% (n = 17) LN stage was deemed more aggressive by MRI.
Of those who had neoadjuvant therapy, there were 75 males & 37 females. Average age was 62.3 years (range 26−82). In this cohort, 81.3% pts (n = 91) had both a preoperative MRI & pathology report available for comparison. MRI in this group matched histology in 61.5% cases (n = 56). Nx was recorded in 1.1% (n = 1) on pathology & 2.2% (n = 2) on MRI. In 17.6% (n = 16) more aggressive LN involvement was evident at histology while 17.6% (n = 16) had less advanced disease at tissue sampling.
Overall in this study, MRI accurately predicted LN status in 53.4% cases (n = 101). The sensitivity of lymph node invasion was 55% while the specificity was 37%.
Conclusions: While MRI is a valuable tool in determining those pts with rectal cancer that would benefit from neoadjuvant therapy, its predictive value for nodal status has limitations. With further analysis of the dataset at our institution, we aim to identify other factors involved & create a predictive nomogram for the rectal cancer pt with locally advanced disease. We plan to validate this work by including data from other Irish cancer centres.

Image guided surgery: Differentiation of benign and malignant tissue in colon cancer patients using optical spectroscopy

G. Langhout[1], S.J. Schmitz[1], J.W. Spliethoff[1], V.J. Verwaal[1], A.G.J. Aalbers[1], B.H.W. Hendriks[2], T.J.M. Ruers[1], K.F.D. Kuhlmann[1]. *[1]Netherlands Cancer Institute − Anotoni van Leeuwenhoek Hospital, Surgical Oncology, Amsterdam, Netherlands; [2]Philips Research, of Minimally Invasive Healthcare, Eindhoven, Netherlands*

A key prognostic value for both quality of life and survival after colorectal surgery is the presence of local recurrence. Incomplete local excision is the cause of the majority of these recurrences. According to the Dutch national colorectal registry (Dutch Colorectal Cancer Audit), resection was microscopically incomplete in 4% of patients after colon resection. For rectal cancer these figures vary from 9% to 30% according to the level of rectal cancer. Diffuse reflectance spectroscopy (DRS) is a non-invasive technique, discriminating between tissue types based on their optical properties. Within seconds, it defines an 'optical fingerprint' which can be used for tissue discrimination. This proof-of-principle study explores the potential of this new technique in the discrimination between malignant colon tissue and the benign surrounding tissue.
Resection specimens from 19 colon cancer patients were investigated. DRS measurements of the tumor and its benign surrounding tissue (e.g. colon wall, tenia epiploica and mesocolon) were performed directly after resection. An optical needle shaped probe (diameter 2.5 mm) sensitive for a broad light spectrum (400–1600 nm) was used in combination with white light luminescence. The same probe was used to perform fluorescence spectroscopy (FS) after laser excitation with 377nm (blue) light. Trajectory measurements were performed, measuring from the benign tissue into the tumor, to examine tissue transitions. For correlation with histology, a biopsy was taken from the trajectory path. An analytical model extracts a number of validated physiological and metabolic parameters. The robustness of the technique was accessed using a classification and regression tree (CART) algorithm.
A total of 860 measurements were taken in the 19 examined specimens. Distinctive parameters were fat fraction, the amount of collagen, beta-carotene and scattering. Both DRS and FS proofed capable of differentiating tumor from benign tissue with a sensitivity and specificity of 92% respectively 91%. The trajectory measurements enabled real-time recognition of the tissue transitions in all 19 patients.
The changes in optical characteristic during these trajectory measurements could be correlated to histological findings.
The results show high sensitivity of DRS for differentiation of benign and tumorous tissue in colon cancer patients. During surgery, DRS can give real-time guidance in tissue recognition in situations were tactile and visual feedback are limited, for example during laparoscopy. The use of real-time DRS in probing dubious resection margins and its use during the surgical resection of colorectal cancer is currently under investigation.

2289 POSTER

Patients' experience of rectal high-dose rate brachytherapy

S. Neron[1], S. Perez[1], R. Benc[2], Z. Rosberger[1], T. Vuong[2]. *[1]Jewish General Hospital McGill University, Oncology, Montreal, Canada; [2]Jewish General Hospital McGill University, Radiation Oncology, Montreal, Canada*

Background: High-Dose Rate (HDR) brachytherapy is a form of radiation therapy that targets directly various cancerous tumors directly with a devise used to penetrate the body via its natural orifices. While we know that patients often experience varying degrees of pain, discomfort and potentially distress related to cancer treatments, they tend not to report these experiences during the procedure. Because no knowledge exists regarding patient's experience of HDR brachytherapy, the capacity to adapt this innovative treatment to the patient's needs is limited. The aim of the study is to better understand the complexity of the embodied experience of HDR brachytherapy of rectal cancer patients.
Methodology: Twenty-five rectal cancer patients were interviewed using a semi-structured qualitative interview schedule following the completion of their HDR brachytherapy treatment delivered at the Jewish General hospital, in Montreal, Quebec.
Results: The experience of pain and discomfort varies greatly between patients and are linked to the meaning patients attributed to the: treatment, sense of time, body's position, applicator used to penetrate the body as well as patient's sense of agency and empowerment during the procedure. The actual orifice (rectum) used to penetrate the body with the applicator also conveys a gendered meaning to the social experience of patients with the treating team present during the procedure.
Conclusion: These results suggest the importance of informing clinicians about the variation in the experience of pain of patients undergoing this treatment and that the intensity of pain needs to be assessed during the procedure along with itsemotional and semantic dimensions.
No conflict of interest.

2290 POSTER

Metastatic colorectal carcinoma patients: The Glasgow Prognostic Score (GPS) at the era of anti-EGFR therapies

J. Dréanic[1], M. Maillet[1], M. Dhooge[1], A. Cessot[2], O. Mir[2], C. Brezault[1], F. Goldwasser[2], S. Chaussade[1], R. Coriat[1]. *[1]Cochin Teaching Hospital AP-HP Paris Descartes University, Department of Gastroenterology, Paris, France; [2]Cochin Teaching Hospital AP-HP Paris Descartes University, Department of Oncology, Paris, France*

Background: The Glasgow Prognostic Score (GPS), combination of C-reactive protein and albumin, has proven its prognostic value in metastatic colorectal cancer' (CRCm) patients receiving conventional cytotoxic therapy. Recently, anti-EGFR therapies have been validated in CRCm and roll forward the patients' overall survival. Therefore, we aimed to evaluate the effectiveness of the GPS in patients receiving anti-EGFR therapy in addition to conventional chemotherapy.
Materials and Methods: From January 2007 to February 2012, CRCm' patients who received 5-fluorouracil based chemotherapy with the addition of an anti-EGFR, Cetuximab, were included in the present study. Patients were eligible for the study if they met the following criteria: advanced pathologically proven CRCm, age >18 years, C − reactive protein and albumin evaluation, adequate renal function (creatinine clearance >40 ml/min), and Eastern Cooperative Oncology Group performance status (ECOG) evaluation before treatment initiation. Patients received chemotherapy in addition to cetuximab in accordance with digestive oncology multidisciplinary staff' proposal and in line with the French recommendations for treatment of CRCm cancer.
Results: 49 patients received cetuximab plus 5-fluorouracil based chemotherapy (colon, n = 34; rectum, n = 15) and were treated with a median follow-up of 35 months (3–198). Median age was 48 years old. Patients received in addition to cetuximab mainly oxaliplatin (n = 34; 60%) or irinotecan 15 (30%) based chemotherapy. At time of diagnosis, 55%, 29% and 16% of patients were GPS 0 (n = 27), GPS 1 (n = 14) and GPS 2 (n = 8), respectively. 55%, 29% and 14% of patients add one, two or $\geqslant$3 metastatic sites, respectively. Median progression free survivals were 20, 10 and 9 months in the GPS 0, 1 and 2 groups, respectively. Median overall survivals were 48, 28 and 25 months in the GPS 0, 1 and 2 groups, respectively.
Conclusion: The results of the present study confirm that the GPS is still a simple and effective prognostic factor at the era of cetuximab therapy in CRCm patients.
Conflict of interest: *Advisory board: Professor Goldwasser has acted as paid consultant for Bayer Healthcare and Pfizer. Dr Mir has acted as paid consultant for Roche, Servier, and Pfizer. Dr Coriat has acted as paid consultants for Roche and Novartis. For the remaining authors there are no conflicts of interest.*

2291 POSTER

Metastatic colorectal carcinoma patients: The Glasgow prognostic score (GPS) at the era of anti-VEGF therapies

M. Maillet[1], J. Dreanic[1], M. Dhooge[1], A. Cessot[2], O. Mir[2], C. Brezault[1], F. Goldwasser[2], S. Chaussade[1], R. Coriat[1]. [1]*Hopital Cochin, Gastroenterology, Paris, France;* [2]*Hopital Cochin, Oncology, Paris, France*

Background: The Glasgow prognostic score (GPS), an inflammation based scored combination of C-reactive protein and albumin, has been identified as a prognostic score in metastatic colo-rectal cancer (CRCm) patients receiving conventional cytotoxic therapy.
Since 2001, Bevacizumab, a humanized monoclonal antibody targeting VEGF, has been validated in CRCm and improved overall survival associated with chemotherapy. The aim of the present study was therefore to assess the effectiveness of the GPS in patients receiving anti-VEGF therapy in addition to conventional chemotherapy.
Materials and Methods: From August 2005 to August 2012, patients with CRCm who received chemotherapy in addition to an anti-VEGF, bevacizumab, were included in the present study. Clinical stage, C-reactive protein, albumin and Eastern Cooperative Oncology Group performance status (ECOG) were recorded at the time of initiation of treatment by bevacizumab. Patients received chemotherapy in addition to bevacizumab in accordance with digestive oncology multidisciplinary staff proposal and in line with the French recommendations for treatment of CRCm cancer.
Results: 81 patients received bevacizumab plus 5-fluorouracil based chemotherapy (colon, n = 60; rectum, n = 21) and were treated with a 14 months median follow-up (1−58). Median age was 65 years old. Patients received in addition to bevacizumab mainly oxaliplatin (n = 42; 52 %) or irinotecan (n = 27; 34%) based chemotherapy. At the time of diagnosis, 55%, 31% and 14% of patients were GPS 0 (n = 45), GPS 1 (n = 25) and GPS 2 (n = 11), respectively. 53%, 32% and 14% of patients add one, two or $\geqslant$3 metastatic sites, respectively. Median progression free survivals were 10, 6.3 and 5.1 months in the GPS 0, 1 and 2 groups, respectively. Median overall survivals were 18, 9.7 and 6.2 months in the GPS 0, 1 and 2 groups, respectively.
Conclusion: Our study confirmed, at the era of anti-VEGF therapy, the efficacy of the GPS score to identify patients with a worsen survival. The GPS deserves confirmation in a larger cohort.
No conflict of interest.

2292 POSTER

Clinico-pathological characteristics of younger, middle aged, and older patients with colon cancer

M. Salem[1], M. Kaufman[1], N. Stanski[1], G. Dyson[1], B. Krasnick[1], M. Choi[1], N. Hawk[2], B. El-Rayes[2], P. Philip[1]. [1]*Karmanos Cancer Institute, Oncology, Detroit Michigan, USA;* [2]*Emory Winship Cancer Institute, Oncology, Atlanta GA, USA*

Background: There are limited data about tumor features and treatment outcomes in both young and elderly patients with colorectal cancer.
Methods: Total of 393 patients treated for colorectal cancer from 2000 to 2011: group A (younger; 67 patients; age, 17 to 41 y); group B (middle aged; 238 patients; 50 to 70 y); and group C (older; 88 patients; 75 to 93 y) were studied. Patient and tumor features, treatment, and survival were compared. T-tests and Chi-squared tests were used to determine statistical differences between age groups. The Kaplan–Meier method was used to estimate the survival distributions and calculate median survival; while Cox regression was used to estimate the hazard ratios.
Results: The 3 groups had similar sex distribution. Older patients were more likely to be African American (odds ratio [OR], 2.1; $P \leqslant .005$), and to have a right colon primary tumor (OR, 2.6; $P \leqslant .01$). Younger patients were more likely to have a sigmoid primary tumor (OR, 2.1; $P \leqslant .01$). Frequency of mucinous tumors was similar between the 3 groups. Younger patients were more likely to have worse tumor grade (OR, 2.2; $P \leqslant .02$). The most common site of distant metastasis was the liver in all 3 groups. However, older patients were less likely to have lung metastasis (OR, 0.4; $P \leqslant .001$), while younger patients were more likely to have bone metastasis (OR, 3.3; $P \leqslant .001$). Older aged women were less likely to have ovarian metastasis (OR, 0.1; $P \leqslant .001$) in comparison to the other two groups. Older patients had peritoneal metastasis less frequently (OR, 0.5; $P \leqslant .01$). Most tumors (77%) were KRAS wild type. Notably, younger patients had higher frequency of inflammatory bowel disease (6%) than middle aged (1%) or older (0%) patients ($P \leqslant .007$). Chemotherapy was first line treatment more frequently in younger and middle aged patients combined (91%) than older patients (57%; $P \leqslant .001$). The most common chemotherapy was FOLFOX plus bevacizumab in younger and middle age patients; however, capecitabine was the most common chemotherapy used in the older patients. Median survival was: younger, 23 mo [range, 18 to 31 mo]; middle aged, 26 mo [23 to 29 mo]; older, 18 mo [12 to 28 mo]. The 2-year survival was similar between the 3 groups (younger, 49%; middle aged, 54%; older, 40%). Multivariate analysis showed that tumor differentiation, surgery status, and radiation status were independent predictors of survival.
Conclusions: In our patients populations, younger patients with colon cancer are more likely to have poorly differentiated tumors. Younger and middle aged patients are more likely to receive more aggressive treatment. Yet, all groups had equivalent two-year survivals. Pattern of metastases may be different. These results support the need for further prospective investigation in a larger population.
No conflict of interest.

2293 POSTER

Family history and colorectal cancer: A study to investigate the incidence of hereditary and familial colorectal cancer

J. Villa[1], C.S.P. Lima[1], C.S. Bertuzzo[2]. [1]*State University of Campinas, Internal Medicine, Campinas SP, Brazil;* [2]*State University of Campinas, Medical Genetics, Campinas SP, Brazil*

Background*:* The complete medical approach to colorectal cancer often includes not only the treatment of the individual who is sick, but also requires the study of his family, as cancer is eventually linked to some kind of inherited genetic mutation. It is, therefore, very important to completely understand the epidemiology and the genetic aspects of this type of cancer, in order to successfully assist the patient and his family. This study aims to investigate the incidence of colorectal cancer associated to inherited mutations, classifying them, based on the guidelines of the Brazilian Clinical Genetics Society (BCGS), into three categories: hereditary (inherited mutations that can lead directly to cancer), familial (inherited mutations that can predispose to secondary oncogenic mutations) and sporadic (related to non-inherited mutations).
Material and Methods: This research was made based on data collected from 291 patients attended between the years of 2006 and 2011 at the State University of Campinas' oncology service. Data gathered include several of the patient's characteristics, such as age at the diagnosis and familial history related to cancer, as well as tumour related information, such as stage of the tumour and pathological findings. This data was analysed accordingly to the BCGS guidelines and Amsterdam I and II criteria, aiming to determine the role of genetics in each of the 291 cases.
Results: 14% of the patients could not be assigned to one of the three categories, because they alone met the Amsterdam criteria for hereditary cancer, but their family did not present, at the time, positive cancer history. 6.5% of the patients were qualified to hereditary colorectal cancer, while 2.5% of them met the criteria for familial colorectal cancer. The rest of the patients (77%) were assigned to the sporadic colorectal cancer group.
Conclusions: The amount of individuals with colorectal cancer related to inherited mutations indicates that inheritance does not play a major part in this type of cancer, but cannot be ignored. Further research is needed to ensure what's precisely the inherited mutations role in colorectal cancer. This research also shows that it's important to provide proper genetic testing for individuals who are suspected to have a hereditary/familial colorectal cancer, but do not meet all the criteria for the diagnosis, after all, they represent an important share of the total analysed (14%).
No conflict of interest.

2294 POSTER

Physicians and patients adherence rates to recommended screening with colonoscopy for first-degree relatives of patients diagnosed with colorectal cancer before the age 50

G. Garcia[1], R.S.P. Richellman[2], P.M.G. Hoff[2]. [1]*Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil;* [2]*Instituto do Cancer do Estado de São Paulo − ICESP, Oncology, São Paulo, Brazil*

Background: Screening is an important intervention to reduce the colorectal-cancer incidence and mortality. We evaluated physicians' adherence to screening recommendations for first degree relatives of patients diagnosed with colorectal cancer under the age of 50.
Methods: Patients attended to ICESP between July 2007 and January 2010 and diagnosed with colorectal cancer before age 50 answered a questionnaire that evaluated the rate of indication of colonoscopy or other screening exam to their first degree relatives by their treating physicians. The answers provided us the physicians' adherence rate to the recommendation of screening and, allowed us to estimate the rate of adherence of patients' relatives to these recommendations.
Results: Two hundred and three patients were considered eligible for the study, and from those 62 (30.54%) answered the questionnaire. A simple t test showed that the sample had the same medium age of the total population (respectively 43.4 and 43 years). These two groups were compared with Mann-Whitney non-parametric test for tumor

location and cancer stage. There was no statistic significant differences between them (p 0.9671 to tumor location and p 0.7799 to cancer stage). Of the 62 patients in the research 39 (62.9%) declared they had received the recommendation for their relatives to undergo a screening colonoscopy. Two other patients (3.2%) received a fecal occult blood test recommendation for their relatives. The other 21 patients (33.9%) declared they had not received any specific recommendation from their doctors. The study also evaluated the adherence of patients and their relatives to the recommendations made by the physicians. Among the 39 patients that received the recommendation for colonoscopy, only 8 (20.5%) stated that all their siblings had the exam, 10 patients (25.6%) said that some of their siblings had the colonoscopy, and 20 patients (51.3%) stated that none of their siblings had the exam. One patient did not know said if the relatives had the exam.
Conclusion: The adherence of two thirds of physicians to the guidelines regarding colorectal-cancer screening in a reference center was underwhelming. However, the low adherence of patients' relatives to the screening recommendations is more worrisome. We identified the need for more education for both, patients and physicians, regarding potentially life-saving screening, as well as developing tools to encourage physicians to discuss the issue with their patients.
No conflict of interest.

2295 POSTER

Evaluation of vitamin D status and risk factors of osteopenia/osteoporosis in colorectal cancer survivors

M. Sendur[1], S. Aksoy[2], O. Yazici[1], S. Yaman[1], F.T. Kos[1], N.Y. Ozdemir[1], D. Uncu[1], M. Dogan[1], N. Zengin[1]. *[1]Ankara Numune Education and Research Hospital, Medical Oncology, Ankara, Turkey; [2]Hacettepe University Cancer Institute, Medical Oncology, Ankara, Turkey*

Background: The incidence of colorectal cancer increases with vitamin D deficiency as shown in recently published studies. In addition, prospective studies showed that low vitamin D levels associated with increased mortality of colorectal cancer, especially in stage III and IV. But the exact incidence of vitamin D deficiency and the relation between vitamin D deficiency and osteopenia/osteoporosis is still not known. The aim of this study is to identify severity of vitamin D deficiency and absolute risk factors of osteopenia/osteoporosis in colorectal cancer survivors.
Methods: A total of 113 survivors of colorectal cancer treated with surgery and/or chemotherapy ± RT were recruited from medical oncology outpatient clinics during routine follow-up visits in 2011–2012. Patients younger than 40 years and patients with osteopenia/osteoporosis history before diagnosis were excluded. Medical information of patients was obtained from their medical records. Patients completed a survey questionnaire that was designed to obtain information about consisted of demographic characteristics. Bone mineral densitometry (BMD) was performed, and serum 25-OH vitamin D levels were also checked on the same day of the questionnaire. According to the BMD; between −1.0 and −2.5 was accepted as osteopenia, lower than −2.5 was accepted as osteoporosis. The patients was divided into 2 groups. Group A is patients with normal BMD, whereas group B is patients with osteopenia/osteoporosis patients.
Results: The median age of the study population was 58 (40−76). Thirty-four (30.1%) patients of the study population were female, whereas 79 (69.9%) patients were male. The median follow-up of the study population was 48 months (14–120 months). Vitamin D deficiency was found in 109 (96.5%) of patients; mild deficiency (20−30 ng/ml) in 19 (16.8%) patients, moderate deficiency (10−20 ng/ml) in 54 (47.8%) patients and severe deficiency (<10 ng/ml) in 36 (31.9%) patients. Osteopenia was found in 58 (51.4%) patients whereas osteoporosis was found in 17 (15.0) patients. Normal BMD was observed in 38 (33.6%) of patients. No apparent effect of type of surgery, presence of stoma, chemotherapy, radiotherapy and TNM stage was found in the risk of osteopenia and osteoporosis. Also, the severity of the vitamin D deficiency was no effect in the risk of osteopenia and osteporosis (P =0.93). In female patients, osteopenia/osteoporosis were observed in 79.5% patients whereas 60.7% of male patients (P = 0.03).
Discussion: In our study, vitamin D deficiency and osteopenia/osteoporosis was observed in 96.5% and 66.4% of colorectal cancer survivors, respectively. There is no absolute risk factor of osteopenia and osteoporosis in colorectal cancer survivors. To our knowledge, in the literature, our study is the first study that evaluates all the risk factors of osteopenia ans osteoporosis in colorectal cancer survivors.
No conflict of interest.

2296 POSTER

A phase II study of third-line combination chemotherapy with bevacizumab plus S-1 for metastatic colorectal cancer with KRAS mutations: Additional analysis of overall survival in the SAVIOR study

K. Shimada[1], A. Takagane[2], Y. Miyake[3], N. Nagata[4], A. Sato[5], T. Takahashi[6], H. Matsumoto[7], A. Tsuji[8], Y. Matsubara[9], M. Yoshida[10]. *[1]Showa University Northern Yokohama Hospital, Internal Medicine, Yokohama, Japan; [2]Hakodate Goryoukaku Hospital, Department of Surgery, Hakodate, Japan; [3]Minoh City Hospital, Department of Surgery, Minoh, Japan; [4]Kitakyushu General Hospital, Department of Surgery, Kokura, Japan; [5]Showa University Hospital, Department of Medical Oncology, Tokyo, Japan; [6]Gifu University Hospital, Department of Surgical Oncology, Gifu, Japan; [7]University of Miyazaki Hospital, First Department of Internal Medicine, Miyazaki, Japan; [8]Kochi Health Sciences Center, Department of Clinical Oncology, Kochi, Japan; [9]Translational Research Informatics Center, Department of Statistical Analysis, Kobe, Japan; [10]Osaka Medical College Hospital, Cancer Chemotherapy Center, Takatsuki, Japan*

Background: We performed a phase II clinical trial to confirm the efficacy and safety of third-line combination chemotherapy with S-1 plus bevacizumab in metastatic colorectal cancer (mCRC) patients with mutated KRAS. We reported that the disease control rate, the primary endpoint, was 69.0% (95% confidence interval [CI], 49.2–84.7), and the median progression-free survival, a secondary endpoint, was 3.7 months (95% CI, 2.1−6.6) (ASCO-GI 2013).
Material and Methods: Subjects were mCRC patients with mutated KRAS, who showed aggravation even after 2 regimens with oxaliplatin and irinotecan. S-1 (80–120 mg/body) was administered for 4 weeks and withdrawn for 2 weeks. The dose of S-1 was decided according to the subjects' body surface area. Bevacizumab (5 mg/kg) was administered on Days 1, 15, and 29. This treatment was provided until progression. In the present study, we additionally analyzed survival from the starting dates of first-line therapy and second-line therapy and survival according to whether or not patients received fourth-line therapy (subsequent therapy).
Results: A total of 31 patients were enrolled from August 2009 through July 2011, and 29 with assessable lesions according to the Response Evaluation Criteria In Solid Tumors were included in efficacy analyses. Median overall survival (OS) from the date of enrollment, a secondary endpoint, was 9.0 months (95% CI, 7.0–12.0). Median OS from the date of starting first-line therapy was 23.3 months (95% CI, 18.3–31.2), and median OS from the date of starting second-line therapy was 17.0 months (95% CI, 11.3–19.5). Median OS from the date of enrollment was 12.0 months (95% CI, 5.9–20.0) in the patients who received fourth-line therapy (n = 11), as compared with 8.3 months (95% CI, 4.6–11.2) in those who did not receive fourth-line therapy (n = 18).
Conclusions: Survival from the dates of starting first-line therapy and second-line therapy in patients enrolled in this study did not differ appreciably from survival in other studies. This fact and the demographic characteristics of the patients indicate that our subjects were appropriately selected. Our results suggest that combination chemotherapy with S-1 plus bevacizumab is a potentially effective third-line treatment for mCRC with mutated KRAS. Further clinical trials are needed to confirm our results.
No conflict of interest.

2297 POSTER

Clinicopathologic characteristics and outcome of colorectal cancer in young patients: Experience in a cancer clinic in Indonesia

S.H. Hutajulu[1], N. Yoshuantari[2], O.B. Gunawan[2], A. Barmawi[3], A. Ghozali[4], H. Kusumo[5], K.W. Taroeno-Hariadi[2], I. Purwanto[2], J. Kurnianda[2]. *[1]Universitas Gadjah Mada, Department of Internal Medicine Faculty of Medicine, Sekip Yogyakarta, Indonesia; [2]Dr Sardjito General Hospital, Tulip integrated Cancer Clinic, Yogyakarta, Indonesia; [3]Dr Sardjito General Hospital, Department of Surgeon, Yogyakarta, Indonesia; [4]Dr Sardjito General Hospital, Department of Pathology, Yogyakarta, Indonesia; [5]Dr Sardjito General Hospital, Department of Radiology, Yogyakarta, Indonesia*

Background: Colorectal cancer (CRC) generally affects persons older than 40 years. Controversies still exist regarding the feature and prognosis of young CRC patients.
Objective: The present study determined the clinicopathologic characteristics in younger patients and evaluated short-term outcome in comparison with older patients with CRC.
Material and Methods: The records of 336 CRC patients who visited 'Tulip' integrated cancer clinic Dr Sardjito General Hospital Yogyakarta Indonesia

in 2007–2011 were retrospectively analyzed. Clinical and histopathologic parameters and overall 1-year survival rates of 57 patients aged 40 years or less were compared with 279 patients aged more than 40 years.
Results: Young patients represented 17% of data observed. Median age in young cases was 34 year and in old cases was 58 year. Performance status in young cases was marginally better than old cases ($p = 0.052$). Compared with old patients, young patients had more frequent symptom of bloody stool ($p = 0.083$) as early sign. For sex ($p = 0.303$), tumor site ($p = 0.879$), staging ($p = 0.728$), histologic grading ($p = 0.930$) and presentation of synchronous metastasis ($p = 0.870$), no significant differences between both groups were observed. Young and old patients had the same overall 1-year survival rates ($p = 0.690$). In addition, majority of young cases were covered by government insurance for the poor people ($p = 0.001$) indicating that they came from lower economic background.
Conclusions: Clinicopathologic features and short-term outcome in young CRC patients in the local cancer clinic were similar to old cases. However, young cases showed more frequent bloody stool as early complaint although a significant difference was not reached. These results urged a mandatory for all patients with suspicious symptoms, especially young individuals, to undergo early adequate diagnosis.

Cellular interactions during gastrointestinal cancer development

B. Borzenko[1], E.M. Bakurova[1], K.A. Mironova[1], O.A. Verkhova[1].
[1]*Donetsk National Medical University, Chemistry, Donetsk, Ukraine*

Background: Cellular interactions of tumor and stromal components largely determine the formation of the phenotype of the tumor. Herewith, the tumor cells themselves are the active participants in intercellular interactions by secreting of metabolites into the stroma. Some contribution to carcinogenesis can make blood cells and their functional state. Thus, the platelets can secrete the number of growth factors − VEGF, PDGF, PD-ECGF/TP that activate angiogenesis and proliferation. Local immunity disorders also promote the tumor progression. For example, increased levels of adenosine under the low activity of adenosine deaminase (ADA) lead to the development of lymphocyte dysfunction. It is interesting the role of platelet derived endothelial cells growth factor (PD-ECGF/??) which can realize some effects due to enzyme activity because it is structurally identical to thymidine phosphorylase (TP).
Objective: To investigate the TP and ADA activities in platelets and lymphocytes of the peripheral venous blood and venous blood flowing directly from the affected organ.
Methods: Activity of cellular enzymes was determined spectrophotometrically in samples from 25 men with advanced cancer of the stomach or intestine. The patients had a median age of 58 years. The group consisted of 25 cases with adenocarcinoma histologically. The material for the study: platelets and lymphocytes of venous blood that was taken from the cubital vein and blood flowing from the affected organ; the tumor tissue and mucosal resection margin distant from the tumor (control).
Results: The platelets thymidine phosphorylase activity changes in the blood flowing from the tumor were unidirectional with the tumoral TP activity. It was in platelets 22.90 ± 5.49 nmol/mg·ml (in platelets of the peripheral venous blood − 11.15 ± 5.76 nmol/mg·ml). The cancer tissue TP activity was 52.48 ± 15.32 nmol/mg·ml. It was higher then in control tissue (33.17 ± 8.98 nmol/mg·ml). ADA activity of lymphocytes flowing from the tumor was lowest. It decreased from 35.85 ± 10.04 nmol/mg·ml in lymphocytes of the peripheral venous blood to the 15.28 ± 6.22 nmol/mg·ml.
Conclusions: Thereby platelets and tumor cells are capable of responding by increased PD-ECGF/TP expression, under the influence of local signals, such as hypoxia, and also immunosuppressive effect may occur.

2299 POSTER

Intraoperative radiotherapy reduces local recurrence rates in patients with locally advanced rectal cancer with microscopically involved circumferential resection margins

W.J. Alberda[1], C. Verhoef[1], J. Rothbarth[1], J.J. Nuyttens[2], J.W.A. Burger[1].
[1]*Erasmus MC − Cancer Institute, Surgical Oncology, Rotterdam, Netherlands;* [2]*Erasmus MC − Cancer Institute, Radiotherapy, Rotterdam, Netherlands*

Background: Local control is one of the main goals of the surgical treatment of rectal cancer. The most important predictive factor for local control is the circumferential resection margin (CRM). Unfortunately, CRM involvement still occurs in 19−24% of the patients with locally advanced rectal cancer (LARC), despite the use of (chemo-)radiotherapy and total mesorectal excision (TME). In patients with a CRM at risk, local recurrence rates may be reduced by administering intra-operative radiotherapy (IORT). One single dose of IORT is considered the biological equivalent of two to three times the dose given by conventional fractionation and this dose, preceded by an external radiation dose, may be sufficient to eradicate microscopic remnants. In addition, IORT may also be beneficial in patients with a clear but narrow CRM (<2 mm), because these patients have a higher risk of local recurrence. This study evaluated the effect of IORT in patients with LARC after TME with a microscopic involved CRM or a clear but narrow CRM.
Methods: Between 1996 and 2012, all surgically treated patients with LARC and a CRM less than 2 mm after (chemo-)radiotherapy followed by TME were analyzed. These patients were divided into a group with radical resections with a clear but narrow CRM (<2 mm) and a group with a microscopic involved CRM. In these groups, the outcome of the patients who were treated with IORT was compared to the outcome of patients who were treated without IORT.
Results: Ninety-five of the 409 surgically treated patients with LARC had a CRM less than 2 mm after neoadjuvant (chemo-)radiotherapy. Forty-three patients had a radical resection with a clear but narrow CRM and 48 patients had a microscopic involved CRM. Four patients were excluded from further analysis due to a macroscopic irradical resection. Of the patients with radical resection with a clear but narrow CRM, 21 patients were treated with IORT and 22 patients were treated without IORT. The baseline characteristics of the patients treated with and without IORT were similar. There was no difference in the cumulative 5-years local recurrence-free survival (70 vs. 79%, $p = 0.63$). Of the patients with a microscopic involved CRM, 31 patients were treated with IORT and 17 patients were treated without IORT. Baseline characteristic of the patients treated with and without IORT were similar, except that patients treated without IORT had more stage IV disease (52 vs. 13%, $p = 0.01$). In this group, there was a significant difference in the cumulative 5-years local recurrence-free survival in favor of the 31 patients treated with IORT compared with the 17 patients who were not treated with IORT (84 vs. 41% $p = 0.01$). Multivariable analysis confirmed that IORT was independently associated with a decreased local recurrence rate in these patients.
Conclusion: IORT reduces local recurrence rates in patients with LARC with a microscopic involved CRM.
No conflict of interest.

2300 POSTER

Long-term outcome of sphincter preserving operation after preoperative short-term radiotherapy and delayed surgery for T3 rectal cancer

B. Naohito[1], H. Yanagi[2], N. Yamanaka[2], H. Doi[3], N. Kamikonya[3], N. Matsubara[4], N. Tomita[4]. [1]*Hyogo College of Medicine, Nishinomiya, Japan;* [2]*Meiwa Hospital, Surgery, Nishinomiya, Japan;* [3]*Hyogo College of Medicine, Radiology, Nishinomiya, Japan;* [4]*Hyogo College of Medicine, Surgery, Nishinomiya, Japan*

Background: It is said that short-term radiotherapy (sRT) and immediate surgery does not lead to increase the sphincter preserving rate for rectal cancer. We hypothesised that a long interval before surgery is necessary to allow for a tumour response and to improve chances of sphincter preservation. The purpose of this study is to review the long-term outcome of sphincter preserving operation after sRT and delayed surgery for T3 rectal cancer.
Material and Methods: Between January 2001 and December 2011, patients with cT3N0−2 mid or low rectal cancer after sRT were enrolled in this study. 140 patients were treated with a total dose of 25 Gy (25 Gy in 10 fractions for 5 days) with sensitiser (S-1; 80 mg/m^2 day1−10). Radical surgery with TME was performed 3−4 weeks (median: 24 day) following the end of the sRT. No eligible patients received lateral lymph node resection except for 15 patients with lateral lymph node swelling.
Results: The median follow-up term was 45.6 (range: 15–146) months. Patient characteristics were as follows; Male-to-female ratio; 98 : 42. The median age was 65.0 (range: 39−85) years. Median distance from anal verge was 6.5 (0−9) cm. Preoperative radiologic diagnosis was N-/N+; 49/91. Histology was well or moderately differentiated/poorly or mucinous = 127/13. Type of resection was APR/non-APR= 8/132 (anal preserving rate; 94.3%). The reason for APR was that 4 were elderly patient or their private affairs. 2 were selected by patients and 2 were invaded to anal verge. Postoperative T stage was ypT1 or 2/ypT3 or 4 = 54/86, Postoperative N stage was ypN- /yp N+ = 87/53. Tumour regression grade by Dworak classification was TRG0 /1 /2 /3 /4 =0 /52 /38 /45 /5. Median length of distal margin (DM) and circumferential resection margin (CRM) was 11 (0−40) mm and 4 (0−7) mm. Long-term outcome were as follows; the local recurrence rate was 8/140 (5.7%). 1 (12.5%) had anastomosis site recurrence, 1 (12.5%) had anterior pelvic organ recurrence, and 6 (75.0%) had lateral pelvic recurrence. The overall survival rate at 5 years was 80.1% and the recurrence-free survival rate was 68.5%.

Conclusions: We presented a long-term outcome of sphincter preserving operation after preoperative short-term radiotherapy and delayed surgery for T3 mid to low rectal cancer. sRT with delayed surgery could expect for high rate of sphincter preservation and produced feasible long-term outcomes.
No conflict of interest.

2301 POSTER

Phase II trial of short-course radiotherapy alone followed by delayed surgery for locally advanced rectal cancer

T. Hijal[1], S. Faria[1], N. Kopek[1], S. Liberman[2], P. Charlebois[2], B. Stein[2], P. Meterissian[2], A. Meguerditchian[2], G. Artho[3]. *[1]McGill University Health Centre, Radiation Oncology, Montréal, Canada; [2]McGill University Health Centre, Surgery, Montréal, Canada; [3]McGill University Health Centre, Radiology, Montréal, Canada*

Background: The short-course radiotherapy (SCRT) regimen has been used in part of Europe as preoperative treatment in rectal cancer. It is a convenient regimen because it consists of only 5 fractions of 5 Gy without chemotherapy followed by immediate surgery. However, one criticism of the SCRT regimen is the lower complete pathological response rate (pT0) when compared to the long-course regimen which consists of 25−28 fractions of 1.8 Gy with chemotherapy followed by delayed surgery. We performed a prospective phase II study to investigate the feasibility and the rate of pT0 after the SCRT but followed by delayed surgery.
Materials and Methods: Operable patients with pathologically proven localized rectal cancer staged as T3−4N0/+ or T2N+ were eligible. They received 25 Gy in 5 consecutive fractions to the posterior pelvis. Patients were oriented to have TME surgery 8 weeks after the SCRT. Pathological response to the treatment and radiotherapy and surgical toxicities were assessed in all patients.
Results: Between October 2008 and December 2011 the target sample of 52 patients finished the treatment according to protocol. Median age was 68 years; median tumoral distance from the anal verge was 6.5 cm. Median interval to surgery was 52 days. 38/52 (73%) patients underwent low anterior resection. The median number of days in hospital for the surgical procedure was 8 days. All patients were able to undergo a complete surgical resection with 100% having pathological negative margins. 5/52 (10%) patients had complete pathological response. Toxicity was acceptable and comparable with the rates reported for SCRT followed by immediate surgery and the long course followed by delayed surgery.
Conclusions: From the results of our study and the recent publications it appears that: 1) an appropriate surgical resection with acceptable toxicity can be achieved with SCRT alone followed by delayed (4−8 weeks) surgery; 2) there is a better rate of complete pathological response (10%) with the SCRT followed by delayed compared to immediate surgery (0.7%). Our study is underpowered to evaluate whether a SCRT followed by delayed surgery achieves pT0 rates similar to the long-course. This question remains open and warrants further investigation.
No conflict of interest.

2302 POSTER

Post-chemoradiation laparoscopic resection and intraoperative electron-beam radiation therapy in locally advanced rectal cancer: Long-term outcomes

C. Solé[1], F.A. Calvo[2], J. Serrano[3], M. Gomez-Espi[3], E. Del Valle[4], M. Rodriguez[4], J.L. Garcias-Sabrido[4], P. Garcia-Alfonso[5], I. Peligros[6], E. Alvarez[6]. *[1]Instituto de Radiomedicina, Radioterapia, Santiago, Chile; [2]Hospital General Gregorio Marañón, Oncología, Madrid, Spain; [3]Hospital General Gregorio Marañón, Radioterapia, Madrid, Spain; [4]Hospital General Gregorio Marañón, Cirugia General, Madrid, Spain; [5]Hospital General Gregorio Marañón, Oncologia Medica, Madrid, Spain; [6]Hospital General Gregorio Marañón, Anatomía Patológica, Madrid, Spain*

Background: It has been previously reported that in selected patients with rectal cancer, laparoscopic surgery resulted in similar safety, resection margins, and completeness of resection to that of open surgery, and recovery was improved after laparoscopic surgery. We analysed long-term outcomes in a group of patients with locally advanced rectal cancer (LARC) treated with preoperative combined therapy followed by laparoscopic surgery and intraoperative electron-beam radiotherapy (IOERT).
Material and Methods: From 06/05 to 12/10, 125 LARC patients were treated with 2 courses of induction FOLFOX-4 (oxaliplatin 85 mg/m^2/d1, intravenous leucovorin at 200 mg/m^2/d1−2, and an intravenous bolus of 5-fluorouracil 400 mg/m^2/d1−2) and preoperative chemoradiation (4500–5040 cGy) followed by a total mesorectal excision (laparoscopic 35%, open surgery 65%) and a IOERT presacral boost.
Results: Patients in the laparoscopic surgery group lost less blood (median 200 mL vs 350 mL, $p < 0.01$) and hospital stay was shorter (7 days vs 11 days; $p = 0.02$) than did those in the open surgery group. Laparoscopic procedures did not take longer (270 min vs 302 min; $p = 0.67$) than open surgery procedures. In the laparoscopic and open surgery groups, postoperative morbidity (32% vs 44%; $p = 0.65$), RTOG grade $\geqslant 3$ acute (25% vs 25%; $p = 0.97$), and RTOG grade $\geqslant 3$ chronic toxicity (7% vs 9%; $p = 0.48$) were similar. With a median follow-up time for the entire cohort of patients was 59.5 months (range, 7.8−90); locoregional control (HR 0.91, $p = 0.89$), disease-free survival (HR 0.80, $p = 0.65$) and overall survival (HR 0.67, $p = 0.52$) did not differ significantly between the groups.
Conclusions: Post-chemoradiation laparoscopically assisted surgical-IOERT approach is feasible with an acceptable risk of postoperative complications, shorter hospital stay and similar long-term outcomes when compared to the open surgery approach.
No conflict of interest.

2303 POSTER

Prognostic factors analysis of postoperative radiotherapy for upper rectal cancer: Ten years experience from Cancer Hospital, Chinese Academy of Medical Sciences 2000–2010

X. Wang[1], J. Jin[1], H. Ren[1], H. Fang[1], N.N. Lu[1], Q. Xiao[1], Y.R. Feng[1], W.Y. Liu[1], J.Y. Wang[1], L. Deng[1]. *[1]Cancer Institute & Hospital, Chinese Academy of Medical Sciences, Department of Radiation Oncology*

Background: Whether postoperative radiotherapy (RT) will benefit for stage II/III upper rectal cancer after a complete resection is not clear. The aim of this study was to compare the outcomes of treatment with or without adjuvant chemoradiotherapy (CRT) or RT in pathological T3−4N0−2 upper rectal cancer.
Material and Methods: This retrospective analysis included 547 primary upper rectal cancer patients who were extracted from 3995 rectal cancer patients admitted in Cancer Hospital, Chinese Academy of Medical Sciences from January 2000 to December 2010. Lower margin of the tumor located 10−16 cm from the anal verge determined by colonofiberscope, underwent radical proctectomy (R0) and pathologically staged as II/III were included. Nearly two-thirds patients received adjuvant CRT/RT (S+RT, 375) and the rest did not (S, 172).
Results: The median age was 59 years old (range 23−84) and the male to female ratio was 1.75:1. The patients were pathologically staged as stage IIa (25.4%), IIb (16.6%), IIc (3.5%), IIIa (2.7%), and IIIb (36.7%) and IIIc (15.0%) according to 7th TNM staging system. Of 375 patients in S+RT, 287 (76.5%) received RT concurrently with chemotherapy. With a median follow-up of 51 months (range 5–159), the 5-year overall survival (OS), disease free survival (DFS), cancer specific survival (CSS), locoregional recurrence free survival (LRFS) and distant metastasis free survival (DMFS) were 79.0%, 76.8%, 83.0%, 94.0% and 80.1%, respectively. The addition of postoperative CRT/RT did not improve estimated 5-year OS (S+RT 79.0% vs S 78.5%, P=.465), DFS (S+RT 75.5% vs S 79.5%, P=.739), CSS (S+RT 81.6% vs S 86.1%, P=.411), LRFS (S+RT 94.2% vs S 93.2%, P=.408) and DMFS (S+RT 78.6% vs S 83.4%, P=.565). But the fact was that more patients in S+RT had positive lymph nodes as compared with those in S (54.7% vs 39.8%, $P = 0.001$). In the subgroup of patients staged as T4bN0 or anyT, N1b-2b, multivariate analysis indicated postoperative CRT/RT was independently associated with higher OS (HR 0.462, 95% CI 0.240–0.887, $P = 0.2$), DFS (HR 0.576, 95% CI 0.321–1.031, $P = 0.63$), CSS (HR 0.522, 95% CI 0.256–1.063, $P = 0.73$) and LRFS (HR 0.362, 95% CI 0.142–0.920, $P = 0.33$).
Conclusions: The outcomes of upper rectal cancer treated with radical surgery with or without postoperative RT was definitely good. More patients with adverse N stage would like to receive postoperative RT, however, patients in advanced stage (T4bN0 or anyT, N1b-2b) maybe benefit from the postoperative RT.
No conflict of interest.

2304 POSTER

Outcome of stereotactic ablative body radiotherapy in patients with lung oligo-metastases from colo-rectal cancer primary

A.M. Mihai[1], M. Rajagopalan[2], J. Westrup[3], P. Thirion[1], J.G. Armstrong[1], D.E. Heron[2], L.A. Rock[1], M.S. Huq[2], R. McDermott[3]. *[1]UPMC Beacon Hospital National Centre for Radiosurgery Beacon Hospital, Radiation Oncology, Dublin, Ireland; [2]University of Pittsburgh Cancer Institute, Radiation Oncology, Pittsburgh, USA; [3]UPMC Beacon Hospital, Medical Oncology, Dublin, Ireland*

Background: The reported early clinical experience in Stereotactic Ablative Body Radiotherapy (SABR) in patients (pts) with lung oligo-metastases (L-OMD) is promising. Our objective was to assess our multi-

institutional experience with SABR in heavily pre-treated colo-rectal cancer (CRC) patients with isolated L-OMD.
Material and Methods: From April/09 to Jan/13, 44 pts received SABR for isolated L-OMD from CRC primaries. 10 pts (22%) had multiple L-OMD treated concurrently. All had primary disease controlled at the time of SABR. The median age was 70 years (39−84). All patients had KPS>80%. 34 pts(77%) had prior chemotherapy (at least 2 lines), and 15pts (33.5%) had prior treatment for L-OMD (sugery, 13 pts, RFA, 2 pts). The median disease free interval from initial diagnosis to diagnosis of L-OMD requiring SABR was 33 months (0–144). Median tumour size was 1.35 cm (0.8−4). Centralised protocols for IMRT- SABR developed by University of Pittsburgh Cancer Institute were used. SABR was performed with using Body Fix^{TM} immobilisation, image-guided dynamic IMRT and respiratory motion management. Target volumes were adapted to account for respiratory motion. Varian Trilogy TX with high definition MLC and on-board image guidance (KV, CBCT, fluoroscopy) were used. Tumor location risk adapted fractionation schedules were used: 60 Gy/3 (20 pts), 60 Gy/5 (6 pts), 48 Gy/4 (10 pts), 60 Gy/8 (7 pts), and 50 Gy/10 (1 pt), delivered in 2−3 weekly treatments.
The primary end-points were local control and survival. Secondary endpoints were pattern of failure and toxicity.
Results: Post-SABR, the median follow-up time was 12 months (2−33). At 1- and 2- years, the actuarial in-field control rates were 82.5% and 51.8%, progression free survival (PFS) 47% and 14.1%, overall survival (OS) 87% and 53% respectively. Median survival time was 24 months from completion of SABR. There was no significant correlation between survival and age, tumor size, number of treated metastases, dose schedule or disease free interval.
After a median of 6 months post-SABR (1−26), 27 pts (61%) experienced a first progression, mainly extra-target new pulmonary nodules (11 pts isolated, 4 pts associated with extra-thoracic metastases). Isolated in-field failure was recorded in 4 pts. Salvage SABR was used in 7 pts with new single pulmonary nodule, while further chemotherapy was recommended in 20 pts. After first progression, the 1- and 2- years OS were 71% and 41% respectively.
No high grade (>G3) acute or long term toxicities were reported.
Conclusions: Our early multi-institutional experience shows that SABR achieves good local control and promising PFS and OS rates, with low toxicity in pretreated, selected patients with isolated L-OMD from CRC primaries. The reported pattern of failure shows high rates of extra-target volume disease progression, illustrating the challenges in patient selection. The best patient group to benefit from SABR remains to be determined.
No conflict of interest.

2305 POSTER

Determination of the delivered dose to scrotum and testis in radiotherapy of rectal cancer by thermoluminescence dosimetry (TLD), with a comparison to the dose calculated by the planning software

P. Haddad[1], Z. Karimimoghaddam[1], F. Farhan[1], M. Esfahani[2], M. Afkhami[2], F. Amouzegar-Hashemi[1]. *[1]Cancer Institute Tehran University of Medical Sciences, Radiation Oncology, Tehran, Iran; [2]Cancer Institute Tehran University of Medical Sciences, Radiation Physics, Tehran, Iran*

Background: Rectal cancer is a common malignancy, in treatment of which pelvic radiotherapy plays an important role. But this may lead to azospermia and infertility. We designed a study to determine the delivered dose to the scrotum and testes with thermoluminescence dosimetry (TLD) and compare it to the dose calculated by the 3-dimensional planning software.
Materials and Methods: We measured the scrotum and testicular doses by TLD; the TLDs were fixed to the scrotum in six points anteriorly and posteriorly in two random fractions of the radiation course. All patients received a 50 −50.4 Gy radiation dose to the pelvis in a prone position with standard fractionation and 3-dimensional planning, through three or four fields. The average dose of the TLD measurements was compared to the average of 6 relevant point doses calculated by the planning software.
Results: In 33 patients with a mean age of 56 (range 24−72) years, the mean testis dose of radiation measured by TLD was 3.77 Gy (range 4.08–15.81 Gy), equal to %7.5 of the total prescribed dose. The mean of point doses calculated by the 3-dimensional planning software was 4.11 Gy (range 0.17–23.4 Gy), equal to %8.1 of the total prescribed dose. A significant relationship was seen between the position of the inferior edge of the fields and the mean testis dose (P = 0.04). Also body mass index (BMI) was inversely related with the testicular dose (P = 0.049).
Conclusion: In this study, the mean testis dose of radiation was 3.77 Gy, similar to the dose calculated by the planning software (4.11 Gy). This dose could be significantly harmful for spermatogenesis, though low doses of scattered radiation to the testes in fractionated radiotherapy might be followed with better recovery. Based on above findings, careful attention to testicular dose in radiotherapy of rectal cancer for the males desiring continued fertility seems to be required.
No conflict of interest.

2306 POSTER

Does radiotherapy of the primary rectal cancer affect prognosis after pelvic exenteration for recurrent rectal cancer?

A. Rombouts[1], C.E. Koh[2], J.M. Young[2], L. Masya[2], R. Roberts[2], K. De-Loyde[2], J.H.W. De Wilt[1], M.J. Solomon[2]. *[1]Radboud University Medical Centre Nijmegen, Department of Surgery, Nijmegen, Netherlands; [2]Sydney Local Health District & Sydney School of Public Health University of Sydney, Surgical Outcomes Research Centre (SOuRCe), Sydney, Australia*

Background: The role of radiotherapy in reducing local recurrence for rectal cancer is well-documented, albeit at the expense of potential short and long term toxicity. Radiotherapy may also render the treatment of local recurrence more challenging should it develop despite previous radiotherapy. This study examined the impact of radiotherapy for primary rectal cancer on outcomes after pelvic exenteration for locally recurrent rectal cancer.
Materials and Methods: Patients who underwent pelvic exenteration for locally recurrent rectal cancer at the Royal Prince Alfred Hospital in Sydney were identified from an electronic exenteration database. Medical records were reviewed for supplementary data on adjuvant therapy and follow-up. Outcomes between patients who did and did not receive radiotherapy were compared. The main outcomes of interest were resection margins, overall survival, disease free survival and surgical morbidities.
Results: Between 1994 and 2012, 108 patients underwent pelvic exenteration for LRRC. Of these, 87 were eligible for analysis (radiotherapy= 41, non-radiotherapy= 46). There was no peri-operative mortality. Patients who received radiotherapy for their primary rectal cancer required more radical exenterations (68% vs 44%, p= 0.020), had significantly lower rates of clear resection margins (63% vs 87% p= 0.010), an increased rate of surgical complications per patient (p= 0.014) and a lower disease free survival (p= 0.022). 5 year overall survivals were 26.8% and 66.9% in the radiotherapy and non-radiotherapy groups respectively. Although this was not statistically significant (p = 0.115), it was considered clinically significant. Further, overall survival and disease free survival in patients with clear margins was also lower in patients who received radiotherapy for their primary rectal cancer (p= 0.049, and p< 0.0001 respectively). This difference in survival persisted on multivariate analysis after correcting for T and N stages of the primary tumour.
Conclusions: This study shows that patients who received radiotherapy as part of their treatment of primary rectal cancer have worse oncological outcomes than those who did not after pelvic exenteration for locally recurrent rectal cancer. Further research is necessary to clarify potential long term adverse effects of radiotherapy in rectal cancer patients.
No conflict of interest.

2307 POSTER

The relation of ypT, ypN and tumor regression grade in rectal cancer treated with preoperative short-term chemoradiotherapy

K. Nagata[1], N. Beppu[1], F. Kimura[1], H. Yanagi[1], M. Yamanaka[1]. *[1]Meiwa Hospital, Surgery, Nishinomiya, Japan*

Purpose: Preoperative chemoradiotherapy applied to the locally advanced rectal cancer reduces local recurrence and improves survival. We assessed tumor regression grade (TRG) and shrinkage pattern in rectal cancer patients treated with short-term chemoradiotherapy followed by surgical resection.
Methods: Between 2001 and 2011, 140 patients with locally advanced rectal cancer treated with short-term preoperative chemoradiotherapy followed by surgical resection were retrospectively analysed. Patients received preoperative short-term chemoradiotherapy (25 Gy/10 fractions/ 5 days) with S-1 as a sensitizer for 10 days. Operation was performed at 3−4 weeks after the end of chemoradiotherapy. We examined resected samples in pathological status of ypT, ypN and TRG. We evaluated by using the TRG proposed by Dworak et al. We analyzed the relation of ypT, ypN and TRG in pathology, retrospectively.
Results: The ypT distribution was shrinkage pattern (ypT0, ypT1 or ypT2)/ fragmentation pattern (ypT3 or ypT4) = 54/86. The ypN distribution was N(−)/N(+) = 53/87. The TRG distribution was TRG0/TRG1/TRG2/ TRG3/TRG4 =6/45/38/52/0. The shrinkage patterns in T feature were significantly greater in the radioresponders group (TRG2, 3, 4) (48.3% vs 22.6%, P<0.05). Lymph node metastasises were significantly less in the shrinkage patterns group. (81.5% vs 50.0% p < 0.05) Lymph node metastasises tended to be less in the radioresponders group (66.7% vs 54.7% p = 0.15).

Conclusion: Higher TRG closely correlates with better ypT and ypN after short-term preoperative chemoradiotherapy followed by surgical resection.
No conflict of interest.

2308 POSTER

Neoadjuvant radiotherapy in rectal carcinoma: Therapeutic response and toxicity

J. Casalta-Lopes[1], I. Nobre-Góis[2], T. Teixeira[2], M.R. Silva[3], A. Sá[4], M. Borrego[2], P. Soares[2]. *[1]Centro Hospitalar e Universitario de Coimbra/ Biophysics Unit IBILI − Faculty of Medicine University of Coimbra Portugal, Radioterapia, Coimbra, Portugal; [2]Centro Hospitalar e Universitário de Coimbra, Radioterapia, Coimbra, Portugal; [3]Centro Hospitalar e Universitário de Coimbra, Anatomia Patológica, Coimbra, Portugal; [4]Centro Hospitalar e Universitário de Coimbra, Oncologia Médica, Coimbra, Portugal*

Background: Locally advanced rectal carcinoma (LARC) is usually treated with radiotherapy (RT) followed by surgery. There are two schemes for neoadjuvant irradiation: long-course (LC), associated with chemotherapy (CT), and short-course (SC). The aim of this study is to compare response and toxicity to RT using LC and SC irradiation in patients with LARC.
Material and Methods: We included patients with LARC treated between 2002 and 2012 in our Institution using pre-operative RT, either using LC or SC. Response was assessed by pTNM classification and Dworak Regression Grade (DRG). Toxicity was assessed using CTCAE4.0 scale.
Results: 215 patients treated with LC and 55 treated with SC were included. SC patients were older and had lower performance status than LC patients ($p < 0.001$). 20% of SC patients were stage IV and 92.6% of LC patients were stage III ($p < 0.001$). Surgery with curative-intent was performed in 208 LC patients and 47 SC patients; sphincter-preserving surgery was performed in most cases. DRG 4 was obtained in 16.8% vs. 6.4%, nodal downstaging in 66.3% vs 23.4% and loco-regional response in 79.8% vs. 57.4% (LC vs. SC; $p < 0.001$). No acute toxicity was described in SC patients; in other hand, we observed acute toxicity in 77.7% of LC patients ($p < 0.001$), with 7.9% of grade 3 or 4 ($p = 0.028$). No differences in post-operative complications were observed ($p = 0.299$). More LC patients were submitted to adjuvant CT ($p < 0.001$). Worse pathologic response pTN and DRG 0 or 1 in LC treatment are related to more R+ resections ($p < 0.01$).
Conclusions: LC irradiation is associated with better response than SC irradiation, allowing more curative resections, at the expense of an acceptable toxicity.
No conflict of interest.

2309 POSTER

Neoadjuvant chemoradiotherapy in rectal carcinoma: Therapeutic response as prognostic factor

I. Nobre-Góis[1], J. Casalta-Lopes[2], T. Teixeira[1], M.R. Silva[3], A. Sá[4], M. Borrego[1], P. Soares[1]. *[1]Centro Hospitalar e Universitário de Coimbra, Radioterapia, Coimbra, Portugal; [2]Centro Hospitalar e Universitário de Coimbra/ Biophysics Unit IBILI Faculty of Medicine University of Coimbra, Radioterapia, Coimbra, Portugal; [3]Centro Hospitalar e Universitário de Coimbra, Anatomia Patológica, Coimbra, Portugal; [4]Centro Hospitalar e Universitário de Coimbra, Oncologia Médica, Coimbra, Portugal*

Background: Chemoradiotherapy (CRT) followed by surgery is a consensual approach for locally advanced rectal cancer (LARC). In this CRT regimen, known as long-course (LC), radiation dose is 45–50.4 Gy/25−28fr/5−5.5wk. Pathologic response (PR) might have prognostic impact in these patients. This study aims to compare disease-free (DFS) and overall survival (OS) in patients with LARC, stratified for PR.
Material and Methods: We included LARC patients treated in our Institution between 2002 and 2011, using LC irradiation. Response was assessed using pTNM classification and Dworak Regression Grade (DRG). Survival was estimated by Kaplan–Meier method and multivariate analysis was performed using Cox Proportional Hazards Regression. A type I error of 0.05 was considered.
Results: 199 patients were included. Complete response (GROUP1) was obtained in 13.6% of patients, ypT1−2 N0 (GROUP2) in 30.2% and ypT3−4 or N+ (GROUP3) in 56.3%. In univariate analysis, DFS and OS were lower in GROUP3 ($p = 0.001$, Hazard Ratio (HR)=3.283 and $p = 0.004$, HR = 8.188, respectively); other significant prognostic factors were R+ resection ($p < 0.001$) and distance to anal verge lower than 6 cm ($p < 0.05$). In multivariate analysis complete PR had significant impact in DFS and R+ resection in DFS and OS ($p < 0.05$). Higher DRG was associated with better DFS ($p = 0.017$).
Conclusions: PR assessed by pTNM staging or by DRG had significant prognostic impact in DFS and OS, in patients with LARC treated with CRT.
No conflict of interest.

2310 POSTER

Effect of neoadjuvant chemoradiotherapy on lymph node harvest in rectal cancer surgery

K. Goonetilleke[1], S. Addison[2], S. Odogwu[2]. *[1]Walsall Hospital NHS Trust, Birmingham, United Kingdom; [2]Walsall Hospital NHS Trust, Surgery, Birmingham, United Kingdom*

Background: Current guidelines suggest for proper TNM staging, 12 lymph nodes per specimen are critical. This study assessed the role of preoperative radiochemotherapy on the number of lymph nodes detected in the tumor-bearing specimen.
Material and Methods: Data on 93 patients who had resection of rectal adenocarcinoma stage II and III at a single cancer center in the United Kingdom were retrospectively reviewed during the period April 2009 to May 2012.
Results: Of a total of 93 patients, 51 received neoadjuvant therapy and 42 did not. Positive lymph nodes (minimum 12) were detected in 85% patients in the neoadjuvant group as compared with 98% patients in the surgery group ($P<0.05$). Significantly fewer total lymph nodes were retrieved in the neoadjuvant therapy patients compared to those who did not receive preoperatively therapy (16 vs. 21, $p < 0.05$). There was a significantly higher extramural venous spread in the surgery alone group. (27 vs.18, $P<0.05$). Tumor regression was seen in 40% patients who received neoadjuvant therapy.
Conclusions: Preoperative radiochemotherapy could induce a significant downsizing and downstaging of advanced rectal cancer. Great care in operative and pathologic examination techniques must be taken to ensure appropriate staging.
No conflict of interest.

Sampling rectal mucus DNA − a new method for early diagnosis of colorectal cancer?

A. Tzivanakis[1], C. Ferrett[1], R. Hargets[2], B. George[1]. *[1]Churchill Hospital, Oxford Colorectal Centre, Oxford, United Kingdom; [2]University Hospital of Wales, Section of Surgery Cardiff University School of Medicine, Cardiff, United Kingdom*

Introduction: Increased colonocyte exfoliation in colorectal cancer (CRC) is well described. Higher DNA counts have been observed in rectal mucus from CRC patients, but the amount of DNA at varying distances from the primary tumour has not been determined.
Methods: 25 specimens from patients with CRC were used to measure the amount of human DNA in muscosal samples at the tumour site and at set distances from it. Results were expressed as ratio of the value at a particular site to value at tumour site. Rectal mucus DNA count was measured in 58 patients with suspected CRC. These were later divided into cancer or benign groups and the amount of rectal mucus DNA in the two groups was compared.
Results: The ratio of DNA counts was significantly higher for measurements taken at up to 15 cm distal to the tumour, compared with those from the most proximal margin of the specimen. However there was no significant difference in the ratio of DNA counts taken from the 20 cm immediately proximal to the primary tumour, and those taken distal to the tumour. The 39 patients who were eventually diagnosed with CRC had higher DNA in their rectal mucus, compared to those ($n = 19$) that had no disease or small benign polyps.
Conclusion: These results suggest distal accumulation of tumour DNA within colonic mucus which can be easily obtained via proctoscopy. This may allow future work on identifying biomarkers within rectal mucus which would indicate preclinical development of CRC and earlier diagnosis.
No conflict of interest.

Colorectal liver metastases and peritoneal metastases: Prognostic equivalences and differences after complete surgery

D. Elias[1], M. Faron[1], M. Ducreux[2], P. Dartigues[3], J.L. Bourgain[4], D. Goéré[1]. *[1]Institut Gustave Roussy, Oncological Surgery, Villejuif, France; [2]Institut Gustave Roussy, Medical Oncology, Villejuif, France; [3]Institut Gustave Roussy, Pathology, Villejuif, France; [4]Institut Gustave Roussy, Anesthesiology, Villejuif, France*

Background: No where in the literature is there mention of equivalent survival results after curative surgery treating colorectal metastases emerging at different sites.
Objective: To present prognostic similarities and differences between patients treated for liver metastases (LM) and patients treated for peritoneal metastases (PM).

Patients and Methods: A retrospective analysis of prospective databases concerning 287 patients with LM and 119 patients with PM treated by surgery plus chemotherapy between 1993 and 2009. Patients presenting with LM + PM (n = 37) were excluded for methodological reasons. The overall tumour load was the main prognostic factor, LM-patients were divided in 2 subgroups (1−10 LM and 11−50 LM) and PM-patients were divided into 3 subgroups according to the peritoneal cancer index (PCI): 1−5, 6−15, and >15. All of them had also received peri-operative systemic chemotherapy.
Results: 5-year survival rates, mortality and morbidity were not statistically different between the two treatment groups (respectively 38.5%, 2.7% and 11% in the LM-group, and 36.5%, 4.2% and 17% in the PM-group). The 5-year overall survival rate was the highest in the subgroup with minimal peritoneal disease (PCI 1−5): 72.4%. It was similar for the 1−10 LM and 6−15 PCI score subgroups (respectively 39.4% and 38.7%), lower for the 11−50 LM (18.1%) subgroup, and dramatically low for the >16 PCI score (11.8%) subgroup.
Conclusion: Equivalent survival results exist when resected LM and resected PM are compared. Minimal PM carries a far better prognosis than LM. Classification into subgroups according to the overall tumour load (2 subgroups for LM and 3 for PM) enabled us to obtain a simple and clear prognostic assessment.
No conflict of interest.

Irreversible electroporation, a novel, non-thermal ablation technique to treat colorectal liver metastases: Results of an 'ablate and resect' study

K. Nielsen[1], H.J. Scheffer[2], A.A.J.M. Van Tilborg[2], G. Kazemier[1], J.M. Vieveen[3], J.W.M. Niessen[4], W.H. Schreurs[5], S. Meijer[1], M.R. Meijerink[2], M.P. Van der Tol[1]. *[1]VU Medical Center, Surgery, Amsterdam, Netherlands; [2]VU Medical Center, Radiology, Amsterdam, Netherlands; [3]VU Medical Center, Anaesthesia, Amsterdam, Netherlands; [4]VU Medical Center, Pathology, Amsterdam, Netherlands; [5]Medical Centre Alkmaar, Surgery, Alkmaar, Netherlands*

Background: Irreversible electroporation (IRE) is a new, non-thermal, image guided technique for tumor ablation. The application of an electric field across cells creates nanopores in the cell membrane, inducing cell death. Surrounding -acellular- connective tissue is relatively preserved, so the framework of vulnerable structures such as blood vessels and bile ducts should remain intact. We present results of the COLDFIRE study: a prospective single centre pilot study of patients with colorectal liver metastases treated with IRE before surgical resection. The aim was to evaluate safety, feasibility and (histological) changes of the ablated tissue after IRE.
Material and Methods: After informed consent, 11 patients with resectable colorectal liver metastases <3.5 cm were included. Exclusion criteria were chemotherapy <6 weeks prior to surgery or a history of cardiac arrhythmias or epilepsy. During laparotomy, one of the resectable metastases was ablated with IRE. Sixty minutes after ablation, the ablation zone was visualized using ultrasound and that same lesion was resected. Safety and feasibility were determined based on blood samples, (S)AE's and procedure time. The vitality of the ablation zone was visualized macroscopically using triphenyl tetrazolium chloride (TTC) and microscopically using different immuno-histological stainings. Inclusion has been completed.
Results: Eleven lesions were treated with IRE in respect to this study with a mean diameter of 2.2 cm. No SAE's occurred during the procedure and technical failure was reported once. Two or 4 electrodes were used for ablation and correct placement took on average 2.5 min per electrode. Median total ablation time was 2.6 minutes (1−7). One ablation took 55 minutes, due to over-current. Median time until resection was 85 minutes (51–153). The ablation zone was hypo-echogenic on ultrasound. The specimen showed red discoloration of the ablated area which turned grey after TTC staining, indicating avitality. Bile ducts and blood vessels were macroscopically intact in all cases.
Conclusion: This study suggests that IRE is a quick, safe and feasible technique for local treatment of colorectal liver metastases. Macroscopic results are promising, but histology needs to be awaited to determine the exact effect on the tissue and to define the transition-zone between reversible and irreversible electroporation.
Trial registration at clinicaltrials.gov, NCT01799044. The trial is sponsored by CCA/V-ICI

2314 POSTER

Factors affecting the number of retrieved lymph nodes in patients with stage II colon cancer − lymph-node size and area ratios of B cells and T cells in lymph nodes

K. Okada[1], S. Sadahiro[1], T. Suzuki[1], A. Tanaka[1], G. Saito[1], A. Kamijo[1], S. Masuda[2]. *[1]Tokai University, Surgery, Isehara, Japan; [2]Nihon University, Pathology, Isehara, Japan*

Background: In patients with stage II colon cancer, large numbers of retrieved lymph nodes have been associated with good survival. We tested the hypothesis that lymph node size was large in patients with many retrieved lymph nodes and then investigated the cause of increased lymph-node size.
Methods: The study group comprised 320 patients with stage II colon cancer who underwent radical (R0) resection from 1991 through 2003. All patients underwent elective surgery performed by the same team of colorectal-cancer specialists. Lymph-node dissection extended to the origin of the feeding artery. The long- and short-axis diameters of retrieved nodes were measured on H-E stained specimens. Lymph nodes are divided into 3 compartments: the cortex, paracortex, and medulla. B cells reside mainly in the cortex, and T cells mainly in the paracortex. B-cells and T-cells were immunohistochemically stained with CD20 and CD3, respectively, and CD20-positive area ratio and CD3-positive area ratio were measured with image analyzer.
Results: A total of 4745 lymph nodes were examined. The mean number of retrieved nodes was 15±10. The long-axis diameters of the lymph nodes were as follows: mean, 4.8±2.6 mm; median, 4.3 mm; and maximum, 20.4 mm. The short-axis diameters were 3.4±1.7 mm, 3.0 mm, and 15.1 mm, respectively. Correlation coefficients (Pearson) for the number of retrieved nodes and their long-axis diameters were as follows: mean, 0.23; median, 0.16; and maximum, 0.59. The respective correlation coefficients for the short-axis diameters were 0.18, 0.13, and 0.54. There were moderate positive correlations between the number of retrieved nodes and the maximum long- and short-axis diameters of the nodes. Based on these results one lymph node with the greatest long-axis diameter was selected per patient and was immunohistochemically stained with CD20 and CD3. The mean area ratio was 0.42±0.10 for CD20 and 0.39±0.08 for CD3. When the cutoff value of the CD20-positive area ratio was set at 0.4, the mean long-axis diameter was significantly greater for nodes with a CD20-positive area ratio of ⩾0.4 than for those with a ratio of <0.4 (9.4±3.7 mm vs. 8.3±3.4 mm; $p < 0.01$). There was no significant relation between CD3-positive area ratio and the mean long-axis diameter. Survival analysis showed that age, depth of invasion, and CD20-positive area ratio were independent prognostic factors. The hazard ratio was 2.31 (95% confidence interval [CI], 1.52–3.62; $p < 0.01$) for age (younger than 63 years vs. 63 years or older), 2.82 (95% CI, 1.86–4.20; $p < 0.01$) for depth of invasion (T3 vs. T4), and 0.58 (95% CI, 0.39–0.85; $p = 0.01$) for CD20-positive area ratio (<0.425 vs. ⩾0.425).
Conclusions: The number of retrieved lymph nodes correlated with the longest diameter of retrieved nodes. The B-cell area ratio of lymph nodes increased in parallel to maximum lymph-node diameter and positively correlated with better survival.
No conflict of interest.

2315 POSTER

Prospective randomized study comparing robotic-assisted surgery with laparotomy for rectal cancer in India

K.R. Ashwin[1], S.P. Somashekhar[1], Z. Shabber[1]. *[1]Manipal Comprehensive Cancer Center, Surgical Oncology, Bangalore, India*

Background: Rectal cancer is one of the common cancers in India. Surgical management is the mainstay of initial treatment for majority of patients. Open rectal surgery is considered the gold standard treatment for rectal cancer. Minimally invasive surgery has gained acceptance for the surgical treatment of rectal cancer because, compared with laparotomy and is associated with fewer complications, shorter hospitalization, and faster recovery. The aim of this study is to evaluate the safety, feasibility, technique and outcomes (oncological and functional) of robotic rectal surgery in comparison with open surgery in the Indian population.
Materials and Methods: A prospective randomized study was undertaken from April 2011 to March 2013. 90 patients who presented with rectal carcinoma were randomized to either robotic arm (RA) or open arm (OA). Both groups were matched for clinical stage and operation type.
Results: The mean operative time was significantly longer in the RA than in the OA (310 vs 246 min, P<0.001. The operative time but was significantly reduced in the latter part of the RA patients compared with the initial few patients. The mean estimated blood loss was significantly less with RA compared to OA (165.14 ml vs 406.04 ml, P<0.001). None of the patients had margin positivity. The mean distal resection margin

was significantly longer in the RA than OA (3.6 vs 2.4 cm, P < 0.001). One of the most important factors relating to adequacy of rectal excision is the mesorectal grade, which is related to oncological outcome.100% of patients in RA had complete mesorectal excision while five patients in the OA had incomplete mesorectal excision. Incomplete mesorectal excision with distal 'Coning' was more common in OA due to lack of sufficient space in the pelvis. The average number of retrieved lymph nodes was adequate for accurate staging. Number of lymph nodes removed by robotic method is slightly higher than the open method (16.88 vs 15.20) but with no statistical significance. Conversion rate was nil. The mean hospital stay was significantly shorter in RA (7.52 versus 13.24 days, P<0.001). Post-operative and functional outcomes (urinary function, erectile dysfunction & retrograde ejaculation) were comparable between the two groups.
Conclusion: Robotic assisted surgery is an emerging technique in our country. In comparison to open method, it has advantages of decreased blood loss, less postoperative complication and shorter length of hospital stay. The patients who underwent robotic surgery had a superior mesorectal grade and longer distal resection margins. Morbidly obese patients are more suitable for robotic assisted approach, as chances of arm clash decrease due to adequate spacing.We conclude that robotic assisted rectal cancer surgery is safe with low conversion rates, acceptable morbidity and is oncologically feasible.
No conflict of interest.

2316 POSTER

Treatment of ovarian metastases of colorectal carcinoma in the era of hyperthermic intraperitoneal chemotherapy

A.M.J. Kuijpers[1], A.M. Mehta[1], A.G.J. Aalbers[1], H. Boot[2], V.J. Verwaal[1]. *[1]Netherlands Cancer Institute, Surgical Oncology, Amsterdam, Netherlands; [2]Netherlands Cancer Institute, Medical Oncology, Amsterdam, Netherlands*

Background: Patients with ovarian metastases of colorectal carcinoma have a high risk of developing peritoneal metastases in the course of the disease. The current gold standard in treatment of peritoneal metastases consists of cytoreductive surgery (CRS) in combination with hyperthermic intraperitoneal chemotherapy (HIPEC). This study evaluated outcome of patients with ovarian metastases of colorectal carcinoma who were treated with CRS and HIPEC.
Methods: From the local institute's cancer registry, all female patients with a history of colorectal carcinoma were identified. Patients with ovarian metastases suspected on radiological review or proven by pathological findings were included. Patient, tumour and treatment characteristics were retrospectively obtained. Survival analysis was performed for the patient group that underwent CRS and HIPEC and compared to a control group of women who underwent CRS and HIPEC with only extra-ovarian peritoneal metastases.
Results: In the period 2000–2012, 125 women were treated for ovarian metastases of colorectal carcinoma in our institute. Seventy-eight patients underwent curative oophorectomy with CRS and HIPEC, 43 patients underwent (mostly palliative) oophorectomy only and 2 patients received palliative chemotherapy only. Of the 78 patients undergoing CRS and HIPEC, 57 patients had synchronous peritoneal metastases (73%), 18 had isolated ovarian metastases (23%) and 3 had systemic metastases with complete radiological response following neo-adjuvant chemotherapy (4%). Median overall survival was 40 months (95% confidence interval (CI)25.7–54.3) in the ovarian metastases group and 64 months (95% CI 33.4–94.6) in the control group (p = 0.151). Median progression free survival was 19 months (95% CI 11.7–26.3) in the ovarian metastases group and 17 months (95% CI 10.8–23.2) in the control group (n = 52) (p = 0.688). Primary failure sites were distributed equally between patients with and without ovarian metastases, with intraperitoneal recurrences occurring in 52% and 58% respectively (p = 0.182).
Conclusion: Outcome of CRS and HIPEC for colorectal carcinoma does not differ among women with ovarian metastases when compared to women with only extra-ovarian peritoneal metastases. Moreover, patterns of recurrence were not influenced by the presence of ovarian metastases. These data confirm the role of CRS and HIPEC in patients with ovarian metastases of colorectal origin treated with curative intent.

2317 POSTER

Preoperative neutrophil to lymphocyte ratio over 3.0 independently predicts disease-free survival after curative resection of colorectal cancer

G. Malietzis[1], M. Giacometti[1], A. Askari[1], S. Nachiappan[1], R.H. Kennedy[1], O.D. Faiz[1], O. Aziz[1], J.T. Jenkins[1]. *[1]St Mark's Hospital, Colorectal Surgery, Harrow Middlesex, United Kingdom*

Background: Neutrophil to lymphocyte ratio (NLR) reflects the host systematic inflammatory response, with some evidence suggesting that a preoperative NLR >5.0 is associated with poorer survival in colorectal cancer patients. This study aims to determine the role of the NLR as a prognostic marker for colorectal cancer patients with non-metastatic disease undergoing curative resection.
Materials and Methods: 506 consecutive patients diagnosed with non-metastatic colorectal adenocarcinoma undergoing curative surgical resection between 2006 and 2011 were included. Receiver Operating Characteristics (ROC) curve analysis was used to identify the optimal sensitivity and specificity for NLR in relation to disease-free and overall survival. Univariate and multivariate Cox regression models were used to determine the role of NLR after stratification by several clinicopathological factors. Patients were followed by a standardised surveillance protocol until February 2013.
Results: Median follow-up was 44.57 months [IQR, 20.97–65.16]. Multivariate Cox regression analysis identified NLR>3 as an independent prognostic factor for disease free survival (OR 2.41, (95% CI 1.12–5.15) P = 0.024,) but not for overall survival (OR 1.23, (95% CI 0.80–1.90) P = 0.347). A high NLR was significantly associated with patient and tumour-related factors: age, low pre-operative albumin levels and ASA status of the patient; higher T and N stage, and presence of microvascular invasion.
Conclusion: For patients diagnosed with CRC, a pre-operative NLR>3 is an independent prognostic factor for disease-free survival. A longer follow-up period may identify associations with overall survival. Considering NLR>3.0, in addition to well-established prognostic variables, may improve the processes of identifying patients at higher risk of recurrence who would benefit from adjuvant therapies, thereby offering more personalised cancer care.
No conflict of interest.

2318 POSTER

Sustainability of an enhanced recovery programme in colonic surgery in the Netherlands

F. Gillissen[1], S.M.C. Ament[2], J.M.C. Maessen[2], C.D. Dirksen[3], T. Van der Weijden[2], M.F. Von Meyenfeldt[4]. *[1]Maastricht University Medical Centre, Surgery GROW, Maastricht, Netherlands; [2]Maastricht University Medical Centre, Caphri, Maastricht, Netherlands; [3]Maastricht University Medical Centre, Kemta, Maastricht, Netherlands; [4]Maastricht University Medical Centre, Surgery, Maastricht, Netherlands*

Background: Implementing an effective innovation into daily routines is a dynamic and difficult process. Even in successfully implemented innovations there is a tendency for return to old routines once the implementation activities have ended. Surgical care, as other specialties, is a domain in healthcare that has a high turn-around and fast changing character. In the Netherlands, the Enhanced Recovery After Surgery (ERAS) programme was implemented in colonic surgery in 33 hospitals by means of a generic implementation strategy. This resulted in enhanced recovery and a decrease of hospital length of stay after colonic surgery from a median of 9 at baseline to 5 days at one-year follow-up. To study whether these results were sustained we assessed the performance of the ERAS programme 3 to 5 years after the implementation activities had been ended.
Material and Methods: A retrospective audit of 30 consecutive patients undergoing colonic surgery in 2012 was performed in 10 hospitals selected out of the original 33 hospitals for having been successful in the implementation of the ERAS programme in the primary study. Whether the ERAS programme was sustained was assessed using hospital length of stay (LOS), functional recovery (FR) and protocol compliance. These retrospective audit data were compared with the pre-implementation and implementation phase data.
Results: Overall median LOS increased from 5 days (IQR 4−8) in the implementation phase to 6 days (IQR 5−10) in the post-implementation phase. Two hospitals achieved a further reduction, one showed an equal LOS, six hospitals showed an increase but did not return to the pre-implementation level, and one hospital relapsed to the same level as before the pre-implementation level.
Overall FR was reached in a median of 3 days in the post-implementation phase (IQR 2−4), which was equal to the median FR in the implementation phase (IQR 3−5).

Table 1 (abstract 2320). Results of the DSCA 2009–2011

Total	4960		6293		6263			2035		2484		2494		

MDT: Multidisciplinary Team; MRI: Magnetic Resonance Imaging; CRM: Circumferential Resection Margin.

Protocol compliance decreased from 74% in the implementation phase to 70% in the post-implementation phase.
Conclusions: This shows that for the ERAS programme sustainability was reasonably achieved in the 10 most successful hospitals, although it also makes clear that sustainability is indeed not guaranteed. It is by which criteria one measures that sustainability of health care innovations may be judged successful or not. More research is needed to determine which factors contribute and which factors inhibit the sustainability of proven health care innovations.

Large variation in the utilization of liver resections in colorectal cancer patients with synchronous liver metastases

R.H.A. Verhoeven[1], J.H.W. De Wilt[2], A.M. Rijken[3], R.M.H. Roumen[4], V.E.P.P. Lemmens[1]. *[1]Eindhoven Cancer Registry/Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands; [2]Radboud University Nijmegen Medical Centre, Surgery, Nijmegen, Netherlands; [3]Amphia Hospital, Surgery, Breda, Netherlands; [4]Máxima Medical Centre, Surgery, Eindhoven, Netherlands*

Background: Most patients with synchronous metastases from colorectal cancer have incurable disease. Patients with synchronous colorectal liver metastases (SCRLM) can, however, potentially be cured with resection of primary tumor and resection of the liver metastases. Studies have suggested that up to 40% of the patients with SCRLM should potentially be candidates for resection of the liver metastases. We investigated the utilization and survival of resection of SCRLM in the south of the Netherlands.
Methods: Data on patients with SCRLM without metastases in any other organ, diagnosed in the period 2004–2011, were extracted from the population-based Eindhoven cancer registry (n=1441). We investigated institutional variation in the utilization of SCRLM resections. Kaplan–Meier curves of patients with SCRLM were made according to type of treatment and Cox-regression on overall survival was used to asses which factors influenced the survival of patients with SCRLM.
Results: The percentage of patients that underwent a liver resection increased from 8% in 2004 to 16% in 2011 for patients in which the primary tumor was located in the colon and increased from 15% to 28% in the same period for patients in which the primary tumor was located in the rectum. In the period 2008–2011 the proportion of patients with SCRLM that underwent a liver resection varied between 6% and 33% according to the hospital in which the patients were diagnosed. Overall median survival was 8 months for patients who underwent no resection, 17 months for patients who only underwent a resection of the primary tumor and 55 months for patients who underwent a resection for both the primary tumor and the liver metastases. Cox-regression showed a hazard-ratio of 0.30 (95% confidence interval: 0.23–0.40) for patients who underwent a liver resection after adjustment for gender, age, location of primary tumor, period of diagnosis, number of comorbidities and chemotherapy.
Conclusion: Although it is well known that patients with SCRLM who have undergone resection of the liver metastases have a large survival benefit, there still seems to be an underutilization of this potentially curative therapy in some hospitals in the region.
No conflict of interest.

2320 POSTER

The Dutch surgical colorectal audit

N. Van Leersum[1], H.S. Snijders[1], D. Henneman[1], N.E. Kolfschoten[1], G.A. Gooiker[1], M. Ten Berge[1], E. Eddes[2], M.W.J.M. Wouters[3], R.A.E.M. Tollenaar[1]. *[1]Leiden University Medical Center, Surgery, Leiden, Netherlands; [2]Deventer Hospital, Surgery, Deventer, Netherlands; [3]Antoni van Leeuwenhoek Hospital, Surgery, Amsterdam, Netherlands*

Background: In 2009, the nationwide Dutch Surgical Colorectal Audit (DSCA) was initiated by the Association of Surgeons of the Netherlands (ASN) to monitor, evaluate and improve colorectal cancer care. The DSCA is currently widely used as a blueprint for the initiation of other audits, coordinated by the Dutch Institute for Clinical Auditing (DICA). This article illustrates key elements of the DSCA and results of three years of auditing.
Material and Methods: Key elements include: a leading role of the professional association with integration of the audit in the national quality assurance policy; web-based registration by medical specialists; weekly updated online feedback to participants; annual external data verification with other data sources; improvement projects.
Results: In two years, all Dutch hospitals participated in the audit. Case-ascertainment was 92% in 2010 and 95% in 2011. External data verification by comparison with the Netherlands Cancer Registry showed high concordance of data items. Within three years, guideline compliance for diagnostics, preoperative multidisciplinary meetings and standardised reporting increased; complication-, re-intervention and postoperative mortality rates decreased significantly (table 1).
Conclusion: The success of the DSCA is the result of effective surgical collaboration. The leading role of the ASN in conducting the audit resulted in full participation of all colorectal surgeons in the Netherlands. By integrating the audit into the ASNs' quality assurance policy, it could be used to set national quality standards. Future challenges include reduction of administrative burden; expansion to a multidisciplinary registration; and addition of financial information and patient reported outcomes to the audit data.

2321 POSTER

Increased disease-free survival following colorectal cancer surgery when performed by a 'high-volume' surgeon

M. Buurma[1], H.M. Kroon[1], M.S. Reimers[1], P.A. Neijenhuis[1]. *[1]Rijnland Hospital, Department of Surgery, Leiderdorp, The Netherlands*

Background: Patients undergoing surgical resection for colorectal cancer have an improved short-term outcome with regards to adverse events, hospital-stay and postoperative mortality when performed by a 'high-volume' surgeon. To date, however, not much is known about its long-term effects. Therefore, we conducted the current study to evaluate the impact of a 'high-volume' surgeon on disease-free and overall survival.
Materials and Methods: We conducted a retrospective analysis of our prospectively collected colorectal cancer database including all patients who underwent a resection in our hospital between 2004 and 2011. Patients were divided into two groups based on the surgeon who performed the procedure: 'high-volume' (>25 cases/year) or 'low-volume' (<25 cases/year) surgeon. Peri-operative characteristics were collected as well as recurrence rates, follow-up and survival data.

Results: A total of 774 patients underwent a colon or rectal resection for a malignancy. Fourteen 'low-volume' surgeons operated 453 patients, and 3 'high-volume' surgeons operated 321 patients. After a median follow-up of four years a resection performed by a 'high-volume' surgeon proved to be an independent prognostic factor for disease-free survival in the multivariate analysis (hazard ratio [HR] 0.739; 95% CI 0.56-.099; p = 0.039). Although overall survival showed a significant difference in favour of the 'high-volume' surgeon in the univariate analysis (HR 0.495; 95% CI 0.35–0.69; P<0.001) it failed to do so in the multivariate analysis (HR 0.731; 95% CI 0.71–1.68; P = 0.088).
Conclusions: In our analysis an increased volume of colorectal cases performed per surgeon was associated with a longer disease-free survival. Although overall survival showed a statistical significant difference in favour of the 'high-volume' surgeon in the univariate analysis it failed to do so in the multivariate analysis, possibly due to the relatively short follow-up period.
No conflict of interest.

2322 POSTER

Survival after resection plus intra-operative radiofrequency ablation (IRFA) to treat colorectal liver metastases (CLM): Results of an international collaborative study

S. Evrard[1], A. Diallo[2], V. Brouste[2], S. Mathoulin-Pelissier[2], P. Kissmeyer-Nielsen[3], F. Mortensen[3], G. Poston[4], S. Staettner[4], I. Konstantidinis[5], Y. Fong[5]. *[1]Institut Bergonié, Digestive Tumours Unit, Bordeaux, France; [2]Institut Bergonié, Department of Biostatistics, Bordeaux, France; [3]Aarhus University Hospital, Department of Surgery, Aarhus, Denmark; [4]Aintree University Hospitals, Department of Hepatobiliary Surgery, Liverpool, United Kingdom; [5]Memorial Sloan-Kettering Cancer Center, Department of Surgery, New York, USA*

Background: Adding IRFA to parenchymal resection to treat CLM is gaining increasing acceptance in specialized HPB teams treating complex, bilobar disease. Objectives were to confirm the promising results of the prospective *CLOCC* and *ARF2003* trials on a larger international scale.
Material and Methods: Four centers combined their clinical databases regarding IRFA for CLM. Demographics, treatments, CLM characteristics, complications (Clavien-Dindo), local recurrence, and survivals (liver progression-free, LPFS, relapse-free, RFS and overall, OS) were analysed.
Results: 280 patients (38% female, median age 61 y) received resection plus IRFA over 2001–2011. 205 had synchronous CLM (73%) and 247 bilateral (88%). 227 patients received pre-operative chemotherapy (173 one line, 37 two lines, 10 three lines, 7 missing); 189 received post-operative chemotherapy (103 one line, 46 two lines, 40 three lines). Median number of tumours resected was 2 (range 1−19) and ablated 2 (1−12). Median size (mm) of largest CLM ablated per patient was 8.5(0.1−50). 96 patients experienced complications: 29 G1, 19 G2, 35 G3, 10 G4, and 3 deaths. 48 patients had local recurrence of ablated CLM. 155 patients developed new CLM, 165 extra-hepatic metastases, and 119 patients died during follow-up. One-year, 3-year and median (months) RFS, LPFS and OS were respectively: RFS 41%(95CI35−47), 14%(95CI9−19), 9m (95CI8−11); LPFS 53%(95CI47−59), 31%(95CI25−37), 15m (95CI11−19); OS 90%(95CI85−93), 58%(95CI51−65), 40m (95CI37−50). Median follow-up was 38m (95CI34−49).
Conclusions: In this difficult-to-treat group, survival results were good and comparable with rates reported after resection only. IRFA complements resection, enabling to treat more patients, and offers the advantage of sparing healthy parenchyma.
No conflict of interest.

2323 POSTER

Aggressive surgical treatment with bony pelvic resection for locally recurrent rectal cancer

K. Uehara[1], Y. Yoshioka[1], T. Aiba[1], Z. Ito[2], S. Imagama[2], S. Tsukushi[2], Y. Nishida[2], Y. Yoshino[3], T. Ebata[1], M. Nagino[1]. *[1]Nagoya University Graduate School of Medicine, Division of Surgical Oncology Department of Surgery, Nagoya, Japan; [2]Nagoya University Graduate School of Medicine, Department of Orthopaedic Surgery, Nagoya, Japan; [3]Nagoya University Graduate School of Medicine, Department of Urology, Nagoya, Japan*

Background: Although introduction of TME has improved local control revolutionarily, approximately 9% of patients with rectal cancer still develop local relapse after curative resection in Japan. The aim of this study was to evaluate the safety and outcome of aggressive surgical treatment with bony pelvic resection for locally recurrent rectal cancer (LRRC) in TME era.
Patients and Methods: A total of 32 patients (8 females; median age, 63 years) with LRRC who underwent extended surgical resection combined with bony pelvis between August 2006 and October 2012 at Nagoya University Hospital were recruited for this study. The mean duration of follow-up was 23 months.
Results: Most of the patients (94%) underwent initial surgery for primary cancer at the referring hospital. Neoadjuvant chemotherapy was applied in 63% of the patients. Sacrectomy was performed in 30 patients and the level of amputation was high (S1) in 6 patients and middle (S2−3) in 18 patients using combined abdominal-sacral approach, and it was low (S4−5) in 6 patients using only abdominal approach. Two patients underwent combined ischiopubic rami resection. Urinary tract reconstruction was usually performed using the ileal conduit. Two patients had concomitant liver metastases at the time of surgery, which was resected completely. Median operative time was 16 hr 47min, and median blood loss was 2701 ml. R0 resection was achieved in 25 patients (78%). Median postoperative hospital stay was 46 days. There was no in-hospital mortality. According to the complication, the most frequent complication was pelvic sepsis in 44%, followed by urinary tract infection in 31%. Re-recurrence occurred in 19 patients (59%). The most frequent recurrent site was the lung in 10 patients (31%) followed by the local in 6 patients (19%). Re-recurrent tumor could be resected in 5 patients. In patients who achieved R0 resection, overall 3-year DFS was disappointing (27 %). However, when the period after resection of re-recurrent tumor with curative intent was regarded as tumor-free time, the overall 3-year tumor-free survival (TFS) was 45% and 3-year local recurrence-free survival (LRFS) was 84%. R0 resection was independent factor for favorable TFS (OR=0.32, p = 0.048) and LRFS (OR=0.07, p = 0.002).
Conclusions: Aggressive surgical resection combined with bony pelvis for highly selected patients with LRRC was safe and could offer high rate of R0 resection. R0 resection was independent factor for favorable TFS and LRFS.
No conflict of interest.

2324 POSTER

Peritoneal carcinomatosis is less frequently diagnosed during laparoscopic surgery compared to open surgery in patients with colorectal cancer

I. Thomassen[1], Y.R.B.M. Van Gestel[2], A.G.J. Aalbers[3], T.R. Van Oudheusden[4], V.E.P.P. Lemmens[2], I.H.J.T. De Hingh[4]. *[1]Comprehensive Cancer Centre South, Eindhoven, Netherlands; [2]Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands; [3]The Netherlands Cancer Institute, Surgery, Amsterdam, Netherlands; [4]Catharina Cancer Center, Surgery, Eindhoven, Netherlands*

Background: During resection of a colorectal tumour a careful inspection of the abdomen should be performed to detect metastases. To date, no data were given on intra-operative findings with regard to synchronous peritoneal carcinomatosis. The aim of this study was to compare the proportions of patients diagnosed with PC during laparoscopic resection (LR) and open resection (OR).
Methods: All patients who underwent resection for colorectal cancer in the Eindhoven Cancer Registry area between 2008 and 2012 were included. Proportions of patients with PC were compared between surgical techniques. Multivariate logistic regression analysis was performed.
Results: 6,687 Patients underwent resection for colorectal cancer, of which 1,631 patients (24%) underwent LR, 4,665 patients (70%) underwent OR and in 391 patients (6%) conversion took place. PC was diagnosed in 1.4% of patients undergoing LR, in 5.0% of patients undergoing OR, and in 3.3% of patients in which LR was converted to OR (p < 0.001). After adjustment for patient and tumour characteristics (e.g., T- and N-stage), patients who were treated by LR had a lower chance to be diagnosed with PC during surgery than patients undergoing OR (odds ratio=0.42, p < 0.001).
Conclusions: Patients undergoing surgery for colorectal cancer are less frequently diagnosed with PC during LR in comparison to OR. Since effective treatment is currently available for selected patients with PC, a thorough inspection of the peritoneum during surgery is of paramount importance to offer these patients a chance for long-term survival and even cure.

2325 POSTER

Primary anastomosis, defunctioning stoma or end-colostomy; outcomes of mid rectal cancer surgery

I.S. Bakker[1], H.S. Snijders[2], J.W.T. Dekker[3], T. Vermeer[4], E.C.J. Consten[5], C. Hoff[6], J.M. Klaase[7], K. Havenga[1], R.A.E.M. Tollenaar[2], T. Wiggers[1]. *[1]University Medical Center Groningen, Surgery, Groningen, Netherlands; [2]Leiden University Medical Center, Surgery, Leiden, Netherlands; [3]Reinier de Graaf Hospital, Surgery, Delft, Netherlands; [4]Catharina Hospital, Surgery, Eindhoven, Netherlands; [5]Meander Medical Center, Surgery, Amersfoort, Netherlands; [6]Medical Center Leeuwarden, Surgery, Leeuwarden, Netherlands; [7]Medical Spectrum Twente, Surgery, Enschede, Netherlands*

Background: Low anterior resection is the cornerstone of treatment for patients with mid rectal cancer. Surgical options consist of a primary anastomosis, anastomosis with a defunctioning stoma or end-colostomy. The aim of this study is to describe short-term and one-year outcomes of these three surgical strategies.
Material and Methods: This retrospective study with one year follow up was conducted in 7 hospitals in the Netherlands. All patients undergoing colorectal resection for mid rectal cancer were included. Patients with a T4 tumour were excluded. Short term endpoints were postoperative complications, re-interventions, prolonged hospital stay and postoperative mortality. One year outcomes were unplanned readmissions and re-interventions, hospital stay, presence of stoma and mortality.
Results: 388 patients undergoing low anterior resection for mid rectal cancer between the 1st January 2009 and 31st of June 2011 were included. From all included patients 72 obtained a primary anastomosis, 214 an anastomosis with defunctioning stoma and 102 patients had an end-colostomy. Short term outcomes showed postoperative complications in one third of all patients. Anastomotic leakage occurred in 10% of patients with a primary anastomosis and 7% in the defunctioning stoma group. No differences were found in re-intervention rate, prolonged hospital stay or mortality. One year outcomes showed, compared to patients with a primary anastomosis, more readmissions and re-interventions in patients with a defunctioning stoma or end-colostomy, with as main cause anastomotic leakage and stoma or abscess problems respectively. In the first year postoperative there was a 30% increase in percentage of patients with an end-colostomy (Table 1).
Conclusions: Many patients obtained a defunctioning stoma, which was associated with significant long term morbidity including anastomotic leakage. An end-colostomy may be a safe alternative in high risk patients, but long-term stoma complications should be taken into account.
No conflict of interest.

Table 1. One-year outcomes. Numbers in bold were statistically significant compared to the anastomosis group ($p < 0.05$).

	Anastomosis		Anastomosis with defunctioning stoma		End-colostomy

2326 POSTER

Colon cancer surgery increases levels of vascular endothelial growth factor open more than laparoscopic approach: Results of a randomised controlled trial

A. Tamburini[1], A. Castiglioni[2], E. Orsenigo[1], A. Manfredi[2], C. Stuadacher[1]. *[1]University Vita-Salute San Raffale, Gastrointestinal Surgery, Milan, Italy; [2]University Vita-Salute San Raffale, Regenerative Medicine and Gene Therapy Dept, Milan, Italy*

Background: Elevations of plasma vascular endothelial growth factor (VEGF) have been noted early after colorectal resection. Because VEGF is a potent promoter of angiogenesis, which is critical to tumor growth, a sustained increase in blood VEGF levels after surgery may stimulate the growth of residual metastases early after surgery. This preliminary report aimed to determine VEGF levels after different colorectal resection.
Methods: This prospective randomised trial included 56 patients with nonmetastatic colorectal cancer. 28 were assigned to laparoscopic surgery group and other 28 patients underwent open colorectal resection. Demographic, perioperative, pathologic, and complication data were collected. Plasma samples were obtained for all patients preoperatively and postoparative (POD) day 1, POD 3, POD 5, POD 7 for all patients and POD 30 for most patients. Levels of VEGF were determined via enzyme-linked immunoassay (ELISA) and compared using Wilcoxon's matched pairs test.
Results: The median plasma value was not significately correlated with age, sex, tumor stage and nodal status. The serum VEGF levels were not significantly different between the laparoscopic and open group at baseline (312 vs 389 pg/ml). A statistical difference was noted regarding the surgical approach. (laparoscopic versus open) VEGF levels were POD 1 (and 300 vs 453 pg/ml) POD 3 (412 vs 600 pg/ml) POD 5 (423 vs 844 pg/ml) POD 7 (414 vs 615) respectively. ($p = 0.003$). The correlation between serum VEGF levels and inflammatory factors, such as white blood cell (WBC) and C-reactive protein (CRP) demonstred a statistically significative correlation in POD5 between WBC and CRP and VEGF ($p = 0.006$ and $p = 0.007$) respectively.
Conclusion: This preliminary report demonstrates that after colorectal resection for cancer with open surgery median VEGF levels are significatively more elevated as after laparoscopic colorectal surgery. The clinical impact from increased blood levels of VEGF is uncertain. It is possible that the growth of residual tumor deposits may be stimulated early after surgery. These results warrant a larger study as well as endothelial cell in vitro assays to determine whether postoperative plasma stimulates proliferation and invasion.
No conflict of interest.

2327 POSTER

Colorectal surgery in octogenarians: Age is the sole relevant risk factor

L.B.M. Weerink[1], C.M. Gant[1], E.A. Kouwenhoven[1], I.F. Faneyte[1]. *[1]ZGT Almelo, Surgery, Almelo, Netherlands*

Background: Colorectal carcinoma (CRC) is the most common malignancy in the elderly. Published data regarding postoperative survival of this specific patient category are not available. The aim of this study is to analyze survival after CRC surgery in octogenarians and to identify predictors of an impaired survival.
Material and Method: Between 2008 and 2011 113 patients aged 80 years and older underwent a colectomy for primary CRC in our hospital. We collected data on the oncological status, pre-existent comorbidities and relevant postoperative parameters.
Results: Patients' mean age was 83.4 years (range 80−94), the mean and median duration of follow up were 22 months. We observed a total mortality of 48 patients (42.5%). 30-day mortality was 7.1% and mortality after one year was 20.4%.
Emergency versus elective surgery and higher ASA class did not influence the overall survival in a Logrank test. Incomplete tumor removal, increased cancer stage, and occurrence of postoperative complications did.
We observed in multivariate analysis that age per adjusted life year is a strong independent predictor of survival in octogenarians (HR 1.17, 95-CI 1.06–1.28, P<0.001).
Conclusions: For patients 80 and older, age per se is the single most important risk factor for influencing survival, besides obvious impairing conditions. In patients aged 80 and older each extra life year increases the risk of death risk 1.16 per annum. So that a patient at 90 years of age at time of surgery has an a baseline risk of dying 4.61 times greater compared to an 80 year old patient.
In the older population age alone is a strong predictor of mortality and as such it exceeds significantly the effect of comorbidities. We therefore conclude that age should get a more important role in risk stratification and decision making in elderly patients with colorectal carcinoma.
No conflict of interest.

2328 POSTER

Bilateral colorectal liver metastases: Towards the end of the two-stage hepatectomy?

D. Goere[1], M. Faron[1], E. Thibaudeau[1], F. Faitot[1], M.A. Allard[1], F. Deschamps[1], F. Dumont[1], C. Honoré[1], D. Malka[1], D. Elias[1]. *[1]Institut Gustave Roussy, Surgical Oncology, Villejuif, France*

Introduction: Surgical treatment of colorectal bilateral liver metastases (LM) is essentially based on a two-stage hepatectomy strategy. However, technical progress in local ablation could afford to treat all the LM in a single surgery. The aim of this study was to analyze the immediate postoperative course and the long-term outcome of patients operated on for bilateral LM in a one stage-hepatectomy.

Patients and Methods: In a prospective database, patients operated on for bilateral LM in a one-stage hepatectomy, were selected. Patients, who underwent a right hepatectomy extended to segment IV, without further action, were excluded from the study.
Results: From January 2000 to December 2010, 174 patients were operated on for bilateral LM. Among them, 155 patients (89%), with a mean age of 57±9 years, underwent resection in one-stage hepatectomy. The median number of LM was 7 [3−42]. A major hepatectomy was performed in 63 patients (41%), minor in 31 (20%) and multiple limited resections in 55 (35%). At least one radiofrequency ablation (RFA) was associated in 131 (85%) patients with a median number per patient of 3 [1−16]. Three patients died postoperatively, and the rates of overall and specific complications were 57% and 20%, respectively. After a median follow-up of 47 [IC95% 40−62] months, overall and recurrence-free survivals at 3 years were 57 % [IC95% 48.1–66.2] and 12.3 [IC95% 7.6–20.2]. The T3 or T4 status of the primary tumor ($p = 0.001$) and the absence of postoperative chemotherapy ($p = 0.0005$) were the only independent factor of poor prognosis.
Conclusion: A surgical strategy combining hepatectomy and local ablation in one-stage is feasible, safe and achieves long-term survivals. This one-stage strategy could increase the prognosis of such patients, compared to the two-stage hepatectomy, by avoiding the tumor progression between the two-stage, reported in 20 to 30% of the patients, and appears to have a less cost-effectiveness.
No conflict of interest.

2329 POSTER

The incidence of nodal involvement after chemoradiation for locally advanced rectal cancer: who might benefit from local excision? Results from a pooled analysis of 2026 patients

K. Peeters[1], M. Maas[2], V. Valentini[3], C. Rödel[4], L. Kuo[5], F. Calvo[6], J. Garcia-Aguilar[7], R. Glynne-Jones[8], R. Beets-Tan[9], G. Beets[10]. *[1]Maastricht University Medical Center, Department of Surgery, Maastricht, Netherlands; [2]Maastricht University Medical Center, Department of Radiology, Maastricht, Netherlands; [3]Universita Cattolica S. Cuore, Department of Radiation Oncology, Rome, Italy; [4]Universitätsklinikum, Department of Radiation Oncology, Frankfurt, Germany; [5]Tapei Medical University Hospital, Department of Colorectal Surgery, Taipei, Taiwan; [6]General University Hospital Gregorio Marañón, Department of Oncology, Madrid, Spain; [7]City of Hope, Department of Oncology, Duarte, USA; [8]Mount Vernon Hospital, Department of Clinical Oncology, London, United Kingdom; [9]Maastricht University Medical Center, Department of Radiology, Maastricht, USA; [10]Maastricht University Medical Center, Department of Surgery, Maastricht, USA*

Background: For locally advanced rectal cancer preoperative (chemo)-radiotherapy facilitates radical resection and improves locoregional control. If there is a good response to neoadjuvant treatment local excision and even a wait and see policy in case of complete clinical response are currently being explored. For early rectal cancer local excision without preoperative treatment is a good option, provided that lymph node metastasis are ruled out. Data on the correlation between bowel wall involvement and the risk of node metastases are rather consistent in the literature, which helps to select patients that are candidates for local excision. For patients with advanced disease that requires preoperative chemoradiation, there are few data on this issue. In the current study we investigated the correlation between ypT and ypN stage for patients with locally advanced rectal cancer who are treated with chemoradiation and total mesorectal excision.
Material and Methods: Patients were selected from a pooled data set that consisted of 10 published studies. Proportions of patients with positive ypN stage according to ypT stage after chemoradiation were derived from the individual studies. Pooled proportions with 95% confidence intervals were calculated using a random effects model. The analyses were performed with STATA (version 11.0).
Results: Of the 2026 analyzed patients 95% was diagnosed with cT3/4 disease. 66% was clinically node positive whereas only 26% had N+ disease at pathological examination. ypTstage was distributed as follows: ypT0 16.8%, ypT1 5.7%. ypT2 28.9%, ypT3 44.8% and ypT4 3.9%. The pooled proportion of ypN+ disease per ypT-stage was 6.6%, 12.6%, 17.1%, 40.0% and 45.7%, respectively.
Conclusions: The incidence of nodal involvement per ypT stage after chemoradiation is only slightly lower than in patients who are not treated preoperatively. As for early disease, local excision after chemoradiation has a substantial risk of leaving lymph node metastases untreated. Only patients with favourable pathological characteristics of the primary tumour who are clinically node negative prior to neoadjuvant treatment are possibly candidates for local excision.
No conflict of interest.

2330 POSTER

The importance of the minimal resection margin in locally recurrent rectal cancer

W.J. Alberda[1], C. Verhoef[1], J.J. Nuyttens[2], J. Rothbarth[1], J.W.A. Burger[1]. *[1]Erasmus MC − Cancer Institute, Surgical Oncology, Rotterdam, Netherlands; [2]Erasmus MC − Cancer Institute, Radiotherapy, Rotterdam, Netherlands*

Background: Curative surgical treatment of locally recurrent rectal cancer (LRRC) is possible, but the outcome strongly depends on whether a radical resection can be performed. In contrast to primary rectal cancer, the importance of a minimal resection margin in radical resections of LRRC is not well defined. We examined the association between the minimal resection margin and long-term outcome after curative surgical treatment of LRRC.
Methods: All surgically treated patients with LRRC between 1990 and 2013 were retrospectively analyzed. Based on final pathology reports, patients were divided into 4 groups: A, radical resections with margins >2 mm; B, radical resections with margins >0−2 mm, C, microscopic irradical resections and D, macroscopic irradical resections. Kaplan–Meier curves were generated and factors affecting local control and survival were assessed by univariate and multivariate analysis.
Results: A total of 161 patients underwent curative surgery for LRRC. The resection margin was unknown in 14 patients and 9 patients had a complete pathological response, leaving 138 patients eligible for analysis. Five-year local control in patients with resection margins >2 mm (n = 32) was 86% compared to 58% for the 35 patients with margins >0−2 mm ($p = 0.02$). Patients with microscopic (n = 51) or macroscopic irradical resections (n = 20) had 5-year local control rates of 25% and 0%, respectively. These were both significantly worse than those of patients with resection margins >2 mm or 0−2 mm ($p < 0.05$).
There was a significant difference in 5-year overall survival in favor of patients with resection margins >2 mm compared to those with margins >0−2 mm (56 vs. 48%, $p = 0.02$). Patients with a microscopic or macroscopic irradical resection had 5-year overall survival rates of 16% and 5%, respectively. These were both significantly worse than those with resection margins >2 mm ($p < 0.05$), but the overall survival of patients with microscopic irradical resections did not significantly differ from those with resection margins >0−2 mm ($p = 0.11$). Multivariate analysis confirmed that the minimal resection margin was an independent prognostic factor for local control and overall survival.
Conclusion: The resection margin status is an independent prognostic factor after curative surgical treatment of LRRC. Patients with radical resection margins >2 mm have a significantly higher local control rate than patients with radical margins $\leqslant$2 mm and patients with irradical resections. Patients with a margin >2 mm also have a longer overall survival than patients with radical resections margins $\leqslant$2 mm.
No conflict of interest.

2331 POSTER

The utility of PET scanning in colorectal cancer liver metastases being considered for surgery

C. Kelly[1], A. O'Reilly[1], K. O'Regan[2], P. McEneaney[3], E. Mulvihill[4], A. O'Sullivan[4], C. O'Suilleabhain[4], J. McCaffrey[5], S. O'Reilly[1], D.G. Power[1]. *[1]Mercy University Hospital, Medical Oncology, Cork, Ireland; [2]Cork University Hospital, Radiology, Cork, Ireland; [3]Mercy University Hospital, Radiology, Cork, Ireland; [4]Mercy University Hospital, Hepatobiliary Surgery, Cork, Ireland; [5]Mater Misericordiae University Hospital, Medical Oncology, Dublin, Ireland*

Background: Liver resection remains the only potentially curative option for a subset of patients with colorectal cancer liver metastases (CRCLM). Preoperative imaging used to determine resectability includes contrast enhanced computed tomography (CT), magnetic resonance imaging (MRI) and positron emission tomography (PET). The objective of this study was to determine the utility of PET scanning for potentially resectable metastatic CRC to liver.
Material and Methods: We retrospectively reviewed a prospectively maintained database for all patients considered for resection of CRCLM from July 2010 to January 2013 in two specialist colorectal/hepatobiliary cancer centres. We extracted and analyzed data with respect to preoperative staging imaging and definitive treatment performed on completion of staging.
Results: We identified 114 patients who underwent preoperative staging investigations for potentially resectable CRCLM. The imaging techniques performed included: CT (n = 113, 99%), MRI liver (n = 89, 78%), PET (n = 105, 92%). In 22 (22/105, 21%) patients PET scanning added to the preoperative cross sectional staging information, identifying local

recurrence (n = 3, 2.8%), confirming liver metastases following an inconclusive CT/MRI (n = 2, 1.9%), outruling liver metastases (n = 1, 0.9%) and identifying extrahepatic sites suspicious for disease (n = 16, 15.2%). The extrahepatic sites included either lung (n = 6), bone (n = 2), peritoneum (n = 1) or lymph nodes (n = 7). There were 2 false positive results. One patient with FDG-avid mediastinal lymph nodes had no cancer on endobronchial biopsy. One patient with FDG avidity at the primary anastomosis had no evidence of disease at colonoscopy. PET scanning definitively changed the therapeutic strategy in 16 patients (16/105, 15.2%): precluding liver resection in 10 patients (10/105, 9.5%), leading to resection of extrahepatic disease in 4 patients (4/105, 3.8%), resection of local recurrence in 1 patient (1/105, 0.9%) and resection of hepatic metastases in one patient (1/105, 0.9%).
Conclusion: In this small retrospective cohort the addition of metabolic imaging altered the management in 15.2% of patients with potentially resectable CRCLM. There is a need for randomized evidence to support the routine use of PET in addition to cross-sectional imaging in this setting.
No conflict of interest.

2332 POSTER

Surgical resection of metastases and survival outcomes in patients with metastatic colorectal cancer (mCRC) treated with cetuximab (CTX) in the EREBUS cohort of real-life use

D. Smith[1], A. Sa Cunha[2], M. Rouyer[3], P. Noize[4], J. Jové[3], E. Bignon[3], A. Monnereau[5], E. François[6], E. Mitry[7], A. Fourrier-Réglat[8]. *[1]CHU Bordeaux, Oncologie Médicale, Bordeaux, France; [2]Hôpital P Brousse, Chirurgie Digestive, Villejuif, France; [3]Université Bordeaux Segalen, Pharmacologie, Bordeaux, France; [4]CHU Bordeaux, Pharmacologie, Bordeaux, France; [5]Institut Bergonié, Recherche Clinique et Information Médicale, Bordeaux, France; [6]Centre Lacassagne, Oncologie Médicale, Nice, France; [7]Institut Curie, Oncologie Médicale, St Cloud, France; [8]Université Bordeaux Segalen-CHU Bordeaux, Pharmacologie, Bordeaux, France*

Background: CTX has demonstrated improved survival outcomes in mCRC. Surgical resection of metastases has become an option in the multidisciplinary management of unresectable mCRC, but few data are available concerning its benefit in real-life practice.
Methods: EREBUS is a French multicentre (n = 65) cohort that included patients with unresectable wt KRAS mCRC in whom 1st-line CTX-based therapy was initiated in 2009–2010. Patients were followed for 12 months. A committee of experts validated baseline resectability and resection results. Resection rates and survival outcomes were described according to metastatic sites: liver-only, liver-not exclusively, other. Overall and progression-free survival (OS and PFS) were analysed using Kaplan–Meier method.
Results: 389 patients were included: 37.8% liver-only metastases, 38.3% liver-not exclusively, 23.9% other. Among these, 97 patients (24.9%, 95% CI [20.6–29.2]) underwhent resection; rates for liver-only: 36.7% [28.9–44.5], liver-not exclusively: 20.8% [14.3–27.3], other: 12.9% [6.9–21.5]. Baseline characteristics of these 97 operated patients: median age 62 years, 67.0% male, 91.8% ECOG=0−1, 62.9% primary tumour resection, 64.9% single metastatic site, and 55.7% only liver. Combined chemotherapy regimens included irinotecan (53.6%), oxaliplatin (40.2%), or irinotecan+oxaliplatin (5.2%). Median duration of CTX use was 6.3 months and chemotherapy use 7.9 months. The median interval from initiation of 1st-line to 1st surgery was 6.1 months; mainly one-stage operative procedures were performed (69.1%). There was 63.5% radical resection with R0/R1/radiofrequency (liver-only: 77.8% and liver-not exclusively: 35.5%), 9.4% missing metastases (liver-only: 7.4% and liver-not exclusively: 9.7%) and 27.1% had R2 resection (liver-only: 14.8% and liver-not exclusively: 54.8%). 52.6% had post-operative complications (20.6% infection, 9.3% thromboembolic event, 8.2% other cardiovascular event, 3.1% death). The 1-year OS probability for operated patients was 94.8% [87.8–97.8] and the 1-year PFS probability was 59.0% [48.4–68.1]. Median OS and PFS were not reached.
Conclusion: Metastases resection rate was very close to that found in RCTs of CTX even though real-life patients are more heterogeneous. There was a higher rate of resection among patients with liver-only metastases as compared to other more rarely studied mCRC patients (liver-not exclusively and other metastases). Survival outcomes and recurrence at 36 months follow-up will be investigated.
Conflict of interest: *Advisory board: Sanofi, Merck-Serono. Corporate-sponsored research: Merck-Serono*

2333 POSTER

Impact of postoperative complications on long-term survival after resection for rectal cancer

K. Mrak[1], T. Eberl[1], A. Laske[1], M. Jagoditsch[1], J. Fritz[2], J. Tschmelitsch[1]. *[1]Barmherzige Brüder, Surgical Department, St. Veit/Glan, Austria; [2]Assign Data Management and Biostatistics GmbH, Biostatistics, Innsbruck, Austria*

Background: The relevance of type and severity of postoperative complications after curative resection for rectal cancer on survival and recurrence rates is a matter of controversy. The aim of this study was to investigate the impact of postoperative complications on long-term outcome after resection for rectal cancer.
Materials and Methods: Between January 1984 and October 2008, 811 patients with rectal cancer underwent curative resection. Patients who experienced postoperative complications were divided into a minor complication group (grade I and II) and a major complication group (grade III and IV) according to the Clavien classification. The influence of several pathological and clinical factors including complications in terms of overall and disease-free survival was tested and compared in univariate and multivariate analyses.
Results: Curative resection was performed in 811 patients, median age was 65 years. The Kaplan–Meier estimates ($\pm$ the standard error) for five- and ten-year overall cumulative survival were 70.3% $\pm$ 1.8% and 54.5% $\pm$ 2.4%; Kaplan–Meier estimates for five- and ten-year disease-free survival were 64.0% $\pm$ 1.8% and 50.9% $\pm$ 2.3%. Some 165 patients (20.3%) had minor complications and 103 patients (12.7%) had major complications. Twelve patients (1.48%) died within 30 days after surgery. There was no significant difference between patients with no complications, patients with minor and patients with major complications in terms of overall (p = 0.41) or disease-free survival (p = 0.32).
Conclusions: Following resection for rectal cancer, severity of post-operative complications (minor or major) according to a standardised classification system does not demonstrate a statistically significant effect on either overall or disease-free survival.
No conflict of interest.

2334 POSTER

No association between volume and outcome after colorectal cancer surgery in southern Netherlands

F.N. Van Erning[1], L.N. Van Steenbergen[1], W.T. Van den Broek[2], H.J.T. Rutten[3], V.E.P.P. Lemmens[1]. *[1]Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands; [2]St. Anna Hospital, Surgery, Geldrop, Netherlands; [3]Catharina Hospital, Surgery, Eindhoven, Netherlands*

Background: Uncertainty remains whether hospital resection volume is associated with surgical outcome and survival in colorectal cancer.
Methods: Patients who underwent resection for primary colorectal cancer diagnosed between 2008 and 2011 in the southern Netherlands were included (n = 5655). Hospitals performing <130 resections per year were classified as low volume; hospitals performing $\geqslant$130 resections per year were classified as high volume. Differences in surgical approach, circumferential resection margins, anastomotic leakage and 30-day mortality between high volume and low volume hospitals were analysed using Chi^2 tests. Expected proportions of anastomotic leakage and 30-day mortality were calculated using multivariable logistic regression. Crude 5-year overall survival was calculated using Kaplan–Meier curves. Cox regression analyses were used to discriminate independent risk factors for death.
Results: 5 hospitals were classified as high volume and 5 hospitals as low volume. 23% of patients with locally advanced rectal cancer (LARC) diagnosed in a low volume center was referred to a high volume center. Patients with colon cancer underwent less laparoscopic surgery and less urgent surgery in low volume hospitals compared to high volume hospitals (10% versus 32%, p < 0.0001, and 8% versus 11%, p = 0.003, respectively). For rectal cancer, rates of abdominoperineal resections versus low anterior resections, and circumferential resection margins were not associated with hospital volume. Crude and adjusted rates of anastomotic leakage, 30-day mortality, and long-term survival after resection for CRC did not differ between low volume and high volume hospitals.
Conclusion: In the southern Netherlands, low volume hospitals deliver similar high quality surgical colorectal cancer care as high volume hospitals in terms of circumferential resection margins, anastomotic leakage, 30-day mortality and survival, also after adjustment for casemix. However, this excludes patients with locally advanced rectal cancer since a substantial proportion was referred from low volume to high volume hospitals.
No conflict of interest.

2335 POSTER

Higher risk for recurrences in colon cancer patients with postoperative complications

A.J. Breugom[1], E. Bastiaannet[2], C.B.M. Van den Broek[1], J.W.T. Dekker[3], L.G.M. Van der Geest[4], C. Puylaert[1], C.J.H. Van de Velde[1], G.J. Liefers[1], J.E.A. Portielje[5]. *[1]Leiden University Medical Center, Surgery, Leiden, Netherlands; [2]Leiden University Medical Center, Surgery and Gerontology and Geriatrics, Leiden, Netherlands; [3]Reinier de Graaf Gasthuis, Surgery, Delft, Netherlands; [4]Comprehensive Cancer Center the Netherlands, Region Leiden, Leiden, Netherlands; [5]HAGA Hospital, Internal Medicine, The Hague, Netherlands*

Background: Colorectal cancer is a major health problem, with a high recurrence rate. This study aimed to describe the incidence of loco-regional and distant recurrence among patients with colorectal cancer in the Netherlands and to identify prognostic factors for recurrences.
Material and Methods: All 646 patients operated with curative intent for stage I−III colorectal cancer between January 1, 2006 and December 31, 2008 in one university and two teaching hospitals in the western region of the Netherlands were analysed. Cumulative incidences of loco-regional and distant recurrence were computed with death as competing risk. To identify prognostic factors, Cox's proportion hazards regression model was used.
Results: For colon cancer, the 1-year and 3-year cumulative incidences were 3.1% and 8.0% for loco-regional recurrence and 8.6% and 15.1% for distant recurrence. For rectal cancer, these percentages were 2.1% and 5.6% for loco-regional recurrence and 4.8% and 13.4% for distant recurrence. The risk of developing a recurrence was highest between 0.5−2 years after surgery. Prognostic factors for loco-regional and distant recurrences for colon cancer were complications requiring readmission, T3 -T4 tumours and positive lymph nodes. Emergency surgery was only a prognostic factor for loco-regional recurrence. For rectal cancer, T3 -T4 and N2 tumours were prognostic factors for distant recurrences.
Conclusions: Colorectal cancer recurrences continue to be a serious concern with an incidence up to 15% in 3 years. Next to known prognostic factors, complicated operations seem to have an impact on the rate of recurrences. Clearly, operative complications have long term detrimental effects on colorectal cancer outcome and reducing operative complications may improve recurrence rates.
No conflict of interest.

2336 POSTER

Laparoscopic TME: Short and long-term results in a single institutional series including 516 patients

A. Tamburini[1], S. Di Palo[1], E. Orsenigo[1], C. Staudacher[1]. *[1]University Vita-Salute San Raffale, Gastrointestinal Surgery, Milan, Italy*

Background: To assess short and long-term oncologic outcome after laparoscopic total mesorectal excision (TME) for rectal cancer in a single Institution series including 516 patients.
Methods: We reviewed the prospective database of 516 unselected consecutive patients with histologically proven cancer of the mid and distal rectum undergoing laparoscopic TME between January 2000 and January 2012. Those with T3-T4 or N+ received long course preoperative radiochemiotherapy. Surgical technique and follow-up were standardized. Data evaluated included short and long-term results with survival outcomes calculated using the Kaplan-Meyer method.
Results: Some 516 patients underwent laparoscopic TME. Conversion to open surgery was required in 4.8% of patients. Adjuvant treatment was given in 60.5% (312/516) of the patients. A Sphincter-preserving surgery was performed in 484 patients, while an abdominoperineal resection of the rectum was necessary in 32 cases. The overall postoperative mortality rate was 1.7%. The overall morbidity rate was 30.9%.
Clinical anastomotic leak occurred in 17% (82/484) of the patients. The reoperation rate was 11%. With respect to short-term oncological variables, mean (SO) distal resection margin was 2.9 (2) centimetres and the mean (SO) number of lymph nodes intraoperatively collected was 15.5 (9.3). A RO resection rate was obtained in 95.9% (495/516) of the patients. Mean (range) follow-up period was 72 (10–156) months.
Overall and disease free survival rate were 71.3% and 63.4%, respectively. There was no case of trocar site recurrence. The local recurrence rate occurred in 5.3% of the patients after curative resection.
Conclusions: The results of these study with large number of patients over a long follow-up period suggested that laparoscopic TME is safe with a good oncological outcome.
No conflict of interest.

2337 POSTER

An interim analysis of a single arm, open-label, multicenter phase II study of capecitabine plus oxaliplatin (XELOX) as the perioperative treatment of patients with potentially resectable liver-only metastases from colorectal cancer (ML22298; NCT00997685)

F. Li[1], G. Li[2], Z. Chu[3], C. Hao[4], M. Chen[5], H. Chen[6], J. Lin[7], D. Li[8], B. Hu[9], X. Wang[10]. *[1]Guangdong General Hospital, GI Surgery, Guangzhou City, China; [2]Guangzhou South Hospital, GI Surgery, Guangzhou City, China; [3]The Second Affiliated Hospital of Zhong Shan University, GI Surgery, Guangzhou City, China; [4]Beijing Cancer Hospital, GI Surgery, Beijing City, China; [5]The First Affiliated Hospital of Kunming Medical University, GI Surgery, Kunming City, China; [6]Jiangsu Cancer Hospital, GI Surgery, Nanjing City, China; [7]The First Affiliated Hospital of Zhejiang University, GI Surgery, Hangzhou City, China; [8]Zhejiang Cancer Hospital, GI Surgery, Hangzhou City, China; [9]Anhui Province Hospital, GI Surgery, Hefei City, China; [10]The Affiliated Cancer Hospital of Harbin Medical University, GI Surgery, Harbin City, China*

Background: The liver is the most common metastatic site of colorectal cancer (CRC). Surgical resection is currently considered a standard of carefor all resectable colorectal liver metastases (CLMs). Therefore,it is importantto convert unresectable CLM to resectable CLM to improve survival rate of CRC patients. The purpose of this studyis to investigatethe efficacy and safety of capecitabine plus oxaliplatin(XELOX)in the perioperative treatment of patients with potentially resectable CLM.
Method: The interim analysis of this single arm, open-label, multicenter phase II trial assessed objective response rate (ORR) and R0 resection rate after perioperative chemotherapy of XELOX in patients with potentially resectable CLM.The primary endpoint of this study is progression-free survival(PFS);Secondary endpoints includeORR, R0 resection rate, overall survival (OS) and the safety profile of perioperative treatment of XELOX.Patients with CLM that wasdiagnosed as potentially resectable were treated with XELOX. After 6 weeks (2 cycles) of chemotherapy, tumor remission was assessed by CT scan. Resectability of CLM was assessed by CT after 12 weeks (4 cycles) of chemotherapy. If patient was diagnosed as not suitable for resection during or after neoadjuvant chemotherapy, alternative chemotherapy regime was used and corresponding patients were withdrawn from this study.After hepatectomy, adjuvant chemotherapy of XELOX was started based on patients' conditions (but not later than 8 weeks after surgery).
Results: 30 patients (17 males/13 females)were enrolled from 10 medical sitesbetween January 2010 and November 2011. The ORR was 33.3% (95% CI: 47.2%-82.7%). The conversion rate from unresectable to resectablewas 36.7% (11/30). Amongthese 11 patients,10 (90.9%) had R0 resection. There were 4 (4/30)patients with post-operation complications of ascites and/orhydrothorax.3 cases of SAE were reported due to leukopenia, hepatotoxicity (elevated serumalanine transaminase&γ-glutamyltransferase levels)and diarrhea. Other AEs mainly were neutropenia, vomiting and intestinal obstruction.
Conclusion: Perioperative chemotherapyofXELOX in patients with potentially resectable CLM possesses high conversion rate and R0 resection rate, with manageable toxicities and post-operation complications.
No conflict of interest.

2338 POSTER

Improvement of the learning curve of cytoreduction and HIPEC in the Netherlands

A.M.J. Kuijpers[1], M. Hauptmann[2], A.G.J. Aalbers[1], S.W. Nienhuijs[3], I.H.J.T. De Hingh[3], B. Van Ramshorst[4], R. Wiezer[4], R.J. Van Ginkel[5], K. Havenga[5], V.J. Verwaal[1]. *[1]Netherlands Cancer Institute, Surgical Oncology, Amsterdam, Netherlands; [2]Netherlands Cancer Institute, Statistics, Amsterdam, Netherlands; [3]Catharina Hospital, Surgery, Eindhoven, Netherlands; [4]St. Antonius Hospital, Surgery, Nieuwegein, Netherlands; [5]University Medical Center Groningen, Surgery, Groningen, Netherlands*

Introduction: The combination of cytoreduction (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC) has become the preferred treatment for many peritoneal surface malignancies. Experience with this procedure is needed to achieve a macroscopic complete resection with a low morbidity. In the Netherlands, new HIPEC centres are mentored by surgeons from experienced HIPEC centres to set up the treatment safely. In this study learning curves were analyzed of a pioneer institution and three institutions that started recently with CRS and HIPEC.
Methods: The first consecutive 100 CRS and HIPEC procedures of four institutions in the Netherlands were included, when available. Indications were peritoneal carcinomatosis (PC) from colorectal carcinoma and pseudomyxoma peritonei (PMP). Patient, tumour and treatment

characteristics were retrospectively obtained. Operation characteristics, morbidity and completeness of cytoreduction were the main outcome parameters for the learning curves. The learning curves of the pioneer institution were compared to the learning curves of the three later institutions together. Learning curves were determined by a regression model with the rank of the operation as a covariate.
Results: Three-hundred seventy-two cases were included in the four institutions. In total 167 procedures were performed for PC from colorectal carcinoma and 105 for PMP. The number of abdominal regions affected (0−7) was larger in the procedures of the pioneer hospital than in the other hospitals (mean abdominal region count 4.3 vs 3.2, $p < 0.001$). Grade III−V morbidity rates were 64% in the pioneer centre and 32% in the later centres. A macroscopic radical resection was reached in 66% of the cases in the pioneer centre and in 86% of the cases in the later centres. The rank of the operation (OR 1.02, 95% CI 1.011–1.03), treatment in the new centres (OR 2.50, 95% CI 1.33−4.9) and number of abdominal regions affected (OR 0.60, 95% CI 0.50–0.71) were predictors for a complete macroscopic resection in a multivariate logistic regression model.
Conclusions: Recently started HIPEC centres in the Netherlands showed improved learning curves compared to the pioneer institution with a better starting point for all main outcome parameters and a significant learning curve in the first 100 patients regarding complete cytoreduction, which is an indicator for survival. Patient selection was an important independent factor for this learning curve.
No conflict of interest.

2339 POSTER

Curative cytoreductive surgery followed by intraperitoneal chemotherapy in patients with colorectal peritoneal carcinomatosis and synchronous resectable liver metastases: A French monocentric experience

B. Linot[1], O. Capitain[1], N. Paillocher[2], R. Wernert[2], V. Guerin-Meyer[1], G. Lorimier[2]. *[1]Cancer Institut Paul Papin, Medical Oncology, Angers, France; [2]Cancer Institut Paul Papin, Surgical Oncology, Angers, France*

Background: Cytoreductive surgery followed by hyperthermic intraperitoneal chemotherapy (HIPEC) increases overall survival in patients with peritoneal carcinomatosis (PC) from colorectal origin. However the optimal treatment both for PC and for resectable liver metastases (LMs) in the same surgical time remains controversial. The objective of our monocentric retrospective study was to describe the outcome of patients with LMs or not and to examine predictive factors after curative surgery combined with HIPEC.
Material and Methods: From 1999 to 2011, all patients with colorectal PC who underwent curative cytoreductive surgery followed by HIPEC in our institute were evaluated from a prospective database. Overall survival (OS) and disease free survival (DFS) in patients with PC and synchronous liver metastases were compared with PC only. Univariate and multivariate analyses were performed to evaluate variables predictive for OS.
Results: Fifty height patients were enrolled. 22 patients (first group) with colorectal PC and synchronous LMs of which 17 (77%) underwent a minor hepatic resection, were compared to 36 patients with PC only (second group). No significant difference was found between the two populations according to the following criteria: age, performance status, peritoneal cancer index (PCI), completness cytoreductive score (CCS) and post-operative comorbidity. The median OS were 36.1 months [95% CI: 20.9; 125.8] for the first group and 22.9 [95% CI: 14.8; 82.6] for the second ($p > 0.05$) with 38.2% and 40.4% as 5-years OS rates ($p > 0.05$). The median DFS were 8.4 [95% CI: 5.5; 12.0] and 7.9 months [95% CI: 4.6; 11.2] respectively ($p > 0.05$). Only CCS >0 [odds ratio (OR): 1.29, $p < 0.0001$] was identified as independent factor for poor OS in multivariate analysis.
Conclusions: In our experience, synchronous cytoreduction with peritonectomy and liver metastases resection plus HIPEC is a feasible therapeutic option. This process suggests an improvement to overall survival such as patient with PC only. This multimodal procedure would have to be performed in selected patients and in an experienced center for oncology.
No conflict of interest.

2340 POSTER

Laparoscopic colorectal surgery leads to increased overall survival when compared to a conventional open approach

H.M. Kroon[1], M. Buurma[1], M.S. Reimers[1], P. Neyenhuis[1]. *[1]Rijnland Hospital, General Surgery, Leiderdorp, Netherlands*

Introduction: Over the past decade laparoscopic surgery has become increasingly popular in the treatment for colorectal malignancies. Short-term results are equivocal and skepticism regarding safety is rapidly diminishing. To date however, not much is known about its effect on the long-term outcome. Therefore, we conducted this study to evaluate the impact of a laparoscopic approach on the survival of patients operated in our hospital.
Methods: We conducted a retrospective analysis of our prospectively collected colorectal cancer database, including all patients who underwent a resection between 2004 and 2011. Patients were divided into two groups based on surgical technique: an open versus a laparoscopic approach. Peri-operative data were collected as well as follow-up, recurrence rates and survival data.
Results: A total of 774 patients underwent a colorectal resection for a malignancy. The open approach was performed in 259 patients and the laparoscopic approach in 515 patients. Rectal cancer patients were also included, 60 abdominoperineal (APR) resections were performed and a total of 165 low anterior resections (LAR). These patients received preoperative (chemo)radiation according national guidelines. Groups showed an equal distribution for pre-operative characteristics. After a median follow-up of four years, multivariate analysis showed a resection performed by a laparoscopic approach as an independent prognostic factor for disease-free survival (hazard ratio [HR] 0.737; 95% CI 0.55-.099; $P = 0.046$) as well as for overall survival (HR 0.595; 95% CI 0.43−83; $P = 0.002$).
Conclusions: In our experience a laparoscopic approach is associated with both an increased disease-free survival as well as a longer overall survival in the multivariate analyses. Therefore, when there are no contra-indications for laparoscopic surgery, surgeons performing colorectal surgery should offer this approach to their patients as the technique of choice.
No conflict of interest.

2341 POSTER

Morbidity associated with colostomy reversal after cytoreductive surgery and HIPEC

E.M.V. De Cuba[1], V.J. Verwaal[2], I.H.J.T. De Hingh[3], L.J.J. Van Mens[1], S.W. Nienhuijs[3], A. Aalbers[2], H.J. Bonjer[1], E.A. Te Velde[1]. *[1]VU University Medical Center Amsterdam, Surgical Oncology, Amsterdam, Netherlands; [2]Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, GI Surgical Oncology, Amsterdam, Netherlands; [3]Catharina Hospital Eindhoven, Surgical Oncology, Eindhoven, Netherlands*

Background: Cytoreductive surgery (CRS) and Heated Intra-Operative Peritoneal Chemotherapy (HIPEC) has improved the survival in selected colorectal cancer patients with peritoneal metastases (PM). In some of these patients a low rectal anastomosis is avoided by placement of a stoma during CRS. Currently, the morbidity and mortality accompanying the reversal procedure of the colostomy in this population is unknown.
Methods: Our study involved two prospectively collected databases including all patients who underwent CRS and HIPEC. We identified all consecutive patients who had a colostomy and requested a reversal procedure. The distribution of clinical and treatment related factors are described in our cohort. The associations between four clinical and 10 treatment related factors with the outcome of the reversal procedure were determined by univariate analysis.
Results: Twenty-one patients of 336 (6.3%) with a median age of 50.8 years (SD 10.2) underwent reversal of their colostomy. Eleven patients had pseudomyxoma peritonei and ten had colorectal adenocarcinoma. One patient was classified as American Society of Anesthesiologists (ASA) grade III, six as ASA grade II and the remainder as ASA grade I. A median of 394 days (range 133–1194) elapsed between the initial CRS & HIPEC and the subsequent reversal procedure. No life threatening complications requiring intensive care management or mortality were observed after reversal. The reversal related morbidity was 67%. Infectious complications, including intra-abdominal abscess formation and enterocutaneous fistulization, were observed in seven patients (33%). Infectious complications after CRS & HIPEC, including development of a fistula, were negatively correlated with the ultimate restoration of bowel continuity *($P = 0.05$)*. The bowel-continuity was successfully restored in 76% of the patients.
Conclusions: Although the restoration of bowel continuity after CRS & HIPEC was successful in the majority of patients, it was associated with a relatively high complication rate. Particularly patients with infectious complications after HIPEC have a diminished chance of successful restoration of bowel continuity.
No conflict of interest.

2342 POSTER

Variation in circumferential resection margin: Reporting and positivity in the South-Netherlands

J. Homan[1], V.E. Lemmens[2], G.M. Bökkerink[1], H.J. Rutten[2], I.H. De Hingh[2], J.W.H. De Wilt[1]. [1]*Radboud University Medical Centre Nijmegen, Surgery, Nijmegen, Netherlands;* [2]*Comprehensive Cancer Centre South (IKZ), Eindhoven Cancer Registry, Eindhoven, Netherlands*

Background: An involved circumferential resection margin (CRM) in rectal cancer surgery is a predictor of a higher local recurrence and distant metastases rate and decreased overall survival. In previous studies patients with distal tumors who underwent an Abdomino Perineal Resection (APR) had significantly higher rates of CRM positivity. However, since the introduction of the total mesorectal surgery and standard pathology results have dramatically improved. The aim of this study is to analyze reporting of CRM and to study predictive factors for CRM positivity.
Materials and Methods: 1136 consecutive patients who underwent a resection for rectal cancer in the Eindhoven Cancer Registry area in the period 2008–2010 were included. This area includes 10 hospitals where rectal cancer surgery is performed. The number of patients with missing CRM in the pathology report, and CRM positivity-rates were assessed.
Results: CRM was missing in 26.2% of the cases in 2008, in 2009 in 16.5% and in 2010 in 13.0%. CRM reporting varied between hospital and pathology departments, with missing cases ranging from 8.0% to 64.4% between hospitals and 8.6% to 64.4% pathology laboratories. CRM positivity after Low Anterior Resection (LAR) and APR was respectively 7.8% and 10.0%. The CRM positivity was stable over the years, around 9.1% (range 8.1%-10.1%). CRM reporting became more detailed in terms of reporting the number of mm versus 'positive' or 'negative' margin. The two most important factors associated with CRM positivity were high T-stage (32.7% CRM positivity in T4 rectal cancer) and absence of neoadjuvant (chemo)radiation treatment (CRM positivity of 16.9% in the group who underwent surgery only). No differences in sex, age, distance of the tumor to the anus and type of operation were found.
Conclusions: There is a high variation in reporting of CRM positivity in the South-Netherlands, although significant improvements are made during the last years. In contrast to the literature, CRM positivity is no longer dependent of the location of the tumor or the surgical procedure, but only on tumor stage and the use of neoadjuvant (chemo)radiation.
No conflict of interest.

2343 POSTER

Rectal cancer proctectomy in the elderly − The National Cancer Centre "G. Paolo II" experience

R. De Luca[1], S. Montemurro[1], C. Caliandro[1], E. Ruggieri[1], A. Rucci[1], N. Silvestris[2], A.E. Brunetti[3]. [1]*National Cancer Centre "Giovanni Paolo II", Surgical Oncology, Bari, Italy;* [2]*National Cancer Centre "Giovanni Paolo II", Medical Oncology, Bari, Italy;* [3]*National Cancer Centre "Giovanni Paolo II", Scientific Direction, Bari, Italy*

Background and Aim: Rectal cancer shows a high incidence in older patients, however, only few reports focused exclusively on rectal cancer with the exclusion of the surgery of the colon. This retrospective study aimed to compare short-term and long-term outcomes for rectal cancer in patients more than 75 years old with that observed in younger patients.
Patients and Methods: Four hundred consecutive patients operated on for primary rectal adenocarcinoma at National Cancer Centre 'G. Paolo II' were collected in a prospective institutional database and divided into two groups: group 1 ($\geqslant$75 years, n = 98); group 2 (<75 years, n = 302). Restaurative proctectomy was the only procedure considered. Main clinical and pathological data, morbidity, clinical anastomotic leakage, reoperation rate, 30-day mortality, overall survival, and cancer-related survival were assessed and compared.
Results: Significant differences between the two groups were detected with regard to the the American Society of Anesthesiologists classification, comorbidities and the emergency presentation. Overall morbidity rate was 30.4% and 20.2% in group 1 and group 2, respectively. Clinical anastomotic leakage rate was 6.1% in group 1 while 10.9% in group 2. The reoperation rate was 7.1% and 9.9% respectively in group 1 and group 2, mainly related to anastomotic leakage. The operative mortality rate was 6.1% in group 1 and 1.3% in group 2. In patients operated on for cure the overall 5-year survival rate was 76 % in group 1, 84 % in group 2 ($P = 0.0223$). The cancer-specific 5-year survival rate was 86 % in group 1 while 91 % in group 2 ($P = 0.0179$).
Conclusions: In our experience advanced age itself is not a contraindication to surgery, although it is associated with higher morbidity and mortality. Overall survival is lower in patients over 75 age, but cancer-related survival is not different between the two groups.
No conflict of interest.

2344 POSTER

Cetuximab plus mFOLFOX-6 as first-line therapy for unresectable liver metastases from colorectal cancer: an open-label, non-randomized, multicenter phase II clinical trial (CLIME Study)

S. Cai[1], W.E.N. Zhang[2], W. Li[2], Y. Xu[1], W. Gu[1], Z. Guan[1], J.Q. Cai[3], C. Song[4], J.M. Xu[5], P. Chi[6]. Background: We designed this study to observe whether the addition of cetuximab to chemotherapy yields a high response and curative resection rates, long progression-free survival (PFS) and long-term overall survival (OS) in a patient population treated in a real life setting in China.
Methods: An open-label, multi-center, phase II study of cetuximab in combination with mFOLFOX-6 as first-line treatment in patients with KRAS wt, unresectable liver metastases of CRC. Patients received cetuximab (500 mg/m^2 q2w) plus mFOLFOX-6 including oxaliplatin 85 mg/m^2 plus CF 400 mg/m^2 and 5-FU as a 400 mg/m^2 bolus followed by 2400 mg/m^2 infusion over 46 hours on day 1, repeated every 2 weeks for maximum of nine cycles. The primary endpoint was R0 resection rate. Secondary endpoints included objective response rate (ORR), PFS, OS and safety.
Findings: Between Dec. 7th 2010 and Sep. 17th 2012, 194 patients were screened at 17 centers in China. Among them 126 were KRAS wild-type cases (65.0%) and 97 cases were enrolled. ORR was 81.3% (95% CI 69.5%, 90.0%) among 64 patients with efficacy assessment available. Of 31 patients undergoing surgical evaluation (finishing medication), 20 patients underwent R0 resection yielding an R0 resection rate of 31.3% (95% CI 20.2%, 40.1%). Among these 20 cases with R0 resection, the median interval between the first and last medication was 64.5 days and the median interval between the last medication and surgery was 29 days. Median PFS was 12.16 months among 67 evaluable patients (95% CI 10.78,-). Incidence of adverse events of any grade was 79.4%, mainly including rash and malaise.
Conclusion: Combination therapy with cetuximab and mFOLFOX-6 was well tolerated and provided ORR, R0 resection rates, PFS and less time between medication and surgery that compares well with data from other clinical trials.
Funding: This study was supported by Merck KGaA Darmstadt, Germany and Sanofi-aventis.
No conflict of interest.

2345 POSTER

Colorectal cancer in high-risk patients: Is laparoscopic surgery really suitable and effective?

F. Roscio[1], A. De Luca[1], P. Frattini[1], F. Clerici[1], V. Girardi[1], I. Scandroglio[1]. [1]*Ospedale Galmarini, General Surgery, Tradate, Italy*

Background: Colorectal cancer (CRC) is a major cause of morbidity and mortality. Laparoscopic colorectal surgery (LCS) allows good short-term outcomes and provides oncologic results comparable to open surgery. However, often LCS is not suitable for high-risk patients (HRP) due to significant comorbidities. This study aims to evaluate the short-term results of LCS for CRC in HRP, assuming that there are no statistically significant differences compared to low-risk patients (LRP).
Methods: According to the current literature, HRP are defined as those>80 years, with ASA score$\geqslant$3, preoperative radiotherapy, T4 tumor or BMI$\geqslant$30 kg/m^2. We considered a consecutive unselected series of 215 patients who underwent elective LCS for CRC at our institution between January 2008 and December 2011. Of these patients 85 (39.6%) were HRP, and 130 (60.4%) LRP. Data on the patients' demographics, disease features, operative details and follow up were prospectively recorded in a specific database and retrospectively analyzed. Comorbidity was quantified by using the Charlson Comorbidity Index (CCI). All the procedures were performed by the same fully trained team (IS, ADL, FR), instrumentation and perioperative management were standardized. Right colectomies were performed until 2009 through a laparoscopic-assisted approach while we used a totally laparoscopic technique from then on, in left colectomies we made a Knight-Griffen anastomosis, a total mesorectal excision was always performed for rectal cancers, whereas a temporary loop ileostomy was created for tumors localized at middle and low rectum. The group 'others' collected laparoscopic transverse or splenic flexure resections, and Miles' procedures. Complications were classified using the Clavien–Dindo system (CDCS).

Results: We reviewed right colectomies (30.2%), left colectomies (44.2%), rectal resections (19.5%), and others (6.1%). There was no significant difference in sex ratio and type of surgical procedures between HRP and LRP, while, by definition, age, body mass index, American Society of Anesthesiology score and tumor stage were statistically different. An higher comorbidity according to CCI characterized HRP (4.6 vs 2.2; P < 0.1). Median operative time (235.6±97.6 vs 223.4±75.1 min; NS), estimated blood loss (52.2±72.7 vs 60.5±94.8 mL; NS), conversion rate (1.2% vs 1.5%; NS), and timing to canalization (4.4±1.4 vs 4.2±1.8dd; NS) were comparable in both groups. HRP was associated with a significantly longer length of hospital stay compared with LRP (10.6±8.6 vs 7.8±4.6dd; P < 0.1). There was no statistically significant difference in postoperative complications according to CDCS (27.0% vs 21.5%; NS), reoperations (1.2% vs 1.5%; NS), and 30-day mortality (0% vs 0.8%; NS).
Conclusions: LCS is safe and efficacious even in HRP. The risk variables considered do not significantly increase either operative time or postoperative complications and short-term outcome. We believe that HRP may have a greater benefit from a minimally invasive approach to CRC.
No conflict of interest.

2346 POSTER

Pelvic exenteration for locally advanced primary and recurrent rectal cancer

D. Ng[1], Y.X. Koh[1], G. Tan[1], M. Teo[1]. *[1]National Cancer Centre Singapore, Department of Surgical Oncology, Singapore, Singapore*

Aim: A review of a single-centre experience of pelvic exenteration as a treatment modality for patients with locally advanced primary and recurrent rectal cancer. The perioperative outcomes, morbidity and long term oncological outcomes are reviewed.
Materials and Methods: Patients undergoing pelvic exenterations for recurrent and locally advanced rectal cancer between 1st January 2006 to 1st August 2012 were identified from a prospective database. All patients underwent pre-operative staging investigations with Computed Tomography (CT) scan of chest, abdomen and pelvis and pelvic Magnetic Resonance Imaging (MRI). Patients with locally advanced primary rectal cancer were counselled for pre-operative chemo-radiation. Pelvic exenteration is defined as en bloc removal of the pelvic organs to which the primary tumour was adherent to. Structures such as the urinary bladder, female reproductive organs were resected en-bloc where indicated with the lesion. Urological or plastic reconstructions were employed where indicated. Patients were followed up according to a standard protocol of colonoscopy, CEA measurements and imaging modalities CT/MRI/Positron Emission Tomography (PET). The primary outcome measured was overall survival (OS) and disease free survival (DFS) and secondary outcomes measured were time to local recurrence (LR) and systemic recurrence. DFS was examined by the Kaplan–Meier Method.
Results: Pelvic exenterations were performed in 13 patients with a median age of 59 (range 26−81). The rate of major postoperative complications was 8% (n = 1), where the patient had anastomotic leakage. There were no mortalities in the perioperative period. All patients were operated with curative intent and negative circumferential margins were achieved in 9 out of 13 patients (70%). With a median follow-up of 23 months, the DFS and OS were 19.4 and 22.5 months respectively.
Conclusion: An aggressive approach with en bloc resection of organs involved provides survival benefit to patients with locally advanced primary and recurrent rectal cancer. Overall survival benefits outweigh the morbidity of surgery.
No conflict of interest.

2347 POSTER

Strategies to minimize the influence of chemotherapy-induced liver injury before the resection of colorectal liver metastasis: Liver surgeons' suggestions

T.T. Takamoto[1], T.H. Hashimoto[1], K.I. Inoue[1], Y.M. Maruyama[1], M.M. Makuuchi[1]. *[1]Japanese Red Cross Medical Center, Hepatobiliary-Pancreatic Surgery, Tokyo, Japan*

Background: To minimize the influence of chemotherapy-induced liver injury on the patients undergoing a hepatectomy for colorectal liver metastases (CRLM), it is necessary to clarify preoperative risk factors for liver injury and adequate choice of operative procedure for impaired liver function.
Material and Methods: A total of 94 patients underwent a hepatectomy following oxaliplatin and/or irinotecan-based chemotherapy and were divided into 2 groups according to the indocyanine green retention rate at 15 minutes (ICGR15), (normal ICGR15, n = 24, ICGR15>10%, n = 60). Portal vein embolization (PVE) prior to hepatectomy was conducted when future remnant liver volume ratio was estimated to be less than 40% in the patients with a normal ICGR15 or less than 60% in patients with ICGR15>10%. Preoperative factors associated with ICGR15>10% were indentified in the multivariate analysis.
Results: Eighteen patients (19%) received PVE. Postoperative complications occurred in 45 (48%) and were more frequent in the patients who had ICGR15>10% and received PVE than the others(73% vs. 43%, p = 0.029). The occurrence of complications classified grade III or severer was comparable (6.7% vs. 5.1%, p = 0.81). An age of 60 years or older (odds ratio 2.72, P = 0.04) and 3 or more cycles of oxaliplatin-based chemotherapy without bevacizumab (odds ratio 2.82, P = 0.04) were significantly associated with ICGR15>10%.
Conclusions: Application of criteria based on the ICGR15 value including PVE and choice of chemotherapy, avoiding oxaliplatin-based chemotherapy without bevacizumab especially in the patients aged 60 years or older, can minimize postoperative complication of hepatectomy for CRLM.
No conflict of interest.

2348 POSTER

Synchronous colorectal liver metastases: Simultaneous vs delayed liver surgery in an Italian district community hospital

G. Griseri[1], M. Ceriotti[1], A. Percivale[2], E. Benatti[2], G. Curletti[1], R. Pellicci[2]. *[1]Ospedale S. Paolo Valloria, Chirurgia Generale, Savona, Italy; [2]Ospedale Santa Corona, Chirurgia Generale, Pietra Ligure, Italy*

Background: The optimal surgical strategy for the treatment of resectable synchronous colorectal liver metastases (CLMs) is still unclear.
According to literature, simultaneous resection seems to be safe and efficient, both avoiding a second major operation (with a positive impact on postoperative immunodepression, early instigation of adjuvant therapy and patient's discomfort) and reducing social costs. Nevertheless, it's related to negative impact on long term survival.
Moreover, to perform a simultaneous technique, two different specialized surgical equipes are needed (mainly for rectal and hepatic resection). That is not so easy to obtain in most community district hospitals.
Materials and Methods: Aim of the study is to compare simultaneous colorectal and hepatic resection (SR) with a delayed strategy (DR) in patients with synchronous CLMs. All patients, referring to our district community hospital in Savona, with synchronous CLMs who underwent hepatic resection between 1st October 1998 and 31st March 2013 were analyzed retrospectively. We excluded from the study 18 patients who underwent a two stage hepatectomy for multiple bilobar metastases. Short-term outcome and overall survival were compared in patients having SR and those treated by DR.
Results: Of 53 patients undergoing hepatectomy for synchronous CLMs, 43 (81%) had a SR and 10 (19%) had a DR. The 90 days mortality rate following hepatectomy was 4 (7.5%) in the two groups (7% versus 10% in SR and DR respectively). The mean survival rate was 39 months in the two groups (34.3 for SR group, 58.3 for DR group). Three and five-year overall survival rates were 50 and 33% (54 and 37% in the SR group; 56 and 44% in the DR group).
Conclusions: In this limited and low powered study, combined strategy seems to be safe in patients with synchronous CLMs without clear differences in terms of mortality and overall survival compared to a delayed procedure. Nevertheless, considering data regarding 90 days mortality, SR in elderly patients should be carefully considered.
No conflict of interest.

	Study Population (N = 53)		*P*

2349 POSTER

Total anorectal and pelvic floor reconstruction after Mile's resection: A special technique

O. Nassar[1]. [1]*National Cancer Institute, Surgical Oncology, Cairo, Egypt*

Background: Innovative techniques created to restore gastrointestinal perineal continuity after abdominoperineal resection in patients with anorectal cancer include pseudocontinent perineal colostomy, in which the colon is pulled to the perineum and wrapped with a sleeve of stretched colon segment to act as a new sphincter.
Objective: We investigated perineal reconstruction with a modified pseudocontinent perineal colostomy technique.
Design: Prospective cohort study.
Settings: Tertiary care university hospital in Egypt.
Patients: Patients with T2 or T3 anorectal cancer invading the sphincter who underwent Miles abdominoperineal resection and immediate total pelvic reconstruction between 2003 and 2007.
Intervention: Pelvic floor reconstruction by a vertical rectus abdominis myocutaneous flap with modified perineal colostomy pulled through the flap in order to add the high-pressure zone of the flap to that of the colostomy and to create a persistent new anorectal angle.
Main outcome measures: Early and late complications were recorded. Functional results were evaluated at regular intervals by questionnaire, physical examination, and balloon manometry. Continence was graded according to Kirwan. Satisfaction with continence was assessed by questionnaire.
Results: A total of 14 patients (3 women) were included. Tumors were adenocarcinoma (n = 11), squamous cell carcinoma (n = 2), and melanoma (n = 1).
Complete (R0) resection was achieved in all patients without perioperative deaths, major postoperative morbidity, or conversion to permanent iliac colostomy. Early postoperative complications (perineal wound infection, flap dehiscence, and partial perineal stoma necrosis) occurred in the first 4 patients. Late complications occurred in 7 patients, with mucosal prolapse in 3, stomal stricture in 4, and tumor recurrence in 1. Fecal continence progressed consistently with time, and by the end of the first year 8 patients (57%) had complete continence (grade A), 5 (36%) were continent with minor soiling (grade C), and 1 (7%) still had major soiling (grade D). After 6 months, 9 patients (64%) were satisfied with continence; after 1 year, 13 patients (93%) were satisfied. Regular enemas were necessary during the first year to improve soiling, and 8 patients (57%) were not in need after that. At 37 months median follow-up, 8 of 9 evaluable patients (89%) were satisfied with continence (grade A) without regular enemas.
Limitations: This was a preliminary observational study with no control group.
Conclusions: Total orthotopic pelvic reconstruction with autologous tissues transposition to rebuild the principle anorectal continence elements is feasible with minor complications and oncologically safe. This new technique offered high continence satisfaction independent of regular enemas and electrical stimulation.
No conflict of interest.

2350 POSTER

No change in disease free survival of node negative patients after improved nodal staging of colon cancer

D. Hooijberg[1], B. Inberg[2], J.T.M. Plukker[2], P.C. Baas[1], A.T.M.G. Tiebosch[3], W. Kelder[1]. [1]*Martini Hospitaal, Surgery, Groningen, The Netherlands;* [2]*UMCG, Surgery, Groningen, The Netherlands;* [3]*Martini Hospitaal, Pathology, Groningen, The Netherlands*

Background: Since July 2004 colorectal resection specimens in our hospital have been processed and fixated using modified Davidson Fixative (mDF). Earlier study showed that this technique improved nodal harvest and changed nodal staging in a substantial number of patients (stage migration). Primary aim of this study is to evaluate if the improved staging after the introduction of mDF affects disease free survival in the node negative group. Secondary aims were to investigate if the number and size of lymph nodes and metastases affect survival rates.
Patients and Methods: The specimens of 125 patients operated after July 2004 where fixated using mDF. The other 117 patients were operated before the introduction of mDF. Patients with rectal cancer, distant metastases (DM) or non-radical resection ($\geqslant$R1) were excluded. The size of the metastatic and non-metastatic lymph nodes was measured. Overall (OS) and disease free survival (DFS) between the groups were compared. Kaplan–Meier curves were used for univariate analysis.
Results: 215 patients were analyzed. The groups were similar for tumour and patient characteristics. Between the groups, differences were observed in the number of detected lymph nodes, node positive rate (no mDF 30%, mDF 41%), number of positive lymph nodes and size of metastatic lymph nodes. In 55 patients tumour recurred. The DFS and OS did not differ between groups. In univariate analysis for the total group, T-status, N-status, number of positive lymph nodes, size of nodal metastasis, adjuvant therapy and ASA 3 classification affected DFS, while fixation method and number of examined lymph nodes did not. Size of metastatic node almost reached significance. In the node negative group fixation method and number of nodes were not significant while T status was. In multivariate analysis, only T- and N-status remained significant factors for disease free survival.
Conclusion: mDF leads to a higher number of examined lymph nodes and nodal upstaging. However, improved nodal staging did not affect the DFS in node negative patients. Except for T- and N-status and number of nodal metastases, size of metastatic nodes may also play a pivotal role with a trend towards significance. Improved staging leads to detection of more and smaller metastatic nodes (stage migration/upstaging) with a change in treatment (adjuvant chemotherapy) for some patients who are upstaged from N0 to N+. Prospective studies on large numbers of patients are necessary to provide changes in survival rates.
No conflict of interest.

2351 POSTER

Association between bevacizumab administration and postoperative wound complications in patients who undergo surgery for liver metastasis of colorectal cancer

H. Utsumi[1], Y. Honma[1], K. Kato[1], T. Hamaguchi[1], Y. Yamada[1], Y. Shimada[1], Y. Kishi[2], S. Nara[2], M. Esaki[2], K. Shimada[2]. [1]*National Cancer Center Hospital, Gastrointestinal Medical Oncology Division, Tokyo, Japan;* [2]*National Cancer Center Hospital, Hepato-Biliary-Pancreatic Surgery Division, Tokyo, Japan*

Background: Bevacizumab, a humanized monoclonal antibody against vascular endothelial growth factor, is known to inhibit wound healing. For bevacizumab, the appropriate rest period between the last administration of chemotherapy and surgery (6−8 weeks) is decided on the basis of only on pharmacokinetics data. Our primary objective in this study was to investigate the adverse effect of bevacizumab on surgical wound healing and to clarify the appropriate rest period between the last administration of chemotherapy and surgery in terms of clinical outcome.
Materials and Methods: We retrospectively analyzed 373 surgical cases in 297 patients who underwent surgery for liver metastasis of colorectal cancer at our institution between February 2003 and September 2012. Differences in the distribution of the variables and odds ratio were evaluated using the chi-squared test or Fisher exact test, as appropriate.
Results: Before surgery, 35 patients (9.4%) underwent chemotherapy with bevacizumab (group A), 110 (29.5%) underwent chemotherapy without bevacizumab (group B), and 228 (61.1%) did not undergo chemotherapy (group C). The median time between the last administration of chemotherapy and surgery was 11.1 weeks (range, 2.7–86.1 weeks) in group A and 22.4 weeks (range, 2.1–401.6 weeks) in group B. A total of 90 patients (24.1%) had primary lesions and underwent synchronous colectomy. Postoperative wound complications occurred in 28 cases (7.5%): wound infection, 20 cases; wound dehiscence, 5 cases; ecchymoma, 2 cases; and skin flap necrosis, 1 case. The difference between groups was not associated with wound complications; only synchronous colectomy showed a strong correlation (20.0% vs 3.5%; odds ratio [OR], 6.83; 95% confidence interval [CI]; 3.02–15.43, P <0.001). In group A, the median time between the last administration of bevacizumab and surgery was 15.0 weeks (range, 5.4–86.1 weeks). The patients who were treated with bevacizumab less than 7 weeks before surgery had more frequent wound complications than those at 7 weeks or later (40.0% vs 3.4%; OR, 18.667; 95% CI, 1.28–272.12; P = 0.05). Only one patient underwent synchronous colectomy 7.6 weeks after the last administration of bevacizumab in group A. In contrast, in group B, the incidence of wound complications did not differ between patients who received chemotherapy less than 7 weeks before surgery and those who received chemotherapy more than or equal to 7 weeks before surgery (4.0% vs 4.7%; OR, 0.844; 95% CI, 0.09–7.91; P = 1.00).
Conclusions: In conclusion, this study demonstrated that preoperative chemotherapy or bevacizumab administration does not influence the risk of postoperative wound complications. For patients with a history of bevacizumab treatment, a rest period of 7 weeks between the last administration of chemotherapy and surgery seemed to be appropriate.
No conflict of interest.

2352 POSTER

Colorectal peritoneal carcinomatosis treated with cytoreductive Surgery (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC): The experience of a tertiary Asian centre

G. Tan[1], C.K. Tham[2], C. Lim[3], K.C. Soo[4], M. Teo[1]. *[1]National Cancer Centre, Surgical Oncology, Singapore, Singapore; [2]National Cancer Centre, Medical Oncology, Singapore, Singapore; [3]National Cancer Centre, Statistics, Singapore, Singapore; [4]National Cancer Centre, Director, Singapore, Singapore*

Background: Peritoneal metastases occur in up to 20% of colorectal cancers, and accounts for 40−70% of all recurrent disease. In 10−30% of these recurrences, the disease is confined to the peritoneum, with no distant metastases. In these patients, cytoreductive surgery (CRS) and hyperthermic intraperitoneal chemotherapy (HIPEC) have been shown to improve survival when compared to intravenous chemotherapy alone. We review our institutional experience with this group of patients, and evaluate their overall (OS) and disease-free survival (DFS) rates.
Method: Data was prospectively collected from all patients with colorectal peritoneal carcinomatosis treated by CRS and HIPEC at the National Cancer Centre Singapore between Jan 2001 and December 2012. Our primary end points were overall and disease-free survival.
Results: A total of 35 patients underwent CRS and HIPEC. The majority of the patients (89%) were of Chinese ethnicity. Median follow up duration was 24.7 months. The 1, 3- and 5- year disease-free survival was 43.8%, 22.3% and 22.3% respectively, and the overall survival was 83.7%, 38.2% and 19.1% respectively. Factors influencing OS were age at surgery, N stage, completeness of cytoreduction (CC) score, and disease-free interval (DFI); Age, CC score and DFI remained significant for DFS. The 30-day morbidity was 40% and there were no 30-day inpatient mortalities.
Conclusion: CRS and HIPEC can be safely carried out in Asian patients with colorectal peritoneal carcinomatosis, and confers significant disease-free and overall survivals. The age of the patient, DFI and nodal status, together with careful patient selection to ensure that optimal cytoreduction can be achieved is essential for the success of this procedure.
No conflict of interest.

Selective decontamination of the digestive tract in gastrointestinal surgery: A valuable addition to infection prevention? A systematic review

G. Abis[1], H.B.A.C. Stockmann[2], M. Van Egmond[1], H.J. Bonjer[1], C.M.J.E. Vandenbroucke-Grauls[1], S.J. Oosterling[3]. *[1]VU Medical Center, Surgery, Amsterdam, Netherlands; [2]Kennemer Gasthuis, Surgery, Haarlem, Netherlands; [3]Erasmus Medical Center, Surgery, Rotterdam, Netherlands*

Background: Gastrointestinal surgery is associated with high incidences of infectious complications. The most severe is anastomotic leakage, associated with considerable morbidity and mortality. The use of prophylactic antibiotics strongly reduces infectious complications. The aim of this systematic review was to evaluate effects of perioperative selective decontamination of the digestive tract (SDD), an antimicrobial prophylaxis regimen of oral nonabsorbable selective antibiotics eradicating gastrointestinal carriage of potentially pathogenic micro-organisms, on infectious complications after abdominal surgery.
Methods: Relevant studies were identified using computerised bibliographic searches of MEDLINE, EMBASE, and the Cochrane database (published between 1970 and November 2012) and a manual search of reference lists and the review of 'epub ahead of print' articles. A comprehensive search was performed using the search terms: gastrointestinal tract, gastrointestinal disease, antibiotic prophylaxis, decontamination. Additional keywords and further logical combinations were used to maximise sensitivity.
Results: Of the 1257 abstracts, 96 articles met the primary criteria and were identified for potential inclusion and reviewed in detail. After appliance of the secondary criteria, defined as studies investigating SDD in abdominal surgery, eight randomised controlled trials, one meta-analysis and one retrospective analysed case-controlled clinical trial were selected. One study explored SDD in oesophageal resections, one in gastrectomy and another study in both total gastrectomy and oesophagectomy patients. Three clinical trials investigated SDD in colorectal cancer and one meta-analysis and two studies in liver transplantation. SDD in pancreatic surgery was inquired in one study.
Discussion: The available evidence for the use of SDD in colorectal surgery indicates that SDD, in addition to intravenous antibiotics, reduces (surgical site) infections and the clinical anastomotic leakage rates. For oesophageal and gastric cancer surgery, results are encouraging but heterogeneous. Therefore SDD might be considered as a valuable adjuvant tool for perioperative infection prophylaxis in colorectal cancer surgery. We believe that these results provide a rationale for a large multicenter randomized clinical trail with SDD in colorectal cancer surgery to confirm these effects with sufficient level of evidence.

One-stapler technique for right colectomy in colon cancer: A safe and fast technique

G. Fragandreas[1], M. Verroiotou[2], S. Ainalis[2]. *[1]Aristotle University of Thessaloniki Hippokrateio, Thessaloniki, Greece; [2]Aristotle University of Thessaloniki Hippokrateio, Ippokrateio, Thessaloniki, Greece*

Background: Right colectomy can be effectuated with various methods as far as anastomotic technique is required. One-stapler technique, although has been described almost 20 years ago, is becoming more and more popular among surgeons due to the significant advantages that presents.
Materials and Methods: From January 2012 until December 2012 eleven patients had been submitted to right colectomy due to colon cancer using one-stapler technique. Seven patients were male with an average age of 78 years and four patients were female with an average age of 69 years. Five patients were diagnosed with cancer of the cecum, four were diagnosed with cancer of ascending colon and one was diagnosed with cancer of hepatic flexure. All patients were treated by the same surgeon and one-stapler technique was applied with a subsequent latero-lateral ileocolic anastomosis. The patients in whom this technique was applied were chosen randomly.
Results: The parameters that were taken under consideration were the duration of anastomotic time and post-operative complications of this technique. Anastomotic time was calculate to have an average duration of eight minutes while post-operative complications included one male patient, 80 years old, who presented melena on the 1st post-operative day and was treated conservatively. Melena was attributed to a limited micro-bleeding in the anastomotic area. All the other patients had a normal post-operative course and on a follow-up of 3−11 months had not presented any complications.
Conclusions: One-stapler technique with a subsequent latero-lateral ileocolic anastomosis on the case of right colectomy for colon cancer is a fast technique that can contribute significantly to reducing surgical time. This fact is of major importance for patients submitted to this kind of operation, given their advanced age and the concomitant diseases that aggravate their situation. The fore-described technique is safe, time-saving and of minimal contamination risk, while risk of hemorrhage in the anastomotic area can be avoided by controlling thoroughly the stapling line intra-operatively and reinforcing the stapling line with absorbable sutures. Taking under consideration our experience from these patients, this technique has become our treatment of choice in case of cancer of right colon.

2355 POSTER

Utility of preoperative colonoscopy in localization of colorectal cancer

G. Santak[1], Z. Glavic[1], L.J. Begic[1], D. Simlesa[1], J. Cosic[1], K. Matkovic[1], G. Zukanovic[1]. *[1]County Hospital Pozega, Department of Surgery, Pozega, Croatia*

Background: Erroneous localization of colorectal carcinomas puts the patients at risk for inappropriate use of adjuvant therapy, inadequate operative approach, prolonged surgery or missing the lesion.
Material and Methods: A retrospective chart review was conducted on a total of 146 patients who had complete endoscopic and CT reports available and had undergone surgery for colon or rectal malignancies between January 2007 and January 2013. The purpose of this study was twofold: (a) to determine the accuracy of colonoscopy and CT scanning in localizing colorectal tumors and (b) to examine the utility of preoperative colonoscopy performed by surgeon.
Results: Tumor location was accurately determined via colonoscopy in 80.5% of cases and erroneously in 19.5% of cases. CT scan confirmed colonoscopic localization in 59.6% of cases, and did not detect known tumors in 40.4% of cases. Of the tumors erroneously located by colonoscopy, 2.7% were accurately localized by CT scan. 48.4% of the patients with undetected tumors on CT scans, underwent second (preoperative) colonoscopy, performed by surgeon. The location of the tumor as determined by preoperative colonoscopy differed from the location noted on referral colonoscopy in 14.6% of patients. Tumor localization was determined correctly in all patients with preoperative colonoscopy and the difference in the accuracy of tumor localization between the patients which underwent two colonoscopies and those which did not, was statistically

significant. The average size of the tumors not detected by CT was 2.98 cm. Large (>4 cm) tumors were rarely missed.
Conclusions: Identifying localization of colorectal tumors by two complementary methods is essential before resection is undertaken. Preoperative colonoscopy, performed by surgeon, would decrease the likelihood of mislocalization of the small lesions detected on the first colonoscopy.
No conflict of interest.

2356 POSTER

Surgical treatment of rectal cancer: A single center experience

R. Tamrazov[1], Y. Barsukov[1], S. Gordeyev[1]. [1]*Russian Cancer Research Center, Proctology, Moscow, Russian Federation*

Background: Evaluation of the results of surgical treatment in patients with resectable rectal cancer based on multivariate analysis.
Methods: This study is based on the analysis of 680 consecutive resectable rectal cancer patients, which underwent radical surgical-only treatment during 1990–2010. Localization of rectal tumors ranged from 4 to 15 cm above the anal verge. 333 patients (49%) had upper rectal cancer, 170 patients (25%) − middle, 177 patients (26%) − low. 456 patients (67.1%) had anterior resection (AR), 97 (14.3%) had low anterior resection with coloanal anastomosis (LAR-CAA) and 127 (18.6%) had abdominoperineal resection (APR). Stage distribution was following: T1−2NoMo (Stage I) − in 145 patients (20.6%), T3−4NoMo (Stage II) − 341 (50.6%) and T2−3N1−2Mo (Stage III) in 194 (28.8%).
Results: Local recurrences rate was 11.8%: 9% after AR − 9% after LAR-CAA − 21.6%, after APR − 16.5%; depending on tumor localization: 9% for upper rectal cancer, 26.6% − middle, and 21.2%- low; depending on TNM stage: I − 9%, II − 10.4%,III − 23.5%. Overall 5-year survival rate was 63.8%, 5-year disease-free survival − 58.2%. Relapse rate during 1990–2000 was 18.6%, during 2000–2010 − 5.1%.
Conclusion: Based on our experience, learning curve is crucial factor influencing treatment outcome. Distal localization of rectal cancer is the most important prognostic factor for rectal cancer. Quality surgery allows to achieve local control in 95% of the patients.
No conflict of interest.

2357 POSTER

Significance of BMI over complications in laparoscopic colorectal cancer

E. Rubio[1], G. Supelano[2], V. Garcia[2], T. Butron[2], M. Ortiz[2], B. Cristobal[2], L. Brandariz[2], C. Cobo[2], E. Ferrero[2], M. Lomas[2]. [1]*Mdaie, Surgical Oncology, Madrid, Spain;* [2]*Universitary Hospital "12 de octubre", Digestive Surgery B, Madrid, Spain*

Background: Numerous studies have explored the association between outcomes and risk factors for surgical procedures. One recent study determined the most important predictors of complications that need to be included in models for adequate risk adjustment. The outcome of colorectal surgical procedures is influenced by a variety of factors, including the quality of care, patient characteristics, preoperative risk factors, and operative details. Obesity is a risk factor to develop complications.
Objective: To identify of significance of BMI (Body mass index) >30 iver complications in patients with laparoscopic colorectal cancer (LCC).
Patients: 90 patients with colorrectal laparoscopic surgery.
Results: Only 16 patients with >30 BMI (18%). Mean age: 53.31 years old, 15 are men, 81.3% have a biopsy of colorectal adenocarcinoma. ASA II was grade of the classification for anesthetic risk in 75.5%. In 17% an endoprosthesis was required in the evolution of disease. Surgical mean time was 243 minutes. In 68% patients the reconstruction was mechanical. Conversion to open surgery was necessary in 1 patient by tumoral adhesions. Some kind of complication (wound infection, urinary infection, etc) was identified in the 56.3%. One reoperation was realized for complications (fistulae). In one patient a double ureteral injury was identified (BMI >40). Surgical wound was complicated in 37.6%. A previous diagnosis of colorectal adenocarcinoma was made in 85.7%. Mean number of resected lymph nodes was 16 (11−56). Dukes (Modified Astler-Coller) more frequent was C2 with a 37.5%. Oral intake oral was begin in the first 24−48 hours after surgery in 64.2%. Only 18.8% patients presented a recurrence of initial tumor.
Conclusions: Obesity is known to lead to higher complication rates across a wide variety of surgical procedures. It is not sur-prising that, in our study, increasing BMI was associated with increased postoperative complication rates.
No conflict of interest.

2358 POSTER

Efficiency of multivisceral resection for T4 rectal cancer

I. Shchepotin[1], O. Kolesnik[1], V. Prymak[1], D. Mahmudov[1], A. Beznosenko[1]. [1]*National Cancer Institute, Kyiv, Ukraine*

Background: Review a single-center experience of multivisceral resections (MVR) for rectal cancer to determine the accuracy of intraoperative prediction of potential curability and to examine the effect of surgical experience on short-term outcome and long-term results.
Material and Methods: A retrospective study was performed to analyze the data collected 278 patients who underwent a curative resection for $T_4N_{0-2}M_0$ primary rectal cancer (2000–2009). Chemoradiation was using a 3-field belly-board technique. The median total dose was 45 Gy (range 40−60). Estimated overall survival, overall recurrence and local recurrence were compared using the log rank method and Cox regression analysis.
Results: In 136 cases of 278, the patients had macroscopically direct invasion of adjacent organs and underwent a MVR (main group): $T_4N_0M_0$ − 86 (63.2%), $T_4N_{1-2}M_0$ − 50 (36.8%). A control group − 142 patients with T4 rectal cancer without either macro- or microscopic invasion into adjacent organs, who underwent standard surgery: $T_4N_0M_0$ − 99 (70%), $T_4N_{1-2}M_0$ − 43 (30%). Common resected organs were the uterus (45%), vagina (25%), prostate and bladder (23%). In the MVR group, tumor infiltration was confirmed histologically in 38% of the cases, and peritumorous adhesion had mimicked tumor invasion in 62%. Postoperative complications (class III Clavien − Dindo) occurred in 6% of the patients who underwent standard surgery vs. 12% of those who underwent a MVR ($P < 0.0001$). The survival rate of patients after a MVR was similar to that of patients after standard surgery (5-year survival rates: 44.4% vs. 52.8%; $P = 0.36$), thus a recurrence − free survival rate in both groups showed no statistical significance (30% vs. 36%; $P = 0.59$). On univariable analysis, the only factor associated with local recurrence was completeness of resection (local recurrence rate 16% vs 74% for R0 vs R1 resection; $P < 0.001$). On multivariable analysis, factors associated with overall survival were absence of metastatic disease and R0 resection.
Conclusion: MVR was associated with higher postoperative morbidity, but the long-term survival and disease − free survival is similar to that after a standard resection. MVR for T4 rectal cancer had good oncological outcomes when clear resection margins were achieved. Less advanced pathologic N-stage is a significantly favorable prognostic factor for disease-free and overall survival.
No conflict of interest.

2359 POSTER

Initial results of a new antibody-drug conjugate (ADC), IMMU-130 (labetuzumab-SN38), in patients with metastatic colorectal cancer (mCRC)

N.H. Segal[1], J. Verghis[1], S. Govindan[2], P. Maliakal[2], R.M. Sharkey[2], W.A. Wegener[2], D.M. Goldenberg[2], L.B. Saltz[1]. [1]*Memorial Sloan-Kettering Cancer Center, Gastrointestinal Oncology Service, New York, USA;* [2]*Immunomedics Inc., Morris Plains, USA*

Background: IMMU-130 is an ADC comprising labetuzumab (hMN-14) bound to the active metabolite of irinotecan, SN-38. hMN-14, a slowly-internalizing monoclonal antibody (mAb), binds CEACAM5 (CD66e), expressed in >80% CRC. In vitro, the Ab-drug linkage is cleaved in serum, with 50% of SN-38 released in ~1 d, suggesting that most SN38 is released at the tumor in enhanced concentration. Since irinotecan, a standard therapy of mCRC, can have major gastrointestinal (GI) and hematologic toxicity, conjugating insoluble SN-38 to this tumor-targeting mAb should improve the prodrug's therapeutic index. A safe starting dose of IMMU-130 was determined from preclinical toxicology studies showing no GI toxicity and transient mild myelosuppression. This single-arm, open-label, dose-escalation, phase I study was undertaken to define the MTD of IMMU-130 in mCRC pts.
Material and Methods: Eligible pts had received at least 1 prior irinotecan-containing regimen, and serum CEA >5 ng/mL. Permission for this study was obtained from the FDA and local IRB, and informed consent was given. IMMU-130 is administered biweekly, with a goal of 12 cycles in the absence of unacceptable toxicity or disease progression. Pt cohorts are treated at increasing dose levels. DLT is defined as Grade 4 neutropenia $\geqslant$5 d, $\geqslant$ Grade 3 thrombocytopenia, Grade 3 anemia, $\geqslant$ Grade 3 nausea, vomiting or diarrhea >48 h, or other $\geqslant$ Grade 3 non-hematological toxicity in the first 2 doses.
Results: To date, 11 pts have been treated at 2, 4, 8 and 16 mg/kg. The median number of doses given is 4.09, 7 pts received $\geqslant$3 doses. Of 5 pts having >2 doses of 16 mg/kg, one received 18 and achieved a PR after 8, which lasted 8 mos. One DLT was observed at 16 mg/kg: Grade 3 thrombocytopenia. The same pt, and another at the same dose, had Grade 4 neutropenia <5 d. Importantly, no Grade $\geqslant$2 drug-related GI

toxicities were observed. A single case of hypersensitivity occurred. No human anti-human antibodies (HAHA) have been detected. PK analysis shows the intact conjugate clears quicker than the Ig in the circulation, consistent with SN-38 being gradually released from the ADC.
Conclusion: This first-in-man study indicates that IMMU-130, an ADC comprising SN-38, is safe and reasonably well tolerated within a clinically effective dosage range. Dose escalation is continuing.

2360 POSTER

Regorafenib dose modifications in patients with metastatic colorectal cancer in the phase III CORRECT study

A. Falcone[1], E. Van Cutsem[2], A. Sobrero[3], S. Siena[4], M. Ychou[5], H.J. Lenz[6], T. Yoshino[7], F. Cihon[8], A. Wagner[9], A. Grothey[10]. *[1]Azienda Ospedaliero-Universitaria Pisana, U.O. Oncologia Medica, Pisa, Italy; [2]University Hospitals Leuven, Digestive Oncology, Leuven, Belgium; [3]Ospedale San Martino, Medical Oncology, Genova, Italy; [4]Ospedale Niguarda Ca' Granda, Oncology, Milan, Italy; [5]ICM − Val d'Aurelle, Oncology, Montpellier, France; [6]VSC/Norris Comprehensive Cancer Centre, Division of Medical Oncology, Los Angeles, USA; [7]National Cancer Center Hospital East, Department of Gastroenterology and Gastrointestinal Oncology, Chiba, Japan; [8]Bayer HealthCare Pharmaceuticals, Global Biostatistics, Montville, USA; [9]Bayer Pharma AG, Global Clinical Development − Oncology, Berlin, Germany; [10]Mayo Clinic, Department of Oncology, Rochester, USA*

Background: CORRECT (NCT01103323) was a randomized, double-blind, placebo-controlled, phase III study that evaluated the multikinase inhibitor regorafenib (REG) in patients (pts) with metastatic colorectal cancer (mCRC) that had progressed on standard therapy. REG-treated pts showed a clinically significant improvement in overall and progression-free survival *vs* placebo (P). Adverse events (AEs), such as hand–foot skin reaction (HFSR), could be managed with dose interruptions or reductions. This abstract reports details of dose modifications in CORRECT.
Materials and Methods: The CORRECT study, sponsored by Bayer HealthCare, randomized pts to receive REG 160 mg or P once daily for weeks 1−3 of each 4-week cycle. AEs could be managed with interruption or a reduction in treatment dose by 40 mg. In addition, the study protocol provided specific dose modification recommendations for HFSR, hypertension and liver function abnormalities.
Results: 753 pts (500 REG, 253 P) received at least one dose of treatment (median 2 cycles in each group, mean 3.3 cycles of regorafenib, 2.3 cycles of placebo). Dose modifications were reported in 76% of REG-treated pts and 38% of P recipients. The number and duration of dose modifications is reported in the table. The most common AEs requiring dose reduction were HFSR (18% of REG-treated pts *vs* 0.4% of P recipients), diarrhea (4% *vs* 0%), hypertension (3% *vs* 0.4%), fatigue (3% *vs* 2%), and rash/desquamation (3% *vs* 0%). The most common AEs requiring dose interruption were HFSR (19% *vs* 0%), fatigue (6% *vs* 2%), diarrhea (6% *vs* 1%), rash/desquamation (5% *vs* 0%), and hypertension (3% *vs* 0.4%). AEs leading to permanent discontinuation were reported in 18% and 13% of pts in the REG and P groups, respectively.
Conclusion: Although significantly more REG-treated pts than P recipients had dose modifications due to AEs, the difference in the incidence of permanent treatment discontinuation was relatively small. This suggests that dose modifications are effective for managing AEs, and allow pts to continue REG treatment.

2361 POSTER

Time to health status deterioration in regorafenib-treated patients with metastatic colorectal cancer (mCRC): A post-hoc analysis of the phase III CORRECT study

J. Chang[1], V. Pawar[1], A. Grothey[2], A. Sobrero[3], S. Siena[4], A. Falcone[5], M. Ychou[6], H.J. Lenz[7], T. Yoshino[8], A. Wagner[9], E. Van Cutsem[10]. *[1]Bayer Healthcare Pharmaceuticals, Global HEOR Specialty Medicine, Montville, NJ, USA; [2]Mayo Clinic, Department of Oncology, Rochester, USA; [3]Ospedale San Martino, Medical Oncology, Genova, Italy; [4]Ospedale Niguarda Ca' Granda, Oncology, Milan, Italy; [5]University of Pisa, Dept. of Translational Research and New Technologies in Medicine, Pisa, Italy; [6]ICM − Val d'Aurelle, Oncology, Montpellier, France; [7]VSC/Norris Comprehensive Cancer Centre, Division of Medical Oncology, Los Angeles, CA, USA; [8]National Cancer Center Hospital East, Department of Gastroenterology and Gastrointestinal Oncology, Chiba, Japan; [9]Bayer Pharma AG, Global Clinical Development − Oncology, Berlin, Germany; [10]University Hospitals Leuven, Digestive Oncology, Leuven, Belgium*

Background: The phase III CORRECT study (NCT01103323) was a randomized, double-blind, placebo-controlled study sponsored by Bayer HealthCare. The study showed that the oral multikinase inhibitor regorafenib (REG) improved overall and progression-free survival in patients with mCRC refractory to standard therapy. This post-hoc analysis assessed time to deterioration (TTD) of health status in the CORRECT study.
Materials and Methods: Patients with mCRC progressing after all standard therapies were randomized to receive REG 160 mg (n = 505) or placebo (P; n = 255) once daily for weeks 1−3 of each 4-week cycle. TTD was analysed using three definitions of deterioration: a 3-component composite of ⩾10 point reduction in EORTC quality of life questionnaire (EORTC QLQ-C30) global health status (GHS) score, disease progression, or death; a 2-component composite of ⩾10 point reduction in GHS score or death; and ⩾10 point reduction in GHS score alone. Additional analyses assessed these endpoints using physical functioning (PF) score in place of GHS.
Results: REG was associated with significantly longer TTD *vs* P when assessed with the GHS-based 3-component endpoint (hazard ratio [HR] 0.77; 95% confidence interval [CI] 0.65–0.91; p < 0.01). TTD did not differ significantly in the REG group *vs* P using the 2-component composite and GHS only definitions (HR 0.91; 95% CI 0.75–1.09; p = 0.35 and HR 0.96; 95% CI 0.77–1.20; p = 0.80, respectively). Results for analyses performed with the PF-based endpoints were consistent with those for GHS, with HRs for the 3-component, 2-component, and PF-only endpoints of 0.74; 0.62–0.88; p < 0.01, 1.03; 0.84–1.25; p = 0.98, and 1.14; 0.90–1.44; p = 0.26, respectively. Patient censoring was high in the 1 and 2-component analyses, and was disproportionately greater in the P group.
Conclusion: REG is associated with a significantly longer median TTD than P when deterioration is measured using a 3-component composite endpoint, but not when deterioration is measured using a 2-component endpoint or GHS alone. This suggests that deterioration in health status in this patient group is driven by disease progression, not by quality of life. The 1 and 2-component analyses should be interpreted with caution due to high patient censoring.

Median TTD, weeks (95% CI)	P (n = 255)	REG (n = 505)	HR (95% CI)
3-component composite	7.0 (6.0−7.1)	7.0 (6.0−7.4)	0.77 (0.65–0.91)
2-component composite	8.1 (8.0−8.6)	8.1 (7.7−8.4)	0.91 (0.75–1.09)
GHS	8.1 (8.1−8.4)	8.0 (7.1−8.3)	0.96 (0.77–1.20)

2362 POSTER

Efficacy and safety in elderly patients on adjuvant therapy with UFT+LV or S-1 for stage III colon cancer: ACTS-CC trial (TRICC0706)

M. Ishiguro[1], E. Nakatani[2], T. Ishikawa[3], H. Uetake[1], K. Sugihara[3]. [1]*Tokyo Medical and Dental University, Department of Translational Oncology, Tokyo, Japan;* [2]*Foundation for Biomedical Research and Innovation, Translational Research Informatics Center, Hyogo, Japan;* [3]*Tokyo Medical and Dental University, Department of Surgical Oncology, Tokyo, Japan*

Background: The ACTS-CC trial (ClinicalTrials.gov:NCT00660894) is a randomized phase III trial designed to validate non-inferiority of S-1 to UFT/LV which is a standard adjuvant therapy for stage III colon cancer in Japan. Adverse events (AEs) and disease free survival (DFS) at 3 years (primary endpoint) were previously reported. To evaluate the efficacy and safety in elderly patients (pts), subgroup analysis was performed.
Patients and Methods: 20−80 aged pts with stage III colon cancer were randomly assigned to receive UFT/LV (UFT: 300 to 600 mg/day and, LV: 75 mg/day on days 1−28, followed by 7 days rest, 5 courses) or S-1 (80 to 120 mg/day on days 1−28, followed by 14 days rest, 4 courses). We compared AEs and DFS between group A (age $\leqslant$70) and group B (age 71−80).
Results: A total of 1518 pts (760 in S-1 arm, 758 in UFT/LV arm) were analyzed. The proportion of pts of group A and B were 69% (1043 pts) and 31% (475 pts), respectively, and there was no difference in stage distribution between the age groups. Pts with PS1 were more in group B than in group A (2.6% in group A vs. 8.7% in group B).
In S-1 treatment, incidences (any grades) of anemia (29% in group A vs. 40% in group B), decreased platelet count (11% vs.16%), anorexia (29% vs. 38%) and fatigue (25% vs. 33%) were higher in group B than in group A. In $\geqslant$ grade 3 AEs, anorexia (3% vs. 9%), nausea (1% vs. 3%) and fatigue (2% vs. 4%) were more frequent in group B.
In UFT/LV treatment, incidence (any grades) of anorexia (22% vs. 32%) and anemia (24% vs. 33%) were higher in group B, while that of elevation of AST (23% vs. 14%) and ALT (25% vs. 14%) were higher in group A. In $\geqslant$ grade 3 AEs, the difference between age groups was observed only in anorexia (3% vs. 6%).
Both in S-1 and UFT/LV treatment, there was no difference in the treatment completion rate between group A and B (78% and 74% in S-1, 75% and 71% in UFT/LV). The rate of discontinuation due to pts' request regarding AEs was higher in group B (4.3% vs. 8.8% in S-1, 4.4% vs. 8.2% in UFT/LV).
There was no difference in DFS between group A and B both in pts receiving S-1 (log-rank test: $p = 0.535$, 3-year DFS rate: 75% and 78%) and in pts receiving UFT/LV ($p = 0.315$, 73% and 69%).
Conclusions: Both S-1 and UFT/LV as adjuvant therapy for stage III colon cancer maintained their efficacy and feasibility in elderly pts (age 71−80).

2363 POSTER

Hospital variation in type of adjuvant chemotherapy for patients with stage III colon cancer

F.N. Van Erning[1], N. Bernards[2], G.J. Creemers[2], C.J.P.A. Lensen[3], G. Vreugdenhil[4], V.E.P.P. Lemmens[1]. [1]*Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands;* [2]*Catharina Hospital, Internal Medicine, Eindhoven, Netherlands;* [3]*Hospital Bernhoven, Internal Medicine, Oss, Netherlands;* [4]*Máxima Medical Centre, Internal Medicine, Veldhoven, Netherlands*

Purpose: To assess which factors determine whether or not platinum-based chemotherapy is administered to patients with stage III colon cancer.
Patients and Methods: 1113 patients who underwent resection for primary colon cancer stage III diagnosed in the Southern Netherlands between 2008–2011 were included. Differences in patient and tumour characteristics between patients receiving platinum-based chemotherapy, non-platinum-based chemotherapy or no chemotherapy were analysed using Chi^2 tests. After stratification by age group, crude and adjusted proportions of patients receiving platinum-based chemotherapy and non-platinum-based chemotherapy were calculated for each of 10 hospitals. Multivariable logistic regression analysis was conducted to assess the influence of several patient and tumour characteristics and hospital on the administration of platinum-based chemotherapy among the subgroup of patients treated in adjuvant setting.
Results: 87% of patients aged <70 years received adjuvant chemotherapy. In patients aged 70−74 years, 66% received adjuvant chemotherapy and among patients aged $\geqslant$75 years, this percentage was 24%. A large hospital variation in the addition of oxaliplatin could be noted, ranging from 73%-96% for patients aged <70 years, from 50%-100% for patients aged 70−74 years, and from 8%-100% for patients aged $\geqslant$75 years. Older patients and patients with T1 stage were less likely to receive platinum-based chemotherapy (adjusted $OR_{\geqslant 75 years\_vs\_<70 years}$ 0.02, 95% CI <0.001–0.58 and adjusted $OR_{T1\_vs\_T3}$ 0.17, 95% CI 0.05–0.62, respectively). Patients from two hospitals were less likely to receive platinum-based chemotherapy (adjusted $OR_{G\_vs\_C}$ 0.36, 95% CI 0.14–0.89 and adjusted $OR_{H\_vs\_C}$ 0.34, 95% CI 0.13–0.87, respectively).
Conclusion: The decision to withhold platinum-based chemotherapy does not only depend on predictable factors such as age and stage, but also on hospital. The impact of hospital variation in type of adjuvant chemotherapy on outcome is important but remains to be established in future research.
No conflict of interest.

2364 POSTER

Prospective analysis of UGT1A1 genotyping for predicting toxicities in advanced colorectal cancer (ACRC) treated with irinotecan (IRI)-based regimens: The development of nomogram predicting severe neutropenia

W. Ichikawa[1], I. Hyodo[2], K. Fujita[3], M. Nakamura[4], A. Tsuji[5], S. Morita[6], Y. Ando[7], T. Sugiyama[8], Y. Ohashi[9], Y. Sakata[10]. [1]*National Defense Medical College, Dept. of Clinical Oncology, Saitama, Japan;* [2]*University of Tsukuba, Dept. of Gastroenterology, Tsukuba, Japan;* [3]*Saitama Medical University International Medical Center, Dept. of Medical Oncology, Saitama, Japan;* [4]*Aizawa Hospital, Comprehensive Cancer Center, Matsumoto, Japan;* [5]*Kobe City Medical Center General Hospital, Dept. of Medical Oncology, Kobe, Japan;* [6]*Yokohama City University Medical Center, Dept. of Biostatistics and Epidemiology, Yokohama, Japan;* [7]*Nagoya University Hospital, Dept. of Clinical Oncology and Chemotherapy, Nagoya, Japan;* [8]*Iwate Medical University School of Medicine, Dept. of Obstetrics and Gynecology, Morioka, Japan;* [9]*The University of Tokyo, Dept. of Biostatistics, Tokyo, Japan;* [10]*Misawa City Hospital, CEO, Misawa, Japan*

Background: *UGT1A1*6* and *UGT1A1*28* are risk factors for severe IRI-related toxicities in Asians, and recommended IRI doses based on *UGT1A1* genotypes has not been established. We conducted a prospective analysis to examine the correlation between *UGT1A1* genotypes and safety/efficacy of IRI-based regimens in Japanese ACRC patients (pts), (NCT 01039506).
Methods: Pts who had histologically confirmed ACRC with PS of 0−2 and received IRI-based regimens (FOLFIRI, IRI+S-1, IRI monotherapy) were genotyped for *UGT1A1*. All pts provided written informed consent. *UGT1A1* polymorphisms were analyzed and categorized into 3 groups: wild (**1/*1*), hetero (**1/*6, *1/*28*), and homo (**6/*6, *6/*28, *28/*28*). Detailed toxicities in the first 3 months of treatment were prospectively recorded. For interim safety analysis, incidences of grade 3−4 (severe) toxicities were assessed among *UGT1A1* genotypes and a logistic regression model was used to determine the associated risk factors for severe toxicities. Then a nomogram for predicting severe toxicities was developed, and bootstrap validation was performed.
Results: We enrolled 1376 pts between October 2009 and March 2012. At the time of this abstract submission, toxicity data of 1062 pts were available. The prevalence of UGT1A1 polymorphisms, 47% wild, 42% hetero, and 11% homo, were similar to those previously published in Japanese population. FOLFIRI was administered to 63% pts, initial IRI doses (mean$\pm$SD mg/m^2) were 138.6$\pm$25.3 in wild, 137.4$\pm$27.7 in hetero, and 121.1$\pm$33.2 in homo. During the first 3 months of treatment, severe neutropenia developed in 32% pts: 25% in wild, 35% in hetero [Odds ratio (OR) to wild, 1.7; 95% CI, 1.3−2.2], and 51% in homo [OR to wild, 3.1; 95% CI, 2.0−4.8]. Severe diarrhea was 4% in wild, 4% in hetero [OR to wild, 1.0; 95% CI, 0.5−1.9], and 10% in homo [OR to wild, 3.3; 95% CI, 1.4−7.4]. We developed a nomogram for predicting severe neutropenia in the first treatment cycle using a multiple logistic regression model included regimen, initial IRI dose, gender, age, *UGT1A1* genotype, and PS. The resulting nomogram demonstrated good accuracy in predicting severe neutropenia, with a bootstrap-corrected concordance index of 0.7033.
Conclusions: *UGT1A1* genotype along with other clinical factors has been confirmed to be a critical risk factor for severe toxicities of IRI-based regimens. We will provide the final nomogram based on 1320 pts data and its additional validation results. This nomogram would help us to find the individual starting dose of IRI.

2365 POSTER

The relevance of thymidine kinase 1 (TK1) expression to treatment efficacy of TAS-102 and prognosis in patients (pts) with metastatic colorectal cancer (mCRC)

Y. Komatsu[1], T. Yoshino[2], N. Mizunuma[3], K. Yamazaki[4], T. Nishina[5], H. Baba[6], A. Tsuji[7], K. Yamaguchi[8], K. Muro[9], A. Ohtsu[2]. [1]*Hokkaido University Cancer Center, Cancer Chemotherapy, Sapporo, Japan;* [2]*National Cancer Center Hospital East, Department of Gastroenterology & GI Oncology, Kashiwa, Japan;* [3]*The Cancer Institute Hospital of JFCR, Division of Chemotherapy Gastrointestinal Oncology, Tokyo, Japan;* [4]*Shizuoka Cancer Center, Division of Gastrointestinal Oncology, Shizuoka, Japan;* [5]*National Hospital Organization Shikoku Cancer Center, Department of Gastrointestinal Medical Oncology, Ehime, Japan;* [6]*Kumamoto University Hospital, Gastroenterological Surgery, Kumamoto, Japan;* [7]*Kochi Health Sciences Center, Department of Medical Oncology, Kochi, Japan;* [8]*Saitama Cancer Center, Department of Gastroenterology, Saitama, Japan;* [9]*Aichi Cancer Center Hospital, Department of Clinical Oncology, Nagoya, Japan*

Background: TAS-102 is a novel oral nucleoside antitumor agent, consisting of trifluorothymidine (FTD) and thymidine phosphorylase inhibitor that prevents degradation of FTD. FTD is incorporated into DNA after phosphorylation by thymidine kinase 1 (TK1), and leading to antitumor effects. In addition, TK1 is believed to play an important role in the prognosis of various cancers. TAS-102 improved the prognosis of mCRC pts in Phase II study conducted in Japan. The first report of the relationship between TK1 and TAS-102 expression was already presented, and we performed further analysis to clarify the role of TK1 in mCRC and TAS-102 treatment.
Material and Methods: Immunohistochemical analysis of TK1 was performed in 150 (TAS-102: 99, placebo: 51) of 169 pts and TK1 expression in cytoplasm was blindly assessed at the central laboratory. The relationship between TK1 expression and efficacy of TAS-102 was retrospectively investigated with variable cut-off value which evaluates occupancy of TK1 positive cell in tumor cells. This study was supported by Taiho Pharmaceutical CO., LTD. (JAPIC Clinical Trials information Identifier: JapicCTI-090880.)
Results: The median OS of the population with a high TK1 expression tend to shorter than that of the population with a low TK1 expression in the placebo group, whereas TAS-102 reduced the risk of death at each cut-off point irrespective of TK1 expression. At a cut-off of 30%, the median OS of pts with high TK1 expression (n = 13) and low (n = 38) expression was 4.9 and 7.2 months in the placebo group. In contrast, the median OS of pts with high TK1 expression (n = 27) and low (n = 72) expression was 10.4 and 7.7 months (p = 0.04, HR = 0.51, 95% CI=0.27–0.97) in the TAS-102 group. TAS-102 is highly effective in prolonging the survival of pts with high TK1 expression. The hazard ratio for OS by TAS-102 was 0.14 (p = 0.0013, 95% CI=0.04–0.46) in pts with high TK1 expression and 0.62 (p = 0.044, 95% CI=0.39–0.99) in pts with low TK1 expression. The decrease in the risk of death was favored in the population for which the TK1 high expression cell revealed $\geqslant$30% occupancy. HR for OS adjusted by *KRAS* mutational status and the other background factors be significant from pre-planned multivariate analysis was 0.52 (p = 0.0019, 95% CI=0.35–0.79) and interaction between treatment effect and TK1 expression could be suggested (p = 0.083).
Conclusions: TK1 could be a prognostic factor of mCRC and TAS-102 could be more effective in pts with high TK1 population.

2366 POSTER

Liver resection in patients (pts) treated with 1st line chemotherapy (CT) for metastatic colorectal cancer (mCRC) from Japanese cross-sectional cohort study (EMERaLD study)

S. Iwamoto[1], K. Yoshioka[1], K. Tokuhara[1], S. Okazaki[1], K. Inoue[1], T. Michiura[1], A. Kwon[1], T. Amano[2], Y. Ohashi[3]. [1]*Kansai Medical Univesity, Surgery, Hirakata, Japan;* [2]*Hokkaido Univesity, Medical Oncology, Sapporo, Japan;* [3]*School of Public Health The University of Tokyo, Department of Biostatistics, Tokyo, Japan*

Background: Complete resection of metastatic diseases can only result in cure with metastatic colorectal cancer (mCRC). We planned and conducted a large cross-sectional cohort study which investigates 1st line CT and metastasectomy in mCRC in Japan.
Methods: EMERaLD study evaluated the 6-month efficacy and safety data on 1,005 pts, recruited from 132 centers in Japan between October 2010 and September 2011, treated with 1st line CT including oxaliplatin and bevacizumab (BV) for mCRC. Among the total 1,005 pts, 627 pts has liver metastasis (mets) from colorectal cancer. We performed a sub-group analysis focused on 627 pts with liver mets from colorectal cancer.
Results: The background of 627 pts were the following; male/female, 411/216; median age of 64 (range, 27−89); ECOG PS 0/1/2/3, 534/86/6/1; site of primary tumor colon/rectum/others, 356/267/4; site of metastatic disease liver limited/with extrahepatic, 362/265; vascular invasion of liver mets with/without/unknown, 102/504/21; FOLFOX/ CapeOx/ others with BV, 285/324/18, KRAS-status wild/mutant/unknown, 138/113/376. Median number of liver mets was 5 (pts with the number of liver mets 1−4/$\geqslant$5/unknown, 296/321/10). Median maximum diameter of liver mets was 3.5 cm (range, 0.25−23). Among 627 pts, 106 pts (16.9%) received liver resection following 1st line CT. 90 pts (14.4%) had R0 liver resection. As a result of multivariate analysis, the following variables at baseline were associated to liver resection; age ($\geqslant$/<75 years old) (p = 0.0787; Odds Ratio (OR) = 1.844), extrahepatic diseases (p < 0.0001; OR = 0.194), the number of liver mets (p < 0.0001; OR = 0.812), peritoneal effusion (p = 0.034; OR = 0.265) and the response to 1st line CT (p < 0.0001; OR = 0.301). For the number of liver mets, Receiver Operating Characteristic analysis identified a cut-off value of 5 (1−5/$\geqslant$6) to distinguish between pts with or without liver resection.
Conclusions: Multivariate analysis showed liver resection of mCRC was associated to the following variables; no extrahepatic diseases, the number of liver mets of 1−5, no peritoneal effusion and the response to 1st line CT. We will further investigate and analyze the 2-year data including survival.
This study is sponsored by the Public Health Research Center Foundation CSPOR in Japan.

Background: 5-FU-containing chemotherapy is commonly used as first-line therapy for mCRC. Although response rates are high, most tumors eventually progress, indicating a need for agents that provide improved efficacy. REG is a novel oral multikinase inhibitor that blocks the activity of kinases involved in angiogenesis, oncogenesis, and tumor microenvironment signaling. A recent phase III trial demonstrated that REG monotherapy improved overall survival (OS) in patients (pts) with mCRC previously treated with other approved agents. The combination of REG and 5-FU-based chemotherapy showed acceptable tolerability in an earlier phase I trial. In the current phase II study (NCT01289821, sponsored by Bayer HealthCare) we evaluated REG in combination with mFOLFOX6 as first-line mCRC therapy.
Materials and Methods: Key inclusion criteria were mCRC that was not/unlikely to be resectable and an ECOG performance status of 0 or 1.

Exclusion criteria included prior systemic anticancer therapy for mCRC. Pts received REG 160 mg orally once daily on days 4−10 and 18−24 of each 28-day cycle, in combination with mFOLFOX6 on days 1 and 15 of each cycle. The primary endpoint was objective response rate (ORR), based on blinded central radiological review using RECIST v1.1. Additional endpoints included disease control rate (DCR), OS, progression-free survival (PFS), and safety.
Results: The study recruited 54 patients, all Caucasian (men n = 28, 51.9%; women n = 26, 48.1%), aged <65 (n = 33, 61.1%) or ⩾65 years (n = 21, 38.9%), with baseline ECOG scores of 0 (n = 35, 64.8%) or 1 (n = 19, 35.2%). 49 pts discontinued treatment, and five pts are still in the study. The median duration of REG treatment was 7 cycles (range 1−21). ORR was 43.9% (all partial responses); DCR was 85.4%. Median PFS was 8.5 months (95% CI 7.4–11.3). Median OS was not yet reached (range 0–19.9 months, including censored data). All pts experienced drug-related adverse events (AEs); four pts stopped treatment permanently because of AEs. The most common REG-related grade 3/4 AEs were increased lipase (n = 10, 19%), hypertension (n = 9, 17%), diarrhea (n = 7, 13%), and hypophosphatemia (n = 6, 11%). Among 24 pts who had mutational data available, nine tumors were *KRAS* wild type, eight were *KRAS* mutant, four were *PIK3CA* mutant, and three had other mutations.
Conclusion: The results of this study indicate that the combination of mFOLFOX6 with REG is feasible with a manageable safety profile in pts with mCRC.

2368 POSTER

A phase 1B study of second-line therapy with panitumumab, irinotecan and everolimus (PIE) in metastatic colorectal cancer (mCRC) with KRAS wild type (WT)

T.J. Price[1], L. Pirc[1], P. Cooper[1], N. Tebbutt[2], C. Karapetis[3], N. Singhal[4], A.R. Townsend[1]. *[1]The Queen Elizabeth Hospital, Haematology/Oncology, Adelaide, Australia; [2]Austin Health, Oncology, Melbourne, Australia; [3]Flinders Medical Centre, Oncology, Adelaide, Australia; [4]Royal Adelaide Hospital, Oncology, Adelaide, Australia*

Background: The mammalian target of rapamycin (mTOR) is a key downstream protein activated via PI3K-AKT pathway,that regulates cell growth, proliferation, and survival. Inhibition of mTOR in addition to EGFR may overcome upstream resistance to EGFR inhibitors in CRC. This is a phase Ib study to determine the maximum tolerated dose (MTD) of the PIE combination.
Patients and Methods: Patients with *KRAS* WT mCRC following failure of first line fluoropyrimidine-based therapy received IV irinotecan and panitumumab every 2 weeks, and everolimus orally throughout a 14-day cycle. Dose finding used a standard 3+3 design with the MTD defined as the dose with dose limiting toxicity (DLT) in ⩽1/6 patients. A DLT is any of the following in the first 28 days: febrile neutropenia, G3/G4 neutropenia >14 days, any G4 thrombocytopenia, any non-haematologic event of G4 or of G3 for >7 days, or treatment delays of >14 days. Dose level 1; irinotecan 200 mg/m^2, panitumumab 6 mg/kg, everolimus 5 mg alternate days. Dose level 2; irinotecan 200 mg/m^2, panitumumab 6 mg/kg, and everolimus 5 mg daily.
Results: Of the 16 patients enrolled into the study, 2 withdrew prior to receiving any therapy. Five patients were enrolled at dose level 1. Two patients were not evaluable. Of the 3 evaluable patients there was no DLT. Three patients were then treated at dose level 2. Following one DLT (grade 3 mucositis >7 days), the cohort was expanded to 5 evaluable patients but suspended after a further DLT (grade 3 mucositis). Other grade 3 toxicities were anorexia, rash, vomiting, and hypersensitivity. There were no grade 4 toxicities. Dose level 1 was expanded by 4 to a total of 7 evaluable patients. Grade 3 toxicities were mucositis (14%), fatigue (14%), diarrhoea (29%), rash (14%), hypomagnesaemia (14%), and neutropenia (14%). There was no DLT. At dose level 1 the partial response rate was 29% and stable disease 43%.
Conclusions: Dose level 2 exceeded the MTD. Dose level 1 appears tolerable and warrants further investigation. The phase II component of the study is ongoing.
Conflict of interest: *Advisory board: TJ Price, N Tebbutt and C Karapetis all uncompensated members of Amgen advisory board. Corporate-sponsored research: Amgen and Novartis are supporting this study*

2369 POSTER

Phase II study of linifanib in KRAS mutated metastatic refractory colorectal cancer

E. Chan[1], G.D. Ayers[2], L. Goff[1], P. McClanahan[3], M. Holloway[3], K. Ciombor[1], S.J. Smith[1], K. Ancell[1], D.B. Cardin[1], J. Berlin[1]. *[1]Vanderbilt University Medical Center, Division of Medical Oncology, Nashville TN, USA; [2]Vanderbilt University Medical Center, Center for Quantitative Sciences, Nashville TN, USA; [3]Vanderbilt University Medical Center, Clinical Trials Shared Resource, Nashville TN, USA*

Background: Vascular endothelial growth factor (VEGF) pathway blockade has proven efficacy in metastatic colorectal cancer (mCRC). Linifanib is a potent tyrosine kinase inhibitor (TKI) of VEGF and platelet-derived growth factor receptors. NCT01365910 evaluated the efficacy of linifanib in patients with KRAS mutated refractory mCRC.
Methods: Patients with KRAS mutated mCRC refractory to 1−3 lines of chemotherapy were treated with linifanib at 17.5 mg orally daily per 28 day cycle. Disease evaluations were every 2 cycles. Primary endpoint was response rate (RR) in the intent to treat population with a target of at least 15% overall RR using RECIST 1.1. Simon two-stage design was used. Stage 1 enrolled 30 patients and required ⩾2 responses to proceed to stage 2, for a total of 52 patients. The design provided 80% statistical power to detect a difference of 10% (15% vs 5%) with a significance level <0.05 (type 1 error).
Results: 30 patients were accrued. One patient never started linifanib. Absolute decrease in tumor size was seen in 8 patients (26.7%), without any partial response (PR). Cavitary lesions as seen with some TKI's were seen without meeting RECIST response. 21 patients (70%) had stable disease (SD). 4 patients (13.3%) had progressive disease (PD). 5 patients (16.7%) were not evaluable secondary to early withdrawal and lack of post baseline imaging. Progression free survival (PFS) was 4.1 months (CI 3.6−5.5). Overall survival was 7.0 months (CI 4.3–10.9). All evaluable patients required ⩾1 dose reduction. 26 patients (86.7%) had a maximum grade 3 adverse event (AE) at least possibly related to study drug. Most common related grade 3 AEs were fatigue (43.3%), hypertension (36.7%), proteinuria (10%), oral pain (10%), thrombocytopenia (6.7%), and arthralgia (6.7%). One patient remained on study for 72 weeks.
Conclusions: Linifanib was intolerable at 17.5 mg daily in this population, with 16.7% of patients withdrawing prior to the first post baseline imaging from poor tolerability. Only 16 patients (53.3%) were removed for RECIST progression. With dose reduction, tumor control was seen in the majority of the patients, manifested as RECIST SD and a PFS similar to what has been seen in monotherapy trials of agents active in refractory mCRC. Nonetheless, this study was terminated as it did not meet criteria to proceed to stage 2.
This study was supported by AbbVie and by the Vanderbilt-Ingram Center Support Grant P30CA68485.
Conflict of interest: *Advisory board: Amgen: Emily Chan. Genentech: Emily Chan. Corporate-sponsored research: Study was an ITT awarded to Jordan Berlin. AbbVie provided research support for the study. I was the institutional PI on another AbbVie study but all the money went to the institution for the conduct of the study.*

2370 POSTER

Kinetics of CEA, CA19-9 and circulating tumor cells in patients treated with chemotherapy for a metastatic colorectal cancer

D. Sefrioui[1], F. Ziegler[2], J.P. Basuyau[3], E. Toure[4], H. Quintard[5], C. Bazille[6], K. Bouhier-Leporrier[7], J.C. Sabourin[4], F. Di Fiore[1], P. Michel[1]. *[1]Digestive Oncology Unit Department of Hepato-Gastroenterology Rouen University Hospital, Seine-Maritime, Rouen, France; [2]Institute of Clinical Biology INSERM UMR 1073 Rouen University Hospital, Seine-Maritime, Rouen, France; [3]Laboratory of Clinical Biology Henri Becquerel Center Rouen, Seine-Maritime, Rouen, France; [4]Department of Pathology Rouen University Hospital, Seine-Maritime, Rouen, France; [5]Department of Pathology Francois Baclesse Center Caen, Calvados, Caen, France; [6]Department of Pathology Caen University Hospital, Calvados, Caen, France; [7]Digestive Oncology Unit Department of Hepato-Gastroenterology Caen University Hospital, Calvados, Caen, France*

Background: Clinical management of patients with cancer could be significantly improved through the development of a non-invasive method for the evaluation of treatment sensitivity or resistance. We have previously reported that CEA kinetic at the 0.05 threshold may be used as an accurate and non-invasive marker to predict chemotherapy (CT) efficiency in metastatic colorectal cancer (mCRC). The primary objective of this multicenter study was to validate prospectively the relevance of the CEA kinetic at the 0.05 threshold in an independent set of mCRC patients. The secondary objectives included the analysis of CA 19−9 and Circulating Tumor Cells (CTC) during the chemotherapy sequence.

Methods: From 11/2010 to 03/2013, 100 mCRC patients who started a CT regimen with an informative CEA and/or CA19-9 (⩾5 μg/L or ⩾30UI/mL, respectively) were included. For each patient, plasma was assessed at baseline and at the fourth cycle of CT for assay of CEA and CA19-9. CTC were analyzed using the ScreenCell® method at baseline, weeks 6 and 12. Response to CT based on RECIST criteria, progression-free survival (PFS) and overall survival (OS) were analyzed according to baseline value and kinetic of each marker.
Results: CEA kinetic at the 0.05 threshold was significantly associated with disease control (p = 0.003) with a positive and negative predictive value of 61% and 78%, respectively. The CA19-9 kinetic using the threshold of −0.07 determined by ROC curves (sensibility of 77% and specificity of 71%) was also significantly associated with disease control (p = 0.0004). CTC were detected in 53% and 63% of patients at baseline and weeks 6 respectively with a trend for disease progression for baseline value (p = 0.06) without impact on survival. In contrast, univariate analysis showed that CEA kinetic (p = 0.05), increased baseline CEA>25 μg/L (p = 0.01) and CA19-9 kinetic (p = 0.0009) were correlated with PFS. Moreover, baseline CEA>25 μg/L (p = 0.05) and CA19-9 kinetic (p = 0.05) were associated with OS.
Conclusions: In an independent series of mCRC patients treated with CT, our results confirm that CEA kinetic is a non-invasive marker associated with response to CT and PFS. CA19-9 kinetic is also clinically relevant in this setting whereas no conclusive results have been yet observed for CTC analysis.
Conflict of interest: *Corporate-sponsored research: Roche, Amgen et Merck-Serono*

2371 POSTER

Effect of adjusting the pH of oxaliplatin solution by mixing steroid on venous pain: Randomized phase II APOLLO study

M. Kobayashi[1], T. Hata[2], A. Toyokawa[3], M. Miyake[4], M. Tsuda[5], Y. Tokunaga[6], K. Takase[7], S. Morita[8], J. Sakamoto[9], H. Mishima[10]. *[1]Kochi University, Gastrointestinal Surgery, Nankoku, Japan; [2]Osaka University, Gastroenterological Surgery, Suita, Japan; [3]Yodogawa Christian Hospital, Surgery, Osaka, Japan; [4]Toyonaka Municipal Hospital, Gastroenterological Surgery, Toyonaka, Japan; [5]Hyogo Cancer Center, Gastrointestinal and Hepato Biliary Oncology, Akashi, Japan; [6]Kyoto Japan Post Hospital, Surgery, Kyoto, Japan; [7]Kobe Rosai Hospital, Surgery, Kobe, Japan; [8]Yokohama City University Medical Center, Biostatistics and Epidemiology, Yokohama, Japan; [9]Tokai Central Hospital, Director, Kagamihara, Japan; [10]Aichi Medical University, Digestive Surgery, Nagakute, Japan*

Background: Administration of oxaliplatin through peripheral vein can cause venous pain. The pH level of oxaliplatin solution is about 4.8 and that of buffered by steroid is around 7.0.
To assess the hypothesis that adjusting the pH of oxaliplatin solution by mixing steroid can reduce venous pain, we have conducted a randomized control study to compare pH adjusted oxaliplatin solution with unadjusted oxaliplatin solution.
Material and Methods: This was a single-blinded multicenter randomized phase II study. Colorectal cancer patients receiving oxaliplatin through peripheral vein were enrolled and randomly assigned to arm A (oxaliplatin 130 mg/m^2 with dexamethasone 1.65 mg) or arm B (the same, without dexamethasone). Venous pain was evaluated according to CTCAE criteria (ver. 4.0) and the verbal rating scale (VRS). Assessments were conducted every 3 weeks until cycle 4.

Venous pain	Arm A (%)	Arm B (%)	risk ratio
Grade >=2 (CTCAE ver.4.0)	33.3	58.3	0.57 [0.30–1.10]
Score >=3 (VRS)	12.5	37.5	0.33 [0.10–1.08]

Results: A total of 53 patients (38 men and 15 women; median age, 67 yr) were enrolled. Of these, 48 evaluable patients were randomized to either arm A (n = 24) or arm B (n = 24). Incidence of venous pain (grade>=2) was 33.3%(n = 8) in arm A and 58.3%(n = 14) in arm B (relative risk 0.57 [0.30–1.10]). Incidence of venous pain (VRS score>=3) was 12.5%(n = 3) in arm A and 37.5%(n = 9) in arm B (relative risk 0.33 [0.10–1.08]). Among 9 pts who received pH adjustment in the course of treatment, venous pain was slightly decreased in 5 pts. Response rate was 62.5% in arm A and 66.7% in arm B. No difference was observed in safety.
Conclusions: Mixing steroid reduced grade>=2 venous pain with unaffected efficacy or adverse events. When oxaliplatin is administered through peripheral vein, it is recommended that pH is adjusted by mixing steroid at the start of chemotherapy.
No conflict of interest.

2372 POSTER

Chemotherapy delivery and tolerability of FOLFOX vs FOLFIRI in a phase 3 trial of pegfilgrastim in patients with colorectal cancer (CRC)

P. Gibbs[1], T. Pinter[2], T. Salek[3], J. Novotny[4], M. Mo[5], E. Abella[5], M. Choi[5], F.D. Vogl[5], S. O'Reilly[6]. *[1]Western Hospital, Footscray, Australia; [2]Petz Aladar Teaching Hospital, Gyor, Hungary; [3]National Cancer Institute, Bratislava, Slovak Republic; [4]Institute of Oncology and Rehabilitation, Na Plesi, Czech Republic; [5]Amgen Inc., Thousand Oaks CA, USA; [6]Cork University Hospital, Cork, Ireland*

Background: The Pegfilgrastim Anti-VEGF Evaluation Study (PAVES) evaluated the efficacy of pegfilgrastim (Neulasta®) to reduce the incidence of grade 3/4 febrile neutropenia (FN) in 845 patients with CRC receiving first-line bevacizumab with FOLFOX or FOLFIRI. Here we describe the tolerability of FOLFOX vs FOLFIRI and low-dose regimens (LDR: FOLFOX4/FOLFIRI Douillard) vs high-dose regimens (HDR: FOLFOX6/mFOLFOX6/FOLFIRI).
Methods: This double-blind, placebo-controlled, phase 3 trial included patients ⩾18 years with measurable locally advanced (LA) or metastatic (m) CRC per RECIST 1.1. Patients were randomized 1:1 to chemotherapy plus bevacizumab and either placebo or 6 mg pegfilgrastim. Study treatment period: 4 Q2W cycles. Randomization stratification factors: North America/rest of world, LA/mCRC, and FOLFOX/FOLFIRI. Grade 3/4 FN: absolute neutrophil count (ANC) <1.0x10^9/L the same (±1) day as a temperature ⩾38.0ºC, sepsis, infection, or neutropenia-related hospitalization. Grade 3/4 neutropenia: ANC <1.0x10^9/L. Long-term follow-up of this Amgen-sponsored trial (NCT00911170) is ongoing.

2373 POSTER

S-1 and irinotecan versus 5-fluorouracil and leucovorin plus oxaliplatin with or without bevacizumab in metastatic colorectal cancer: a pooled analysis of 4 phase II studies

A. Goto[1], Y. Yamada[2], S. Iwasa[2], K. Nagashima[3], T. Yamaguchi[4], Y. Ichikawa[1], H. Yasui[5], K. Kato[2], N. Tsuda-Okita[2], Y. Shimada[2]. *[1]Yokohama City University Graduate School of Medicine, Department of Clinical Oncology, Yokohama, Japan; [2]National Cancer Center Hospital, Gastrointestinal Medical Oncology Division, Tokyo, Japan; [3]Chiba University Hospital, Clinical Research Center, Chiba, Japan; [4]Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Department of Surgery, Tokyo, Japan; [5]Kyoto Medical Center, Medical Oncology Division, Kyoto, Japan*

Background: S-1, a novel oral prodrug of 5-fluorouracil (5-FU), and irinotecan with or without bevacizumab is known to be effective for metastatic colorectal cancer (mCRC). However, it is not clear whether S-1 and irinotecan confers benefit compared to 5-FU and leucovorin plus oxaliplatin (FOLFOX) in patients with mCRC.
Patients and Methods: We analyzed 187 patients with previously untreated mCRC who were enrolled in four phase II studies of SIR study (S-1 and irinotecan, n = 40), SIRB study (S-1 and irinotecan with bevacizumab, n = 51), FOLFOX study (5-FU and leucovorin plus oxaliplatin, n = 46), and STOX study (stop and go strategy of modified FOLFOX-6 with bevacizumab, n = 50). We evaluated efficacy and safety between SIR/SIRB group and FOLFOX/STOX group.
Results: Baseline characteristics were similar between two groups of SIR/SIRB (n = 91) and FOLFOX/STOX (n = 96). There was no significant difference in overall response rate between two groups (65% in SIR/SIRB group versus 52% in FOLFOX/STOX group, p = 0.125). Median progression-free survival was 10.9 months in SIR/SIRB group versus 12.1 months in FOLFOX/STOX group (p = 0.58). Median overall survival was 27.3 months in SIR/SIRB group versus 26.8 months in FOLFOX/STOX group (p = 0.97). The most common grade 3 or 4 adverse events in SIR/SIRB group versus FOLFOX/STOX group were neutropenia (24% versus 45%; p = 0.0036) and anorexia (12% versus 3%; p = 0.025). The multivariate analyses demonstrated that female (hazard ratio [HR], 1.70; 95% confidence interval [CI], 1.18–2.45) and synchronous metastases (HR 1.77; 95% CI, 1.19–2.63) were independent poor prognostic factors for patients received first-line 5-FU-based combination chemotherapies.
Conclusions: S-1 and irinotecan with or without bevacizumab was well tolerated and similar response rate and survival compared to FOLFOX with or without bevacizumab. This combination should be considered as an experimental first-line treatment for mCRC.
No conflict of interest.

Analysis of Köhne's prognostic index in KRAS wild type patients with metastatic colorectal cancer (mCRC) treated with salvage-line cetuximab-based regimen: HGCSG0901

S. Yuki[1], Y. Komatsu[2], Y. Tsuji[3], K. Hatanaka[4], H. Okuda[5], K. Fujikawa[6], Y. Watanabe[7], A. Hosokawa[8], T. Amano[9], Y. Sakata[10]. *[1]Hokkaido University Hospital, Gastroenterology and Hepatology, Sapporo, Japan; [2]Hokkaido University Hospital, Cancer Center, Sapporo, Japan; [3]Tonan Hospital, Medical Oncology, Sapporo, Japan; [4]Hakodate Municipal Hospital, Gastroenterology, Hakodate, Japan; [5]Keiyukai Sapporo Hospital, Medical Oncology, Sapporo, Japan; [6]Hokkaido Cancer Center, Gastroenterology, Sapporo, Japan; [7]Hakodate Central General Hospital, Internal Medicine, Hakodate, Japan; [8]Toyama University, Gastroenterology, Toyama, Japan; [9]Hokkaido University Hospital, Medical Oncology, Sapporo, Japan; [10]Misawa City Hospital, Medical Oncology, Misawa, Japan*

Background: In treatment for metastatic colorectal cancer, it is essential for understanding the prognosis of each individual patient. Köhne's prognostic index based on performance status, white blood cell count, alkaline phosphatase and number of metastatic sites has been previously proposed(Köhne CH, et al. Ann Oncol. 13:308−17, 2002). However, in the salvage setting, the validity of Köhne's classification has not been reported in patients treated by cetuximab-based chemotherapy.
Methods: 269 patients with mCRC treated by cetuximab contained chemotherapy were retrospectively registered from 27 centers in Japan (HGCSG 0901 study). Of these, the *KRAS* wild type patients that were refractory to or intolerant for 5-FU/ irinotecan/ oxaliplatin, and were never administered anti-EGFR-antibody, were included in this analysis. Univariate and multivariate analysis for overall survival were performed using patient characteristics. Survival analyses were performed with Kaplan–Meier method, log-rank test and Cox proportional hazards model.
Results: All data were available for prognostic categorization in 127 patients. Median survival was 9.8 months. The distribution and median survival for Köhne's prognostic groups were as follows: low risk (n = 40; 13.1 months), intermediate risk (n = 17; 9.6 months), and high risk (n = 70; 7.6 months). The survival difference was significant between low and high risk groups (p = 0.004), but not between intermediate and high risk groups (p = 0.213), and between low and intermediate risk groups (p = 0.321). In Cox multivariate analysis, Köhne's prognostic index had shown an independent prognostic impact (hazard ratio: 1.370, 95% CI: 1.078–1.742, p = 0.010).
Conclusions: It was shown that Köhne's prognostic index might provide valuable information in salvage treatment with cetuximab-based regimen. Moreover, the prospective evaluation is needed for the further validation.

2375 POSTER

Phase II trial of Irinotecan and S-1 (IRIS) combination chemotherapy as preoperative chemotherapy for operable advanced colorectal cancer (NCCSG03)

S. Maruyama[1], Y. Takii[1], Y. Sakai[2], T. Iiai[3], T. Yamazaki[4], K. Furukawa[5], J. Hasegawa[6], K. Akazawa[7], K. Hatakeyama[3]. *[1]Niigata Cancer Center Hospital, Gastroenterological Surgery, Niigata, Japan; [2]Saiseikai Niigata Second Hospital, Surgery, Niigata, Japan; [3]Niigata University General Hospital, Gastroenterological Surgery, Niigata, Japan; [4]Niigata City General Hospital, Gastroenterological Surgery, Niigata, Japan; [5]Niigata City General Hospital, Gastroenterological Medicine, Niigata, Japan; [6]Nagaoka Red-Cross Hospital, Surgery, Niigata, Japan; [7]Niigata University, Madical Informatics, Niigata, Japan*

Background: We found the patients diagnosed as the lymph node positively colorectal cancer (CRC) before the surgery a prognosis is worse than after the surgery by our retrospective investigation. Irinotecan plus S-1(IRIS) combination chemotherapy reported an active for metastatic colorectal cancer (mCRC) in the FIRIS study (Muro K et al. Lancet Oncol 2010;11:853–860). We planned a phase II trial to evaluate the efficacy and safety of IRIS as preoperative chemotherapy for patients with operable lymph node positively CRC.
Material and Methods: The study design was multicenter, single-arm, open-label phase II study. Eligible patients had to have operable advanced colorectal cancer confirmed diagnosis of adenocarcinoma, positive lymph nodes (⩾10 mm) and no radiologic evidence of metastatic disease on abdominal and pelvic computed tomography (CT) scans, no previous chemotherapy or radiotherapy, an age from 20 to 80 years, ECOG performance status (PS) of 0−1. S-1 80 mg/m^2 daily p.o. was given on days 1−14 and irinotecan 100 mg/m^2 was given on days 1 and 15 of a 28-day cycle. Surgery with curative intent was undertaken at least 4 weeks after completing 2 cycles of preoperative chemotherapy, followed by a further 24 weeks of postoperative chemotherapy. The primary endpoint was overall response rate (OR). The secondary endpoints included overall survival (OS), relapse free survival (RFS), completion of planned surgery rate, curative resection rate and safety.
Results: From 09/05 until 01/10, 35 patients were enrolled and investigated. Median age was 64 years (range, 40 to 79). Twenty-eight patients were male. All patients starting preoperative chemotherapy completed the 8-week course with two stopping early because of toxicity. The OR was 45.7% (16/35). Completion of planned surgery rate was 97.1% (34/35). Only one patient didn't undergo surgery, because of chemotherapy was continued by the clinician's choice. No patient had surgery delayed. Curative resection rate was 88.2% (30/34). 3-year RFS rate was 76.5% and 3-year OS rate was 93.3% in curative resected patients. On safety analysis, the incidence of grade 3 or 4 adverse reactions were as follows: anorexia, 17.1%; diarrhea, 11.4%; neutropenia, 8.6%; nausea, 5.7%; vomiting, 5.7%; leucopenia, 2.9%; anemia, 2.9%; fatigue, 2.9%. There was no treatment or surgery related death.
Conclusions: IRIS as preoperative chemotherapy for radiologically staged operable lymph node positively CRC is an active and well-tolerated.
No conflict of interest.

2376 POSTER

Chemotherapy as palliative treatment of peritoneal carcinomatosis of gastric origin

I. Thomassen[1], N. Bernards[2], G.J. Creemers[3], E.M.V. Jacobs[4], V.E.P.P. Lemmens[2], I.H.J.T. De Hingh[5]. [1]*Comprehensive Cancer Centre South, Eindhoven, Netherlands;* [2]*Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands;* [3]*Catharina Hospital, Internal Medicine, Eindhoven, Netherlands;* [4]*Elkerliek Hospital, Internal Medicine, Helmond, Netherlands;* [5]*Catharina Hospital, Surgery, Eindhoven, Netherlands*

Background: Peritoneal carcinomatosis (PC) is an important cause of morbidity and mortality among patients with gastric cancer, and can be treated by palliative systemic chemotherapy at most. The aim of the current population-based study was to evaluate trends in systemic treatment and survival of patients with peritoneal carcinomatosis of gastric origin.
Materials and Methods: All patients with an adenocarcinoma of the stomach diagnosed between 1995–2011 in the area of the Eindhoven Cancer Registry in the Netherlands were included.
Results: In total, 5,220 patients were diagnosed with gastric cancer of whom 706 patients (14%) were diagnosed with PC. Patients who were treated with chemotherapy were younger (40% of patients <60 years vs. 16% of patients 70−79 years), had less comorbidities (32% of patients without comorbidities vs. 18% of patients with >2 comorbidities), lower N-stage (35% of patients with N0 vs. 18% of patients with >N2) and were diagnosed more recently. In the period 1995–1998 11% of the patients with PC were treated with chemotherapy, compared to 42% in the most recent period (2007–2011), however, median survival did not increase (5.7 to 7.9 months, p=.310).
Conclusions: PC is a frequent condition in patients presenting with gastric cancer. Increased palliative systemic chemotherapy did not show an effect on survival on a population-based level. Therefore further efforts should be undertaken to further explore other strategies such as intra-peritoneal chemotherapy.
No conflict of interest.

2377 POSTER

Final results of the CONCERT cohort study with bevacizumab and chemotherapy in patients with mCRC and subgroup analysis of patients with resected or unresected primary tumor

M. Ducreux[1], J.M. Phelip[2], T. André[3], H. Senellart[4], D. Lepille[5], G. Breysacher[6], L. Bastit[7], F. Burki[8], H. Perrier[9], J. Bennouna[4]. [1]*Institut Gustave Roussy, Digestive Oncology, Villejuif, France;* [2]*CHU de Saint-Etienne, Gastro-enterology and Hepatology, Saint-Etienne, France;* [3]*Hôpital Tenon, Medical Oncology, Paris, France;* [4]*Centre René Gauducheau, Medical Oncology, Nantes, France;* [5]*Clinique Pasteur, Medical Oncology, Evreux, France;* [6]*Hopital pasteur, Gastro-enterology and Hepatology, Colmar, France;* [7]*Clinique Pasteur, Radiology, Evreux, France;* [8]*Clinique Pasteur, Oncology, Toulouse, France;* [9]*Hôpital Saint-Joseph, Oncology-Oncogenetic, Marseille, France*

Background: CONCERT is a large, prospective, multicenter, cohort study conducted in patients (pts) with metastatic colorectal cancer (mCRC) starting a treatment with bevacizumab (Avastin®). Results at 12 and 24 months were already presented. We report final efficacy results (at a maximum of 36 months) and descriptive subgroup analyses in mCRC pts with synchronous metastases at diagnosis and resected/unresected primary tumor.
Methods: mCRC pts (n = 737 for efficacy, n = 760 for safety) treated for the first time with bevacizumab (Bv) and chemotherapy (CT), whatever the line, were eligible. They were followed-up for 36 months. Progression-free survival (PFS) was the primary endpoint. Secondary endpoints included overall survival (OS), safety (targeted and non-targeted adverse effects − AEs) and quality of life.
Results: As of February 2013, median follow-up was 17 months [0; 42], and median PFS was 10.4 months [95% CI: 9.6–11.3] in pts treated with 1st line Bv (n = 521), 8.5 months [95% CI: 7.0−9.2) in 2nd line (n = 154) and 6.3 months [95% CI: 4.5−8.9] in ⩾3rd line (n = 62). Median OS was 25.3 months [95% CI: 21.5–28.6] in 1st line Bv, 19.1 months [95% CI: 15.7–22.6] in 2nd line and 14.9 months [95% CI: 11.6–20.4] in ⩾3rd line.
In pts with synchronous metastases treated with 1st line Bv (n = 305), 121 (40%) had an unresected primary tumor and 184 (60%) were resected. Median PFS was 9.4 months [95% CI: 8.2–11.0] vs 11.5 months [95% CI: 10.4–13.8] and median OS was 17.5 months [95% CI: 14.8–20.4] vs 29.6 [95% CI: 23.9 − -], respectively.
AEs were reported in 57%, 67% and 48% of pts in 1st, 2nd and 3rd line or more. Grade 3/4 AEs were reported in 12% of pts overall. Most frequent grade 3/4 targeted AEs were venous thromboembolic events (2%) and hypertension (1%). Serious targeted AEs were venous thromboembolic events (1.7%), fistula (0.8%), bleeding (1.0%), gastro-intestinal (GI) perforation (0.8%).
In the 1st line Bv unresected/resected subgroups (n = 310), grade 3/4 bleeding was reported in 0.8%/2.2% pts (including GI bleeding in 0.8%/0%) and grade 3/4 GI perforation in 0.8%/0.6%.
Conclusion: Final efficacy and safety results of the CONCERT cohort study in mCRC pts initiating a treatment with Bv and CT in daily practice in France are consistent with the data of Bv already described. These results confirm data in the literature suggesting that resection of the primary could have a positive impact on overall survival in mCRC (stage IV) pts with synchronous metastases.

2378 POSTER

FGFR3 and FGFR4 contribute to resistance in the therapy of colorectal cancer in vitro

Z.N. Erdem[1], C. Heinzle[1], G. Sonvilla[1], B. Grasl-Kraupp[1], K. Holzmann[1], M. Grusch[1], W. Berger[1], B. Marian[1]. [1]*Institut für Krebsforschung, Clinic for Internal Medicine I, Wien, Austria*

Colorectal Cancer is one of the leading causes of death worldwide. Although therapy has been improved, survival-rate for late-stage tumours is not significantly changed. Response to classical chemotherapy drugs as well as drugs targeting EGFR signalling fails to achieve the desired effect as resistance develops after some time. Mechanisms described in the literature suggest an important role of the FGF signalling, be it by the positive regulation of anti-apoptotic signals or triggering G1-arrest.
Using the colorectal cancer cell line SW480 and appropriate vectors, we created FGFR3-IIIb, FGFR3-IIIc and FGFR4^{arg} as well as FGFR4^{gly} overexpressing cells and performed dose-response curves for the chemotherapy drugs Oxaliplatin and Irinotecan, and, the EGFR/HER2 dual inhibitor Lapatinib as well as the FGFR3 inhibitor PD173074.
Here, we report a significantly decreased sensitivity to (1) Oxaliplatin in cells overexpressing FGFR3-IIIb (IC50=3.7μM) as well as FGFR3-IIIc (4μM) when compared to the control cell line (3μM). Significantly higher IC50 values were also observed when (2) Irinotecan was added to FGFR4^{arg} (18.4μM), R3-IIIb (41.5μM) and R3-IIIc (36.7μM) transfected cells when compared to control (11.3μM). Treating the cells with the R3 inhibitor PD173074 revealed a significantly higher sensitivity of FGFR4^{gly} overexpressing cells (14.8μM) than control cells (18.9μM) while R3-IIIb overexpressing cells were more resistant (22.8μM).
The presence of FGFR3 splice variants as well as the FGFR4 G388R polymorphism may lead to less cell damage and negatively affect response to chemotherapy drugs and EGFR targeting compounds. Based on these results, combination treatment with Oxaliplatin/Irinotecan and PD173074 as well as Lapatinib and PD173074 is currently being tested.
No conflict of interest.

2379 POSTER

Phase II study of first-line single-agent panitumumab in frail elderly patients with advanced wild type KRAS colorectal cancer with poor prognostic factors

J. Sastre[1], B. Massuti[2], A. Gomez[3], C. Guillén[4], S. Gil-Calle[5], J.L. Manzano[6], C. Grávalos[7], M.J. Safont[8], E. Díaz-Rubio[1], E. Aranda[3]. [1]*HC San Carlos Madrid Spain, Center affiliated to the Red Temática de Investigación Cooperativa (RD06/0020/002, Instituto Carlos III Spanish Ministry of Science an;* [2]*Hospital General Universitario, Medical Oncology, Alicante, Spain;* [3]*Hospital Reina Sofía, Medical Oncology, Córdoba, Spain;* [4]*Hospital Ramón y Cajal, Medical Oncology, Madrid, Spain;* [5]*Hospital Regional Universitario Carlos Haya, Medical Oncology, Málaga, Spain;* [6]*Hospital Germans Trias i Pujol-Institut Català d'Oncologia, Medical Oncology, Badalona, Spain;* [7]*Hospital 12 de Octubre, Medical Oncology, Madrid, Spain;* [8]*Hospital General Universitario, Medical Oncology, Valencia, Spain*

Background: Frail elderly patients (pts) with metastatic colorectal cancer are considered not candidates for chemotherapy due to functional status and associated comorbidities. Median survival for non-frail pts treated with 5-FU based therapy is 10.7 and 6.1 months for intermediate and high risk group according to the Köhne Prognostic Classification (KPC). Anti-EGFR monoclonal antibodies have shown activity as monotherapy and have few

toxic effects regarding organs and body systems and may be an option for selected frail pts.
Methods: This is a single-arm multicenter phase II clinical trial conducted in 14 Spanish centers. Pts ⩾70 years with metastatic wild type KRAS colorectal cancer, ECOG status <3, intermediate or high-risk group according to the KPC and one or more of the following criteria were included: a)dependence for one of the basic daily living activities (Katz Index); b)three or more comorbid conditions according to the Charlson scale plus dependence for one of the instrumental activities of daily living; c)presence of one or more of the following geriatric syndromes (age >85 years, fecal or urinary incontinence in the absence of stress, frequent falls, spontaneous bone fractures, neglect). Pts received Panitumumab 6 mg/kg every 2 weeks until progression or unacceptable toxicity. The primary endpoint was progression-free survival rate at 6 months.
Results: 33 pts were included. Median age was 81 years (range 73−89), 22 male and 11 female, ECOG 0/1/2: 6%/39%/55%. 22 pts (66.7%) underwent previous surgery for the primary tumor and only 2 (6.1%) had received previous neoadjuvant/adjuvant chemotherapy. KPC intermediate: 52%, high: 45%. Panitumumab-related grade 3 adverse events: skin toxicity 15%, hypocalcemia 3%, hypokalemia 3%, hypomagnesemia 3%. One pt required a dose-reduction and 7 pts dose delay of panitumumab due to adverse event (only in one case the adverse event was related to panitumumab). Seventeen pts (51.5%) died during the study due to disease progression (14 pts), intercurrent event not related (2 pts), or unknown reason (1 pt). There were 3 partial responses (9%) and 18 stable disease for an overall disease control of 54%. 12 patients (36%) were free of progression at 6 months. Median progression-free survival was 4.2 months and median overall survival 8.1 months.
Conclusions: Single-agent panitumumab is active and well tolerated and may be a therapeutic option for high risk wild-type KRAS tumors in selected frail elderly pts.
No conflict of interest.

2380 POSTER

Bevacizumab + capecitabine and oxaliplatin (XELOX) as first-line treatment for elderly patients with metastatic colorectal cancer (mCRC) suitable for combination chemotherapy: Efficacy and safety findings from the phase II BECOX study (GEMCAD Study Group)

J. Feliu[1], A. Salud[2], M.J. Safont[3], C. García-Girón[4], J. Aparicio[5], R. Vera[6], O. Serrá[7], E. Casado[8], M. Jorge[9], J. Maurel[10]. *[1]Hospital Universitario La Paz, Medical Oncology, Madrid, Spain; [2]Hospital Arnau de Vilanova de Lleida, Medical Oncology, Lleida, Spain; [3]Hospital General de Valencia, Medical Oncology, Valencia, Spain; [4]Hospital Gral Yagüe, Medical Oncology, Burgos, Spain; [5]Hospital La Fe De Valencia, Medical Oncology, Valencia, Spain; [6]Complejo Hospitalario de Navarra, Pathology, Pamplona, Spain; [7]Hospital Creu Roja de L'Hospitalet, Medical Oncology, Barcelona, Spain; [8]Hospital Infanta Sofía, Medical Oncology, Madrid, Spain; [9]Complejo Hospitalario Xeral Cies, Medical Oncology, Vigo, Spain; [10]Hospital Clinico y Provincial de Barcelona, Medical Oncology, Barcelona, Spain*

Background: Subgroup analyses of clinical studies have demonstrated that bevacizumab + XELOX is effective and tolerable in otherwise healthy elderly patients with mCRC. We undertook the BECOX study to investigate the efficacy and safety of bevacizumab + XELOX followed by bevacizumab + capecitabine in elderly patients with mCRC who were considered suitable for combination chemotherapy.
Materials and Methods: Patients aged ⩾70 years with Eastern Cooperative Oncology Group performance status (ECOG PS) of 0/1 and histologically or cytologically confirmed mCRC were included in this phase II study. Patients received capecitabine 1000 mg/m^2 po twice daily on days 1−14 plus oxaliplatin 130 mg/m^2 and bevacizumab 7.5 mg/kg on day 1 every 21 days; oxaliplatin was discontinued after 6 cycles. The primary endpoint was time to progression (TTP); secondary endpoints included overall survival (OS), progression-free survival (PFS), overall response rate (ORR) and adverse events (AEs). Clinicaltrials.gov number NCT01067053 (this trial was sponsored by the GEMCAD Group).
Results: Sixty-nine patients were recruited, one of whom received no treatment. The intent-to-treat population comprised 68 patients (65% male, median age 76 years, ECOG PS 0/1 in 47%/53% of patients). Treatment was associated with good response and survival outcomes (see table). Grade 3/4 AEs occurred in 45 patients (66%); the most common grade 3/4 AEs were hand–foot syndrome (grade 3/4 in 7%/0%), diarrhoea (16%/2%), nausea (9%/2%), mucositis (13%/3%) and asthenia (16%/0%). Grade 3/4 AEs of special interest for bevacizumab included proteinuria (2%/0%), deep-vein thrombosis (6%/0%) and pulmonary embolism (3%/2%). There were no grade 5 AEs.
Conclusion: The combination of bevacizumab and XELOX was effective and well tolerated in elderly patients in the BECOX study. The AE profile was similar to that seen in younger patients and no new safety concerns were identified. Elderly patients with mCRC should therefore be considered candidates for treatment with bevacizumab plus combination chemotherapy.
No conflict of interest.

Outcome	N = 68
Median TTP, months (95% CI)	11.0 (8.1–14.1)
Median PFS, months (95% CI)	10.6 (8.3–12.8)
Median OS, months (95% CI)	20.4 (13.2–27.6)
Response, n (%)	
Complete response	2 (3)
Partial response	29 (43)
Stable disease	23 (34)
Progressive disease	14 (21)
ORR, % (95% CI)	45.6 (33.6–58.1)

2381 POSTER

Further efficacy and safety analyses from AVEX, a randomized phase 3 trial of bevacizumab with capecitabine in elderly patients with metastatic colorectal cancer

M. Saunders[1], I. Lang[2], E. Marcuello[3], V. Lorusso[4], J. Ocvirk[5], D. Jonker[6], S. Osborne[7], M. Loeffler[8], D. Cunningham[9]. *[1]Christie Hospital NHS Trust, Clinical Oncology, Manchester, United Kingdom; [2]National Institute of Oncology, Department of Medical Oncology, Budapest, Hungary; [3]Hospital de Sant Pau de Barcelona, Department of Medical Oncology, Barcelona, Spain; [4]Oncologic Institute Vito Fazzi Hospital, Department of Medical Oncology, Lecce, Italy; [5]Institute of Oncology Ljubljana, Department of Medical Oncology, Ljubljana, Slovenia; [6]The Ottawa Hospital, Department of Medical Oncology, Ottawa, Canada; [7]F. Hoffman-La Roche Ltd, Department of Biostatistics, Basel, Switzerland; [8]F. Hoffman-La Roche Ltd, Global Medical Affairs, Basel, Switzerland; [9]Royal Marsden NHS Foundation Trust, Department of Medicine, Sutton, United Kingdom*

Background: The open-label, multinational, randomized phase 3 trial AVEX (NCT00484939) evaluated first-line bevacizumab (BEV) + capecitabine (cape) in elderly patients (pts) with metastatic colorectal cancer.
Material and Methods: AVEX (sponsored by F. Hoffmann-La Roche, Ltd.) was completed on Dec 14, 2012. 280 pts aged ⩾70 y for whom doublet chemotherapy was not appropriate were randomized to first-line BEV (7.5 mg/kg) + cape (1000 mg/m^2 bid d1−14; n = 140) or cape (n = 140) q3w. The primary endpoint was progression-free survival (PFS). A post hoc analysis assessed treatment (tx) duration, dose intensity (% of expected dose received), on-tx PFS (time from enrollment to disease progression [PD] or death from any cause in pts receiving tx at PD or stopping tx ⩽28 d before PD; pts stopping tx >28 d before PD were censored), and adverse events (AEs) in pts with or without baseline hypertension (HTN).
Results: Median age was 76 y (range, 70−87) and pt characteristics were balanced between tx arms. Comorbidities were common; HTN was the most frequent (52%). BEV + cape significantly prolonged PFS compared with cape (hazard ratio [HR], 0.53; 95% confidence interval [CI], 0.41–0.69; P<.001). The majority of pts continued tx to PD or stopped tx ⩽28 d before PD (Table 1). On-tx PFS was significantly prolonged with BEV + cape vs cape (77 pts vs 102 pts had a PFS event on tx) (HR, 0.46; 95% CI, 0.34–0.62; P<.001; median 10.5 vs 5.0 mo), consistent with overall PFS. Mean cape dose intensity was similar in the BEV + cape (85.2% [standard deviation (SD), 20.1]) vs cape arms (89.6% [SD, 17.2]); mean BEV dose intensity was 99.1% (SD, 4.4). 96% of pts in each arm had an AE on study. Incidence of AEs in pts with or without baseline HTN are shown (Table 2).
Conclusions: Most of the pts received tx to PD or ⩽28 d before PD. On-tx PFS was consistent with the overall PFS analysis. Baseline HTN did not increase overall rates of AEs; however, pts without baseline HTN receiving BEV + cape had more epistaxis and on-tx HTN, whereas pts with baseline HTN had more proteinuria.

Table 1.

	BEV + Cape (n = 140)	Cape (n = 140)
Pts with PD, n	113	127
Cape or BEV, %		
Treated to PD	34.5	36.2
Stopped tx ⩽28 d before PD	33.6	44.1
Stopped tx >28 d before PD	31.9	19.7

Table 2. Adverse events

AE	Percentage of patients			
	BEV + Cape (n = 134)		Cape (n = 136)	
	HTN (n = 78)	No HTN (n = 56)	HTN (n = 67)	No HTN (n = 69)
Any AE	94.9	96.4	94.0	97.1
On-tx HTN	17.9	21.4	7.5	2.9
Epistaxis	11.5	25.0	4.5	2.9
Proteinuria	11.5	1.8	0	1.4
Any AE leading to tx discontinuation	28.2	21.4	16.4	11.6
Any serious AE	23.1	41.1	34.3	30.4
Any AE with outcome of death	5.1	12.5	16.4	7.2

2382 POSTER

Impact of the 12-gene colon cancer recurrence score assay on clinical decision-making for adjuvant therapy in stage II colon cancer patients in Israel

B. Brenner[1], M. Lopatin[2], M. Lee[3], R. Geva[4], A. Beny[5], Y. Dror[6], M. Steiner[7], A. Hubert[8], E. Idelevich[9], N. Liebermann[10]. *[1]Davidoff Cancer Center Beilinson Hospital, Petach Tikva, Israel; [2]Genomic Health Inc., Biostatistics Department, Redwood City, USA; [3]Genomic Health Inc., Oncology Development, Redwood City, USA; [4]Tel-Aviv Sourasky Medical Center, Division of Oncology, Tel Aviv, Israel; [5]Rambam Medical Center, Department of Oncology, Haifa, Israel; [6]Sapir Medical Center Meir Hospital, Department of Oncology, Kfar Saba, Israel; [7]Carmel Hospital, Department of Oncology, Haifa, Israel; [8]Hadassah Medical Center, Sharett Institute of Oncology, Jerusalem, Israel; [9]Kaplan Medical Center, Institute of Oncology, Rehovot, Israel; [10]Clalit Health Services, Community Division, Tel Aviv, Israel*

Purpose: The 12-gene Recurrence Score (Onco*type* DX® Colon Cancer) assay has been clinically validated as a predictor of recurrence risk in stage II colon cancer patients following surgery and has been reimbursed by Clalit Health Services (CHS) in Israel since January 2011. The impact of the 12-gene assay on treatment decision-making for T3N0 MMR-P stage II colon cancer patients within CHS was evaluated.
Patients and Methods: CHS prospectively collected treatment recommendations before Recurrence Score testing and actual treatment received following receipt of test results. Change in treatment intensity was defined as: increased if change from observation to any chemotherapy or from 5FU to 5FU + Oxaliplatin, no change, or decreased if any change from 5FU + Oxaliplatin or from 5FU to observation.
Results: 273 stage II colon cancer patients with T3 MMR-P tumors had assay testing from Jan 2011 to May 2012; one sample did not yield a valid score (0.3%) and 3 patients (1%) had no pre-assay recommendation resulting in 269 evaluable patients. Median age was 68 (IQR: 60−75), 85% had 12+ lymph nodes examined, 7% high grade. Median assay result was 28 (IQR: 22−34) with 58% and 10% of patients in low and high Recurrence Score groups, respectively. Pre-assay treatment recommendation differed from post-assay treatment delivered in 102 (38%) of 269 patients, with less treatment delivered for 76 (28%) and more for 26 (10%). Pre-assay, 121 (45%) patients received recommendation for chemotherapy; post-assay, 75 (28%) received chemotherapy. Changes in treatment intensity were generally consistent with the Recurrence Score results with increased treatment intensity observed more often at higher scores and decreased intensity at lower scores.
Conclusion: We observed a 38% change in pre-assay treatment recommendation to post-assay actual treatment delivered for T3 MMR-P stage II colon cancer patients, consistent with previous US studies. The use of the 12-gene colon cancer assay impacted treatment decision-making in Israel in this study where overall net reduction of recommended chemotherapy use was observed, from 45% planned for treatment to 28% actually receiving it.

2383 POSTER

Survival outcomes and prognostic factors in real-life practice after treatment with cetuximab in 1st-line metastatic colorectal cancer in the EREBUS cohort

A. Fourrier-Réglat[1], M. Rouyer[2], N. Noize[3], E. Bignon[2], J. Jové[2], A. Monnereau[4], A. Sa Cunha[5], E. François[6], E. Mitry[7], D. Smith[8]. *[1]Université Bordeaux Segalen-CHU Bordeaux, Pharmacologie, Bordeaux, France; [2]Université Bordeaux Segalen, Pharmacologie, Bordeaux, France; [3]CHU Bordeaux, Pharmacologie, Bordeaux, France; [4]Institut Bergonié, Recherche Clinique et Information Médicale, Bordeaux, France; [5]Hôpital P Brousse, Chirurgie Digestive, Villejuif, France; [6]Centre Lacassagne, Oncologie Médicale, Nice, France; [7]Institut Curie, Oncologie Médicale, St Cloud, France; [8]CHU Bordeaux, Oncologie Médicale, Bordeaux, France*

Background: Cetuximab (CTX) has demonstrated improved survival outcomes in unresectable metastatic colorectal cancer (mCRC) patients but data from real-life use are sparse.
Methods: EREBUS, a French multicentre (n = 65) cohort, included patients with unresectable wild-type KRAS mCRC in whom CTX-based 1st-line therapy was initiated in 2009–2010. Patients were followed for 12 months. Clinical data, treatment, response, and survival were collected from medical files. Overall and progression-free survival (OS and PFS) were analysed using Kaplan–Meier method. Factors associated with death and progression were identified using Cox proportional hazards models.
Results: A total of 389 patients were included. Baseline characteristics were: median age 64 years, 67.4% male, 77.9% ECOG=0−1, 55.5% primary tumour resection, 53.0% single metastatic site. Combined chemotherapy regimens included irinotecan (56.6%) and oxaliplatin (38.2%). The 1-year OS rate was 71.3%, 95% CI [66.4–75.6]. In multivariate Cox analysis, death was less likely in responders with resection (HR = 0.26 [0.08–0.90]) or without resection (HR = 0.37 [0.21–0.63]) and in patients with primary tumour resection before initiation of 1st-line (HR = 0.48 [0.32–0.72]). Death was also associated with a poor performance status at baseline (ECOG score $\geqslant$2: HR = 4.50 [2.59–7.84]) and poor tolerance (grade 3−4 adverse events during 1st-line: HR = 1.54 [1.03–2.30]). For the whole cohort, median PFS was 9.5 months (95% CI [8.6–10.1]). In multivariate Cox analysis, compared to patients with liver-only metastases, progression was more likely in patients with metastasis sites other than liver (HR = 1.85 [1.32–2.61]) and in patients with not exclusively liver metastases (HR = 1.41 [1.03–1.94]). Progression was also associated with poor performance status at baseline (ECOG score $\geqslant$2: HR = 2.63 [1.84–3.77]).
Conclusions: Median PFS and 1-year OS rate were comparable with those obtained in clinical trials with 1st-line CTX-based chemotherapy. Treatment response was associated with better survival in all patients irrespective of resection. Disease progression was more frequent in those with non-exclusively liver metastases.

2384 POSTER

Single centre experience of drug use for metastatic colorectal cancer before and after the English Cancer Drugs Fund implementation

V. Plested[1], A.S. Dhadda[2], M. Iqbal[3], R. Roy[2]. *[1]Castle Hill Hospital, Hull East Yorkshire, United Kingdom; [2]Castle Hill Hospital, Clinical Oncology, Hull East Yorkshire, United Kingdom; [3]Castle Hill Hospital, Medical Oncology, Hull East Yorkshire, United Kingdom*

Background: The Cancer Drugs Fund (CDF) was established in April 2011 in England to 'enable patients to access the drugs their doctors think will help them'. With reference to metastatic colorectal cancer, two drugs have been available within our locality since that date (Bevacizumab in the second line setting and Cetuximab in the third line setting). Our aim was to review practice within our centre before and after the CDF implementation and assess impact on patient outcomes.
Materials and Methods: All patients accessing Bevacizumab and Cetuximab via the CDF between April 2011 and April 2012 at the Queen's Centre for Oncology were identified. A separate cohort of metastatic colorectal cancer patients treated with palliative chemotherapy between April 2008 and April 2011 were randomly selected. A retrospective review of clinical records was conducted to include: date of diagnosis of metastatic disease, lines of treatment, dates of progression and date of death. Data was analysed using SPSS 19. Median follow-up was 19 months (range 2−72 months).
Results: A total of 100 patient records were reviewed; 51 patients in the Pre-CDF time period and 49 patients in the year after the CDF became available (Post-CDF group). Prior to the CDF implementation access to monoclonal antibodies was low at 6% for Bevacizumab and 12 % for

Cetuximab. The median overall survival in the pre-CDF group was 16 months (95% CI 12.1–19.9 months) and in the post CDF group was 25 months (95% CI 20.3–29.7 months). Log rank test showed this difference to be statistically significant (p = 0.008).

Table: Comparison of patients undergoing treatment for metastatic colorectal cancer before and after CDF implementation

	Pre-CDF	Post-CDF
N	51	49
Mean age (range), years	66 (31−85)	65 (26−83)
M:F	1.7:1	1.6:1
Median overall survival (95% CI), months	16 (12.1–19.9)	25 (20.3–29.7)

Conclusion: This data suggests there has been an improvement in overall survival in patient's undergoing treatment for Metastatic Colorectal cancer following the implementation of the Cancer drugs fund. The marked differences in overall survival may relate to increased access to newer monoclonal antibodies. However, this is a small data set and groups have not been matched for other variables including differences in disease volume or performance status.
No conflict of interest.

2385 POSTER

A first combination phase I study of TAS-102 and irinotecan (Iri) in Japanese patients (pts) with metastatic colorectal cancer (mCRC) refractory to fluoropyrimidine (FU) and oxaliplatin (Ox)

K. Yamazaki[1], T. Doi[2], T. Yoshino[2], N. Fuse[2], N. Boku[1], W. Koizumi[3], K. Shimada[4], Y. Takinishi[4], A. Ohtsu[5]. *[1]Shizuoka Cancer Center, Division of Gastrointestinal Oncology, Shizuoka-pref., Japan; [2]National Cancer Center Hospital East, Department of Gastroenterology & GI Oncology, Chiba-pref., Japan; [3]Kitasato University East Hospital, Division of Gastroenterology, Kanagawa-pref., Japan; [4]Showa University Yokohama Northern Hospital, Department of Internal Medicine, Kanagawa-pref., Japan; [5]National Cancer Center Hospital East, Research Center for Innovative Oncology, Chiba-pref., Japan*

Background: TAS-102 is a novel oral nucleoside antitumor agent that consists of trifluridine and tipiracil hydrochloride. In a randomized phase II study for mCRC, TAS-102 monotherapy significantly improved overall survival (OS) compared with placebo (Takayuki Yoshino, et al. Lancet Oncol. 2012;13:993–1001.), and currently, a phase III study (RECOURSE) is being conducted in the world. In addition, preclinical studies demonstrated TAS-102 additively enhanced the antitumor effect of Iri.
Material and Methods: We conducted a first combination phase I study of TAS-102 and Iri in Japanese pts with mCRC refractory to FU and Ox. The primary objectives were to assess the safety and maximum tolerated dose (MTD), using a modified 3 + 3 design. Secondary objectives included the evaluation of efficacy and pharmacokinetics (PK). TAS-102 was administered at the starting dosage of 25 mg/m^2 BID in a 28-day cycle (2-week cycle of 5 days of treatment followed by a 2-day rest period, and then a 14-day rest period), with a fixed-dose of Iri (150 mg/m^2) q2wks. Dose-limiting toxicity (DLT) was evaluated during the 1st cycle. This study treatment was continued until disease progression or intolerability was observed.
Results: A total of 10 pts were enrolled in the study, and 9 pts were evaluable for DLTs (dose levels: [DL1] 25 mg/m^2 BID, n = 6; [DL2] 30 mg/m^2 BID, n = 3). One pt was not evaluable for DLT because of pt withdrawal. The median age 61 years (range, 31−72 years); 6 male; ECOG PS 0/1 (8/1). The median number of cycles was 3 (range, 1−29). The treatment of 8 pts was discontinued because of PD. One pt in DL1 and 2 pts in DL2 developed DLTs, including Gr 4 neutropenia and Gr 3 febrile neutropenia (FN). Thus, MTD was confirmed to be 30 mg/m^2 BID of TAS-102. The most common Gr 3/4 adverse events were neutropenia (10), leukopenia (7) and FN (3). Administration of Iri on day 15 was omitted because of hematological toxicities (89%), and the relative dose intensity (RDI) during treatment period was 82% for TAS-102 and 62% for Iri. PK drug–drug interactions were not observed between TAS-102 and Iri. There were 2 PR (22%) and 3 SD (33%). Median progression-free survival and OS were 2.3 and 15.6 months, respectively.
Conclusions: The combination therapy of TAS-102 and Iri was manageable up to 30 mg/m^2 BID in pts with mCRC, resulting in the promising antitumor activities. However, because the RDI of Iri was low, further studies with schedule modifications are warranted.

Updated results of a phase II study of neoadjuvant chemotherapy with mFOLFOX6 + bevacizumab for the synchronous liver metastases from colorectal cancer

K. Nakagawa[1], Y. Katayose[1], K. Yamamoto[2], J. Yamauchi[3], M. Oikawa[4], H. Shimamura[5], K. Takahashi[6], K. Miura[2], F. Motoi[7], M. Unno[8]. *[1]Tohoku University Graduate School of Medicine, Division of Integrated Surgery and Oncology, Sendai, Japan; [2]Miyagi Cancer Center, Division of Surgery, Sendai, Japan; [3]Sendai Kousei Hospital, Division of Surgery, Sendai, Japan; [4]Sendai Open Hospital, Division of Surgery, Sendai, Japan; [5]Sendai Medical Center, Division of Surgery, Sendai, Japan; [6]Tohoku Rousai Hospital, Division of Surgery, Sendai, Japan; [7]Tohoku University Hospital, Division of Hepato-Biliary Pancreatic Surgery, Sendai, Japan; [8]Tohoku University Graduate School of Medicine, Division of Surgery, Sendai, Japan*

Background: The synchronous liver metastases (SLM) from colorectal cancer (CRC) have a poor prognosis, though treatment results can be improved with the advent of new agents. Therefore, our group, the Miyagi Hepato-biliary pancreatic clinical oncology group (Miyagi-HBPCOG), conducted a phase II study of neoadjuvant chemotherapy for SLM to determine the appropriate initial treatment. Here, we assessed the effectiveness of bevacizumab (BV) combined with mFOLFOX6 and report updated results including survival.
Patients and Methods: The main inclusion criteria of SLM were within 10 nodules and measurable disease. The primary endpoint was the response rate (RR). Between June 2008 and November 2010, 47 patients (pts) were enrolled from 17 centers. These pts were enrolled after R0-resection of the primary CRC and received 8 courses of mFOLFOX6 with BV (the first and last courses were mFOLFOX6 alone). After this 'neoadjuvant' chemotherapy pts underwent resection of liver metastases within 4−8 weeks.
Results: The mean age was 60.8 years. The median number of metastases was 2 nodules, and the maximum diameter of tumors was 12.9 cm. Three pts were excluded from evaluation of RR because they did not receive any scheduled chemotherapy. The overall RR was 70.5% (2 complete and 29 partial responses). Eleven pts (25%) showed stable disease and 2 pt (4.5%) had progressive disease. The liver resection rate was 93.2% (41 pts) and the R0-resection rate was 88.6% (39pts). The histological tumor response (HR) was assessed on the basis of the tumor regression grade (TRG). Twenty-two pts (55.0%) achieved TRG 1−2 (major HR), 13 pts (32.5%) had TRG 3 (partial HR), and 5 pts (12.5%) had TRG 4−5 (no HR). With a median follow-up of 35 months, the 1- and 2-year progression-free survival (PFS) rates were 45.1% and 27.3%, respectively, and the 1- and 2-year overall survival (OS) rates were 95.4% and 88.4%, respectively. Grade 3 and 4 adverse events (AEs) occurred in 21 pts with the most common being neutropenia (28.9%) and leucopenia (11.1%). There were 3 Grade 4 AEs: 1 case of renal failure and 2 cases of neutropenia.
Conclusions: Neoadjuvant chemotherapy with BV combined with mFOLFOX6 for liver metastases is effective and well tolerated. The benefit of this therapy as the initial treatment of SLM might need to be evaluated further by comparison with adjuvant therapy.
This trial is on University hospital Medical Information Network-Clinical Trials Registry (UMIN-CTR); UMIN000001568.

Updated survival results and analysis according to the prognostic factor in the BASIC trial of bevacizumab and S-1 in elderly metastatic colorectal cancer patients

Y. Hamamoto[1], D. Takahari[2], A. Tsuji[3], M. Yohida[4], T. Takahashi[5], K. Muro[2], Y. Miyata[6], T. Yoshino[7], K. Shirao[8]. *[1]Tochigi Cancer Center, Department of Medical Oncology, Utsunomiya, Japan; [2]Aichi Cancer Center Hospital, Department of Clinical Oncology, Nagoya, Japan; [3]Kochi Health Sciences Hospital, Department of Medical Oncology, Kochi, Japan; [4]Osaka Medical College Hospital, Cancer Chemotherapy Center, Takatsuki, Japan; [5]Gifu University Graduate School of Medicine, Department of Surgical Oncology, Gifu, Japan; [6]Saku Central Hospital, Department of Gastroenterology, Saku, Japan; [7]National Cancer Center Hospital East, Department of Gastrointestinal Oncology/Gastroenterology, Kashiwa, Japan; [8]Oita University Faculty of Medicine, Department of Medical Oncology, Oita, Japan*

Background: We previously reported short term results of a phase II to evaluate the efficacy and safety of combined therapy with S-1 and bevacizumab in elderly patients who had advanced or recurrent colorectal cancer. The median progression-free survival (PFS) was 9.9 months (95% CI, 7.6–11.0) with median follow-up time 18.6 months (Takahari et al, ESMO 2011).
Methods: Study subjects comprised diagnosis of elderly patients 65 years or older who had a histologically confirmed advanced or recurrent colorectal cancer and were scheduled to receive first-line chemotherapy. As for the treatment regimen, bevacizumab (5 mg/kg) was given intravenously on days 1, 15, and 29, and S-1 (80 to 120 mg/day according to body-surface area in two divided doses daily, after meals) was administered orally on days 1 to 28 of a 42-day cycle, which was repeated until progression or unacceptable toxicity. We updated overall survival (OS) results with 34.6 months of median follow-up and analyzed them to classify according to a general prediction model reported by Kohne et al.
Results: From October 2007 through March 2010, a total of 56 patients were enrolled.
Their median age was 75 years. The median OS was 25.0 months (95% CI, 19.4 to 31.6). In high-risk (n = 14), intermediate-risk (n = 19), and low-risk (n = 23) patients, the median OS was 14.4 months (95% CI: 7.5–25.0), 28.5 months (95% CI: 18.5–32.3), and 35.3 months (95% CI: 22.3–Not Reached) (P = 0.0011), respectively. The hazard ratio for OS between the risk groups was 2.58 (95% CI: 1.17–5.69, P = 0.019) between high risk and intermediate risk, 4.21 (95% CI: 1.83–9.91, P<0.001) between high risk and low risk, and 1.63 (95% CI: 0.72–3.76, P = 0.237) between intermediate risk and low risk.
Conclusions: S-1 plus bevacizumab therapy is therapeutically effective and safe for elderly patients with metastatic colorectal cancer. The analysis with Kohne model suggested that it is useful to predict OS in elderly colorectal cancer patients treated with S-1 and bevacizumab.
No conflict of interest.

NK-EGFR01: Feasibility of allogenic natural killer cell (NK) adoptive transfer by intra-arterial injection in combination to cetuximab − a phase I clinical trial in EGFR+ gastrointestinal adenocarcinoma

O. Adotevi[1], S. Kim[2], Z. Lakkis[3], F. Fein[4], M. Jary[5], E. Dobi[5], I. Idirene[6], J.M. Certoux[6], Y. Godet[7], C. Borg[1]. *[1]University Hospital of Besançon, Oncology-INSERM-UMR 1098, Besancon, France; [2]University Hospital of Besançon, Oncology-Clinical Investigational Center-Biotherapy-506, Besancon, France; [3]University Hospital of Besançon, Clinical Investigational Center-Biotherapy-506, Besancon, France; [4]University Hospital of Besançon, Gastroenterology, Besancon, France; [5]University Hospital of Besançon, Oncology, Besancon, France; [6]Etablissement Français du Sang de Bourgogne Franche-Comté, INSERM-UMR 1098, Besancon, France; [7]University of Franche Comté, INSERM-UMR 1098, Besancon, France*

Background: NK cells are components of innate immunity recognizing and killing tumor or virus-infected cells. Major advances in NK cell alloreactivity biology resulted in the successful introduction of NK-based cellular therapy in the treatment of myeloid leukemia (Velardi A, *et al.* Science 2001 and Miller J, *et al.* Blood 2005). Our pre-clinical experiments confirmed the ability of activated alloreactive NK cells to recognize the chemoresistant colorectal cancer cell line HT29. The use of cetuximab improved NK cell cytotoxicity in this setting and prompted us to combine NK cell alloreactivity and Antibody-Dependent Cell-mediated Cytotoxicity (ADCC).
Materials and Method: Patients with liver metastases of colorectal or pancreatic cancers were included. Main inclusion criteria were: a positive expression of EGFR on tumor cells by immunohistochemistry, the absence of a specific Killer cell Immunoglobulin-like Receptors (KIR) ligand, a performance status of 0 or 1, an age below 75 years, the absence of an important extra-hepatic disease, and absence of standard therapeutic options. Patients were treated with a lymphodepleting chemotherapy (d-6 to J-2: fludarabine 25 mg/m^2 and d-6 cyclophosphamide 60 mg/kg) before adoptive transfer of NK by the liver artery (day 0). Cetuximab was administered at d-1 and every week for 7 weeks. Three dose levels were performed (3×10^6 NK/kg, 6×10^6 NK/kg, 12×10^6 NK/kg). Injections of interleukin 2 were performed after the adoptive transfer, every 3 days for 6 injections.
Results: Three patients were included at each dose level. The production of allogenic NK was possible for all patients. NK cells were cultured overnight in Xvivo 15 medium complemented with 10% of serum and 1000UI of interleukin 2/mL. Lymphodepleting chemotherapy was feasible in all selected patients. Main non-hematological toxicities included grade 3 chills and fever after IL-2 injections in 6 patients, grade 3 asthenia in 5 patients and grade 2 alopecia in 6 patients. Grade 4 neutropenia and lymphopenia were observed in all patients. The mean time of lymphopenia <100/mm^3 was 14 days. No dose limiting toxicity was reported. We could observe one partial objective response in CT-scan and PET-scan. The time of disease control was 4 months in this patient. Two additional disease stabilizations were achieved.
Conclusion: Allogenic NK cell adoptive transfer by injection in the liver artery is feasible.
No conflict of interest.

2389 POSTER

Analysis of cumulative neurotoxicity improvement by withdrawal of L-OHP (Subset analysis of T-CORE0901 Japan-Modified CONcePT trial)

S. Kato[1], M. Gamoh[2], H. Shimdaira[3], Y. Murakawa[4], K. Amagai[5], H. Isobe[6], T. Niitani[7], J. Itoh[8], T. Yoshioka[9], C. Ishioka[1]. *[1]Institute of Development Aging and Cancer Tohoku University, Dept. Clinical Oncology, Sendai, Japan; [2]Osaki Citizen Hospital, Dept. Medical Oncology, Osaki, Japan; [3]Tohoku University Hospital, Dept. Clinical Oncology, Sendai, Japan; [4]Miyagi Cancer Center, Dept. Chemotherapy, Natori, Japan; [5]Ibaraki prefectural Central Hospital and Cancer Center, Dept. Gastroenterology, Kasama, Japan; [6]Faculty of Medicine Yamagata University, Dept. Gastroenterological General Breast and Thyroid Surgery, Yamagata, Japan; [7]South Miyagi Medical Center, Dept. Medical Oncology, Ohgawara, Japan; [8]Graduate School of Medicine Hirosaki University, Dept. Medical Oncology, Hirosaki, Japan; [9]Faculty of Medicine Yamagata University, Dept. Clinical Oncology, Yamagata, Japan*

Background: The CONcePT trial revealed that intentional withdrawal of L-OHP administration of Bevacizumab (BV) + FOLFOX7 is effective and safe in view of deterioration of cumulative neurotoxicity against mCRC. However it is unknown of appropriable period of withdrawal of L-OHP. We carried out subset analysis of Japan-Modified CONcePT trial that withdrawal of L-OHP improved cumulative neurotoxicity before re-administration L-OHP in Japanese pts.
Material and Method: Japan-Modified CONcePT trial is a phase II trial to evaluate the efficacy and safety of intermittent L-OHP administration of first-line BV + mFOLFOX6 or CapeOX therapies. Six cycles of bi-weekly BV + mFOLFOX6 regimen is followed by 6 cycles of bi-weekly BV + sLV5FU2 or 4 cycles of tri-weekly BV + CapeOX regimen is followed by 4 cycles of tri-weekly BV + capecitabine regimen. Primary endpoint is to evaluate median progression free survival (PFS). Safety is one of secondary endpoints and cumulative neurotoxicity is evaluated by DEB-NTC.
Results: Sixty eight pts were enrolled and median PFS was 347 days (95% CI 286–462 days) and TTF was 229 days (95% CI 187–263 days). Thirty seven pts were re-administrated L-OHP after 12 weeks of withdrawal. The cumulative neurotoxicity was observed in 26 pts just before withdrawal L-OHP and 11 pts feels improvement of cumulative neurotoxicity. However 8 pts feels deterioration of cumulative neurotoxicity.
Conclusions: The intentional withdrawals of L-OHP administration of BV + mFOLFOX6 or CapeOX therapies were effective for Japanese mCRC pts. However 12 weeks of withdrawal of L-OHP is not enough for improvement of cumulative neurotoxicity.
No conflict of interest.

2390 POSTER

A randomized Phase II study of tegafur/uracil (UFT), oral Leucovorin and irinotecan, combination therapy (TEGAFIRI)+bevacizumab versus FOLFIRI+bevacizumab for the first-line treatment of patients with metastatic colorectal cancer

H. Hasegawa[1], T. Endo[1], D. Ochiai[1], H. Uchida[2], T. Okabayashi[1], S. Imai[3], Y. Ishii[1], M. Tsuruta[1], Y. Kitagawa[1]. [1]*Keio University, Surgery, Tokyo, Japan;* [2]*Saitama Social Insurance Hospital, Surgery, Saitama, Japan;* [3]*Hiratsuka City Hospital, Surgery, Hiratsuka, Japan*

Background: CPT-11 base chemotherapy plus bevacizumab (Bmab) is one of the first line standard therapies for metastatic colorectal cancer (mCRC). TEGAFIRI (UFT/LV+CPT-11) is new CPT-11 base chemotherapy. There has been no clinical data regarding TEGAFIRI+Bmab to date. We previously reported the results of a phase I study using TEGAFIRI, and the recommendation dose of CPT-11 (Cancer Chemother Pharmacol 2009). This study was designed to evaluate the efficacy and safety of TEGAFIRI+Bmab in mCRC patients.
Material and Methods: The study design was multicenter randomized phase II.The major inclusion criteria were previously untreated mCRC (age 20−75, PS 0−1). Patients were randomized to receive either TEGAFIRI+Bmab[UFT(300 mg/m^2/day) & LV(75 mg/day) orally for three weeks and CPT-11(150 mg/m^2) and Bmab(5 mg/kg)on day 1 and 15, every 4 weeks] (Group A) or FOLFIRI+Bmab (Group B). The primary endpoint was progression free survival (PFS).
Results: From 2007 to 2010, 72 patients (36 Group A and 36 group B) were randomized. Median PFS for Group A and Group B was 15.7 months and 9.6 months. The most common Grade3/4 adverse events were stomatitis(5.2% GroupA, 9.5% Group B), anorexia (0% and 4.8%), nausea(0% and 9.5%), diarrhea (5.3% and 4.8%), fatigue (0% and 4.8%). Post treatments with bevacizumab were performed in 10 patients (4 Group A and 6 Group B), and median overall survival was 25.1 months.
Conclusions: It was demonstrated that the first-line treatment of TEGAFIRI+Bev was effective and tolerable, and could be an additional option for first-line treatment.
No conflict of interest.

2391 POSTER

A phase II study of cetuximab in combination with irinotecan plus S-1 as first-line treatment in patients with KRAS wild-type metastatic colorectal cancer: CIRIS study

T. Masuishi[1], Y. Sakai[1], T. Matsui[1], R. Nakamura[1], S. Anzai[1], Y. Suzuki[1], I. Kobori[1], Y. Fukami[1], K. Suzuki[1], J. Tazawa[1]. [1]*Tuchiura Kyodo General Hospital, Gastroenterology, Ibaraki, Japan*

Background: The CRYSTAL study demonstrated that the addition of cetuximab (Cmab) to FOLFIRI as first-line treatment improved the clinical benefit in patients (pts) with KRAS wild-type (wt) metastatic colorectal cancer (mCRC). Because the FIRIS study demonstrated the non-inferiority of irinotecan plus S-1 (IRIS) to FOLFIRI for mCRC, we conducted a phase II study to evaluate the efficacy and safety of Cmab in combination with IRIS as first-line treatment in pts with KRAS wt mCRC (clinical trial information: UMIN000004580).
Methods: Eligibility criteria included histologically confirmed colorectal cancer; KRAS wt; no previous chemotherapy; ECOG performance status (PS) 0−1 and adequate organ function. S-1 was administered at 80 mg/m^2 on days 1−14 and irinotecan at 100 mg/m^2 on days 1 and 15 every 28 days. Cmab was administered at a loading dose of 400 mg/m^2, followed by weekly infusions of 250 mg/m^2. The primary endpoint was response rate (RR), and the secondary endpoints were progression-free survival, overall survival, rate of tumor shrinkage and safety. The sample size calculation was carried out to reject a 37% response rate in favor of a target response rate of 60%, with a significance level of 0.05 and a statistical power of 80%.
Results: Between November 2010 and January 2013, 31 pts were enrolled. One patient was ineligible with inadequate renal function. The characteristics of the pts were as follows; median age: 65.5 (range: 38−79), male/female: 20/10, ECOG PS 0/1: 24/6, colon/rectum: 22/8, unresectable/recurrent: 21/9. The RR was 70% [95% confidence interval (CI): 52.1–83.3%] with complete response: 2, partial response: 19, stable disease: 9 and progressive disease: 0. With a median follow-up time of 13.1 months, the median PFS was 13.1 months (95% CI: 7.7–18.5 months). The most common grade 3−4 adverse events were leukopenia (22.6%), neutropenia (41.9%), febrile neutropenia (9.7%), anemia (9.7%), hypoalbuminemia (16.1%), anorexia (16.1%), diarrhea (9.7%), mucositis (9.7%), acne-like rush (9.7%), dry skin (19.4%) and paronychia (9.7%). There were no treatment-related deaths.
Conclusions: Cmab in combination with IRIS as first-line treatment was considered one of the promising options and showed manageable toxicities in pts with KRAS wt mCRC.
No conflict of interest.

2392 POSTER

Long term outcomes after neoadjuvant hyperfractionated short-course chemoradiotherapy for rectal cancer

H. Yuki[1], N. Beppu[1], F. Kimura[1], H. Yanagi[1], N. Yamanaka[1]. [1]*Meiwa Hospital, Surgery, Nishinomiya, Japan*

Background: Short course radiotherapy has advantages of less acute toxicity and less cost than long-term radiotherapy. One of the disadvantages is downsizing of the primary tumor cannot occur, because preoperative short-course radiation standard timing of surgery is day 7−9. But delayed surgery has been shown downsizing of the tumor recently. The aim of this study is to evaluate long term outcomes after neoadjuvant hyperfractionated short-course radiotherapy (NAHSRT) for rectal cancer.
Material and Methods: Between March 2008 and May 2012, 140 patients with rectal cancer were treated with NAHSRT. NAHSRT was performed with a dose of 2.5 Gy twice daily with an interval of 6 hours between fractions, up to a total dose of 25 Gy with chemotherapy (S-1 80 mg/m^2 day 1−10). Surgery was performed within 3−4 weeks following the end of the NAHSRT.
Results: 140 patients included 98 men and 42 women. The median age was 65.2±11.0. The median follow-up term was 45.2 months. 54 patients has tumor shrinkage (36.0 percent). No patients showed grade 4 toxicities. Sphincter preserving surgery was performed in 94.2 percent. The overall cumulative five-year survival rate was 81.5 percent. The local recurrence free survival rate was 90.3 percent. The disease free survival rate was 68.5 percent.
Conclusions: We presented long term outcomes after neoadjuvant hyperfractionated short-course chemoradiotherapy for rectal cancer. NAHSRT was considered feasible option and produced excellent long-term outcomes.
No conflict of interest.

2393 POSTER

Biweekly cetuximab in combination with FOLFOX-4 in the first-line treatment of KRAS wild-type metastatic colorectal cancer: Final results of a phase II open-label clinical trial

J. Fernández[1], L. Cirera[1], C. Pericay[2], E. Saigi[2], V. Alonso[3], G. Quintero[4], A. Salud[5], M. Mendez[6], M. Salgado[7], on behalf of ACROSS Group. [1]*Hospital Universitario Mutua Terrassa, Oncología Médica, Terrassa, Spain;* [2]*Corporación Sanitaria Parc Taulí, Oncología Médica, Sabadell, Spain;* [3]*Hospital Miguel Servet, Oncología Médica, Zaragoza, Spain;* [4]*Hospital Xeral-Calde, Oncología Médica, Lugo, Spain;* [5]*Hospital Arnau de Vilanova, Oncología Médica, Lleida, Spain;* [6]*Hospital de Móstoles, Oncología Médica, Móstoles, Spain;* [7]*Hospital de Ourense, Oncología Médica, Ourense, Spain*

Background: The addition of weekly cetuximab to FOLFOX-4 as first-line treatment of metastatic colorectal cancer (mCRC) improves the overall response rate (ORR) and reduces the risk of disease progression in patients with KRAS wild-type tumours. Seeking to increase convenience for patients and health care providers, the objective of this phase II study was to evaluate the efficacy and safety of biweekly cetuximab in combination with FOLFOX-4.
Methods: Previously untreated patients with KRAS wild-type tumours received biweekly cetuximab (500 mg/m^2 on day 1) plus FOLFOX-4 (oxaliplatin 85 mg/m^2 on day 1, leucovorin 200 mg/m^2 on days 1 and 2, and fluorouracil as a 400 mg/m^2 bolus followed by a 600 mg/m^2 infusion during 22 hours on days 1 and 2). Treatment was continued until disease progression, onset of unacceptable drug toxicities or patient/physician request to discontinue. The primary endpoint of the study was ORR. Secondary endpoints included progression-free survival (PFS) and overall survival (OS).
Results: A total of 99 patients were included in the intention-to-treat population, mean age was 63.9 (±9.2) years. The ORR was 60.6% (95% CI, 50.3% to 70.3%). Median PFS was 10.1 months. With a short median follow-up of 17.8 months, the OS was 20.8 months. Metastases from colorectal cancer were surgically resected in 26 (26.3%) patients, with complete surgical resection achieved in 18 (69.2%) patients. Median relapse free survival in patients undergoing resection of metastases was 12.6 months. The most common grade 3−4 toxicities were neutropenia (32.3%), acne-like rash (15.2%) and diarrhoea (11.1%).
Conclusions: The efficacy of biweekly combination of cetuximab with FOLFOX in patients with KRAS wild-type tumours is similar to what has been reported for the weekly administration of cetuximab. Reported toxicity

was also consistent with the known toxicity profile of weekly cetuximab. Our results support the administration of cetuximab in a dosing regimen more convenient for patients and health care providers.
Conflict of interest: *Other substantive relationships: This study was supported by Merck, S.L.*

2394 POSTER

Japanese cross-sectional cohort study of 1st line chemotherapy (CT) for metastatic colorectal cancer (mCRC) (EMERaLD study)

A. Maeda[1], T. Amano[2], Y. Ohashi[3]. [1]*Ogaki Municipal Hospital, Digestive Surgery, Ogaki Gifu, Japan;* [2]*Hokkaido University Graduate School of Medicine, Medical Oncology, Sapporo, Japan;* [3]*School of Public Health the University of Tokyo, Biostatistics, Tokyo, Japan*

Background: An observational cohort study plays a crucial role to establish a database to assess clinical status of patients (pts). There is no database which shows the current status including treatments of mCRC pts in Japan.
Methods: We planned and conducted a large cross-sectional cohort study which investigates 1st line CT in mCRC to establish a database to improve future clinical practice in Japan.
Data from the following pts are eligible to the study: treated with 1st line CT including oxaliplatin and bevacizumab (BV) for mCRC; started treatment in or after January 2010. The primary objectives are to evaluate overall survival (OS), liver resection rate, R0 liver resection rate; the secondary objectives are to evaluate response rate (RR), progression-free survival (PFS). We performed a preplanned interim analysis of 6-month efficacy and safety data after the 1,000th registration.
Results: A total of 1,353 pts were recruited from 132 centers in Japan between October 2010 and September 2011, and we analyzed data on 1,005 pts of them. The background of 1,005 pts were the following; male/female, 614/391; median age of 65 (range, 27−89); ECOG PS 0/1/2/3, 854/139/10/2; site of primary tumor colon/rectum/others, 549/451/5; and site of metastatic disease liver/lung/others, 627/308/421; FOLFOX/ CapeOx/ others with BV, 437/540/28, KRAS-status wild/mutant/ unknown, 225/168/612. Six-month efficacy data were the following; liver resection rate 10.5%, R0 liver resection rate 8.9%, RR 51.6%, PFS 83.9%. Six-month grade 3/4 (CTC-AEv3.0) adverse events related to BV were hypertension 2.4%, proteinuria 0.2%, thromboembolism 1.1%, bleeding 0.6%, and gastrointestinal perforation 1.5%. We also performed a subgroup analysis by ages, primary tumor sites, regimens, and KRAS-status.
Conclusions: We performed a preplanned interim analysis on 1,005 pts and this could be a large database to investigate 1st line CT in clinical practice of mCRC pts in Japan. We will further investigate and analyze the 2-year data including survival on all 1,353 pts.
This study is sponsored by the Public Health Research Center Foundation CSPOR in Japan.
No conflict of interest.

2395 POSTER

Chemotherapy in elderly patients with metastatic colorectal cancer: relation to co-morbidities and functional abilities

L.M. El-Helw[1], H.F. Elkhenini[2], H.H. Abou Hatab[3], R. Kulkarni[1]. [1]*The Royal Derby Hospital, Clinical Oncology, Derby, United Kingdom;* [2]*The University of Manchester, North West E-Health, Manchester, United Kingdom;* [3]*The Royal Derby Hospital, Gastroenterology, Derby, United Kingdom*

Background: We aimed to study the management of elderly patients with metastatic colorectal cancer (mCRC) in relation to their co-morbidities and functional abilities.
Material and Methods: An observational study of a cohort of mCRC patients (65 years or older) treated by our oncology team between April 2010 until December 2012. There were 4 groups of patients according to the first line chemotherapy regimens they received; XELOX (oxaliplatin and capecitabine), capecitabine, FOLFIRI (Irinotecan and modified Degramont) and raltitrexed. Cumulative Illness Rating Scale for Geriatric (CIRS-G) and Lawton Instrumental Activity of Daily Living (IADL) (table 1) as well as response to chemotherapy were studied.
Results: There were 43 patients in this study. Thirteen patients were treated with XELOX regimen. They had CIRS-G score of 0−3, IADL score of 8 and performance status (PS) of 0−1. Three patients had dose reduction for co-morbidities and 7 for chemotherapy toxicities. Partial response (PR) of 61.5% and stable disease (SD) of 30.8% were achieved. The median progression free survival (PFS) and overall survival (OS) durations were 10 and 16 months respectively.
Ten patients had oral capecitabine. They had CIRS-G score of 0−3, IADL score of 4−8 and PS 2. Dose reduction was required in 7 patients for either co-morbidities (4 patients) or toxicities (3). Two had PR (20%) and 6 SD (60%). The median PFS and OS were 11 and 12 months respectively.
Five patients were treated with FOLFIRI (Irinotecan and modified Degramont) regimen. They had CIRS-G 1−3, PS 1 and Lawton IADL of 5−8. Dose reduction was required in 2 patients due to toxicities. Two patients had PR (40%) and 1 (20%) SD. Median PFS and OS were 9 months and 14 months respectively.
Fifteen patients with ischaemic heart diseases were treated with Raltitrexed. They had CIRS-G score of 2−3, IADL score of 4−8 and PS $\leqslant$2. Three patients had dose reduction due to mild renal impairment (1 patient) or significant side effects (2 patients). PR and SD rates were 35.7% each. Median PFS and OS were 7 and 10 months respectively.

Table 1.

Instrument	Score
Cumulative Illness Rating Scale for Geriatric (Miller MD, et al 1992)	
No problem	0
Current mild problem or past significant problem	1
Moderate disability or morbidity requiring first line therapy	2
Severe/constant significant disability/un-controllable chronic problems	3
Extremely severe/end organ failure	4
A total score is then calculated with particular focus on level 3 or 4 co-morbidities.	
Lawton Instrumental Activity of Daily Living (Lawton et al 1969)	
Ability to use telephone	0/1
Food preparation	0/1
House keeping	0/1
Laundry	0/1
Responsibility for own medications	0/1
Mode of transportation	0/1
Shopping	0/1
Ability to handle finances	0/1
A score of either 0 or 1 is assigned for each of the 8 patient's functional abilities. A summary score ranges from 0 (dependent) to 8 (independent).	

Conclusions: Elderly patients with mCRC can cope with chemotherapy but with occosional need for dose reduction. CIRS-G score, IADL and PS are quite helpful tools in assessing them prior to chemotherapy.
No conflict of interest.

2396 POSTER

Comparison of cetuximab with panitumumab in salvage-line monotherapy against KRAS wild type patients with metastatic colorectal cancer: Analysis of HGCSG0901 and HGCSG1002

K. Hatanaka[1], S. Yuki[2], T. Sasaki[2], Y. Tsuji[3], H. Okuda[4], Y. Takahashi[5], A. Hosokawa[6], I. Iwanaga[7], Y. Sakata[8], Y. Komatsu[9]. [1]*Hakodate Municipal Hospital, Department of Gastroenterology, Hakodate, Japan;* [2]*Hokkaido University Hospital, Department of Gastroenterology and Hepatology, Sapporo, Japan;* [3]*Tonan Hospital Sapporo, Department of Medical Oncology, Sapporo, Japan;* [4]*Keiyukai Sapporo Hospital, Department of Medical Oncology, Sapporo, Japan;* [5]*Hokkaido Cancer Center, Department of Gastroenterology, Sapporo, Japan;* [6]*University of Toyama, Department of Gastroenterology and Hematology Faculty of Medicine, Toyama, Japan;* [7]*Japanese Red Cross Kitami Hospital, Department of Gastroenterology, Kitami, Japan;* [8]*Misawa City Hospital, Department of Medical Oncology, Misawa, Japan;* [9]*Hokkaido University Hospital Sapporo, Department of Cancer Center, Sapporo, Japan*

Background: Monoclonal antibodies targeting the epidermal growth factor receptor (EGFR) such as cetuximab and panitumumab have antitumor activity and acceptable safety profiles in patients with metastatic colorectal cancer (mCRC). Although monotherapy with cetuximab or panitumumab has demonstrated the effectiveness in salvage-line, there are no trials comparing these antibodies directly.
Methods: Data of 31 patients (pts) with mCRC treated by cetuximab (HGCSG 0901 study) and 51 pts treated by panitumumab (HGCSG 1002 study) registered from 27 institutions in Japan were retrospectively analyzed. All patients with *KRAS* wild type were refractory to or intolerant for 5-FU/ irinotecan/ oxaliplatin and also were never administered anti-EGFR-antibodies. Survival analyses were performed with Kaplan–Meier method and log-rank test.
Results: Patient characteristics were as below (cetuximab vs. panitumumab); male/female 20/11 vs. 27/24, median age (range) 65(44−76) vs. 64.5(44−81), PS 0−1/2−3 21/10 vs. 46/5, number of metastatic sites 1−2/3−22/9 vs. 25/16, prior bevacizumab administration 81% vs. 86%. Skin toxicity was common adverse events and was generally similar in two groups. The median overall survival was 8.4 months in the cetuximab group, as compared with 8.1 months in the panitumumab ($p = 0.32$). The median progression-free survival was 3.8 months in the cetuximab, as compared with 3.1 months in the panitumumab ($p = 0.60$); the corresponding response rate was 19.4 percent and 13.7 percent ($p = 0.54$).

Conclusions: In this retrospective comparison of two studies, there were no significant difference in efficacy between cetuximab and panitumumab in the salvage-line treatment of patients with mCRC. As there are no known predictive factors for anti-EGFR-antibodies in mCRC, anti-EGFR-antibodies should be chosen based on preferred treatment interval.

2397 POSTER

Randomized phase II study of oxaliplatin reintroduction and biweekly XELOX in previously treated patients with metastatic colorectal cancer (mCRC): ORION study

I. Keiichiro[1], K. Ishibashi[1], C. Matsuda[2], H. Tamagawa[2], Y. Munemoto[3], C. Tanaka[4], M. Fukunaga[5], Y. Tokunaga[6], K. Oba[7], J. Sakamoto[8], H. Mishima[9]. *[1]Saitama Medical Center Saitama Medical University, Digestive Tract and General Surgery, Kawagoe, Japan; [2]Osaka General Medical Center, Surgery, Osaka, Japan; [3]Fukui-ken Saiseikai Hospital, Surgery, Fukui, Japan; [4]Gifu Prefectural Genenral Medical Center, Surgery, Gifu, Japan; [5]Sakai City Hospital, Surgery, Sakai, Japan; [6]Kyoto Teishin Hospital, Surgery, Kyoto, Japan; [7]Hokkaido University Hospital, Translational Research and Clinical Trial Center, Sapporo, Japan; [8]Tokai Central Hospital, Kakamigahara, Japan; [9]Aichi Medical University, Cancer Center, Nagakute, Japan*

Background: Reintroduction of oxaliplatin is shown to be of benefit in patients with mCRC who have failed standard treatment. The aim of this study is to assess the efficacy and safety of oxaliplatin reintroduction as two different regimens of XELOX.
Methods: Patients with mCRC who have previously received both oxaliplatin and irinotecan therapy were randomly allocated to Arm A (tri-weekly XELOX; oxaliplatin 130 mg/m^2 on day 1 followed by capecitabine 1,000 mg/m^2 twice daily from days 1 to 14, q3w) or Arm B (bi-weekly XELOX; oxaliplatin 85 mg/m^2 on day 1 followed by capecitabine 1,000 mg/m^2 twice daily from days 1 to 7, q2w). Primary endpoint was time to treatment failure (TTF). The secondary endpoints include relative dose intensity (RDI), overall response rate (ORR), progression-free survival (PFS), overall survival (OS) and safety.
Results: Between December 2010 to April 2011, a total of 46 patients were randomized. The median age was 65 (range: 40−80). Major grade 3/4 toxicities were fatigue 17.7%/16.2%, HFS 3.2%/2.7%, allergic reaction 4.8%/5.4%, neuropathy 3.2%/5.4% in arm A and B respectively. TTF was 105 days (arm A: 122 days, arm B: 86 days) Disease control rate(DCR) was 60%(12 SD) in arm A and 65.2%(1 PR, 14SD) in arm B.
Conclusions: Reintroduction of oxaliplatin can be administered safely and effectively. We found no obvious difference between two different regimens of XELOX.
No conflict of interest.

2398 POSTER

Bi-weekly XELOX (capecitabine/oxaliplatin) plus bevacizumab as first-line treatment of metastatic colorectal cancer (mCRC): PHOENiX trial

N. Nagata[1], T. Okada[2], S. Okazaki[3], S. Sato[4], H. Kin[5], M. Nakamura[6], K. Kunieda[7], K. Oba[8], J. Sakamoto[9], H. Mishima[10]. *[1]Kitakyushu General Hospital, Surgery, Kitakyushu, Japan; [2]Aichi Cancer Center Aichi Hospital, Surgery, Aichi, Japan; [3]Kansai Medical University Kori Hospital, Surgery, Osaka, Japan; [4]Yokohama Asahi Chuo General Hospital, Surgery, Yokohama, Japan; [5]Osaka Rosai Hospital, Surgery, Osaka, Japan; [6]Aizawa Hospital, Cancer Center, Matumoto, Japan; [7]Gifu Prefectural General Medical Center, Surgery, Gifu, Japan; [8]Hokkaido University Hospital, Translational Research and Clinical Trial Center, Sapporo, Japan; [9]Tokai Central Hospital, Director, Kakamigahara, Japan; [10]Aichi Medical University, Cancer Center, Nagakute, Japan*

Background: The aim of this phase II study was to assess the efficacy and toxicity of an intermittent weekly capecitabine regimen in combination with oxaliplatin plus bevacizumab.
Methods: Fifty-one Japanese patients (pts) with measurable metastatic colorectal cancer (mCRC) who were conducted for the first line chemo-therapy were enrolled on to this disease-oriented multicenter Phase II trial. Pts with mCRC were required to have ECOG of 0 to 1, to be age of >20 years, and to have adequate organ function. Primary endpoint was progression-free survival (PFS). Secondary endpoints included response rate (ORR), overall survival (OS), time to progression (TTP), relative dose intensity (RDI) and safety. Capecitabine dose was 2000 mg/m^2/day on days 1−7 (n = 47) and was increased to 2500 mg/m^2/day (n = 4) in combination with oxaliplatin (85 mg/m^2) and bevacizumab (5 mg/kg), repeated every 2 weeks.
Results: 51 pts have been enrolled from 14 institutions by 12/2011 from 06/2012 and started a median of 11 (range 1−21) cycles. The median age was 66 (range: 38−85), colon 29(56.9%) and rectum 22(43.1%) in this study. Pertinent grade 3/4 toxicities seen were leukopenia (7.8%), neutropenia (7.8%), allergy (5.9%), hypertention (13.7%), hand–foot syndrome (2%), and peripheral neuro pathy (7.8%). Response rate (RR) was 51% (1 CR and 25 PRs). Median PFS was 13.1 months (95% CI, 7.5–14.4) and Median TTF was 6.5 months (95% CI, 4.9−7.3). Median OS has not yet been reached. Mean relative dose intensities (RDI) in this trial were 100% for oxaliplatin, bevacizumab and capecitabine.
Conclusion: The first-line treatment of mCRC using a bi-weekly combination of XELOX plus bevacizumab can also be administered safely and effectively in Japan. It is suggested that this regimen is one of the appropriate option for chemotherapy.
No conflict of interest.

2399 POSTER

Candidate genes associated with primary resistance to panitumumab (Pmab) in a phase II biomarker study of patients with KRAS wild-type (wt) metastatic colorectal cancer (mCRC)

G.S. Barry[1], M.C. Cheang[2], S. Leung[1], C. Zhou[3], H.F. Kennecke[4]. *[1]University of British Columbia, Pathology and Laboratory Medicine, Vancouver, Canada; [2]University of North Carolina at Chapel Hill, Pathology and Laboratory Medicine, Chapel Hill, USA; [3]BC Cancer Agency, Pathology and Laboratory Medicine, Vancouver, Canada; [4]BC Cancer Agency, Medical Oncology, Vancouver, Canada*

Background: Pmab monotherapy targeting the Epidermal Growth Factor Receptor (EGFR) results in improved Progression Free Survival in previously treated *KRAS* wt mCRC, but not all patients benefit from therapy. In this phase II study, we sought to identify genes differentially expressed with early resistance to Pmab therapy.
Material and Methods: Patients with measurable *KRAS* wt mCRC were treated until progression with q2weekly Pmab 6 mg/kg IV and response was assessed q2monthly by RECIST criteria. Pathologist-guided tissue macrodissection and RNA isolation was performed on formalin-fixed paraffin-embedded archival tissue of primary tumor and paired metastatic lesions, when available. Gene expression profiles of 100 knowledge-based selected genes, associated with *BRAF* mutation and cetuximab response in mCRC, were done using the Nanostring nCounter® system. Unsupervised hierarchical clustering of these 100 genes was used to test whether *KRAS* wt tumors formed biased clusters from 220 CRC tumors from The Cancer Genome Atlas (TCGA). Two-class Significance Analysis of Microarrays (SAM) compared expression profiles of tumors with a best response of progressive disease (PD) to those with stable disease (SD) or partial response (PR) to Pmab. Genes with a false discovery rate (FDR) $\leqslant$ 20% were analyzed with Database for Annotation, Visualization and Integrated Discovery (DAVID) to identify enrichment for specific pathways and chromosomes.
Results: Best response to Pmab therapy among 37 enrolled patients was PD in 12 (median # of cycles = 4), SD in 17 (median # of cycles = 12), and PR in 8 (median # of cycles = 15.5). Clustering analysis showed 9/12 paired primary and metastatic tumors were tightly grouped together, indicating the 100-gene expression profiles were conserved within pairs. There was no statistically significant clustering, indicative of an expression bias, of the *KRAS* wt tumors within the TCGA dataset. Using SAM at a FDR $\leqslant$ 11%, patients with PD had significant upregulation of *ERBB2*, but not *EGFR*, and *RAD51*, identified by DAVID analysis to be significantly involved (p = 0.0012) in the ErbB signaling pathway and DNA damage repair, respectively. Patients with PD also displayed marked upregulation of *MLPH*, *KLK6*, *MYRF*, and downregulation of *KLK10* and *TM4SF4*.
Conclusions: In this phase II biomarker study, early progression as best response to Pmab was documented in 32% of cases and was associated with distinct expression of 7 genes, including *ERBB2* and *RAD51*, as possible markers of inherent resistance to EGFR therapy.
No conflict of interest.

2400 POSTER

Novel molecular assay system for accurate lymph node staging in colorectal cancer patients: Results of prospective multicenter study in Japan (Japanese OSNA® Colorectal Cancer Study Group)

T. Naohira[1], N. Tomita[1]. [1]*Hyogo College of Medicine, Department of Surgery, Nishinomiya Hyogo, Japan*

Background: Occult metastases detected in node-negative patients point to lower survival rates. To improve patients' prognosis, treatment is required based on more accurate lymph node (LN) staging than provided by the standard histopathological method. The one-step nucleic acid amplification (OSNA®) assay is a novel molecular testing system for detecting LN metastases of colorectal, breast and gastric cancer. This OSNA assay allows assessing the metastases of a whole lymph node by homogenizing LN and detecting clinically relevant metastases quantified based on CK-19 mRNA copy number. In this study we investigated whether routinely classified patients can be upstaged by using OSNA assay results.
Patients and Methods: 3359 LNs from 159 clinically N0 and N1 colorectal cancer patients were collected from 11 institutes: Osaka Univ., Hyogo College of Medicine, Suita Municipal Hospital, Surugadai Nihon Univ. Hospital, Oita Univ., Mino City Hospital, Sapporo Medical Univ., Tochigi Cancer Center, Tokyo Women's Medical Univ., Kansai Rosai Hospital, and Osaka Medical Center for Cancer and Cardiovascular Diseases. All LNs were examined by one-slice H&E staining histopathology and staged according to the Japanese guideline (7th edition, Japanese Society for Cancer of the Colon and Rectum). In addition, when the LN was larger than 3 mm, it was sliced and half of it was examined by OSNA assay. We investigated the upstaging rate for stageI, II, and IIIa patients, and also characterized upstaged patients by stageII high-risk factors (T size, lympho-vascular invasion, and number of detected LNs).
Results: 2 to 25 (mean; 9.1) LNs per patient were examined by OSNA (total 1439 LNs). In total, 12.5% (18/159) were upstaged with OSNA results. 3.1% (1/32) of stageI and 18.3% (11/60) of stageII were upstaged to stageIIIa, and 12.8% (6/47) of stageIIIa were upstaged to stageIIIb. All upstaged histology stageII patients have at least one high-risk factor, and 45% (5/11) of them have more than two.
Conclusion: OSNA assay is a novel molecular system for detecting colorectal cancer LN metastases. This study confirmed that OSNA provides more accurate lymph node staging than standard histopathology. Future follow-up studies of the upstaged patients in this study will reveal the clinical benefit of the OSNA assay for colorectal cancer patients.

Effects of intraluminal chemotherapy on colorectal cancer − study in an orthotopic murine model

J. Bhullar[1], G. Subhas[1], A. Damadi[1], J. Tilak[1], M. Decker[2], B. Silberberg[2], V. Mittal[1]. [1]*Providence Hospital & Medical Centers, General Surgery, Southfield, USA;* [2]*Providence Hospital & Medical Centers, of Patient Care Research, Southfield, USA*

Introduction: Previously, intraluminal chemotherapy was used as an adjunct to surgery to decrease tumour micro metastasis. Theoretically, transanal chemotherapy offers benefits over conventional chemotherapy as it acts directly on the mucosal surface where the tumour transformation takes place. The purpose of our study was to evaluate the effects of transanal chemotherapy in a true orthotopic colorectal cancer murine model for subsequent potential application in humans.
Material and Methods: An intraluminal-mucosal orthotopic colon cancer murine model was made by doing transanal low dose mucosal coagulation, using a specially designed electrode, 2 cm inside the anus. Followed by transanal instillation of LS174T human colon cancer cells($1x10^6$) in NOG mice. Control, 5FU, Irinotecan and Oxaliplatin groups had 10 mice each. Treatment groups underwent weight adjusted 3 doses of alternate day transanal drug instillation after intraluminal tumour was confirmed by Coloview-mouse colonoscope.
Results: Control group showed a mean survival of 3.5wks, tumour size of 14±4 mm with widespread metastasis. 5FU group had an increased mean survival of 12wks, disappearance of primary tumour in 7 mice and mean tumour size of 0±3 mm with decreased metastasis. The Irinotecan and Oxaliplatin groups showed increased survival of 5wks and 6.5wks with tumour sizes of 5±2 mm and 3±2 mm respectively.
Conclusions: Transanal chemotherapy shows promising effects on colonic tumour with considerably decreased primary tumour size and increased survival. This treatment option could be applied to patients with colonic dysplasia, rectal tumours and obstructing colonic tumours as a bridge to surgery. This is the first report of effects of transanal chemotherapeutic agents in a true orthotopic colorectal cancer model.
No conflict of interest.

2402 POSTER

Identification of novel driver genes for colorectal cancer

R. Cormier[1], B.L.N. Than[1], L. Zhao[1], P.M. Scott[1], K.A.T. Silverstein[2], Y. Zhang[2], J.A.C.M. Goos[3], R.J.A. Fijneman[3], G. Meijer[3]. [1]*University of Minnesota Medical School, Biomedical Sciences, Duluth, USA;* [2]*University of Minnesota, Supercomputing Institute, Minneapolis, USA;* [3]*VUMC Medical Center, Pathology, Amsterdam, The Netherlands*

Background: Using our *Sleeping Beauty (SB*) model system we have been able to effectively identify more than 100 low penetrance common insertion site (CIS) drivers of colorectal cancer (CRC), confirming transformation phenotypes for many of these CIS genes when disrupted *in vitro* in 2D and 3D cell culture; *in vivo* in mouse models; and in human CRC. Here, we present studies of two novel classes of CRC driver genes. *First,* the *ion channel* genes *KCNQ1* and *CFTR*, high frequency CIS genes identified in multiple *SB* screens. *Second*, *fusion oncogenes*, a class of mutations that include three CIS genes, *RSPO2*, *RSPO3,* and *PTPRK* that form fusion genes in up to ~10% of human CRCs. We extend our previous work by identifying more than 400 new fusions in stage IV CRC.
Materials and Methods: *Ion Channel Genes:* Knockout (KO) alleles of *Kcnq1* and *Cftr* were introgressed into the Apc^{Min} model, followed by extensive tumour and tissue phenotyping, plus *in vitro* studies employing intestinal organoid cultures. Gene expression studies employing Illumina Bead Arrays were conducted and results confirmed by qRT-PCR. Pathways were analysed by Ingenuity Pathway Analysis and Gene Set Enrichment Analysis. The role of *KCNQ1* and *CFTR* in human CRCs was examined by Immunohistochemisty.
Fusion Oncogenes: Twenty stage IV CRC liver metastases (plus matching normal tissue, and primary cancer) samples were analysed by RNA Seq and deFuse. Confirmation of expression was confirmed by Nanostring counting and qRT-PCR, followed by functional validation of fusions *in vitro*.
Results: (I) Ablation of either *KCNQ1* or *CFTR* caused a significant enhancement in mouse tumour phenotypes, including a significant increase in intestinal tumour multiplicity, the development of adenocarcinomas in the proximal small intestine, inflammation in the rectum, stomach tumours, and pancreatic abnormalities. Gene expression studies and pathway analyses identified a large number of genes regulated by *KCNQ1* and *CFTR,* including many genes involved in immune responses and inflammation. Importantly, there was significant overlap between *KCNQ1* and *CFTR* target genes. Notably, loss of expression of KCNQ1 was associated with a reduction in median overall survival of 23 months in CRC patients following hepatic resection.
(II) More than 400 fusion genes were identified, including one fusion transcript that was found in 25% of the samples. Data will be presented to confirm whether this high frequency fusion is a driver of CRC metastasis.
Conclusions: The ion channel tumour suppressor genes *KCNQ1* and *CFTR*, along with high frequency fusion oncogenes identified in CRC liver metastases offer novel prognostic predictors and therapeutic targets for patients with advanced CRC.
No conflict of interest.

2403 POSTER

CD163 gene expression correlates with thymidine phosphorylase expression in colorectal cancer

E. Bexe Lindskog[1], B. Gustavsson[1], Y. Wettergren[1]. [1]*Sahlgrenska University Hospital Institute of Clinical Sciences, Surgery, Gothenburg, Sweden*

Background: Tumour-associated macrophages (TAMs) are macrophages with an M2-polarization, which differs from the regular M1-polarization associated with pro-inflammatory cytokines and microbicidal/tumouricidal activity. M2 macrophages instead have tumour promoting properties and promote tissue remodelling and angiogenesis. They secrete several growth factors and release anti-inflammatory cytokines. CD163 is a scavenger receptor expressed by M2, but not by M1, macrophages. The aim of this study was to correlate CD163 expression to clinical and pathological parameters. We also wanted to evaluate the relation between CD163 and thymidine phosphorylase (TP) which is an enzyme predominantly expressed in macrophages. We have previously reported that high TP gene expression relate to high number of positive nodes and a worse N stage, indicating a prognostic value.
Material and Methods: CD163 gene expression was analysed by real-time quantitative polymerase chain reaction in 254 tumour samples. All patients underwent radical surgery for colon (n = 139) or rectal (n = 115) adenocarcinoma in stage III. Tumour TP gene expression values were available from a previous study.
Results: The median age of the patients was 64 (interquartile range 57−75) years with an even gender distribution. The mean ± standard deviation of the relative CD163 gene expression was 0.29±0.52. No difference in

CD163 gene expression was seen according to age, gender or tumour location. T stage was not related to CD163 expression. CD163 expression in tumours correlated with lymph node staging, with higher expression relating to a higher number of positive nodes ($r = 0.15$, $p < 0.05$) and a worse N-stage ($p < 0.01$). The CD163 expression in rectal tumours of patients subjected to preoperative radiotherapy was significantly higher compared to tumours of non-irradiated patients ($p < 0.01$). There was a positive correlation between CD163 and TP gene expression ($r = 0.25$, $p < 0.01$).
Conclusions: Higher intratumoural CD163 expression was related to worse N stage and tumour grade and thereby associated with a worse prognosis. These findings are in line with results found in other cancer types. There was a positive correlation between CD163 and TP gene expression indicating that TP expression in a tumour microenviroment is partly generated by M2 macrophages.
No conflict of interest.

2404 POSTER

Establishing a diagnostic algorithm for HER2 amplification in colorectal cancer: The HERACLES-DGX study

E. Valtorta[1], C. Martino[2], F. Penault-Llorca[3], G. Viale[4], M. Risio[5], M. Rugge[6], W. Grigioni[7], J. Noè[8], S. Marsoni[2], M. Gambacorta[1].
[1]Ospedale Niguarda Ca' Granda, Department of Pathology, Milano, Italy; [2]Fondazione del Piemonte per l'Oncologia − IRCCS, Clinical Trial Coordination Unit, Candiolo (TO), Italy; [3]Centre Jean Perrin, Department of Pathology, Clermont-Ferrand, France; [4]European Institute of Oncology − IEO, Department of Pathology, Milano, Italy; [5]Fondazione del Piemonte per l'Oncologia − IRCCS, Department of Pathology, Candiolo (TO), Italy; [6]Università degli Studi di Padova, Department of Pathology, Padova, Italy; [7]Policlinico Sant'Orsola Malpighi, Department of Pathology, Bologna, Italy; [8]F.Hoffman-La Roche, Oncology Biomarker Development, Basel, Switzerland

Background: We have identified the amplification of *HER2* occurring in 3−5% of genetically unselected colorectal cancer (CRC) as a potential onco-driver and marker of *de novo* resistance to anti-EGFR therapy in patients for whom other known genetic alterations conferring resistance to cetuximab were excluded. We have also shown that HER2-positive patient-derived CRC xenografts are impressively sensitive to anti-HER2 combinations (Bertotti et al., Cancer Discov 2011). Accurate HER2 assessment is crucial for patient selection for anti-HER2 therapy. Since the same scoring criteria for HER2 testing are not automatically applicable to different cancer types, as learned from breast and gastric cancer, we launched a retrospective study to establish a specific HER2 scoring in CRC.
Methods: CRC samples were centrally evaluated for HER2 expression using Ventana 4B5 antibody (V) and Dako HercepTest (D) HER2 immunohistochemistry (IHC) assays. Samples were scored positive if a moderate or intense basolateral or complete membrane staining was present. *HER2* gene amplification was tested by Ventana Inform Platform silver *in situ* hybridisation (SISH) using normal colon tissue as internal negative control. Samples with a *HER2*:CEP17 ratio >2.0 were considered amplified. Twenty samples were also tested by fluorescence ISH (FISH) (Abbott).
Results: 348 formalin-fixed, paraffin-embedded samples from 293 patients were centrally analysed and reviewed by a consensus panel (CP) of independent pathologists (MG, FP-L, GV). V yielded an 11.3% positivity (2+/3+, n = 33/293), of which 39.4% was amplified by SISH (n = 13/33). D staining bore a positivity rate of 5.5% with an 81.3% SISH confirmation (n = 16/293 and n = 13/16, respectively). Overall *HER2* amplification was detected in 5.1% of KRAS-WT and in none of the KRAS-mutated patients, suggesting mutual exclusion of the two mutations. SISH/FISH concordance was 100% (N = 20).
Conclusions: The CP defined HER2-positivity as: IHC 3+ and/or SISH/FISH amplification in more than 50% of cells, with central SISH re-testing in equivocal cases (IHC 2+ or heterogeneous 3+ cases; IHC 0 and 1+ cases were excluded). This practical algorithm is currently used for selecting HER2-positive cases for the HERACLES Phase II trial assessing the efficacy of the combination of lapatinib and trastuzumab in chemotherapy- and cetuximab-resistant patients.

2405 POSTER

Next generation sequencing reveals high concordance for recurrent somatic mutations in primary and matched metastasis from patients with colorectal cancer

S. Vignot[1], G. Frampton[2], C. Lefebvre[1], R. Yelensky[2], A. Bardier[3], V. Lazar[1], V. Miller[2], P. Stephens[2], J.C. Soria[1], J.P. Spano[3]. *[1]Institut Gustave Roussy, INSERM U981, Villejuif, France; [2]Foundation Medicine, Cambridge, USA; [3]GH Pitié Salpêtrière, Paris, France*

Background: Characterization of the genomic changes that drive an individual patient's disease is critical in the management of many cancers, including colorectal cancer (CRC). Spatial and temporal heterogeneity in mutational status can represent a major issue for personalized medicine. We undertook the present study to determine, using next generation sequencing (NGS) technology, the extent of molecular variability between primary tumors and matched metastasis for CRC with a special focus on known recurrent somatic mutations with established role in the pathogenesis of CRC.
Material and Methods: Surgical samples from primary and matched metastatic tumor pairs plus adjacent normal tissue from patients (pts) with metastatic CRC were analyzed using a targeted NGS assay in a CLIA laboratory (Foundation Medicine). Genomic libraries were captured for 3,230 exons in 182 cancer-related genes plus 37 introns from 14 genes often rearranged in cancer and sequenced to an average median depth of 778X with 99% of bases covered >100X.
Results: 13 pts were included, 11 had received chemotherapy between primary and metastasis surgery, either as adjuvant treatment or as first line chemotherapy at relapse, including anti-angiogenic agent for 2 pts. Among the 26 samples, 191 somatic alterations were identified including mutations in genes previously characterized to be altered in CRC (recurrent mutations) such as APC (13 pts), TP53 (11 pts), KRAS (7 pts), SMAD4 (3 pts). The total number of alterations between primaries (95) and metastasis (96) was remarkably similar. Primary and metastatic tumors from the same patient demonstrated 77% global concordance for mutations. The concordance rate was 86% for 12 known recurrent mutations in CRC. No discrepancies in KRAS status were in particular observed between primary tumor and metastasis.
Conclusions: These results suggest that genomic profiles of primary tumor can identify the key somatic alterations present in matched CRC metastases and therefore is a suitable specimen for clinical decision making in the majority of cases. Our data does not support the routine need for a new biopsy upon first recurrence since variability in recurrent mutations is low.
Conflict of interest: *Other substantive relationships: GF, RY, VM and PS are employees of Foundation Medicine and all receive stock compensation*

2406 POSTER

Exploitation of colorectal carcinoma microenvironment shows a central anti-cancer role for FcgRIII+ macrophage and CD8+ cells and auxiliary role for natural killer cells

G. Sconocchia[1], S. Eppemberger[2], I. Zlobec[3], G. Iezzi[4], G.C. Spagnoli[4], L. Tornillo[2], S. Ferrone[5], L. Terracciano[2]. *[1]Translational Pharmacology, Biomedicine, Rome, Italy; [2]Pathology, Basel, Switzerland; [3]Pathology, Bern, Switzerland; [4]Surgical Research and Hospital Management, Biomedicine, Basel, Switzerland; [5]Harvard Medical School, Surgery, Boston, USA*

Background: Convincing evidence suggests that T lymphocytes infiltration in the CRC microenvironment improves survival in colorectal carcinoma (CRC) patients (pts). Conversely, the importance of innate immune cell inflammation in the CRC milieu is unclear.
Materials and Methods: We investigated the clinical impact of macrophage and NK cell based inflammation in CRC pts utilizing a tissue microarray composed of 1420, clinically well documented, CRC lesions by immunohistochemistry. Innate and NK cell infiltration were studied utilizing flow cytometry analysis of freshly removed CRC lesions.
Results: We found homogeneous infiltrations of CRC lesions by CD8+ and CD4+ T lymphocytes as well as CD68+ tumor associated macrophages (TAMs). Further phenotypic analysis showed that TAMs were composed of 2 distinct populations: CD16+HLA-DR−CD33+ but negative for NK cell markers and CD16−CD33+HLA-DR+/−. Notably, NK cells slightly infiltrated CRC lesions. We found NK cell infiltration only in 132 of 423 CRC lesions evaluable for CD56+ cell infiltration. Then, we investigated the clinical impact of T and innate cell infiltration in the CRC milieu. As expected, pts with >10 positive cells per lesion survived significantly longer ($P = 0.0002$) than CRC pts with $\leqslant$10 positive T cells. Similarly, only pts with an infiltration of CD16+ TAMs >30 cells survived significantly longer ($P = 0.0005$) than pts with CD16+ TAMs infiltration less than 30 cells and CD16− TAMs regardless their level of infiltration. CD16+ TAMs infiltration resulted to be a positive,

independent prognostic factor in CRC pts. In contrast, NK cells regardless their level of CRC infiltration did not affect CRC pts survival. To test the hypothesis whether NK cells could mediate an indirect clinicopathological effect in the development of CRC, perhaps potentiating the beneficial effect of CD3+ T cells, we compared the clinical outcome of CD8+, CD3+, or CD4+ cell infiltration in the presence or absence of NK cells on CRC pts survival. In univariate analysis, within 5 years follow-up, only CRC pts with NK and CD8+ T cell infiltration had the longest overall survival (P = 0.007), which declined after 5 years (P = 0.03), suggesting that NK cells specifically increased the anti-CRC effects of CD8+ T cells.
Conclusions: This study, for the first time, provides evidence that NK cell based inflammation in the CRC microenvironment improves the anti-CRC effects of CD8+ T cell based inflammation in CRC pts at clinical level.
No conflict of interest.

2407 POSTER

Molecular biomarkers for a prognostic stratification of K-RAS wild type colorectal cancer patients receiving irinotecan–cetuximab: Preliminary results of a prospective study

M. Scartozzi[1], R. Giampieri[1], A. Mandolesi[2], K.M. Abouelkhair[3], C. Loretelli[4], M. Del Prete[4], L. Faloppi[4], M. Bianconi[4], E.M. Ibrahim[3], S. Cascinu[4]. *[1]Azienda Ospedaliera Regionale Torrette, Clinica di Oncologia Medica, Ancona, Italy; [2]Azienda Ospedaliera Regionale Torrette, Anatomia Patologica, Ancona, Italy; [3]International Medical Center, Oncology Department, Jeddah, Saudi Arabia; [4]Azienda Ospedaliera Regionale Torrette, Clinica di Oncologia Medica, Ancona, Italy*

Background: Translational research identified numerous putative markers for a 'beyond-k-ras' selection of colorectal cancer patients receiving cetuximab, but none of these entered clinical practice mainly because prospective validation is lacking.
The aim of our study was to evaluate whether a panel of biomarkers, prospectively analysed may be able to predict patients' clinical outcome more accurately than K-RAS status alone.
Material and Methods: Metastatic, K-RAS wild type colorectal cancer patients, candidate to receive second/third-line cetuximab with chemotherapy have been prospectively allocated, after informed consent, into 2 groups on the basis of their genetic profile: favourable (BRAF and PIK3CA exon 20 wild type, EGFR GCN $\geqslant$2.6, HER-3 Rajkumar score $\leqslant$8, IGF-1 immunostaining <2) and unfavourable (any of the previous markers altered or mutated). All patients received cetuximab treatment as planned by treating physician who was unaware of biomarkers results. To detect a difference in terms of response rate (RR) among patients with an unfavourable profile (estimated around 25%) and patients with a favourable profile (estimated around 60%), assuming a probability alpha of 0.05 and beta of 0.05, required sample size will be 46 patients.
Results: Thirty-one patients have been enrolled, most patients (27, 86%) received cetuximab as third-line. Eleven patients (35%) were allocated to the favourable profile and 20 patients (75%) to the unfavourable profile. Patients with the unfavourable profile showed 1 BRAF mutation, 2 PIK3CA exon 20 mutations, 12 cases of EGFR GCN <2.6, 13 cases of HER-3 and 11 cases of IGF-1 overexpression respectively. RR in the favourable and unfavourable group was 7/11 (64%) and 1/20 (5%) (p = 0.008) respectively. The favourable group also showed an improved median TTP (8 months vs. 2.6 months, p = 0.0007) and OS (16 months vs. 6 months, p = 0.0002).
Conclusions: Our results suggest that prospective selection of candidates for cetuximab may be able to improve clinical outcome in patients with a favourable profile. This approach, if confirmed, may also allow an early switch to alternative treatment in patients with an unfavourable profile.
No conflict of interest.

2408 POSTER

Transcript profiling of patient-derived (PD) colorectal cancer (CRC) xenografts for the identification of biomarkers for regorafenib (REG; BAY 73-4506)

R. Adams[1], R. Schmieder[2], J. Hoffmann[3], M. Becker[4], A. Rosenthal[5], J. Mueller[6], D. Zopf[7]. *[1]Bayer Pharma AG, Berlin, Germany; [2]Bayer Pharma AG, TRG ONC/GT-CCA, Berlin, Germany; [3]EPO-Berlin-Buch GmbH, Oncology, Berlin, Germany; [4]EPO-Berlin-Buch GmbH, Oncology, Buch, Germany; [5]Signature Diagnostics AG, Management, Potsdam, Germany; [6]Bayer Pharma AG, CMR-TD Technologies, Berlin, Germany; [7]Bayer Pharma AG, TRG ONC/GT-I&ADC, Berlin, Germany*

Background: REG is an oral multi-kinase inhibitor approved in the USA for treatment of metastatic CRC after failure of other standard therapies.
REG targets oncogenesis, tumor angiogenesis and maintenance of tumor microenvironment signalling by inhibiting multiple protein kinases, eg, VEGFR 1−3, TIE2, KIT, RET, PDGFR and FGFR. In preclinical studies, REG inhibited the growth of PD CRC xenografts and prolonged time to tumor progression in a mouse model of CRC liver metastases. Anti-tumor activity did not correlate with mutational status of known oncogenes associated with CRC (eg, *KRAS*, *APC* and *CTNNB1*).
The objective of this study (sponsored by Bayer HealthCare) was to try to identify biomarkers for REG by looking at genes possibly involved in resistance to treatment.
Materials and Methods: Transcript profiles − generated from RNA isolated from xenografts grown subcutaneously in mice and hybridized to human Affymetrix Gene 1.0 ST Arrays in quintuplicate − of 6 PD CRC models were compared: 1 from a mucinous CRC and not responsive to REG (Co8541); 5 REG-sensitive models.
For a transcript to be considered significantly differentially expressed, a p-value of <0.01, a false discovery rate (FDR) of <0.05 and a >5 fold change was needed in up- or down-regulation in all comparisons of non-responsive *vs* individual responsive tumor samples.
Gene ontology term enrichment and pathway analysis was done comparing resistant and sensitive groups respectively.
Results: The expression profile and clustering behaviour of Co8541 differed substantially from the other 5 models, with 15 genes significantly differentially expressed. Gene ontology term enrichment and pathway analysis showed several enriched processes and pathways related to inflammation in the insensitive *vs* sensitive models. Selective overexpression of the *COX2* gene, previously associated with colon tumorigenesis, was seen in the non-responsive model (p=1E-13, FDR=1E-10; fold change=10.3). Selective overexpression of the *MUC2* gene, implicated in resistance to anticancer drugs, in the non-responsive model was also detected, which is consistent with histological characterisation of this model and with published immunohistochemical analyses of mucinous CRC samples.
Conclusion: *MUC2* and *COX2* may play a role in resistance of mucinous CRC to REG. To further correlate these genes with resistance to REG, profile analyses of additional PD CRC models and confirmatory immunohistochemical analyses are in progress. Results will be presented.
Conflict of interest: *Ownership: (stock ownership) Bayer, EPO, Signature Diagnostics. Advisory board: n/a. Board of directors: n/a. Corporate-sponsored research: n/a. Other substantive relationships: (employee) Bayer Pharma AG, EPO-Berlin-Buch GmbH, Signature Diagnostics*

Background: Approximately 20% of colon carcinoma patients classified as lymph node negative by standard histopathology will suffer from recurrence, possibly due to undetected lymph node metastases. A new diagnostic semi-automated system, One Step Nucleic Acid Amplification (OSNA), detects cytokeratin (CK) 19 mRNA in lymph node metastases. The objective of this prospective, European, multicenter study was to assess whether histopathological pN0 patients can be upstaged to stage UICC III by OSNA.
Material and Methods: From patients who were classified as lymph node negative after standard histopathology (single haematoxylin & eosin (H&E) slice), the lymph nodes were subjected to OSNA analysis. An OSNA result revealing a CK19 mRNA copy number exceeding 250 was regarded as positive for lymph node metastases based on previous threshold investigations.
Results: In total, 1594 pN0 lymph nodes from 103 colon carcinomas (median lymph node/patient: 14, range: 1−46) were analyzed with OSNA. From 103 pN0 patients 26 had OSNA positive lymph nodes, resulting in an upstaging rate of 25.2%. Hereunder were 6/37 (16.2%) stage UICC I and 20/66 (30.3%) stage UICC II. Overall, 38 lymph nodes were OSNA positive: nineteen patients had 1, three had 2, three had 3, and one patient had 4 OSNA positive lymph nodes.
Conclusion: OSNA resulted in an upstaging of over 25% of initially lymph node negative patients after H&E analysis. OSNA is a standardized, observer-independent technique and may be more sensitive due to allowing the analysis of the whole lymph node. Therefore, the use of OSNA avoids

sampling bias due to not investigated lymph node tissue and could result in a more accurate staging in colon carcinoma patients.

Hsa-miR-31-3p expression in FFPE tumor samples as a predictor of anti-EGFR response in patients with metastatic colorectal cancer (mCRC)

G. Manceau[1], S. Imbeaud[2], N. Mosakhani[3], R. Thiébaut[4], F. Liebaert[4], J.L. Van Laethem[5], P. Demetter[6], B. Chibaudel[7], T. André[8], P. Laurent-Puig[1]. [1]*Université Paris-Descartes INSERM, UMR-S775, Paris, France;* [2]*Université Paris-Descartes INSERM, UMR-S674, Paris, France;* [3]*Haartman Institute University of Helsinki, Department of Pathology, Helsinki, Finland;* [4]*INTEGRAGEN SA, Evry, France;* [5]*Erasme University Hospital-ULB-Brussels, Gastroenterology-GI Cancer Unit, Brussels, Belgium;* [6]*Erasme University Hospital-ULB-Brussels, Department of Pathological anatomy, Brussels, Belgium;* [7]*Hôpital Saint-Antoine, Department of Medical Oncology, Paris, France;* [8]*GERCOR − Hôpital Saint-Antoine, Department of Medical Oncology, Paris, France*

Background: In mCRC, KRAS mutations are associated with anti-EGFR antibodies resistance. Expression level of miR-31-3p was associated with the progression free survival (PFS) on frozen tumor of KRAS wild type (WT) mCRC patients treated with anti-EGFR. To explore the role of miR-31-3p,we studied and validated the association of miR-31-3p expression level with PFS on formalin fixed paraffin embedded (FFPE) tumor samples and identified some target genes of miR-31-3p in a CRC context.
Material and Methods: Association between PFS and miR-31-3p expression level on FFPE samples was performed on two series of patients 1/35 KRAS WT patients treated with cetuximab or panitumumab (PMB) based chemotherapy, 2/39 KRAS WT patients treated with PMB and irinotecan as third-line from a phase II clinical trial. Identification of miR-31-3p target genes was conducted on Caco-2, Colo205 and Colo320HSR cell lines which were transfected with miR-31-3p mimic or control mimic. Total RNA was extracted for an expression array analysis using linear models for micro-arrays analysis. A miRNA predictive target database including 6 available databases was created. Identified target genes were validated on tumors sample of the second series of 39 patients.
Results: Correlation between miR-31-3p expression value of 15 frozen and the corresponding FFPE samples was done and a linear regression was determined with r^2=0.98. We built a nomogram allowing to calculate a risk score of progression based on miR-31-3p expression based on RNA extracted from paraffin embedded tissues. A significant link between survival and the expression of the miR-31-3p was established in both independent FFPE series by a Cox model. Using expression array and miR prediction databases we identified 25 direct putative target genes and 27 genes up-regulated in miR-31-3p overexpressing cells. 45 out of these 52 genes were validated with RT qPCR on tumor samples of PMB treated patients. Expression level of 2 putative direct target genes was anti-correlated with miR-31-3p expression level and was associated with PFS.
Conclusions: MiR-31-3p expression level is associated with PFS in mCRC patients in frozen and FFPE samples. The nomogram described is the first tool to select individuals with a WT KRAS tumor for anti-EGFR therapy. Furthermore, this study identified 2 new genes of interest in mCRC.

VEGF and eNOS gene polymorphisms as predictors of efficacy of bevacizumab-based chemotherapy in patients with metastatic colorectal cancer

P. Ulivi[1], A. Passardi[2], G. Marisi[1], F. Casacci[2], E. Scarpi[3], M. Valgiusti[2], D. Calistri[1], M. Del Re[4], G.L. Frassineti[2], D. Amadori[2]. [1]*Istituto Scientifico Romagnolo per lo Studio dei Tumori, Biosciences Laboratory, Meldola, Italy;* [2]*Istituto Scientifico Romagnolo per lo Studio dei Tumori, Medical Oncology Unit, Meldola, Italy;* [3]*Istituto Scientifico Romagnolo per lo Studio dei Tumori, Unit of Biostatistics and Clinical Trials, Meldola, Italy;* [4]*Clinical and Experimental Medicine University of Pisa, Clinical Pharmacology Unit, Pisa, Italy*

Background: Bevacizumab (B) + chemotherapy (CT) is a widely used therapeutic option for the first-line treatment of metastatic colorectal cancer (mCRC). However, molecular predictors of B efficacy have not yet been identified. We verified the role of specific VEGF and eNOS polymorphisms as predictive markers of B efficacy in mCRC patients.
Methods: 149 patients enrolled onto the phase III prospective multicentric randomized ITACA (Italian Trial in Advanced Colorectal Cancer) trial were considered for this study. 74 patients received either FOLFIRI or FOLFOX plus B, while 75 patients received CT only. A peripheral blood sample was collected from each patient for genomic DNA extraction. Five VEGF and two eNOS polymorphisms (VEGF −2578 C/A, −1498 C/T, −1154 G/A, −634 G/C, +936 C/T, eNOS 894 G/T and eNOS VNTR 27bp 4a/b) were analyzed by direct sequencing, and one eNOS polymorphism (eNOS 786 C/T) was assessed by a Real Time PCR method. All the candidate genotypes were evaluated to identify a potential correlation with progression-free survival (PFS), overall survival (OS) (log-rank test) and objective response rate (ORR) (Chi-square test).
Results: In B-treated patients the presence of VEGF −634 GC genotype was associated with shorter PFS and worse ORR than the other genotypes. The presence of eNOS 894 GT genotype was associated with both shorter PFS and OS and with worse ORR, while the presence of eNOS 27bp 4ab genotype was correlated with shorter PFS and OS.

	Median PFS (95% CI)	Median OS (95% CI)	ORR (CR or PR/No. patients)
VEGF-634			
GC	8.6 (6.8–10.6)	17.8 (11.6-nr)	38.5% (10/26)
GG/CC	12.4 (9.6–14.1)	30.4 (21.8–36.7)	73.9% (34/46)
	p = 0.040	p = 0.118	p = 0.005
eNOS 894			
GT	9.1 (4.5–10.9)	17.8 (10.3–30.4)	42.96% (12/28)
TT/GG	12.6 (9.6–18.5)	31.6 (21.0–47.1)	72.7% (32/44)
	p = 0.024	p = 0.009	p = 0.013
eNOS VNTR 27bp			
4ab	8.4 (4.5–10.0)	21.0 (8.2–26.2)	50% (12/24)
4bb	12.3 (9.7–16.0)	30.4 (20.9–36.7)	66.7% (32/48)
	p = 0.023	p = 0.054	p = 0.174

No differences in terms of PFS, OS and ORR were observed in patients treated with chemotherapy only. Interaction testing between eNOS 894 G/T variants and treatment effect suggested that the association of eNOS 894 GT genotype with shorter PFS (p = 0.044), shorter OS (p = 0.025) and worse ORR (p = 0.047) was caused by the effect of B. Other investigated polymorphisms did not affect outcome.
Conclusions: VEGF −634 GC, eNOS VNTR 27bp 4ab and, in particular, eNOS 894 GT genotypes seem to be potentially negative predictive markers for B-based CT in mCRC patients.
No conflict of interest.

SLCO1B1 and SLC19A1 gene variants and irinotecan-induced rapid response and survival: A prospective multicenter pharmacogenetics study of metastatic colorectal cancer

X. Yuan[1], L. Huang[2], T. Zhang[3], C.H. Xie[4], X. Liao[2], Q.Q. Yu[2], J.P. Feng[5], J.G. Chen[6], A.H. Zang[7], K. Qin[2]. [1]*Tongji Cancer Center Tongji Hospital Tongji Medical College, Wuhan, China;* [2]*Tongji Hospital Tongji Medical College Huazhong University of Science and Technology, Oncology, Wuhan, China;* [3]*Cancer Center of Union Hospital Tongji Medical College Huazhong University of Science and Technology, Oncology, Wuhan, China;* [4]*Department of Radiation and Medical Oncology Zhongnan Hospital Wuhan University, Oncology, Wuhan, China;* [5]*Wuhan Pu-Ai Hospital Tongji Medical College Huazhong University of Science and Technology, Oncology, Wuhan, China;* [6]*Department of Surgery Wuhan 8th Hospital, Oncology, Wuhan, China;* [7]*Hubei Cancer Hospital, Oncology, Wuhan, China*

Background: Rapid response to chemotherapy in metastatic colorectal cancer (mCRC) patients (response within 12 weeks of chemotherapy) may increase the chance of complete resection and improved survival. Few molecular markers predict irinotecan-induced rapid response and survival. Single-nucleotide polymorphisms (SNPs) in solute carrier genes are reported to correlate with the variable pharmacokinetics of irinotecan and folate in cancer patients. This study aims to evaluate the predictive role of 3 SNPs in mCRC patients treated with irinotecan and fluoropyrimidine-containing regimens.
Material and Methods: Three SNPs were selected and genotyped in 137 mCRC patients from a Chinese prospective multicenter trial (NCT01282658). The chi-squared test, multivariable logistic regression model, and receiver operating characteristic analysis were used to evaluate correlations between the genotypes and rapid response. Kaplan–Meier survival analysis and Cox proportional hazard models were used to evaluate the associations between genotypes and survival outcomes.
Results: Genotype GA/AA **of** SNP rs2306283 of the gene *SLCO1B1* and genotype GG of SNP rs1051266 of the gene *SLC19A1* were associated with a higher rapid response rate (odds ratio [OR] =3.583 and

3.521, 95% CI =1.301–9.871 and 1.271–9.804, $p = 0.011$ and p = 0.013, respectively). The response rate was 70% in patients with both genotypes, compared with only 19.7% in the remaining patients (OR = 9.489, 95% CI = 2.191–41.093, Fisher's exact test $p = 0.002$). The rs2306283 GA/AA genotype was also an independent prognostic factor of longer progression-free survival (PFS) (hazard ratio = 0.400, 95% CI = 0.183–0.873, p=0.021). None of the SNPs predicted overall survival.

Conclusions: Polymorphisms of solute carriers' may be useful to predict rapid response to irinotecan plus fluoropyrimidine and PFS in mCRC patients.

No conflict of interest.

Table 1. Polymorphisms' association with RRR, PFS and OS

Genotype	n	RRR (%)	P	Median PFS (days)	P	Median OS (days)	P
rs2306283

CT/CC	20	5 (25.0)	0.868	89	0.498	501	0.293
rs2306283 (GA/AA) + rs4149056 (GG)	10	7 (70)		89		410	
others	76	15(19.7)	0.002*	111	0.736	501	0.840

RRR, rapid response rate; PFS, progression-free survival; OS, overall survival.
*Retained its significant association in multivariate analysis.

2413 POSTER

Prognostic significance of VEGFR-2 and 18F-FDG PET/CT SUVmax relative percentage co-reduction in patients with locally advanced rectal cancer treated with neoadjuvant therapy

C. Solé[1], F. Calvo[2], E. Alvarez[3], I. Peligros[3], P. Garcia-Alfonso[4], R. Herranz[4], J.L. Carreras[5]. *[1]Instituto de Radiomedicina, Radioterapia, Santiago, Chile; [2]Hospital General Gregorio Marañón, Oncología, Madrid, Spain; [3]Hospital General Gregorio Marañón, Anatomía Patológica, Madrid, Spain; [4]Hospital General Gregorio Marañón, Oncologia Medica, Madrid, Spain; [5]Hospital General Gregorio Marañón, Radiologia, Madrid, Spain*

Background: Vascular Endothelial Growth Factor Receptor-2 (VEGFR-2), Epidermal Growth Factor Receptor-1 (EGFR) and Cyclooxygenase-2 (Cox-2) stimulate key processes involved in tumor progression and are important targets for cancer therapeutics. 18F-fluorodeoxyglucose (18F-FDG)-positron emission tomography (PET)-computed tomography (CT) maximum standardized uptake value (SUVmax) is a marker of tumor metabolic activity. The purpose of this study was to measure SUVmax (ΔSUVmax%), VEGFR-2 (ΔVEGFR-2%), EGFR (ΔEGFR%) and COX-2 (ΔCOX-2%) percentage reduction after preoperative treatment for locally advanced rectal cancer (LARC) patients, and to correlate response with pathologic response [Tumor Regression Grade Rödel's scale (TRG)] and long-term clinical outcome.

Methods: VEGFR-2, EGFR and COX-2 was measured using a quantitative and qualitative compound immunohistochemistry analysis [Immunoreactive score (IRS score)] in the pretreatment endoscopic biopsy and definitive surgical specimen. A composite index using ΔSUVmax% and the 3 molecules was developed in order to stratify patients with metabolic and molecular response from non-responders. Cox proportional hazards models were used to explore associations between the tumor markers, disease-free survival (DFS) and overall survival (OS).

Results: Thirty-eight patients with a median follow-up of 69.3 months (range, 4.5−92) were analyzed.

Using the ΔVEGFR-2%/ ΔSUVmax% index, pathologic responders (TRG 3−4) and non-responders (TRG 0−2) were correctly identified in 13 of 19 (1 of these 6 non-responders died of disease progression), and 17 of 19 [Sensitivity 68%, specificity 89%, accuracy 79%, positive predictive value (PPV) 87%, negative predictive value (NPV) 74%]. On multivariate analysis, only ΔVEGFR-2%/ ΔSUVmax% responder index was associated with DFS (HR 0.15, p = 0.04) and OS (HR 0.19, p = 0.05).

Conclusions: LARC patients with a ΔVEGFR-2%/ ΔSUVmax% responder index are associated with improved overall outcomes. Determination of the optimal diagnostic cut-off level for this novel biomarker association should be explored. Evaluation within a clinical trial is required to determine whether selected patients could benefit from an VEGFR targeted therapeutic agent.

No conflict of interest.

Tumour infiltrating lymphocytes levels within colorectal liver metastases correlate with oncological outcomes

N. Curtis[1], J.N. Primrose[1], A.H. Mirnezami[1], G.J. Thomas[1], A. Bruce[1], S. Pugh[1], C.H. Ottensmeier[1]. *[1]University of Southampton, Cancer Sciences Unit, Southampton, United Kingdom*

Introduction: The study of tumour infiltrating lymphocytes (TIL) within resected colorectal cancer has been shown to offer new individualised prognostic information independent to standard radiological and histopathological staging systems. TIL within metastatic tissue has not been investigated but is highly relevant as case numbers and experience of surgically resecting colorectal liver metastases (CRLM) is increasing. This purpose of this study was to see if reported TIL findings were applicable to metastatic tissue.

Methods: A single centre, prospective, observational cohort study of consecutive patients undergoing CRLM resection with curative intent was performed. All patients were managed by a specialist multi-disciplinary team. Tissue microarrays were created in triplicate with 1 mm cores from matched primary (centre of tumour and invasive margin) and secondary tissue from each patient. $CD8^+$ and $CD45RO^+$ immunohistochemistry was performed in using standard practices. Samples were manually quantified and divided into TIL high and low groups using the overall mean TIL count. Overall and disease free survival was calculated using Kaplan–Meier analysis.

Results: 59 patients were recruited, 33 (56%) had liver metastases on presentation. All had undergone prior colorectal R0 resection with curative intent. Mean follow up from colorectal and metastasis resection was 66 and 42 months respectively. Three year overall and disease free survival following CRLM resection in the High vs. Low TIL groups was 69% vs. 22% and 62% vs. 18% respectively (p < 0.001). Five year overall and disease free survival was 58% vs. 0% and 41% vs. 0% (p < 0.001). In those that relapsed (69%), time to recurrence was double in the high group (12.3 vs. 5.5 months, p = 0.02). Mean TIL counts were double in overall and disease free survivors (310 vs. 164, p = 0.02; 351 vs. 174, p = 0.036). Positive correlation was seen in TIL counts in primary and CRLM tissues (p = 0.024) but no redundancy between CD8 and CD45RO markers was seen.

Conclusion: CD8+ and CD45RO TIL analysis within CRLM gives clinically useful prognostic information that correlates with oncological outcomes and is not available through current practice. High TIL counts are associated with improved overall and disease free survival and longer time to recurrence. This easily obtainable information may lead to individualisation of post operative prognosis, follow up and adjuvant treatment strategies.

No conflict of interest.

2415 POSTER

p38α: A key factor in CRC resistance

V. Grossi[1], A. Germani[2], G. Forte[1], A. Peserico[2], S. Murzilli[3], M. Liuzzi[4], G. Ingravallo[4], C. Simone[2]. *[1]IRCCS "De Bellis", Cancer Genetics Laboratory, Castellana Grotte (BA), Italy; [2]Consorzio Mario Negri Sud, Laboratory of Signal-dependent Transcription, Santa Maria Imbaro (CH), Italy; [3]Consorzio Mario Negri Sud, Laboratory of Lipid Metabolism and Cancer Animal Care Facility Dept of Translational Pharmacology, Santa Maria Imbaro (CH), Italy; [4]University of Bari "A. Moro", Division of Pathological Anatomy DIM, Bari, Italy*

Background: Targeted molecular therapies in addition to standard chemotherapeutic treatments have significantly improved patient survival rates. However, development of chemoresistance often makes treatments for colorectal cancer (CRC) ineffective. Identifying the cellular mechanisms that lead to resistance is a crucial issue for improving CRC treatment and survival.

Material and Methods: In this work we tested p38α inhibitors in combination with molecularly-targeted drugs and chemotherapeutic agents in CRC cell lines *in vitro* and in CRC-xenografted nude mice, APCmin/+ mice and in the AOM/DSS colitis-associated carcinoma preclinical model. To this aim, animals were treated with the p38α inhibitor SB202190 alone or in combination with the MEK1 inhibitor PD0325901, the multikinase inhibitor Sorafenib or cisplatin (CDDP).

Results: We previously demonstrated that p38α is required to maintain CRC metabolism and recent studies identified p38α as a mediator of resistance to irinotecan and of impaired response to FOLFIRI therapy, while its inhibition sensitized resistant CRC cells to irinotecan and 5-fluorouracil. Our data show that p38 is activated in response to cisplatin treatment and mediates chemoresistance in HT29-xenografted tumors. MEK1 inhibition has been found to reduce CRC cell proliferation *in vitro* and to decrease tumor growth in xenograft models and we recently reported that MEK-ERK1/2 inhibition is followed by over-activation of the p38 MAPK pathway.

Here we found that p38a and MEK combined inhibition specifically induces apoptosis by enabling TRAIL signaling propagation through t-Bid and caspase 3, and fosters cell death in CRC cells. Sorafenib is reported to inhibit nine protein kinases, including BRAF, VEGF and the DGF-out conformation state of p38α. Our results show that the SB202190 (type I-p38a inhibitor) and Sorafenib (type II-p38a inhibitor) synergize at the molecular and biological level enhancing tumor growth inhibition and induction of apoptosis in CRC both *in vitro* and *in vivo*. The combined use of SB202190 and PD0325901, Sorafenib or CDDP significantly reduced tumor growth by inducing a higher degree of apoptosis compared to each single treatment.
Conclusions: Our data validate *in vivo* the combined inhibition of the p38α and ERK pathways or their association with chemotherapy as a promising approach to treat CRC. Moreover, they suggest that the phosphorylation status of p38 MAPK may be a marker of resistance in CRC.
No conflict of interest.

Notch and Delta-like 4 ligand (DLL4) expression in bevacizumab-treated colorectal cancer patients

F.V. Negri[1], C. Bozzetti[1], P. Crafa[2], C. Lagrasta[2], G. Pedrazzi[3], G. Gardini[4], I. Tamagnini[4], R. Porzio[5], G. Tomasello[6], A. Ardizzoni[1]. *[1]University Hospital, Medical Oncology Unit, Parma, Italy; [2]University Hospital, Department of Pathology, Parma, Italy; [3]University of Parma, Department of Neurosciences Unit of Medical Physics, Parma, Italy; [4]Istituto di Ricerca e Cura a Carattere Scientifico (IRCCS)-Arcispedale S. Maria Nuova, Pathology Unit, Reggio Emilia, Italy; [5]Hospital of Piacenza, Department of Onco-Hematology, Piacenza, Italy; [6]Ospedale Civile, Medical Oncology Division, Cremona, Italy*

Background: DLL4-induced Notch signalling has been found to mediate tumour-resistance to anti-vascular endothelial growth factor therapy by inducing the formation of large vessels and by activating multiple pathways in preclinical models and has recently emerged as an attractive target for angiogenesis-based cancer therapies. In order to investigate potential mechanisms of resistance to angiogenesis inhibitor bevacizumab, Notch and DLL4 expression was correlated with response and survival in a series of bevacizumab treated advanced colorectal cancer patients.
Material and Methods: Notch and DLL4 expression was evaluated by immunohistochemistry (IHC) on 67 primary colorectal cancer patients enrolled within randomized clinical trials assessing first-line bevacizumab plus chemotherapy. A control series of advanced colorectal cancer patients treated with chemotherapy alone was also examined.
Results: Notch positivity was localized to the cytoplasm or nucleus of malignant epithelial cells. In all, 12/63 (19%) evaluable primary tumours had a high Notch expression (IHC 3+). A cytoplasmic DLL4 immunoreactivity of large and small tumour vessels was observed in 21/46 (46%) and in 10/58 (17%) evaluable colorectal cancers, respectively. Seven of the 12 cases (58%) with high Notch expression experienced progressive disease compared with 5/51 (10%) Notch negative cases ($p < 0.01$). Median progression-free survival was 2.4 months for Notch positive cases compared with 12.2 months for Notch negative cases ($p < 0.01$). Median overall survival was 17.7 months for Notch positive cases compared with 30.8 months for Notch negative cases ($p < 0.01$). No correlation was found between Notch expression and clinical response in a smaller series of patients treated with chemotherapy without bevacizumab. No correlation was found between DLL4 expression and outcome.
Conclusions: Clinical trials investigating the therapeutic efficacy of bevacizumab in colorectal cancer did not explore the impact of DLL4-Notch pathway on response and clinical outcome. Our results might suggest the involvement of Notch pathway in mediating tumour resistance to bevacizumab in colorectal cancer patients.
No conflict of interest.

2417 POSTER

MET expression and prognostic effect in metastatic colorectal cancer (mCRC)

H. Kennecke[1], D.F. Schaeffer[2], Y. Yin[3], I.T. Tai[4]. *[1]Vancouver Cancer Centre BCCA, Vancouver BC, Canada; [2]Vancouver General Hospital, Pathology, Vancouver BC, Canada; [3]British Columbia Cancer Agency, Population Oncology, Vancouver BC, Canada; [4]British Columbia Genome Sciences Centre, Gastroenterology, Vancouver BC, Canada*

Background: MET is a transmembrane receptor tyrosine kinase (RTK) mediating downstream signaling in human malignancies. In clinical trials, high METexpression by immunohistochemistry is predictive of response to MET targeted therapy in lung, gastric and hepatocellular carcinomas. The objective of this study is to determine MET expression and prognostic effect in mCRC and to measure association with other biomarkers.
Methods: A previously well characterized tissue microarray of 96 patients with advanced colorectal cancer was stained for MET [SP44; Ventana® CONFIRM anti-total rabbit monoclonal antibody]. Immunohistochemical MET expression was scored as either absent (<10% stain), low (>10% to <50% of tumor cells with >1+ cytoplasmic staining) or high (>50% of tumor cells with >1+ cytoplasmic staining). Phosphorylated AKT (pAKT) was scored as negative (no staining) or positive (1, weak; 2, moderate; 3, intense). Kaplan–Meier survival analysis was conducted from diagnoses of distant disease to death [Overall Survival (OS)] and from early stage disease to relapse [Disease Free Survival (DFS)]. Fishers exact and chi-square tests were used to compare MET expression between primary and distant disease and association with biomarkers.
Results: Median age among 96 patients was 60 of which 34% had rectal cancer and 51% presented with early stage disease. A KRAS mutation was documented in 35%. MET expression was high in 45% and associated with a trend for inferior OS, Hazard Ratio 1.4, 95% CI: (0.92, 2.2), $p = 0.12$. MET was not prognostic of relapse in early stage disease. Among 28 cases with paired primary and metastatic tumors, MET status was concordant among 71%, $p = 0.051$. pAKT was positive in 65% and was associated with high MET expression, $p = 0.035$.
Conclusion: High MET expression is documented in a significant proportion of patients with colorectal cancer and is associated with a trend to inferior outcome in the advanced setting. High concordance of MET expression between primary and metastatic tumors was seen and high MET status was associated with activation of PI3KCA-AKT signaling. Results suggest that MET may be a relevant therapeutic target in mCRC. FISH analysis will be presented.

2418 POSTER

Ex-vivo activation of natural killer (NK) cell effector by cetuximab (CTX) is effective in patients (pts) with colorectal cancer (CRC)

T. Lecomte[1], M. Caulet[1], A. Payance[1], A. Aubourg[1], E. Sicard[2], C. Javaud[3], E. Dorval[4], H. Watier[5], G. Thibault[5]. *[1]CHU Trousseau, Sce Hepato Gastro Enterologie, Chambray Les Tours, France; [2]CHU de Tours, Laboratoire d'immunologie, Tours, France; [3]GLYCODE, Uzerche, France; [4]CHU Trousseau, Service d'hépatogastroentérologie et de cancérologie digestive, Chambray Les Tours, France; [5]CHU de Tours, Laboratoire d'immunologie Labex MabImprove, Tours, France*

Background: Antibody-dependent cellular cytotoxicity (ADCC) may play a role in antitumor activity of CTX. The efficacy of this is determined by the interaction of the Fc portion of the target cell-bound antibody and Fc receptors (FcγR) present on the immune effectors cells. This study aimed to evaluate the *ex vivo* immune response of NK cells from pts with CRC to CTX and panitumumab (PANI).
Material and Methods: Activation of NK cell from CRC pts and healthy donors (HD) was measured with a flow cytometry (FC)-based assays. FC was used to measure CD16 modulation and CD107a expression on NK cells incubated in microplates (10^5cells/well) sensitized with a saturating concentration (5 μg/mL) of 3G8 (mouse anti-FcγRIIIA), human myeloma (hm) IgG1, IgG2, CTX or PANI. The % and absolute number of peripheral blood CD3+ (T cells), CD19+ (B cells), CD4+, CD8+ and CD3−CD56+ cells (NK cells) were evaluated by FC after staining with fluorescent mAbs in 15 CRC pts before and after chemotherapy (CT) and in 5 HD.
Results: No difference was found between CRC pts and HD in terms of % of T, B, CD4+, CD8+ and NK cells. The number of each population was slightly decreased in CRC pts (compared to HD) and further after CT (in CRC pts), whereas the therapy did not modify the % of each sub-population. We observed CD16 modulation on 59% and 62% of NK cells from HD and CRC pts after hm IgG1 stimulation and on 60% and 50% of NK cells from HD and CRC pts after CTX stimulation, respectively. Whatever the group, CD16 modulation was significantly reduced after stimulation with hm IgG2 (30% and 17% of NK cells from HD and CRC pts, respectively. $p < 0.001$ compared to IgG1) and with PANI (8% and 7% of NK cells from HD and CRC pts, respectively. $p < 0.001$ compared to PANI). We observed CD107a expression on 14% and 11.5% of NK cells from HD and CRC pts after hm IgG1 stimulation and on 10% and 9% of NK cells form HD and CRC pts after CTX stimulation, respectively. In accordance with the CD16 modulation, CD107a expression was significantly reduced after stimulation with hm IgG2 (5% and 2.5% of NK cells from HD and CRC pts, respectively. $p < 0.001$ compared to IgG1) and with PANI (3% and 1% of NK cells from HD and CRC pts, respectively. $p < 0.001$ compared to PANI). The % of CD16 modulation and of CD107a expression on NK cells from CRC pts observed before and after 2 months of CT were very similar. The difference between CTX and PANI remained significative after CT.
Conclusion: These results suggest that this novel cell-based assay is able to predict ADCC effect of CTX.

Comparison between different scoring systems for pathological response in relation with clinical assessment in the EORTC liver metastases intergroup randomized phase III study 40983

C. Julié[1], E. Tanis[2], B. Nordlinger[3], M.E. Mauer[4], A. Roth[5]. [1]*CHU Ambroise Pare, Assitance Publique, Hopitaux de Paris;* [2]*EORTC Headquarters, FellowShip Programme Unit, Brussels, Belgium;* [3]*CHU Ambroise Pare, Assitance Publique, Hopitaux de Paris;* [4]*EORTC Headquarters, Statistics, Brussels, Belgium;* [5]*Hopitaux Universitaires de Geneve, Hug, Site de Cluse-Roseraie*

Background: The EORTC study 40983 demonstrated that perioperative chemotherapy with FOLFOX increases progression free survival compared to surgery alone for patients with resectable liver only metastases from colorectal cancer (ASCO 2007). The secondary endpoint overall survival results were reported (ASCO 2012). A retrospective central collection of tumor tissue was organized to assess pathological response and compare different scoring systems for the first time in a randomized study.
Methods: Pathological response (PR) was evaluated by one senior pathologist blinded from clinical data, according to Blazer's score (percentage of residual viable cancer cells), tumor regression grade according to Rubbia-Brandt (TRG), and tumor thickness at the tumor-normal interface (TTTNI). The results are presented by treatment arm and the correlation with radiological responses was assessed. Radiological response to preoperative chemotherapy was locally assessed using RECIST (version1.0) in the CT arm. No type I error adjustment was made for multiple testing.
Results: Tumor tissue (liver metastasis) was available for 89 patients with a R0-R1 resection achieved after surgery, 42 in the perioperative chemotherapy arm (CT arm) and 47 in the surgery alone arm (S arm). Patients' demographics and baseline disease characteristics were balanced between the two arms of this subset. As expected, there were more PR in the CT arm than in the S arm (Blazer 45.2% vs 25.5% $p = 0.07$, TRG 47.6% vs 19.1% $p < 0.01$, TTTNI<0.5 mm 41% vs 21.7% $p = 0.06$). In the S arm, while Blazer and TTTNI classified more than 21% of the patients as major response, TRG classified no patient as major response. In the table, correlation between RECIST and PR is provided for the CT arm. Spearman's rank correlation was significant for TRG only (0.4716, $p < 0.01$).

CT arm	RECIST response (N = 23)	RECIST no response (N = 19)
TRG		
partial response	11 (47.8%)	3 (15.8%)
major response	5 (21.7%)	1 (5.3%)
Blazer major response	12 (52.2%)	7 (36.8%)
TTTNI <0.5 mm	10 (43.5%)	6 (31.6%)

Conclusions: The TRG, which takes into account the extent of fibrosis, was the more accurate pathological score for evaluating tumor response, and the only one to correlate significantly with radiological response in our series. The new ongoing EORTC trial on resectable liver metastasis (BOS2) shall provide us with larger tissue sample sizes enabling us to correlate pathological response to DFS after targeted therapies.

2420 POSTER

Non-invasive detection and monitoring of plasma KRAS mutation status in advanced colorectal cancer using Therascreen® KRAS RGQ PCR

K.L. Aung[1], S. Mullamitha[2], J.W. Valle[2], M. Saunders[3], J. Theaker[4], J. Lauber[4], G. Ellison[5], A. Hughes[5], G. Brady[1], C. Dive[1]. [1]*Paterson Institute for Cancer Research, Clinical and Experimental Pharmacology, Manchester, United Kingdom;* [2]*The Christie NHS Foundation Trust, Medical Oncology, Manchester, United Kingdom;* [3]*The Christie NHS Foundation Trust, Clinical Oncology, Manchester, United Kingdom;* [4]*QIAGEN Manchester Ltd, Research and Development, Manchester, United Kingdom;* [5]*AstraZeneca Pharmaceuticals, Alderley Park, Cheshire, United Kingdom*

Background: Presence of *KRAS* mutations in tumor negatively predicts patients' response to cetuximab and panitumumab in advanced colorectal cancer (CRC). The FDA approved therascreen® KRAS RGQ PCR Kit (Qiagen) can detect six codon 12 and one codon 13 *KRAS* mutations. Limited data is available as to whether plasma *KRAS* mutation status can be assessed and longitudinally monitored in CRC using therascreen® KRAS RGQ PCR Kit.
Materials and Methods: Patients with advanced CRC undergoing palliative chemotherapy were prospectively recruited from the Christie Hospital, Manchester, UK between February 2011 and April 2012. The study was approved by a local research ethics committee. Plasma samples were collected before (TP1) and 6 weeks after (TP2) chemotherapy for each patient. *KRAS* mutation status in plasma was assessed using KRAS RGQ PCR. Tumor mutation status was examined by pyrosequencing and/or KRAS RGQ PCR.
Results: Matched tumor/plasma (taken at both TP1 & TP2) *KRAS* mutation data was available in 30 patients. Ten patients (33%) had *KRAS* mutations in tumor. Of those, 8 (80%) had the same mutation in TP1 plasma. Of 20 patients with *KRAS* wild type tumor, a *KRAS* mutation was found in TP1 plasma of one patient. Sensitivity of plasma *KRAS* mutation detection was 80% and specificity 95%. Concordance between TP1 plasma and tumour *KRAS* mutation status was 90%. Of 11 patients who achieved partial response to chemotherapy (by CT scan after 6 cycles of 2 weekly chemotherapy), 5 patients had detectable plasma *KRAS* mutation in TP1 but only 1 (20%) had persistent mutation at TP2. In contrast, of 9 patients who had progressive disease, 4 patients had mutation in TP1 plasma which remained detectable in 3 (75%) at TP2. In 22 patients whose tumor *KRAS* mutation was examined by both KRAS RGQ PCR and pyrosequencing, tumor mutation status was 100% concordant between the two methods.
Conclusions: *KRAS* mutation can be detected in plasma of advanced CRC patients with high sensitivity and specificity using therascreen® KRAS RGQ PCR Kit in this exploratory study. Longitudinal monitoring of *KRAS* mutation status in plasma may help identify patients who are unlikely to respond to anticancer treatments early in the course of their treatments.

2421 POSTER

The prognostic value of total cell free DNA measurement in patients with heavily pre-treated metastatic colorectal cancer treated with gemcitabine and capecitabine

K. Garm Spindler[1], N.P. Pallisgaard[2], R.F.A. Fredslund Andersen[2], J. Ploeen[1], A.J. Jakobsen[1]. [1]*Vejle Sygehus, Department of Oncology, Vejle, Denmark;* [2]*Vejle Sygehus, Department of Clinical Chemistry, Vejle, Denmark*

Background: Translational research is important regarding all clinical investigations, and our previous data have shown promising results for cell-free DNA (cfDNA) measurements in mCRC. Patients with chemotherapy refractory metastatic colorectal cancer (mCRC) have no established treatment options when standard chemotherapy with 5-FU, oxaliplatin and irinotecan or new biological agents fails. Gemcitabine acts synergistically with fluoropyrimidines and the combination is known to be clinically active in patients with mCRC and has an acceptable toxicity profile. Capecitabine is orally administered and convenient for treatment in this setting. The present study aimed to investigate the efficacy and safety of the combination of capecitabine and gemcitabin (GemCap) in heavily pre-treated, therapy-resistant mCRC patients and to validate previous observations of the clinical importance of cell-free DNA measurement.
Methods: Inclusion criteria comprised: histopathologically verified mCRC refractory to standard chemotherapy, adequate organ function and performance status. Patients received capecitabine (2000 mg/m^2 day 1−7 q2w) and gemcitabine (1000 mg/m^2 day 1) until progression or unacceptable toxicity. Plasma was obtained from a pre-treatment EDTA blood-sample, and the number of DNA alleles was assessed using an in-house qPCR as previously described.
Results: Forty-nine patients were included and GemCap was well tolerated. The rate of disease control was 30% at three months, and the median PFS and OS by intention to treat analysis were 2.7 (95% CI 2.6−2.8) and 6.8 (95% CI 5.0−7.7) months, respectively. Data showed impaired survival with increasing levels of cfDNA at baseline, and the median OS in patients with cfDNA concentrations above the median of 13200 alleles/ml was 4.7 months (3.7−9.6 mo) compared to 7.8 months in the remaining patients (HR 2.22 (1.07−3.9), $p = 0.0186$). The prognostic value was confirmed in a multivariate analysis.
Conclusions: GemCap was well tolerated with moderate but encouraging efficacy, and data revealed shorter OS with increasing levels of pre-treatment cfDNA, which could serve as a new prognostic marker in mCRC. Further investigations of both aspects are justified.
No conflict of interest.

2422 POSTER

Prediction of mitomycin C sensitivity in peritoneal metastases of colorectal carcinoma

R. Kwakman[1], E.M.V. De Cuba[1], I.H.J.T. De Hingh[2], J.P. De Winter[3], P.M. Delis-van Diemen[4], B. Carvalho[4], G.J. Peters[5], H.J. Bonjer[6], G.A. Meijer[4], E.A. Te Velde[1]. *[1]VU University Medical Center, Surgical Oncology, Amsterdam, Netherlands; [2]Catharina Ziekenhuis Eindhoven, Surgery, Eindhoven, Netherlands; [3]VU University Medical Center, Oncogenetics, Amsterdam, Netherlands; [4]VU University Medical Center, Pathology, Amsterdam, Netherlands; [5]VU University Medical Center, Oncology, Amsterdam, Netherlands; [6]VU University Medical Center, Surgery, Amsterdam, Netherlands*

Background: Patients with peritoneal metastases (PM) originating from colorectal carcinoma (CRC) are curatively treated by cytoreductive surgery (CRS) and hyperthermic intra-peritoneal chemotherapy (HIPEC) with Mitomycin C (MMC). We aim to improve patient selection and personalize treatment for patients treated with HIPEC by predicting MMC sensitivity.
Methods: MMC sensitivity was determined *in-vitro* for 12 CRC cell lines using two separate assays. This was correlated to mRNA expression levels of 36 known genes related to the Fanconi Anaemia-BRCA pathway, ATM-ATR pathway and enzymatic activation of MMC. We also determined Fanconi Anaemia-BRCA pathway functionality in cell lines using chromosomal breakage assay and Western Blot for key protein FANCD2. Genes showing significant up- or downregulation on mRNA level were subsequently validated by staining for the corresponding protein with immunohistochemistry (IHC) on both CRC cell lines and patient material.
Results: In 12 CRC cell lines two out of 36 analyzed genes showed significant correlation between MMC sensitivity and mRNA expression. Sensitivity to MMC correlated with a decrease in BLM ($p = 0.01$) and BRCA2 ($p = 0.02$) mRNA expression levels. Chromosomal breakage assay showed no correlation to MMC sensitivity nor did FANCD2 protein expression, indicating no effect by BRCA2. BLM IHC staining in cell lines, showed that weak intensity correlated with high sensitivity to MMC ($p = 0.04$). This effect was also found in patient material: High BLM protein expression was significantly correlated to a decrease in overall survival in patients with minimal residual disease after CRS and HIPEC ($p = 0.04$).
Conclusion: Analysis of 36 known genes related to the Fanconi Anaemia-BRCA pathway and enzymatic activation of MMC correlated to MMC sensitivity, revealed that BLM expression, not FA-BRCA functionality, corresponds with MMC sensitivity. Moreover, high BLM protein expression was negatively correlated to survival in patients with minimal residual disease after CRS and HIPEC. BLM could be a potential clinical predictive biomarker for PM with CRC.

2423 POSTER

Predictive value of plasma angiopoietin-2 level in metastatic colorectal cancer patients treated with anti-VEGF containing chemotherapy

E. Dobi[1], T. Lecomte[2], F. Ghiringhelli[3], F. Monnien[4], O. Boucher[5], L. Queiroz[6], O. Adotevi[1], S. Fratté[7], S. Kim[8], C. Borg[1]. *[1]University Hospital of Besançon, Oncology-INSERM-UMR 1098, Besacon, France; [2]University Hospital of Tours, Gastroenterology, Tours, France; [3]Georges-Francois Leclerc Cancer Centre, Oncology, Dijon, France; [4]University Hospital of Besançon, Oncology, Besacon, France; [5]University Hospital of Reims, Gastroenterology, Reims, France; [6]University of Franche Comté, INSERM-UMR 1098, Besacon, France; [7]Hospital of Belfort Montbeliard, Gastroenterology, Belfort, France; [8]University Hospital of Besançon, Oncology-Clinical Investigational Center-Biotherapy-506, Besacon, France*

Background: Angiogenesis is a complex process implicated in carcinogenesis and associated with tumor progression. Nevertheless, specific prognostic biomarkers related to angiogenesis are still lacking in metastatic colorectal cancer (mCRC) patients. Angiopoietin-2 (Ang-2) is a ligand of Tie-2 receptor involved in the regulation of vascular remodeling. Then, we decided to monitor the prognostic value of baseline level of plasmatic Ang-2 in prospective studies of mCRC patients treated with bevacizumab.
Material and Method: Plasmatic Ang-2 was measured in healthy volunteers, and in patients with first-line mCRC treated with bevacizumab containing chemotherapy in a prospective phase 2 clinical trial (training cohort). Plasma samples of the patients were taken at baseline. Enzyme-linked immunosorbent assays (ELISA) were used to measure Ang-2 in plasma samples (sensitivity: 21.3 pg/ml). We determined cut-off value of Ang-2 levels using ROC curve for treatment response. A second set of 132 mCRC patients prospectively included in multicentric clinical trial (STIC-Avastin study) was used as a confirmatory cohort.
Results: In our training cohort, Ang-2 levels remained below 5ng/mL in all normal volunteers ($n = 20$) and all stage II−III CRCs ($n = 20$). Ang-2 level was significantly higher in patients with mCRC ($n = 51$) compared to healthy controls and stage II−III CRCs ($p = 0.03$). There was no significant difference between high Ang-2 level (Ang-2 high, >= 5ng/ml) and low baseline plasma Ang-2 level (Ang-2 low, <5ng/ml) regarding age, sex, *KRAS* status and metastatic sites. Median progression-free survival (PFS) and overall survival (OS) were significantly prolonged in patients with low Ang-2 levels (13.7 vs. 7.7 months, $p < 0.01$; and 36.6 vs. 7.7 months, $p < 0.001$; respectively). Response rate was also higher in patients with low Ang-2 levels (71.4 vs. 28.6%; $p = 0.06$).
These results were validated in an independent confirmatory cohort. In this cohort, median PFS and OS were significantly prolonged in patients with low Ang-2 levels compared to patients with Ang-2 levels higher than 5ng/mL (11.8 vs. 8.6 months, $p < 0.001$; and 28.2 vs 15.7 months, $p < 0.001$; respectively). In multivariate analysis, Ang2 levels and metastatic surgery were the only independent factor for PFS and OS.
Conclusion: These results underscore the negative impact in terms of response rate, PFS and OS of high baseline plasma levels of Ang-2 in mCRC treated with bevacizumab containing therapy.
No conflict of interest.

2424 POSTER

RAC1b and activated Insulin-like growth factor receptor as markers of resistance to cetuximab and panitumumab in metastatic colorectal cancer

I. Victoria[1], O. Reig[1], L. Gaba[1], P. Jares[2], M. Rubini[3], X. García-Albéniz[4], M. Cuatrecasas[2], J. Maurel[1]. *[1]Hospital Clínic, Medical Oncology, Barcelona (Barcelona), Spain; [2]Hospital Clínic, Pathology, Barcelona (Barcelona), Spain; [3]Hospital Ferrara, Pathology, Ferrara, Italy; [4]Harvard School of Public Health, Epidemiology, Boston, USA*

Introduction: Rac1b (a splicing activated form of Rac1) constitute an alternative survival pathway to oncogenic KRAS in mCRC (Matos et al, 2009). IGF-1R activation may result in resistance to anti-EGFR targeted treatment. We examined potential correlations between markers related to activation and location of p-IGF-1R and Rac1b expression pathways and clinical benefit from the anti-EGFR monoclonal antibodies plus irinotecan in pre-treated mCRC patients (pts).
Methods: A cohort of 54 pre-treated mCRC pts, who were treated with cetuximab (C) or panitumumab (P) plus irinotecan as second or third-line, was tested for anti-pY1316 antibody (provided by M. Rubini) IGF-1R and Rac1b immunoreactivity (ie, immunohistochemistry [IHC]) and KRAS and BRAF mutations. The association among IHC (p-IGF-1R, Rac1b), KRAS and BRAF mutational status on both, primary tumor and paired metastases, and treatment outcomes were investigated.
Results: Forty-five (14 KRAS mutant, 3 BRAF mutant and 28 WT/WT for KRAS/BRAF) of 54 pts were evaluable for concordance analysis. Phospho-IGF-1R show a similar pattern of IHC expression in primary and paired metastases (76−67% peri-nuclear, 12−10% apical-membrane and 12−22% peri-nuclear associated with apical-membrane) respectively. 14% of pts also show concomitant nuclear p-IGF-1R (np-IGF-1R) staining. The percentage of np-IGF-1R expression increases in metastatic samples compared with primary tumors in 67% of pts. Levels of concordance between primary tumors and paired metastases were 45%, 62% and 83% for Rac1b, p-IGF-1R and np-IGF-1R respectively. Phospho-IGF-1R and np-IGF-1R status on primary tumors or metastases, did not predict response or progression free survival (PFS). 6/23 (26%) metastatic samples with KRAS wt and low Rac1b expression were responders, compared with 0/11 (0%) that showed high Rac1b immunoexpression ($p = 0.022$). The median PFS of patients with Rac1b-positive metastases was 3.1 months compared with 4.7 months for those with Rac1b-negative metastases ($p = 0.29$).
Conclusion: Percentage of np-IGF-1R expression increases in metastatic samples compared with primary tumors. Rac1b positive expression in metastases may be predictive of resistance to anti-EGFR antibodies in WT KRAS pts.
No conflict of interest.

2425 POSTER

Drug-disease model of tumor size and overall survival in metastatic colorectal cancer patients treated with cetuximab administered weekly or every second week

P. Girard[1], T. Brodowicz[2], A. Kovar[3], B. Brockhaus[3], M. Zühlsdorf[3], M. Schlichting[3], A. Munafo[4], R. Esser[3], E. Van Cutsem[5], J. Tabernero[6]. *[1]Merck Serono S.A., Modeling and Simulation, Geneva, Switzerland; [2]Medical University of Vienna, Vienna, Austria; [3]Merck KGaA, Darmstadt, Germany; [4]Merck Serono S.A., Geneva, Switzerland; [5]University Hospital Gasthuisberg, Leuven, Belgium; [6]Vall d'Hebron University Hospital, Barcelona, Spain*

Background: Cetuximab, administered in a standard weekly regimen (q1w) with first-line chemotherapy (CT) can improve tumor response and overall survival (OS) in metastatic colorectal cancer (mCRC) pts. Cetuximab (400 or 500 mg/m^2) every second week (q2w) was safely administered with reported activity in mCRC pts. Tumor size (response) and OS were further studied in a drug-disease model.
Material and Methods: A pharmacokinetic (PK)-disease model of tumor size was constructed (using NONMEM7.2) in a pooled analysis of mCRC pts from the 502 (EVEREST, second-line CT + cetuximab q1w) study, and 045 and CECOG/CORE.1.2.002 (CORE) studies (both first-line CT with either cetuximab q1w or q2w). The model estimated changes in tumor size from baseline for early tumor shrinkage (ETS, % change in tumor size at wk 8) and time to tumor (re)growth (TTG, time to smallest tumor size). Covariates were examined including the effects of cetuximab q1w and q2w regimens. ETS and TTG were tested as predictors of OS using Cox models.
Results: 369 pts from the 3 studies provided 3821 PK, 2053 tumor size and 233 death observations. Tumor size model fit was very good. Excluding study 502 (irinotecan-refractory pts), covariate analysis identified study (baseline tumor size was 32% lower in the CORE study; $p < 0.01$) and *KRAS* status (treatment was 43% less effective in *KRAS* mutated tumors; $p < 0.01$) as significant. TTG ($p = 0.12$) and ETS ($p = 0.28$) were not markedly different between the q2w and q1w regimens, were positively correlated (Spearman's rho=0.64), and were identified as individual predictors of OS. For ETS and TTG, pts were grouped by low (L), intermediate (I), and high (H) terciles. In pts with *KRAS* wild-type tumors, OS was longer in the H-TTG (27 to 118 wk, median OS 31.4 mth) vs L-TTG group (0 to 11 wk, median OS 15.1 mth), or H-ETS (−66 to −22%, median OS 25.9 mth) vs L-ETS group (−9 to +2%, median OS 12.8 mth). In a Cox model excluding study 502 ($n = 215$, death=93), ECOG PS grouped as fully active or restrictive activity (RA, $p = 0.038$), TTG ($p < 0.001$) and baseline tumor size ($p < 0.001$) were independent predictors of OS. In a model including ETS, ECOG PS RA ($p = 0.0044$), ETS ($p = 0.013$) and baseline tumor size ($p = 0.0055$) were independent predictors of OS. Treatment regimen was not significant.
Conclusions: In this analysis changes in tumor size from baseline and OS were not significantly modified by the cetuximab dosing regimen in mCRC pts. The model identified TTG and ETS as predictors of OS.

2426 POSTER

Death Associated Protein-1 (DAP-1) is associated with the clinical outcome of the patients with colorectal cancer and its role in the regulation of cell death

Y. Jia[1], L. Ye[1], K. Ji[1], A. Toms[1], M.L. Davies[1], R. Hargest[1], J.F. Ji[2], W. Jiang[1]. *[1]Cardiff University, Wales College of Medicine Metastesis and Angiogenesis Research Group, Cardiff, United Kingdom; [2]Peking University Cancer Hospital, Gastroenterology, Beijing, China*

Background: Death Associated Protein-1 (DAP-1), is a member of the DAP family and has been indicated in the regulation of cell growth and death including that of cancer cells. Its clinical value in patients with cancers has been reported in recent years. However, the role of DAP-1 in clinical cancer and the regulation of colorectal cancer cells is largely unknown. The present study investigated the expression profile of DAP-1 in human colorectal cancer and the impact of DAP-1 on the apoptosis and cellular response to 5-FU.
Materials and Methods: Human colorectal cancer fresh frozen specimens ($n = 94$) were used for gene transcript analysis and immunohistochemical analysis of DAP1. Expression of DAP1 was analyse against patients clinical, pathological and outcome features. Human colorectal cancer cell lines HRT18 and HT115 cells were used in *in vitro* studies. DAP-1 knockdown cells were generated using anti-DAP-1 transgenes. The cellular functions including cellular growth, migration and apoptosis were evaluated on these cells, together with the cells response to chemotherapeutic drugs.
Results: Human colorectal cancer tissues had lower levels of DAP-1 compared with normal tissues. The reduced levels were associated with higher Dukes staging and lymph node metastasis. Patients with low DAP-1 expression had a markedly reduced overall survival ($p < 0.01$). Together with grade, TNM staging, DAP1 were independent prognostic factor in the patients. Loss of DAP-1 in colorectal cancer cells resulted in a gain in cellular migration and loss of their sensitivity of apoptosis to chemotherapeutic agent, 5-FU.
Conclusions: DAP-1 is correlated with the disease progression and long term survival of the patients. It is also a pivotal regulator of the growth and apoptosis and cellular response to chemotherapy agents.
No conflict of interest.

2427 POSTER

Ultra-deep sequencing of plasma, matched primary tumor and matched liver metastasis in 16 patients with metastatic colorectal cancer reveals significant differences in the mutation pattern of these three tissue types

A. Rosenthal[1], K. Stecker[1], P. Pechanska[1], B. Hinzmann[1], H.P. Adams[1], M. Pross[2], S. Weise[3], K. Ridwelski[4], K. Gellert[5], J. Pertschy[6]. *[1]Signature Diagnostics AG, Potsdam, Germany; [2]DRK Kliniken Köpenick, Klinik für Chirurgie, Berlin, Germany; [3]Hufeland Klinikum Standort Mühlhausen, Klinik für Allgemein- und Viszeralchirurgie, Mühlhausen, Germany; [4]Klinikum Magdeburg, Klinik für Allgemein- und Viszeralchirurgie, Magdeburg, Germany; [5]Sana Klinikum Berlin, Klinik für Allgemein- und Viszeralchirurgie, Berlin, Germany; [6]Katholisches Krankenhaus St. Johann Nempomuk, Klinik für Allgemein- und Viszeralchirurgie, Erfurt, Germany*

Background: Sequencing of circulating, cell-free DNA (cf-DNA) from plasma of cancer patients (pts) is a promising new field in cancer diagnostics and personalized oncology. This technology would allow to determine the mutation status of important driver genes in the plasma of patients rather than in the primary tumor or in the metastatic (mets) tissue. As it is often difficult or unethical to obtain mets tissue from pts by biopsies plasma samples which are readily available represent an attractive alternative. Here we report on a feasibility study in metastatic colorectal cancer and show ultra-deep sequencing of plasma samples side-by-side with matched primary tumor and metastatic tissues.
Material and Methods: For this proof-of-principle study 16 pts with metastatic CRC (mCRC) were selected from a total of 1400 mCRC patients that are part of our prospective multicenter MSKK study with 40 hospitals in Germany. These 16 pts were selected on the ground that matched plasma, primary tumor and liver metastasis tissues were available in our MSKK biobank. All 16 pts had undergone surgical resection of the liver mets and the primary tumor. Blood was drawn from these 16 pts prior to surgery: 7 male, 9 female; 50−79 years of age (median: 66); 12 colon, 4 rectum tumors; no neo-adjuvant therapy. Cf-DNA was isolated from 2 ml of EDTA plasma using QIAamp kit (Qiagen). In parallel DNA was isolated from 16 matched pairs primary tumor and liver metastasis tissue and showed a minimum tumor cell content of 15%. For ultra-deep sequencing of the plasma samples and matched primery tumors a panel of 49 highly multiplexed amplicons (IonAmplicon, LifeTechnologies) representing 10 important driver genes was designed. For sequencing the liver mets and matched primary tumors a different custom panel of 37 driver genes (120 amplicons) was designed and used.
Results: In 6/18 pts (33%) no differences in mutations pattern were observed between plasma, primary tumor and mets tissue. In 12/18 pts significant differences in the mutations pattern were found. In two pts the primary tumor and the mets tissue had the same additional mutation (case 1: SMAD4 S138*, case 2: KRAS G12A) that was not present in the plasma. In six pts the plasma showed additional APC or TP53 mutations not present in the primary and mets tissue. In one case the primary tumor only showed two additional mutations (APC Q1406* and FBXW7 R465H) that were not present in plasma or mets tissue. In pts 68177 both the plasma and the liver mets had an additional TP53 A276T mutation which was not present in the primary tumor. The plasma though did not show the KRAS Q61K mutation that was identified in the primary and mets tissue. In addition, the mets tissue had a PTEN R173C mutation that was not present in the plasma and primary. In pts 6816 the plasma and mets tissue displayed an additional PIK3CA E545K mutation in addition to a KRAS G12V and APC R1450X mutation that was present in all three tissue types. The primary tumor had on top a TP53 C275F mutation.
Conclusions: Ultra-deep plasma sequencing side-by-side with matched liver mets and primary tumor tissue can be used to identify de-novo actionable mutations in the plasma not present in the primary tumor. This

technology holds promise to change the diagnostic practise in mCRC patients.

2428 POSTER

Increased TGFa as a mechanism of acquired resistance to the anti-EGFR inhibitor cetuximab through EGFR–MET interaction and activation of MET signaling in colon cancer cells

T. Troiani[1], E. Martinelli[2], S. Napolitano[2], D. Vitagliano[2], F. Morgillo[2], A. Capasso[2], R. De Palma[2], L. Berrino[2], R. Bianco[2], F. Ciardiello[2]. *[1]Seconda Università degli Studi di Napoli, Napoli, Italy; [2]Seconda Università degli Studi di Napoli, Medical Oncology, Napoli, Italy*

Background: Although cetuximab, an anti-EGF receptor (EGFR) monoclonal antibody, is an effective treatment for KRAS wild type metastatic colorectal cancer (mCRC) patients, its clinical use is limited by onset of resistance.
Material and Methods: We characterized a CRC model to study the mechanisms of acquired resistance to cetuximab.
Results: Following chronic treatment of nude mice bearing cetuximab-sensitive human GEO colon xenografts, cetuximab-resistant GEO cells (GEO-CR) were obtained. In GEO-CR cells proliferation and survival signals were constitutively active despite of EGFR inhibition by cetuximab treatment. Whole gene expression profiling identified a series of genes involved in the hepatocyte growth factor HGF-MET-dependent pathways, that were up-regulated in cetuximab-resistant GEO-CR cells. Further, activated, phosphorylated MET was detected in GEO-CR cells. Inhibition of MET expression by siRNA restored cetuximab sensitivity in GEO-CR cells, whereas exogenous activation of MET by HGF stimulation in cetuximab-sensitive GEO cells induced resistance to cetuximab. Treatment of GEO-CR cells with PHA665752, a selective MET inhibitor, inhibited cell growth, proliferation and survival signals and impaired cancer cell migration. Overexpression of transforming growth factor α (TGFa), a specific EGFR ligand, was involved in the acquisition of cetuximab resistance in GEO-CR cells. In fact, TGFα overexpression induced the formation of EGFR–MET *heterodimers*, with subsequent MET phosphorylation and activation of MET down-stream effectors in GEO-CR cells.
Conclusions: These results suggest that overexpression of TGFα through induction of EGFR–MET interaction contributes to cetuximab resistance in CRC cells. The combined inhibition of EGFR and MET receptor could represent a strategy for preventing and/or overcoming cetuximab resistance in CRC patients.

Exposure to nintedanib, a triple angiokinase inhibitor, is accompanied by activation of EGFR and other ErbB/HER-family members in colorectal cancer (CRC) models, providing a rationale for combinations of nintedanib with the ErbB family blocker afatinib

V. Poindessous[1], P. Mésange[1], A. Battistella[1], A. Afchain[1], M.E. Forgue-Lafitte[1], A. De Gramont[2], A.K. Larsen[1]. *[1]INSERM and UPMC, Cancer Biology & Therapeutics Saint-Antoine Research Center INSERM U938, Paris 12, France; [2]INSERM UPMC and Hôpital Saint-Antoine, Cancer Biology & Therapeutics Saint-Antoine Research Center INSERM U938 and Medical Oncology Hôpital Saint-Antoine, Paris 12, France*

Background: Combinations of EGFR and VEGF(R)-targeted agents have consistently shown at least additive activity in preclinical CRC models when the targeted agents were administered alone. We have recently shown that combinations of afatinib, a pan-HER/ErbB family blocker and nintedanib, a triple angiokinase (VEGFR, FGFR, PDGFR) inhibitor show synergistic activity in CRC models (*Poindessous et al., Clin Cancer Res 17:6522, 2011*). However, the mechanistic basis for the synergistic effects of the combination is incompletely understood. EGFR is activated following exposure to a wide range of therapeutic modalities including ionizing irradiation and irinotecan. We speculated that nintedanib exposure could also activate EGFR signaling which might explain the synergistic activity of the combination.
Material and Methods: Mice with human CRC xenografts were treated with nintedanib and afatinib alone or in combination and the influence on tumor growth, viability and the presence of phosphorylated HER family members was determined. Different scheduling regimens were explored to identify an administration schedule which combined optimal antitumor activity with minimal toxic side effects. Finally, the combination was tested in three CRC xenograft models with mutant *KRAS* status.
Results: We here show that nintedanib treatment results in activation of EGFR and HER2 in multiple CRC xenograft models in a dose-dependent manner. Among the different regimens tested, continuous nintedanib with administration of afatinib every second week proved almost as efficient as continuous administration of the two agents together and was less toxic. Furthermore, the proportion of apoptotic cells, as measured by the TUNEL assay, was compatible between the two regimens. Finally, nintedanib plus afatinib was superior to nintedanib alone in three different tumor xenografts with mutant *KRAS*.
Conclusions: We here report that prolonged exposure to nintedanib, a small molecule angiogenesis inhibitor, is accompanied by activation of EGFR and HER2. Accordingly, afatinib, an ErbB family blocker, was synergistic with nintedanib. We subsequently identified a novel regimen for optimizing the antitumor effects of the combination with limited toxic side effects and showed that this regimen is active in four different CRC tumor models including three with mutant *KRAS*. These findings provide a rationale for clinical trials of the two small molecules.

The detection of low frequency KRAS mutant alleles by pyrosequencing predicts the response to EGFR therapy in metastatic colorectal cancer

M. Landriscina[1], M.I. Natalicchio[2], G. Improta[3], A. Zupa[3], A.M.T. Gerardi[1], A. Cassano[4], G. Vita[5], M. Aieta[6], C. Barone[4]. *[1]University of Foggia, Department of Medical and Surgical Sciences, Foggia, Italy; [2]Riuniti Hospital, Molecular Biology Laboratory, Foggia, Italy; [3]IRCCS-CROB, Laboratory of Clinical Research and Molecular Diagnostics, Rionero in Vulture, Italy; [4]Catholic University, Medical Oncology Unit, Rome, Italy; [5]IRCCS-CROB, Pathology Unit, Rionero in Vulture, Italy; [6]IRCCS-CROB, Medical Oncology Unit, Rionero in Vulture, Italy*

Background: KRAS mutational status is the only biomarker routinely used to select EGFR therapy in metastatic colorectal cancer (mCRC), with direct sequencing (DS) being the gold standard for the detection of KRAS mutations. However, other high sensitive technologies have been proposed, and, among others, pyrosequencing (PS), but, at present, the level of test sensitivity which is required to provide predictive information in clinical practice is still in question.
Patients and Methods: A retrospective analysis of KRAS codons 12 and 13 mutations by PS and DS was performed in 192 mCRCs to evaluate whether PS may improve the predictive value of KRAS mutational status.
Results: DS failed to detect KRAS mutations in 4/31 mCRCs with low frequency of mutated alleles, whereas PS allowed the detection of an additional 12 low frequency KRAS mutations in 141 mCRCs KRAS-wild type at DS. After analyzing the cohort of 97 KRAS-wild type tumors treated with anti-EGFR antibodies, 9 additional mutations were revealed in the non-responders, whereas none of the responders exhibited a KRAS-mutated genotype upon PS re-evaluation. Of note, KRAS-mutated tumors upon PS re-evaluation showed a worst progression free survival after EGFR therapy. Finally, KRAS-wild type mCRCs with both technologies, but primarily resistant to EGFR therapy, exhibited 3 BRAF and 5 exon 20 PIK3CA mutations which were absent in the responder subgroup.
Conclusions: The capacity of PS to detect low frequency of mutant alleles suggests that it may improve the KRAS predictive value for the selection of anti-EGFR agents.
No conflict of interest.

Prognostic value of incidental betablockers use in metastatic colorectal cancer patients receiving first-line treatment: An update

M. Del Prete[1], R. Giampieri[1], M. Scartozzi[2], L. Faloppi[1], M. Bianconi[1], A. Bittoni[1], S. Cascinu[2]. *[1]Università Politecnica delle Marche, Oncology, Ancona, Italy; [2]Ospedali Riuniti, Oncology, Ancona, Italy*

Background: Preclinical and retrospective studies suggested an antitumor activity for the incidental use of anti-hypertensive betablockers in various tumour types, reducing metastasis, tumor recurrence and increasing survival. Data regarding colorectal cancer are lacking. We tried to assessed the correlation between the incidental use of betablockers and clinical outcome in colorectal cancer patients receiving first-line therapy.
Material and Methods: 250 colorectal cancer patients, treated with first-line chemotherapy alone (135 patients) and with chemotherapy plus Bevacizumab (115 patients), were analysed for progression free survival and overall survival, using the Kaplan–Meier method. A p value <0.05 was considered for statistical significance. Patients were stratified for betablockers use, age, sex, site of metastases, previous adjuvant chemotherapy and ECOG performance status.
Results: 31 patients (12%) were on treatment with betablockers at the time of first-line therapy: 22 (16%) in the chemotherapy alone group and

9 in the bevacizumab group (8%). In both groups patients receiving or not betablockers were similar for all main clinical characteristics. In the chemotherapy alone group, patients receiving betablockers showed an improved RR (60% vs. 33%, p = 0.044) and overall survival (mOS 41.3 vs 25.7 months, p = 0.03, HR:2.26, 95% CI: 1.05–3.24). Only a trend for improved progression free survival was noticed.
In the 115 patients receiving chemotherapy with bevacizumab a trend towards a worse overall survival was seen for patients receiving betablockers, although this was not statistically significant (mOS 16 vs 23.7 months, p = 0.26, HR:0.64, 95% CI: 0.22–1.49). No significant differences were seen in regards of progression free survival or different response rate patterns between the two groups.
Conclusions: Our analysis confirms a potential prognostic role for the use of betablockers in colorectal cancer patients treated with chemotherapy. Our findings are in line with preclinical studies suggesting that beta-adrenergic signalling may regulate cancerogenesis and tumor invasiveness. Our analysis suggests a potential worse outcome for patients on betablockers receiving Bevacizumab-based treatment, although the small number of patients precludes any definitive conclusion. We suggest that in future prospective trials the incidental use of betablockers will be considered a stratification factor for clinical outcome.
No conflict of interest.

2432 POSTER

Thymidine phosphorylase induction with chemotherapy in metastatic site as predictive marker for response to chemotherapy and survival: Analysis of six biomarkers in primary site and liver metastatic site of colorectal cancer

K. Kataoka[1], A. Kanazawa[1], A. Nakajima[1], A. Arimoto[1]. [1]*Osaka Red-cross Hospital, Surgery, Osaka, Japan*

Background: Some groups have evaluated the predicative relevance of several biomarkers on the response to chemotherapy and the survival of patients with metastatic colorectal cancer (mCRC). But the association of expression of such biomarkers between primary tumor site and chemotherapy-treated metastatic site, is not known. In this study, we assessed the difference of expression of molecular biomarkers between primary site and liver metastatic site treated with chemotherapy in mCRC.
Materials and Methods: We analysed 43 mCRC patients with liver-limited disease from January 2007 to November 2011. They all received resection of primary tumors followed by oxaliplatin-based chemotherapy. After chemotherapy, they all received secondary hepatic resection. Total 86 RNA was derived from paraffin-embedded primary and metastatic tumor specimens to measure mRNA expression of six biomarkers (thymidylate synthase (TS), dihydropyrimidine dehydrogenase (DPD), excision repair cross complementing gene 1 (ERCC1), thymidine phosphorylase (TP), folylpolyglutamate synthase (FPGS), and regenerating islet-derived family, member 4 (REG4)), using Danenberg Tumor Profile (DTP) method.
Results: 36 good quality tumor mRNA were identified. High TP expression in liver metastatic site, and ratio of TP expression in liver metastatic site to primary site (L/P ratio) were significantly associated with response to chemotherapy (P = 0.046 and 0.038, respectively). And L/P ratio of TP, TP expression in primary site, DPD in primary and metastatic sites, REG4 in primary site were significantly associated with overall survival (OS). (P = 0.039, 0.045, 0.016, 0.032, 0.022, respectively) In multivariate analysis, high DPD expression in primary site was significant poor prognostic factor of OS (HR: 9.66 (95% CI: 1.04–89.52), P = 0.046).
Conclusions: High L/P ratio of TP was significantly associated with response to oxaliplatin-based chemotherapy and survival. It may be useful predictive biomarker of survival, and potential indicator for the individualization of postoperative chemotherapy for mCRC patients.
No conflict of interest.

2433 POSTER

Peripheral CD45RO, PD1, and TLR4 expression in metastatic colorectal cancer patients treated with bevacizumab/5FU/irinotecan (B-FOLFIRI)

V. Formica[1], V. Cereda[1], M.G. Di Bari[2], I. Grenga[1], M. Tesauro[3], R. Palmirotta[2], P. Ferroni[2], F. Guadagni[2], M. Roselli[1]. [1]*University of Rome "Tor Vergata", Medical Oncology, Rome, Italy;* [2]*IRCCS San Raffaele Pisana, Department of Laboratory Medicine and Advanced Biotechnologies, Rome, Italy;* [3]*University of Rome "Tor Vergata", Internal Medicine, Rome, Italy*

Background: CD45RO, PD1 and TLR4 immune pathways have proven pivotal in regulating antitumour response and correlate with survival for localised colorectal cancer (CRC). We evaluated if their peripheral expression was associated with outcome in metastatic (m) CRC.
Material and Methods: 31 mCRC patients (Male:Female=13:18, colon:rectum=26:5, median age=69 years) were eligible for this prospective study (clinicaltrial.gov registration NCT01533740) and treated between april 2010 and may 2011 with standard firstline B-FOLFIRI (n. of administered cycles: median 12, range 3−24). Blood was drawn before the first and third cycle, and analysed by flow cytometry for frequency(%) of CD4+,CD8+,CD45RO+and PD1+mononuclear cells and for TLR4 expression on neutrophils.
Results: A trend towards increased CD45RO expression was seen after two cycles (median CD45RO+cell% from 55% to 57%, Wilcoxon test p-value: 0.09). At survival analysis, pre-third-cycle (ptc) CD45RO+CD8+cell% displayed a significant association with progression-free Survival (PFS) (median PFS 22.4 vs 9.4 months and 1 year PFS rate 80% vs 33% for patients with CD45RO+CD8+cell% > vs < the median value of 12%, respectively, HR 0.30, p 0.02). Patients with high ptc-CD45RO+CD8+cell% had also prolonged overall survival (OS) (2 year OS rate 70% vs 44% for CD45RO+CD8+cell% > vs <12%, respectively). Surprisingly, ptc-PD1 overexpression was also associated with improved PFS (HR 0.31, p 0.02). A Cox-regression multivariate analysis for PFS including ptc-CD45RO+CD8+, ptc-PD1+cell%, CEA, CA19.9, LDH and Köhne risk class demonstrated low ptc-CD45RO+CD8+cells to be the strongest independent prognostic factor (HR 6.95, p 0.02). Moreover, the trend of CD45RO+CD8+cell% after two cycles (increase vs decrease) significantly correlated with RECIST response rate (83% v 14%, p 0.01). TLR4 was not associated with outcome.
Conclusions: CD8+CD45RO+ cells were confirmed to be of independent prognostic value in mCRC patients. Overexpression of the PD1 immunosuppressor after two cycles may be an indirect sign of a triggered antitumour response (negative feedback) and thus be associated with better outcome. Enhancement of CD8+CD45RO+immune response may be a fascinating therapeutic target to improve efficacy of standard chemotherapy.
No conflict of interest.

Gastric differentiation markers expression in ulcerative colitis-associated dysplasias

A. Takeda[1]. [1]*Saiseikai-Hiratsuka General Hospital, Digestive Surgery, Kanagawa, Japan*

Background: It is predictable that we can easily calculate the increase in colorectal cancer (CRC) patients complicating ulcerative colitis (UC) with the increasing prevalence of UC. The development of carcinoma in patients with UC has been thought to be involving precursor stages of low- and high-grade epithelial dysplasias against inflamed colonic mucosa. No definite strategies for detection of dysplasias which are potentially progressive to carcinoma in longstanding UC patients have established yet. For practical purposes, the useful markers to detect potentially progressive lesions of dysplasia in longstanding UC patients are required. Gastric-type mucin secretion has been reported to be affected in inflammatory bowel disease. Recent identification of several mucin genes could contribute to the differential diagnosis between UC-associated neoplasms and sporadic CRC. We have herein described the obviously frequent expression of gastric differentiation markers, such as human gastric mucin (HGM), MUC5AC and pS2 in lesions of dysplasia and the surrounding mucosa around tumours with 4 patients(case1−4) of UC accompanying advanced colorectal cancer already.
Materials and Methods: Immunohistochemical examination for gastric phenotypic markers was carried out using an ENVISION/HRP kit (DakoCytomation, Glostrup, Denmark) after antigen retrieval by autoclaving was performed with the following monoclonal antibodies, (clones, dilution): HGM (45M1, 1:50), MUC5AC (CLH2, 1:100), and pS2 (NCL-pS2, 1:200). Immunopositivity was designed as sporadically positive (1+) when <5% of cells were positive, focally positive (2+) when 5−50% cells were positive, and diffusely positive (3+) when >50% cells were positive.
Results: All patients underwent surgical treatment because of having advanced cancer (case2, 3: Total colectomy and case1, 4: partial colectomy). Case 3 and 4 were almost diffusely positive for all gastric-type markers, and case 1 and 2 were partly diffusely positive. HGM expression was also detected diffusely or partly in goblet cells in surrounding mucosa around dysplasias in all cases, which was not showed in the epithelium away from disease.
Conclusions: Our results suggested that gastric differentiation markers expression is potentially useful for the easy detection of UC-associated dysplasias potentially progressive to carcinoma, which contributes to clarify the characteristics of UC-associated colorectal carcinogenesis as well as the good prognosis of UC-associated neoplasms.

Interim results of observational study to determine K-ras mutation rates in patients with metastatic colorectal cancer in Turkey (TURKRAS study)

M. Gumus[1], F. Dane[2], B. Karabulut[3], K. Uygun[4], B. Orhan[5], K. Aydin[6], S. Buyukberber[7], S.K. Okutur[8], T. Unek[9], R.S. Ozen[10]. *[1]TURKRAS Study Group, Medical Oncology, Istanbul, Turkey; [2]Marmara University Pendik Research and Training Hospital, Medical Oncology, Istanbul, Turkey; [3]Ege University Tulay Aktas Oncology Hospital, Medical Oncology, Izmir, Turkey; [4]Kocaeli University Hospital, Medical Oncology, Kocaeli, Turkey; [5]Bursa Acibadem Hospital, Medical Oncology, Bursa, Turkey; [6]Kartal Dr.Lutfi Kirdar Research and Training Hospital, Medical Oncology, Istanbul, Turkey; [7]Gazi University Hospital, Medical Oncology, Ankara, Turkey; [8]Samsun Research and Training Hospital, Medical Oncology, Samsun, Turkey; [9]Tepecik Research and Training Hospital, Medical Oncology, Izmir, Turkey; [10]TURKRAS Study Group, Medical Genetic, Istanbul, Turkey*

Background: K-ras mutation in metastatic colorectal cancer (mCRC) patients is an important bio marker in determining the response to targeted therapies. In our study, primarily we aimed to investigate the frequency of K-ras mutation in colorectal cancer patients in Turkey, and secondly to determine the frequency of sub-types of the K-ras mutation and the regional distribution of this distinction, and the relationship between demographic characteristics.
Material and Methods: Prospective, single-arm, multi-center, non-comparative, case-based, epidemiologic observational study of one year duration. All samples for K-ras examination were evaluated by an accredited, independent central laboratory in Turkey and data were recorded in a collective data base to provide reliability. Written informed consent was obtained from all patients. The laboratory procedures to be performed for pathologic specimens obtained from the patients are sample preparation, DNA isolation, amplification by polymerase chain reaction method and identification of the mutations in codons 12 and 13 of the K-ras gene using minisequencing method. For statistical analysis chi-square test were used to perform comparisons of independent bilateral and multilateral categorical variables.
Results: We have planned to enroll 2500 metastatic colorectal cancer patients to the study from 52 centers in Turkey. This is the first interim analysis with the data obtained from 1106 patients. 40% of patients were female. Half of the patients (50.1%) were from Marmara region. Patients from other regions were distributed as the Aegean, the Middle and East Anatolia, the Mediterranean and Southeastern Anatolia, the Black Sea regions; and the percentage of patients included from these regions were 17.3%, 14.1%, 11%, and 7.5% respectively. The frequency of K-ras mutation in all patients was 45%. G12D mutation is the most common mutation (28.9%). There is no significant difference between the frequency of G12 and G13 mutations when compared according to gender and regional distribution. ($p>0.05$).
Distribution of mutations frequency according to gender and geography is shown in the table.
Conclusion: K-ras mutation frequency for Turkish population is compatible with other studies reported in the literature. In our study, G12D mutation the most common mutation seen in Turkish population and gender and regional distribution of mutations did not differ significantly. In addition to comparison of gender and geographical distribution of mutations, comparison of histopathological features and other demographic characteristics will be useful for appropriate treatment approach.
No conflict of interest.

(n, %)		Mutant (N = 498, % 45)	Wild Type (N = 608, % 55)	p

K-ras status in colorectal cancer tumors from 292 Saudi patients: Frequency, clinco-pathological association and clinical outcome

J. Zekri[1], A. Al-Shehri[2], M. Mahrous[3], A. Rizvi[1], S. Al-Rehaily[2], T. Darwish[4], S. Bassi[5], H. El Taani[6], A. Al Zahrani[6], S. Elsamany[6]. *[1]King Faisal Specialist Hospital Research Centre, Oncology, Jeddah, Saudi Arabia; [2]National Guard Hospital, Oncology, Jeddah, Saudi Arabia; [3]King Fahad Hospital, Oncology, Madinah, Saudi Arabia; [4]King Abdullah Medical City and Oncology Center, Oncology, Jeddah, Saudi Arabia; [5]King Faisal Specialist Hospital & Research Centre, Research Centre, Jeddah, Saudi Arabia; [6]King Abdullah Medical City, Oncology, Mekkah, Saudi Arabia*

Background: K-ras oncogene mutations are confirmed factor for lack of clinical benefit from antibodies targeting EGFR in patients with colorectal cancer (CRC). Mutations are reported in 40% of CRC tumors in western patients. There is scarcity of data on population from Asia and the Middle East. The primary endpoint of this study is to determine the frequency of K-ras mutation in Saudi patients with CRC. Secondary endpoint is association between clinico-pathological features and K-ras. Outcome of primary endpoint is presented in this report.
Patients and Methods: 292 consecutive patients diagnosed with CRC between September 2001 and April 2012 in 5 hospitals in western province of Saudi Arabia. K-ras status was determined at some stage of their disease as requested by treating oncologist. Clinical information was extracted retrospectively from paper and electronic records.
Results: Median age at primary diagnosis was 56 (20−87) years. Site of primary disease was available in 233 patients (rectum: 34%, left colon: 41% and right colon: 26%). AJCC staging at primary diagnosis was available in 264 patients (stage I: 1%, II: 26%, III: 20% and IV: 53%). K-ras was wild type in 173/293 patients (59.2%) and mutant type in 119/293 patients (40.8%). Site of codon mutation was reported in 105 out of the 109 mutant genes. Mutations were at codon 12 in 95/105 patients (90.5%) and at codon 13 in 10/105 patients (9.5%). Results of secondary endpoint will be presented at the meeting.
Conclusion: This is the largest study investigating K-ras status in Middle Eastern CRC patients. This series shows that rate of K-ras mutation and codon site of mutation in Middle Eastern Saudi patients with CRC is similar to what is reported in western Caucasian population.
No conflict of interest.

2437 POSTER

Tolerance and antigenic flare in chemoimmunotherapy of advanced colorectal cancer

E. Lasalvia-Prisco[1], P. Goldschmidt[2], F. Galmarini[3], J. Vázquez[1], E.E. Lasalvia-Galante[1], W. Golomar[1], T. Carlevaro[1], J. Larrañaga[1]. *[1]Interdoctors-Telemedical, Oncology, Montevideo, Uruguay; [2]Interdoctors-Telemedical, Oncology, Paris, France; [3]Interdoctors-Telemedical, Oncology, Buenos Aires, Argentina*

Background: In blood of cancer patients (Pts), autologous tumor antigens with immunotherapeutic activity have been described, but the development of procedures to translate such activity to medical practice has been difficult. In the past years, two phenomena that could improve the feasibility of autologous hemoderivative cancer vaccination have been reported.
First, the role of chemotherapy as releaser and presenter of autologous tumor antigens was monitored in Pts with colorectal cancer (CRC) treated with oxaliplatin (OX) through a flare of blood CEA levels. Second, the immunity tolerance, which is induced by carcinogenesis and it conditions the immunization failure to tumor antigens, was monitored through level of circulating T-regulatory cells (T-Reg).
In this study, we explored the correlation among OX effects on survival and antitumor immunity versus flare of CEA release and level of circulating T-Reg.
Methods: Data of 204 Pts from several reported clinical trials were analyzed. Characteristics: metastatic CRC, recurrent after surgery and adjuvant 5FU-chemotherapy, treated with OX and available CEA and T-Reg assessment in peripheral blood. Four groups were configured according to T-Reg high or normal, with or without CEA flare after OX. Statistical differences (ANOVA test) among the 4 groups were calculated: response, 1 year survival, and IFN-γ ELISPOT test challenged with an antigenic blood fraction that was previously described.
Results: See the table.
Conclusions: In this series, although small and retrospective, the prevalence of CEA flare and increased T-Reg has reproduced values previously reported. These parameters did not modify the response rate to OX, but 1-year survival was significantly higher in the group that associates CEA flare phenomena and not-High T-Reg level. The study suggests that the primary cytotoxic effects of chemotherapy could be prolonged by endogenous hemoderivative immunotherapy. This protective antitumor

immunity of chemotherapy would require an Immunomodulatory procedure which will be the target of future studies.
No conflict of interest.

Table: Colorectal cancer recurrence post surgery + adjuvant FU

Groups	Not CEA flare		CEA flare	
	T-Reg High (n = 98)	T-Reg Not-High (n = 16)	T-Reg High (n = 10)	T-Reg Not-High (n = 12)
IFN-γ ELISPOT + (%)	7.7	12.5	10.0	83.3
Response rate (%)	35.2	31.3	30.0	33.3
1 Year Survival (%)	50.0	56.3	50.0	91.7

CEA flare ⩾15% baseline after oxaliplatin. High/Not-High: ⩾/<2SD + mean normal control. IFN-γ ELISPOT +>10/10^5 PBMC. Response rate according to RECIST.

2438 POSTER

A randomised clinical trial of chemotherapy compared to chemotherapy in combination with cetuximab in k-RAS wild type patients with operable metastases from colorectal cancer: The new EPOC study

J. Bridgewater[1], S. Falk[2], M. Finch-Jones[3], J. Valle[4], S. Pugh[5], L. Stanton[6], L. Little[6], M. Bowers[6], W. Wood[6], J. Primrose[5]. [1]*University College London Medical School, Cancer Institute, London, United Kingdom;* [2]*Bristol Haematology and Oncology Centre, Oncology, Bristol, United Kingdom;* [3]*United Hospitals Bristol, Surgery, Bristol, United Kingdom;* [4]*The Christie Hospital, Oncology, Manchester, United Kingdom;* [5]*University of Southampton, Surgery, Southampton, United Kingdom;* [6]*University of Southampton, Clinical Trials Unit, Southampton, United Kingdom*

Resection of liver metastases from colorectal cancer with or without neoadjuvant chemotherapy is the standard of care. The EPOC study (Nordlinger *et al.*, Lancet 2008) randomised patients between surgery and surgery with chemotherapy and demonstrated an improvement in 3 year progression free survival (PFS) of 7.3% (from 28.1% to 35.4%). As a rational extension to the EPOC study data, the New EPOC study evaluates the benefit of cetuximab, an EGF receptor antibody, in addition to standard chemotherapy in patients with operable liver metastases.
272 patients were randomised between February 2007 and November 2012 into the New EPOC study. Eligible patients were required to be k-RAS wild type, have operable liver metastases and to be sufficiently fit for chemotherapy and surgery. Patients with the primary tumour in situ, and those who required short course rectal radiation were eligible. Patients were randomised to receive a fluoropyrimidine and oxaliplatin plus or minus cetuximab. Patients who had been treated with adjuvant oxaliplatin could receive irinotecan and 5 − fluorouracil.
Following a recommendation from the Independent Data Monitoring Committee on 19/11/2012, the New EPOC study was stopped when the study met a protocol pre-defined futility analysis. With 45.3% (96/212) of the expected events observed, progression free survival was significantly worse in the cetuximab arm (14.8 vs 24.2 months, HR (95% CI) 1.50037 (1.000707 to 2.249517) p < 0.048).
It can be concluded that the addition of cetuximab to chemotherapy as neoadjuvant therapy for operable liver metastasis from colorectal cancer is unhelpful. Although the data are too immature to conclude that this approach is harmful, more events are unlikely to change this result, indeed the data are likely to become more significant over time. The addition of cetuximab to chemotherapy for k-RAS wild type tumours in this context is currently accepted clinical practice, but these data suggests that this approach is not beneficial. Updated data will be presented.

Background: WISP proteins (Wnt-inducted secreted proteins) are a subfamily of the CCN [Cyr61 (cysteine rich as a protein), connective tissue growth factor, and Nov (nephroblastoma overexpressed gene)] family of growth factors. The CCN family proteins share conserved multimodular domains with diverse biological functions, including angiogenesis, stem cell differentiation, and carcinogenesis. However, the role of WISP proteins in cancer cells and in clinical cancers remains controversial. The present project aimed to investigate the clinical relevance and the role of WISP played in human gastric cancer.
Materials and Methods: The expression of the three WISP molecules at the mRNA and protein levels in a cohort of 316 cases of human gastric cancers and normal gastric tissues were analysed using Q-RT-PCR and immunohistochemistry (IHC) assays respectively and correlated with the clinicolpathological features and clinical outcome of the patients. We also carried out genetic manipulation and created sublines from human gastric cancer cell lines, HGC27 and AGS, that differentially expressed the WISP molecules. The biological impact of differentially expressed WISP(s) on the biological functions, namely, cell growth, adhesion, migration and invasion, on the cells and potential mechanisms by which cells were influenced.
Results: WISP-2 and WISP-3, but not WISP-1 showed significant difference between normal tissues and tumours (P = 0.0009, P = 0.027 and P = 0.46, respectively). Expression of WISP2 was more interesting in that it was correlated with several clinicopathological parameters. Levels of the WISP2 transcript were found significantly lower in TNM1 and 2 stage tumours (P =0.012) compared with TNM3 and 4 stages, lower in T1 than in T4 tumours (P = 0.007), and significantly lower in node negative tumours than node positive tumours (P = 0.0029). IHC assay of WISP2 in corresponding gastric cancer pathological slides showed significant correlation with poor differentiation (P = 0.024). Using Cox Regression analysis, WISP2 protein was a significant independent prognosis indicator of gastric cancer patients (P = 0.018). In in-vitro studies, WISP2 gene was successfully knocked down in HGC27 and AGS cells. WISP2 knockdown resulted in significant change in the growth rate and in vitro invasiveness, with little effect on the adhesive capability, compared with its transfection controls This was found to be linked to the MMP activities, mediated by the JNK pathway.
Conclusion: WISP family proteins, in particular WISP-2, have different expression profile in gastric cancers and affects the biological functions of gastric cancer cells. The WISP family is therefore an important prognostic regulator in gastric cancer.

Pilot study for a European upper GI cancer audit (EURECCA Upper GI)

J.L. Dikken[1], J.W. Van Sandick[2], W.H. Allum[3], J. Johansson[4], L.S. Jensen[5], H. Putter[6], V.H. Coupland[7], M.W.J.M. Wouters[2], V.E.P.P. Lemmens[8], C.J.H. Van de Velde[1]. [1]*Leiden University Medical Center, Surgical Oncology, Leiden, Netherlands;* [2]*Netherlands Cancer Institute, Surgical Oncology, Amsterdam, Netherlands;* [3]*The Royal Marsden NHS Foundation Trust, Surgery, Londen, United Kingdom;* [4]*Lund University Hospital, Surgery, Lund, Sweden;* [5]*Aarhus University Hospital, Surgery, Aarhus, Denmark;* [6]*Leiden University Medical Center, Medical Statistics, Leiden, Netherlands;* [7]*King's College London Thames Cancer Registry, Londen, United Kingdom;* [8]*Comprehensive Cancer Center South, Epidemiology, Eindhoven, Netherlands*

Background: In Europe, several countries have implemented audit programs to improve national care for oesophageal and gastric cancer patients. So far, no international comparisons have been made. Purposes of the present study were to compare patterns of care and outcomes in several European countries and to assess the possibility for a European Upper GI Cancer audit.

Methods: National data were obtained from cancer registries or clinical audits in the Netherlands, Sweden, Denmark, and England. Differences in 30-day postoperative mortality and two-year survival were analyzed between countries and between hospital volume categories, adjusting for available case-mix factors.
Results: Between 2004 and 2009, 10,854 oesophagectomies and 9,010 gastrectomies were registered. Resection rates varied widely between countries (18−30% for oesophageal, 22−42% for gastric cancer). Adjusted 30-day mortality after oesophagectomy was lowest in Sweden (1.9%, Table). After gastrectomy, adjusted 30-day mortality was significantly higher in the Netherlands (6.9%) compared with Sweden (3.5%) and Denmark (4.3%). Oesophagectomies and gastrectomies were performed in highest hospital volumes in Denmark, and in lowest hospital volumes in Sweden. Increasing hospital volume was associated with lower 30-day mortality after oesophagectomy and gastrectomy.
Conclusions: The present results confirm a volume-outcome relationship in oesophagogastric cancer surgery. However, differences in outcomes between several European countries could not be explained by existing differences in hospital volumes. To understand these differences in outcomes across Europe, a European Upper GI Cancer Audit (EURECCA Upper GI) with uniform data registration is currently developed.
No conflict of interest.

Clinical validation on the role of FDG-PET/CT in radiation treatment planning for patients with esophageal cancer

C. Muijs[1], J.C. Beukema[1], D. Woutersen[2], V.E.M. Mul[1], J. Pruim[3], E.J. Van der Jagt[4], G.A.P. Hospers[5], H. Groen[6], J.T.H. Plukker[7], J.A. Langendijk[8]. *[1]University Medical Center Groningen University of Groningen, Radiation Oncology, Groningen, Netherlands; [2]Medisch Spectrum Twente, Radiation Oncology, Groningen, Netherlands; [3]University Medical Center Groningen University of Groningen, Molecular imaging and Nuclear Medicine, Groningen, Netherlands; [4]University Medical Center Groningen University of Groningen, Radiology, Groningen, Netherlands; [5]University Medical Center Groningen University of Groningen, Medical Oncology, Groningen, Netherlands; [6]University Medical Center Groningen University of Groningen, Epidemiology, Groningen, Netherlands; [7]University Medical Center Groningen University of Groningen, Surgical Oncology, Groningen, Netherlands; [8]University Medical Center Groningen University of Groningen, Radiology Oncology, Groningen, Netherlands*

Background: The aim of this prospective study was to determine the additional value of PET/CT for (chemo)radiotherapy treatment planning in esophageal cancer by assessing the proportion of patients in which locoregional recurrences (LRR) could have been prevented if PET/CT-based treatment planning was used instead of CT-based treatment planning.
Materials and Methods: Sixty-five esophageal cancer patients who were planned for high dose (chemo)radiotherapy, as primary treatment or in neo-adjuvant setting followed by surgical resection, were included in this prospective cohort trial (RESPECT). All patients underwent a planning FDG-PET/CT-scan. Radiotherapy target volumes were delineated on planning CT only and patients were treated according to the CT-based treatment plans. The PET images remained blinded. After treatment, the PET/CT was used to adjust the target volumes when appropriate. Follow up included routine CT-thorax/abdomen every half year. If LRR was suspected, an additional PET/CT was conducted in the original treatment position and the site of recurrence was compared to the original target volumes. If the recurrence was located outside or at the border of the CT-based clinical target volume (CTV) and inside the PET/CT-based CTV, we considered this as an event and as a possibly preventable.
Results: Based on the additional PET information, the gross tumour volume (GTV) was enlarged in 23% and reduced in 27% of the cases. The proportion of the PET/CT-based GTV which would be missed if the treatment planning was based on CT, was >5% in 28 patients (43%). The median follow up time was 27 months (95% CI 24.1–30.0). LRR were seen in 6 patients (9%), with synchronic distant metastases in 3 patients. All LRR were considered not preventable by the use of PET/CT, since 3 were located within the radiation-field, while in 3 the recurrences were located regionally, far from both the CT- and PET/CT-based CTV. Distant metastases were the most frequently reported first site of recurrence (35%).
Conclusion: In this prospective study, no preventable LRRs were found by the addition of FDG-PET/CT. Therefore, the additional value of PET/CT for the radiotherapy treatment planning for esophageal cancer remains limited in terms of prevention of LRRs.
No conflict of interest.

Evaluation of HER2 status in advanced or metastatic gastric, esophageal, or gastro-esophageal adenocarcinoma for entry to the TRIO-013/LOGiC trial of lapatinib in combination with capecitabine plus oxaliplatin

M. Press[1], G. Sauter[2], T. Grob[2], Z. Liang[3], Y.J. Bang[4], S.K. Qin[5], S. Santillana[6], C. Ellis[6], R. Hecht[7], D.J. Slamon[7]. *[1]University of Southern California, Los Angeles, USA; [2]University Medical Center Hamburg-Eppendorf, Oncology, Hamburg, Germany; [3]Peking Union Medical College Hospital, Department of Pathology, Beijing, China; [4]Seoul National University Hospital, Department of Medicine, Seoul, South Korea; [5]Nanjing Bayi Hospital, PLA Cancer Centre, Nanjing, China; [6]GlaxoSmithKline, Oncology, Collegeville, USA; [7]UCLA Medical Center, Department of Medicine, Los Angeles, USA*

Background: The human epidermal growth factor receptor (EGFR) type 2 (HER2) is commonly amplified and overexpressed in adenocarcinomas of the stomach, gastroesophageal junction (GEJ) and esophagus and is a potential target for therapeutic intervention. We report on the HER2 screening in a trial of lapatinib, a dual tyrosine kinase inhibitor of HER2 and EGFR, in combination with chemotherapy in advanced HER2-positive upper gastrointestinal (UGI) adenocarcinomas.
Material and Methods: Patients enrolled in this randomized, phase III trial had advanced, HER2-positive UGI adenocarcinomas as evaluated in local laboratories (Immunohistochemistry [IHC] 2+ and fluorescence in situ hybridization [FISH]-amplified, or IHC3+, or FISH-amplified) or a central laboratory (FISH-amplified). Patients were required to have tumor tissue submitted to a central laboratory for assessment of HER2 gene amplification by FISH (PathVysion) and expression by IHC (HercepTest) either for eligibility screening or confirmation of local result. The primary efficacy population (PEP) of the trial was composed of all patients whose tumors were centrally determined as HER2-amplified. The primary endpoint was overall survival in the PEP.
Results: Overall, 4674 patients underwent screening for eligibility; central HER2 testing was performed in 1995 patients for eligibility and 339 for confirmation of local result. Of the carcinomas screened by the central laboratory, 324 (16.2%) had *HER2* amplified disease. *HER2* genomic heterogeneity was evident in 2.1% of cases. In the patient cases centrally assessed, HER2 status by FISH and IHC is known for 1250 with 83.4% of amplified cases IHC3+/2+; 96.7% of non-amplified cases IHC1+/0. There were no cases that were IHC3+/FISH-negative. In total, 545 patients were accrued to the trial: 87.3% with gastric, 8.3% GEJ and 4.4% esophageal cancer. 487 patients were centrally confirmed as having HER2 amplified disease; 51 had HER2 non-amplified disease and HER2 amplification status was unknown in 7 patients. The concordance with central and local HER2 testing was 83%. In the 487 patients who comprise the PEP, 297 had cancers that were HER2 IHC3+ (61%), 108 were IHC2+ (22%), 54 were IHC1+ (11%), 27 were IHC 0 (6%), 1 was IHC unknown.
Conclusions: *HER2* is commonly amplified in adenocarcinomas of stomach, GEJ and esophagus and gene amplification is highly correlated with overexpression. While *HER2* genomic heterogeneity does occur, the prevalence rate is low.

Influence of time interval from histologic diagnosis to chemotherapy (CTx) on benefit of chemotherapy for advanced pancreatic adenocarcinoma

M. Teo[1], S. Deady[2], H. Comber[2], R.S. McDermott[1]. [1]*Adelaide & Meath Hospital Incorporating National Children's Hospital, Department of Medical Oncology, Dublin, Ireland;* [2]*National Cancer Registry of Ireland, Cork, Ireland*

Introduction: In our previous study, we found that variation in time interval between diagnosis and CTx did not significantly affect survival (OS) in these patients (pts) (Teo et al, ASCO GI 2013, abstr 306), which might be due to less effective CTx or inherent aggressiveness of pancreatic adenocarcinoma. This follow-up study aimed to investigate if the time interval impacts on the benefit of CTx, based on landmark analysis of Irish population-based registry data.
Methods: Anonymised individual level data were obtained from National Cancer Registry of Ireland. Pts who underwent curative surgery were excluded. OS was calculated from diagnosis to death or last follow-up. Pts who started CTx within 28 days were compared to untreated pts surviving at least 28 days; Pts who started CTx between days 29 and 56 were compared to untreated pts surviving at least 56 days; and pts who started CTx between 57 and 84 days were compared to untreated pts surviving at least 84 days; Pts were analysed as per disease stage (M0 − non-metastatic vs M1 − metastatic vs Mx − unknown stage) and age (⩾70 vs <70 years old). Benefit of CTx was presented as Cox estimated hazard ratio (HR), controlling for age and M status, respectively.
Results: Between 1998 and 2010, a total of 4509 pts were identified. Median age group was 70−74 and 49.5% were males. 942pts (21.0%) received CTx. 28.1% of treated pts and 73.3% of untreated pts were ⩾70 ($p < 0.001$). Amongst treated pts, 21.3% were M0 and 53.9% were M1, compared to 15.0% M0 and 38.6% M1 in untreated pts ($p < 0.001$). 417 received CTx within 28 days of diagnosis, 317 between 29 and 56 days and 108 pts between 57 and 84 days. Time intervals between diagnosis and CTx and their influence on CTx benefit were tabulated below.

	CTx within 28 Days			CTx within 29−56 Days			CTx within 57−84 Days		
	HR	95% CI	p	HR	95% CI	p	HR	95% CI	p
M0	0.63	0.44–0.88	0.005	0.76	0.56–1.02	0.068	0.67	0.42–1.03	0.070
M1	0.70	0.60–0.82	<0.001	0.77	0.62–0.93	0.008	0.93	0.65–1.29	0.669
Mx	0.83	0.65–1.05	0.128	0.80	0.59–1.06	0.124	0.86	0.58–1.22	0.412
⩾70	0.80	0.65–0.97	0.026	0.83	0.64–1.05	0.117	0.95	0.65–1.33	0.769
<70	0.71	0.62–0.82	<0.001	0.74	0.62–0.87	<0.001	0.85	0.64–1.11	0.240

Conclusion: Our population-based data suggests a uniform diminish of CTx benefit with increasing time interval between diagnosis and treatment. This effect appears most pronounced in elderly or M1 pts.
No conflict of interest.

Comprehensive arrays for expression profiling identify key microRNA to distinguish short and long survivors among resected pancreatic cancers patients

E. Giovannetti[1], M. Maftouh[1], N. Funel[2], L.G. Leon[3], A. Avan[1], S. Caponi[4], A. Van der Velde[3], E. Vasile[4], U. Boggi[2], G.J. Peters[1]. [1]*VU University Medical Center, Medical Oncology, Amsterdam, Netherlands;* [2]*University of Pisa, Surgery, Pisa, Italy;* [3]*VU University, Centre integrative Bioinformatics, Amsterdam, Netherlands;* [4]*University of Pisa, Medical Oncology, Pisa, Italy*

Background: Extensive studies have characterized the complex genetic networks and transcriptomics alterations underlying the progression of pancreatic ductal adenocarcinoma (PDAC). The recent discovery of microRNAs (miRNAs) provided additional insights potentially explaining the gap that exists between tumor genotype and phenotype. However, high-throughput technologies detecting hundreds of miRNAs provide new effective ways to unravel key miRNAs that might explain why patients with similar clinicopathological characteristics can have different clinical outcomes. Therefore, in this study we evaluated whether comprehensive miRNA profiling, using a chip detecting more than 1200 types of human miRNA, can distinguish between PDAC patients with very short OS compared to long-term survivors.
Material and Methods: High-resolution miRNA profiles were obtained with the Toray's 3D Gene-miRNA-chip. RNA was isolated from paraffin-embedded tumors of 26 radically-resected stage-pT3N1 homogeneously treated patients (gemcitabine 1000 mg/m^2/day, days 1/8/15, every 28 days), selected according to their outcome (OS<12 vs. OS>30 months, i.e. short/long OS). Highly stringent statistics included t-test, distance matrix with Spearman-ranked correlation, and iterative approaches.
Results: Unsupervised hierarchical analysis revealed that PDACs clustered according to their short-/long-OS classification, while the feature selection algorithm RELIEF identified the top 4 discriminating miRNAs. Validation of these miRNAs was performed by PCR in a second cohort of patients (N = 60), showing a strong correlation of miR-211 expression and outcome (i.e., low miR-211 expression was an independent factor of poor prognosis, hazard ratio 2.3, P = 0.03, at multivariate analysis). Conversely, patients with miR-4231 expression below median had only a trend towards a significant longer OS (25.8 vs. 16.7 months, P = 0.194).
Among predicted targets of miR-211, we performed functional analyses on ribonucleotide reductase subunit 2 (RRM2), an important target of gemcitabine, showing its significant reduction in the pancreatic cells MIA PaCa-2 and LPC028 after transfection with pre-miR-211. These findings support the hypothesis that modulation of gemcitabine sensitivity by miR-211 might be caused at least in part by inhibition of RRM2. Finally, pre-miR-211 significantly decreased cell migration and invasion, as demonstrated in 2 clones of the SUIT02 cells characterized by differential metastatic capability (SUIT02–028 and −007), using wound-healing and invasion assays.
Conclusions: Through comprehensive microarray analysis we identified miRNA with prognostic potential resected PDAC. Functional analyses suggested the role of RRM2 as target of miR-211 in the modulation of gemcitabine activity. These results prompt further prospective studies as well as research on the biological role of selected miRNAs in PDAC.

2456 POSTER DISCUSSION

Intraperitoneal chemotherapy in advanced gastric cancer − meta-analysis of randomised trials

F. Coccolini[1], E. Cotte[2], O. Glehen[2], Y. Yonemura[3], L. Ansaloni[1]. [1]*Papa Giovanni XXIII Hospital, Surgery, Bergamo, Italy;* [2]*Centre Hospitalier Lyon Sud, Surgery, Lyon, France;* [3]*Kishiwada Tokushukai Hospital, Surgery, Osaka, Japan*

Background: Gastric cancer (GC) is the second leading cause of cancer death and the fourth most common cancer in the world. GC disseminates principally through the haematic torrent or through the peritoneal cavity fluids. An important component of treatment failure is cancer dissemination within the peritoneal cavity and nodal metastasis. Intraperitoneal chemotherapy (IPC) gave a fundamental contribute in treating advanced GC. The purpose of the study is to investigate the effects of IPC in patients with advanced GC.
Material and Methods: A meta-analysis of randomised trials was performed.
Results: Twenty prospective randomized trials have been included for a total of 2145 patients. 1152 into surgery + IPC arm and 993 into control arm. 1, 2 and 3-years mortality rate were favourable to the surgery plus IPC arm (OR = 0.31, 0.27, 0.29 respectively). 2 and 3 years mortality in patients with loco-regional nodal metastasis were favourable to the surgery plus IPC arm (OR= 0.28, 0.16 respectively). 1 and 2-years mortality rate in patients with serosal infiltration was favourable to the surgery plus IPC arm (OR = 0.33, 0.27 respectively). The overall recurrence rate was favourable to the surgery plus IPC arm (OR = 0.46). The peritoneal recurrence rate was favourable to the surgery plus IPC arm (OR = 0.47). There were no statistically significant differences in lymph-nodal recurrence rate. The rate of haematogenous metastasis was favourable to the surgery plus IPC arm (OR = 0.63).
Conclusions: 2 and 3 years mortality rates in patients with nodal invasion are improved by the use of IPC. Loco-regional nodal invasion in patients affected by advanced GC is not a contraindication to IPC. 1, 2 and 3 years survival is incremented by IPC. No differences have been found at 5 years in survival rate. A positive effect of IPC has been found on distant metastasis.
No conflict of interest.

2457 POSTER DISCUSSION

Adjuvant chemoradiotherapy improves survival after a microscopically irradical (R1) gastric cancer resection

J. Stiekema[1], A.K. Trip[2], E.P.M. Jansen[2], M.J. Aarts[3], H. Boot[4], A. Cats[4], O. Balague Ponz[5], M. Verheij[2], J.W. Van Sandick[1]. [1]*The Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Surgery, Amsterdam, Netherlands;* [2]*The Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Radiation Oncology, Amsterdam, Netherlands;* [3]*Eindhoven Cancer Registry/Comprehensive Cancer Centre South, Research, Amsterdam, Netherlands;* [4]*The Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Gastroenterology, Amsterdam, Netherlands;* [5]*The Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Pathology, Amsterdam, Netherlands*

Background: A microscopically irradical (R1) resection is a known unfavourable prognostic factor after gastric cancer surgery. Currently, there are no clear guidelines how to manage patients who underwent an R1 gastric cancer resection. Adjuvant chemoradiotherapy (CRT) has been proposed, but evidence for any substantial benefit is very limited. In this study, overall survival of patients with non-metastatic gastric cancer who had undergone an R1 resection with and without adjuvant CRT was evaluated.
Material and Methods: Patients who had undergone an R1 resection for non-metastatic gastric cancer between 2002 and 2011 were included. We compared a cohort of patients from the population-based Netherlands Cancer Registry who did not receive adjuvant CRT (no-CRT group) with a group of patients who had been treated with adjuvant chemoradiotherapy (CRT group) at our institute. CRT consisted of radiotherapy (45 Gy/25 fractions) combined with concurrent cisplatin and/or 5FU based chemotherapy. Independent prognostic factors for overall survival were identified using multivariable Cox regression analyses.
Results: A series of 409 gastric cancer patients who had undergone an R1 resection was studied, including 369 patients who did not receive adjuvant CRT and 40 patients who were treated with adjuvant CRT. Median follow-up was 11 months in the no-CRT group and 18 months in the CRT group, respectively. In the no-CRT group, median age was higher (70 versus 57 years, $p < 0.001$) and the percentage of patients with diffuse type tumours according to Laurén was lower (43% versus 80%, $p < 0.001$). Tumour location was also significantly different between the two groups ($p = 0.005$). There were no significant differences in pathological T- and N-stage. Three-year overall survival was 19% in the no-CRT group, compared to 40% in the CRT group. There was a significant difference in median overall survival between the no-CRT and CRT group (13 versus 24 months, respectively, $p = 0.003$). In a multivariate analysis, adjuvant CRT was an independent prognostic factor for improved overall survival (HR 0.556, $p = 0.004$). Other factors that affected prognosis significantly were tumour location ($p = 0.047$), pathological T-stage ($p < 0.001$) and pathological N-stage ($p < 0.001$).
Conclusions: In this study, adjuvant chemoradiotherapy after a microscopically irradical (R1) resection for non-metastatic gastric cancer was associated with a significant survival benefit.
No conflict of interest.

2458 POSTER DISCUSSION

KIAA1199 knockdown attenuates cell growth of gastric cancer cells and its over-expression is associated with disease progression in patients with gastric cancer

S. Jia[1], J. Ji[2], W. Jiang[3]. [1]*Surgery Laboratory of the Affiliated Hospital of Inner Mongolia Medical University, Surgery, Hohhot, China;* [2]*Cardiff University-Peking University Joint Cancer Institute Peking University Cancer Hospital Beijing China, Metastasis and Angiogenesis Research Group, Cardiff, United Kingdom;* [3]*Cardiff University-Peking University Joint Cancer Institute Cardiff University School of Medicine, Metastasis and Angiogenesis Research Group, Cardiff, United Kingdom*

Background: KIAA1199, also named CCSP1 (colon cancer secreted protein 1) and TMEM2L, was originally described as an inner ear specific protein but emerging evidence has demonstrated that over-expression of KIAA1199 in human cancer is linked to poor survival. The clinical implications of this molecule in human gastric cancer and the biological impact on gastric cancer cells remain unknown. In this study, we aimed to investigate the influence of KIAA1199 on cell functions in gastric cancer cells and the potential clinicolpathological value in patients with gastric cancer.
Materials and Methods: Human gastric cancer cell lines HGC27 and AGS were used for screening the levels of KIAA1199 gene transcripts using q-RT-PCR analysis. Anti-KIAA1199 transgene ribozymes were constructed and transfected into HGC27 and AGS to stably down-regulate the expression of KIAA1199. Cell growth, adhesion, migration and invasion assays were carried out using conventional or ECIS (Electrical Cellular Impedance Sensing) methods. Wnt-pathway small inhibitors FH535 and IWP2 were used to elucidate the potential pathways involved in migration potentially regulated by KIAA1199. The levels of KIAA1199 gene transcripts were determined using high throughput cDNA microarrays analysis and q-RT-PCR analysis in a cohort of human gastric tissues ($n = 313$). Patients' clinicolpathological parameters and outcome results were analysed against the levels of KIAA1199.
Results: KIAA1199 gene was successfully knocked down in HGC27 and AGS cells. The KIAA1199-knockdown cells displayed significantly influence on the growth rate, cell mobility, invasiveness and apoptosis. There was no difference in adhesive capability compared with the transfection controls. β-Catenin/Tcf Inhibitor FH535 and Wnt Inhibitor IWP-2 had no effects on cell migration. In clinical cohort, the KIAA1199 transcript was over-expressed in gastric cancers compared with adjacent normal tissues ($P<0.001$). High levels of KIAA1199 were associated with tumour infiltration, advanced TNM staging and poor cell differentiation ($P<0.001$, $P<0.001$ and $P = 0.0002$, respectively).
Conclusion: KIAA1199 is a potential oncogene over-expressed in gastric cancer cells and tissues. It is closely related with cell growth, apoptosis, cell cycle, migration and invasive ability of HGC27 and AGS cells. High levels of KIAA1199 expression in gastric cancer patients are seen in advanced stages and poorer prognosis, thus indicating a potential prognostic value.
No conflict of interest.

2459 POSTER DISCUSSION

The prediction using artificial neural network of the outcome of radiotherapy for esophageal cancer

K. Atsumi[1], K. Nakamura[2], Y. Shioyama[3], H. Arimura[4], R. Hirayama[4], M. Hirakawa[1], K. Sakamoto[1], T. Sasaki[2], S. Ohga[2], H. Honda[2]. [1]*Kyushu University Beppu Hospital, Radiology, Beppu, Japan;* [2]*Graduate School of Medical Sciences Kyushu University, Clinical Radiology, Fukuoka, Japan;* [3]*Graduate School of Medical Sciences Kyushu University, Heavy Particle Therapy and Radiation Oncology, Fukuoka, Japan;* [4]*Faculty of Medical Sciences Kyushu University, Health Sciences, Fukuoka, Japan*

Background: Esophageal cancer continues to have a poor prognosis despite recent improvements in diagnosis and treatment. It is widely considered chemoradiation for esophageal cancer may achieve the same survival benefit as radical surgery especially for responders. In light of these findings, it may be desirable to choose an appropriate treatment option on an individual-patient basis and to identify responders for CRT, who can avoid surgery and its risk. An artificial neural network (ANN) is one of machine learning classifiers and a computational model simulating neural networks in the human brain. The ANN can learn the relationship between input data and teaching data. The purpose of this study was to construct of an ANN for the prediction of the tumor response of the patients treated with radiation therapy for esophageal cancer and its varidation.
Methods and Materials: The study group consisted of 167 patients with esophageal cancer of T1−4 and Stage I−III for the construction of an ANN for prediction of tumor response. We investigated the correlation between the tumor response of primary tumor after radiation therapy and each of the clinical factors in regard to patients or tumors with 167 patients. We constructed and trained an ANN to predict the tumor response using these correlative factors. The relationship between the predictive value using this ANN model and actual response was examined in 167 patients. In addition, the ANN constructed by the 167 patients was applied to a different group of 23 patients for variation analysis, and the correlation between the predictive response and actual response was also tested. We estimated the correlation between the predictive value by these ANN model and the actual value in tumor response by ROC analysis.
Results: We selected the predictive factors; T stage, tumor finding type, tumor length and SUVmax of primary tumor in 56 patients who performed FDG-PET before radiation (arm A) or wall thickness of tumor region in 111 patients which were not performed (arm B), which were significantly correrated with tumor response. We constructed two ANN models in arm A and B, and trained in each four predictive factors, respectively. In ROC analysis for the comparison between the predictive values by these ANN models and the actual value in tumor response, area under the curve (AUC) were 78% and 91% in arm A and B when the ANN constructed by the 111 patients was applied to the 111 patients. When the ANN was applied to the different set of 23 patients, AUC were 88% and 90% in arm A and B, respectively.
Conclusion: We constructed the ANN model to be able to predict the tumor response after radiation therapy. This ANN model could be used for determination of an optimal treatment strategy for esophageal cancer.

2460 POSTER DISCUSSION

Comparison of adverse effects of proton and X-ray chemoradiotherapy for oesophageal cancer using an adaptive dose-volume histogram analysis

H. Makishima[1], H. Ishikawa[1], T. Terunuma[1], T. Hashimoto[1], K. Yamanashi[1], T. Sekiguchi[1], M. Mizumoto[1], T. Okumura[1], K. Tsuboi[1], H. Sakurai[1]. *[1]Tsukuba University, Proton Medical Research Center, Tsukuba Ibaraki, Japan*

Background: Concurrent Chemo-radiotherapy (CCRT) is playing an important role in treating patients with oesophageal cancer, but late toxicities of the heart and lung are an issue. The anatomical arrangement of the oesophagus, and the characteristics of oesophageal cancer make it difficult to decrease the toxicities after CCRT. Proton beam therapy (PBT) can deliver high doses to deep tissues reducing doses of organs at risk (OAR), and could be an answer to this. We conducted a dose volume histogram (DVH) study to compare dose distributions of PBT with those of conventional 3D conformal radiation therapy (3DCRT) in oesophageal cancer and to evaluate dose differences of the heart and lung when target volumes in PBT and 3DCRT were identical.
Materials and Methods: CCRT using PBT was performed in 25 oesophageal cancer patients (stage I, II, III, and IV in 11, 5, 8, and 1, respectively) from 2009 to 2011 at our department. We recalculated all treatment plans using 3DCRT, and compared DVHs of the heart and lung as OARs. Dose of planning target volumes treated by PBT were same as those by 3DCRT. Dose constraints were set only for the spinal cord at a maximum (Dmax) of 40 Gy (2 Gy/Fr equivalent dose), and doses of other OARs were minimized as possible observing these constraints. Planning CTs were generally obtained multiple times during treatment, and all of them were used to calculate accumulated plans. In order to accumulate doses more accurately, we fused the structures and doses of these plans utilizing deformation techniques provided by MIM Software (Cleveland, USA).
Results: After CCRT using PBT, we have experienced no Grade 2 or severe late toxicity at the heart and lung and only one Grade 1 pericardial effusion. Lung V5, V10, V20 and MLD, heart V30, V40 and V50 for each patient were significantly lower in PBT plans compared to those in 3DCRT plans ($p < 0.01$ paired t-test). Similarly, median of these doses of all 25 patients were significantly lower in PBT plans ($p < 0.01$ t-test).
Conclusion: There were no severe toxicity in this series, and this volumetric study for patients with oesophageal cancer showed that the irradiated doses to the heart and the lung in PBT were significantly lower than those in 3DCRT. Hence, superiority of PBT in the DVH analysis possibly affected these favorable results. As a next step, making PBT plans for patients who actually received 3DCRT will inform us whether this hypothesis is true or not.

2461 POSTER DISCUSSION

Centralization of esophagectomy for cancer: How far should we go?

J.L. Dikken[1], D. Henneman[1], H. Putter[2], V.E.P.P. Lemmens[3], L.G. Van der Geest[4], R. Van Hillegersberg[5], C.J.H. Van de Velde[1], M.W.J.M. Wouters[6]. *[1]Leiden University Medical Center, Surgical Oncology, Leiden, Netherlands; [2]Leiden University Medical Center, Medical Statistics, Leiden, Netherlands; [3]Comprehensive Cancer Center South, Epidemiology, Eindhoven, Netherlands; [4]Comprehensive Cancer Center Netherlands, Epidemiology, Utrecht, Netherlands; [5]University Medical Center Utrecht, Surgical Oncology, Utrecht, Netherlands; [6]Netherlands Cancer Institute, Surgical Oncology, Amsterdam, Netherlands*

Background: Increasing hospital volume is associated with improved outcomes after esophagectomy, but reported definitions of 'high hospital volume' in literature vary (>7 to >80). Therefore, guidelines for minimal annual hospital volume standards in different countries around the world show considerable variation. Most studies aiming to define the optimal annual hospital volume for esophagectomy use predefined volume categories which are based on the available data. Non-linear statistical modeling techniques allow the use of annual hospital volume as a continuous variable, thereby providing the ability to define a meaningful cutoff point regardless of predefined categories.
The purpose of the current study is to define a statistically sound and clinically meaningful cutoff point for optimal annual hospital volume in esophagectomy for cancer.
Methods: Data were derived from the Netherlands Cancer Registry. Annual hospital volumes were analyzed as a continuous variable, and not as a categorical variable. Restricted cubic splines were used to investigate the non-linear effects of annual hospital volume on 6-month and 2-year (conditional on surviving 6 month) overall mortality rates. Outcomes were adjusted for year of diagnosis, case-mix and (neo)adjuvant treatment.
Results: Between 1989 and 2009, 10,025 patients underwent esophagectomy for stage I−III esophageal carcinoma in the Netherlands. Annual hospital volumes varied between 1/year to 83/year and increased over time. Increasing annual hospital volume showed a continuous, non linear decrease in HR (Hazard Ratio) for mortality along the curve. Increasing hospital volume from 20/year (baseline, HR = 1.00) to 40/year and 60/year was associated with a decrease in 6-month mortality with a HR of 0.73 (95% Confidence Interval (0.60–0.90) and 0.67 (0.58–0.77) respectively. Beyond 60/year, no further decrease in HR was detected. Higher hospital volume was also associated with a decrease in 2-year mortality until 50 esophagectomies/year with a HR of 0.84 (0.79–0.90).
Conclusions: Centralization of esophagectomy to a minimal annual hospital volume of 20/year has been effectively introduced in the Netherlands. Increasing annual hospital volume was associated with a non-linear decrease in mortality up to 40−60 esophagectomies/year, after which a plateau was reached. This finding may guide quality improvement efforts worldwide.
No conflict of interest.

2462 POSTER DISCUSSION

CT-based predictive model for circumferential resection margin in oesophageal cancer

C. Yip[1], E. Perry[2], A. Jacques[2], V. Goh[2], A. Davies[3], R. Mason[3], D. Landau[4]. *[1]King's College London, Division of Imaging Sciences, London, United Kingdom; [2]Guy's & St Thomas NHS Foundation Trust, Radiology, London, United Kingdom; [3]Guy's & St Thomas NHS Foundation Trust, Upper GI & General Surgery, London, United Kingdom; [4]Guy's & St Thomas NHS Foundation Trust, Oncology, London, United Kingdom*

Background: Circumferential resection margin (CRM) is an important prognostic factor in oesophageal cancer (OC) but there are no established assessment criteria to predict CRM status preoperatively. We aimed to define and validate a CRM predictive model based on computed tomography (CT) findings in OC.
Material and Methods: Following IRB approval, we retrospectively identified 234 consecutive patients who underwent oesophagectomy between 2000–2007 from our institutional database. A total of 68 patients were included in the development of the model. Exclusion criteria were failure to retrieve CT images for review (n = 162), poor image quality (n = 3) and absence of postoperative pathology (n = 1). All patients underwent contrast enhanced CT prior to surgery which were reviewed by radiologists blinded to the pathological results. CT parameters analysed included invasion/contact of adjacent structures (ICA), circumferential aortic contact >90º, largest primary tumour axial dimension (LAD), maximum wall thickness, tumour length, presence and number of lymph nodes >1 cm and presence of intact fat plane around tumour. Aortic contact >90º and ICA were combined and considered as a separate variable (ICAA). Univariate (UVA) and multivariate analyses (MVA) were performed and significant variables with $p \leqslant 0.21$ in the MVA were included in the predictive model (CRM3); continuous variables were dichotomised using median values. The performance of this model was assessed using receiver operating characteristic (ROC) curve analysis − area under the curve (AUC). This

model was validated in a separate validation cohort of 67 patients identified from our database who were treated between 2007–2010.
Results: Prevalence of positive CRM were 40% and 36% in the development and validation cohort respectively. The following parameters were significant predictors of CRM in UVA and were independent predictive factors in MVA: ICAA (UVA: p= 0.040, MVA: p=0.210), LAD (UVA: p = 0.004, MVA: p = 0.020) and nodal status (UVA: p = 0.050, MVA: p=0.180). In the CRM3 model, a score of 1 was given for presence of either ICAA, enlarged node or LAD greater than median value of 2.6 cm. The AUC for this model was 0.73 (95% CI 0.61–0.85) with 33% sensitivity and 95% specificity for a score of 3 in the development cohort. The AUC was 0.64 (95% CI 0.50–0.77) with 36% sensitivity and 86% specificity for a score of 3 when the model was applied in the validation cohort.
Conclusions: The CRM3 model has good discriminatory ability to identify patients at risk of positive CRM and could be useful in stratifying patients for more intensive neoadjuvant therapy.
No conflict of interest.

2463 POSTER DISCUSSION

Everolimus plus octreotide long-acting release (LAR) for the treatment of advanced neuroendocrine tumors (NET) associated with carcinoid syndrome (RADIANT-2): Updated overall survival results

M. Pavel[1], K.E. Oberg[2], J.D. Hainsworth[3], D. Lam[4], S.G. Stergiopolos[4], N. Rouyrre[5], M. Peeters[6], E. Baudin[7], D. Gross[8], J.C. Yao[9].
[1]Universitätsklinikum Charité, Campus Virchow-Klinikum Hepatologie and Gastroenterologie, Berlin, Germany; [2]University Hospital, Department of Endocrine Oncology, Uppsala, Sweden; [3]Sarah Cannon Research Institute, Nashville, USA; [4]Novartis Pharmaceuticals Corporation, Florham Park, USA; [5]Novartis International AG, Basel, Switzerland; [6]Antwerp University Hospital, Department of Oncology, Edegem, Switzerland; [7]Institut Gustave-Roussy, Department of Nuclear Medicine and Endocrine Oncology, Villejuif Cedex, France; [8]Hadassah-Hebrew University Medical Center, Neuroendocrine Tumor Unit, Jerusalem, Israel; [9]University of Texas, M. D. Anderson Cancer Center, Department of Gastrointestinal Medical Oncology Div

Background: RADIANT-2 (NCT00412061) showed that everolimus (EVE) + octreotide (OCT) LAR improved median adjudicated central review-assessed progression-free survival (PFS) by 5.1 months versus placebo + OCT LAR in patients with advanced NET and carcinoid syndrome (HR 0.77, 95% CI. 59−1.0; one-sided P=.026; prespecified $P \leqslant .0246$). Here we report the secondary endpoint of overall survival (OS).
Methods: Patients were randomized to EVE (10 mg/d, n = 216) or placebo (n = 213), both + OCT LAR (30 mg q28d). Survival endpoints were calculated using the intent-to-treat patient population (N = 429; all randomized patients). Patients in the placebo arm who switched to open-label everolimus after disease progression (n = 143) were retained in the placebo arm for OS analysis. Final OS analysis was planned after 252 events.
Results: Data cut-off date was April 23, 2012. Median EVE exposure was 37.0 wks (range 1–270) in pts randomized to EVE and 34.1 wks (range 1–200) in pts randomized to placebo who switched to open-label EVE; 36 patients had $\geqslant$144 wks of EVE exposure, including 8 randomized to placebo and switched to open-label EVE. Kaplan–Meier estimates (95% CI): 1 year, 80.5% (74.5–85.3) and 81.8% (75.8–86.4); 2 years, 57.0% (49.9–63.4) and 63.6% (56.6–69.8); 3 years, 42.9% (36.0–49.6) and 48.5% (41.4–55.3) in the EVE + OCT LAR and placebo + OCT LAR arms, respectively. Median OS (95% CI) after 253 events was 29.2 (23.8–35.9) months for EVE + OCT LAR and 35.2 (30.0–44.7) months for placebo + OCT LAR (HR 1.16, 95% CI. 91–1.49). When adjusted for baseline covariates (age, gender, race, WHO PS, and prior SSA usage), HR was 1.06, 95% CI. 82–1.36. Adverse events (AEs) reported during the open-label phase (n = 170) were consistent with those observed during blinded treatment; the most common included diarrhea (47.1%), stomatitis (37.6%), nausea (35.3%), edema (35.3%), fatigue (34.7%), and rash (34.1%).
Conclusions: There was no significant difference in OS between the EVE + OCT LAR and placebo + OCT LAR arms of RADIANT-2, even after adjusting for imbalances in baseline covariates. The likelihood of detecting OS differences may have been compromised by the crossover of many patients from the placebo arm to open-label EVE. Other factors that may have confounded the OS comparisons include imbalanced informative censoring, unknown therapy after study end, and imbalance in other baseline characteristics between treatment arms which could not be adjusted.

Clinical characteristics in 127 patients with advanced G3 gastrointestinal neuroendocrine carcinoma: The FFCD-GTE national cohort study

T. Walter[1], D. Tougeron[2], S. Manfredi[3], T. Lecomte[4], J.L. Legoux[5], R. Guimbaud[6], K. Le Malicot[7], C. Lombard-Bohas[1], C. Lepage[8], G. Cadiot[9]. *[1]Hôpital Edouard Herriot, Service d'Oncologie, Lyon, France; [2]Hôpital de la Milétrie, Service d'HGE, Poitiers, France; [3]CHU de Rennes, Service de gastroentérologie, Rennes, France; [4]Hôpital Trousseau, Service d'HGE, Tours, France; [5]Hôpital de la Source, Service HGE, Orléans, France; [6]CHU de Rangueil, Service de d'oncologie digestive, Toulouse, France; [7]Fédération Francophone de Cancérologie Digestive, Dijon Cedex, France; [8]CHU du Bocage, Service d'HGE, Dijon Cedex, France; [9]Hôpital Robert Debré, Service d'HGE, Reims, France*

Background: Data on grade 3 gastrointestinal neuroendocrine carcinoma (GI-NEC) are limited or retrospective. We designed a French national cohort study to describe the clinical characteristics of GI-NEC at diagnosis and evaluated prognostic factors for overall survival (not presented).
Patients and Methods: All patients with a G3 GI-NEC (WHO 2010) and a diagnosis done after 01/01/2010 could be included in this national prospective cohort study using an e-crf available online (www.cepd.fr). The cut-off for data was March 7, 2013.
Results: 127 patients were included in 33 centers: 62% were male, median age was 66 (23−90) years. No GI-NEC was associated with a familial syndrome. Main primary locations were duodenum-pancreas (24%), unknown (18%), rectum (16%), stomach (13%), oesophagus (11%) and colon (11%). None was located in the appendix and only two in the small bowel. The initial symptom was pain (58%). At diagnosis, the performance status was 0−1 in 78% of the patients. Most of the patients were metastatic (79%), with a median of 2 (0−5) metastatic sites (liver (76%), distant lymph nodes (54%), lung (15%), bone (16%), peritoneal (12%), cerebral (5%), other (11%)). Median (range) chromogranine A, NSE (Neuronal-Specific Enolase) and lactate dehydrogenase (LDH) levels were 151 μg/L (27–23500), 61 μg/L (2–3460), and 427 U/L (145–5115), respectively. 18F-FDG TEP scan and Octreoscan® were positive in 46/52 (89%) and 12/20 (60%), respectively. Pathological data showed: small/large cell NEC in 40%/60%, with necrosis in 76%, and a Ki67 index of 70% (15%-100%). 74 (58%) tumors are currently reviewed by the French national referent network (TENpath). The primary tumor was resected in only 18 (14%) patients. At least one (cisplatin/etoposide in 53/79 (67%) or carboplatin/etoposide in 16/79 (20%) of cases), two (Folfiri in 18/39 (46%) of cases) or >2 palliative systemic chemotherapies were given in 79 (62%), 39 (31%) and 19 (15%) patients, respectively.
Conclusions: GI-NEC are mainly diagnosed at advanced stage. Several parameters should be considered to evaluate the prognosis and adjust the treatment, which will be presented at the meeting.
No conflict of interest.

2465 POSTER DISCUSSION

Circulating tumor cells and circulating endothelial cells as predictors of efficacy of pazopanib in patients with progressive neuroendocrine tumors

J. Earl[1], C. Guerrero-Arroyo[1], J. Capdevila[2], D.E. Castellano[3], R. Garcia-Carbonero[4], A. Teule[5], J. Garcia-Donas[6], J. Fuster[7], A. Carrato[8], E. Grande[8]. *[1]Ramon y Cajal University Hospital, Laboratory of Medical Oncology, Madrid, Spain; [2]Vall d'Hebron University Hospital, Medical Oncology, Barcelona, Spain; [3]Hospital Universitario 12 de Octubre, Medical Oncology, Madrid, Spain; [4]Hospital Universitario Virgen del Rocio Instituto de Biomedicina de Sevilla (IBIS), Medical Oncology, Sevilla, Spain; [5]IDIBELL Institut Català d'Oncologia L'Hospitalet, Medical Oncology, Barcelona, Spain; [6]Centro Integral Oncológico Clara Campal, Medical Oncology, Madrid, Spain; [7]Hospital Son Espases, Medical Oncology, Palma de Mallorca, Spain; [8]Ramon y Cajal University Hospital, Medical Oncology, Madrid, Spain*

Background: The objective of this study is to evaluate the predictive and prognostic role of circulating tumor cells (CTC) and circulating endothelial cells (CEC) in patients with progressive neuroendocrine tumors (NETs) treated with Pazopanib (PAZONET trial − ESMO 2012).
Methods: Patients with advanced NETs progressing with prior treatment, including antiangiogenic drugs were treated with Pazopanib 800 mg/day until progression or unacceptable toxicity. Blood samples were retrieved at baseline and after 12 weeks of treatment. CTC and CEC were detected by immunomagnetic isolation. Disease was evaluated bimonthly via CT scans (RECIST1.0).
Results: 44 patients were included and baseline CTC were determined in 21 patients, 11 of which had detectable CTC (range 1 to 108 cells/ml).

One patient (9.1%) with a baseline presence of CTC presented a partial response (PR) compared with 4 patients (44.4%) without (p = 0.13). Duration of pazopanib-adjusted OR for PR is 6.2 (95% CI 0.45–86.5, p = 0.17) for patients without CTC compared with patients with CTC at baseline. Patients without and with baseline CTC had a median progression-free survival (PFS) of 9.1 versus 5.8 months, respectively (p = 0.12). There were no changes in CTC in the second determination. CEC were determined at baseline and after 12 weeks of therapy in 18 and 9 patients respectively. Median decrease in CEC was −12.5% (p = 0.077). Patients with a lower baseline CEC count (⩽median) had a trend towards a higher response rate (44.4% vs. 12.5%, p = 0.29) and longer PFS (duration of pazopanib-adjusted OR 0.58, 95% CI 0.17–1.98, p = 0.22).
Conclusions: Baseline CTC were detected in 52% of patients tested, and did not change during pazopanib therapy. A trend for an association between the presence of CTC and higher CEC counts at baseline and worse clinical outcome was observed. CEC seemed to decrease during pazopanib treatment, although the association with clinical outcome is unclear.

NADEGE prospective cohort: Demographic data of 335 small bowel adenocarcinomas

T. Aparicio[1], S. Manfredi[2], D. Tougeron[3], O. Bouché[4], D. Pezet[5], C. Mariette[6], R. Coriat[7], A. Zaanan[8], J.L. Legoux[9], P. Afchain[10]. *[1]CHU Avicenne, Gastroenterology, Bobigny, France; [2]CHU Rennes, Gastroenterology, Rennes, France; [3]CHU Poitiers, Gastroenterology, Poitiers, France; [4]CHU Reims, Gastroenterology, Reims, France; [5]CHU Clermont Ferrand, Digestive Surgery, Clermont Ferrand, France; [6]CHU Lille, Digestive Surgery, Lille, France; [7]CHU Cochin, Gastroenterology, Paris, France; [8]CHU Pompidou, Gastroenterology, Paris, France; [9]CH Orleans, Gastroenterology, Orleans, France; [10]CHU Saint Antoine, Oncology, Paris, France*

Background: Small bowel adenocarcinoma (SBA) is a rare tumour poorly studied. Data are coming from register study or monocentric retrospective studies. The purpose of the NADEGE cohort (*Cohorte Nationale d' ADEnocarcinomes du GrêlE*) is to describe characteristics, prognosis and chemotherapy regimens of SBA in unselected patient at a nationwide level.
Material and Methods: All the patients with a SBA diagnosed from January 2009 to December 2012 were enrolled in the NADEGE cohort. The study involved 72 centres in France that enrolled 335 patients. This work presents the first demographic data.
Results: Patients were predominantly male (58) and median age was 63 years [23−90]. The median number of patient enrolled by center was 2 (1−33). The primary locations were duodenum (51%), duodeno-jejunum (8.7%), jejunum (20.6%), ileum (16.1%) and not determined (ND) (3.6%). The tumour was poorly differentiated (12%), moderately (33%), and well differentiated (32%). A predisposing disease was reported in 63 (18.8%) of cases: Crohn disease 29 (46%), Lynch syndrome 19 (30%), familial adenomatous polyposis (FAP) 7 (11%), celiac disease 6 (9.5%) and Peutz-Jeghers syndrome 2 (3%). The disease was localized and resected in 55% of patients, locally advanced and not resected in 5.7%, metastatic and resected in 10.1%, metastatic and not resected in 23% and ND in 6.2%. The 184 tumours resected without metastases were 6 stage 0, 55 stage I−II, 77 stage III, and 48 ND. Adjuvant chemotherapy, mainly by FOLFOX regimen (88%), was performed in 16% of stage I−II, 56% of stage III and 26% of resected stage IV. A palliative chemotherapy was performed in 74% of cases in metastatic disease, by FOLFOX regimen in 60% of cases. According to the location of primary tumours duodenum/jejunum/ileon, the tumours were T4 in respectively 27%, 41% and 33% of cases, metastatic in 33%, 29% and 35% of cases and poorly differentiated in 11%, 13% and 19% of cases. Primary tumours were mainly ileal in 76% of patient with Crohn disease and duodenal in 42% of patient with a Lynch syndrome and 57% of patients with FAP.
Conclusions: NADEGE cohort is the largest prospective SBA study. A high rate of predisposing disease is observed with a difference in tumor site according to the predisposing disease. FOLFOX chemotherapy is the main regimen used in adjuvant and metastatic setting. Follow-up is ongoing until 2015.

Sorafenib alone versus Sorafenib combined with Gemcitabine and Oxaliplatin (GEMOX) in the first-line treatment of advanced hepatocellular carcinoma: final analysis of the randomized phase II GoNext trial (a UNICANCER/FFCD/PRODIGE 10 study)

E. Assenat[1], V. Boige[2], S. Thezenas[3], G.P. Pageaux[4], J.M. Perron[5], Y. Becouarn[6], J.F. Seitz[7], P.H. Merle[8], J.F. Blanc[9], M. Ychou[10]. *[1]University Hospital Montpellier, Digestive Oncology, Montpellier cedex 05, France; [2]IGR Cancer Center, Digestive Oncology, Villejuif, France; [3]ICM Cancer Center, Statistics, Montpellier, France; [4]CHU Saint Eloi, Hepatology, Montpellier, France; [5]CHU, Hepatology, Toulouse, France; [6]Institut Bergonier, Medical Oncology, Bordeaux, France; [7]CHU La Timone, Digestive Oncology, Marseille, France; [8]CHU, Digestive Oncology, Lyon, France; [9]CHU Saint Andre, Digestive Oncology, Bordeaux, France; [10]ICM Cancer Center, Digestive Oncology, Montpellier, France*

Background: Hepatocellular carcinoma (HCC) is a vascular tumor with poor prognosis. Even though Sorafenib has been shown to improve survival, its ability to induce tumor shrinkage is very low. Given the reported activity of Gemcitabine and Oxaliplatin (GEMOX) in HCC, a randomized phase II study testing Sorafenib combined to GEMOX was undertaken to define efficacy and safety profile in HCC patients.
Methods: Patients with inoperable advanced and/or metastatic HCC (BCLCC B or C), with or without prior palliative chemoembolization, Child pugh score A, WHO performance status (PS) 0−1, were eligible for this open-label, two-stage, randomized phase II trial. Patients received Sorafenib (S) (400 mg BID) alone (ARM A) or in combination with GEMOX every 2 weeks (gemcitabine, 1000 mg/m^2 [10 mg/m^2/min] at day 1; oxaliplatin, 100 mg/m^2 at day 2) (arm B). Randomization was stratified according to CLIP score (0−1 vs 2−3) and center. Tumor assessments were performed every 8 weeks according to RECIST 1.0. The primary endpoint was crude 4-month Progression-Free Survival (PFS) rate (H0, <50%; H1, ⩾70%; α = 10%; 1- β= 90%). Secondary endpoints were Objective Response Rate (ORR), Disease Control Rate (DCR), PFS, Overall Survival (OS), and toxicity (NCI-CTC v3.0); translational studies consisted of pharmacokinetic, pharmacogenetic, mRECIST assessment and blood/tumor VEGFR signalling pathway analysis.
Results: From 12.2008 to 10.2011, we enrolled 94 pts: median age, 64 yrs; male, 88%; PS 0 (69%) 1(31%), CLIP 0−1 (48%) 2−3 (52%), cirrhosis (63%), portal vein thrombosis (29%), extra hepatic metastasis (69%). These characteristics were well balanced in both arms. Median duration and dose intensity of Sorafenib were respectively 4 months (1−27) and 81% in both arms. Median number of GEMOX cycles was 7 (1−12) in arm B. Main severe (grade 3−4) toxicity (arm A/B) consisted of neutropenia (grade 3−4: 0%/7%), fatigue (18%/24%), thrombocytopenia (0%/9%), diarrhea (grade 2−4: 10%/21%), peripheral neuropathy (grade 2−3: 0%/10%), and hand foot syndrome (grade 2−3: 13%/7%). For evaluable pts (n = 83), the ORR was 9%/16% and the DCR was 70%/77%, in arm A/B respectively. For all pts (median follow-up, 17.6 months), 4-month PFS rate was 54%/61%, median PFS was 4.6 (3.9−6.2)/6.2 (3.8−6.8) months, and median OS was 13.0 (10.4–22.2)/13.5 (7.5–19.1) months, in arm A/B respectively.
Conclusions: Sorafenib plus GEMOX regimen is feasible in HCC and this randomized trial met its primary endpoint (4-month PFS ⩾50%). Moreover, ORR, median PFS and OS are encouraging compared to the literature data. Exploratory analyses are underway to try to identify subgroups of patients most willing to derive benefit from this combination.

Chemotherapy induced DNA repair enhancement is a potential resistant mechanism in hepatocellular carcinoma

S.T. Yang[1], X.Q. Wang[1]. *[1]The University of Hong Kong, Surgery, Pokfulam, Hong Kong*

Background: Hepatocellular carcinoma (HCC) has long been recognized as a chemotherapy refractory cancer. Antitumor activity of most chemotherapeutic drugs depends on the induction of DNA damage. In eukaryote, DNA end-joining (EJ) is the predominant repair mechanism of the most toxic DNA double strand breaks (DSBs). In this study, we tried to investigate the role of EJ repair in HCC chemo-resistance.

Methods: Drugs induced HCC cells characters changes were assessed using flow cytometry, immunofluorescence staining, MTT assay, quantitative real-time PCR, small interfering RNA and western blotting. Cancer stem cell population was separated by MACS®.
Results: We observed drugs (cisplatin, oxaliplatin, doxorubicin and 5-FU) with different antitumor mechanism can all induce γ-H2AX foci (a DSBs marker) formation and increase DNA repair gene expression in HCC cells (97L and PLC) shortly (2 h) after treatment. Significant decrease of foci number in 97L cells 48 h afterwards indicated 97L may possess a more efficient DSBs repair. Cytotoxicity assay showed that 97L was more resistant to chemotherapy than PLC cells. Furthermore, 97L presented a significantly enhanced EJ activity after chemotherapy both *in vivo* and *in vitro*. XRCC4-like factor (XLF), also known as NHEJ1 or cernonnus, is an important protein involved in EJ repair. We transient knocked down XLF in the more resistant 97L cells by siRNA. EJ repair activity was significantly suppressed and subsequently restore chemo-sensitivity in XLF-deficient 97L compared with wild type 97L, indicated inhibit XLF may be a potential chemo-sensitizer for HCC. Recently, cancer stem cells attract great interest as the origin of recurrence following chemotherapy. CD133 is the most widely used cell surface marker to distinguish CSCs subpopulation from HCC cells. We first segregated CD133+ from CD133− HCC cells by magnetic cell separation technology. Compared with CD133− HCC cells, CD133+ cells were more resistance to chemotherapy and possessed a significant increment of chemotherapy induced EJ genes expression and EJ repair capacities. ERCC1 is an important protein involved in nucleotide excision repair (NER), the major repair mechanism of DNA crosslink damage. Also ERCC1 expression is closely associated with platinum based chemotherapy outcomes in NSCLC. Interestingly, we found a significantly suppression of ERCC1 expression in XLF-deficient HCC cells which implied a cross-regulation between ERCC1 and XLF.
Conclusions: Chemotherapy can induce DSBs and activate relative repair in HCC. Suppression of XLF can significantly inhibit EJ repair and restore chemo-sensitivity in HCC cells. HCC CSCs subpopulation may contribute to chemotherapy activated EJ repair and consequent chemo resistant. Our results suggested that HCC cells may develop an enhanced DNA EJ repair to eliminate induced DSBs during chemotherapy and targeting XLF could be a potential supplement to HCC treatment as a chemo-sensitizer.

Clinical relevance and functional role of nuclear Met in hepatocellular carcinoma

S.K. Tey[1], E.Y. Tse[1], J.W. Yam[1]. [1]*The University of Hong Kong, Pathology, Hong Kong, Hong Kong*

Background: Met is a receptor tyrosine kinase which triggers a wide range of normal physiological signalling cascades. However, a perturbation of the Met pathway is commonly found in human cancers. Emerging evidence has shown the presence of nuclear Met (nMet) in some cancerous tissues and cell lines, suggesting that nMet could have unexplored functions in the nucleus. The present study aimed to assess the expression and functions of nMet in hepatocellular carcinoma (HCC).
Material and Methods: nMet expression of 103 clinicopathologically characterised HCC paired samples was examined by immunohistochemistry using an antibody against the carboxyl terminus of Met. Statistical analyses were applied to evaluate the association of nMet with different clinical parameters. Nuclear localisation of Met was determined by western blot analysis and immunofluorescence microscopy. Met cytoplasmic fragments were characterised by *in vitro* functional assay such as migration, invasion and proliferation in HCC cells.
Results: nMet is overexpressed in 89.3% samples and its expression is progressively increased along HCC development from non-tumorous liver tissue to advanced HCC. Nonetheless, nMet overexpression is significantly associated with venous invasion and poorer overall survival. We found that nMet, which has a lower molecular weight than Met, could only be detected using an antibody against the carboxyl terminus of Met (C28) in tumorous tissues. This finding strongly suggests that nMet only comprises of the carboxyl cytoplasmic region of full length Met. Moreover, both western blot analysis of nuclear fraction of HCC cells and immunofluorescence confirmed the nuclear localization of Met. We designed construct J1, J3 and T2 that encode Met fragment truncated after tyrosine residues D972 and P1027 in the juxtamembrane region and after tyrosine kinase domain beginning at L1157, respectively. Immunofluorescence microscopy showed both J1 and J3 constructs are dominantly expressed in the nucleus whereas T2 construct is expressed in the cytoplasm. These observations indicated the region in between J1 and T2 as the important region that facilitates the nuclear localisation of Met. *In vitro* functional study showed that overexpression of nMet augments the invasiveness of HCC cells suggesting the unexplored functional effect of nMet exerted within nucleus in promoting HCC invasiveness.
Conclusions: nMet is overexpressed and associated with venous invasion and poorer overall survival in HCC. We found that nMet is actually the carboxyl terminal fragment of Met and translocates into nucleus to promote invasiveness in HCC cells.

MAGIs, membrane-associated guanylate kinase with inverted structure protein, involved in the metastatic properties of gastric cancer cells, the clinical implications

S. Jia[1], J. Ji[2], W. Jiang[3]. [1]*Surgery Laboratory of the Affiliated Hospital of Inner Mongolia Medical University, Surgery, Hohhot, China;* [2]*Cardiff University-Peking University Joint Cancer Institute Peking University Cancer Hospital Beijing China, Metastasis and Angiogenesis Research Group, Cardiff, United Kingdom;* [3]*Cardiff University-Peking University Joint Cancer Institute, Metastasis and Angiogenesis Research Group, Cardiff, United Kingdom*

Background: Tumor metastasis is a multistage process in which a network of related molecules and signal pathways are intimately involved. Tumor invasion and metastasis are directly related to the prognosis of patients with gastric cancer. Membrane-Associated Guanylate Kinase With Inverted Structure, MAGIs are a relatively new gene family that has been postulated to have a role in invasion and metastasis based on the predicted protein structure and functions. The MAGI proteins are a group of scaffolding proteins located in cell-cell junctions and play important roles in the process of tissue development, the stabilization/maintenance of tight junctions and cell signaling. However, there has been very limited clinical and scientific evidence on this suggestion. The present project aimed to investigate the clinical relevance and the biological impact of differentially expressed MAGI(s) on the biological functions as cell growth, adhesion, migration and invasion, on the cells and potential mechanisms by which cells are influenced.
Materials and Methods: The levels of MAGI1, 2 and 3 transcripts were determined using quantitative transcript analysis in a cohort of human gastric tissues (n = 317). Patients' clinicolpathological parameters and more than 5 year's outcome results were analysed against the levels of MAGI 1, 2 and 3. For the potentially interested gene(s), we would either knockdown or over-express the gene(s) in human gastric cancer cell lines HGC27 and AGS and use the newly created sublines to investigate cell functions including growth, adhesion, migration and invasion using conventional and ECIS (Electrical cellular impedance sensing) methods.
Results: The gene expression of MAGI1, and to a lesser degree MAGI2 and MAGI3, was linked to infiltration depth of the stomach wall and distant metastasis of the patients. Levels of the MAGI1 transcript were negatively correlated with distant metastasis (disease free VS. distant metastasis, P = 0.0015). Human gastric cancer cell lines HGC27 and AGS highly expressed MAGI-1. We successfully knocked down MAGI1 from both cells and produced stable MAGI-1 knockdown sublines. MAGI1-knockdown rendered cells with significantly decreased growth rate and adhesive capability but increased cell mobility, invasive ability compared with control cells.
Conclusion: MAGI1, rather than MAGI2 and MAGI3, has a metastasis suppressive role in gastric cancer, by influencing the invasiveness and growth of the cells. Its prognostic and therapeutic value warrant further exploration.

2471 POSTER

Clinical significance and cell functions of Tubedown-100 (TBDN100) in gastric cancer

S.Q. Jia[1], J.F. Ji[2], W.G. Jiang[3]. [1]*Surgery Laboratory of the Affiliated Hospital of Inner Mongolia Medical University, Surgery, Hohhot, China;* [2]*Cardiff University-Peking University Joint Cancer Institute Peking University Cancer Hospital Beijing China, Metastasis and Angiogenesis Research Group, Cardiff, United Kingdom;* [3]*Cardiff University-Peking University Joint Cancer Institute Cardiff University School of Medicine, Metastasis and Angiogenesis Research Group, Cardiff, United Kingdom*

Background: Protein acetylation is an important posttranslational modification regulating oncogenesis, apoptosis and cell cycle. Tubedown-100 (TBDN100), also known as NAA15 (N(alpha)-acetyltransferase 15), is a gene encoding a protein of unknown function. It was expressed at a low level in most human adult tissues, including the normal thyroid gland. Increased TBDN100 expression has been seen in a Burkitt lymphoma cell line and in adult human testis. Knockdown of TBDN100 may trigger apoptosis in human cancer cell line Hela. Although TBDN100 has been indicated in the regulation of apoptosis, its biological function and involvement in cancers remained to be elucidated. Here, we report the expression of TBDN100 in gastric cancer and the effect of TBDN100 on human gastric cancer cells.

Materials and Methods: The levels of TBDN100 gene transcripts were tested using q-RT-PCR analysis in human gastric cancer cell lines HGC27 and AGS, and a gastric cancer cohort. TBDN100 over-expression plasmid were constructed using a mammalian expression vector and was used to transfect into gastric cancer cells to generate TBDN100-overexpresion sublines. Cell growth, apoptosis, cell cycle, adhesion and migration were evaluated. TBDN100 expression levels in the clinical cohort were analysed against patient's clinicolpathological parameters and prognosis results.
Results: HGC27 and AGS cells were negative for TBDN100 expression. Overexpression of TBDN100 in HGC27 and AGS cells by way of transfection resulted in significant changes in the growth rate, cell cycle distribution, adhesive capability and *in vitro* invasiveness. However, levels of TBDN100 transcript were significantly higher in gastric tumours compared with adjacent normal gastric tissues ($p < 0.001$). More interestingly, level of the TBDN100 transcript was significantly higher in tumours of who remained alive than from those who died of gastric cancer 5 years after surgery ($P = 0.0484$). It was also higher in cardiac tumours than on corpus tumours ($P = 0.0079$) and higher in those without lymph node metastasis.
Conclusions: TBDN100 has different expression profile in gastric cancer tissues and cells, with high levels seen in gastric tumours from patients with longer survival and negative lymph node metastasis, thus indicating a potential prognostic value.

The "cavitary" type of vessels formation in gastric cancer: Morphological characteristics and clinical significance

M. Senchukova[1]. [1]*Orenburg State Medical Academy, Oncology, Orenburg, Russian Federation*

Background: For the first time, a 'cavitary' type of vessels (CTVs) formation was described in patients with gastric cancer (GC). The morphological features and clinical significance of the CTVs were the objects of this study.
Material and Methods: The samples of tumor and adjacent gastric mucosa (GM) in 69 radically operated patients with GC were studied. The sections were stained with hematoxylin and eosin and by IGH using antibodies to CD34. The number of CTVs was assessed the visual analog way (no, single, multiple). The obtained data were compared with clinical features, 2-year overall (OS) and relapse-free survival (RFS).
Results: The following steps of the CTVs formation were identified: 1) a formation of the cavitary structures in the tumor and adjacent GM; 2) then they are being lined by endothelial cells (ECs); 3) and merged with the blood vessels of the organ. Two main mechanisms of the CTVs formation were marked:

1. The 'cavities' can be formed at the expense of desquamation layers of epithelial cells (both normal and tumor) in the lumen of the gastric glands (GG) having no connection with gastric lumen. By IHC it was revealed that the internal surface of the described 'cavities' can be fully or partially lined by ECs. The newly formed vessels (type I) had different shapes and often have been spaced according to the virtual topographic projection of GG on the section plane. Both the columnar epithelium and ECs lining the blood vessel wall can sometimes be seen in the area of vessel and GG 'merger'. The epithelial and tumoral emboli were often found in the lumen of such vessels.
2. The 'cavities' can also be formed by dilatation of the GG with a gradual reduction of the epithelial cells height, their flattening, thinning and then merging with vessels adjacent to theirs wall. The vessels of type II, as well as adjacent GG were dilated and often had irregular shape. By IGH it sometimes seemed that the endothelial lining was over the epithelial layer.

The vessels of type I significantly correlated with the presence of metastases in regional lymph nodes (RLN) ($R = 0.494$, $p < 0.0002$); OS ($R = -0.709$, $p < 0.0001$) and RFS ($R = -0.701$, $p < 0.001$). Multiple vessels of this type are found significantly more often in patients with metastases in RLN (50% and 14.3% respectively in stage N1−2 and N0, $p < 0.006$). RFS was 89.6% and 41.2% ($p < 0.0003$) and OS was 95.8 and 70.6% ($p < 0.004$) in patients with the absence or the single vessels in GM and in patients with multiple vessels, respectively. A presence in anamnesis of antibacterial therapy (AT) in connection with the preliminary diagnosis of a gastritis or a stomach ulcer considerably improved the 2-year survival of patients with metastasis in RLN (RFS was 80% and 43.5%, $p = 0.03$ and OS was 100% and 66.7%, $p < 0.04$ respectively with and without AT) and decreased the number of patients with multiple vessels of type I (18.2% and 58.3% respectively with and without AT, $p < 0.04$). The vessels of type II significantly correlated only with the degree of GM metaplasia ($r = 0.590$, $p < 0.0002$).
Conclusions: The described CTVs formation has a large clinical importance.
No conflict of interest.

2473 POSTER

Mutant GNAS found in IPMN can alter global gene expressions with mucin upregulation

H. Komatsu[1], N. Sakata[2], T. Aoki[2], F. Motoi[2], T. Naitoh[2], Y. Katayose[2], S. Egawa[2], M. Unno[2], T. Furukawa[1]. [1]*Tokyo Women's Medical University, Institute for Integrated Medical Sciences, Tokyo, Japan;* [2]*Tohoku University Graduate School of Medicine, Department of Surgery, Sendai, Japan*

Background: *GNAS*, a gene encoding G-protein stimulating alpha subunit, is frequently mutated in intraductal papillary mucinous neoplasms (IPMNs), which is an indolent and slow-growing pancreatic neoplasm that secretes abundant mucin. *GNAS* mutation is not observed in conventional ductal adenocarcinomas of the pancreas or pancreatic cystic neoplasms except IPMN. Mutated *GNAS* has been reported to induce the high intracellular cAMP concentration and to activate GPCR pathway. However, the phenotypes in pancreatic ductal cells with mutated *GNAS* are still unknown.
Materials and Methods: To determine the functional significance of *GNAS* mutation, we examined the *in vitro* phenotypes and gene expression profiles of pancreatic cancer cells with exogenous expression of either wild-type or mutant (R201H) *GNAS*, using PK-8, PCI-35, and MIA PaCa-2 cells. Measurement of cAMP, real time PCR for mucin gene expressions, colony formation assay for survival, MTT assay for proliferation, flow cytometry for cell cycle and serial analysis of gene expression were performed. The experiments using a MAPK inhibitor were also carried out to clarify the crosstalk between GPCR and MAPK signaling pathway, and to determine the contribution of MAPK activity to mucin gene expression.
Results: The exogenous expression of *GNAS* increased intracellular cAMP, however, the degree of this upregulation appeared to be cell-type specific. The exogenous expression of *GNAS* induced no obvious cell-growth promotion; rather, it suppressed the proliferation and survival of cells. Cell cycle was not affected by exogenous *GNAS*. The exogenous expression of *GNAS* induced varying degrees of alterations in global gene expression profiles. PK-8 was most sensitive to the mutated *GNAS*, as it exhibited drastic alterations in the gene expression profile and upregulation of *MUC2* and *MUC5AC*. PCI-35 and MIA PaCa-2 cells were less sensitive and exhibited a lower number of genes with altered expression, with downregulation of mucin genes. Pathway analysis revealed that genes on PI3K-AKT and MAPK signaling pathway were primarily altered by mutated *GNAS*. Moreover, MAPK activity partially contributed to mucin gene expression under active *GNAS*.
Conclusion: PK-8 cells expressing mutated *GNAS* exogenously can be used as an ideal model of IPMN for its GPCR-dependent character. The *GNAS* mutation can play an important role in altering gene expression profiles, with promotion of mucin gene expression.

2474 POSTER

Id1-induced IGF2 promotes bidirectional interaction between esophageal cancer cells and fibroblasts in the tumor microenvironment

A.L.M. Cheung[1], W.W. Xu[1], B. Li[1], S.W. Tsao[1], K.W. Chan[2]. [1]*University of Hong Kong, Anatomy, Hong Kong;* [2]*University of Hong Kong, Pathology, Hong Kong*

Background: Esophageal squamous cell carcinoma (ESCC) is highly prevalent in Asia. Over 90% of ESCC overexpress Id1 protein. This study aims to investigate the interaction between Id1-overexpressing ESCC cells and stromal fibroblasts, and the mechanism and role of this crosstalk in ESCC progression.
Material and Methods: Human ESCC cell lines with ectopic expression of Id1, co-expression of Id1 and shRNA against insulin-like growth factor-2 (shIGF2), or empty vector were established. MTT assay was used to compare the proliferation of cells. Western blotting and ELISA were used to analyze the protein expressions in cell lysates or conditioned medium. Boyden chamber assays were performed to investigate the migration and invasive potential of cells. Tumor xenografts were established by subcutaneous injection of cancer cells into the flank of nude mice.
Results: Our data showed that the conditioned medium harvested from ESCC cells with overexpression of Id1 could induce esophageal fibroblasts to produce vascular endothelial growth factor (VEGF) *in vitro,* and co-expression of shIGF2 greatly abrogated this effect. The conditioned medium collected from Id1-overexpressing ESCC cells also significantly increased the migration potential, but not the proliferation, of fibroblasts. Similar results were obtained by treating fibroblasts with synthetic recombinant human IGF2, in the presence or absence of neutralizing antibody against IGF2, which confirmed that Id1-induced IGF2 secreted by ESCC cells could induce esophageal fibroblasts to produce VEGF and actively migrate. Interestingly, the invasive potential of ESCC cells was enhanced by the conditioned medium from the IGF2-treated

fibroblasts, and addition of IGF2-neutralizing antibody partially attenuated these effects. To mimic the condition of tumor microenvironment, 3D co-culture system of fibroblasts with ESCC cell lines expressing Id1, Id1-shIGF2 or empty vector was performed, and the same effects were observed. Furthermore, our *in vivo* data indicated that mice bearing Id1-overexpressing ESCC xenografts had significantly higher microvessel density and host-derived VEGF in serum than the Id1-shIGF2 and control vector groups.
Conclusions: IGF2 secreted by Id1-overexpressing ESCC cells can promote bidirectional interaction between ESCC cells and stromal fibroblasts in a paracrine manner.
This study was supported by the Research Grants Council of the Hong Kong SAR, China, GRF Project No. HKU762610M and HKU763111M.

2475 POSTER

Effects of carbon ion beam alone or in combination with sorafenib on putative liver cancer stem cells

S. Sai[1], T. Wakai[2], J.D. Zhao[3], T. Shirai[1], T. Kamada[1]. [1]*National Institute of Radiological Sciences, Research Center for Charged Particle Therapy, Chiba, Japan;* [2]*Niigata University Graduate School of Medical and Dental Sciences, Division of Digestive and General Surgery, Niigata, Japan;* [3]*Fudan University, Shanghai Cancer Center, Shanghai, China*

Purpose: To investigate whether carbon ion beam alone or in combination with sorafenib has beneficial effects compared to X-ray by targeting putative cancer stem cells.
Methods: Human liver cancer stem-like cells sorted from HepG2 and Huh7 cells were treated with carbon ion or X-ray irradiation alone or in combination with sorafenib, and then colony and spheroid formation assay, apoptosis assay, ϒH2AX foci formation assays were performed. Histopathological changes of xenograft tumours after carbon ion beam or X-ray irradiation was also examined.
Results: CD133+/CD90+ cells significantly have higher number of colony and spheroid compared to CD133−/CD90− cells. CD133+/CD90+ cells have shown more potential to form tumours in SCID mice than CD133−/CD90− cells. Colony assay showed that CD133+/CD90+ cells appeared to be radioresistant to both X-ray and carbon ion beam, but carbon beam, especially carbon ion combined with sorafenib remarkably destroyed those of cancer stem-like cells. The percentage of apoptotic cells as well as the number of ϒH2AX foci in the CD133+/CD90+ cells was significantly lager after carbon ion beam compared to X-ray irradiation, and it was more increased when combined with sorafenib. Carbon ion irradiation with 15 Gy induced more severe xenograft tumour cell cavitation and fibrosis compared with 30 Gy X-rays, and tumours were significantly regressed following 30 Gy carbon ion irradiation.
Conclusion: Taken together, carbon ion beam combined with sorafenib has more potential to kill CD133+/CD90+ cancer stem-like cells at relatively lower doses via unrepairable DNA damage *in vitro* as well as tumour regression *in vivo* compared to X-ray.
No conflict of interest.

2476 POSTER

JAK2 inhibitor blocks the inflammation and development of esophageal squamous carcinoma in vitro through JAK/STAT3 signaling pathway

J. Fang[1], L. Chu[1], C. Li[1], F. Hu[1], X. Zhang[1], Y. Chen[1], H. Zhao[1], Q. Xu[1]. [1]*Shanghai Tenth People's Hospital, Medical Oncology, Shanghai, China*

Background: It has been found that the abnormal activation of JAK/STAT3 (Janus kinase/signal transducer and activator of transcription3) signaling pathway in a variety of human tumors. This study aimed to investigate the role of JAK2 inhibitor AG490 in the development of esophageal squamous carcinoma cells and the cross talk between JAK/STAT3 signaling pathway and nuclear factor-kappa B (NF-KB) and cyclooxygenase-2 (COX-2) which are important inflammatory factors associated with tumorigenesis.
Material and Methods: Three esophageal squamous carcinoma cell lines were selected to detect the basal expression of STAT3. The Jak2 inhibitor AG490 and interleukin-6 (IL-6) were added to the culture media of human esophageal squamous carcinoma cell TE-1 and EC-1, respectively. Cell growth was measured by CCK8 assays. Cell cycle and apoptosis was detected by flowcytometry. The expression of STAT3-phosphorylated STAT3 (p-STAT3), vascular endothelial growth factor (VEGF), NF-KB p65, phosphorylated NF-KB p65 (p-NF-KB p65) and COX-2 proteins after treated with AG490 or IL-6 were detected by western blotting.
Results: STAT3 was abnormally activated in three esophageal squamous carcinoma cell lines in varying degrees. The Jak2 inhibitor AG490 remarkably decreased the expression of p-STAT3 and VEGF in TE-1 cells. And AG490 also inhibited the cell growth and affected the cell cycle and apoptosis ($p < 0.05$). Protein expression of p-STAT3 and VEGF was increased significantly in EC-1 cells after IL-6 stimulation. In addition, the expression of inflammatory factors NF-KB p65 and COX-2 was also elevated in three cell lines. P-NF-KB p65 and COX-2 proteins were elevated in EC-1 cells treated with IL-6 and decreased in TE-1 cells treated with AG490.
Conclusions: The Jak2 inhibitor AG490 inhibits the growth and metastasis in esophageal cancer cell lines through ablation of the JAK/STAT3 signaling pathway. Additionally, our results demonstrate AG490 decreases the expression of inflammatory factors NF-KB p65 and COX2, indicating a cross talk between JAK/STAT3 signaling pathway and NF-KB pathway. The JAK/STAT3 signaling pathway may also play a critical role in tumor inflammation through interaction with NF-KB and COX-2 to promote tumorigenesis.

2477 POSTER

***Antrodia camphorata* exhibits antitumor activity via down-regulation of IL-6 signaling in hepatocellular carcinoma**

S.F. Wen[1], M.H. Li[1], Z.K. Kuo[1], H.W. Tseng[1], H.C. Wu[1], H.J. Yao[1], I.H. Pan[1]. [1]*Industrial Technology Research Institute, Biomedical Technology and Device Research Laboratories, Hsin-chu, Taiwan*

Background: *Antrodia camphorata* (*AC*), a medicinal mushroom indigenous to Taiwan, is well known for its anticancer, antioxidant, hepatoprotective, immunomodulatory, and anti-inflammatory properties. *AC* has been widely used as a dietary supplement for cancer prevention in several Asian and European countries. However, mechanisms responsible for its antitumor effects are not fully understood. Cancer-related inflammation is thought to promote tumor progression in many ways, such as cell proliferation, survival, and migration. Given that IL-6, a major cancer-related inflammatory cytokine, mediates STAT3 activation and is upregulated in hepatocellular carcinoma (HCC), we aimed to investigate the IL-6-regulated mechanisms underlying the antitumor effects of *AC* on HCC.
Material and Methods: The present study evaluated antitumor activity of an ethanol and water extract of *AC* fruiting body. Human HCC cell lines, Huh7 and PLC/PRF/5, were treated with *AC* alone or in combination with antitumor agents, and the antiproliferative effect of *AC* was determined by MTT assay. IL-6 levels were measured by ELISA. Protein levels of STAT3 and phosphor-STAT3 (Y705) were determined by immunoblotting and mRNA levels of STAT3 target genes were measured by qRT-PCR. The effect of *AC* on *in vivo* tumor growth was evaluated by xenograft and allograft tumor models, and combination effect of *AC* and doxorubicin was assessed in the former model.
Results: *AC* enhanced growth inhibition by antitumor agents in HCC cells, and significantly reduced IL-6 in cell culture supernatants and mouse tumor allografts. Additionally, *AC* treatment led to the reduction of IL-6-induced STAT3 activation, as well as the inhibition of downstream target genes, including cyclin D1, survivin, and c-Myc. Oral administration of *AC* attenuated tumor growth in allograft mouse models without significant toxicity to normal tissues. The growth of subcutaneous tumor xenografts was delayed by a combination of *AC* and doxorubicin treatment. Collectively, these findings suggest that *AC* exhibits anti-HCC potency through inhibition of IL-6 signaling.
Conclusions: The current study sheds new light on the role of *AC* as an antitumor agent through inhibiting the IL-6 signaling pathway. Moreover, *AC* enhances the efficacy of doxorubicin in minimizing the tumor size. Thus, *AC* offers new prospects for overcoming antitumor drug resistance, with great potential as an adjuvant in the treatment of HCC.

2478 POSTER

Prognostic assessment of cofilin in patients with gastric cancer

F. Toniazzo Lissa[1], F. Dal Pizzol[2], B. Assad[2]. [1]*Cironco, Criciuma, Brazil;* [2]*Cironco, Oncology, Criciuma, Brazil*

The estimated new cancer cases worldwide in 2008 were 12.6 million, with 5.4 million cases diagnosed in developed and 6.7 millions in developing countries. The number of cancer-related deaths was 7.6 million, 2.9 million in developed and 4.7 million in developing countries. Malignant neoplasm ranks second (12.5%) as causes of death worldwide, surpassed by cardiovascular causes (19.6%). Gastric Cancer (GC) ranks fourth as the most frequent cause of cancer worldwide, with one million new cases in 2007, behind lung, breast and colon and rectum. 70% of new cases occur in developing countries. Currently, GC is the second most common cause of cancer deaths, accounting for 800,000 deaths annually. In Brazil, estimates for 2013 point to the occurrence of 518,510 new cases of cancer, and the GC occupying fifth place in attendance with 20,000 new cases. The acquisition of the migratory behaviour of cancer cells is a prerequisite to

break up organized tissue structures, invade and metastasize. Recently, the expression of proteins that block actin has been associated with the invasive behaviour of tumours. The cofilin is an actin-blocking protein, which regulates the actin cytoskeleton to maintain and depolymerize actin filaments. The interest for cofilin and its cascade have increased because of its relationship with tumour invasion, metastasis and be a potential prognostic factor in cancer. We conducted a retrospective study, observational, descriptive and analytical. We used all the pathological reports of patients undergoing gastrectomy for adenocarcinoma between June 2002 and June 2012, totalling 380 cases. The average age of patients was 68 years, with 63.6% of male sex. In assessing the depth of invasion, advanced lesions with involvement beyond the submucosa corresponded with 72.7% of cases. The diffuse type in Lauren's classification was the most prevalent with 68.1%. The bacterium *H. pylori* was positive in 72.7% of carcinomas. Lymph nodes involvement accounted for 70.4% of cases. At the end of the study 56.8% of patients were alive. When applied statistical tests to assess the relationship of cofilin with the other independent variables, the depth of tumour invasion and the presence of positive lymph node were statistically significant. In conclusion, despite the cofilin is not statistically significant in overall survival, high cofilin is correlated positively with advanced and lymph node metastatic tumours. Cofilin can be regarded as valuable tool for predicting metastasis to lymph nodes in patients with gastric cancer.

Metalloproteinases gene polymorphism and prognosis of HCV related hepatocellular carcinoma in Alsharkia governorate, Egypt

N. Raafat[1], R.L. Etewa[1], K.M. Elgerby[1], S. Galal[1]. *[1]Zagazig Faculty of Medicine Zagazig University, Biochemistry & Molecular Biology, Zagazeg, Egypt*

Background: Liver cancer is the sixth most common form of cancer and the third most common cause of cancer death worldwide. Hepatocellular carcinoma (HCC) accounts for a vast majority − 84% − of all liver cancers, and a large proportion of HCC cases are attributable to hepatitis C virus (HCV) infectionthe. Matrix metalloproteinases (MMPs) are a prerequisite for cancer invasion, metastasis, and angiogenesis. In this study, we examined the relationship between the gene polymorphisms of MMP-1, MMP-3, and MMP-9 and the prognosis of hepatitis C virus HCV-related HCC.
Subjects and Methods: 60 HCV and 60 HCV-related HCC patients were enrolled in the study, and gene polymorphisms of MMP-1 −1,607 1G/2G, MMP-3 −1,171 5A/6A, and MMP-9 −1,562 C/T were analyzed using PCR RFLP technique.
Results: In HCC, MMP-3 5A carriers had significantly larger tumor size than MMP-3 6A homozygotes. In HCC prognosis, MMP-3 5A carriers had a significantly poorer prognosis than MMP-3 6A homozygotes.
Conclusion: MMP-3 5A allele is cooperative risk factors for poor prognosis in HCC patients, suggesting that this gene polymorphism might be potential markers for predicting the prognosis of HCC patients.
No conflict of interest.

Expression and prognostic significance of livin in gastric cancer

Y.E. Joo[1], Y.R. Park[1], D.S. Myung[1], J.S. Kim[1], S.B. Cho[1], W.S. Lee[1], I.J. Chung[1], K.K. Kim[2]. *[1]Chonnam National University Medical School, Department of Internal Medicine, Gwangju, South Korea; [2]Chonnam National University Medical School, Department of Pharmacology, Gwangju, South Korea*

Background: Livin is one of the most important members of the inhibitors of apoptosis protein family. It is overexpressed in various tumours and may have prognostic significance. The study investigated the biologic roles of livin on oncogenic behaviours of gastric cancer cells, the expression of livin in gastric cancer tissue and the relationship of its expression with various clinicopathological parameters and patient survival.
Materials and Methods: Small interfering RNA blocked livin gene expression in AGS and SNU638 human gastric cancer cell lines. The expression of livin by RT-PCR, Western blotting and immunohistochemistry was investigated in gastric cancer tissues. Associations with various clinicopathological parameters and survival were analysed.
Results: Livin knockdown inhibited tumour cell migration, invasion and proliferation in AGS and SNU638 cells. Livin knockdown induced apoptosis by activating caspase-3, −7 and PARP. Livin knockdown induced cell cycle arrest by decrease of cyclin D1, cyclin-dependent kinase 4 and 6 and increased expression of p21 and p27. The ERK1/2 and JNK signalling pathways were inhibited by livin knockdown. Livin expression was up-regulated in gastric cancer tissues at mRNA and protein levels. However, no significant correlation was found between livin expression and various clinicopathological parameters including survival.
Conclusions: Livin expression may be important in the alteration of invasive and oncogenic phenotypes of gastric cancer cells. The prognostic relevance of livin remains unclear.
No conflict of interest.

2481 POSTER

Induction chemotherapy followed by surgery for primarily incurable oesophageal carcinoma

E. Toxopeus[1], S. Talman[1], A. Van der Gaast[2], V.M.C.W. Spaander[3], C.M. Van Rij[4], H.W. Tilanus[1], J.J.B. Van Lanschot[1], B.P.L. Wijnhoven[1]. *[1]Erasmus Medical Center, Surgery, Rotterdam, Netherlands; [2]Erasmus Medical Center, Internal Oncology, Rotterdam, Netherlands; [3]Erasmus Medical Center, Gastroenterology, Rotterdam, Netherlands; [4]Erasmus Medical Center, Radiotherapy, Rotterdam, Netherlands*

Introduction: In patients with advanced oesophageal carcinoma that are not eligible for a curative multimodal treatment, induction chemotherapy can be applied with the aim to downstage the tumour. After response evaluation, an oesophagectomy can be performed in selected cases. The aim of this study was to evaluate the clinical outcome of these patients.
Methods: All patients with primarily incurable loco regional oesophageal or gastroesophageal junction cancers who are treated with induction chemotherapy between January 2005 and December 2012 were identified from a prospectively collected database. The indication, assessment of radiological response with CT scanning and plan of treatment were determined at multidisciplinary team meetings. Clinical outcome was analysed for all patients who received induction chemotherapy. Survival was calculated from the date of diagnosis until last date of follow up or death using Kaplan Meier method. Univariate and multivariate analyses were performed to identify prognostic factors for survival.
Results: A total of 134 patients received induction chemotherapy mainly for loco regional advanced disease (n = 85) determined by T- and/or N-staging and involvement of lymph nodes outside the planned radiation field (n = 34). Carboplatin-paclitaxel (78.4%) and epirubicin-oxaliplatin-capecitibine (11.9%) were the commonly used regimes. After response evaluation, surgery was withheld in 45 patients because of progressive disease (n = 21), stable disease or partial response but still irresectable (n = 13), severe co morbidity (n = 2) or other reasons (n = 9). Median overall survival of this group was 14 months (95% CI: 12.3–15.7).
Thirteen patients had an irresectable tumour or distant metastatic disease at explorative surgery. Seventy-six patients underwent oesophagectomy, with a median survival of 20 months (95% CI: 9.9–30.1) and a 5-year survival of 27%. Tumour free resection margins (R0) were achieved in 50 (66%) patients and the median survival in this group was 39 months (95% CI: 11.4–66.6), with a 5-year survival of 37%. In uni- and multivariate analyses resection margins and pathological N-stage influence survival in this selected group of patients.
Conclusion: After induction chemotherapy for primarily incurable oesophageal cancer, oesophagectomy was feasible in the majority of patients (57%). Patients who had tumour free resection margins without positive lymph nodes had the most favourable prognosis, with a 5-year survival of 37%.
No conflict of interest.

2482 POSTER

Residual esophageal cancer after neoadjuvant chemoradiotherapy frequently involves the mucosa and submucosa

J. Shapiro[1], F.J.W. Ten Kate[2], P. Van Hagen[1], K. Biermann[2], B.P.L. Wijnhoven[1], J.J.B. Van Lanschot[1]. *[1]Erasmus MC, Surgery, Rotterdam, Netherlands; [2]Erasmus MC, Pathology, Rotterdam, Netherlands*

Objective: To gain insight into the exact location of residual esophageal cancer in the esophageal wall and regional lymph nodes after neoadjuvant chemoradiotherapy (nCRT) and to determine the pattern of regression.
Background data: Data from the recently published CROSS trial showed that 49% of squamous cell carcinomas and 23% of adenocarcinomas had a pathologically complete response (pCR) in the resection specimen after nCRT. These results impose the ethical imperative to reconsider the necessity of esophagectomy with its substantial morbidity and mortality in patients with pCR. However, it remains challenging to accurately identify these patients before resection.
Methods: Between January 2003 and July 2011, all patients with esophageal cancer in a tertiary referral center, who underwent nCRT (5 weekly courses of carboplatin and paclitaxel plus 41.4 Gy concurrent radiotherapy) and surgical resection, were analyzed. The resection specimens were carefully re-evaluated by an experienced gastrointestinal

pathologist. Tumor regression grade (TRG) was meticulously scored for each specific layer of the esophageal wall and for all removed lymph nodes.
Results: One-hundred and two consecutive patients were included. Seventy-one (70%) of 102 patients were non-complete responders (⩾TRG2) and in 63 of these patients (89%) residual tumor cells were seen in the mucosa and/or submucosa. Five of eight patients without involvement of the mucosa and submucosa had isolated remnants in the muscle layer (5/102=5%); the other three patients had tumor cells only in a single lymph node (3/102=3%). The surrounding stroma showed the highest percentage of TRG1 (=pCR: 47%). In patients with pretreatment lymph node positivity, the percentage of TRG1 in all lymph nodes was also favorable (52%). Overall regression showed a non-random mixed pattern of both concentric regression and regression towards the lumen.
Conclusions: After neoadjuvant chemoradiotherapy for esophageal cancer both the mucosa and submucosa show frequent residual malignant involvement. The surrounding stroma and the regional lymph nodes show the highest percentage of pathologically complete response and the overall regression pattern is most frequently a mixed pattern of both concentric regression and regression towards the lumen. This overall regression pattern lends support to careful testing of a wait-and-see approach in a subgroup of esophageal cancer patients after nCRT.
No conflict of interest.

2483 POSTER

Primary tumour resection impact on survival in patient with carcinoid syndrome (CS). Analysis of 139 patients (pts) with well differentiated neuroendocrine tumors (WDNETs) from database of Istituto Nazionale Tumori Milano

S. Pusceddu[1], R. Buzzoni[2], V. Mazzaferro[3], M. Pacifici[4], G. Procopio[1], A. Damato[1], E. D'Autilia[5], G. Bertarelli[4], E. Seregni[6], F. De Braud[1].
[1]Fondazione IRCCS Istituto Nazionale Tumori, Medical Oncology, Milan, Italy; [2]Fondazione IRCCS Istituto Nazionale Tumori, Day Hospital/Ambulatorial Unit, Milan, Italy; [3]Fondazione IRCCS Istituto Nazionale Tumori, Surgery and Liver Transplantation Unit, Milan, Italy; [4]Fondazione IRCCS Istituto Nazionale Tumori, Statistical Unit, Milan, Italy; [5]Fondazione IRCCS Istituto Nazionale Tumori, Medical Engeneer Unit, Milan, Italy; [6]Fondazione IRCCS Istituto Nazionale Tumori, Nuclear Medicine Unit, Milan, Italy

Background: The tumors causing CS arise from enterochromaffin (EC) or enterochromaffin-like cells (ECL) and can originate throughout the digestive system. About 10% of NET pts develope CS clinically evident. Serotonin which normally regulates intestinal movements is most often hyper-secreted by the EC/ECL cells in the gut and in such condition an increase in urinary5-hydroxyindoleacetic acid (5-HIAA) levels is observed. The overproduction of serotonin determines the typical CS: skin flushing, chronic diarrhea, bronchoconstriction, and right heart disease (CHD), which accounts for 95% of cases. Atypical CS is rare, associated with foregut NETs and histamine hyperproduction. It is characterized by flushing, salivation, bronchoconstriction, lachrymation and hypotension.
Aim: To assess the clinical features and survival of WDNETs pts with CS.
Materials and Methods: We analyzed 1100 NET pts, followed between 1979 to 2012 at our Institution, identifying a cohort of 139 consecutive pts with Typical (98%) or Atypical (2%) CS.
Results: Median age was 53 years, male/female = 67/72. All histological types were classified as WDNET and the majority were Gastro-entero-pancreatic tumors (77%), distinct by sites: Midgut/Foregut/Hindgut/Primary unknown: 60/53/6/20. Liver involvement was found in 115 pts: synchronous (89%); metacronous (11%). Primary tumor resection was performed in 95% of midgut (57) in 55% of foregut (29) and 100% of hindgut (6) pts. The most common symptoms were flushing/diarrhea/CHD in 43.5%/37%/7% of cases respectively. Cromogranin-A/5-HIAA pathological levels, were reported in 59.5% − 47.5% of pts. Significant difference in median overall survival (mOS) was found for age (cut off = median age 56 years), $p < 0.05$, but not for gender. Median OS was 93 months (mos) (95% CI 74–135 range), 5 and 10 years survival rates were 66% and 43%, respectively. Significant difference in mOS was evident considering carcinoid/ pancreatic NET/primary unknown, 130/62/46 mos, respectively ($p < 0.05$). Primary tumor resection improves survival independently of histology: 141/37 mos in resected/ not resected pts, respectively ($p < 0.05$).
Conclusions: Liver involvement was the main feature related to CS appearance. The resection of primary tumour was an independent and favourable prognostic factor related to survival in syndromic WDNETs. Impact evaluation of surgery and loco-regional treatment in pts with only liver metastases is ongoing.
No conflict of interest.

2484 POSTER

Phase I open label multicenter trial SAKK 77/09/SASL 30 investigating the combination of everolimus and transarterial chemoembolisation (TACE) with doxorubicin in patients with hepatocellular carcinoma

J. Dufour[1], M. Montemurro[2], Q. Li[3], I. Cvijetic[4], P. Knuesel[5], S. Terraz[6], A. Cerny[7], D. Koeberle[8]. *[1]Bern University Hospital, DMLL UVCM Hepatologie, Bern, Switzerland; [2]Zurich University Hospital, Gastroenterology, Zürich, Switzerland; [3]Swiss Group for Clinical Cancer Research, SAKK Statistician, Bern, Switzerland; [4]SAKK Koordinationszentrum, Studienkoordinatorin, Bern, Switzerland; [5]Kantonsspital Graubünden, Radiologie, Chur, Switzerland; [6]Hôpitaux Universitaires de Genève, Radiologie, Genève, Switzerland; [7]Clinica Luganese, Hepatology, Bern, Switzerland; [8]Kantonsspital St. Gallen, Fachbereich Onkologie/Hämatologie, St. Gallen, Switzerland*

Background: Everolimus is an inhibitor of mTOR, a central kinase linking cell metabolism to cell proliferation. The combination of sorafenib 400 mg bid with everolimus 5 mg qd was investigated in a recently closed randomised phase II SAKK/SASL trial. There is a strong rationale to combine also everolimus with TACE. TACE stimulates the release of growth factors, whose carcinogenic effects can be prevented by everolimus. The goal of this phase I trial was to determine the recommended dose (RD) of everolimus in patients (pts) with HCC treated with TACE.
Methods: Using a 3+3 design with dose de-escalation, pts with BCLC B HCC were enrolled to receive continuous everolimus starting 1 week before the first TACE with doxorubicin eluting beads. Dose limiting toxicity (DLT) was defined mainly as ⩾G3 febrile neutropenia or any ⩾G3 haematological toxicities requiring dose interruption or any >G3 non-haematological toxicities or any toxicities requiring >2 weeks dose interruption, which occurred during the first TACE period (5 weeks after first everolimus treatment). Pts enrolment at a given dose level (DL) had to be discontinued as soon as 2 DLTs were observed.

DL	Dosage by therapy	
	TACE (mg)	Everolimus (mg qd)
1	150	7.5
−1	150	5.0

Results: Between June 2009 and May 2011, 10 pts were accrued, 4 of which were in DL 1. Two DLTs (1 neutropenia with fever and 1 thrombocytopenia which persisted for more than 6 days) occurred 35 and 30 days after registration in DL 1 while no DLT was found in DL −1. Further G3 toxicities were dyspnea (G3, 1 pt in DL 1), mood alteration (G3, 2 pts in DL −1), platelets (G3, 1 pt in DL −1) and pulmonary (G3, 1 pt in DL 1) during the first TACE period, in which no G4 toxicity was seen. Three pts in DL1 as well as in DL −1 had stable disease and three pts in DL −1 had complete response.
Conclusion: The results of this phase I study establish 5 mg qd as the RD for everolimus in combination with TACE and support the decision to proceed to a randomized phase II trial (NCT01009801).
Conflict of interest: *Advisory board: Bayer, BMS, Gilead, MSD, Novartis, Roche.*

2485 POSTER

Clinical outcomes in patients with resectable esophageal squamous cell carcinoma with supraclavicular lymph node metastasis: Surgery versus definitive chemoradiotherapy

Y. Homma[1], K. Kato[1], T. Hamaguchi[1], Y. Yamada[1], Y. Shimada[1], N. Hokamura[2], H. Igaki[2], Y. Tachimori[2], Y. Ito[3], J. Itami[3]. *[1]National Cancer Center, Gi Oncology, Tokyo, Japan; [2]National Cancer Center, Esophageal Surgery Division, Tokyo, Japan; [3]National Cancer Center, Department of Radiation Oncology, Tokyo, Japan*

Background: In the 7th edition UICC-TNM classification, supraclavicular lymph node (SCLN) metastasis in thoracic esophageal cancer is regarded as distant metastasis and is not considered to warrant surgery. In contrast, in Japan, three-field lymphadenectomy is a standard procedure for thoracic esophageal squamous cell carcinoma (ESCC), and in the 10th-edition Japanese classification of esophageal cancer the SCLNs are regarded as regional lymph nodes. A recent report showed the clinical benefits of SCLN dissection and suggested that resectable ESCC with SCLN metastasis (rSCLN+) has no worse a prognosis than TNM-N3 [J Surg Oncol. 2012; 106: 742–747]. Therefore, in Japan, surgery with curative intent is considered to be indicated in rSCLN+. However, there are no data on clinical outcomes and promising treatments for rSCLN+.

Our primary objective was to explore the most promising treatment for rSCLN+ after adjusting for background factors by multivariate analysis. The secondary objective was to clarify prognostic factors in rSCLN+.
Materials and Methods: We retrospectively analyzed 97 patients with rSCLN+ initially treated by surgery (S group) or with definitive chemoradiotherapy (CRT group) at our institution (January 2001 through April 2012). Preoperative resectability was reviewed by surgical specialists. Overall survival (OS) and relapse-free survival (RFS) in the S group and progression-free survival (PFS) in the CRT group were calculated by the Kaplan–Meier method. Groups were compared by log-rank test. Univariate and multivariate analysis were calculated with Cox's proportional hazards model.
Results: There were 66 patients in the S group and 31 in the CRT group. There was no significant difference in patient demographics across groups. Median follow-up period was 21.8 months. Median RFS was 11.7 months in the S group. In the CRT group the clinical complete response rate was 58% and the median PFS was 9.3 months. Median OS was 26.5 months in the S group and 24.4 months in the CRT group. There was no significant difference between groups (log-rank: $P = 0.275$). The 3-year OS was 46.2% in the S group and 34.5% in the CRT group; the 5-year OS was 40.8% in the S group and 24.1% in the CRT group. The S group therefore seemed to have an advantage. In the multivariate analysis, age ($\geqslant$65 vs. <65 years old; HR 1.803, 95% CI 1.067–2.993, $P = 0.05$) and primary lesion depth (T1−T2 vs. T3; HR 0.326, 95% CI 0.129–0.826, $P = 0.018$) were strongly associated with poor survival. With background factor adjustment by multivariate analysis, treatment procedure (S vs. CRT) was not significantly associated with survival (HR 0.859, 95% CI 0.493–1.497, $P = 0.592$).
Conclusion: There was no significant survival difference between the S and CRT groups. There was a trend for the S group to have better long-term survival than the CRT group.
There seems to be a subgroup with curative potential in the rSCLN+ population. For these patients, surgery might be an important option for eradicating esophageal cancer.
No conflict of interest.

2486 POSTER

Phase I trial of chemoradiation with capecitabine and vorinostat in pancreatic cancer

E. Chan[1], L.R. Arlinghaus[2], D.B. Cardin[1], L. Goff[1], J. Berlin[1], A. Parikh[3], R.G. Abramson[2], N. Merchant[3], S. Hiebert[4], A.B. Chakravarthy[5].
[1]Vanderbilt University Medical Center, Division of Medical Oncology, Nashville TN, USA; [2]Vanderbilt University Medical Center, Institute of Imaging Science, Nashville TN, USA; [3]Vanderbilt University Medical Center, Divsion of Surgical Oncology, Nashville TN, USA; [4]Vanderbilt University Medical Center, Biochemistry, Nashville TN, USA; [5]Vanderbilt University Medical Center, Radiation Oncology, Nashville TN, USA

Background: Histone deacetylase inhibitors (HDACi) and fluoropyrimidines are synergistic and are radiation (R) sensitizers. NCT00983268 evaluated the fluoropyrimidine capecitabine (C) and the HDACi vorinostat (V) with R in the treatment (tx) of non-metastatic pancreatic cancer(NMPC).
Methods: Patients (Pts) with NMPC received C + V + R. C dose was 1000 mg q12 Monday (M) − Friday (F) on the days of R. R was given via 3D conformal therapy to a total dose of 3000 cGy in 10 fractions over 2 weeks (wk). V was given daily M-F x 4 wk. Primary endpoint was maximum tolerated dose (MTD) of V when given with C + R. Planned V doses for evaluation were: 100, 200, 300, and 400 mg. Resectability assessment occurred within 6 wk after R completion. Unresectable pts could opt for continuation of C + V (CCV) at systemic doses (C 1000 mg q12 x 14 days and V 300 mg QD x 14 days q21 day cycle) or come off study. DW-MRIs were obtained pre tx and one wk after tx initiation to assess tumor cellularity. Peripheral blood mononuclear cells (PBMCs) were collected to assess tx effects on histone acetylation (HA).
Results: 21 pts were accrued from Nov 2009-Dec 2012. Tumor statuses pre-tx were: resectable (n = 1), borderline resectable (n = 12), and unresectable (n = 8). One DLT each occurred at dose levels 1, 3, and 4: 2 GI toxicities and one thrombocytopenia. Most common related grade $\geqslant$3 adverse events were lymphopenia (76%), nausea (14%), and fatigue (9%). On DW-MRI, the apparent diffusion coefficient (ADC) increased in most tumors but did not correlate to clinical outcome. PBMC HA increased in some pts. 19 (90%) pts had stable disease (SD), and 2 (10%) pts had progressive disease at tumor re-evaluation. 11 pts underwent exploration with 4 R0 resections and one R1 resection. 25% of the initially borderline resectable pts ultimately underwent an R0 resection. No unresectable pt converted to resectable. 4 unresectable pts opted for CCV, 2 with SD for 6 cycles.
Conclusions: C + V + R is feasible with no unexpected toxicity. The MTD was dose level 4: C 1000 mg q12 on days of radiation, V 400 mg daily M-F x 4 wk. CCV after chemoradiation was tolerated. PBMC HA and ADC increase on DWI-MRI were seen.
This study was approved and funded by the National Comprehensive Cancer Network (NCCN) from general research support provided by Merck & Co., Inc. Study was also supported by the Vanderbilt-Ingram Center Support Grant P30CA68485.
Conflict of interest: *Advisory board: Emily Chan serves on the Colon/Rectal/Anal Panel of the National Comprehensive Cancer Network (NCCN), which is the non-profit organization that funded this trial. Jordan Berlin serves on the Neuroendocrine Panel of the NCCN. Corporate-sponsored research: All industry sponsored trial funding goes to the institution rather than individual investigators.*

2487 POSTER

Outcomes and prognostic factors following R1 and R2 resection of non-metastatic pancreas cancer

K. Merrell[1], C. Hallemeier[1], F. Quevedo[2], M. Kendrick[3], M. Haddock[1], R. Miller[1]. *[1]Mayo Clinic Cancer Center, Radiation Oncology, Rochester Minnesota, USA; [2]Mayo Clinic Cancer Center, Medical Oncology, Rochester Minnesota, USA; [3]Mayo Clinic Cancer Center, General Surgery, Rochester Minnesota, USA*

Background: We previously reported outcomes and prognostic factors in patients with complete resection of pancreas cancer at our institution. The purpose of this study was to review outcomes and examine potential prognostic factors in patients with incomplete resection.
Materials and Methods: A retrospective chart review was performed on 172 consecutive patients with non-metastatic exocrine pancreas carcinoma who underwent curative intent, but margin positive resection at Mayo Clinic between 1985 and 2009. Extent of resection was R1 (microscopic residual) or R2 (macroscopic residual). Tumor (T) and nodal (N) staging was performed as per AJCC 7th edition. Post-operatively 30 (17.5%) patients were observed (Ob), 114 (66.3%) received immediate chemoradiation (ICR), 21 (12.2%) received 2 cycles of gemcitabine, chemoradiation (CR) and 2 additional cycles of gemcitabine (GCR), and 7 (4%) patients received gemcitabine alone (GA).
Results: Median patient age and follow-up time was 68.2 years (range, 32−86) and 15 months (range, 2–139), respectively. Tumor location was pancreas head (85.5%), body (4%), tail (4.5%), or unspecified (6%). Tumor grade was I (1%), II (12%), III (77%), or IV (10%). T stage was 1 (2.3%), 2 (14%), 3 (68.2%), or 4 (15.5%). N stage was 0 (35%) or 1 (65%). Extent of resection was R1 (77%) or R2 (23%). Three- and 5-year overall survival (OS) for the entire group was 17.9% and 9.53%, respectively. Prognostic factors of improved OS include tumor grade <4 ($p = 0.0006$), R1 resection ($p = 0.003$), use of adjuvant RT ($p = 0.0002$), and use of up front chemotherapy followed by chemoradiation ($p = 0.0039$). Three and 5 year OS in the R1 group for Ob, ICR, GCR and GA was 9% and 4.5%, 20% and 10.7%, 47.6% and 26.5%, 28.6% and 14.3%, respectively ($p = 0.0005$). To account for improvements in recent radiation delivery systems, we excluded patients treated prior to 2000, and similarly statistically significant results were observed. In R2 patients median survival (MS) for Ob and ICR was 8 months and 15.3 months, respectively. R2 patient numbers were insufficient to analyze GCR and GA.
Conclusions: In patients with R1 and R2 resection of pancreas cancer, MS is improved with CR. GA also improved survival above Ob, yet the magnitude of benefit improved further with the addition of CR after 2 cycles of gemcitabine. Further studies are warranted to evaluate the benefit of adjuvant therapy.
No conflict of interest.

2488 POSTER

Toxicity of definitive chemoradiation in patients with inoperable or irresectable esophageal carcinoma

N. Haj Mohammad[1], M.C.C.M. Hulshof[2], J. Bergman[3], E.D. Geijsen[2], J.W. Wilmink[1], M.I. Van Berge Henegouwen[4], H.W.M. Van Laarhoven[1].
[1]Academic Medical Center, Medical Oncology, Amsterdam, Netherlands; [2]Academic Medical Center, Radiation Oncology, Amsterdam, Netherlands; [3]Academic Medical Center, Gastroenterology and Hepatology, Amsterdam, Netherlands; [4]Academic Medical Center, Surgery, Amsterdam, Netherlands

Background: Definitive chemoradiation (dCRT) is considered curative intent treatment for patients with inoperable or irresectable esophageal cancer. In the Netherlands the preferred radiochemotherapy regimen consists of carboplatin plus paclitaxel concurrent with radiation, which is based on the results of the Dutch CROSS study. Toxicity data are lacking.
Methods: A retrospective analysis of all patients treated with definitive chemoradiation consisting of 6 cycles of paclitaxel 50 mg/m^2 and

carboplatin AUC2 concomitant with radiotherapy (50.4 Gy\1.8 Gy) from 2006 through 2011 at a single tertiary referral center was performed. Patients were divided into two groups based on the reason for treatment with dCRT.
Inoperable patients were defined as patients with surgical contraindications because of comorbidity. Irresectable patients were technically irresectable patients. Toxicity, hospital admissions, recurrence and survival were analysed.
Results: 127 patients were treated with definitive chemoradiation. 33 patients were medically inoperable, 94 patients were irresectable, Grade $\geqslant$3 toxicity was significantly recorded more often in the inoperable patients (44%) than in irresectable patients (20%) ($p < 0.05$). The patients with inoperable esophageal carcinoma had a significantly shorter tumor length (5.1 cm vs 6.6 cm, $p < 0.05$) and consequently a smaller radiation field. Furthermore in the inoperable group 40% of the patients had low stage disease with stadium I−II disease. In spite of a smaller radiation field and lower tumor stage the observed toxicity was significantly higher. Hospital admission occurred more often in the inoperable patients (39%) than in the irresectable patients (22%) ($p < 0.05$). Reasons for hospital admission were dehydration as a result of mucositis or esophagitis and neutropenic fever. Median number of cycles of chemotherapy was five for inoperable patients ($p = 0.01$), while six cycles could be administered to patients with irresectable disease. Recurrence and survival were not significantly different. The odds ratio for developing toxicity $\geqslant$ grade 3 was 2.8 (95% CI 1.1−7.5 $p = 0.04$) for being an inoperable patient and 1.3 (95% CI 1.1−1.5 $p = 0.01$) per 10 extra micromol/l creatinine.
Conclusion: Our data show that toxicity of definitive chemoradiation is worse in patients with medically inoperable esophageal carcinoma compared to patients with irresectable esophageal cancer, mainly occurs in the 5th cycle of treatment and requires hospital admission. Improvement of supportive care should be undertaken in this more fragile group.
No conflict of interest.

2489 POSTER

Recent trends in multidisciplinary treatment of oesophageal and gastric cancer in The Netherlands

A. Trip[1], J.L. Dikken[2], O. Visser[3], J. Stiekema[4], A. Cats[5], H. Boot[5], J.W. Van Sandick[4], E.P.M. Jansen[1], M. Verheij[1]. *[1]Netherlands Cancer Institute, Radiation Oncology, Amsterdam, Netherlands; [2]Leiden University Medical Centre, Surgery, Leiden, Netherlands; [3]Comprehensive Cancer Centre, Epidemiology, Amsterdam, Netherlands; [4]Netherlands Cancer Institute, Surgical Oncology, Amsterdam, Netherlands; [5]Netherlands Cancer Institute, Gastroenterology and Hepatology, Amsterdam, Netherlands*

Objectives: In recent years, evidence for multidisciplinary treatment of oesophageal, oesophagogastric junction (OGJ) and gastric cancer has grown. The objective of this population-based study was to investigate changes in treatment strategies for oesophageal, OGJ and gastric cancer in The Netherlands during the last decade.
Methods: Data on treatment of M0 oesophageal, OGJ and gastric cancer patients were obtained from the Netherlands Cancer Registry. Factors associated with the administration of (neo-)adjuvant therapy were adjusted for age, year of diagnosis, clinical tumour stage, geographic region and hospital type.
Results: Between 2000 and 2011, a total of 13,041 patients underwent surgical resection for M0 oesophageal ($n = 5,039$), OGJ ($n = 1,959$) or gastric ($n = 6,043$) cancer. The percentage of patients who received neo-adjuvant and/or adjuvant therapy increased in oesophageal cancer patients from 23% in 2000 to 91% in 2011, in OGJ cancer patients from 6% to 87%, and in gastric cancer patients from 1% to 50%. In oesophageal cancer patients, neo-adjuvant chemoradiotherapy (CRT) was most frequently administered (83% of patients in 2011). In OGJ cancer patients, neo-adjuvant CRT was administered to 8% of patients in 2008 increasing to 46% of patients in 2011. In gastric cancer patients, the use of neo-adjuvant chemotherapy (CT) with or without adjuvant CT increased from 3% in 2005 to 41% in 2011. Adjuvant CRT was administered to 4% of gastric cancer patients in 2005, slightly increasing to 7% in 2011. Oesophageal cancer patients who were treated in academic hospitals were more likely to receive (neo-)adjuvant therapy than those treated in non-academic hospitals ($p = 0.028$). In the group of gastric cancer patients, a similar trend was seen, but the effect of hospital type did not reach statistical significance ($p = 0.12$). Oesophageal, OGJ and gastric cancer patients who were treated with (neo-)adjuvant therapy had a lower risk of death than those who did not receive (neo-)adjuvant therapy ($p < 0.001$ for all groups).
Conclusions: In The Netherlands, the use of multidisciplinary treatment in oesophagogastric cancer has increased during the past decade. In oesophageal and OGJ cancer patients, neo-adjuvant therapy has become standard practice. In gastric cancer treatment, however, there is room for improvement as 50% of patients were not treated with (neo-)adjuvant therapy.
No conflict of interest.

Chemoradiotherapy for locally advanced inoperable gastric cancer: A prospective analysis of survival

A.A. Ruzhnikova[1], S.M. Asakhin[2], M.Y. Valkov[2]. *[1]Regional Clinical Oncological Hospital, Dept of Chemotherapy, Arkhangelsk, Russian Federation; [2]Northern State Medical University, Dept of Radiology Radiotherapy and Clinical Oncology, Arkhangelsk, Russian Federation*

Background: The proportion of patients with initially locally advanced inoperable gastric cancer (LAIGC) is up to 30%. Currently, chemotherapy (CT) is the only and purely palliative treatment approach for patients with LAIGC. Radiation therapy (RT) alone or in combination with the CT of 5-fluorouracil, for inoperable gastric cancer is usually administered for relieving the symptoms of disease. Studies have shown the advantage of chemoradiotherapy (CRT) compared to RT, CT, but the study on the efficacy of platinum-based CT in combination with RT in LAIGC has not been published yet.
Purpose: To compare the effectiveness of CRT and CT by means of progression-free survival in patients with LAIGC in an one-center, open, prospective, randomised study.
Methods and Materials: Randomisation was carried out by the ratio 1:1. Radiation therapy was administered to a total dose of 50−68 Gy on defined target, with the first 40−44 Gy delivered within an area, encompassing lymphatic stations up to the D2+ level. Chemotherapy scheme included cisplatin 100 mg/m^2 i.v. on the D 1, 5-fluorouracil 1000 mg/m^2 by 24-hour intravenous infusion on D 1−5, totally 4−6 courses. Primary end point for comparison was progression-free survival (PFS), while secondary endpoints were response rate, toxicity of treatment, and overall survival (OS). Distributions were estimated using the chi-square test. Survival was evaluated using Kaplan–Meier method, with the differences determined by log-rank method. The influence of initial factors on was studied using Cox regression.
Results: Sixty-four patients with LAIGC were totally enrolled to CRT ($n = 32$) and CT ($n = 32$) arms. Median follow-up of all patients was 15.1 months, 28 (43.8%) patients have died. Median PFS in patients, receiving CRT, was 8.8 (95% CI 6.5–11.1) months, CT 6.5 (95% CI 3.9−9.2) months, respectively ($\chi 2 = 8.988$, $p = 0.003$). The median OS in the CRT and CT groups was 15.1 (95% CI 13.1–17.0) months and 11.1 (95% CI 8.9–13.3) months, respectively ($\chi 2 = 0.878$, $p = 0.349$). Objective response rate in the CRT group was 18.8%, in the CT group 9.4%. The multivariate Cox analysis after adjustment for other parameters showed CRT being associated with reduced progression risk, OR=0.48, (95% CI 0.23–0.96). The toxicity did not differ between the groups.
Conclusion: The progression-free survival rate was found to be higher in patients with LAIGC who received CRT compared to patients receiving CT only. Addition RT to CT in LAIGC does not lead to significant increase in toxicity compared with only CT. Phase III comparison is warranted.
No conflict of interest.

2491 POSTER

Pre-therapeutic hemoglobin level has a significant impact on tumor response and outcome in neoadjuvant chemoradiotherapy for esophageal squamous cell carcinoma

Y. Hamai[1], J. Hihara[1], J. Taomoto[1], I. Kishimoto[1], Y. Ibuki[1], M. Okada[1]. *[1]Hiroshima University, Surgical Oncology, Hiroshima, Japan*

Background: Neoadjuvant chemoradiotherapy (CRT) followed by esophagectomy confers a survival benefit upon patients with locally advanced esophageal cancer. However, neoadjuvant CRT might be less meaningful for poor responders. Therefore, the prediction of effect after neoadjuvant CRT is clinically important for the selection of optimal therapy for patients with advanced esophageal cancer.
Methods: We reviewed data from 123 patients with esophageal squamous cell carcinoma who underwent neoadjuvant CRT comprising 40 Gy of radiation with concurrent 5FU plus one of docetaxel, cisplatin or combined docetaxel/cisplatin followed by esophagectomy. We retrospectively assessed associations between clinical data obtained before starting neoadjuvant CRT and pathological responses.
Results: We compared good responders (over two-thirds of the primary tumor reduced by neoadjuvant CRT; Japan Esophageal Society response evaluation criteria Grades 3 and 2; $n = 89$, 72.4%) and poor responders (less than two-thirds of the primary tumor reduced by neoadjuvant CRT; Japan Esophageal Society Grades 1 and 0; $n = 34$, 27.6%). Primary tumor length ($p = 0.02$), hemoglobin (Hb) ($p = 0.007$) and platelet numbers ($p = 0.03$) were statistically significant parameters. Multivariable analysis

subsequently revealed Hb (OR, 1.51; 95% CI, 1.14–1.98; p = 0.004) as the sole independent covariate for a response to neoadjuvant CRT. The receiver operating characteristic curve showed that the optimal cutoff for pre-therapeutic Hb was 13 g/dL for predicting a response, and 82.9% and 51.2% of patients with Hb > and ⩽13 g/dL, respectively, were good responders (p = 0.0002). The 5-year overall survival rates of patients with Hb >13 and ⩽13 g/dL were 61.8% and 43.0%, respectively (p = 0.03).
Conclusions: Responses to neoadjuvant CRT and the survival of patients with esophageal squamous cell carcinoma can be predicted from the pre-therapeutic Hb level. Pre-therapeutic evaluation based on Hb could be easily incorporated into routine clinical practice.
No conflict of interest.

Combination of transarterial chemoembolization plus sorafenib in Chinese patients with unresectable hepatocellular carcinoma: A subgroup results of the START final analysis

G. Han[1], J. Yang[2], G. Shao[3], G. Teng[4], M. Wang[5], J. Yang[6], Z. Liu[7], G. Feng[8], Y. Chao[9], J. Wang[10]. *[1]Xijing Hospital the Fourth Military Medical University, Gastroenterology, Xi'an, China; [2]Changhai Hospitai the Second Military Medical University, Interventional Radiology, Shanghai, China; [3]Zhejiang Cancer Hospital, Interventional Radiology, Hangzhou, China; [4]Zhongda Hospital Southeast University, Interventional Radiology, Nanjing, China; [5]PLA General Hospital, Interventional Radiology, Beijing, China; [6]The First Affiliated Hospital of Sun Yat-Sen University, Interventional Radiology, Guangzhou, China; [7]Shengjing Hospital China Medical University, Interventional Radiology, Beijing, China; [8]Union Hospital Tongji Medical College Huazhong University of Science and Technology, Interventional Radiology, Wuhan, China; [9]Veterans General Hospital, Division of Chemoradiotherapy, Taipei, Taiwan; [10]Zhongshan Hospital Fudan University, Interventional Radiology, Shanghai, China*

Background: START is a phase II, multicenter, open-label, single-arm study investigating the therapeutic effect of transarterial chemoembolization (TACE) plus sorafenib (sor) for intermediate stage unresectable hepatocellular carcinoma (uHCC) in Asia (NCT00990860). The preliminary final analysis was presented in the ILCA 2013. Here, we report Chinese patients subgroup results.
Methods: Intermediate stage (BCLC B) uHCC patients and candidates for TACE were enrolled. Patients received conventional TACE with lipiodol and doxorubicin (30−60 mg), followed by embolization with absorbable particles. Sor (400 mg, po, bid) was administrated 4 days after the first TACE, and then continuously with interruption of 3 days before and after TACE. Tumor response was assessed 4 weeks after every TACE, and every 3 months thereafter if no TACE was indicated. Patients continued sorafenib until disease progression or unacceptable toxicity. The primary endpoint was safety/tolerability. Secondary endpoints included progression-free survival (PFS), time to progression (TTP), overall survival (OS), and number of TACE cycles.
Results: A total of 70 Chinese patients were enrolled. The median age was 52 years (range 31−75) and 58 (83%) were male. The main etiology for HCC is hepatitis B in 63 (94%) patients. 68 (97%) patients had cirrhosis. 65 (93%) patients were BCLC B stage and all patients were in ECOG Performance Status 0−1 at baseline. 68 patients who had taken at least one dose of sor were eligible for safety and efficacy analysis.
Mean daily dose of sor was 788.24 mg, and median duration was 343.5 days (range 23 −770). Mean and median TACE cycles were 2.9 and 3.0 respectively. 88.2% of patients had ⩾1 sorafenib-related adverse events (AEs), most commonly were hand–foot skin reaction (HFSR) (52.9%), alopecia (39.7%), diarrhea (35.3%) and rash (20.6%). 11 (16.2%) patients had more than one grade 3 or 4 AEs which were predominantly hepatic function abnormal (6), HFSR (3) and diarrhea (3). 4 patients discontinued sor due to adverse events. 21 and 10 patients had complete and partial response respectively. 28 patients had stable disease. Disease control rate reached 88%. The median TTP and OS were 12.3 and 25.1 months respectively.
Conclusion: TACE and sor combination in Chinese uHCC patients is safe and tolerable. The efficacy results are consistent with preliminary final data.

2493 POSTER

Surgical (S) vs non-surgical (NS) treatment for stage I esophageal cancer (EC): Single center experience

I. Park[1], Y.H. Kim[2], D.H. Yoon[1], H.R. Kim[2], J.H. Kim[3], H.Y. Jung[4], G.H. Lee[4], K.J. Cho[5], S.B. Kim[1]. *[1]Asan Medical Center, Oncology, Seoul, South Korea; [2]Asan Medical Center, Thoracic Surgery, Seoul, South Korea; [3]Asan Medical Center, Radiation Oncology, Seoul, South Korea; [4]Asan Medical Center, Gastroenterology, Seoul, South Korea; [5]Asan Medical Center, Pathology, Seoul, South Korea*

Background: Surgical resection (S) is a mainstay treatment for stage I esophageal cancer (EC). Although surgical outcome is favorable, patients (pts) often suffer from postoperative complications and decreased quality of life. Furthermore, medically-unfit pts cannot undergo surgery. Definitive chemoradiotherapy (CRT) or radiotherapy (RT) as an alternative treatment for stage I EC is not well delineated. We aimed to compare NS with S in stage I EC pts to verify its efficacy and feasibility.
Material and Methods: We retrospectively reviewed medical records of pts having received treatment for histologically confirmed, clinical stage I EC at Asan Medical Center from 2003 to 2012. Those pts with T1aN0M0 who received EMR were excluded. Routine clinical diagnostic work up included endoscopy, endoscopic ultrasound, computed tomography, and positron emission tomography. Baseline characteristics, treatment outcomes and complications, and survival were compared.
Results: There were 264 pts in S group, whereas 20 pts in NS group. Median age was 69.5 and 63.0, respectively. Male was predominant, and squamous cell carcinoma was main histology in both groups (97% and 100%, respectively). ECOG performance status was poorer in NS group. In NS group, 13 pts received concurrent CRT, 2 pts sequential CRT, and 5 pts RT alone. Most adverse effects were grade 1 or 2. All grade 3 or 4 toxicities were hematological, but manageable without serious complications. In S group, vocal cord palsy (13%), esophageal stricture (11%), infection (11%), wound problem (8%) were frequent. There were 5 pts (2%) with in-hospital 30 days mortaliy in S group. With a median follow up of 41.8 months, 31 pts (12%) in S group and 3 pts (15%) in NS(2 pts in RT alone, 1 pt in CRTgroup) recurred. First sites of recurrence for S and NS were locoregional (17pts vs 3pts), distant (6 vs0), and both locoregional and distant (8vs0), respectively. Median time-to-recurrence was not reached in both groups (log-rank test p = 0.583). Seven pts (35%) and 50 pts (19%) died in NS group and S group respectively.Median overall survival was 71.4 months (95% CI 30.7–112.0 months) in NS group and not reached in S group (p = 0.052).
Conclusions: For stage I EC, NS can be alternative to S, especially in medically unfit pts for surgery. The role of definitive CRT for early stage EC needs to be verified in future prospective randomized trial.
No conflict of interest.

2494 POSTER

Survival outcomes in potentially resectable T3 node positive gastroesophageal carcinomas treated with perioperative chemotherapy

S. Sharma[1], L. Khoja[1], K. Chan[1], V.O. Holt[1], W. Mansoor[1]. *[1]Christie Hospital NHS Foundation Trust, Medical Oncology, Manchester, United Kingdom*

Background: Perioperative (MAGIC protocol, Cunningham et al NEJM 2006) chemotherapy has improved outcomes in resectable gastric and distal oesophageal carcinomas. However, a significant proportion of patients with localised disease present with T3 disease which is often node positive. Outcome after perioperative therapy in these patients is unclear. Furthermore, the effect of stage migration on survival is unknown.
Materials and Methods: Between December 2009 and December 2011 104 patients with T3N0/N+ potentially resectable oesophageal or gastric carcinoma were identified. Radiological pre-therapy and post resection pathological staging was recorded in accordance with TNM 7 pathological staging. Patients were treated with perioperative ECX chemotherapy (Epirubicin, cisplatin and capecitabine) at the Christie Hospital, United Kingdom. Clinical, radiological and pathological characteristics were correlated with survival (progression free (PFS) and overall survival (OS)).
Results: 104 patients (Table 1) were commenced on perioperative chemotherapy with curative intent. 34/104 patients (33%) either progressed on neoadjuvant chemotherapy or were deemed unfit and did not have surgery. 27/104 (27%) patients completed the full course of chemotherapy treatment.
The median follow up was 15.5 months. The median progression free survival (PFS) and overall survival (OS) for all patients was 18.5 months and 21 months respectively. 1 year relapse free survival was 51%.
With respect to radiological staging, the median PFS for T3N0 patients compared to T3N+ patients (was 19.3 months and 14 months respectively (HR 0.72 95% CI 0.39–1.34 p = 0.30). Moreover, overall survival (OS) for

T3N0 and T3N+ patients was not significantly different (21.8 vs. 21.0 months HR 0.38 95% CI 0.17–0.86 p = 0.78). Comparison of T3N0−1 with T3N2+ was significant for PFS alone (18.89 vs. 10.12 months HR 0.48 95% CI 0.25–0.91 p = 0.025).
When pathological nodal staging was assessed, the median PFS for ypT3N0 patients had not been reached compared to pyT3N+ patients which was 18.9 months (HR 0.37 95% CI 0.17–0.77 p = 0.001). Similarly, overall survival (OS) for pyT3No had not been reached and for pyT3N+ patients was 22.47 months (HR 0.38 95% CI 0.17 to 0.86 p = 0.02). Increase in pathological T stage and number of pathologically involved nodes were also significant for diminishing PFS and OS by univariate analysis. There was no correlation between radiological and pathological staging of either T or N status (r^2=0.007 and 0.002).
Conclusions: T3 cancers of the oesophagus/stomach have a high relapse rate. Radiological staging of T3 cancers can predict for PFS. Pathological stage predicts for PFS and OS and may be a more accurate indicator of survival in accordance with stage migration.
No conflict of interest.

Brain metastasis in patients with esophageal squamous cell carcinoma

Y. Chen[1], S. Li[1], Y. Wang[2], H. Lu[3], T. Lee[4], C. Huang[1], M. Hsieh[3], F. Fang[2], K. Rau[1], Y. Chen[1]. *[1]Chang Guang Memorial Hospital Kaohsiung Branch, Hemato-Oncology, Kaohsiung, Taiwan; [2]Chang Guang Memorial Hospital Kaohsiung Branch, Radiation Oncology, Kaohsiung, Taiwan; [3]Chang Guang Memorial Hospital Kaohsiung Branch, Thoracic & Cardiovascular Surgery, Kaohsiung, Taiwan; [4]Chang Guang Memorial Hospital Kaohsiung Branch, Neurosurgery, Kaohsiung, Taiwan*

Background: Patients with esophageal squamous cell carcinoma have a poor outcome. The lungs, liver, bone, pleura and adrenal gland are the most common sites of visceral metastasis, but brain metastasis is exceedingly rare. The reports about the clinical outcome of brain metastasis in esophageal squamous cell carcinoma are few. Therefore, we performed a retrospective review of esophageal squamous cell carcinoma patients with brain metastasis to assess the incidence of brain metastasis and their prognosis.
Material and Methods: Between January 1996 and December 2011, 1011 patients with esophageal squamous cell carcinoma were retrospectively reviewed, and 14 patients with brain metastases were identified. Diagnoses of brain metastasis were established using brain computer tomography (CT) scan, or magnetic resonance imaging (MRI).
Results: The incidence of brain metastasis in our series was 1.4%. The median survival from the diagnosis of brain metastasis in these 14 patients with esophageal squamous cell carcinoma was 1.9 months. The median follow-up from the diagnosis of esophageal cancer to the diagnosis of brain metastasis was 6.6 months. Systemic metastasis at the diagnosis of brain metastasis was found in 10 patients (71%). A single brain metastasis was found in 6 patients (43%), two brain lesions were found in 2 patients (14%), and multiple brain metastases were found in 6 patients (43%). Primary treatment was whole brain irradiation therapy (WBRT) alone in 5 patients (36%), surgical resection in 6 patients (43%), 5 of whom (36%) subsequently were treated with WBRT, and best supportive care in three patients (21%). Univariate analysis showed that patients with single brain metastasis (P = 0.004), treatment with surgical resection plus whole brain radiation therapy (P = 0.002), and absence of systemic metastasis (P = 0.03) were significantly associated with better clinical outcome.
Conclusions: The incidence of brain metastasis in esophageal squamous cell carcinoma is 1.4%, and the prognosis is poor. Patients without systemic metastases or with single brain metastasis have significantly superior survival, suggesting that aggressive therapy should be considered in these groups of patients.
No conflict of interest.

Table: The clinical outcome of 14 esophageal cancer patients with brain metastasis

Characteristic	Number of patients	Median overall survival (mos)	P value
Number of brain metastases			0.004
Single	6	13.4 (1.2–54.4)	
Multiple	8	1.5 (0.3−3.9)	
Treatment modality			0.002[#]
WBRT*	5	1.5 (1.2−3.9)[#]	
Resection alone	1	1.6	
Resection + WBRT	5	14.6 (6.0–54.4)[#]	
Supportive care	3	0.4 (0.3−0.7)	
Systemic metastasis			0.03
Yes	10	1.6 (0.4–12.1)	
No	4	29.3 (0.3–54.4)	

WBRT: whole brain radiation therapy.

2496 POSTER

Efficacy and safety of chemoradiotherapy using intensity-modulated radiotherapy (IMRT) for locally advanced esophageal cancer

M. Nakamura[1], K. Oda[1], T. Aizawa[1], K. Taguchi[1], N. Kasai[1], Y. Ito[1], H. Kamikawa[1], K. Tauchi[1]. *[1]Jisenkai Medical Corporation Aizawa Hospital, Aizawa Comprehensive Cancer Center, Matsumoto, Japan*

Background: The outcome of inoperable esophageal cancer has been reported as extremely poor. For locally advanced T4 and/or M1 (LYM) cases, chemoradiotherapy is recommended. Historically, radiation to the esophagus was delivered with 2D techniques that affected a large volume of normal tissue. This irradiation of normal tissue causes acute and late toxicity such as myelosupression, gastrointestinal symptoms, pericarditis, heart failure and radiation pneumonitis. With intensity-modulated radiotherapy (IMRT), there is not one individual beam of uniform dose but rather a series of individual beamlets each programmed to vary the dose intensity across the target/normal tissue interface. IMRT enables the intended dose to be shaped three-dimensionally to maximize the dose to the intended target and minimize the dose to the healthy tissue. We evaluated the clinical efficacy and safety of IMRT for locally advanced esophageal cancer retrospectively.
Methods: Between May 2008 and December 2012, 23 (22 male and 1 female, median age 71(56−78)) T4 and/or M1 (LYM) locally advanced esophageal cancer patients were treated with IMRT+chemotherapy. The treatment consisted of chemotherapy (5-FU and cisplatin; FP) and concurrent irradiation using IMRT of 50−60 Gy in 25−30 fractions to the esophageal primary tumor and regional lymph nodes. Histologically, 21 patients had squamous cell carcinoma, 1 patient had adenocarcinoma and 1 patient was uncertain due to undifferentiation. Clinically, 22 patients had dysphagia due to primary tumor before treatment, and when there was a need, nutritional support was provided by intravenous hyperalimentation or feeding through a percutaneous gastrostomy tube.
Results: The overall response rate of the primary lesion was 96.5%, including 13 patients (56.5%) who achieved a complete response. Dysphagea was improved in 19 patients (86.4%; p>0.01 paired t test). The median overall survival was 13.8 months, and the 1-year and 3-year survival rate were 50.0% and 36.3% respectively. The median progression-free survival was 6.5 months. Recurrences were observed in 18 patients and recurrent sites were distant metastasis, with only 1 patient having local recurrence. Three patients showed lymph node metastases within 1 year after IMRT+FP underwent secondary IMRT+FP, and have been in remission for more than 2 years. Severe (over grade 3) adverse events were observed in 9 patients. Major severe adverse events were leucocytopenia (34.8%) and neutrocytopenia (17.4%). No patient died within the treatment schedule or for 30 days after treatment.
Conclusions: IMRT+FP for inoperable locally advanced esophageal cancer showed a very high local control rate and improved dysphagea. Distant metastases were the main cause of death and adjuvant treatment will be needed to prevent them. To our knowledge, this is the first report about the use of IMRT for locally advanced esophageal cancer.
No conflict of interest.

2497 POSTER

Yttrium-90 (Y90) radioembolization for primary and metastatic liver cancer in British Columbia

R. Peixoto[1], D. Liu[2], D. Klass[2], B. Lum[2], D. Renouf[1], H. Lim[1]. [1]*BC Cancer Agency, Medical Oncology, Vancouver BC, Canada;* [2]*University of British Columbia, Interventional Radiology, Vancouver BC, Canada*

Background: Y90 is a potential therapy for both unresectable hepatocellular carcinoma (HCC) and liver metastases. Little data is available regarding differences in efficacy for different tumour primaries.
Methods: We retrospectively reviewed 41 consecutive patients (pts) with different primary cancers who were treated with Y90 between November 2009 and December 2012 at Vancouver General Hospital. Median overall survival (OS) and progression free survival (PFS) from the first Y90 treatment were examined by Kaplan–Meier. Log-rank was used to test differences in OS and PFS between groups.
Results: Forty-one pts (male: 28, female: 13) received 66 Y90 treatments and were discharged on the same day. Four pts received repeated Y90 therapy after progression on the first. Mean age was 62.2 years (range 32−83). There were 20 neuroendocrine tumours (NETs), 9 HCCs, 8 colorectal adenocarcinomas (CRCs), 1 cholangiocarcinoma, 1 urothelial carcinoma, 1 jejunum adenocarcinoma and 1 choroidal melanoma. Among pts with HCC, 77.7% had cirrhosis and 66.6% portal vein thrombosis. At the time of Y90 treatment, 34.1% of the pts had extra-hepatic disease. At the first response assessment, 25 pts (61%) achieved a partial response in the liver and 2 (4.8%) had stable liver disease. Of the 27 pts who had liver disease control, 30% had progressive extra-hepatic disease. The median PFS and OS were 5.0 months (95% CI 2.5−7.5) and 16.4 months (95% CI 10.2–22.5), respectively. Those without extrahepatic disease had a better median OS (18 vs 7.7 months), although not statistically significant ($p = 0.14$). Pts with NETs had a better median OS (not reached yet) when compared to HCC (3.03 months; $p = 0.005$) and CRC (4.37 months; $p < 0.001$). Y90 was well tolerated with no grade 4 or 5 adverse events. Only one patient died within 30 days of Y90 due to complications of small bowel obstruction. The most common side effects were abdominal pain (48.7%), nausea (29.2%) and fatigue (29.2%).
Conclusion: Our data support the safety and efficacy of palliative Y90 for both unresectable HCC and liver metastases. NETs seem to derive the greatest benefit.
No conflict of interest.

2498 POSTER

The evaluation of factors predicting recurrence and prognosis for patients with node-negative gastric cancer after curative resection

A. Bilici[1], F. Selcukbiricik[1], B.B. Ustaalioglu[2], M. Seker[3], F. Dane[4], M. Aliustaoglu[3], M. Gumus[3], F. Demirelli[5]. [1]*Sisli Etfal Education and Research Hospital, Department of Medical Oncology, Istanbul, Turkey;* [2]*Haydarpasa Numune Education and Research Hospital, Department of Medical Oncology, Istanbul, Turkey;* [3]*Dr.Lutfi Kirdar Kartal Education and Research Hospital, Department of Medical Oncology, Istanbul, Turkey;* [4]*Marmara University Medical Faculty, Department of Medical Oncology, Istanbul, Turkey;* [5]*Istanbul University Cerrahpasa Medical Faculty, Department of Medical Oncology, Istanbul, Turkey*

Background: Patients with node-negative gastric cancer (GC) have better overall survival (OS) than lymph node positive GC, but some of them may develop relapse and need adjuvant therapy. In the present study, we aimed to evaluate the predictors for recurrence and prognostic factors for survival in patients with node-negative GC.
Methods: A total of 231 patients with node-negative GC who underwent curative D2 gastrectomy were retrospectively reviewed. Clinicopathological factors predicting the recurrence and survival for were evaluated.
Results: pT stage, gender, lymphatic vessel invasion, blood vessel invasion and perineural invasion were significantly associated with recurrence. Sixty-two patients developed relapse. The majority of patients had haematogenous recurrence pattern (62.7%). Patients with loco-regional recurrence had significantly better median disease-free survival (DFS) and OS intervals than those of patients with peritoneal and haematogenous recurrence (DFS, 79.3 vs. 41.8 vs. 29 months, $p = 0.04$; OS, 97.4 vs. 58.6 vs. 36.6 months, $p = 0.01$, respectively). Surgery type, advanced pT stage, clinical stage, larger tumour size and the presence of adjuvant treatment were found to be independent risk factors for recurrence by logistic regression analysis. However, multivariate analysis demonstrated that clinical stage and recurrence pattern were independent prognostic indicators for OS.
Conclusions: Patients with node-negative GC had high incidence of recurrence and some clinicopathological factors may affect the developing of relapse. Recurrent patients had worse survival except for those of loco-regional recurrence. Adjuvant treatments should be considered for node-negative GC patients with high recurrence risk.
No conflict of interest.

2499 POSTER

Prognostic significance of FDG-PET scanning in curatively resected hepatocellular carcinoma

J.Y. Kim[1], Y.R. Do[1], K.U. Park[1], K.J. Kang[2], Y.H. Kim[2], K.S. Won[3], H.S. Song[1]. [1]*Dongsan Medical Center Keimyung University, Haematooncology, Daegu, Korea;* [2]*Dongsan Medical Center Keimyung University, General Surgery, Daegu, Korea;* [3]*Dongsan Medical Center Keimyung University, Nuclear Medicine, Daegu, Korea*

Background: Fluorine-18 fluorodeoxyglucose (FDG) positron emission tomography (PET) has proven to be a valuable tool in the initial diagnosis, staging, and restaging of a variety of cancers. The potential use of FDG-PET in the evaluation and management of hepatocellular carcinoma (HCC) continues to evolve.
Methods: The purpose of this study was to investigate the correlation between SUVmax, tumour to non-tumour ratio (TNR), tumour size and histologic grade in curatively resected hepatocellular carcinoma. All patients underwent PET scanning between January 2008 and December 2011. Results of the PET scan were compared with tumour size, AFP levels and histologic grade retrospectively.
Results: Of the 65 patients who underwent ^{18}F-FDG PET, the mean age was 57.5±8.9 (39−74), male and female was 46 (70.8%), and 19 (29.2%) and increased FDG uptake was noted in 44 patients (67.7%). The mean tumour size was 4.8±3.3 cm (1.0–18.0) and mean SUVmax was 3.4±3.1 (0.0–15.7). Histologic grade were as follows: Grade 1 in 1 (1.5%), 2 in 35.4% 23 (35.4%), 3 in 34 (52.3%) and 4 in 7 (10.8%). The total numbers of relapsed patients were 26 (40.0%). Progression free survival (PFS) was 30.0±3.1 (23.9–36.0) months and overall survival (OS) was 45.7±1.9 (41.9–49.4) months. We divided 2 groups according to TNR: below 2.0 ($n = 48$) and above 2 ($n = 17$). Tumour size, SUVmax, AJCC stage, TNR, and elevated AFP after operation were significant factors of PFS in univariate analysis. Tumour size, TNR and elevated AFP after operation were significant factors of PFS in multivariate analysis. OS did not relate with tumour size, SUVmax, stage, TNR and AFP level.
Conclusion: TNR over 2 is isolated significant prognostic factor of PFS in curatively resected hepatocellular carcinoma.
No conflict of interest.

2500 POSTER

Peri-operative and quality of life outcomes after cytoreductive surgery and hyperthermic intraperitoneal chemotherapy − the Asian perspective

W.J. Tan[1], C.S. Chia[1], J.F.S. Wong[1], G.H.C. Tan[1], K.C. Soo[1], M.C. Teo[1]. [1]*National Cancer Centre Singapore, Department of Surgical Oncology, Singapore, Singapore*

Background: Although cyto-reductive surgery with hyperthermic intraperitoneal chemotherapy (CRS+HIPEC) has gained acceptance for the treatment of peritoneal carcinomatosis, the data on quality of life (QOL) after treatment remains scarce, particularly among the Asian population. This study aims to assess long term patient rated outcomes and QOL post CRS and HIPEC in an Asian cancer centre.
Methods: All patients who completed CRS+HIPEC between 6 to 18 months ago (27 patients) were enrolled in the study. QOL was measured via the administration of the European Organization for Research and Treatment of Cancer (EORTC) QLQ-C30 questionnaires by 2 healthcare professionals. The control group consists of QOL scores obtained from 393 disease free cancer patients, of ECOG status 0 or 1, who were not on active treatment. The one sample t-test was used to compare differences in QOL scores between the 2 groups of patients.
Results: 27 patients were analysed of which 22 (81%) were females. Median age was 51 years (15−59 years). CRS + HIPEC were performed for ovarian cancer in 15 patients (55%), appendiceal carcinoma in 5 patients (19%) and Colorectal carcinoma in 4 patients. The other primary tumours include primary peritoneal carcinoma (2 patients) and endometrial carcinoma (1 patient). The median intra-operative Peritoneal Carcinomatosis Index (PCI) score was 15 (2−31) while the Completeness of Cytoreduction (CC) Score was 0 and 1 in 25 and 2 patients respectively. The median duration post CRS+HIPEC was 10 months (6−16 months).
Peri-operative morbidities occurred in 13 patients (48%) of which 7 patients (26%) had Class III and IV morbidities. These included intra-abdominal collections requiring percutaneous drainage (4 patients), intestinal obstruction secondary to adhesions requiring repeat laparotomy (2 patients) and anastomotic leak which required operative repair (1 patient).

The QOL scores of patients post CRS+HIPEC compared to that of the control group are illustrated in Table 1. Global health status, functional and symptom scores were largely similar between our cohort of patients and the control group. Cognitive functioning scores and fatigue scores were significantly better in the group post CRS + HIPEC ($p = 0.014$ and $p = 0.04$) respectively.
Conclusion: Despite the initial morbidity associated with CRS and HIPEC, long term QOL in survivors can be comparable to that of disease free cancer patients on follow up.
No conflict of interest.

Table 1.

QOL parameter	Mean score of study population (95% confidence interval)	Control (n = 393)	p value
Function Score			
Global Health	67 (59–75)	71	0.335
Physical Functioning	85 (78–91)	85	0.908
Role Functioning	89 (83–96)	87	0.487
Emotional Functioning	83 (76–89)	81	0.567
Cognitive functioning	88 (83–94)	81	0.014*
Social Functioning	83 (74–93)	86	0.567
Symptom Score			
Fatigue	17 (10–25)	25	0.040*
Nausea and vomiting	7 (1–13)	4	0.308
Pain	13 (5–21)	18	0.204
Dyspnoea	8 (2–15)	15	0.051
Insomnia	16 (6–25)	24	0.052
Appetite Loss	7 (1–14)	11	0.230
Constipation	12 (4–20)	11	0.820
Diarrhoea	7 (1–14)	6	0.720
Financial Difficulties	21 (10–33)	23	0.776

2501 POSTER

A three-step neoadjuvant strategy for locally advanced gastric cancer: A single institutional experience

P. Martin Romano[1], L. Arbea[1], A. Chopitea[1], C. Garzon[1], J.J. Aristu[1], E. Castañon[1], J.L. Hernandez[2], J.C. Subtil[3], J. Rodriguez[1]. *[1]University of Navarre, Oncology, Pamplona, Spain; [2]University of Navarre, General Surgery, Pamplona, Spain; [3]University of Navarre, Gastroenterology, Pamplona, Spain*

Background: To assess the efficacy, toxicity and long term outcome of induction chemotherapy (ICT) followed by chemoradiotherapy (CRT) and surgery in patients with locally advanced gastric or gastro-esophageal adenocarcinoma (GEA).
Methods: Patients (pts) with CT-scan and endoscocopic ultrasound (EUS) T2–4 and/or N+, M0 GEA were retrospectively analyzed. ICT consisted of 3–4 cycles of Docetaxel (D) and Oxaliplatin (O) on day 1 and Capecitabine twice daily for 14 days on a 3 weekly schedule. CRT included weekly D and O administered on weeks 1, 2, 4 and 5 and daily Capecitabine concurrently with external beam radiotherapy (45 Gy). Surgery was scheduled 4 to 6 weeks after the end of CRT. Pathological response was graded according to the Becker criteria. Toxicity was scored according to NCI-CTC.
Results: From November 2004 to April 2012, 73 pts (M/F; 41/22, median age 59 were included. Pretreatment T3-T4 and/or N+ were encountered in 67 pts (92%). Grade 3–4 toxicity during ICT included anemia (3 pts), neutropenia (1 pt), diarrhea (1 pt) and vomiting (1 pt). Grade 3–4 toxicity during CRT included neutropenia (9 pts), g.i. toxicity (3 pts) and asthenia (6 pts). Admission to hospital due to toxicity was required in 22 pts (30%). Sixteen pts (21.9%) progressed while on neoadjuvant therapy. Fifty-seven pts underwent radical surgery with an R0 resection rate of 95%. Pathological response according to Becker criteria was grade1a (35%), grade1b (23%), grade 2 (26%) and grade 3(16%). pN0 was achieved in 35 pts (60.3%). Median DFS for pN0 and pN+ was NR and 17 months, respectively ($p = 0.043$). Among all operated pts, local and distant failures were reported in 21 (28.8%) and 40 pts (54.8%). After a median follow-up of 55 months (range 9–98 months) the 5-year overall and disease-free survival, were 37% and 36%, respectively.
Conclusion: Induction CT followed by CTH in locally advanced gastric and gastroesophageal adenocarcinoma is feasible and achieves a remarkable long-term outcome, with an acceptable toxicity.
No conflict of interest.

2502 POSTER

Health service research mirrors conventional and additional therapies in patients with pancreatic cancer in integrative oncology

F. Schad[1], J. Axtner[2], A. Happe[2], M. Kröz[3], G. Spahn[4], H. Matthes[5]. *[1]Hospital Havelhoehe, Oncological Center, Berlin, Germany; [2]Research Institute Havelhoehe, Network Oncology, Berlin, Germany; [3]Hospital Havelhoehe, Internal Medicine, Berlin, Germany; [4]Hospital Oeschelbronn, Internal Medicine, Berlin, Germany; [5]Hospital Havelhoehe, Gastroenterology, Berlin, Germany*

Background: Integrative oncology (IO) responds to patients needs by offering a variety of additional therapies like non-pharmacotherapeutic interventions (NPI) or *Viscum album* extracts (VA), which activate patients' resources, can enhance health-related quality of life and reduce adverse effects caused by standard chemo- or radiotherapy. In the present study we characterize the use of therapies in pancreatic cancer patients in IO settings.
Methods: 527 patient records diagnosed with ICD-10 C25 were collected by the Network Oncology, a conjoint clinical registry of German hospitals and out-patient practitioners active in integrative oncology. We used non-parametric Fisher exact test (F) to compare observed frequencies, Wilcoxon rank sum (W), for differences between groups. Bonferroni correction was used to adjust the level of significance in the case of multiple testing.
Results: The observed sex ratio of 0.86 (female:284, male: 243) was comparable to German incidence data of the Robert-Koch Institute. Men (66 yrs) were in median younger than women (68 yrs; $p_W = 0.02$). 58% were of UICC stage IV at first diagnosis, 6% of stage III, 37% of stage II and 1% of stage I. 16% received radiation, 76% surgery and 79% a chemo therapy. 99% received cytostatic drugs, 18% signal transduction inhibitors, other chemo-therapeutics were less than 5%. 64% had a gemcitabine mono-therapy and it was part of 74% of the recorded combinations. 7% received a combination of 5-FU/FA/oxaliplatin, 5% of erlotinib/gemcitabine, other combination occurred less than 5%. 76% received at least one additional integrative therapy. Most common were VA (f: 80%, m: 72%), nursing interventions (f: 74%, m: 59%), movement therapies (f: 58%, m: 43%), or art therapies (f: 44%, m: 29%). Except for VA, women chose additional therapies significantly more often than men in those groups (all $p_F < 0.0125$). Other types of NPI were recorded in lower frequencies. Female patients received up to 9, males up to 7 different NPI. 61% of women and 45% of men choose at least three NPI. 33% of the men and 20% of women chose none NPI at all.
Conclusions: Beside gemcitabine, VA and NPI are part of standard care and used in high frequencies by patients with pancreatic cancer in an IO setting. Although women were more likely to choose NPI there was no significant bias towards a higher proportion of women in the data base. This data reflect every day care in cancer therapy and can provide a basis for prospective studies on outcome in IO.

2503 POSTER

Chemo-sensitization and immunological reactions to hyperacute immunotherapy, a novel approach to cancer treatment

J.C. Morris[1], G.R. Rossi[2], N.N. Vahanian[2], C. Rocha Lima[3], E. Kennedy[2], W.J. Ramsey[2], L. Tennant[2], C.J. Link[2]. *[1]Cincinnatti, Department of Surgery, Ohio, USA; [2]NewLink Genetics, Tumor Immunology, Ames, USA; [3]University of Miami, Comprehensive Cancer Center, Miami FL, USA*

Introduction: Hyperacute rejection in higher primates is a well-characterized potent innate immune defense mechanism by which antibodies directed against alpha(1, 3)-Galactosyl carbohydrate epitopes leads to the rapid destruction of xenografts and zoonotic agents from lower mammals. HyperAcute™ cancer immunotherapies consist of genetically modified irradiated allogeneic tumor cells expressing αgal moieties that stimulate the development of immunity directed against antigens shared by immunotherapy cells and host tumors. Drugs of this class have been used in clinical trials with promising results in DFS, OS, tumor responses and correlative immunological data. Chemosensitizaton after immunotherapy has been anecdotally reported. We studied this effect after HyperAcute Immunotherapy.
Methods: HyperAcute immunotherapies are administered intradermally and have been tested in multiple indications; non-small cell lung (Phase, 1/2, N = 54), advanced melanoma (P, 1–2, N = 31), refractory prostate (P, 1, N = 8), and resected pancreatic cancer (P, 1–2, N = 86). Patients were followed for objective responses to follow-on chemotherapy.
Results: A potential sensitizing effect of HyperAcute immunotherapy to salvage therapy was observed with 2 different HyperAcute vaccines.

Three patients with recurrent pancreatic cancer who progressed with metastatic disease after chemo-immunotherapy subsequently had complete responses to various 2nd line regimens and all 3 are still alive (24 −48M). In the HyperAcute-Lung (tergenpumatucel-L) trial 9 of 16 patients that progressed had objective response to chemotherapy. In addition, intriguing immunological and clinical reactions have been observed with HyperAcute immunotherapies. Skin reactions ranging from immediate sensitization with wheal and flare reactions to DTH responses have regularly been observed. Most reactions are localized but some patients experience recrudescent flares at distant previously injected sites as late as one year after vaccination. In the HyperAcute melanoma trial patients developed auto antibodies (100%), Vitiligo (16%) and 2 CR's, including infiltration of tumor with CD8+ lymphocytes. Biopsy of injection sites demonstrated eosinophilic infiltrates. Interestingly, in the NLG0205-pancreas study, 70% of patients experienced some degree of peripheral eosinophilia during treatment.
Conclusions: These novel observations of greater than expected chemotherapy response after HyperAcute Immunotherapy warrants further study.

Residual nodal disease in gastroesophageal adenocarcinoma treated with perioperative chemotherapy and surgery: Its impact on disease-free survival

A. Garg[1], L.E. Ferri[2], N. Danyliuk[3], J. Asselah[1], M. Vanhuyse[1], M.P. Thirlwell[1], T. Alcindor[1]. *[1]McGill University Health Centre-MGH, Oncology, Montreal QC, Canada; [2]McGill University Health Centre-MGH, Surgery, Montreal QC, Canada; [3]McGill University, Faculty of Medicine, Montreal QC, Canada*

Background: Perioperative chemotherapy is a standard approach to resectable locally advanced gastroesophageal adenocarcinoma. Randomized studies have shown that it improves disease-free survival and overall survival in comparison with surgery alone. Patients with pathological complete response (pCR) enjoy a long disease-free survival (DFS). However, pCR is only seen in 10−15% of cases, so other markers of prognosis would be helpful. In this study, we assessed the impact on DFS of residual nodal disease (RND) after the preoperative part of chemotherapy.
Patients and Methods: This study, which includes patients from May 2007 to December 2011, is a continuation of the McGill 0620 clinical trial, approved by the Ethics Review Board. Data have been extracted from the prospectively maintained database, built with individual patient consent. We identified 82 patients with resectable locally advanced gastroesophageal adenocarcinoma. Patients were to receive 3 cycles of chemotherapy before and after surgical resection. Postoperative chemotherapy started 6 to 12 weeks after surgery. Chemotherapy consisted of docetaxel, cisplatin and 5-flurouracil given every 3 weeks. Surgery consistently included D2 lymph node dissection. RND is defined as presence of adenocarcinoma in any lymph node retrieved at time of surgery. DFS is defined as time from surgery to time of recurrence or last follow-up. DFS was compared between 2 groups: presence of RND (RND+) or absence of RND (RND-). The log-rank test was used for analysis, with stratification for clinical staging and calculation of impact of administration or nonadministration of postoperative chemotherapy.
Results: Of 82 patients, 12 were excluded for the following reasons: no follow-up after surgery (4), no preoperative chemotherapy (3), neuroendocrine tumor or squamous cell carcinoma pathology (5). Therefore, a total of 70 patients were included in the analysis. RND was found in 50 patients. RND+ was associated with a shorter DFS in comparison with RND- (180 days vs. 720 days, *p* value <0.0001). This association was still significant after controlling for clinical lymph node disease, as diagnosed by computed tomography and/or endoscopic ultrasound (stratified log-rank test: *p* value=0.0002). Regarding possible influence of postoperative chemotherapy, 54 patients received at least one cycle of chemotherapy, 7 patients received none because of personal preference. In addition, nine cases were excluded because no postoperative chemotherapy information was available. Median DFS was respectively 358 vs. 581 days, respectively, for postoperative chemotherapy vs. no postoperative chemotherapy (stratified log-rank test: *p* value=0.6856). This was not considered statistically significant.
Conclusions: This analysis confirms that patients with residual nodal disease after preoperative chemotherapy for gastroesophageal adenocarcinoma have shorter duration of DFS, even after adjustment for clinical staging and administration of postoperative chemotherapy.

Hyperthermic intraperitoneal chemotherapy in combined treatment of local-advanced and peritoneal disseminated gastric cancer: Results of prospective non-randomized study

R. Yarema[1], T. Fetsych[1], M. Ohorchak[2], G. Zubarev[2], Y. Olijnyk[1], M. Zubarev[1], P. Gyrya[2], Y. Kovalchuk[2], V. Safiyan[2]. *[1]Lviv National Medical University, Oncology, Lviv, Ukraine; [2]Lviv Regional Cancer Center, Digestive Surgery, Lviv, Ukraine*

Background: A novel strategy of cytoreductive surgery with hyperthermic intraperitoneal chemotherapy (HIPEC) has been shown to confer long-term survival for patients with peritoneal carcinomatosis from colorectal cancer. Patients with intraperitoneal disseminated gastric cancer (GC) have a dismal prognosis despite systemic chemotherapy or palliative surgery. Assesment of results use HIPEC in the combined treatment of such patients was purpose of the study.
Material and Methods: Between 2008 and 2012, 49 patients with advanced GC (19 patients with 'serosoinvasive' GC and high risk of metachronous peritoneal carcinomatosis, 20 patients with limited peritoneal carcinomatosis and 10 patients with diffuse peritoneal carcinomatosis and intense malignant ascitis) received treatment including HIPEC and 49 same patients received standard treatment (control group). HIPEC was performed an closed method for 90 min with mean intraperitoneal temperature 42.5ºC (range, 39.5–44.5ºC), mitomycin C 12.5 mg/m^2 and cisplatin 75 mg/m^2.
Results: The frequency of postoperative complications with the use of HIPEC was 26.5%, postoperative mortality − 4.1%. The use of HIPEC in adjuvant regime in patients with high risk of metachronous carcinomatosis permitted to obviously decrease the level of intraperitoneal relapse from 73.7% to 11.1% ($p < 0.001$), and increase 1-year and median survival from 52.6% and 12 month (group of surgical control) to 100% and 22.5 month respectively ($p = 0.001$). The use of HIPEC in combined with cytoreductive interventions and systemic chemotherapy for patients with GC with peritoneal metastasis 1-year and median survival was 68.8% and 12 months, the application of systemic palliative chemotherapy − 25% and 8 months respectively ($p = 0.004$). The use of HIPEC permitted to efficiently liquidate recurrent ascites in patients with diffuse peritoneal carcinomatosis without significant improve on survival ($p = 0.49$).
Conclusion: The HIPEC is a well-tolerated and effective method of adjuvant treatment GC with high risk of intraperitoneal progression. Cytoreduction followed by HIPEC improves survival in patients with limited peritoneal carcinomatosis of gastric origin. The HIPEC is an effective method of treating patients with recurrent intense ascites.
No conflict of interest.

Neoadjuvant chemotherapy for advanced gastric cancer; combined analysis to explore prognostic factors

M. Terashima[1], S. Satoh[2], H. Okabe[3], R. Hosotani[4], Z. Saze[5], S. Teramukai[6], S. Sakabayashi[7], Y. Kusunoki[8], Y. Sakai[3], M. Gotoh[5]. *[1]Shizuoka Cancer Center, Division of Gastric Surgery, Sunto-gun, Japan; [2]Fujita Health University, Department of Gastro-enterological Surgery, Nagoya, Japan; [3]Kyoto University, Department of Gastrointestinal Surgery, Kyoto, Japan; [4]Kobe City Medical Center General Hospital, Division of Surgery, Kobe, Japan; [5]Fukushima Medical University, Department of Regenerative Surgery, Fukushima, Japan; [6]Kanazawa University, Innovative Clinical Research Center, Kanazawa, Japan; [7]Translational Research Informatics Center, Department of Statistical Analysis, Kobe, Japan; [8]Translational Research Informatics Center, Department of Clinical Operations, Kobe, Japan*

Background: Prognosis of advanced gastric cancer is still poor even after extended lymph node dissection and adjuvant chemotherapy. Neoadjuvant chemotherapy (NAC) had been energetically investigated to improve the survival of these patients. However, solid survival benefit from NAC had not yet been demonstrated. Patient selection those will obtain the benefit from NAC will be of great importance. To explore the prognostic factors in patients received NAC for advanced gastric cancer, combined analysis of two Japanese phase II study (GC-0301 and GC-0402) was performed.
Methods: 1. GC-0301: Patients with M1 disease staged by conventional CT scan and staging laparoscopy were included in this study. Patients received two courses of cisplatin and S-1 and then underwent gastrectomy with lymph node dissection. 2. GC-0402: Patients with locally advanced gastric cancer, T3−4, N0−3, M0, for whom curative surgery was planned after NAC were included. Staging laparoscopy was not mandatory in this study. Patients received 2 courses of irinotecan and S-1 and then underwent gastrectomy with lymphadenectomy. In both study, patients resumed treatment with S-1 alone for 1 year after surgery. 3. Combined

analysis: To explore the prognostic factor in patients received surgery after NAC and in patients underwent R0 resection, Cox regression analyses (univariate and multivariate) were performed.
Results: GC0301: Fifty-one patients were enrolled and all patients were eligible. Surgery was performed in 44 patients. R0 resection was possible in 26 patients (51%). Median survival time (MST) was 19.2 months. Patients received R0 resection and those with Cy1 alone demonstrated a better survival. GC0402: Of 39 enrolled, 37 were eligible. Surgery was performed in 33 patients. R0 resection was possible in 17 (46%) patients. MST was 15.9 months. Overall survival was significantly better in patients underwent R0 resection. Combined analysis: In all patients received surgery, MST from surgery was 17.1 months. There was no significant difference of survival between the treatment arms. As independent prognostic factors, cN stage, histological type, final stage, and R-number were identified. In subgroup patients underwent R0 resection, only final stage was identified.
Conclusion: These results suggest that R0 resection is essential to achieve long-term survival and highly active regimen to obtain down staging is recommended.
No conflict of interest.

2507 POSTER

Efficacy and toxicity results of neoadjuvant gemcitabine-based combined chemoradiotherapy in patients with borderline resectable pancreatic adenocarcinoma: A single-institution experience

R. Diaz Beveridge[1], C. García-Mora[2], A. Moya[3], G. Bruixola[1], J. Aparicio[1], E. Reche[1], A. Segura[1], J. Caballero[1], A. Gimenez[1], H. Bennis[1]. *[1]University Hospital La Fe, Medical Oncology Department, Valencia, Spain; [2]University Hospital La Fe, Radiotherapy Department, Valencia, Spain; [3]University Hospital La Fe, Surgery Department, Valencia, Spain*

Introduction: The management of borderline resectable pancreatic adenocarcinoma patients (pts) is challenging. A 1st-line surgical approach can lead to an unacceptably high rate of incomplete resections. Neoadjuvant protocols with chemotherapy (CT) and radiotherapy (RT) might improve response rates and allow a margin-free R0 resection, and could improve long-term survival rates.
Material and Methods: Pts with borderline resectable pancreatic adenocarcinoma according to the AHPBA-SSO-SSAT criteria were enrolled. Prediagnostic evaluation: dedicated pancreatic triple-phase CAT and endoscopic ultrasound. Histologic confirmation mandatory. EGOG PS 0−1. Normal blood, hepatic and renal function (bilirrubin levels <3 mg/dl).
2 cycles of gemcitabine-oxaliplatin q14 days followed by combined CT-RT: weekly gemcitabine 300 mg/m^2; 45 Gy of external-beam RT followed by 5 Gy tumour boost (1.8 Gy/ fraction). Staging CAT after neoadjuvant CT and after combined CT-RT. If feasible, surgery was performed 4 to 6 weeks after end of protocol.
Results: *Patient characteristics*: 16 ptsbetween 02.2008–02.2013. Mean age 55 years (r 37−70). 62 % males. 69% with pretreatment biliary drainage. All PS 0−1. 100%: histologic confirmation of malignancy. Reasons for borderline resectability: mesenteric-portal confluence in 75%, superior mesenteric vein in 19% and espleno-portal confluence in 6%. No arterial involvement.
Treatment: 7% of patients progressed systemically during the neoadjuvant CT; the remaining 93% all finished the protocol. Grade 3−4 toxicity observed (during CT-RT): diarrhoea (19%), abdominal pain (19%) and afebrile neutropenia (19%). Radiological response: 31% minor partial response, 44% stable disease, 25% progressive disease. In 9 patients (56%) a surgical exploration was performed: in 37% a complete resection was possible (cephalic duodenopancreatectomy in 31% and corporo-caudal resection in 6%); in 12% only a palliative derivative procedure was done and in 6% no surgical act was performed. 2 episodes of intestinal ischemia were seen after the end of CT-RT, with one patient death.
Pathologic classification: complete pathologic response in 6%, ypT1N1 in 6%, ypT3N1 in 6%, ypT4N0M0 in 6%; 12% with a neuroendocrine tumour. All R0 resections.
Survival: Median follow-up of 16 m (r 2−28 m). Relapses in 60%: systemic in 37%, local in 19% and both in 4%. Median overall survival (OS) of 8 m (r 5.6–10.8 m). OS according to surgical resection (excluding neuroendocrine): resection vs no resection, 10 months versus 7.3 months, p 0.230.
Conclusions: In our series of clearly defined borderline resectable patients, neoadjuvant CT-RT is feasible and it can identify a subgroup of patients (37%) who can benefit from a radical surgical procedure with clear margins. However, the protocol is technically challenging and should probably be restricted to fit patients who are candidates for radical surgery. The main site of relapse is systemic and improvements in systemic therapies are clearly necessary. Small pretreatment biopsies can be a problem.
No conflict of interest.

2508 POSTER

Prognostic indicators in gastric cancer after neo-adjuvant chemotherapy and surgery

A. Tufo[1], R. Persiani[1], A. Biondi[1], F.C.M. Cananzi[1], F. Sicoli[1], A.A. Marra[1], D. D'Ugo[1]. *[1]Catholic University "A. Gemelli" Hospital, Department of Surgery, Roma, Italy*

Background: The aim of this study was to identify reliable factors affecting the survival of locally advanced gastric cancer (LAGC) patients treated with neoadjuvant chemotherapy followed by surgery.
Material and Methods: We reviewed the data of 60 patients underwent gastrectomy after neoadjuvant chemotherapy for LAGC in a clinical trial setting. Univariate and multivariate survival analysis were performed in order to determine the independent prognostic factors. A scoring system was developed including these factors.The time-dependent receiver operating characteristic (ROC) curve was constructed and the area under the ROC curve (AUC) were employed to assess the performance of the score.
Results: On univariate analysis, multivisceral resection ($p < 0.001$), residual disease after surgery ($p < 0.001$), tumour diameter ($p < 0.001$), Lauren's histotype ($p < 0.001$), pT ($p = 0.023$), pN ($p < 0.001$) and T-downstaging ($p = 0.004$) were significantly associated with overall survival. Residual tumour, Lauren's histotype and pN were found to be independent prognostic factors at the Cox's regression. After rounding the regression coefficients, a score ranging from 0 to 4 was obtained. According to the survival estimates and the log-rank test differences, three groups were identified: group I (0 points), group II (1−1.5 points), group III (2.5−4 points). Time-dependent ROC curve analysis provided an AUC of 0.89, 0.90, 0.88 and 0.86 at 1-yr, 2-yrs, 3-yrs and 5-yrs of follow-up, respectively.
Conclusions: Residual disease after surgery, Lauren's histotype and nodal involvement are the most reliable prognostic indicators in patients treated with neoadjuvant chemotherapy. A score combining these variables could correctly predict survival in these patients.
No conflict of interest.

2509 POSTER

Nomogram prediction of overall survival in patients with extrahepatic bile duct cancer undergoing curative resection followed by adjuvant chemoradiotherapy

K. Kim[1], C. Song[1], E.K. Chie[1], J.H. Kim[1], J.Y. Jang[2], S.W. Kim[2], K.H. Lee[3], D.Y. Oh[3], Y.J. Bang[3], S.W. Ha[1]. *[1]Seoul National University Hospital, Radiation Oncology, Seoul, Korea; [2]Seoul National University Hospital, Surgery, Seoul, Korea; [3]Seoul National University Hospital, Internal Medicine, Seoul, Korea*

Background: To develop a nomogram for predicting the overall survival in patients with extrahepatic bile duct cancer undergoing adjuvant chemoradiotherapy.
Material and Methods: From January 1995 through August 2006, 166 consecutive patients underwent curative resection followed by adjuvant chemoradiotherapy. Multivariate analysis using Cox proportional hazards regression was performed and this Cox model was used as the basis for the nomogram. We calculated concordance indices of the constructed nomogram and American Joint Committee on Cancer (AJCC) staging system.
Results: The overall survival rate at 2 years and 5 years was 60.8% and 42.5%, respectively. The tumor location, involved lymph node, and histologic differentiation were retained in the multivariate Cox proportional hazards model as independent prognostic factors for overall survival. The bootstrap-corrected concordance index of the nomogram and the AJCC staging was 0.63 and 0.50, respectively.
Conclusions: We developed a nomogram that predicted survival better than AJCC staging. It could be useful when counseling patients and choosing treatment strategies.
No conflict of interest.

2510 POSTER

Concurrent chemoradiation of patients with inoperable non-metastatic pancreatic cancer

I. Awad[1], M. Elawadi[1], M. Elzahi[1], H. Wahba[1]. *[1]Mansoura University Hospital, Department of Clinical Oncology, Mansoura, Egypt*

Background: Inoperable non-metastatic pancreatic cancer is a great challenge because the median survival is generally less than 1 year and the impact of standard therapies is so limited. All patients should be considered for protocol-based therapy. The aim of this study is to determine the tolerability and efficacy of Gemcitabine concurrent with 3D conformal

radiotherapy for locally advanced, unresectable, non-metastatic pancreatic cancer.
Methods: Thirty three patients received the following protocol in 3 phases; induction phase: weekly Gemcitabine at a dose of 1,000 mg/m^2 over 30 minutes infusion for 7 weeks, chemoradiotherapy phase: gemcitabine 600 mg/m^2 weekly for 5 weeks concurrent with 3 dimensional (3D) conformal radiotherapy for a total dose of 50.4 Gy in 28 fractions in 5.5 weeks, 5 days per week, and maintenance phase: Gemcitabine at a dose of 1,000 mg/m^2 weekly for 3 weeks with 1 week rest between 2 cycles.
Results: Forty eight patients with locally advanced unresectable pancreatic cancer were enrolled; only 33 patients completed the treatment protocol. After a median follow up period of 20 months 15 patients were alive. The median progression free survival (PFS) was 15 months; the median overall survival was 19 months. The estimated 12 months, 18 months and 24 months survival was 79%, 52%, and 18% respectively. Grade III toxicity were reported in 38% of patients with no grade IV toxicity, vomiting were the most common toxicity (35.5%) followed by fatigue (21.5%).
Conclusions: Gemcitabine concurrent with 3D conformal radiotherapy is active, well tolerated and associated with encouraging survival in patients with locally advanced pancreatic cancer.
No conflict of interest.

2511 POSTER

Reality of adjuvant treatment with chemoradiation in gastric cancer in non-selected patients. Is it possible to achieve the results of controlled trials?

A. Segura[1], M.H. Bennis[1], J. Caballero[1], L. Palomar[1], R. Diaz-Beveridge[1], G. Bruixola[1], E. Reche[1], A. Gimenez[1], J. Aparicio[1]. [1]*University Hospital la Fe, Medical Oncology, Valencia, Spain*

Background: Adjuvant treatment in cancer gastric is controversial. Postoperative chemoradiotherapy has been a standard since publication of the INT0116 trial (MacDonald, N Eng J Med, 2001). Toxicity and the difficulty to standardize surgery protocols are main weak points. Over the last years, perioperative treatment (MAGIC trial) has emerged as a valid strategy and minor toxicity. We present our results of patients treated with Macdonald schedule.
Material and Methods: Between 2001 and 2012 a total of 88 patient with advanced gastric cancer (T3−4 and/or N+), where treated. Treatment according Macdonald article. Survival was analysed by Kaplan–Meier method. The TNM version is the 6th edition, 1997.
Results: Median age: 59 (35−79). Performance status: ECOG 1 or 0 in all patients. TNM stage: IB (3, 3%), II (27, 31%), IIIA (20, 23%), IIIB (17, 19%), IV (21, 24%). Total gastrectomy: 53 patients (60%) and subtotal gastrectomy in 35 patients (40%). 77% of patients had D2 lymph node resection. Median number of lymph nodes resected: 20 (4−73) and median positive lymph nodes: 4 (0−55). Adjuvant treatment indication: T3−4 (22%), N1 (33%), N2 (24%), N3 (21%). Grade 3−4 toxicity achieved in 40% of patients: mucositis (20%), diarrhoea (20%), nausea (8%), asthenia (7%), febrile neutropenia (6%), thrombocytopenia (2%) and 20 patients (23%) were admitted to hospital. Treatment delayed in 26 patients (30%), dose of chemotherapy was reduced by 25% in 13 patients (15%) and 19 patients (22%) did not complete treatment, 13 (15%) of them due to toxicity, 1 due to progression in course of treatment. Two patients died due to toxicity. With a median follow-up period of 94 months (3–141), 32 (36%) patients are still alive, 31 (35%) of them with disease-free recurrence, 56 (64%) died, 47 (54%) of them due to disease relapse and 7 (8%) due to other causes. Median overall survival (OS) was 23 months with a median disease free survival of 12 months.
Conclusions: Our results are worse than in the INT0116 trial. Possible explanations must be: non-selected population, probably different to those in clinical trials. There are also a high percentage of patients with large number of lymph nodes affected (45% >7 nodes, 21% >15). D2 resection has been achieved in the majority of patients, the indication of postoperative treatment after D2 resection is not clear today. It is difficult to complete the whole treatment: 30% of delays, 25% dose reductions (these data are not reported in the INT0116 trial). We can conclude that due to the poor results, our clinical strategy has been changed to perioperative chemotherapy, similar to the MAGIC trial.
No conflict of interest.

2512 POSTER

Palliative treatment of malignant obstructive jaundice

A. Simsek[1], T. Ozer[2], N. Zeybek[1], N. Ersoz[1], Y. Peker[1], S. Cetiner[1]. [1]*Gulhane Military Medical Academy, General Surgery, Etlik Ankara, Turkey;* [2]*Gulhane Military Medical Academy, Gastrointestinal Surgery, Etlik Ankara, Turkey*

Palliation of malignant biliary tract obstruction is still associated with significant complications.Many techniques for the palliative management of patients with malignant obstructive jaundice have been developed,including endo-prosthesis,operative transtumor stenting and biliary-enteric by-pass,but the general prognosis remains poor.We review our experience with emphasis on therapeutic options.
From 1993 to 2012, 250 patients with malignant obstructive jaundice unsuitable for curative patients were treated in our unit.There were 150 men(60%)and 100 women(40%). With median age 64 years(43−87),60 patients (24%)had associated diseases.Diagnosis was based on ultrasound and computed tomography, supplemented when necessary by direct cholangiography and cytology. Clinical aspects, method of management,complications and mortality were assessed.
The principal sites of the lesion were the periampullary region in 80 patients(32%)and the upper -third-hilus in 40 patients(16%)the middle-third in 50((20%)the lower -third in 60(24%)and diffuse in 20(8%)patients.Surgical treatment was employed in 200(80%)cases,radiological in 50(20%)cases. Surgical therapy included hepaticojejunostomy, choledochojejunostomy and gastroenterostomy.Radiological treatment included percutaneously endo-prosthesis,transtumor stending by CT or US guided.The median hospital stay was 19 days,25 patients (10%)had complications and 10(4%)died.The morbidity was associated mainly with pulmonary complications.The main causes of death were renal dysfunction,sepsis and multiple organ failure,peritonitis.The median survival of the patients available was 11 months with (6%) of the patients alive at 2 years.
These results show that while short-term palliation is reasonable morbidity and mortality are high.The only significant factor influencing mortality was the pretreatment bilirubin level.Surgery for biliary tract obstruction is still associated with significant morbidity and mortality.
No conflict of interest.

2513 POSTER

Lean initiative to develop managed clinical network to improve outcomes for upper GI cancer patients in Saint Helens & Knowsley

K. Siddique[1], J. Holmes[2], A. Kaul[2]. [1]*Kent & Canterbury Hospital, Canterbury Kent, United Kingdom;* [2]*Whiston Hospital, Upper GI, Liverpool, United Kingdom*

Background: The incidence of oesophagogastric cancer has risen in the north west of England. Since advanced cancer is associated with poor prognosis, early diagnosis can improve the patient care. The objective of our study was to assess the burden of disease in Saint Helen's & Knowsley trust and to help develop pathways for early diagnosis and improve outcomes.
Method: A retrospective cross-sectional study was conducted at Whiston Hospital and included all upper GI cancer patients diagnosed between Jan. 2010- Dec 2011. Data regarding demographics, type of cancer, staging, treatment, recurrence rate and follow-up was recorded in a specified proforma and analysed with SPSS.
Results: Total number of cancer patients was 187 (93/year, higher than national figures). Male were 61 % while rest were female (mean age: 71). Out of 187; 34% had oesophageal, 28% gastroesophageal junction and rest had carcinoma stomach (38%). Adenocarcinoma was the commonest histological type. The mean time from referral to diagnosis was 22 days. About 88 % had TNM staging; of which 67% were in advanced stage (III and IV). One third of the patients underwent surgery with a 30-day mortality of 5%, anastomotic leak rate of 11% and 5 year survival of 32%.
Conclusion: The incidence of Upper GI cancer in Knowsley is higher than national figures with more patients presenting with advanced disease. A collaborative strategy in the form of managed clinical network has been proposed involving primary care doctors by rationalisation of existing resources to ensure that all patients benefit from early diagnosis, the appropriate selection and delivery of treatment.
No conflict of interest.

2514 POSTER

Radiofrequency ablation (RFA) is the predominant locoregional treatment modality for elderly hepatocellular carcinoma patients; patterns of care study from Egypt

O. Abdel-Rahman[1], M. Ismail[2], R. Abdel Malek[2], H. Abdel Azim[2]. [1]*Ain Shams University, Clinical Oncology, Cairo, Egypt;* [2]*Cairo University, Clinical Oncology, Cairo, Egypt*

Background: Hepatocellular carcinoma(HCC) in the older individual is an increasingly common problem facing the oncologist. Elderly patients often present with medical and physiological characteristics that make the selection of their optimal treatment more challenging. Moreover, these patients are rarely included in clinical trials. thus we have carried retrospective analysis of our HCC database to determine the patterns of care offered to this peculiar group of patients.
Methods: HCC patients treated at Cairo Oncology Centre (Cairo, Egypt) in the period between January 2012 and December2012 were reviewed.

Eligible patients were those who had complete information on date of diagnosis and radiological or histopathological confirmation of the diagnosis. We compared the difference in clinicopathological parameters between cases that are older than 65 years and cases that are younger. we revised the patterns of care and treatment modalities offered to the elderly group.
Results: 90 patients were included in the analysis fulfilling the inclusion criteria. 27 patients were confirmed to be older than 65 years whilst the rest of the cases were younger than 65 years. Elderly patients were more likely to present with ECOG PS >1 ($p = 0.001$), however, there was no difference between younger and older patients with regard to macrovascular invasion, extrahepatic disease, child class or CLIP score; BCLC stage distribution among our elderly patients were as follows: BCLC A 11%, BCLC B 22%, BCLC C 55%, BCLC D 12%; treatment modalities offered to our elderly patients were as follows: (surgery 4%, TACE 4%, R.F.A 74%, systemic treatment (Sorafenib) 11%, best supportive care 7%; choice of treatment modalities was guided primarily by the BCLC stage.
Conclusion: According to our data, performance status and organ function are more important considerations than age and chronological age alone should not impact our approach to HCC treatment. however, there is tendency among oncologists to recommend using less invasive local treatments (RFA) rather than surgical resection for elderly patients with HCC.
No conflict of interest.

2515 POSTER

Analysis of clinicopathologic prognostic patterns in patients with gastric and esophagogastric junction tumors: Experience of a single academic institution

N. Hindi[1], S. Valderrabano[2], M. Coronado[3], E. Marin[4], C. Froilan[4], E. Burgos[5], M.A. Granados[2], J. Feliu[1], J.A. Gonzalez[2], J. Barriuso[1].
[1]University Hospital La Paz, Medical Oncology, Madrid, Spain; [2]University Hospital La Paz, General Surgery, Madrid, Spain; [3]University Hospital La Paz, Nuclear Medicine, Madrid, Spain; [4]University Hospital La Paz, Digestive Diseases, Madrid, Spain; [5]University Hospital La Paz, Pathology, Madrid, Spain

Background: Gastric (G) and esophagogastric junction (EGJ) tumors remain to be challenging aggresive diseases. Multidisciplinary approach has become the standard of care in this pathology, improving the management and prognosis of these patients.
Material and Methods: We retrospectively studied the data from 116 consecutive patients diagnosed of G or EGJ tumors and treated by surgery in our institution between March 2010 and March 2013. Data regarding clinical and pathological characteristics, staging, surgical and systemic therapy and survival were collected. Univariate analysis was performed using log-rank test, univariate Cox regression and Kaplan–Meier method for overall survival (OS) and relapse free survival (RFS). Cox regression was used for multivariate analysis.
Results: A majority of patients were men (68%). Eastern Cooperative Oncology Group (ECOG) performance status (PS) was 0 in 32.8% of pts, 1 in 56%, 2 in 9.5% of pts and 3 in 1.7%. 53 pts had intestinal-type gastric adenocarcinoma and 32 had diffuse-type gastric adenocarcinoma. Curative surgery was performed in 94.8% of pts. Complete resection (R0) counting for 84.5% of pts, 7.8% had a R1 resection and 7.8% had a palliative surgery (R2). About one third (31%) of pts had a D1 lymphadenectomy, 54.3% D2 lymph node dissection and 14.7% of pts had no lymphadenectomy. Pathologic stage status was: 26.7% had stage II disease, and 38% had stage III disease (21.6% stage IIIC). Adjuvant treatment was recieved for 43% of pts (28.4% chemoradiotherapy with 5FU-Leucovorin). With a median follow-up time of 13.3 months, 48.3% of patients have suffered disease progression and 38.8% have died. Median estimated OS in our series was 27.2 months (95% CI: 21.5–32.8). Diffuse-type adenocarcinoma had a worse RFS (p:0.012) and a worse OS (p:0.001) against intestinal-type adenocarcinoma. Pts with a better ECOG PS had a best OS, (HR: 1.66, 95% CI: 1.10–2.51) (p: 0.054) in the univariate Cox regression analysis. R0 resection was related with better RFS and OS ($p < 0.001$) with a median of 28.4 months (95% CI: 21.8–34.9). In multivariate analysis, a better OS was observed in patients with better ECOG (HR:1.62 95% CI:1.06–2.47, p:0.026) and R0 resection (HR:1.95 95% CI: 1.27–2.96, p:0.02).
Conclusions: In our experience, diffuse-type histology, worse PS at diagnosis and a non-accurate initial resection are independent factors for a poor prognosis in resected gastric adenocarcinoma. These data confirmed the heterogeneity of this pt population and the need of joining efforts between experienced institutions to improve pt care.

2516 POSTER

Clinical, pathological characteristics and the effect on survival in elderly patients with gastrointestinal stromal tumours

N.M. Mandel[1], F. Selcukbiricik[2], G. Demir[3], G. Dogusoy[4], S. Erdamar[5], D. Tural[6], S. Yalcin[7]. *[1]Koc University, Medical Oncology, Istanbul, Turkey; [2]Sisli Etfal Research and Education Hospital, Medical Oncology, Istanbul, Turkey; [3]Bilim University, Medical Oncology, Istanbul, Turkey; [4]Bilim University, Department of Pathology, Istanbul, Turkey; [5]Istanbul University, Department of Pathology, Istanbul, Turkey; [6]Cerrahpasa Medical Faculty, Department of Medical Oncology, Istanbul, Turkey; [7]Hacettepe Medical Faculty, Department of Medical Oncology, Istanbul, Turkey*

Background: Gastrointestinal stromal tumours (GIST) are common tumours of the gastrointestinal system (GIS). Their most frequent location is the stomach. Although the clinical and pathological characteristics of the disease are well-known, the clinical and pathological characteristics and the response to treatment are not clear in the elderly patients.
Materials and Method: In this study, clinicopathological characteristics, treatment evaluations and survival analyses were performed in patients at and above the age of 65 years whose data were registered via a web-based patient records system following admission to three centers.
Results: A total of 85 patients above the age of 65 years were included in the study. According to the risk classification, n = 24 (27.1%) were in low risk group, n = 20 (21.4%) were in moderate risk group, and n = 41 (51.4%) were in high risk group among the patients at and above the age of 65 years. The mean age at diagnosis in all cases was 59 years and the median was 60 years, respectively. At baseline, 69.9% of the patients had localised disease while 30.1% had metastatic disease. The tumour was located in the stomach in the majority (45.6%) of patients. Upon evaluation of tumour diameters, the most commonly seen tumour size was 5−10 cm, n = 85, 34.1%. A hundred seventy-four patients underwent surgery. Of the 67 patients, (26.5%) were treated with imatinib at 400 mg/d. Eight patients (2.4%) with metastatic disease switched from imatinib to sunitinib.
Discussion: These data are important with regards to revealing the clinicopathological characteristics and survival data of elderly patients with GIST. The prognostic factors in elderly patients are not different than that of young patients. However, the existence of comorbid conditions may worse the clinical course in elderly patients. The follow-up and treatment of patients in specialized centers lead to high survival rates.
No conflict of interest.

2517 POSTER

Double-Blind, placebo-controlled, randomized phase II study of TJ-14 (Hangeshashinto) for gastric cancer chemotherapy-induced oral mucositis

K. Nishikawa[1], T. Aoyama[2], N. Takiguchi[3], K. Tanabe[4], M. Imano[5], R. Fukushima[6], A. Tsuburaya[2], J. Sakamoto[7], S. Morita[8], T. Kono[9].
[1]Osaka General Medical Center, Surgery, Osaka, Japan; [2]Kanagawa Cancer Center, Gastrointestinal Surgery, Yokohama, Japan; [3]Chiba Cancer Center, Gastrointestinal Surgery, Chiba, Japan; [4]Hiroshima University, Surgery, Hiroshima, Japan; [5]Kinki University, Surgery, Sayama, Japan; [6]Teikyo University, Surgery, Tokyo, Japan; [7]Tokai Central Hospital, Kakamigahara, Japan; [8]Yokohama City University, Biostatistics and Epidemiology, Yokohama, Japan; [9]Sapporo Higashi Tokushukai Hospital, Advanced Surgery Center, Sapporo, Japan

Background: Oral mucositis is a common complication of cancer chemotherapy and/or radiotherapy, sometimes leading to dose reduction and/or interruption of the treatment. Despite many attempts to reduce those cancer chemotherapy-related mucositis, no standard efficacious prophylactic therapy has been established.
In this regard, an attempt to examine the safety and efficacy of TJ-14 (Hangeshashinto; one of the traditional Japanese medicines (Kampo) for prevention and treatment of chemotherapy-induced oral mucositis was investigated by a placebo-controlled randomized phase II trial.
Methods: We randomly assigned 94 patients with gastric cancer who had developed moderate to severe oral mucositis (NCI-CTC grade $\geqslant 1$) during any course of chemotherapy with S-1, S-1/CDDP, S-1/DTX and so on (regimen) to receive either TJ-14 or placebo. Patients received TJ-14 or placebo for 2−6 weeks according to chemotherapy regimen during the next course of chemotherapy, followed by TJ-14. Patients were assessed three times per week for safety and for oral mucositis incidence and its severity using the NCI-CTC grading.
Results: We analyzed 91 eligible patients (TJ-14; 45, placebo; 46) by a per protocol set analysis after the key-opening. The incidence of $\geqslant$grade 2 oral mucositis was 40.0% in the TJ-14 and 41.3% in the placebo group. In patients with oral mucositis at the start of the next course of chemotherapy (TJ-14; 33, placebo; 30), the median duration of mucositis was 12.0 days

vs. 16.5 days (HR; 1.15 95% CI; 0.61–2.16 p = 0.655). No difference in other treatment toxicity of was observed between the two groups, and patients exhibited high compliance regarding dosing administration.
Conclusion: TJ-14 demonstrated a favorable profile in the treatment of oral mucositis induced by chemotherapy in patients with gastric cancer. TJ-14 might be effective in reducing the duration of oral mucositis compared to the placebo control.
No conflict of interest.

2518 POSTER

Everolimus in combination with octreotide LAR as the first-line treatment for advanced neuroendocrine tumors: efficacy data in pNET and non-pNET patients: I.T.M.O. (Italian Trials in Medical Oncology) group

E. Bajetta[1], L. Catena[1], N. Fazio[2], S. Pusceddu[3], P. Biondani[3], D. Giuffrida[4], S. Ricci[5], M. Aieta[6], F. Pucci[7], N. Bianco[1]. *[1]Policlinico di Monza, Medical Oncology, Monza, Italy; [2]Istituto Oncologico Europeo, Medical Oncology, Milano, Italy; [3]Fondazione IRCCS Istituto dei Tumori, Medical Oncology, Milano, Italy; [4]4Istituto Oncologico del Mediterraneo, Medical Oncology, Catania, Italy; [5]Azienda Ospedaliera S. Chiara, Medical Oncology, Pisa, Italy; [6]Ospedale Oncologico Regionale, Medical Oncology, Rionero in Vulture, Italy; [7]Azienda Ospedaliero − Universitaria, Medical Oncology, Parma, Italy*

Background: Everolimus has shown antitumor activity in patients (pts) with advanced neuroendocrine tumors (NETs). We aimed to assess efficacy and safety of everolimus in combination with octreotide long-acting repeatable (LAR) in patients with well differentiated NETs of gastroenteropancreatic and of lung origin.
Methods: We performed a phase II, multicenter trial using a Simon two-stage minmax design. Pts with advanced well differentiated, previously untreated NETs of the gastroenteropancreatic tract and of the lung received octreotide LAR 30 mg every 28 days in conjunction with everolimus 10 mg per day continuously. The primary endpoint was objective response rate (ORR).
Results: A total of 50 pts (58% males) were enrolled. The median age was 60.5 years (range 25−76). Primary tumor site was pancreas in 14 (28%), unknown in 14 (28%), lung in 11 (22%), ileum in 9 (18%) and jejunum and duodenum in 2 (4%) of pts. 13 (26%) pts had carcinoid syndrome. The ORR, calculated on the ITT population, was 20.0% (95% CI 8.9–31.1): 14. 3 % (2/14) in pNET pts and 22.2% (8/36) in non pNET pts. Thirty-six patients (72%) achieved stable disease (SD). All CR and all PR as well as 91.7% of SD had a duration $\geqslant$6 months. Clinical benefit (CR+PR+SD) was 92%. At a median follow-up of 277 days, the median time to progression (TTP) was 16.3 months (95% CI 10.7–20.1): 17.2 months in pNET pts. Overall survival could not be assessed. Treatment-related adverse events (AEs) were mostly of grade 1 or 2; the only grade 4 AE was mucositis in 1 patient, while grade 3 AEs included skin rash in 1 case, stomatitis in 4 cases (8%) and diarrhea in 11 cases (22%).
Conclusion: Everolimus in combination with octreotide LAR has shown to be active and well tolerated in advanced NETs, both in pancreatic and non -pancreatic primary sites.
Aknowledgements: The Authors thank the Italian Trials in Medical Oncology (I.T.M.O.) group and Novartis Pharma for the support provided.

2519 POSTER

Characteristics and treatment patterns of patients potentially eligible for further therapy after discontinuation of first-line sorafenib for advanced hepatocellular carcinoma (HCC): An EU perspective

A.M. Liepa[1], D. Mitra[2], Y. D'yachkova[3], K. Taipale[4], J.A. Kaye[5]. *[1]Eli Lilly and Company, Global Health Outcomes, Indianapolis, USA; [2]RTI Health Solutions, Health Ecoomics, Jersey City, USA; [3]Eli Lilly GmbH, Global Statistical Sciences, Vienna, Austria; [4]Eli Lilly and Company, Global Health Outcomes, Helsinki, Finland; [5]RTI Health Solutions, Epidemiology, Waltham, USA*

Background: Currently, sorafenib is the only agent indicated for the treatment of advanced HCC. There are no recommended therapies after sorafenib discontinuation, and little information is available to characterize this unmet need. Here we describe treatment patterns for a sample of such patients from France, Germany, Italy, and Spain.
Material and Methods: Physicians who treat patients with advanced HCC were asked to complete an internet-based survey detailing clinical and resource utilization data for 5 de-identified patients (3 patients in Germany) each. The aim was 50 patients per country. Medical records were eligible if the patients were $\geqslant$18 years old, had been diagnosed with advanced HCC, had initiated first-line sorafenib after 2008, had subsequently discontinued sorafenib, had survived $\geqslant$2 months after sorafenib discontinuation, and had $\geqslant$6 months of follow-up data (or had died). Data were summarized descriptively. Time-to-event measures were estimated using the Kaplan–Meier method.
Results: From August to October 2012, 200 physicians (50 per country) provided data for 900 patients. Patients' mean age was 61 years and 72% were male. The most common co-morbidities were cirrhosis 54%, hypertension 29%, and diabetes 23%. For those with cirrhosis, the most common etiologic factors were alcohol 47%, hepatitis C 29%, and hepatitis B 17%. Barcelona Clinic Liver Cancer stage was 31% B, 63% C, and 6% D. At sorafenib initiation, Child-Pugh status was 40% A, 40% B, and 19% C. At sorafenib discontinuation, Child-Pugh status was 17% A, 43% B, and 39% C; 59% had no change from sorafenib initiation. 82% of patients discontinued sorafenib due to HCC progression. 63% were documented as deceased, with 91% of deaths attributed to HCC. Median follow-up from sorafenib discontinuation was 3.8 months for those documented as deceased and 7.7 months for those known to be alive or with unknown status. 15% of patients received systemic anti-cancer therapy after sorafenib discontinuation and an additional 6% re-initiated sorafenib after $\geqslant$2 months of interruption. Procedures following sorafenib discontinuation included transarterial chemoembolization 6% and radiofrequency ablation 3%. 32% of patients were hospitalized and 23% had at least one emergency room visit. Physicians reported providing supportive care to 688 patients. Of these, 63% received routine pain management (most commonly oral opiates), 36% nutritional support (enteral or parenteral), and 17% transfusions. For all patients, median survival from sorafenib discontinuation was 6.5 months ($\geqslant$2 months required by design).
Conclusions: For this select group of advanced HCC patients, few received anti-cancer therapy after discontinuation of sorafenib. However, these patients continued to receive supportive care and many required hospitalization. Interventions that improve survival and reduce supportive care needs would be beneficial.

2520 POSTER

Conditional survival in patients with advanced pancreatic cancer − improvement as time passes by?

B. Kasenda[1], A.B. Bass[2], D.K. Koeberle[3], B.C.P. Pestalozzi[4], M.B. Borner[5], L.J. Jost[6], A.L. Lohri[6], V.H. Hess[7]. *[1]Medical Oncology, Basel, Switzerland; [2]University Hospital Basel, Medical Oncology, Basel, Switzerland; [3]Cantonal Hospital of St. Gallen, Department of Oncology, St. Gallen, Switzerland; [4]University Hospital of Zurich, Department of Oncology, Zurich, Switzerland; [5]University Hospital of Bern, Department of Oncology, Bern, Switzerland; [6]Cantonal Hospital Basel-Land, Department of Oncology, Basel-Land, Switzerland; [7]University Hospital Basel, Department of Oncology, Basel, Switzerland*

Background: Survival projections are usually estimated from the date of diagnosis to the date of death. However, these estimates can lose validity once a patient survives longer than predicted. Conditional survival (CS) probabilities provide guidance for such situations. We investigated conditional survival probabilities for patients with advanced pancreatic cancer.
Patients and Methods: Clinical data of all patients diagnosed with unresectable stage III or IV pancreatic cancer between 2000 and 2008 at 4 Swiss medical centres were retrospectively collected. We calculated overall survival (OS) as time from diagnosis until death. We used the landmark approach to calculate conditional survival estimates defined as the probability to survive another additional time given that the patient has already survived a certain time after diagnosis. For this analysis, we built four patient subsets according to landmark times at 6, 12, 18, and 24 months after diagnosis and calculated the probability to survive another 6 months. Patients who died before the respective landmark times were excluded from each following set.
Results: We included 483 patients (median age 66, 43% female; stage III and IV 19% and 81% respectively). 79% were treated with gemcitabine or gemcitabine plus capecitabine, 11% received other regimens. 448 patients have died; median follow-up for all patients was 8.8 months (inter-quartile range 5−15). Respective 6, 12, and 24-month OS probabilities were 67% (95% confidence interval [CI], 63% − 71%), 37% (95% CI, 33% − 42%), and 11% (95% CI, 8% − 15%). Overall conditional survival estimates are summarized in the TABLE. Patients surviving at least 24 months after diagnosis show a slightly improved 6-months OS probability of 71%.

Conclusions: The 6-months OS probabilities remain stable over time and increase only for those patients who survive at least 24 months after diagnosis. Our CS estimates provide additional information for counselling patients with advanced pancreatic cancer regarding therapy decisions and end of life planning.
No conflict of interest.

Table: 6-months OS probability conditioned on the time survived after diagnosis.

Time survived after diagnosis	6 months	12 months	18 months	24 months
Probability to survive another 6 months, % (95% CI)	56 (50, 61)	58 (51, 66)	52 (43, 63)	71 (58, 85)
Patients at risk in each set	317	170	97	48
Stage at diagnosis N (%)				
III	57 (18)	29 (17)	18 (19)	8 (17)
IV	259 (82)	138 (83)	77 (81)	40 (83)

Incidence of deep venous thrombosis detected by routine surveillance ultrasonography in patients with gastric cancer before operation

Y. Tanizawa[1], E. Bando[1], M. Tokunaga[1], T. Kawamura[1], N. Sugisawa[1], Y. Miki[1], R. Makuuchi[1], M. Terashima[1]. [1]*Shizuoka Cancer Center, Gastric Surgery, Sunto-gun, Japan*

Background: Pulmonary thromboembolism (PTE) is one of the serious postoperative complications of major surgery, and about 80% of PTE results from deep venous thrombosis (DVT) of lower extremity. However, the incidence of DVT in the patients with gastric cancer before operation is unknown. The aim of this study was to clarify the incidence and risk factors of DVT of lower extremity in the patients with gastric cancer before operation.
Patients and Methods: Between May 2010 and August 2011, 293 patients with gastric cancer who had routinely undergone doppler ultrasonography (DUSG) for the diagnosis of lower-extremity deep venous thrombosis before operation at Shizuoka Cancer Center, Japan were analyzed. The clinicopathological data of the patients were collected retrospectively.
Results: Of 293 patients, 25 patients (8.5%) were preoperatively found to have DVT, and all patients with DVT were asymptomatic. The anticoagulant drugs were administered or inferior vena cava filter were placed to prevent PE for the patients with DVT. As a result, no patients developed PE. Among these 25 patients, 9 patients were male and 16 patients were female. The rate of the patients who detected DVT were 30.0% of the patients of 80 years old or more, and 24.4% of the patients with East Cooperative Oncology Group (ECOG) Performance Status (PS) $\geqslant$1. Likewise, 18.2% of the patients with stage IV gastric cancer and 41.7% of the patients with central venous catheter (CVC) were found to have DVT. Atrial fibrillation, ischemic heart disease, congestive heart failure, and leg paralysis were not associated with DVT. In order to select the predictor of DVT before operation, some indicators were enumerated (age, gender, performance status, body mass index, tumor stage, and the presence or absence of previous chemotherapy, previous hormonal therapy, hypertension, hyperlipidemia, varicose vein of lower extremity, CVC). Multivariate logistic regression analysis demonstrated that female, age $\geqslant$80, PS 1 or 2, and the presence of CVC were significantly correlated with DVT before operation.
Conclusions: DUSG was a quite easily performed and non-invasive imaging examination and provide valuable information for thromboprophylaxis. Detection of the patients with asymptomatic DVT before surgery and appropriate prophylaxis for them in the perioperative period might reduce PE. Therefore, we consider that DUSG is useful for the preoperative screening of DVT in patients with gastric cancer.
No conflict of interest.

Clinical significance of HER2 overexpression in gastric and gastro-esophageal junction cancers: Is there any discordance between IHC and FISH

M. Baykara[1], M. Benekli[2], O. Ekinci[3], C. Irkkan[4], U. Demirci[5], H. Karaca[6], O.U. Unal[7], F. Dane[8], B. Akinci[9], F.P. Turkoz[5]. [1]*Sakarya University Training and Research Hospital, Medical Oncology, Sakarya, Turkey;* [2]*Gazi University Medical Faculty, Medical Oncology, Ankara, Turkey;* [3]*Gazi University Medical Faculty, Pathology, Ankara, Turkey;* [4]*Ankara Ataturk Training and Research Hospital, Pathology, Ankara, Turkey;* [5]*Dr.Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Medical Oncology, Ankara, Turkey;* [6]*Erciyes University Medical Faculty, Medical Oncology, Kayseri, Turkey;* [7]*Dokuzeylul University Medical Faculty, Medical Oncology, Izmir, Turkey;* [8]*Marmara University Medical Faculty, Medical Oncology, Istanbul, Turkey;* [9]*Ankara Ataturk Training and Research Hospital, Medical Oncology, Ankara, Turkey*

Objectives: In this study, we investigated the rate of HER2 overexpression in gastric and gastroesophageal junction cancers (GC, GEJC), and the relationship with HER2 expression and clinical, pathological parameters and prognosis.
Materials and Methods: Surgery or biopsy specimen of 598 (436 male, 162 female) patients with GC or GEJC, the presence of HER2 overexpression by immunohistochemistry (IHC) and fluorosein insitu hybridization (FISH) were evaluated. The relationship between HER2 positivity and tumor size (TS), histopathology (H), grade (G), serosal invasion (SI), lenfovascular invasion (LVI), perineural invasion (PNI), Lauren and Borrmann type, tumor location (TL), TNM stage, local recurrence (LR) and metastasis (M) and survival (OS) and the presence of discordance between IHC and FISH results were investigated.
Results: HER2 IHC scores were; 418 (69.9%) IHC 0, 58 (9.7%) IHC +1, 50 (8.4%) IHC +2, 72 (12%) IHC +3. Fifty of 18 (38.2%) patients with IHC +2, FISH positive, and 29 (61.7%) patients FISH negative, 3 of patients not studied FISH because of unsufficient biopsy material. The number of patients evaluated with IHC +3 or IHC +2 and FISH positive, HER2 positivity was 14.6% (Figure 3). IHC and FISH discordance summarized in Table 1. There was no relationship between HER2 positivity and the age, gender, TNM stage, TS, TL, LR, M, LVI, PNI, and Borrmann type. HER2 positivity was higher in intestinal type tumors than in diffuse type (16.9% *vs* 6.6%, $p = 0.014$). HER2 positivity was significantly higher in well-moderately differentiated tumors than poorly differentiated tumors (24.2% and vs 7.3%, $p < 0.0001$). HER2 positivity was higher in adenocarcinomas than the other histologic subtypes; 17.6% of adenocarcinomas, 2.9% of signet-ring cell carcinomas, %11.6 of mixed carcinomas (adenocarcinoma+signet-ring cell carcinomas) were HER2-positive ($p = 0.002$). HER2 pozitivity was no significant effect on median OS (23.2 vs 19.1 months, $p = 0.44$). But in the early stage median OS of HER2-positive patients was shorter than HER2-negative patients (51.4 months vs not reach, $p = 0.047$)(Figure 4). However patients with advaced stage HER2-positive and -negative there was no significant difference between the median OS rates (16.2 vs 13.7 months, $p = 0.72$) (Figure 5).
Conclusion: HER2 positivity is associated with the degree of tumor differentiation and histopathology in GC and GEJC. Patients with early-stage, HER2 positivity is related to poor prognosis.
No conflict of interest.

2523 POSTER

Mediastinal drainage in the management of anastomotic major leakage after subtotal esophagectomy with posterior mediastinal gastric tube reconstruction for thoracic esophageal cancer

K. Shuto[1], K. Koda[1], H. Matsubara[2]. [1]*Teikyo University Chiba Medical Center, Surgery, Ichihara, Japan;* [2]*Chiba University Graduate School of Medicine, Frontier Surgery, Chiba, Japan*

Background: Although gastric tube reconstruction through posterior mediastinal route is considered to have less surgical procedure and lower risk for anastomotic complication compared to through retrosternal route or antethoracic route, major anastomotic complication will easily develop into severe status in mortal danger. The purpose of this study is to evaluate the efficacy and safety of naso-esophageal extra drainage (NEED) in the management of anastomotic major leakage after subtotal esophagectomy for thoracic esophageal cancer (TEC).
Material and Methods: A total of 342 consecutive TEC patients who underwent subtotal esophagectomy with thoraco-abdominal lymphadenectomy and with gastric tube reconstruction through posterior mediastinal route were investigated. All patients received prophylactic thoracic drainage. Forty-one had a complication of anastomotic leakage. In postoperative course, gastro-esophagography was performed when anastomotic complication was suspected with following episodes: fever

(>38ºC) more than 3 days, an increase in WBC or CRP, right back pain or chilling. Leakage was diagnosed when contrast agent flow out through the gastro-esophageal tract into the mediastinum or pleural cavity, and were classified into two types: minor type with linear shaped and narrow abscess cavity and major type with round shaped and expansive cavity. Only naso-gastric tube drainage was performed in minor type, and patients of major type underwent extracorporeal drainage. Patients were divided into two groups as non-NEED group (non-ND, N = 17) and NEED group (ND, N = 24). If extracorporeal drainage is considered ineffective in major type, NEED procedure was performed by inserting continuous aspiration tube from naso-esophageal route through perforation hole into mediastinum or peritoneal cavity. Patients were treated concomitantly with enteral alimentation. We compared both groups about reoperation rate, hospital mortality and cure rate which means the possibility of both oral uptake and independent life.
Results: Reoperation rate was 18% in non-ND and 0% in ND (P = 0.064). There was a significantly difference between non-ND and ND in hospital mortality (29% vs. 0%, P = 0.010) and cure rate (53% vs. 100%, P<0.001). 47% of non-ND could not take oral feeding due to death in hospital, bedridden in residence and status of esophagostomy for years using enteral feeding. Postoperative fasting duration was 52 days in non-ND recover cases and 45 days in ND with no significant difference (P = 0.753). All of major type could survived and live an independent life.
Conclusions: NEED treatment is a noninvasive and very effective procedure in the management of complication of major leakage after subtotal esophagectomy through posterior mediastinal route reconstruction.
No conflict of interest.

Changes in body composition in primary oesophageal cancer: Does it affect immediate and long-term clinical outcomes?

C. Yip[1], R. Mitchell-Hay[2], O. Hynes[3], S. Gourtsoyianni[2], A. Davies[4], R. Mason[4], N. Maisey[5], P. Ross[5], A. Gaya[5], V. Goh[1]. *[1]King's College London, Division of Imaging Sciences, London, United Kingdom; [2]Guy's & St Thomas NHS Foundation Trust, Radiology, London, United Kingdom; [3]Guy's & St Thomas NHS Foundation Trust, Dietitics, London, United Kingdom; [4]Guy's & St Thomas NHS Foundation Trust, Upper GI Surgery, London, United Kingdom; [5]Guy's & St Thomas NHS Foundation Trust, Oncology, London, United Kingdom*

Background: Changes in body composition may influence oncological outcomes. We examined the changes in body composition in patients who received neoadjuvant chemotherapy (NAC) followed by surgery for oesophageal cancer and its association with clinical outcomes.
Material and Methods: IRB approval was obtained for this retrospective study. 37 patients (median age 66 years; 31 males; clinical stage II/III; 32 adenocarcinoma) who received NAC followed by oesophagectomy, and who had pre- and post-treatment CT available for analysis were identified from our institutional database. Body composition analysis was performed on the CT images using a previously described method: Pre- and post-treatment fat-muscle ratio (FMR), fat-free mass (FFM) and skeletal muscle mass (SMM) were obtained, and percentage change for each parameter was calculated. Overall survival (OS), disease-free survival (DFS) and length of hospital stay (LOS) were calculated. Post-operative complications such as wound dehiscence, infection, chyle leak or haematemesis were recorded. Pre- and post-treatment parameters were compared using Wilcoxon signed-rank test. Correlation between LOS and each parameter was done using Pearson's correlation. Median value was used to dichotomise each parameter. Fisher exact and chi-square tests were used to assess for significant association between each dichotomised parameter, and presence of post-operative complications and resection margin status. Survival analysis was performed using Cox proportional hazards model treating each parameter as a continuous variable. Kaplan–Meier survival analysis was done using dichotomised parameters. A p-value<0.05 was deemed significant.
Results: Median follow-up was 24.0 months (range 0.7–54.5) and median LOS was 13 days (range 7–182). Twenty-three (62%) and 14 (38%) patients had R0 and R1 resection, respectively. Thirteen (35%) patients had post-operative complications. Two (5%) and 6 (16%) patients had locoregional and distant recurrence respectively. There were weak and non-significant correlations between each parameter and LOS (r = −0.150–0.226; p = 0.273–0.835). FMR decreased (mean and median changes: −6% and −3%, p = 0.242) whereas FFM (14% and 3%, p = 0.013) and SMM (16% and 3%, p = 0.013) increased following NAC. Post-treatment FMR was associated with resection margin status (p=0.045). There was no significant association between presence of post-operative complications and each parameter. There was no significant association between each parameter, OS and DFS.
Conclusions: FFM and SMM increased following NAC in oesophageal cancer, likely due to improved nutritional care in our institution. However, changes in body composition did not seem to affect post-operative complications and survival outcomes, although this could be attributed to our relatively small sample size and short median follow-up.
No conflict of interest.

2525 POSTER

An early phase II study of salvage photodynamic therapy (PDT) using talaporfin sodium and a diode laser for local failure of esophageal cancer (EC) after chemoradiotherapy (CRT)

Y. Yamamoto[1], M. Muto[2], H. Tada[3], K. Yoshimura[3], T. Yano[4], N. Kakushima[5], R. Ishihara[6], H. Nishisaki[1]. *[1]Hyogo Cancer Center, Department of Gastroenterological Oncology, Akashi, Japan; [2]Kyoto University Hospital, Department of Internal Oncology, Kyoto, Japan; [3]Kyoto University Hospital, Translational Research Center, Kyoto, Japan; [4]National Cancer Center Hospital East, Department of Gastroenterology and Gastrointestinal Oncology, Kashiwa, Japan; [5]Shizuoka Cancer Center, Department of Endoscopy, Shizuoka, Japan; [6]Osaka Medical Center for Cancer and Cardiovascular Diseases, Department of Gastrointestinal Oncology, Oosaka, Japan*

Background: While we reported that PDT has a curative potential for local failure after CRT for EC, porfimer sodium (Photofrin)-based PDT has some problems such as long light shielding and skin phototoxicities. Talaporfin sodium (Laserphyrin), the second generation photosensitizer, has less phototoxicity. In our phase I study, we identified the optimum irradiation dose (100J/cm^2) for Laserphyrin-based PDT. We conducted an early phase II study to evaluate the efficacy and safety of Laserphyrin-based PDT as a salvage treatment after CRT or radiotherapy (RT) for EC (UMIN000003970).
Material and Methods: Patients with histologically proven local failure limited to the T2 after definitive CRT or RT (⩾50 Gy) for EC were enrolled in the study. PDT was applied with an intravenous administration of 40 mg/kg of Laserphyrin followed by a diode laser irradiation of 100J/cm^2 4−6 hr later. The primary endpoint was a complete response (CR) of the primary site, and the secondary endpoints were adverse event, adverse reaction, and device failure related to PDT, progression-free survival (PFS) and overall survival (OS).
Results: Thirteen patients were enrolled in the study. Nine cases were estimated as T1 and 4 cases were T2 by endoscopic ultrasound. Eight cases achieved CR (CR rate, 61.5%:one side 95% CI, 40.2%-). Severe phototoxicities and adverse events greater than grade 3 related to PDT were not observed in all patients. Also, adverse events, such as perforation and hemorrhage were not associated with PDT. We experienced two patients with esophageal pain (Grade2). One year overall survival was 82.5%.
Conclusions: Laserphyrin-based PDT is a safe and potentially curative treatment for local failure after CRT or RT for EC.
No conflict of interest.

2526 POSTER

Multidisciplinary care in the management of oesophagogastric cancer audit − a single institution quality assurance project

J. Whittle[1], C. Hart[1], F. Leow[1], J. Foo[2], R. Wong[1]. *[1]Box Hill Hospital Eastern Health, Medical Oncology, Melbourne, Australia; [2]Box Hill Hospital Eastern Health, Pharmacy Department, Melbourne, Australia*

Background: Peri-operative chemotherapy has demonstrated a survival benefit in early stage oesophagogastric cancer and is a recommended standard of care. Post-operative chemoradiotherapy also has a survival benefit compared to surgery alone. Pre-operative assessment (CT scan +/− PET scan and laparoscopy) remains critical to ensure futile surgical procedures are not performed. We sought to a) demonstrate that by focusing on multidisciplinary care and adhering to guidelines, our institution can deliver best practice outcomes; and b) identify reasons for deviations from recommended standard of care.
Materials and Methods: This is a retrospective cohort of patients diagnosed with oesophagogastric cancer at our institution between 1st July 2007 and 20 June 2012. Patient files were audited for basic demographics including age, sex, histology and stage. Patients with early stage disease were audited for completeness of pre-operative investigations including biopsy, CT scan, laparoscopy and PET scan. Patients presenting to our institution but primarily treated elsewhere were excluded. Descriptive statistics were used to illustrate patient characteristics. These included number (n) and percentages for categorical variables, and arithmetic means, medians and range for continuous variables. These outcomes were compared to the 'gold standard' trials.
Results: Between 2007 and 2011* 181 patients were diagnosed with oesophagogastric cancer at our institution. Of these 60 (33%) had early

stage disease. Median age at diagnosis was 70.2 years. For early stage disease compliance with recommended investigations was 100% for CT, 81% for PET scanning and 62% for laparoscopy. One year survival was 93%, 2 year survival was 76%. From 2007 there was an increased uptake of pre-operative treatment (33%, 40%, 60% and 63% from 2007–2011). Reasons for not receiving pre-operative chemotherapy were: age, early stage tumour, need for emergency surgery. Of those who completed pre-operative chemotherapy 53% commenced post-operative chemotherapy.
Conclusion: This data demonstrates that our small institution can deliver outcomes equivalent to the gold standard trials, which we attribute in part to a strong multidisciplinary care framework and diligence with best practice guidelines. An appreciation of current standards of care and an understanding of reasons for incomplete staging will allow directed strategies to improve outcomes in the future.
* Updated data including 2012 will be presented.
No conflict of interest.

2527 POSTER

Time to health-related quality of life score deterioration as a modality of longitudinal analysis using propensity score method to deal with missing data: A phase II trial in patients with metastatic non pre-treated pancreatic adenocarcinoma

A. Anota[1], I. Trouilloud[2], M. Gauthier[3], J. Taieb[2], F. Bonnetain[4]. *[1]CHU Besancon, Quality of Life in Oncology Platform & Methodology and Quality of Life in Oncology Unit (EA3181), Besançon, France; [2]Europeen Georges Pompidou Hospital, Department of Gastroenterology, Paris, France; [3]Centre Georges-François Leclerc, Biostatistics and Quality of Life Unit (EA4184), Dijon, France; [4]CHU Besancon, Methodology and Quality of Life in Oncology Unit (EA3181), Besançon, France*

Background: To investigate the time to Health-related Quality of Life (HRQoL) score deterioration (TTD) approach as a modality of longitudinal analysis in a phase II trial of pancreatic cancer using the propensity score to deal with the non-random missing data profile.
Material and Methods: A randomized multicentre phase II trial was performed to assess the sequential treatment strategy using FOLFIRI.3 and gemcitabine alternately in one arm and gemcitabine alone in the other arm, in patients with metastatic non pre-treated pancreatic adenocarcinoma.
HRQoL was evaluated using the EORTC QLQ-C30 at baseline and every two months until the end of the study or death. Several definitions of TTD were investigated. The main definition was the time from baseline to a first QoL score deterioration with a minimal clinically important difference of 5 points as compared to the baseline score with no further improvement of more than 5 points or death. In order to deal with the non-random missing data profile, analyses were repeated with inverse probability weighting (IPW) using the propensity score. Profiles compared were patients with at least one missing HRQoL score during the follow-up versus patients with all scores available. Univariate and Multivariate Cox regression analyses were performed to identify independent factors influencing TTD.
Results: Between October 2007 and May 2011, 98 patients were included with a median age of 63 years. At baseline, 64 patients (65%) completed the QLQ-C30 questionnaire. Adjusting on the IPW score, patients who received FOLFIRI.3 and gemcitabine alternately presented a longer time to Global Health Status score deterioration than those who received gemcitabine alone (Log-rank p = 0.008) with an Univariate Hazard Ratio (HR) of 0.52 [95% CI 0.31–0.85]. The same trend was observed for role functioning (HR: 0.41 [0.25–0.69]), emotional functioning (HR: 0.35 [0.21–0.59]) and fatigue (HR: 0.61 [0.38–0.97]).
Conclusions: Patients who received FOLFIRI.3 and gemcitabine alternately presented a longer TTD than those who received gemcitabine alone for most of HRQoL scores. The TTD method as the advantage to provide meaningful longitudinal HRQoL results for clinicians. Moreover, the IPW method allows to take into account the non-random missing data profile.
No conflict of interest.

2528 POSTER

Concurrent chemoradiation with mitomycin C and continuous vs non-continuous 5-fluorouracil infusion for anal squamous carcinoma

I. Miguel[1], T. Marques[1], G. Peralta[2], A. Mayer[3], J. Freire[1]. *[1]Instituto Portugues de Oncologia de Lisboa Francisco Gentil, Medical Oncology, Lisboa, Portugal; [2]Instituto Portugues de Oncologia de Lisboa Francisco Gentil, Radiotherapy, Lisboa, Portugal; [3]Instituto Portugues de Oncologia de Lisboa Francisco Gentil, ROR, Lisboa, Portugal*

Background: Concurrent chemoradiation with 5-fluorouracil (5-FU) and mitomycin-C (MMC) is the standard of care for anal squamous cell carcinoma (ASCC). The best schedule of 5-FU with radiotherapy (RT) is still subject to debate. Continuous 5-FU has been used with shortened irradiation schemes. No comparison between continuous vs non-continuous 5-FU has been done. We aim to compare pts with ASCC treated with RT and MMC with continuous vs non-continuous infusion of 5-FU in a single institution.
Material and Methods: 51 pts treated for ASCC from 2004 to 2010 were retrospectively reviewed. 9 pts were excluded (1 died before completing treatment and 8 had a different RT scheme). Two chemoradiation regimens were used: Group A (24 pts) was treated with MMC (10 mg/m^2 on d1 and d29) and 5-FU (1000 mg/m^2 d1−4 and d29−32) concomitant with external beam radiation (45 Gy 5w) followed by a 15 Gy boost; Group B (18 pts) was treated with MMC (10 mg/m^2 d1 of each RT course), 5-FU (200 mg/m^2/day continuously) with split-course RT (36 Gy and a 23.4 Gy boost with 2w interval). Primary endpoint (at 36 months) was progression-free survival (PFS). Secondary endpoints (at 36 months) were complete response rate (CRR), overall survival (OS) and toxicity.
Results: The groups were well-balanced in age, gender, histology, stage and tumor location. CRR was 62.5% in group A and 94.4% in B (P = 0.016). 3-year PFS was 79.2% in group A and 55.6% group B (P = 0.101). Median PFS was 29.2 months (95% CI: 23.7–34.6) in group A and 28.8 months (95% CI: 23.0–34.6) in B (P = 0.276). 3-year OS was 54.2% in group A and 83.3% group B (P = 0.047). Median OS was 23.4 months (95% CI: 21.1–31.6) in group A and 33.3 months (95% CI: 30.4–36.3) in B (P = 0.045). Grade III/IV toxicity was present in 57.9% in group A and 42.1% in group B. One pt in group A died of cardiac toxicity after completing chemoradiotherapy.
Conclusions: Continuous infusion of 5-FU in ASCC treatment was associated with higher complete response rates and 3-year overall survival, although lower progression-free survival rates require further analysis with longer follow-up. Results of continuous 5-FU should also be compared between split-course vs shortened conformal irradiation scheme.
No conflict of interest.

2529 POSTER

Is the Lean Six Sigma methodology applicable in a multidisciplinary outpatient clinic for gastro-intestinal cancer?

Y. Basta[1], M.C. Monster[2], T. Rohof[2], K.M.A.J. Tytgat[3], J.H.G. Klinkenbijl[1]. *[1]Academic Medical Centre Amsterdam, Surgery, Amsterdam, Netherlands; [2]Academic Medical Centre Amsterdam, Gioca, Amsterdam, Netherlands; [3]Academic Medical Centre Amsterdam, Gastroenterology, Amsterdam, Netherlands*

Introduction: Long waiting times are the main source of prolonged run through time (RTT) in healthcare systems. In the Academic Medical Centre in Amsterdam, a one-stop fast-track multidisciplinary outpatient clinic was founded to shorten waiting times and reduce run through times for patients with a gastro-intestinal malignancy. The Gastro-Intestinal Oncology Centre Amsterdam (GIOCA). At GIOCA, the week has a standard layout, where days are limited to specific tumors, i.e. hepatocellular carcinoma, upper gastro-intestinal (GI) tumors, lower GI tumors and hepatobiliary tumors, Our aim is to admit patients to the outpatient clinic, within one week of referral and to initiate treatment within three weeks after the first appointment.
Lean Six Sigma (LSS) is a combination of Lean-management and the Six Sigma methodology. LSS incorporates means to systematically identify and address suboptimal performance of a process. Lean and Six Sigma have their origins in the manufacturing industry, like the Toyota factory, with largely homogenous products.
A complex high care medical facility deals with heterogeneous patients and human emotions, rather than a production site with largely homogeneous products. Our aims are to explore the possibility to implement LSS in a high care medical facility and thereby identify obstacles that prevent an admission time of less than one week.
Methods: We have applied the DMAIC-cycle (Define Measure Analyse Improve Control) to the referral process of new patients. The DMAIC-cycle is the management cycle of Six Sigma.
Results: Our preliminary results indicate that Lean Six Sigma methodology is applicable in a complex high care medical facility. We have identified obstacles that prevent an admission time of less than one week, inter alia, the division of the tumors into different days, and failure to diagnose the patient in our Multidisciplinary meeting.
Conclusion: Lean Six Sigma is applicable in a high care medical facility, like the Academic Medical Centre and its outpatient clinic. Obstacles in the logistics of a high care medical facility can be identified with LSS. Our next investigative step will explore the applicability of LSS to remove the obstacles and solve the problems surrounding admission time.

A study of growth factor receptor expression and their clinicopathological correlation in gallbladder carcinoma

S. Gupta[1], S. Misra[1], V. Kumar[1], N. Husain[2], J. Pogal[1], S. Rathnawsamy[1]. *[1]King Georgs's Medical University, Department of Surgical Oncology, Lucknow, India; [2]Ram Manohar Lohia Institute of Medical Sciences, Department of Pathology, Lucknow, India*

Background: North India reports one of the highest incidence of gallbladder cancer (GBC) in the world. There are very few studies evaluating differential growth factor receptor expression in GBC and non-malignant gallbladder specimens and study correlation of biomarker expression with clinico-pathological attributes of tumor.
Material and Methods: Present study determines immunohistochemical expression of growth factor receptors (Her-2/neu and EGFR-1) in GBC and the control group (cholelithiasis), which was quantified in accordance with guidelines as followed in *ToGA study* evaluating Her-2/neu expression in gastric cancer. Study evaluated correlation of these biomarkers expression with clinicopathological parameters as histological type and grade, T stage, lymph node status, response to chemotherapy, disease progression and survival.
Results: Study evaluated 75 patients of GBC and 25 in control group (cholelithiasis). Increased expression of Her 2/neu [31/75 positive (41%)] and EGFR-1 [30/75 positive (40%)] observed in GBC patients was statistically significant (p=<.0001) as compared to control group [Her-2 and EGFR-1 positive in 8% each (2/25)]. Increased expression of Her-2/neu (p=.126) and EGFR-1 (p = 0.006) was observed in locally advanced/metastatic GBC patients (Stage IVA-IVB; n = 43) as compared to early stage disease (Stage I−IIIB; n = 32). No observed correlation of biomarker expression with age, cholelithiasis, histological type & grade. EGFR-1 and Her-2 coexpression was associated with poor disease outcome in both palliative (n = 43; p = 0.006) and curative resection subgroups (n = 32; p = 0.086). Statistically significant correlation of EGFR-1 expression with Disease Free Survival (DFS) at 12 months was observed in Radical cholecystectomy subgroup (p = 0.030). Her-2/neu expression was associated with poor Disease Control rate (DCR) and Overall Response rate (ORR) in palliative treatment subgroup.
Conclusions: GBC is characterized by late diagnosis, poor response to treatment and genarally a dismal prognosis. Clearly, newer and more effective therapeutic regimens are the need of the hour, based on our evolving understanding of molecular biology of GBC. Her-2 and EGFR-1 expression in GBC could be predictive of aggressive disease biology, marker of response to chemotherapy and also serve as potential therapeutic targets. Data presented here, from the region with one of the highest incidence of GBC in the world, represents the largest ever such analysis. It presents a case for exploring the use of Her-2/neu specific monoclonal antibodies or EGFR tyrosine kinase inhibitors in combination with Gemcitabine based regimens for treatment of GBC and could prove to be the holy grail in the treatment of GBC.
No conflict of interest.

TWIST1 gene expressions in gastric adenocancer

D. Kivrak Salim[1], H. Adanir[2], M. Sahin[3], S. Koksoy[4], I. Suleymanlar[2]. *[1]Akdeniz University Faculty of Medicine, Medical Oncology, Antalya, Turkey; [2]Akdeniz University Faculty of Medicine, Gastroenterology, Antalya, Turkey; [3]Akdeniz University Faculty of Medicine, Health Sciences Research Center, Antalya, Turkey; [4]Akdeniz University Faculty of Medicine, Medical Microbiology, Antalya, Turkey*

Background: Recent studies have shown that TWIST1 is one of the main regulatory proteins that promote epithelial–mesenchymal transition (EMT). EMT is pivotal for morphogenesis and in the transformation of early stage tumors into invasive malignancies. TWIST1 plays distinct roles in regulating the expression of downstream genes, acting either as activators or repressors. In the present study we aimed to elucidate the expressions of TWIST1 gene in the gastric mucosa of different histopathological variety: normal gastric mucosa (NGM), chronic active gastritis (CAG) and gastric adenocancer (GAC).
Material and Methods: In order to evaluate the utility of TWIST1 as marker associated with increased gastric cancer risk, we investigated gene expression by reverse transcription polymerase chain reaction. Premalign and malignanat gastric samples were obtained from 93 untreated patients.
Results: We evaluated gastric tissues of 93 patients [43 (46.2%) female, 50 (53.8%) male] between the ages of 18−70. According to histopathological groups NGM (32; 34.4%), CAG (33; 35.5%), GAC (28; 30.1%) TWIST1 gene expression levels using RT-PCR method were evaluated prospectively.In univariate analysis, gastric mucosal TWIST1 mRNA expressions were increased in CAG compared to NGM. TWIST1 mRNA expressions were found to have a significant increase in GAC. The relative expression level of TWIST1 mRNA was low to absent in NGM, and aproximately six times less than that of the CAG, whereas it was significantly (P <0.0001) higher in GAC (~200 times). The relative expression ratio of TWIST1 >12.5 is a risk factor for adenocancer development and an augmented TWIST1 expression causes a 10^9 fold increase in adenocancer development risk (OR=1.8X10^9, %95 CI=3.2X10^8-10^9, P=10^{-7}). In advanced stages TWIST1 expression was significantly higher (p = 0.0265).
Conclusion: TWIST1 is found to be an independent risk factor in the prediction of adenocancer development.
No conflict of interest.

2532 POSTER

Perfusion CT in assessing tumor blood flow as an imaging biomarker for gastric cancer

T. Fujishiro[1], K. Shuto[2], A. Sato[1], T. Kono[1], H. Matsubara[1]. *[1]Graduate School of Medicine Chiba University, Department of Frontier Surgery, Chiba, Japan; [2]Teikyo University Medical Center, Department of Surgery, Chiba, Japan*

Background: Intratumoral hemodynamics or tumor perfusion is useful in understanding the pathological background of the cancer. A parameter for a non-invasive, preoperative assessment of tumor perfusion has yet to be developed. The purpose of this study is to evaluate the correlation between tumor blood flow calculated with perfusion CT and clinicopathological status of gastric cancer.
Material and Methods: This study included 50 patients who underwent surgery for advanced gastric cancer. A total or distal gastrectomy with regional lymphadenectomy was performed in 40 patients. In the remaining 10 cases, the tumors were unresectable due to invasion of surrounding tissues (8 cases) and/or peritoneal dissemination (5 cases) and biopsy specimens from preoperative endoscopy were used for the pathological analysis. According to the UICC Stage, patients were classified as stage Ib in 5, stage II in 8, stage III in 12, and stage IV in 25. Out of the 25 patients, 21 were categorized as stage IV for their M1 status. All of these patients possessed peritoneal dissemination, and 2 had metastases to the liver. Perfusion computed tomography (PCT) was performed using a 16-row multidetector CT following intravenous injection of contrast materials, and tumor blood flow (BF: ml/min/100g tissue) values were measured. We compared BF with histopathological characteristics, with microvessel density and tumor stromal density and postoperative outcome.
Results: None of the specimens possessed any necrotic tissue. No significant correlation was found between BF and the tumor location, macroscopic appearance or size. There was a significant decrease in BF in advanced tumor depth (P = 0.0027), peritoneal dissemination (P = 0.0411). Cases with Lauren's diffuse type carcinoma were found to have decreased BF compared to the mixed or intestinal type (34.5 vs. 67.8, P<0.0001). As for the stromal structure, BF significantly decreased with increased stromal density (R=0.861, P<0.0001), despite the lack of correlation with microvessel density (R=0.261, P = 0.266). The 5-year survival rate of high BF group (50<) is significantly better than that of low BF group (<50), 50.8% and 26.5% (P = 0.0367), respectively.
Conclusions: The BF value of the gastric cancer acquired from perfusion CT may reflect the histopathological structure of the tumor, which include the tumor vascularity and the volume of extracellular matrix components of the tumor. In addition, BF value was correlated with 5-year survival rate. This radiological imaging procedure is a valid modality to visualize the decreased tumor blood flow for assessing the malignant level of gastric cancer, especially in those with high-grade malignancy.
No conflict of interest.

2533 POSTER

Real world data on patients with neuroendocrine tumors treated with octreotide LAR

D. Ferone[1], A. Forsythe[2], B. Bakker[2], R. Pedersini[3], A. Goren[4]. *[1]Endocrinology Unit DiMI and Centre of Excellence for Biomedical Research, IRCCS-AOU San Martino − IST, University of Genova, Italy; [2]Novartis Pharmaceuticals, Corporation, East Hanover, USA; [3]Health Sciences Practice, Kantar Health, Epsom, United Kingdom; [4]Health Sciences Practice, Kantar Health, New York NY, USA*

Background: Octreotide LAR (OCT) has been proven effective in controlling the symptoms and delaying disease progression in patients (pts.) with neuroendocrine tumors (NET). Recent real world medical data on OCT use for the treatment of NET are limited. This retrospective study focuses on treatment history, symptom control and disease progression in NET pts. treated with OCT.
Methods: A retrospective chart audit was conducted in the UK, Spain, Germany, Italy, and France (data collected in January 2013). 78 physicians

completed 158 structured case report forms for pts. treated with OCT in the past 12 months. Demographics, treatment history, symptoms and tumor control data were collected.
Results: Of the 158 NET pts., 57% were male, age (mean[SD]) was 60[10] yrs. and mean time since diagnosis 3[2] yrs. 27%, 46% and 22% of pts. had tumor grade 1, 2 and 3 respectively (WHO classification); 67% of pts. had tumors with secretory symptoms; 61% had metastatic disease. Initial tumor site was: 47% small intestine, 23% stomach, 14% appendix, 10% colon and 6% rectum. Site of metastases: 91% liver, 23% pulmonary, 23% peritoneal, 11% other. Besides OCT, prior treatment history included surgery in 64%, chemotherapy in 9% and targeted therapy in 3%. Concomitant treatments included surgery in 8%, chemotherapy in 7% and targeted therapy in 11%. On average, pts. in this review have received OCT for 33 months. Reasons for prescribing OCT were mostly: efficacy in controlling symptoms (69%) and stabilizing/shrinking the tumor (75%). Most prevalent doses were 20 mg (44%) and 30 mg (44%). OCT injections were administered monthly in the majority of pts. (66%), however dose intervals varied from 2 to 6 weeks. 37% of OCT was administered by nurses at pts. home, 59% at doctors' offices and 8% by a family member. 69% of pts. experienced stabilization or shrinkage of the tumor over the last 12 months. Disease progression was reported in 15% of OCT pts. in the last 12 months, as assessed by Chromogranin A levels, CT-scan, MRI, endoscopy, sonography and other diagnostic tests and procedures.
Conclusions: Most of the NET pts. treated with OCT in this study had advanced metastatic disease. This real-world sample showed that majority of OCT-treated patients where on treatment for several years, any form of disease progression was reported in only 15% of study patients over the last 12 months.

2534 POSTER

The influence of income status on survival after chemotherapy in patients with advanced gastric cancer

C. In Keun[1], S.W. Jung[2], J.J. Hyun[2], J.S. Koo[2], R.S. Choung[2], J.H. Kim[3], H.J. Yim[2], S.H. Park[3], S.W. Lee[2], J.H. Choi[2]. *[1]Korea University Medical College, Hemato-oncology, Ansan, Korea; [2]Korea University Medical College, Gastroenterology, Ansan, Korea; [3]Korea University Medical College, General Surgery, Ansan, Korea*

Introduction: It is well-known that socio-economic (SE) inequalities can influence the survival of cancer patients. The association between SE factors and the survival of cancer has been explained by disease extension at diagnosis and different treatment procedures. However, there are few studies that report the influence of income status on survival of advanced gastric cancer patients treated with similar chemotherapy. In South Korea we have Medical Aid Program (MAP) for the poor. For advanced gastric cancer, the patients with MAP can receive same chemotherapeutic agents including trastzumab (Herceptin®) as patients with National Health Insurance Program (NHIP) in South Korea. We think that disease extension at diagnosis is not quite different by income status of patients with advanced gastric cancer. So we planned to study the influence of income status on results of systemic chemotherapy in patients with advanced gastric cancer.
Patients and Methods: One hundred thirty-eight patients with advanced gastric cancer were admitted for chemotherapy at the Korea University Ansan Hospital between March 2004 and February 2011. Chemotherapy was provided based on physician's decision for performance of patients and consideration for benefit of treatment and risk of toxicity. We reviewed clinical information by the electronic medical records of the patients.
Results: One hundred five patients with NHIP and thirty three MAP patients participated in this study. The median age of the patients was fifty-nine. There were 86 men (62.3%) and 52 women (37.7%). The median number of chemotherapeutic agents was five. Patients with HNIP had a median survival time of 9 months (95% CI, 7.8–10.2 months), which was not significantly different from that of patients with MAP (11 months, 95% CI, 8.6–13.4 months, $p = 0.14$). More than five chemotherapeutic agents were used 52% in patients with MAP (17/33) and 33% (35/105) in patients with NHIP. The patients with MAP showed tendency to receive more chemotherapeutic agents than the patients with NHIP ($p = 0.07$).
Conclusions: Because of welfare system, the survival of advanced gastric cancer patients with MAP seems to be not inferior to that of the patients with NHIP in this study. Further prospective large scale studies are warranted to confirm these results.
No conflict of interest.

2535 POSTER

Assessing the prognostic effect of HER3 (mRNA) in gastric cancer

M. Soltani Delgosha[1], Y. Makhdoumi[1]. *[1]Reza Oncology Center, Mashhad, Iran*

Introduction: The epidermal growth factor receptors (EGFR) family stimulates a number of signal transduction cascades that regulate diverse cellular processes, such as proliferation, differentiation, survival, migration and adhesion. These signaling pathways are important in normal cellular homeostasis, but aberrant activation of the EGFR members can cause carcinogenesis. The carcinogenic role of HER3 and HER4 has been seen gastric cancer. In this study, the prognostic effect of HER3 is evaluated in gastric cancer patients.
Material and Methods: Tumoral and free tumoral borders of gastric tissues were freshly obtained from 40 patients with primary gastric adenocarcinoma who underwent a surgical procedure. The patients who underwent gasterectomy did not get any neoadjuvant therapy. Histopathological features including tumor size, location, and grade of differentiation were defined, and surgical stage was determined on the basis of the Union International Cancer TNM classification.
RNA was extracted from normal and cancerous tissue of gastric samples using the RNeasy Mini kit (Qiagen, Hilden, Germany), and then the cDNA was synthesized by using synthesis kit (Fermentas, Lithuania), after that Quantitative Real-time PCR was performed by using SYBR green PCR Master Mix (Fermentas, Lithuania) to determine the expression of HER3 in species. for determining the prognosis, we followed the patients' situation for 6 and 12 months after OR, then the correlation between HER3 (mRNA) with prognosis was determined. Statistical analysis was done by spss ver19, for assessing the correlation between HER3 and clinicopathologic factors used Independent sample t test and Kaplan–Meier curves were generated for overall survival, and statistical significance was determined using the log-rank test.
Results: 77.5% of patients were male and 22.5% were female, 52.5% of patients were older than 65 years whereas, 47.5% were less than 65. 35% of patients have HER3 overexpression. HER3 expression was significantly associated with factors involved with tumor progression, including depth of tumor invasion T1-T2 versus T3-T4 ($P = 0.000$); involved lymph nodes ($P = 0.001$); stage ($P = 0.000$); recurrent disease ($P = 0.000$) and CA19-9 ($P = 0.000$). The significant relationship between mRNA and protein of HER3 was seen. ($P = 0.000$) HER3 overexpression was associated with a significantly worse survival. ($P = 0.000$). The protein of HER3 was an independent prognostic factor in the multivariate analysis. ($P = 0.007$) 95% confidence interval, 0.006–0.454.
Conclusion: HER3 is an independent prognostic factor which can cause tumor progression and poorer survival rate of patients, in cellular and molecular study is demonstrated that anti agents which target HER2 can cause compensatory overexpression of HER3,so that the unexpected result would be gained and prognosis would be poor, therefore, we suggest assessing the expression of HER3 in patients and use regimen which target the band between HER2 and HER3 to get proper results and improve the prognosis.

2536 POSTER

Influence of cytokine gene expressions on development of gastric cancer and chronic active gastritis

D. Kivrak Salim[1], H. Adanir[2], M. Sahin[3], S. Koksoy[4], I. Suleymanlar[2]. *[1]Akdeniz University Faculty of Medicine, Medical Oncology, Antalya, Turkey; [2]Akdeniz University Faculty of Medicine, Gastroenterology, Antalya, Turkey; [3]Akdeniz University Faculty of Medicine, Health Sciences Research Center, Antalya, Turkey; [4]Akdeniz University Faculty of Medicine, Medical Microbiology, Antalya, Turkey*

Background: There have been many studies of cytokine expressions in the gastric mucosa of Helicobacter Pylori (H.pylori) infected patients with chronic gastritis and gastric adenocancer. Alterations of these cytokine genes are associated with individual differences in gastric mucosal cytokine mRNA level, which results in differences in gastric mucosal inflamation, gastroduodenal disease risk in response to H.pylori infection. In the present study we aimed to elucidate the expression of cytokines in the gastric mucosa and the immunopathological roles played by these cytokines in normal gastric mucosa (NGM), chronic active gastritis (CAG) and gastric adenocancer (GAC). The cytokines examined were IFN-γ, TNF-α, IL-4, IL-6, IL-10, TGF-β, IL-17A, IL-32, FGF1 and FGF2.
Material and Methods: In order to evaluate the utility of cytokine mediators as markers associated with increased gastric cancer risk, we investigated cytokine gene expression by reverse transcription polymerase chain reaction in gastric biopsy specimens obtained from 93 patients.

Results: We evaluated gastric tissues of 93 patients [43 (46.2%) female, 50 (53.8%) male] between the ages of 18−70. According to histopathological groups (NGM (32; 34.4%), CAG (33; 35.5%), GAC (28; 30.1%)] cytokine gene expression levels using RT-PCR method were evaluated prospectively. IFN-γ, TNF-α, IL-6, IL-10, IL-17A, FGF1 m RNA were increased in CAG group and TNF-α, IL-6, IL-10, IL-17A, TGF-β, FGF1 mRNA were increased in GAC group. The relative expression ratio of IL-6>22 was found to be an independent predictive factor for adenocancer development with referance to control (NGM) group (OR=43.47, %95 CI=3.79–498.82, p = 0.002). The relative expression ratio of IL-6>22 was shown to have increased risk of CAG development with referance to control (NGM) group (OR=10.63, %95 CI=1.70–66.57, p = 0.012).
Conclusion: Our findings suggest that immune response of gastric mucosa to H.pylori differs from patient to patient. Finally IL-6 expression might be useful as an independent molecular marker for early diagnosis of pre-neoplastic changes might be used for follow up. Its utility and cost-effectiveness must be investigated in further studies.
No conflict of interest.

2537 POSTER

Multi-disciplinary team decisions in hepatocellular carcinoma − process and compliance evaluation

A. Almeida[1], R. Bessa-Melo[1], C. Soares[1], M. Sacchetti[1], L. Graça[1], J. Costa-Maia[1]. [1]*Sao Joao Hospital − Medical School University Oporto, General Surgery, Oporto, Portugal*

Introduction: It is recommended worldwide that treatment decisions concerning oncological patients should be made in a multi-disciplinary team (MDT). However, few studies have analyzed these decisions and their implementation.
The purposes of this study are the evaluation of the MDT decisions concerning hepatocellular carcinoma (HCC), their implementation, and to analyze the reasons for non-compliance.
Methods: All treatment decisions made by a hepato-bilio-pancreatic MDT of a referral Center in Portugal were prospectively recorded during a 3-year period (January 2010 to December 2012). Implementation of decisions and reasons for non-compliance concerning HCC patients were identified and analyzed.
Results: During this period 2071 MDT consultations were performed, 399 (19%) of them in HCC patients. The 399 MDT decisions analyzed concern 149 HCC patients (sex distribution: 127M/22F; median age of 67 years [25−90]). Two hundred and nine therapeutic decisions were proposed. Non-therapeutic attitudes were proposed in 74 instances (best supportive care − 21, follow-up − 53). In 109 situations the MDT decided not to take a treatment decision and proposed further study due to insufficient information.
Fifteen percent of the decisions (58) were not implemented. Factors associated to non-compliance were: progression of the disease or previously undetected anatomical abnormalities that altered the indication or contra-indicated the proposed treatment, patient option or clinical option. In the cases of non-compliance alternate treatment options were more conservative, with the exception of one patient that had a more aggressive approach.
During this period 21 (14%) patients were proposed to a multimodal approach.
Conclusion: The vast majority of MDT decisions in hepatocellular carcinoma were implemented and changes were mostly related to patient or disease factors that had not been taken into account. Systems for evaluating team effectiveness are immature and methods to monitor performance, teamwork and outcomes are required. Analysis of the implementation of team decisions is an informative process to monitor the quality of MDT decision-making.
No conflict of interest.

2538 POSTER

Sann-Joong-Kuey-Jian-Tang could inhibit human pancreatic carcinoma BxPC-3 cells through inducing autophagy

S. Chin Cheng[1]. [1]*Changhua Christian Hospital, Surgery, Changhua, Taiwan*

Background: Pancreatic cancer is the fourth leading cause of cancer death in the USA, remains a challenging disease. Sann-Joong-Kuey-Jian-Tang (SJKJT), a traditional Chinese medicinal prescription, with cytotoxic effects in many human cancer cell lines, has been used as complementary medicine in Taiwan. But the molecular mechanisms have not been elucidated. Our previous studies showed that SJKJT can inhibit colon cancer colo 205 cells through inducing autophagy in vitro. In the present study we evaluated the efficacy of SJKJT in human pancreatic carcinoma BxPC-3 cells.
Material and Methods: The cytotoxic activity of SJKJT in BxPC-3 cells was measured by MTT assay. The autophagy related protein expressions (such as: BECN1, ATG3, ATG 7, ATG12-ATG5 and LC3-II) were measured by Western blotting.
Results: The results showed that SJKJT could inhibit the proliferation of BxPC-3 cells with time and dose dependent manner. The protein expressions of LC3-II were increased, but BECN1, ATG3, ATG 7 and ATG12-ATG5 were increased at first 24 hrs then decreased at 48 to 72 hrs in BxPC-3 cells were treated with SJKJT.
Conclusions: These finding indicated that SJKJT can inhibit the proliferation of a BxPC-3 cells through inducing Autophagy in vitro. The therapeutic potential of SJKJT in human pancreatic cancer need further in vivo study in the future.
No conflict of interest.

2539 POSTER

Clinical significance of serum M30 and M65 levels in metastatic pancreatic adenocarcinoma

R. Ciftci[1], S. Karabulut[1], D. Tastekin[1], F. Sen[1], L. Kilic[1], I. Yildiz[1], S. Keskin[1], F. Tas[1]. [1]*Istanbul University Oncology Institute, Medical Oncology, Istanbul, Turkey*

Background: M30 and M65 are relatively new assays that detect different circulating forms of the epithelial cell structural protein cytokeratin18. This study was conducted to investigate the serum levels of M30 and M65 in patients with metastatic pancreatic adenocarcinoma and the relationship with tumor progression and known prognostic parameters.
Material and Methods: Twenty-six patients with metastatic pancreatic adenocarcinoma were investigated. Serum samples were obtained on first admission before treatment and follow-up. Both serum M30 and M65 levels were determined using enzyme-linked immunosorbent assay (ELISA).
Results: The median age at diagnosis was 59 years, range 32−80 years; 14 patients were male. All patients had metastatic stage and most (n = 21, 81%) had hepatic metastasis. The baseline levels of both serum M30 and M65 levels were significantly higher in patients with metastatic pancreatic adenocarcinoma than the control group (p < 0.001, for both assays). Serum M65 level was significantly higher in the patients with elevated serum LDH (lactate dehydrogenase) levels than those with normal serum LDH levels (p = 0.03). However, serum M30 levels were not corralated with LDH levels. The significant relationship was found between the serum levels of M30 and M65 (r_s = 0.926, n = 26, p < 0.001, Spearman's correlation). Median survival for all patients was 31.7±2.2 weeks (%95 CI=27.31–36.08). Only the serum LDH level was found to be significant for prognosis (p = 0.01). Neither serum M30 nor serum M65 had significant impact on survival (p = 0.28, and p = 0.15, respectively).
Conclusions: Although both serum levels of M30 and M65 assays were found to be diagnostic value, no predictive and prognostic value was determine in metastatic pancreatic adenocarcinoma patients.
No conflict of interest.

2541 POSTER

Clinical significance of coagulation assays in metastatic pancreas adenocarcinoma

S. Karabulut[1], L. Kilic[1], R. Ciftci[1], I. Yildiz[1], S. Vatansever[1], S. Keskin[1], F. Tas[1]. [1]*Istanbul University Oncology Institute, Medical Oncology, Istanbul, Turkey*

Background: Activated coagulation and fibrinolytic system in cancer patients are associated with tumor stroma formation and metastasis in different types of cancer. The aim of this study is to explore the correlation of blood coagulation tests for various clinicopathologic factors in patients with metastatic pancreatic adenocarcinoma (MPA).
Material: A total of 17 MPA patients were enrolled into the study. All the patients were treatment-naive. Pretreatment blood coagulation tests including PT (prothrombin time), APTT (activated partial thromboplastin time), INR (international normalized ratio),D-dimer, fibrinogen levels and platelet counts were evaluated. Control group was comprised with age 50 and sex- matched individuals without history of malignancy and coagulation disorder.
Results: Median age of diagnosis was 59 years old (range: 35−72). The plasma level of all coagulation factors were revealed statistically significant difference between patient and control group (p < 0.001). Anemic patients had associated with higher D-dimer levels (2996 vs. 505 IU/ml, p = 0.001). Similarly, the ones with elevated serum CA199 exhibited significantly higher D-dimer values (1650 vs. 505 IU/ml, p = 0.01). For APTT, significant differences were found in both between gender of patients (p = 0.01) and response to chemotherapy (p = 0.01). The patients with elevated erythrocyte sedimentation rates had associated with lower INR (1.12 vs. 1.24, p = 0.05). Univariate analysis of survival revealed that the patients with

responsive to chemotherapy (25.7 vs. 34.9 month, p = 0.06) and higher INR (25.6 vs. 33.9 month, p = 0.078) had poor overall outcome.
Conclusion: Coagulation assays can be utilized as predictive factors of MPA. Plasma D-dimer level is also elevated among MPA patients with higher serum CA199. The correlection of D-dimer and CA199 is supposed to reflect hyperactivation of fibrinolytic pathway in presense of higer tumor burden. APTT level is elevated among MPA patients to predict the response to chemotherapy. Higher INR levels seem to be poor prognostic factor in MPA.
No conflict of interest.

2542 POSTER

Prognostic factors in metastatic pancreatic cancer: Older patients have poorer prognosis

R. Ciftci[1], S. Karabulut[1], F. Aydogan[1], L. Kilic[1], S. Keskin[1], I. Yildiz[1], S. Vatansever[1], F. Tas[1]. *[1]Istanbul University Oncology Institute, Medical Oncology, Istanbul, Turkey*

Background: Despite all efforts at management, prognosis of metastatic pancreatic cancer is extremely poor, with median survival of a few months. Pancreatic cancer is mainly a disease of the elderly. Incidence of pancreatic cancer increases with age and 60% of patients are older than 65 years. The aim of this study was to identify and evaluate the impact of different clinicopathologic factors, especially age on the prognosis of metastatic pancreatic cancer.
Material and Methods: The data about 154 metastatic patients with histologically confirmed diagnosis of pancreatic cancer who were treated and followed up in our clinic were recorded from their medical charts.
Results: The group included 102 (66%) male patients and median age was 58 years (25−88 years). Majority of the patients had poor performance status (64%), weight loss more than 10% (74%), larger (>3 cm) tumor size (75%), and elevated tumor markers including CEA (66%) and CA19.9 (85%). The distribution of prognostic factors according to the age of patients were generally identical. The median survival of patients was 179 days, and the 1-year survival rate was 7%. The median survival time of the elderly patients was significantly lower than younger ones (148 days *v* 198 days, p = 0.039). The 1-year survival rates in elderly and younger patients were 3% and 10%, respectively. In both univariate and multivariate analyses, elderly patients had poorer outcome than younger ones (p = 0.04, p = 0.05, respectively). In the whole group, univariate analyses showed similar prognostic factors on survival, including performance status and tumor markers (CEA and CA 19.9). In multivariate anaysis, younger patients with poor performance status had a significantly shorter overall survival than those with good performance status (p = 0.008). However, no significant prognostic factor on outcome was found in the elderly patients.
Conclusions: Age of patients is one of the major prognostic factors influencing survival in metastatic pancreatic cancer. In this regard, elderly patients should be evaluated for different treatment options carefully.
No conflict of interest.

2543 POSTER

SWV, elastometry and elastography of autopsy liver tumor specimen in differential diagnostics of hepatocellular carcinoma

V. Sholokhov[1], S. Berdnikov[1], M. Makhotina[1], A. Petrovsky[2]. *[1]Russian Cancer Research Center, Ultrasound Diagnostics, Moscow, Russian Federation; [2]Russian Cancer Research Center, Radiosurgery, Moscow, Russian Federation*

Objective: Ultrasound diagnostics of liver tumors is still a difficult problem in many cases.
Goal: To improve hepatocellular cance rdiagnostics using elastometry and elastigraphy of the autopsy liver tumor specimens.
Materials and Mmethods: 20 aoutopsy liver tumor specimens with a histologically verified hepatocellular carcinoma were examined. The structure of the tumor and of the normal liver parenchyma were analyzed. Elastography of autopsy liver tumor specimen was focused on tumor tissue softness/rigidity qualitative criteria (soft, solid ormixed type of tissue rigidity depending on the structure of the tumor lesion as compared to the normal liver parenchyma).
Results: Mean values of shear wave velocity (SWV) during the elastometry were as follows: in normal liver parenchyma was 2.44 m/s(1.91 m/s − 2.81 m/s), whereas in the tumor tissue was 2.18 m/s (1.62 m/s to2.73 m/s) (p = 0.45). The analysis of the mean SWV value of tissue deformation in this 20 patients before surgery showed that it was 2.28 m/s in the normal liver parenchyma and 2.20 m/s in the tumor tissue (p = 0.7).
According to ARFI data, we invented classification of the tumors rigidity: 1st type − soft consistency, 2nd type − solid, and 3rd type − mixed consistency (soft with solidparts). Using the ARFI technology in gross specimen, it was explored that type 1 was in 9 cases (45.0%), type 2 − in 3 cases (15.0%), and type 3 − in 8 (40.0%). Based on data of the elastography with manual compression, we divided all liver tumors into 4 groups: group 1 − soft, group 2 − soft central parts with solid edges, group 3 − soft with isolated solid inclusions, group 4 − solid with isolated soft inclusions. Examinations of the liver tumor in a gross specimen showed that group 1 included 2 patients (10.0%), group 2−8 (40.0%), group 3−4 (20.0%), and group 4−6 patients (30.0%). That means, that only 30% of tumors could be considered as rigid and 70% − as soft.
Conclusion: According to ARFI data, the hepatocellular cancer with together with severe liver fibrosis has a soft consistency in most of the cases. Elastography and elastometry showed the same results. SWV didn't show significant difference in the value of normal and tumor liver tissue. Therefore, SWV, elastometry and elastography cannot be used for differential diagnostics of the hepatocellular carcinoma.
No conflict of interest.

2544 POSTER

Recurrence after complete resection of gastrointestinal or pancreatic neuroendocrine tumors: Single institution analysis

R. Marconcini[1], S. Ricci[2], L. Galli[1], A. Antonuzzo[2], L. Derosa[1], A. Farnesi[1], E. Biasco[1], E. Vasile[1], M. Lucchesi[1], A. Falcone[1]. *[1]S. Chiara Hospital, U.O. Oncologia Medica 2, Pisa, Italy; [2]S. Chiara Hospital, U.O. Oncologia Medica 1, Pisa, Italy*

Background: Adjuvant therapy is not currently indicated in patients (pts) with completely resected neuroendocrine tumors (NETs). Additional data regarding time to progression (TTP) and overall survival (OS) of pt with resected NETs are necessary to design adequately powered studies in this setting. Whenever possible, complete surgical resection with curative intent of the primary tumor should be performed; however, many pts don't develop disease recurrence. The probability of recurrence may vary depending on tumor site and biologic aggressiveness. Design and completion of definitive studies evaluating adjuvant regimens is challenging, and no adequately controlled studies have been performed. The aims of this study were to evaluate TTP and OS after complete resection of carcinoid (GI NET) or pancreatic NETs (PNET).
Material and Methods: We analyze retrospectively 28 PNET pts and 36 GI NET pts (3 stomach, 4 duodenum, 18 ileum, 7 appendix, 4 colon) with completely resected disease followed at our center between January 1995 and February 2013, evaluating TTP and OS.
Results: Between 28 PNET pts group, 15 pt experience relapse with mTTP 25.43 (3.57–141.00+) months and mOS 123.86 (4.57−77.17+) months, while 13 pts still not present relapse and are still alive (median OS 50.11 m+). Between 36 GINET pts group, 14 pts experience relapse with mTTP 16.92 (0.8–133.40+) months and mOS 150.67 (31.8–1199.3+) months, while 22 pts still not present relapse and are still alive (median OS 95.13 m+). Between 36 GI NET pts resulted in not evidenced disease after surgery, median OS was 119.3 month (5.7–1199.3+): of these, 22 pts still not present relapse and are still alive (median OS 95.13 m+) 14 pts experience relapse with median PFS 16.92 (0.8–133.40+) months, mOS 150.67 (31.8–1199.3+) months. Pts with not evidenced disease after metastatic site completely resected mTTP and MOS were 3.95 (1.93−50.77+) and 36.68 (16.8–55.33+) months in the PNET group (4 pts), 9.03 (5.1−32.77+) and 150.37 (83.8–172.37+) months in the GI NET group (3 pts). Between pts with primary tumor completely resected without synchronous metastasis, mTTP and mOS were 68.83 (7.16–1238.6+) and 38.57 (6.1–1376.87+) months in the PNET group (24 pts), 56.37 (9.2–1112.9+) and 59.93 (5.7–1199.3+) in the GI NET group (34 pts).
Conclusion: P NET and GI NET G1 and G2 have comparable PFS and OS when radically resected. Pts radically resected who have undergone complete resection of metastases seems to have poorer PFS.
No conflict of interest.

2545 POSTER

Clinical significance of serum LDH, CEA and CA19-9 levels in metastatic pancreatic cancer

S. Karabulut[1], R. Ciftci[1], F. Sen[1], F. Tas[1]. *[1]Istanbul University Oncology Institute, Medical Oncology, Istanbul, Turkey*

Background: To evaluate the clinical significance of serum LDH, CEA, and CA19-9 levels in metastatic pancreatic cancer (MPC).
Material and Methods: In this retrospective study, we analyzed the outcome of 196 MPC treated and followed up in our clinic.
Results: Positivity rates of serum LDH, CEA, and CA19-9 were 22%, 40%, and 83%, respectively. Likewise, the rates of very high serum levels of tumor markers were correlated with these positivity rates (2/22, 9% for LDH; 12/40, 30% for CEA; and 46/83, 55% for CA19-9). The serum LDH levels were significantly higher in older patients (p = 0.05) and also in the patients with large tumors (p = 0.05), hepatic metastasis (p = 0.01),

hypoalbuminemia (p = 0.01), unresponsive to chemotherapy (p = 0.04). The distribution of prognostic factors depend on both serum CEA and CA19-9 were identical; no relation was found. The significant relationships were found between the serum levels of CEA and CA19-9 (rs = 0.24, p = 0.004), and serum LDH and CEA (rs = 0.193, p = 0.02). No correlation between serum LDH and CA19-9 levels (p = 0.39). 1-year overall survival rate was 12.8% (95% CI =8−18). Increased serum levels of all the tumor markers significantly adverse affect on survival (p = 0.001 for LDH, p = 0.002 for CEA, and p = 0.007 for CA19-9). No difference was observed in between high levels and very high levels of serum markers for all tumor markers. Patients with normal serum levels of all three tumor markers had better outcome than others (p = 0.002) and with normal serum LDH and CEA levels and whatever CA19-9 levels had associated with better survival compared with other possible alternatives (p < 0.001).
Conclusion: Serum levels of LDH, CEA, and CA19-9 significantly affect on survival in MPC patients.
No conflict of interest.

Prognostic significance of FDG-PET in locally advanced pancreatic cancer treated with carbon-ion radiotherapy and concurrent full-dose gemcitabine

M. Shinoto[1], S. Yamada[2], K. Terashima[1], K. Yoshikawa[2], S. Yasuda[2], H. Imada[2], Y. Shioyama[3], H. Honda[1], T. Kamada[2]. *[1]Kyushu University, Department of Clinical Radiology Graduate School of Medical Sciences, Fukuoka, Japan; [2]National Institute of Radiological Sciences, Hospital of Research Center for Charged Particle Therapy, Chiba, Japan; [3]Kyushu University, Department of Heavy Particle Therapy ad Radiation Oncology Graduate School of Medical Sciences, Fukuoka, Japan*

Background: The aim of this study was to evaluate the prognostic significance of positron emission tomography using 18-fluorodeoxyglucose (FDG-PET) in patients with locally advanced pancreatic cancer (LAPC) treated on a prospective trial of carbon-ion radiotherapy (CIRT) dose escalation with concurrent gemcitabine.
Material and Methods: Forty patients with unresectable LAPC were treated in our institution on a phase I/II trial of CIRT dose escalation with concurrent full-dose gemcitabine. On the FDG-PET before CIRT and concurrent gemcitabine, the maximum standardized uptake value (SUVmax) on primary tumor was calculated. Cox models were used to assess the effect of prognostic factor on freedom from local progression (FFLP), progression-free survival (PFS), and overall survival (OS).
Results: The median SUVmax was 5.2 (range 1.5–13.2). In the univariate analysis, SUVmax predicted FFLP (HR 1.31 $p = 0.014$), PFS (HR 1.18 $p = 0.020$), and OS (HR 1.28 $p = 0.009$). For all 40 patients, the 2- year FFLP rate, PFS rate, and OS rate were 48%, 14%, 36%. The 2-year FFLP rate, PFS rate, and OS rate in patients with SUVmax <5.2 were 63%, 26%, 80%.
Conclusions: In patients with LAPC undergoing CIRT with full-dose gemcitabine, SUVmax was independently prognostic factor.
No conflict of interest.

2547 POSTER

FDG-PET/CT during chemo-radiotherapy for esophageal cancer: Planning higher radiotherapy doses to reduced target volumes

L. Nkhali[1], S. Thureau[1], A. Edet-Sanson[2], K. Doyeux[1], A. Benyoucef[1], I. Gardin[2], P. Michel[3], P. Vera[2], B. Dubray[1]. *[1]Henri Becquerel Cancer Centre, Department of Radiation Oncology and Medical Physics − QuantIF-LITIS (EA4108) Henri Becquerel Cancer Center and Rouen University Hospital, Rouen, France; [2]Henri Becquerel Cancer Centre, Department of Nuclear Medicine − QuantIF-LITIS (EA4108) Henri Becquerel Cancer Center and Rouen University Hospital, Rouen, France; [3]Rouen University Hospital, Department of Hepatogastroenterology and University of Rouen, Rouen, France*

Background: The standard treatment of oesophageal cancer is a concomitant combination of cis-platinum-based chemotherapy and radiotherapy (RT) to a total dose of 50.4 Gy. Higher RT doses are likely to improve the poor results of concomitant chemo-radiotherapy (CRT). We investigated whether RT target volumes reduction, as assessed on FDG-PET/CT before and during CRT, would allow RT dose escalation to 66 Gy without compromising normal tissue tolerance.
Methods and Materials: A prospective study (RTEP3, NCT 00934505) included 57 patients with stage IIB, III or IVA (TNM 2002) oesophageal squamous cell carcinomas. FDG-PET/CT was performed before (PET_1) and at 21 days (PET_2) of CRT. The present analysis is restricted to 13 patients in whom FDG-PET/CTs were acquired in radiotherapy position. The Gross Target Volume (GTV_{PET}) was delineated by a nuclear physician and a radiation oncologist on PET_1 and PET_2. Adequate margins were added to account for microscopic disease around GTV_{PET} (Clinical Target Volume CTV) and set-up uncertainties around CTV (Planning Target Volumes PTV). An initial PTV, to be treated up to 40 Gy, was defined on PET_1. Then, the PTV was reduced to receive 50 or 66 Gy (ICRU 83 report), based on either PET_1 or PET_2. The Organs At Risk (OAR) were the spinal cord, the lungs, and the heart. The RT plans were compared in terms of PTV coverage and doses received by the OARs.
Results: 13 patients had a PET in radiotherapy position. GTV_{PET-2} could not be delineated in 3 patients with acute esophagitis. In the 10 remaining patients, GTV_{PET} decreased by 61% (p = 0.01) between PET_1 and PET_2. The $PTV_{66\,Gy-1}$ and $PTV_{66\,Gy-2}$ were $149 \pm 18\,cm^3$ and $102 \pm 8\,cm^3$, respectively, i.e. a 31% reduction (p = 0.05). The dose objectives to the PTV were achieved for all the plans without impairing PTV coverage. Despite PTV dose escalation, significant reductions in dose to the spinal cord (p = 0.01) and to the lungs ($V_{20\,Gy}$, p = 0.005) were achieved with adaptive radiotherapy based on PET_2.
Conclusion: Target volume adaptation using FDG-PET/CT during CRT allows radiotherapy-dose escalation with improved protection of the OAR's, without compromising target volume coverage. This approach needs clinical validation in a prospective trial.
No conflict of interest.

2548 POSTER

Identifying the optimal criteria for radiotherapy in patients with intermediate and advanced hepatocellular carcinoma

S. Son[1], H.S. Jang[2], S.Y. Sung[1], J.H. Kwon[1], S.H. Bae[2], C.S. Kay[1]. *[1]Incheon St. Mary's Hospital, Radiation Oncology, Incheon, South Korea; [2]Seoul St. Mary's Hospital, Radiation Oncology, Seoul, South Korea*

Purpose: We evaluated the clinical outcomes of radiotherapy (RT) for patients with Barcelona Clinic Liver Cancer (BCLC) intermediate and advanced stage hepatocellular carcinoma (HCC) and established the optimal criteria for RT in these stages.
Methods and Materials: A total of 103 patients were enrolled in this study. All patients received RT delivered using the TomoTherapy Hi-Art system (TomoTherapy Inc., Madison, WI, USA), at Incheon St. Mary's Hospital and Seoul St. Mary's Hospital between March 2006 and February 2012. The planning target volume (PTV) was $330.1 \pm 275.1\,cm^3$, and the non-target normal liver (NTNL) volume was $1209.7 \pm 426.9\,cm^3$. The dose per fraction to the PTV was 1.8−5 Gy, and the total dose was 40−60 Gy (median, 50 Gy). We evaluated the factors associated with the deterioration of hepatic function and the local progression-free survival (PFS) in order to identify the optimal criteria for RT.
Results: A PTV of 225 cc, a total dose of 60 Gy_{10}, and an NTNL-V_{BED20} of 40% were identified as factors associated with the deterioration of hepatic function and local PFS. On the basis of these factors, patients were divided to a favorable group or unfavorable group. The differences in median local PFS, overall survival, and the incidence rate of deteriorated hepatic function between the 2 groups were 10.4 months, 11.2 months, and 66.2%, respectively, all of which were statistically significant (p < 0.001 in each case).
Conclusions: We suggest that the optimal criteria for RT in patients with BCLC intermediate and advanced stage HCC were a PTV <225 cc, a total dose >60 Gy_{10}, and an NTNL-V_{BED20} <40%.
No conflict of interest.

2549 POSTER

The role of postoperative or definitive three-dimensional chemoradiotherapy in pancreatic cancer: A single institution experience

P. Hurmuz[1], G. Ozyigit[1], G. Eren[1], D. Yuce[2], M. Cengiz[1], F. Zorlu[1], S. Yalcin[3], M. Gurkaynak[1]. *[1]Hacettepe University Faculty of Medicine, Radiation Oncology, Ankara, Turkey; [2]Hacettepe University Faculty of Medicine, Preventive Oncology, Ankara, Turkey; [3]Hacettepe University Faculty of Medicine, Medical Oncology, Ankara, Turkey*

Purpose: To evaluate the effect of radiotherapy (RT) in the curative treatment of patients with pancreatic cancer.
Materials and Methods: We retrospectively evaluated the medical records of 176 patients treated in our department between July 2009 and October 2011. RT was delivered as an adjuvant treatment in 98 patients and as a definitive treatment in 78 patients. Median age was 57 years old (range, 30−80 years) and 114 (65%) of the patients were male. The disease was located in the pancreatic head in 78% of the patients. According to AJCC staging system tumor stage was T3 in 36% and T4 in 45% of the patients. Pathological/radiological regional lymph nodes (LN) were involved in 48% of the cases. The median total dose of 50.4 Gy was delivered conformally to the tumor bed and regional LNs. The median daily fraction dose was 1.8 Gy.

A total of 154 patients received concurrent gemcitabine (126 patients) or 5-FU (28 patients) chemotherapy (CT).
Results: Median follow up was 15 months (range, 2–158 months). Median survival in the adjuvant treatment group was 26 months and definitive treatment group was 16 months ($p = 0.004$). Progression free survival (PFS) in the adjuvant and definitive treatment groups were 9 and 6 months respectively ($p = 0.045$). Gender, location of the tumor, CT regimens, tumor and node status did not affect the overall survival (OS) and PFS. In both groups OS and PFS were affected by the ECOG performance status ($p < 0.001$). In the adjuvant group, OS was superior in patients <60 years old ($p = 0.028$). In this group PFS was also superior (12 months vs. 7 months, $p = 0.05$). The patients generally well tolerated our treatment regimen. The most common toxicity was grade 1 emesis according to RTOG acute toxicity criteria (55%).
Conclusions: In this retrospective study we found that ECOG performance status was an important factor that affects OS and PFS in both adjuvant and definitive treatment groups. Postoperative adjuvant radiotherapy seems to be more effective than definitive setting.
No conflict of interest.

2550 POSTER

Adjuvant chemoradiotherapy after distal pancreatectomy for pancreatic cancer

B. Kim[1], K. Kim[1], E. Chie[1], J. Jang[2], S. Kim[2], D. Oh[3], S. Im[3], Y. Bang[3], I. Joo[4], S. Ha[1]. *[1]Seoul National University College of Medicine, Radiation Oncology, Seoul, Korea; [2]Seoul National University College of Medicine, Surgery, Seoul, Korea; [3]Seoul National University College of Medicine, Internal Medicine, Seoul, Korea; [4]Seoul National University College of Medicine, Radiology, Seoul, Korea*

Background: To evaluate the outcome of adjuvant chemoradiotherapy (CRT) after distal pancreatectomy (DP) in patients with pancreatic adenocarcinoma, and to identify the prognostic factors for these patients.
Methods and Materials: We performed a retrospective review of 66 consecutive patients who underwent curative DP followed by adjuvant CRT between 2000 and 2011. There were 34 males and 32 females, and median age was 64 years (range, 38−80). Adjuvant radiotherapy was delivered to the tumor bed and regional lymph nodes with median dose of 50.4 Gy (range, 40–55.8). All patients received concomitant chemotherapy and 55 patients (83.3%) also received maintenance chemotherapy. The median follow-up period was 20 months.
Results: Forty patients (60.6%) experienced relapse. Isolated locoregional recurrence (LRR) developed in 5 patients (7.6%) and distant metastasis (DM) in 35 patients (53.0%), of whom 13 had both LRR and DM. Median disease-free survival (DFS) was 16.5 months. On univariate analysis, splenic artery (SA) invasion, resection margin (RM) involvement, tumor size $\geqslant$3 cm, lymph node metastasis, angiolymphatic invasion, venous invasion, and perineural invasion were identified as significant adverse prognosticators. Multivariate analysis revealed that SA invasion ($p = 0.032$) and RM involvement ($p = 0.005$) were independent prognostic factors for DFS. Grade 3 or higher hematologic and gastrointestinal toxicities occurred in 21.2% and 4.5% of patients, respectively.
Conclusions: Adjuvant CRT resulted in a low rate of isolated LRR with acceptable toxicity, but DM was still frequent despite maintenance chemotherapy. Our results indicated that SA invasion was a significant factor predicting inferior DFS as was RM involvement. When SA invasion is identified preoperatively, neoadjuvant treatment may be considered.
No conflict of interest.

2551 POSTER

Clinical characteristics and prognostic factors of brain metastases from hepatocellular carcinoma

K. Kim[1], K. Kim[1], E. Chie[1], S. Ha[1], Y. Kim[2], J. Yoon[2], H. Lee[2]. *[1]Seoul National University College of Medicine Seoul Korea, Department of Radiation Oncology, Seoul, Korea; [2]Seoul National University College of Medicine Seoul Korea, Department of Internal Medicine, Seoul, Korea*

Background: To evaluate clinical features and prognostic factors of brain metastases from hepatocellular carcinoma.
Materials and Methods: Medical records of 95 patients who have been diagnosed of brain metastases from hepatocellular carcinoma between Jan. 2000 and Dec. 2011 were retrospectively reviewed.
Results: The median age at diagnosis of brain metastases is 56.1 years. Eighty-two patients were male. Median interval from diagnosis of hepatocellular carcinoma to brain metastases was 29.5 months. Eighty eight patents had extracranial metastasis, and the lung was the most frequent involved organ. Motor weakness was the most frequent presenting symptom (49.5%). Intracranial hemorrhage was present in 71 patients (74.7%). Brain metastases were treated with surgery alone in 3 patients, radiosurgery alone in 18 patients, whole brain radiation therapy (WBRT) alone in 57 patients, surgery and radiosurgery in 3 patients, surgery and WBRT in 6 patients, radiosurgery and WBRT in 2 patients, conservative management only in 6 patients. Median overall survival was 3.0 months. Multivariate analysis showed ECOG performance status, AFP level, Child-Pugh class, number of brain lesions, and treatment modality were associated with survival ($P < 0.05$). Diagnosis Specific Graded Prognostic Assessment(DS-GPA) could be suggested with four factors (ECOG performance status, AFP level, Child-Pugh classification, number of brain lesions). We calculated DS-GPA for each patients by scoring individual factors with 0 or 1. Median survival of the patients with DS-GPA score 0 or 1 was 0.6 month (95% CI 0.50–0.70), score 2 was 2.5 months (95% CI 1.90–3.15), and score 3 or 4 was 5.8 months (95% CI 5.21–6.40).

DS-GPA variables	Point 0	Point 1
ECOG PS	>2	$\leqslant$2
Child-Pugh class	B/C	A
AFP (ng/ml)	>1400	$\leqslant$1400
No. of brain metastases	>1	1

Conclusions: Although overall prognosis of patients with brain metastases from hepatocellular carcinoma is poor, we can estimate the survival of patients by employing DA-GPA using four prognostic factors (AFP level, Child-Pugh Class, ECOG PS, number of brain lesions).
No conflict of interest.

2552 POSTER

Benefits of stereotactic body radiotherapy after incomplete transcatheter arterial chemoembolization in inoperable hepatocellular carcinoma

E.K. Paik[1], M.S. Kim[1], W.I. Jang[1]. *[1]Korea Institute of Radiological and Medical Sciences, Department of Radiation Oncology, Seoul, Korea*

Background: To analyze the effects of additional stereotactic body radiotherapy (SBRT) after incomplete transcatheter arterial chemoembolization (TACE) in inoperable hepatocellular carcinoma (HCC), the treatment outcomes of TACE followed by SBRT and TACE followed by treatment modalities other than SBRT were compared retrospectively.
Material and Methods: Between January 2006 and December 2008, 497 patients with HCC were treated with TACE as a primary treatment. In order to compare the effects of SBRT following incomplete TACE with those of modalities other than SBRT, the following criteria were imposed. The eligibility criteria included the following; (1) single tumor, (2) tumor size $\leqslant$10 cm, (3) no extrahepatic metastases, (4) Child-Pugh score $\leqslant$7, (5) no major vessel invasion, (6) Eastern Cooperative Oncology Group performance status $\leqslant$2. The exclusion criteria were as follows; (1) diffuse infiltrative tumor type, (2) tumor occupying $\geqslant$2/3 of the liver volume, (3) liver cirrhosis-associated complications, (4) severe co-morbidity, (5) previous radiation therapy to the upper abdomen, (6) presence of other malignancies within 5 years. One hundred and four patients were evaluated for TACE failure. Complete response was shown in 19 patients (complete TACE group), and incomplete in 85 patients. Among the incomplete TACE group, 39 patients had additional SBRT (TACE+SBRT group), and the remaining 46 patients received repeated TACE (incomplete TACE group).
Results: The patient characteristics were similar among the three groups except for the size of the tumor. The complete TACE group, in which none of the tumors were larger than 5 cm, contained tumors of smaller size compared to other groups. With a median survival time of 34 months, the overall survival (OS) at 2 years for the complete TACE group, incomplete TACE group and TACE+SBRT group were 84.2%, 45.7%, and 76.8%, respectively. The OS at 5 years for the complete TACE group, incomplete TACE group and TACE+SBRT group were 47.4%, 28.3%, and 63.5%, respectively. Compared with the incomplete TACE group, the TACE+SBRT group and the complete TACE group showed significantly improved survival rates ($p = 0.006$ and $p = 0.023$, respectively). Although the complete TACE group was composed of smaller tumors than the TACE+SBRT group, survival appeared to be statistically equivalent in the two groups ($p = 0.948$).
Conclusions: A significantly improved survival benefit was found in the TACE+SBRT group compared to the incomplete TACE group. Therefore, SBRT is strongly recommended for patients with incomplete TACE in inoperable HCC.
No conflict of interest.

YTTRIUM-90 (y-90) radioembolization in patients with unresectable liver metastases: Determining the factors that lead to treatment efficacy

S. Gunduz[1], O. Ozgur[2], H. Bozcuk[1], H.S. Coskun[1], M. Ozdogan[1], M. Erkilic[3], T. Sindel[2], A. Yildiz[3], S. Yilmaz[2], B. Savas[1]. *[1]Akdeniz University Faculty of Medicine, Department of Medical Oncology, Antalya, Turkey; [2]Akdeniz University Faculty of Medicine, Department of Radiology, Antalya, Turkey; [3]Akdeniz University Faculty of Medicine, Department of Nuclear Medicine, Antalya, Turkey*

Introduction: Locoregional treatments, such as radioembolization, can be used to treat patients with unresectable liver metastases. These treatments have been shown to reduce tumor size, lower the risk of recurrence, and increase survival time in these patients. In this study, we aimed to determine the progression-free survival and factors that predict survival of patients with liver metastases whose response to selective internal radiation therapy (SIRT) with Y-90 was assessed by positron emission tomography − computed tomography (PET CT).
Patients: Seventy eight liver cancer patients who were treated with Y-90 radioembolization in the Departments of Medical Oncology, Invasive Radiology and Nuclear Medicine at Akdeniz University Hospital between February 2010 and November 2012 were included in this report.
Results: The post-treatment response rates were as follows: 7 patients (9%) had stable disease (SD), 26 patients (33.3%) had a partial response (PR), 4 patients (5.1%) had a complete response (CR), and progressive disease (PD) was observed in 28 patients (35.9%). The median hepatic progression-free survival (HPFS) was 4.4 months (95% Confidence Interval (CI): 2.5 to 6.3), while median overall survival was 10.1 months (95% CI: 7.4 to 12.9). Univariate analysis revealed that HPFS is significantly affected by international normalized ratio (INR) levels and age (hazard ratio (HR) = 0.54 (95% CI: 0.30–096), P = 0.034, HR = 1.03 (95% CI: 1.00–1.05), P = 0.051, respectively). However, only INR levels retained significance with multivariate analysis (HR = 0.53 (95% CI: 0.30–0.93), P = 0.028), while age had limited significance (HR = 1.02 (95% CI: 1.00–1.05), P = 0.051).
Conclusion: We determined that Y-90 radioembolization is effective as a salvage therapy in patients with predominant liver metastases. For the first time, we showed that age and INR values reflecting the functional hepatic reserve can be used as positive predictive factors for hepatic progression-free survival.
No conflict of interest.

2554 POSTER

High-dose stereotactic body radiotherapy improves local control and overall survival in patients with inoperable hepatocellular carcinoma

W.I. Jang[1], M.S. Kim[1], C.K. Cho[1], H.J. Yoo[1], Y.S. Seo[1], J.K. Kang[1], E.K. Paik[1], D.H. Lee[2], S.Y. Kim[3], S.H. Bae[4]. *[1]Korea Institute of Radiological & Medical Science, Radiation Oncology, Seoul, South Korea; [2]Korea Institute of Radiological & Medical Science, Cyberknfie Center, Seoul, South Korea; [3]Korea Institute of Radiological & Medical Science, Division of Heavy Ion Clinical Research, Seoul, South Korea; [4]Kyung Hee University Gangdong Hospital, Radiation Oncology, Seoul, South Korea*

Background: The purpose of this study is to determine whether high-dose stereotactic body radiotherapy (SBRT) improves survival in patients with inoperable hepatocellular carcinoma (HCC).
Material and Methods: Between March 2003 and February 2011, 108 patients with 122 lesions were treated with SBRT for HCC. The indications for SBRT were unsuitability for surgery or local ablative therapies and incomplete response to transarterial chemoembolization. The inclusion criteria of this study were SBRT in 3 fractions and a longest diameter (LD) $\leqslant$7.0 cm. Eighty-two patients with 95 lesions were analyzed. Seventy-four patients had Child-Turcotte-Pugh class A and 8 had B7. The median LD was 3.0 cm (range, 1.0−7.0 cm). The median dose was 51 Gy (range, 33−60 Gy).
Results: Local control (LC) and overall survival (OS) rates at 2 years after SBRT were 87% and 63%, respectively, with a median follow-up duration of 30 months for all patients. The 2-year local control (LC)/overall survival (OS) rates for patients treated with doses of >54 Gy, 45−54 Gy, and <45 Gy were 100%/71%, 78%/64%, and 64%/30%, respectively ($p = 0.009/p < 0.001$). The 2-year overall survival rates for patients with and without local failure were 27% and 68%, respectively ($p < 0.001$). Multivariate analysis revealed that SBRT dose ($p = 0.005$) and Barcelona Clinic Liver Cancer stage ($p = 0.015$) were significant prognostic factors for OS. Correlation analysis revealed that there was a positive linear relationship between SBRT dose and LC ($p = 0.006$, R=0.899) and OS ($p = 0.002$, R=0.940) at 2 years. Five patients experienced grade 3 or higher gastrointestinal toxicity, and 6 experienced worsening of CTP score by $\geqslant$2 within 3 months of SBRT. Patients with dose >54 Gy had LC and OS rates of 100% and 67%, respectively, at 4.5 years. The estimated SBRT dose to achieve 90% LC at 2 year was 54.8 Gy in 3 fractions.
Conclusions: The present study revealed dose-control and survival relationships in SBRT for HCC. Excellent local control rates were achieved with SBRT dose of more than 54 Gy. Higher local control rates resulted from increasing dose may be survival benefit for inoperable HCC. High-dose SBRT may be as effective and safe a treatment modality as radiofrequency ablation. We suggest SBRT dose of more than 54 Gy in 3 fractions, if normal tissue constraints allow.
No conflict of interest.

2555 POSTER

Radiation dose does not influence anastomotic complications in patients with esophageal cancer treated with neoadjuvant chemoradiation and transhiatal esophagectomy

M. Koëter[1], M.J.C. Van der Sangen[2], C.W. Hurkmans[2], M.D.P. Luyer[1], H.J.T. Rutten[1], G.A.P. Nieuwenhuijzen[1]. *[1]Catharina Hospital, Surgery, Eindhoven, Netherlands; [2]Catharina Hospital, Radiation Oncology, Eindhoven, Netherlands*

Background: According to the Dutch guidelines the preferred curative treatment for non-metastatic esophageal cancer is neoadjuvant chemoradiation followed by surgery. Surgical treatment is associated with high rates of anastomotic leakage and stenosis. Neoadjuvant chemoradiation might increase anastomotic leakage and stenosis. The aim of this study was to determine the influence of radiation dose on leakage and stenosis in patients with esophageal cancer undergoing neoadjuvant chemoradiation followed by a transhiatal esophagectomy.
Material and Methods: A retrospective review was performed of 53 consecutive patients with distal esophageal cancer (C15.5) or gastro-esophageal junction cancer (C16.0), who received neoadjuvant chemoradiation (23 x 1.8 Gy, (41.4 Gy) combined with Paclitaxel and Carboplatin) followed by a transhiatal esophagectomy and a left cervical anastomosis between 2009 and 2011. On the preoperative planning CT the future anastomotic region was determined and the mean radiation dose, V20, V25, V30, V35 and V40 were calculated. Logistic regression analysis was conducted to examine determinants of anastomotic leakage and stenosis.
Results: Anastomotic leaks occurred in 13 of 53 patients (25.5%) and anastomotic stenosis occurred in 24 of 53 patients (45.3%). Median follow up duration was 20 months (range 0.2−25). Logistic regression analysis showed that mean dose, V20 − V40, age, co-morbidity, method of anastomosis, operating time and interval between last radiotherapy treatment and surgery were no predictors of anastomotic leakage and stenosis.
Conclusion: This study demonstrates that the radiation dose of 23 x 1.8 Gy on the future anastomotic region has no influence on the occurrence of anastomotic leakage and stenosis in patients with esophageal cancer treated with neoadjuvant chemoradiation followed by transhiatal esophagectomy.
No conflict of interest.

2556 POSTER

Adjuvant radiochemotherapy in completely resected gastric cancer: Experience of National Cancer Institute of Chile

C. Solé Persutic[1], N. Isa Osman[1], M. Russo Namias[2], H. Lopez Vidal[3]. *[1]National Cancer Institute, Radiotherapy, Santiago, Chile; [2]IRAM, Radiotherapy, Santiago, Chile; [3]University of Chile, Internal Medicine Resident, Santiago, Chile*

Purpose: Cancer in Central America, Caribbean and South America, is the 2º leading cause of death, where gastric cancer (GC) for men is the 3º most frequent and the 3º most deadly, for women is the 3º most common and the 3º most deadly. In the case of Chile, the GC for men is the 2º most common and 1º most deadly, for women is the 4º most common and 3º most deadly. Given its importance, it was necessary for us to review the results obtained in our institution in patients treated with adjuvant radio-chemotherapy.
Material and Methods: From Aug 2004 to Dec 2011, 168 patients, 99 men and 69 women with loco-regionally advanced GC (pT1−4, N0−3, M0), completely resected were treated with concomitant Radiotherapy (RT) and Chemotherapy (CT) based in 5FU (INT0116 scheme) in the National Cancer Institute of Santiago. The median age of diagnosis was 62 years, 99% of patients ECOG 0−1. Treatment consisted of total gastrectomy, subtotal gastrectomy or esophageal-gastrectomy plus D1 lymphadenectomy (14 patients), D2 (153 patients) and D3 (1 patient) respectively, followed by 3DRT, doses of 45 Gy in 25 fractions to tumor bed, regional nodes and anastomoses. The CT consisted of 5 FU (425 mg/mt2/day) and leucovorin (20 mg/mt2/day) for 5 days beginning

on day 1 and then RTCT 5FU (400 mg/mt2/day) and leucovorin (20 mg/mt2/day) for 4 days during the first week and for 3 days at RT the fifth week, then two separate monthly cycles than 1 month 5FU (425 mg/mt2/day) and leucovorin (20 mg/mt2/day) for 5 days or only RTCT 5FU (400 mg/mt2/día) and leucovorin (20 mg/mt2/day) for 4 days during the first week and three days the fifth week of RT. The dosage was adjusted according to toxicity.
Results: With a median follow up of 58 months (minimum 12 months), the median survival was 41 months. The median interval from surgery to start CT was 12 weeks and start RT was 17 weeks. The greater toxicity during RT was grade 3 in 3.5% of patients, mainly gastro-intestinal. Overall survival at 1, 2, 3, 4, 5 years was 88%, 64%, 53%, 47% and 41% respectively. Univariate analysis showed statistically significant factors associated with poor prognosis for overall survival were tumor site in antrum + fundus (p 0.007), presence of signet ring cells (p 0.0061), + LVI (p 0.014), N + (0.0008) with a HR of 1.32 for every stage of N increases and a HR of 1.05 for each positive found node (p 0.001), >15 positive nodes (p 0.001) and pathological increase of stage group (p 0.017). At multivariate analysis, statistically significant factors associated with poor prognosis for overall survival were tumor location in antrum+fundus (p 0.002), presence of signet ring cells (p 0.044), >15 positive nodes (p0.015).
Conclusion: Adjuvant RTCT at our institution has shown to be effective and safe, even at 12 weeks of delay in initiation of CT or 17 weeks to RT after surgery, with results in survival at 3 and 5 years of 53% and 41% respectively, comparable results with INT 0116 and its last update in 2012, with survival at 3 and 5 years of 50% and 41% respectively, this maybe due to the better quality of surgery offered, 91% with D2 lymphadenectomy vs. 10% in the INT 0116 respectively.
No conflict of interest.

2557 POSTER

Treatment of hepatocellular carcinoma with stereotactic body radiation: Experience from two institutions

M. Azoulay[1], N. Kopek[1], D. Roberge[2]. [1]*McGill University Health Centre, Radiation Oncology, Montréal, Canada;* [2]*Centre Hospitalier de l'Université de Montréal, Radiation Oncology, Montréal, Canada*

Background: Hepatocellular carcinomas (HCC) are aggressive liver tumors arising in patients with already limited liver. Treatment options for localized disease include surgery and ablative therapy. Our objective is to review our 4 year experience of stereotactic body radiation therapy (SBRT) for HCC patients ineligible for further local therapy.
Material and Methods: A population of 16 patients diagnosed with HCC and treated with SBRT between January 2007 and December 2011 was collected from two Montreal institutions. Patient characteristics and tumor features, as well as treatment details were obtained from chart review. Eight patients were treated by Cyberknife with synchrony fiducial tracking. The other eight patients treated were treated using conventional isocentric linear accelerators with fiducial-aided respiratory gating. The tolerance dose for the liver used in plan design was the biological equivalent of 700 cc of liver irradiated to less than 15 Gy in 3 fractions.
Results: The mean age of patients treated was 68 years old (range 49−83). Mean follow-up period from time of SBRT was 5.5 month (range 0.97–45.5). Nine patients were classified as a Child-Pugh class A, 4 were class B, and 1 patient was class C. Previous ablative treatments had been attempted in 46% of patients. The mean maximal tumor dimension was 3.75 cm (range 1.4−8.0 cm) and mean gross tumor volume was 52 cc. Nine patients received SBRT administered in 3 fractions (dose 30−45 Gy), four patients received 5 fractions (dose 24−50 Gy), one patient received 6 fractions (total dose 30 Gy), and one patient received 10 fractions (total dose 40 Gy) due to proximity to the stomach. Four patients developed acute SBRT-related toxicity, with two patients complaining of transient abdominal pain, one patient had grade I nausea, and one patient developed grade III dermatitis at the sites of beam entry. Actuarial two-year overall survival was 63%. Two-thirds of deaths were related to intra-hepatic progression. One patient is alive following liver transplant (with complete pathological response) and 2 patients had no residual HCC seen on repeat biopsy. So far, only 2 patients have had progression of the treated lesion.
Conclusion: Although our series is limited in size and follow-up, it confirms that SBRT is a well-tolerated treatment for HCC with the potential for complete response and long-term control in patients ineligible for surgery or other local ablative therapies.
No conflict of interest.

2558 POSTER

IMRT in carcinoma anal canal: Initial dosimetric analysis of a prospective study

S. Mallick[1], S. Sharma[1], R. Benson[1], P.B. Chaudhari[1], V. Roshan[1], D. Mondal[1], A. Sharma[1], S. Pathy[1]. [1]*All India Institute of Medical Sciences, Radiation Oncology, New Delhi, India*

Background: The cornerstone for the treatment of carcinoma anal canal remains concurrent chemo radiotherapy (CTRT). The conventional radiotherapy technique is associated with higher acute toxicity and treatment interruptions, thereby obscuring local control. We are presenting the dosimetric data of IMRT for carcinoma anal canal from a prospective study.
Methods: We prospectively enrolled patients with carcinoma anal canal to undergo CTRT. The radiation was planned by IMRT technique. The CTV-A has been delineated as the GTV with a 3 cm expansion limiting from the bones and uninvolved muscles. The nodal CTV (CTV-B) included the internal iliac, Obturator, External Iliac, Presacral and B/L inguinal group of lymph nodes. 1 cm expansion was used to form the PTV. The PTV-A received 54 Gy in 30 fractions over a period of 6 weeks, except for T2N0 where the dose was delivered in 28 fractions. The dose for PTV-B varied, with T2N0 recieving42 Gy in 28 fractions, while T3-T4 with N0, a dose of 45 Gy, while for Node<3 cm dose of 50.4 Gy and node >3 cm dose of 54 Gy, were given in 30 fractions. All patients were planned with Eclipse planning system version 6.5 with 7 field IMRT using 6 MV photon beam. All patients received concurrent chemotherapy with InjCisplatin and Inj 5FU. Grade III and Grade IV toxicity was taken as indication for admission. All patients were assessed for response and salvage APR done after 6 weeks.
Results: We analyzed data from four patients. All but one patient was female. Median age at diagnosis 52 years (Range: 50−65 years). Bleeding Per rectum (2) and local pain (2) were the most common presenting symptom. Smoking history was associated with three patients. Three patients were in stage II and One in stage III. Treatment plan remained CTRT (2) or NACT followed by CTRT (2). Median V35, V40, V50 for bladder was 55.32%, 42.13%, 21.92%. Median V30, V40, V44 for Left Femur was 97%, 25.16%, 0.71% and Right femur 100%, 43%, 2.26%. Median V30, V35, V45, V50 for small intestine was 164.7 cc, 123.95cc, 53.61 cc, and 1.21 cc. Median V30,V35,V45 and V50 for large intestine was 88.78 cc,39.96 cc,71.95 cc. Median Conformity and homogeneity index were 1.26 (Range: 1–1.55) and 1.1 (Range: 1.09–1.11).
Conclusion: The dosimetric data shows good sparing of critical normal organs and conformal dose distribution. This can predict reduced radiation side effect and treatment interruption with better local control.
No conflict of interest.

2559 POSTER

Noncoplanar three-dimensional radiation therapy for advanced hepatocellular carcinoma

S. Sugahara[1], T. Ikegami[2], S. Yara[2], M. Okubo[3], R. Mikami[4], S. Nogi[4], H. Nakayama[4], F. Kotake[1], Y. Matsuzaki[2], K. Tokuuye[4]. [1]*Tokyo Medical University Ibaraki Medical Center, Radiology, Ami-machi Ibaraki, Japan;* [2]*Tokyo Medical University Ibaraki Medical Center, Gastroenterology and Hepatology, Ami-machi Ibaraki, Japan;* [3]*Tokyo Medical University Hachioji Medical Center, Radiology, Hachioji Tokyo, Japan;* [4]*Tokyo Medical University, Radiology, Tokyo, Japan*

Background: Standard treatments for patients with hepatocellular carcinoma (HCC) are surgery, radiofrequency ablation (RFA) and transcatheter arterial chemoembolization (TACE). However, for patients limited use of these treatments, the efficiency of radiation therapy (RT) has been indicated. In our institution, noncoplanar three-dimensional radiation therapy (NC3DRT) had been performed to increase the efficiency of RT without damaging of the normal liver for advanced HCC from 2010. The purpose of this retrospective study was to evaluate the feasibility and safety of NC3DRT for the treatment of advanced HCC with/without tumor thrombosis.
Material and Methods: From July 2010 to January 2013, 17 patients with advanced HCC were treated with NC3DRT at our institution. Eleven men and six women ages 54 to 86 years (median, 72 years) were included in the study. Of these patients, 11 presented with tumor thrombus in the portal vein (10 patients) or inferior vena cava (one patients). The longest diameter of the lesions ranged in size from 30 mm to 80 mm (median, 45 mm). A total dose of 60 Gy in 30 fractions over the 6 weeks was delivered with noncoplanar three-dimensional technique to a target volume that encompassed the HCC with/without tumor thrombus.
Results: Fifteen patients were local progression-free during a median follow-up period of 8 months (ranging from 3 to 26). Two patients experienced progressive disease. Of these patients, one had tumor progression during treatment and died 3 months after the beginning of

NC3DRT, remaining one patient suffered marginal recurrences 2 months after NC3DRT and died of progressive disease 6 months after the beginning of NC3DRT. Eight patients died and the remaining nine patients were alive as of March 2013. Two patients died of multiple tumors in the liver, two of distant metastases, two of progressive primary tumor as mentioned above, and two of liver failure, respectively. Local progression-free survival rates were 54% at 1 year and 27% at 2 years. No toxicity forced the patients to discontinue the treatment. According to the National Cancer Institute's Common Toxicities Criteria for Adverse Events, version 3.0 (CTCAE v3.0), no acute and late toxicities of grade 3 or higher were observed.
Conclusions: NC3DRT of 60 Gy in 30 fractions seems a safe and effective for patients with advanced HCC.
No conflict of interest.

2560 POSTER

Brain metastases from stomach cancer − the role of different treatment modalities and efficacy of palliative radiotherapy

M. Kraszkiewicz[1], M. Jerzy Wydmanski[2], M.D. Agnieszka Namysl-Kaletka[2], M.D. Rafal Kawczynski[2], M.D. Marcin Bialas[2]. *[1]Center of Oncology M. Sklodowska-Curie, Gliwice, Poland; [2]Center of Oncology M. Sklodowska-Curie, Radiotherapy Department, Gliwice, Poland*

Introduction: Brain metastases from stomach cancer are usually late manifestation of the disease and patients are often in severe cachexia and in bad performance status. There are few literature studies concerning this group of patients, thus the authors decided to evaluate the efficacy of palliative radiotherapy and to describe different treatment modalities and sequences − surgery plus SRS and WBRT, surgery plus WBRT, SRS plus WBRT and WBRT only.
Materials and Methods: Between 2002 and 2011 a total of 16 patients were diagnosed with brain metastases from stomach cancer at Centre of Oncology Institute Maria Sklodowska-Curie Memorial in Gliwice. The data of all the patients were collected and retrospectively analyzed. The patients ranged in age from 51 to 75 years (median 68.5 years). There were 11 men (69%) and 5 women (31%). All patients had histologically verified gastric cancer. Primary metastatic gastric cancer was diagnosed in 6 patients (37.5%), and in 3 cases (18.75%) it was metastasis to the brain.
Results: Median time to brain metastases (TBM) was 12.3 months. Median TBM was shorter for patients with pretreatment metastases to other organs compared with patients without metastases (5.5 months vs. 12.6 months, $p = 0.042$). Median TBM were 12.8 months (range, from 0.8 month to 52 months) and 5.4 months (range, from 0.8 month to 52 months), respectively for 9 patients after R0 resection and for 7 remaining patients. The following clinical features were not prognostic for TBM: gender, age, number, location and largest size of brain metastases, location of other metastases.
The 1- and 2-year OS were 19% and 12.7%, respectively (median OS was 2.8 months). Amongst different clinical factors influencing OS, performance status, number of metastases, pattern of metastases, type of treatment, were statistically significant.
There was no statistically significant effect noted on OS for gender, grade, types of neurological symptoms, or location and largest size of brain metastases. However, patients under the age of 60, and patients with TBM less than 6 months tend to have a more favorable prognosis ($p < 0.1$).
Conclusions: Brain metastases from gastric cancer are very rare and difficult to treat. The response to radiotherapy is worse than in brain metastases from other cancers and the survival is also shorter. Therefore very aggresive treatment schemes are needed to improve the outcome.
The results of this study show that combining neurosurgery with adjuvant radiotherapy and chemotherapy is improving the survival. Our study also indicates the prognostic factors which may be helpful in considering the best treatment options.
No conflict of interest.

2561 POSTER

Radiochemotherapy with capecitabine after surgery for adenocarcinoma of the stomach or gastroesophageal junction

B. Grozdanovska[1], A.N. Angelovska Natalija[1], M.N. Mitrevski Nenad[1], S.Z. Stefanovski Zoran[2]. *[1]University Clinic of Radiotherapy and Oncology, Skopje, Macedonia; [2]University Clinic of Radiotherapy and Oncology, Medical Physicist, Skopje, Macedonia*

Background: Surgical resection of adenocarcinoma of the stomach is the only curative modality. After surgery alone, more than 60 % of the patients will develop distant metastasis or local recidiv.
The Intergroup Study INT-0116 reported significant improvent in survival in patients with resected adenocarcinoma of the stomach or gastro esophageal junction with adjuvant radiochemoterapy.
In the Republic of Macedonia, patients are treated with adjuvant radiochemotherapy, 5-fluorouracyl and leucovorin and 2D radiotherapy since 2002.
In this study we replace 5-fluorouracyl, leucovorin chemotherapy with oral Capecitabine, and instead of 2D we used 3D radiotherapy.
Patients and Method: During 2011–2012, 32 patients with the mean age of 56 years were treated with chemo radiotherapy after surgery for adenocarcinoma of the stomach or gastro esophageal junction. Patients were staged Ib-IIIC, with R0 or R1 resection, (26 patients with R0, and 6 patients with R1 resection).
Patients were treated with one cycle chemotherapy with Capecitabine ($1250\ mg/m^2$) twice daily on day 1−14. After 3 weeks we started with 3D radiotherapy to total dose 45 Gy delivered in 5 weeks, daily dose 1.8 Gy. Computer tomography- based 3 dimensional RT planning was previously performed and radiotherapy was delivered with 15-MV photons, generally by 3 field technique. CTV was defined using preoperative computer tomography, endoscopic findings, stapler. LNs as described in Intergroup 0116 study. Anastomotic regions and safety margin around the former tumor 3 sm. PTV was calculated with 1 sm margin over CTV. The design of the treatment field was individualized according to tumor stage, localization and the type of surgery.
Chemotherapy during irradiation was administered with daily dose $825\ mg/m^2$ twice daily, 5 days per week. First dose was taken 1 hour before irradiation and the second dose 12 hours lately. After finishing irradiation three more cycle chemotherapy were added in 3-week intervals.
Results: The treatment was completed according to the protocol in 26 patients. No death occurred due to the therapy.
Nausea and vomiting, diarrhea, hand foot syndrome, stenocardia, dysphagia grade three occurred in 2, 6, 1, 2, and one patient respectively.
10 patients lost more than 10% body weight (range 10−18%).
At the firs follow up visit, 3 months after completion of treatment all 26 patients were alive, with no side effects of radio chemotherapy.
Conclusion: Adjuvant 3D radio chemotherapy with capecitabine in patients with gastric cancer is feasible and toxicity is low.
No conflict of interest.

2562 POSTER

Quality assurance in lymphadenectomy for gastric cancer in the Dutch randomized gastric cancer trial

W.O. De Steur[1], J.L. Dikken[2], H. Putter[3], H.H. Hartgrink[4], C.J.H. Van de Velde[4]. *[1]Leiden University Medical Center, Surgery, Leiden, Netherlands; [2]Medical Center Haaglanden, Surgery, The Hague, Netherlands; [3]Leiden University Center, Medical Statistics, Leiden, Netherlands; [4]Leiden University Center, Surgery, Leiden, Netherlands*

Background: After a median follow up of 15 years a D2 lymphadenectomy was associated with lower local recurrence and lower gastric cancer related death rates rather than D1 surgery. Several Japanese authors, of high volume institutions with better survival results, argued that a proper a D2 dissection is technically demanding that learning curves had not reached the plateau at the end of the trial. In order to assess the impact of quality assurance prospectively, non-compliance and contamination in both the study arms was investigated with respect to recurrence and survival.
Methods: 1078 patients were included in the trial. 711 patients with potentially curative resections were evaluated. Location and numbers of lymph nodes detected at pathological investigation were compared according to the guidelines of the Japanese Research Society for the study of Gastric Cancer. *Non-compliance* was defined as inadequate removal of lymph node stations and *contamination* was defined as lymph nodes removed outside the intended level of resection. The dissection groups D1 and D2 were divided into non compliant, compliant and contaminated. Long term overall survival was calculated for minor ($\leqslant$2 lymph nodes) and major ($\geqslant$3 lymph nodes) non-compliance and minor ($\leqslant$2 lymph nodes) and major ($\geqslant$3 lymph nodes) contamination in the D1 and D2 group, using Kaplan–Meier plots.
Results: Overall noncompliance was 80.6% in the D1 and 81.5% in the D2 group. In the D1 group minor non-compliance was present in 65.3% and for the D2 group 55.6%. Long-term survival for the correct dissected D1 group (minor non compliance + compliance, $n = 319$) and correct dissected D2 group (minor non compliance + compliance, $n = 245$) was 23.2% versus 32% ($P = 0.259$). When all patients with a accidental spleen resection were excluded the survival was 23.3% for the D1 group versus 39% for the D2 group. ($P = 0.004$) In the D2 dissection group contamination also leads to better survival. In both groups compliance leads to better survival rates.
Conclusion: After 15 years of follow up quality assurance by compliant D2 dissection leads to better survival.
No conflict of interest.

2563 POSTER

Interim analysis of a phase II trial of neoadjuvant chemoradiation therapy followed by conventional resection for cholangiocarcinoma

Y. Katayose[1], K. Nakagawa[1], H. Yoshida[2], H. Hayashi[2], T. Okada[2], S. Ottomo[2], M. Mizuma[2], K. Fukase[2], F. Motoi[2], M. Unno[3]. *[1]Tohoku University Graduate School of Medicine, Integrated Surgery and Oncology, Sendai, Japan; [2]Tohoku University Graduate School of Medicine, Hepato-biliary Pancreatic Surgery, Sendai, Japan; [3]Tohoku University Graduate School of Medicine, Surgery, Sendai, Japan*

Background: Cholangiocarcinoma has one of the worst prognoses among GI tract cancers. To improve the prognosis of cholangiocarcinoma patients, we have applied neoadjuvant chemoradiation therapy followed by conventional resection for possibly resectable cholangiocarcinoma. We published the phase I study (Hepatogastroenterology. 2011;58:1866−72) and showed that neoadjuvant chemoradiation with conventional resection was safe and tolerable. Then, we proceeded Phase II study (P-2). Here, we evaluated P-2 as an interim analysis and compared the P-2 group and 99 patients who were operated on using conventional resection at the same stage and same period as the P-2 group in terms of the perioperative factors and effectiveness.
Material and Methods: Regimen of P-2 was 600 mg/m^2 of gemcitabine (day 1 and 8 x 2 courses) with external beam radiation therapy (1.8-Gy daily fractions to a total dose of 45 Gy). Patients with histologically or cytologically confirmed adenocarcinoma of the extra- and hilar cholangiocarcinoma were enrolled from 2008 to June 2012 at Tohoku University Hospital. The primary endpoint was the R0-resection rate. We thought the R0-resection rate was 60% referring to our previous data, assumed that it would increase to 80% with neoadjuvant chemoradiation treatment and calculated that the number of samples would be 36 cases under the condition that α was 0.05 and the power of the test was 0.8 (β was 0.2). We determined that the enrolment should be 40 cases assuming 10% of the patients would drop out.
Results: 22 patients were enrolled in P-2. 21 patients received complete chemoradiation. Only one case was not completed because of the adverse event of Grade 3 appetite loss. 19 cases were operated on, and 18 cases were resected. 3 cases were not operated on. 2 cases were progressing disease, and one was heart failure. The R0-resection rate of the P-2 group and conventional resection group was 62%(13 cases out of 22 cases) and 36%(36 cases out of 99 cases), respectively ($p < 0.05$). Intraoperative bleeding, operative duration and hospital stay after surgery were not significant (Table 1), and surgical site infection (SSI) was also not significant.
Conclusions: Neoadjuvant chemoradiation therapy with conventional resection appears to be effective and well tolerated. The study is continuing as scheduled to further evaluate the benefits of this regimen.
Trial registration: UMIN Clinical Trials Registry (UMIN-CTR) UMIN UMIN000000992 and UMIN000001754.
No conflict of interest.

Table 1. Perioperative factors

	P-2 Group	non-P-2 Group	p value
Operative bleeding (median)	1426 ml	1486 ml	n.s.
Operative duration (median)	618 min	622 min	n.s.
Hospital stay after operation (median)	30 days	31 days	n.s.

2564 POSTER

Risk factors for non-curative resection of early gastric neoplasms performed endoscopic submucosal dissection: Analysis of 1123 lesions

T. Toyokawa[1], T. Inaba[2], K. Izumikawa[2], I. Fujita[1], S. Ishikawa[2], J. Tomoda[1]. *[1]National Hospital Organization Fukuyama Medical Center, Department of Gastroenterology, Fukuyama, Japan; [2]Kagawa Prefectural Central Hospital, Department of Gastroenterology, Takamatsu, Japan*

Background: The frequency of residual disease and recurrences after endoscopic submucosal dissection (ESD) has markedly decreased compared with conventional endoscopic mucosal resection because ESD procedure facilitates *en bloc* resection. However, a few cases of residual disease and recurrences have been observed after non-curative resection by ESD.
Materials and Methods: We investigated 1123 early gastric neoplasm lesions treated by ESD at three institutions. Non-curative resection was defined as histological positivity of the resected margins, vascular invasion, or failure of *en bloc* resection. Initially, the reasons for non-curative resection were classified as inadequate technique, pre-procedural misdiagnosis, or problems in histological diagnosis. Following this, a comparison between cases of non-curative and curative resection was made on the basis of following patient characteristics: size, type, and location of lesions; as well as procedure time. Statistical analyses were performed using the chi-square test and logistic regression analysis. Statistical significance was deemed at $p < 0.05$.
Results: The frequency of non-curative resection was 16% (182 lesions). The reasons for non-curative resection were as follows: inadequate technique for 59 lesions (32%), pre-procedural misdiagnosis for 88 lesions (48%), and problems in histological diagnosis for 35 lesions (19%). Univariate analysis indicated that the risk factors for non-curative resection due to inadequate technique were large lesion size, lesion complicated with an ulcer scar, long procedure time, and inexperienced endoscopists. Multivariate analysis revealed that large lesion size [odds ratio (OR): 1.05, 95% confidence interval (CI): 1.03–1.07], long procedure time (OR: 1.01, 95% CI: 1.00–1.01), and inexperienced endoscopist (OR: 1.63, 95% CI: 1.18–2.26) were associated with a significantly higher risk of non-curative resection due to inadequate technique. Univariate analysis indicated that the risk factors for non-curative resection due to pre-procedural misdiagnosis included lesions located in the upper area of the stomach, large lesion size, cancer with submucosal invasion, and inexperienced endoscopists. Multivariate analysis revealed that lesions located in the upper area of the stomach (OR: 1.74, 95% CI: 1.02–2.97), and cancer with submucosal invasion (OR: 24.4, 95% CI: 13.9–41.7) were associated with significantly higher risk of non-curative resection due to pre-procedural misdiagnosis.
Conclusions: This study demonstrated that the major reasons for non-curative resection were inadequate technique and pre-procedural misdiagnosis. Furthermore, risk factors for these were clarified. These results highlight the need to conduct ESD procedures more accurately in cases of early gastric neoplasms.
No conflict of interest.

2565 POSTER

Failure-to-rescue after gastric and oesophageal cancer resection: Results of the Dutch Upper GI Cancer Audit (DUCA)

D. Henneman[1], J.W. Van Sandick[2], On behalf of the DUCA working group (M.I. van Berge Henegouwen, K. Bosscha, A. Cats, J.L. Dikken, N.C.T. van Grieken, H.H. Hartgrink, R. van Hillegersberg, P. de Jong, V.E.P.P. Lemmens, G.A.P. Nieuwenhuijzen, J.T. Plukker, C. Rosman, T. Rozema, P.D. Siersema, G.W.M. Tetteroo, P.M.J.F. Veldhuis, B.P.L. Wijnhoven). *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Nederlands Kanker Instituut- Antoni van Leeuwenhoek ziekenhuis, Surgical Oncology, Amsterdam, Netherlands*

Background: In the Dutch Upper GI Cancer Audit (DUCA), as well as other recent studies in the Dutch setting, mortality after surgery with curative intent appears to be higher in gastric cancer patients than oesophageal cancer patients. The purpose of this study was to evaluate differences in postoperative mortality after gastrectomy and oesophagectomy in relation to casemix and failure-to-rescue (FTR) from complications.
Methods: All patients who underwent gastrectomy or oesophagectomy for cancer and registered in the nationwide Dutch Upper GI Cancer Audit in 2011–2012 were selected. FTR was defined as mortality among patients with postoperative complications.
Results: In total, 663 gastric cancer and 1210 oesophageal cancer patients underwent potentially curative surgery in 46 and 25 hospitals, respectively. Patients undergoing gastrectomy were older (mean 68 vs. 64 years), and had more comorbidity (16 vs. 8.4% Charlson comorbidity index of 3 or higher) as compared to oesophageal cancer patients.
The postoperative complication rate was lower after gastrectomy than oesophagectomy (38% versus 59%; $p < 0.001$), but postoperative mortality was higher: 6.6% versus 4.2% ($p < 0.001$). FTR after gastrectomy was significantly higher than after oesophagectomy: 18% versus 7.2% ($p < 0.010$). FTR and associated mortality rates were highest after partial gastrectomy (table 1).

Table 1. postoperative complication-, failure to rescue (FTR)- and mortality rates per type of resection

	Postoperative complications	FTR	Postoperative mortality
Transhiatal oesophagectomy	50%	7.4%	3.7%
Transthoracic oesophagectomy	66%	7.0%	4.6%
Total gastrectomy	39%	13%	4.9%
Partial gastrectomy	35%	22%	7.8%

FTR was significantly higher after gastrectomy than after oesophagectomy when associated with clinical anastomotic leakage (40% for gastrectomy vs 12% for oesophagectomy patients, $p < 0.001$), pulmonary complications

(25% vs. 9.5%, p < 0.001) and cardiac complications (38% vs. 12%, p < 0.001).
Adjusted for age, Charlson comorbidity score, American Society of Anesthesiologists score, body mass index, TNM stage, neoadjuvant therapy and medication use, the difference in mortality after gastrectomy versus oesophagectomy lost statistical significance (Odds ratio 1.16 [95% CI 0.59−2.3]), while the difference in FTR remained (Odds ratio 2.1 [95% CI 1.02–4.01]).
Conclusions: Gastrectomy patients had a 2-fold higher risk of dying from a postoperative complication than oesophagectomy patients. Adequate management of postoperative complications as well as strict patient selection for surgery appears to be crucial in this vulnerable patient group.
No conflict of interest.

2566 POSTER

Long-term outcomes and prognostic factors of T1 squamous cell carcinoma of the esophagus after esophagectomy

T. Tanaka[1], S. Matono[1], N. Mori[1], K. Nishimura[1], K. Shirouzu[1], H. Fujita[2]. *[1]Kurume University School of Medicine, Surgery, Kurume, Japan; [2]Fukuoka Wajiro Hospital, Surgery, Fukuoka, Japan*

Background: Although superficial (T1) esophageal cancer has been separated into mucosal (T1a) and submucosal (T1b) cancer, T1a and T1b esophageal squamous cell carcinoma (ESCC) have often been analyzed together and are staged as the same category in the UICC/TNM staging system. The difference in surgical outcomes between T1a and T1b ESCC therefore remains unclear. The purpose of this study was to examine the differences in surgical outcomes between T1a and T1b ESCC, and to investigate the prognostic factors in T1 ESCC.
Methods: A prospectively maintained database identified 145 previously untreated patients with pT1 ESCC who underwent radical transthoracic (n = 134) or transhiatal esophagectomy (n = 11). Median follow-up was 108 months.
Results: All patients received R0 resection. Of the 145 patients, 35 (24%) had pT1a cancer and 110 (76%) had pT1b cancer. Lymph node metastasis was present in 45 patients (31%): 3 patients with pT1a cancer and 42 patients with pT1b cancer (P = 0.003). Lymphovascular invasion and Grade 2/3 were also more frequent in pT1b cancers than pT1a cancers (P <0.0001, P = 0.0258) The overall 5-year survival rate for the whole group was 77%. The 5-year survival rate of the pT1a patients was 94% compared with 72% for the pT1b patients (P = 0.282). In multivariate analysis, only the depth of tumor invasion (pT1a vs pT1b) was an independent prognostic factor (hazard ratio, 2.358; 95% confidence interval, 1.009–5.513; P = 0.0477).
Conclusions: The prognosis of patients with pT1b ESCC is significantly worse than that of patients with pT1a ESCC after esophagectomy. Submucosal invasion is the only independent prognostic factor affecting survival in patients with pT1 ESCC. These findings suggested that T1a and T1b ESCC could be staged separately in the next version of UICC/TNM staging system.
No conflict of interest.

2567 POSTER

More pathologically complete responders after a longer interval between chemoradiotherapy and surgery for oesophageal cancer

J. Shapiro[1], P. Van Hagen[1], K. Biermann[2], F.W.J. Ten Kate[2], B.P.L. Wijnhoven[1], J.J.B. Van Lanschot[1]. *[1]Erasmus MC, Surgery, Rotterdam, Netherlands; [2]Erasmus MC, Pathology, Rotterdam, Netherlands*

Background: The tumor regression grade (TRG) in the resection specimen has been recognised as a valuable prognostic factor for survival in patients who underwent neoadjuvant chemoradiotherapy (CRT) for oesophageal cancer. Little is known about the influence of the length of the interval between neoadjuvant CRT and surgery on the TRG observed in the resection specimen. Aim of this study was to determine the correlation between this interval and TRG.
Methods: Patients treated with neoadjuvant CRT (5 weekly courses of Carboplatin and Paclitaxel with 41.4 Gy concurrent radiotherapy) for resectable oesophageal cancer between 2002 and 2009 were identified. Patients with irresectable tumors were excluded. The interval between the end of neoadjuvant CRT and surgery, and the TRG in the resection specimen, including adjacent lymph nodes, were determined for each patient.
Results: Two hundred and forty-seven patients were included. Median age was 59.8 years and the majority of patients (74.5%) had an adenocarcinoma. A microscopically radical resection was performed in 234/247 (95%) patients. The median interval between CRT and surgery was 47 days [p25-p75: 39−56]. No significant differences were found in TRG distribution between patients with intervals above and below the median interval length. The percentage of pathologically complete responders (TRG1) was 43% in patients with an interval of more than 55 days (>p75) vs. 24% in patients with an interval of less than 56 days (<p75) (p = 0.005) There was no significant difference in the proportion of adeno- and squamous cell carcinomas between the 4th and the remaining quartiles. Median follow-up for surviving patients was 50.7 months. Disease free survival (DFS) was not significantly different between patients with intervals above and below the median interval (HR 2.1; 95% CI 0.6−7.2). There was no significant difference in DFS between patients with an interval above or below the 75Th percentile (HR 1.01 95% CI0.63–1.62).
Conclusion: In patients with a relatively long interval (>p75) between CRT and surgery, more pathologically complete responders were observed. These results suggest that prolonging the interval between CRT and surgery might increase the pathologically complete response rate.
No conflict of interest.

2568 POSTER

Anti-reflux hand-sewn esophago-jejuno anastomosis following total gastrectomy for gastric cancer

G.V. Bondar[1], Y.V. Dumanskiy[1], O.N. Zaika[1], A.V. Bondar[1]. *[1]Donetsk Cancer Center, Surgical, Donetsk, Ukraine*

Background: Gastrointestinal tract reconstruction is a key procedure in surgery for gastric cancer. Hand-sewn anastomosis after total gastrectomy accompanied relatively high frequency anastomotic leakage. Stapling devices reduce the leakage rate of digestive tract anastomoses, but they increase the risk of strictures, reflux esophagitis and frequency of dumping syndrome. Quality of life in patients after gastrectomy is largely dependent on the method of formation of the esophago-jejuno anastomosis.
Aim: The aim of our study is to evaluate the results of the anti-reflux hand-sewn esophago-jejuno anastomosis by the method of Bondar Gr.V. after total gastrectomy.
Materials and Methods: The Donetsk regional anticancer center has experience in treating 15 000 patients with gastric cancer. We retrospectively reviewed 1477 consecutive patients who underwent total gastrectomy using hand-sewn esophago-jejuno anastomosis at our center between January 1986 and December 2005. There were 65.9% male, mean age was 58.5 years. 81.0% of patients had stage III−IV disease. In all cases applied the anti-reflux hand-sewn esophago-jejuno anastomosis by the method of Bondar Gr.V. Multivisceral en bloc resection were performed in 23.5% of patients, palliative gastrectomy occurred in 20.3% of cases. Functional results and quality of life were studied in terms of 1–240 months after surgery.
Results: There were no technical problems with the technique of forming an anastomosis. The overall morbidity and mortality were 19.1% and 3.7% respectively. Anastomotic leakage occurred only in 1.1%. Five-year survival rates were 35.0%. Anastomotic stricture occurred in 6.4% patients and reflux esophagitis was observed in 6.7% cases. Incidences of dumping syndrome were 7.7%.
Conclusion: Anti-reflux hand-sewn esophago-jejuno anastomosis by the method of Bondar Gr.V. after total gastrectomy led to a reduction in the incidence of anastomotic leakage. The use of this method can minimize the risk of anastomotic stricture, reflux esophagitis and dumping syndrome.
No conflict of interest.

2569 POSTER

Adjuvant endoaortic regional chemotherapy in treatment of extraorgan retroperitoneal tumors

M. Djuraev[1], O. Nematov[1]. *[1]National Cancer Research Center of Uzbekistan, Abdominal Oncology, Tashkent, Uzbekistan*

Background: To improve the results of combined treatment of extraorgan tumors of retroperitoneal space.
Materials and Methods: The research was carried out on 96 patients with extraorgan retroperitoneal tumors during 1996–2009. Patients ranged in age from 18−68 years old, 62 men (63.3%), 34 women (34.7%). According to histological classification 26 patients (26.5%) were diagnosed angiosarcoma, 38 patients (38.8%) fibrosarcoma, 25 patients (25.3%) liposarcoma and 9 patients (9.2%) neurosarcoma. All patients underwent tumor removal, from them in 44 cases (42.8%) were performed combined resections, which include except tumor removal resection of small and large intestines, nephrectomy, tubovarectomy, splenectomy, resection and prosthetics of main vessels, resection of the bladder and others. Depending on the methods of chemotherapy patients were divided into 2 groups: Group 1−53 patients after retroperitoneal space tumor removal were conducted 2 courses of systemic chemotherapy with an interval of 21 days. Group 2−45 patients after tumor removal were conducted 2 courses of prolonged endoaortic regional chemotherapy with an interval of 21

days. For the implementation of prolonged endoaortic chemotherapy was performed catheterization of aorta through the femoral artery by Seldinger and catheter was placed at the level of diaphragm, above the celiac trunk. Establishing at this level provides wide distribution of chemotherapy drugs to the visceral branches of the abdominal aorta, which are the source of blood supply to the tumor and possible regional metastases. Both groups used Doxorubicin 60 mg/m^2, 500 mg/m^2 Ifosfamide and Vincristine 1.5 mg/m^2. Treatment in the first group was held for 3 days and in the second group for 72 hours continuously.
Results: Complications associated with adjuvant chemotherapy in both groups were not observed. Within 5 years in the first group relapses and metastases occurred in 42% and 41% of the patients respectively. Moreover, the combination of relapses and metastases were observed in 33.9% of the patients. In the second group for the same period the relapses appeared in 31.7% of the patients, metastases in 26.6% of the patients, combined relapses with metastases were observed in 31.1% of the patients. 5-year survival rate is 26.9±2.5 in the first group and 25.5±1.9 in the second group. Observations for 10 years has shown that in the first group 73.6% of the patients died from relapses and metastases, and 9.4% died from other causes unrelated to the tumor. 10 years survival was 17±1.4%. In the second group within 10 years 67.8% of the patients died because of relapses and metastases and the percentage of the patients who died because of other causes unrelated to the tumor was 8.8% and 10 years survival rate was 24.4±1.8% in this group.
Conclusion: Prolonged adjuvant endoaortic regional chemotherapy in the cases of extraorgan retroperitoneal tumors significantly reduces the incidence of relapses and metastasis and increases 5 and 10 years survival.
No conflict of interest.

2570 POSTER

Adequacy and impact on survival of lymph node harvesting in gastric cancer

F. Sicoli[1], R. Persiani[1], F.C.M. Cananzi[1], A. Biondi[1], M. Degiuli[2], G.B. Doglietto[1], F. Santullo[1], D. D'Ugo[1]. *[1]Catholic University "A. Gemelli" Hospital, Department of Surgery, Roma, Italy; [2]"San Giovanni Battista" Hospital, Abdominal Surgery Unit, Torino, Italy*

Background: According to the TNM classification, 16 or more lymph nodes are required for appropriate staging of gastric cancer. The aim of this study was to evaluate whether this number of resected lymph nodes affects survival as well.
Materials and Methods: This is a multicentric retrospective study based on an analysis of 992 patients with gastric adenocarcinoma who underwent curative resection (R0) between January 1980 and December 2009. Patients were classified according to the number of resected lymph nodes in <16 lymph nodes and those with >16, the anatomical extent of lymph node dissection (D2 vs D1) and according to the VII edition of the UICC/AJCC TNM staging rules. Survival estimates were determined by univariate and multivariate analyses.
Results: At univariate and multivariate analysis, resection of 16 or more lymph nodes was associated with significantly better survival results [p = 0.002; HR (95% CI): 0.519 (0.345–0.780)]. We modified the pN-TNM stage including the lymph node count obtaining eight new subgroups. Patients with a lymph node count <16 had significantly worse survival rate than >16 group in pN0 (p = 0.001), pN1 (p = 0.007) and pN2 (p = 0.001) but no differences in pN3 stage. In the majority of cases >16 lymph nodes were retrieved when D2 dissection was performed.
Conclusions: In gastric cancer, removal of 16 or more lymph nodes accomplished through a D2 lymph node dissection, significantly affected survival.
No conflict of interest.

2571 POSTER

D1-extra lymphadenectomy for gastric carcinoma; high yield, low morbidity and mortality

A. Dassen[1], D.J. Lips[1], V.E.P.P. Lemmens[2], A.A.M. Van der Wurff[3], K. Bosscha[1]. *[1]Jeroen Bosch Hospital, Surgery, Den Bosch, Netherlands; [2]The South Netherlands Eindhoven Cancer Registry, Epidemiology, Eindhoven, Netherlands; [3]St Elisabeth Hospital, Pathology, Tilburg, Netherlands*

Background: The surgical treatment of gastric cancer consists of a (partial) gastric resection with a lymphadenectomy with a recommended yield of at least 15 lymph nodes, a yield which is normally not met in the Netherlands. Studies conducted in the West comparing a D1 versus a D2 resection did not show an improved survival due to high morbidity and mortality rates in the D2 group. In the southern part of the Netherlands a multicenter phase II study has been conducted investigating the feasibility of, besides neoadjuvant chemotherapy, an extended standardized lymphadenectomy, the so-called D1-extra lymphadenectomy.
Methods: Patients with curable gastric carcinoma (including Siewert 2 and 3 tumours), were treated with 4 cycles of docetaxel (60 mg/m^3 IV day 1), cisplatin (60 mg/m^3 IV day 1) and capecitabine (1.875 mg/m^3 PO day 1−14) every three weeks, followed by standardized (partial) gastric resection and lymphadenectomy. Lymph node stations 3−9 were removed and depending on location of the tumour, stations 1, 2, 10 and 12 (Japanese classification). Pathologic investigation was performed according to a set protocol and all specimens were revised by one pathology center. Descriptive statistics were used to evaluate nodal yield and rates of adverse events.
Results: In total, 51 patients were included, 47 proceeded to surgery. At the time of submission of this abstract data on 37 patients who underwent surgery were available. A mean of 27 nodes was harvested (30 after revision). The median number of harvested nodes was 26 (range 4−52); after revision 30 (range 13−58). Ten serious adverse events (SAE) after surgery were reported. One patient died due to small bowel necrosis and one patient died within 30 days after surgery in a hospice due to his own wish; the other SAE's resolved without sequelae.
Conclusion: Due to the introduction of a standardized D1-extra lymphadenectomy a high yield of lymph nodes was achieved was meeting the threshold as stated by guidelines according to the UICC/AJCC. Morbidity and mortality seem to be very acceptable.
No conflict of interest.

2572 POSTER

Evaluation of aortic non-involvement of esophageal squamous cell cancer by electrocardiogram-gated 320-row area detector computed tomography

K. Shuto[1], M. Yamazaki[1], T. Kosugi[1], K. Koda[1], H. Matsubara[2]. *[1]Teikyo University Chiba Medical Center, Surgery, Ichihara, Japan; [2]Chiba University Graduate School of Medicine, Frontier Surgery, Chiba, Japan*

Background: However preoperative assessment of T4b to adjacent structures of esophageal squamous cell cancer (eSCC) is very important, pericardial invasion is difficult to evaluate precisely because of cardiac pulsation. The purpose of this study is to assess aortic eSCC invasion using electrocardiogram-gated area detector computed tomography (Gate CT) to eliminate the influence of motion artifact and to verify the impact of Gate CT on postoperative outcomes.
Material and Methods: Two-hundred and twenty eSCC consecutive operative patients were enrolled. Depth of tumor invasion was evaluated by routine contrast enhanced 64-row MDCT and revealed 81 pts were T3 and 139 were T4. Treatments were as follows: 50 only with surgery, 43 chemotherapy prior to surgery, 36 chemoradiotherapy prior to surgery and 91 no surgery only with chemoradiotherapy (CRT). Gate CT was performed with a 0.5-mm slice thickness following intravenous injection of contrast material. Images were obtained with retrospective ECG-gated reconstruction at early arterial phase using computer-assisted automatic bolus-tracking technique and were reconstructed every 5% of the R-to-R interval. If a hypodensity layer between the tumor and the thoracic aortic wall is observed by Gate CT animation image, the case is diagnosed as resectable non-T4 and surgical treatment was performed. We compared Gate CT findings with histological results and estimated the impact of Gate CT on postoperative survival rate.
Results: In a total of 129 surgical treated pts, who were diagnosed as clinical non-T4 by Gate CT, 124 underwent radical surgical resection of subtotal esophagectomy with lymphadenectomy and result in histological non-T4. Probe thoracotomy was performed in remaining 5. The negative predictive value (NPV) of non-T4 detection was 96% in all surgical cases. According to the neoadjuvant treatment the NPV were as follows: no treatment 98% (49/50), chemotherapy 93% (40/43) and CRT 97% (35/36). In 127 CRT pts (36+91), 36 were considered to be downstaging by Gate CT and the operation was performed and 1 result in probethoracotomy, remaining 91 were estimated as T4b by Gate CT. The five-year survival rate of these two groups were 69% and 14% (P<0.0001), respectively, with a significant difference.
Conclusions: Histological results can be proved only in clinical non-T4b cases because operations are performed for these cases. Therefore only the NPV can be assessed for T4b. Gate CT can eliminate the influence of pericardial artifact and yield a high predictive power for aortic invasion. It is a valid imaging tool for assessing aortic invasion of esophageal cancer, and patients who were suspected aortic involvement may experience a better survival benefit from Gate CT by discriminating non-T4b from T4b.
No conflict of interest.

2573 POSTER

Oesophageal cancer as a difficult clinical problem

S. Gluszek[1], M. Kot[1], B. Kotucha[1], R. Stepien[2], D. Koziel[2]. [1]*Wojewodzki Szpital Zespolony, Surgery, Kielce, Poland;* [2]*JK University, Faculty of Health Sciences, Kielce, Poland*

Background: Oesophageal cancer remains a complex clinical problem, and the results of its treatment − both surgical and combination- are still unsatisfactory. The aim of this research is a clinical analysis of a group of oesophageal cancer patients who have undergone surgical and combination therapy.
Material and Method: A group of 130 patients with diagnosed oesophageal cancer was analysed, with a special consideration to those, who have undergone resection surgery (type I and type II according to the Siewert classification). The following methods, such as an interview, measurement and analysis of medical documentation are used in research procedures.
Results: Within the group of 130 patients with diagnosed oesophageal cancer, 50 people (38.5%), have undergone resection surgery. The average age of having become ill was 59. Resection of the upper stomach and resection of the lower part of the oesophagus with the 'end-to-end' esophagogastric anastomosis was performed without opening the thorax in 8 patients; resection of the upper stomach and surgical removal of the lower part of the oesophagus with the 'end-to-side' esophagogastric anastomosis was performed through a left thoracotomy in 8 patients, a full surgical removal of the stomach and the lower part of the thoracic segment of oesophagus with the esophago-intestinal anastomosis using the Roux-en-Y method was performed without opening the thorax in the mediastinum in 11 patients, a full removal of the stomach and the lower half of the thoracic segment of the oesophagus with the esophago-intestinal anastomosis using the Roux-en-Y method in the thorax (through left thoracotomy) was performed in 8 patients; nearly full removal of the oesophagus using the Akiyama method through a right-side/right thoracotomy (esophagogastric anastomosis in the neck) was performed in 15 patients. The most numerous group (n = 21) comprised patients in $T_3N_1M_0$ stage. In all cases where the cancer was located in the lower ? of the oesophagus, *adenocarcinoma* tissue was diagnosed in histopalogical examination; whereas in the case of cancers located in one third of the middle part of the thoracic segment of the oesophagus and one third of the upper part of this segment − *carcinoma planoepitheliale* tissue. Leakiness of the anastomoses occurred in 7 patients (7/50−14%), after the Akiyama procedure in 3 patients, after resection of the upper stomach with thoracotomy in 2 patients, after gastrecotomy with thoracotomy in 2 patients. Six old patients (6/50−12%), susceptible to cardiovascular disease and in the highly advanced stage of neoplastic disease died in the post-surgery period. The average survival time in the study group of patients was two years.
Conclusions: An oesophageal and esophagogastric junction cancer is endowed with low resectivity, a high risk of complications after surgical treatment and bad oncological results. It is necessary to seek new methods of treatment.
No conflict of interest.

2574 POSTER

Minimally invasive esophagectomy: Preliminary results after introduction of intrathoracic anastomosis

F. Van Workum[1], F.J.H. Van den Wildenberg[2], F. Polat[2], J.H.W. De Wilt[1], C. Rosman[2]. [1]*Academisch Ziekenhuis Nijmegen, Surgery, Nijmegen, Netherlands;* [2]*Canisius-Wilhelmina Ziekenhuis Nijmegen, Surgery, Nijmegen, Netherlands*

Introduction: An intrathoracic anastomosis after esophagectomy has recently been associated with a reduced incidence of recurrent laryngeal nerve palsy, anastomotic leakage and anastomotic strictures compared to a cervical anastomosis, without compromising other morbidity and mortality.
Material and Methods: From January 2011 until August 2012, all operable patients were planned to undergo MIE with creation of an intrathoracic anastomosis. Patient characteristics, anastomosis related complications, morbidity and mortality were prospectively registered and were analyzed retrospectively.
Results: Forty-five patients underwent MIE with intrathoracic stapled end-to-side anastomosis. Major changes in operative technique and perioperative care were made two times due to non satisfactory results, dividing the patients into three groups: group 1 (n = 9): creation of the anastomosis with a double stapling technique, group 2 (n = 18): creation of the anastomosis with a single stapling technique with application of a large omental wrap and group 3 (n = 18): creation of the anastomosis in the same way as group 2, but with a reduced volume of the omental wrap and addition of pre-operative intravenous injection of 1 mg/kg dexamethasone. One patient died in group 1. The anastomotic leakage rate decreased from 44% in group 1 to 0% in groups 2 and 3 ($p = 0.007$). The pulmonary complication rate decreased from 67% in group 1 to 44% in group 2 (NS) and 22% in group 3 ($p = 0.04$) and the overall complication rate decreased from 89% in group 1 to 78% in group 2 (NS) and 33% in group 3 ($p = 0.01$). The median ICU stay decreased from 9 days in group 1, to 7 days in group 2 (NS) and 2 days in group 3 ($p < 0.001$) and the median hospital stay decreased from 17 days in group 1 to 14 days in group 2 (NS) and 8 days in group 3 ($p < 0.001$).
During a median follow up of 11 months, there were no stenoses, no dilatations and no patients with recurrent laryngeal nerve trauma.
Conclusions: The introduction of an intrathoracic anastomosis after MIE led to favorable functional results but was initially associated with considerable morbidity. Results improved after changes in operative technique and perioperative care were made, but a learning curve may be partially responsible for the improved outcome.
No conflict of interest.

2575 POSTER

Treatment and prognosis for young patients with esophageal cancer

A.M.J. Van Nistelrooij[1], L.N. Van Steenbergen[2], H.W. Tilanus[1], J.J.B. Van Lanschot[1], V.E. Lemmens[3], B.P.L. Wijnhoven[1]. [1]*Erasmus Medical Center, Surgery, Rotterdam, Netherlands;* [2]*Comprehensive Cancer Centre South, Cancer Registry, Eindhoven, Netherlands;* [3]*Erasmus Medical Center, Public Health, Rotterdam, Netherlands*

Background: The incidence of esophageal cancer is rising among all age groups. Hence, esophageal cancer is increasingly recognized in younger patients. In young patients probably diagnosis is often delayed, tumors are more aggressive and survival is worse. We compared clinicopathological characteristics, treatment and subsequently survival of patients aged $\leqslant$50 years with patients aged >50 years diagnosed with esophageal cancer.
Material and Methods: From the nationwide Netherlands Cancer Registry we identified all patients diagnosed with esophageal cancer between January 2000 and December 2010 (n = 18,118). Patients with mesenchyme tumors (n = 618) and patients aged $\geqslant$75 years (n = 4,169) were excluded. Proportions were compared using the $\chi 2$ test for categorical variables. Relative survival was calculated as the ratio of the observed rates in cancer patients to the expected rates in the general population.
Results: Eleven percent of the patients (n = 1,466) were aged $\leqslant$50 years and 89% (n = 11,865) were aged >50 years. Adenocarcinoma was the most common tumor type in both age groups (73.6%). Grade of tumor differentiation was comparable between both age groups ($p = 0.460$), as well as T-stage ($p = 0.058$). Younger patients presented more often with tumor positive lymph nodes (70.1 vs. 66.4%, $p = 0.010$) and distant metastasis (50.5 vs. 44.7%, $p < 0.001$). Younger patients diagnosed with an adenocarcinoma were treated with curative surgery more often (40.6 vs. 37.9%, $p = 0.047$). However, 5-year relative survival after surgery was comparable between both age groups (36.8 vs. 34.4%, NS). Among the patients not qualified for surgery, younger patients were treated with palliative chemotherapy more often (44.8 vs. 32.7%, $p < 0.001$), nevertheless this resulted in a comparable 5-year relative survival with their older counterparts (4.7 vs. 5.9%, NS).
Conclusions: A considerable proportion (11%) of the patients diagnosed with esophageal cancer were aged $\leqslant$50 years. Approximately 80% of the tumors were histologically classified as adenocarcinomas. Younger patients presented with advanced disease stage more often, but received a more aggressive treatment. This resulted in a comparable 5-year relative survival rate with the older patients.
No conflict of interest.

2576 POSTER

Incidental finding of gallbladder carcinoma

A. Ghasoup[1], O. Sadieh[2], A. Mansoor[2], A. Abo Mouess[2], Q. Al Ani[2], A. Al Ani[2], L. Bani Issa[1]. [1]*Princes Raia Hospital-M.O.H, Department of Surgery, Amman, Jordan;* [2]*Al Bashir Hospital-M.O.H, Department of Surgery, Amman, Jordan*

Background: Carcinoma of the gallbladder is the fifth most common gastrointestinal malignancy (and the most common of the biliary tract) and is usually discovered accidentally. Gallbladder carcinoma is diagnosed pathologically in 0.3−1.5% of cholecystectomy specimens.
Aim and Objectives: To evaluate the impact of incidental gallbladder cancer on surgical experience and to establish the overall rate of gallbladder carcinoma.
Methods: We retrospectively evaluated all consecutive cholecystectomies performed in our ward from (2007–2012) in order to determine the incidence of gallbladder carcinoma and to identify common characteristics of this particular group of patients.

Results: Of the 580 cholecystectomies performed in our ward from 2007–2012, gallbladder carcinoma was diagnosed in six patients (1.03%) but was not suspected prior to surgery in any of them. In accordance with the literature, the occurrence in women (4/6) was higher than in men (2/6). The mean age was 64 years (range 55−90). The most common symptom was abdominal pain; the majority (5/6) had cholelithiasis, and the pathologic report confirmed the diagnosis of adenocarcinoma in all six patients.
Conclusions: The overall incidence of unsuspected gallbladder carcinoma in our series was 1.03%. We could not find any common characteristics for this particular group of patients when compared to patients with non-malignant pathology.
No conflict of interest.

2577 POSTER

Positron emission tomography (PET) response from a randomized phase III trial (MPACT) of weekly nab-paclitaxel (nab-P) plus gemcitabine (G) vs G alone for patients (pts) with metastatic adenocarcinoma of the pancreas

R.K. Ramanathan[1], D.D. Von Hoff[1], M. Moore[2], L. Teixeira[3], S. Siena[4], J. Tabernero[5], D. Goldstein[6], X. Wei[7], B. Lu[7]. *[1]Scottsdale Healthcare/TGen, Scottsdale, USA; [2]Princess Margaret Hospital, Toronto, Canada; [3]Hôpital Saint Antoine, Paris, France; [4]Ospedale Niguarda Ca' Granda, Milan, Italy; [5]Vall d'Hebron University Hospital, Barcelona, Spain; [6]Prince of Wales Hospital, Sydney, Australia; [7]Celgene Corporation, Summit, USA*

Background: *nab*-P + G demonstrated superior efficacy vs G alone in the MPACT phase III study of pts with metastatic pancreatic cancer (PC). A significant correlation was observed between overall survival (OS) and complete metabolic response (MR; $P = 0.01$) by PET in the initial phase I/II study. Here we present PET analyses of the MPACT trial, including efficacy in pts with a baseline (BL) PET scan (PET cohort).
Methods: A total of 861 previously untreated pts with metastatic PC were randomized 1:1 to receive *nab*-P 125 mg/m^2 + G 1000 mg/m^2 days 1, 8, and 15 every 4 weeks or G alone 1000 mg/m^2 weekly for 7 weeks followed by 1 week of rest (cycle 1) and then days 1, 8, and 15 every 4 weeks (cycle $\geqslant$2). Tumor responses were evaluated every 8 weeks by computed tomography (CT) using RECIST v1.0. PET scans at BL (n = 257), week 8 (n = 222), and week 16 (n = 134) were evaluated, using EORTC criteria; PET and CT were evaluated by blinded independent radiological review.
Results: PET was evaluable at BL in 252 pts. More than 60% of pts had 5 or 6 PET avid sites at BL, and the median standard uptake values were 18.0 and 19.7 in the *nab*-P + G and G arms, respectively. BL characteristics were well balanced in the PET cohort. The rate of MR (complete or partial) was significantly higher for *nab*-P + G vs G (63% vs 38%; response rate ratio [RRR], 1.67; $P = 0.000051$). The overall response rates (ORRs) by CT scan in the PET cohort were 31% and 11%, respectively ($P = 0.0001$). Concordance of ORR by CT scan with MR was 55% in the *nab*-P + G arm and 67% in the G arm. Both ORR and MR significantly predicted OS. Response by PET correlated with overall survival (median 13.1 months). *nab*-P + G was superior to G in the PET cohort for all efficacy endpoints (Table).

Table: Efficacy in the PET cohort

	nab-P + G (n = 130)	G (n = 127)	RRR or HR (95% CI)	*P* value
ORR by CT, %	31	11	2.79 (1.599–4.874)	0.0001
Median PFS, months	6.7	4.3	0.62 (0.443–0.862)	0.0041
Median OS, months	10.5	8.3	0.71 (0.542–0.920)	0.0096

Conclusions: PC is a PET avid tumor. This is the largest cohort of patients from an international PC trial evaluated for PET. More pts in the *nab*-P + G vs G arm achieved an MR. In the PET cohort, all efficacy endpoints favored *nab*-P + G, consistent with results from the intent-to-treat population. PET response rates were higher than those by CT and should be further tested as a potential improvement upon CT as a marker of efficacy.

Randomized phase II study comparing S-1 plus Leucovorin (SL) versus S-1 alone in patients with gemcitabine-refractory advanced pancreatic cancer (APC)

T. Okusaka[1], M. Ueno[2], Y. Omuro[3], H. Isayama[4], A. Fukutomi[5], M. Ikeda[6], N. Mizuno[7], K. Fukuzawa[8], I. Hyodo[9], N. Boku[10]. *[1]National Cancer Center Hospital, Hepatobiliary and Pancreatic Oncology, Tokyo, Japan; [2]Kanagawa Cancer Center, Division of Hepatobiliary and Pancreatic Medical Oncology, Kanagawa, Japan; [3]Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Department of Chemotherapy, Tokyo, Japan; [4]The University of Tokyo Graduate School of Medicine, Department of Gastroenterology, Tokyo, Japan; [5]Shizuoka Cancer Center, Division of Gastrointestinal Oncology, Shizuoka, Japan; [6]National Cancer Center Hospital East, Division of Hepatobiliary and Pancreatic Oncology, Chiba, Japan; [7]Aichi Cancer Center Hospital, Department of Gastroenterology, Aichi, Japan; [8]Oita Red Cross Hospital, Department of Surgery, Oita, Japan; [9]University of Tsukuba, Division of Gastroenterology, Tsukuba, Japan; [10]St. Marianna University School of Medicine, Department of Clinical Oncology, Kanagawa, Japan*

Background: Gemcitabine (Gem)-based chemotherapy is a standard first-line treatment for advanced pancreatic cancer (APC). There is no consensus on second-line therapy in patients (pts) with disease progression (PD) in Gem-based chemotherapy. Randomized phase III study in Japan and Taiwan showed non-inferiority of S-1, an oral fluoropyrimidine, to gemcitabine in terms of OS for pts with unresectable APC (Ueno et al, JCO in press). Therefore, S-1 is one of the key drugs for APC in Japan. S-1 plus oral leucovorin (LV) showed promising activity with well-tolerated toxicities for metastatic colorectal cancer (Denda et al, ASCO GI 2012). We conducted a randomized phase II study to evaluate the efficacy and safety of S-1 plus LV (SL) compared with S-1 alone in the second-line setting for APC.
Material and Methods: The main inclusion criteria were; 1) pathologically confirmation of adenocarcinoma or adenosquamous carcinoma, 2) received one prior chemotherapy containing Gem and developed PD or recurrence, 3) at least one target lesion by RECIST ver1.1, 4) ECOG Performance Status 0−1, 5) age 20−79 years, 6) written informed consent. Pts were randomized to receive either S-1 (40−60 mg bid) and oral LV (25 mg bid) for one week, repeated every 2 weeks in the SL group, or oral dose of S-1 twice daily for 4 consecutive weeks, repeated every 6 weeks in the S-1 group. The primary endpoint was progression-free survival (PFS). Secondary endpoints were overall survival (OS), response rate (RR), disease control rate (DCR), and safety. Tumor response was assessed by independent review committee. This study was supported by Taiho Pharmaceutical CO.,LTD. (JAPIC Clinical Trials information Identifier: JapicCTI-111554).
Results: From August 2011 to August 2012, 142 pts were enrolled, and 140 were eligible (SL, 69; S-1, 71). There were no imbalances in patient characteristics between the two arms with the exception of some subgroups (e.g., pancreatic resection and the sum of diameter of target lesion). SL significantly improved PFS compared with S-1 (median PFS, 3.8 vs. 2.7 months, HR = 0.56; [95% CI: 0.37–0.85], p = 0.003). Pre-planned multivariate analysis confirmed the result of PFS (adjusted HR = 0.50; [95% CI: 0.33–0.76], p = 0.001). The incidences ($\geqslant$5%) of grade 3/4 adverse drug reactions in the SL and S-1 groups were anemia (9.9% vs. 11.3%), leucopenia (7.0% vs. 4.2%), neutropenia (8.5% vs. 5.6%), lymphopenia (12.7% vs. 11.3%), hyponatremia (5.6% vs. 2.8%), anorexia (14.1% vs. 4.2%), fatigue (7.0% vs. 0%), and diarrhea (5.6% vs. 4.2%), and one patient in the SL group died of treatment-related sepsis.

PFS (SL vs. S-1)	OS (SL vs. S-1)	RR (SL vs. S-1)	DCR (SL vs. S-1)
Median 3.8 vs. 2.7 months Event 42 vs. 55 HR = 0.56, p = 0.003 Adjusted HR = 0.50, p = 0.001	Median 6.3 vs. 6.1 months Event 45 vs. 50 HR = 0.82, p = 0.463 Adjusted HR = 0.72, p = 0.114	27.5 vs. 19.7% p = 0.322	91.3 vs. 71.8% p = 0.004

Conclusions: SL significantly improved PFS compared with S-1 alone, and the primary endpoint of this study was met. This study showed that SL had promising activity with well-tolerated toxicities for unresectable APC refractory to gemcitabine containing regimen. A phase III study is planned to ensure the survival benefit of SL.

2579 POSTER

Intraperitoneal CDDP administration chemotherapy with S-1 and paclitaxel for peritoneal metastatic gastric cancer

N. Takiguchi[1], Y. Nabeya[1], A. Ikeda[1], H. Soda[1], H. Yamamoto[1], O. Kainuma[1], A. Cho[1], T. Tonooka[1], Y. Muto[1], T. Denda[2]. *[1]Chiba Cancer Center, Gastroenterological Surgery, Chiba, Japan; [2]Chiba Cancer Center, Digestive Internal Medicine, Chiba, Japan*

Background: The phase III chemotherapy trials for gastric cancer have showed the median survival time is prolonged up to 13 months by SPIRITS trial (addition of cisplatin to S-1)and START trial (addition of docetaxel to S-1).
Meanwhile the efficacy of intraperitoneal (IP) administration of taxanes or platinum agents has been verified in ovarian cancer.
We reported the efficacy of the metronomic combination chemotherapy with S-1 and Paclitaxel (PTX) for advanced gastric cancer, which achieved 21.9 months as the median overall survival time. We aimed to evaluate the efficacy of the intraperitoneal CDDP administration chemotherapy with S-1 and Paclitaxel for peritoneal metastatic gastric cancer.
Patients and Methods: Gastric cancer patients with peritoneal dissemination and/or cancer cells on peritoneal cytology were enrolled. The surgical interventions such as gastrectomy, enterostomy, or colostomy with IP port implantation were done for all patients before this chemotherapy.
PTX was administered i.v. at 80 mg/m^2 on days 1 and 15. S-1 was administered at 80 mg/m^2/day for 7 consecutive days, followed by 7 days rest, repeatedly. CDDP was administered i.p. at 40 mg/body on day 8. This treatment was repeated every 4 weeks until disease progression or unacceptable toxicity was seen.
We estimated the overall survival (OS), the efficacy, and safety of this treatment.
Results: Fifty patients were enrolled, including 36 peritoneal metastatic cases with gastrectomy, 9 cases with peritoneal recurrence and 5 non-resectable cases with peritoneal metastasis. The median number of courses was 8.1 (range 1−29). The median time to treatment failure was 9.9 months. The 1-year and 3-year OS rates were 77.2% and 34.3%, respectively. The median OS was 18.2 months.The median survival times according to Performance Status (PS) were 21.2 months in PS0, 15.4 months in PS1, and 10.9 months in PS2, respectively.
CDDP allergic reactions occurred in 5 cases (10%), and at the median 7.8 times CDDP administrations. The major adverse reactions were leucopenia and neutropenia. Adverse reactions as gastrointestinal symptoms were few.
Conclusion: Intraperitoneal CDDP administration with S-1 and Paclitaxel for peritoneal metastatic gastric cancer appears to be highly efficacious and safe.
No conflict of interest.

Efficacy and safety of nintedanib vs sorafenib in Asian patients with advanced hepatocellular carcinoma (HCC): A randomised Phase II trial

C. Yen[1], T.Y. Kim[2], Y.H. Feng[3], Y. Chao[4], D.Y. Lin[5], M. Studeny[6], J. Hocke[7], D.C.L. Huang[8], B.Y. Ryoo[9], A.L. Cheng[10]. *[1]National Cheng Kung University Hospital, Tainan City, Taiwan; [2]Seoul National University Hospital, Hematology/Medical Oncology, Seoul, Korea; [3]Chi-Mei Medical Center, Hematology and Oncology, Tainan, Taiwan; [4]Taipei Veterans General Hospital, Cancer Center, Taipei, Taiwan; [5]College of Medicine, Chang Gung University, Taoyuan County; [7]Boehringer Ingelheim GmbH & Co KG, Global BCA, Biberach an der Riß, Germany; [8]Boehringer Ingelheim Taiwan Ltd, Medical, Taipei, Taiwan; [9]Asan Medical Center, Oncology, Seoul, Korea; [10]National Taiwan University Hospital, Internal Medicine & Oncology, Taipei, Taiwan*

Background: Nintedanib is an oral angiokinase inhibitor targeting VEGFRs, PDGFRs, and FGFRs. This multicentre, open-label, randomised, Phase I/II study (NCT00987935) evaluated the efficacy and safety of Nintedanib vs Sorafenib in Asian patients (pts) with advanced HCC. Phase I data established the recommended dose of Nintedanib. Early Phase II data comparing Nintedanib vs Sorafenib are presented.
Methods: Previously untreated pts with advanced HCC not amenable to curative/locoregional therapy, a Child-Pugh score of 5−6, an ECOG PS of $\leqslant$2, and AST/ALT $\leqslant 2 \times$ ULN were enrolled. Pts were randomised 2:1 to receive Nintedanib 200 mg bid or Sorafenib 400 mg bid continuously in 28-day cycles. Treatment beyond disease progression (PD) was allowed. Primary endpoint was time to progression (TTP) by central review (RECIST 1.0). Secondary endpoints included objective response rate (ORR) by central review, overall survival (OS), and AEs. All analyses were descriptive and exploratory in nature.
Results: Ninety-five eligible pts from 16 sites in Taiwan and Korea were treated with Nintedanib (n = 63) or Sorafenib (n = 32). Arms were balanced except for macrovascular invasion (Nintedanib 48% vs Sorafenib 28%). As of Sept 28, 2012, 86 pts had discontinued the study due to PD (n = 67), AEs (n = 13), or other reasons (n = 6). Median time to discontinuation of Nintedanib or Sorafenib was 3.0 and 3.8 mo, respectively (HR 1.19 [95% CI: 0.76–1.88]). TTP (primary endpoint) was comparable in the Nintedanib and Sorafenib arms (median, 2.7 [95% CI: 1.8−3.7] vs 3.7 [95% CI: 2.6−7.3] mo; HR 1.36 [95% CI: 0.80–2.30]), as was ORR (3.2 vs 3.1%) and OS (median, 10.7 [95% CI: 8.1–14.8] vs 9.5 [95% CI: 7.4–11.0] mo; HR 0.77 [95% CI: 0.42–1.41]). CTCAE Gr 3 (32 vs 56%) and Gr 4 (8 vs 16%) AEs were less frequent with Nintedanib than Sorafenib. Any-grade (Nintedanib vs Sorafenib) HFSR (6 vs 50%), diarrhoea (44 vs 56%), hypertension (14 vs 22%), abdominal pain (22 vs 34%), AST increases (14 vs 28%), and ALT increases (11 vs 19%) were more common with Sorafenib; vomiting (30 vs 13%), decreased appetite (37 vs 25%), fatigue (22 vs 13%), and ascites (21 vs 9%) were more common with Nintedanib. 11 pts (18%) in the Nintedanib arm and 18 (56%) in the Sorafenib arm had a dose reduction due to AEs.
Conclusion: Nintedanib appears to be active and show similar efficacy to Sorafenib, with a more favourable and manageable AE profile, in Asian pts with advanced HCC. Further studies of Nintedanib in HCC are warranted.

Analysis of sorafenib starting dose and outcomes from the European subset of GIDEON (Global Investigation of Therapeutic Decisions in Hepatocellular Carcinoma and of its Treatment with Sorafenib [SOR]) in >1000 patients (pts)

B. Daniele[1], A.E. Croitoru[2], C. Papandreou[3], J.P. Bronowicki[4], P. Mathurin[5], F. Serejo[6], P.I. Stal[7], J. Turnes[8], V. Ratziu[9], G.M. Bodoky[10]. *[1]G. Rummo Hospital, Department of Medical Oncology, Benevento, Italy; [2]FUNDENI Clinical Institute, Bucharest, Romania; [3]University Hospital of Larissa, Department of Medical Oncology, Larissa, Greece; [4]Centre Hospitalier Universitaire de Nancy Université Henri Poincaré-Nancy, INSERM Unité 954, Vandoeuvre-lès-Nancy, France; [5]Hôpital Claude Huriez, Services des Maladies de l'Appareil Digestif, Lille, France; [6]Hospital de Santa Maria Faculty of Medicine, Center of Gastroenterology Liver Unit, Lisbon, Portugal; [7]Karolinska University Hospital and Department of Medicine − Huddinge Karolinska Institutet, Department of Gastroenterology and Hepatology, Stockholm, Sweden; [8]Hospital de Montecelo Complejo Hospitalario de Pontevedra, Gastroenterology Department, Pontevedra, Spain; [9]Université Pierre et Marie Curie and Hospital Pitié Salpêtrière, Paris, France; [10]St László Teaching Hospital, Department of Oncology, Budapest, Hungary*

Background: GIDEON is the largest (>3200 pts), global, prospective, non-interventional study of unresectable (u) HCC patients treated with SOR under real-life practice conditions. These data allow for the evaluation of the safety and efficacy of SOR in a diverse range of settings and pt groups where the data are currently limited, including patients with Child-Pugh B disease and those with poor prognostic factors. Here we describe the safety and efficacy in uHCC pts, treated in Europe, according to the initial SOR dose.
Methods: Patient demographics, disease characteristics (including stage according to Barcelona Clinic Liver Cancer [BCLC], tumor node metastases [TNM] and Child-Pugh [CP] score) and treatment history, were recorded at enrolment; SOR dose, concomitant medications, performance status, liver function, adverse events (AEs) and efficacy were recorded at follow-up visits.
Results: 1113 pts in 22 European countries were evaluable for safety. The majority of pts (82%) started SOR therapy at the full prescribing dose of 800 mg/day. Pts who started on 400 mg/day tended to have characteristics consistent with a poorer prognosis, including higher ECOG performance status and worse CP score and BCLC and TNM staging. The incidence of reported AEs was greater in the group starting on 400 mg/day compared to the group starting on 800 mg/day (96% vs 88%), as was the incidence of drug-related AEs (74% vs 69%) and serious AEs (57% vs 45%). The incidence of drug-related serious AEs was 11% in both groups). Hand foot skin reaction (HFSR) was reported by more pts started on 800 mg/day (21% vs 15%). Median duration of treatment was longer in the 800 mg/day starting dose group (18.0 weeks vs 13.0 weeks), as was median overall survival (26 months vs 18 months, whereas time to progression was similar (6.5 vs 6.2 months).
Conclusions: These data suggest that in real-life clinical practice physicians tend to start uHCC pts with poorer prognostic factors on the lower SOR dose (400 mg/day). However, the similar incidences of AEs with both Sor starting doses of r 800 mg/day and 400 mg/day suggest that this may not be necessary. Patients started on 800 mg/day tend to

continue Sor treatment longer and achieve better overall survival, with a slight higher HFSR rate. Further evaluation and analysis with appropriate statistical methods for dosing are ongoing.

SLCO1B1 gene single nucleotide polymorphism is a drug response marker for pancreatic cancer patients treated with gemcitabine

H. Ueno[1], T. Ioka[2], S. Ohkawa[3], M. Ikeda[4], T. Shimamura[5], A. Tsuji[6], Y. Tsuchiya[7], T. Okusaka[1], T. Yoshida[8], Y. Sato[9]. *[1]National Cancer Center Hospital, Hepatobiliary and Pancreatic Oncology Division, Tokyo, Japan; [2]Osaka Medical Center for Cancer and Cardiovascular Diseases, Division of Hepatobiliary and Pancreatic Oncology, Osaka, Japan; [3]Kanagawa Cancer Center, Division of Gastroenterology, Kanagawa, Japan; [4]National Cancer Center Hospital East, Division of Hepatobiliary and Pancreatic Oncology, Chiba, Japan; [5]Saitama Cancer Center, Department of Gastroenterology, Saitama, Japan; [6]Kochi Health Sciences Center, Department of Clinical Oncology, Kochi, Japan; [7]Niigata Cancer Center Hospital, Division of Surgery, Niigata, Japan; [8]National Cancer Center Research Institute, Division of Genetics, Tokyo, Japan; [9]Chiba University Hospital, Clinical Research Center, Chiba, Japan*

Background: We conducted an exploratory pharmacogenomics study to search for genetic factors, which influence overall survival (OS) in 69 stage IV pancreatic cancer patients treated with gemcitabine (GEM) monotherapy. A systemic candidate gene approach was employed by genotyping 5,438 single nucleotide polymorphisms (SNPs) in 219 genes encoding a wide category of drug-metabolizing enzymes and transporters (https://gemdbj.nibio.go.jp/dgdb/PharmaSearch.do). During the first screening, 4 SNPs were found to be associated with OS using statistical criteria ($P \leqslant 0.0005$).
Material and Methods: We validated these SNPs in part of the GEST study, which was a randomized phase III study conducted in 834 patients with unresectable advanced pancreatic cancer who were treated with GEM, S-1 or GEM plus S-1 (GS) (Ueno et al., J Clin Oncol 2013). One hundred eighty-eight patients from the GEST study were enrolled in the present study. Written informed consent was obtained from all the patients. DNA was isolated from peripheral blood and was typed for the 4 SNPs identified during the first screening. The associations between OS and the SNPs were investigated using the log-rank test and the Cox proportional hazards model. Potential treatment-SNP interactions were also evaluated using the Cox model.
Results: The SNP rs4149086 in the 3'UTR of the solute carrier organic anion transporter family, member 1B1 (SLCO1B1) gene exhibited a significant statistical interaction between the treatment and the SNP ($P = 0.02$). In the GEM group, the SNP was significantly associated with a shorter OS (median OS for AG+GG [n = 4] and AA [n = 63] were 6.7 and 9.6 months, respectively; $P = 0.008$; HR = 3.7 [1.3–10.8]) even after adjustment for multiple comparisons. On the other hand, the SNP was not associated with a shorter OS in the S-1 group (median OS for AG+GG [n = 6] and AA [n = 53], 14.4 and 10.7 months, retrospectively; $P = 0.35$; HR = 0.7 [0.3−1.8]) or the GS group (median OS for AG+GG [n = 5] and AA [n = 55], 15.9 and 10.8 months, respectively; $P = 0.72$; HR = 1.1 [0.4−3.0]). The observed interaction with treatment suggests that the SNP is predictive rather than prognostic.
Conclusions: The SLCO1B1 gene SNP may be a drug response marker for pancreatic cancer patients treated with GEM.

2583 POSTER

Evaluation of peripheral neuropathy in a phase III trial (MPACT) of weekly nab-paclitaxel (nab-P) plus gemcitabine (G) vs G alone for patients with metastatic adenocarcinoma of the pancreas

D. Goldstein[1], D.D. Von Hoff[2], M. Moore[3], E. Greeno[4], P. Ritch[5], G. Tortora[6], R.K. Ramanathan[2], J. Tabernero[7], A. Ko[8], B. Lu[8]. *[1]Prince of Wales Hospital, Sydney, Australia; [2]Scottsdale Healthcare/TGen, Scottsdale, USA; [3]Princess Margaret Hospital, Toronto, Canada; [4]University of Minnesota, Minneapolis, USA; [5]Medical College of Wisconsin, Milwaukee, USA; [6]Azienda Ospedaliera Universitaria Integrata di Verona, Verona, Italy; [7]Vall d'Hebron University Hospital, Barcelona, Spain; [8]Celgene Corporation, Summit, USA*

Background: *nab*-P + G demonstrated superior efficacy vs G in the phase III MPACT trial of patients (pts) with metastatic pancreatic cancer (PC). *nab*-P + G was associated with a higher rates of some adverse events, including peripheral neuropathy (PN). Here we further evaluate the frequency, duration, and severity of PN.
Methods: 861 previously untreated pts with metastatic PC were randomized 1:1 to receive treatment with *nab*-P 125 mg/m^2 + G 1000 mg/m^2 days 1, 8, and 15 every 4 weeks or G alone 1000 mg/m^2 weekly for 7 weeks followed by 1 week of rest (cycle 1) and then days 1, 8, and 15 every 4 weeks (cycle $\geqslant$2). PN was evaluated globally by a broad-spectrum group of standardized MedDRA queries (SMQ) and graded by NCI CTCAE v3.0. In addition, a case-report form was completed by physicians on day 1 of each cycle (also graded by NCI CTCAE v3.0).
Results: By SMQ evaluation, the rates of any-grade (54% vs 13%) and grade 3 PN (17% vs 1%) were higher for *nab*-P + G vs G. No grade 4 PN was reported in either arm. Most early-onset PN events (ie, occurring within the first 3 cycles) were grade 1. Treatment-related grade 3 PN occurred in 7% of pts who received up to 3 cycles of *nab*-P (the median number of cycles received in that arm). PN led to *nab*-P dose reduction in 6%, delay/omission in 8%, and treatment discontinuation in 8% of patients in the *nab*-P + G arm. Of the pts who had grade 3 PN in the *nab*-P + G arm (n = 70), the median time to onset was 140 days (4 cycles), 44 (63%) improved by 1 grade (median 21 days), and 30 (43%) pts improved to grade $\leqslant$1 (median 29 days); 44% of pts resumed treatment with *nab*-P. The rates of grade 3 PN by physician-completed case report forms were similar to those of the assessment by SMQ terms: 14% for *nab*-P + G vs <1% for G; no grade 4 neuropathy was observed. There were no noted differences in baseline characteristics between pts who developed PN vs those who did not.
Conclusions: The rate of grade 3 PN for patients in the *nab*-P + G arm who received up to the median of 3 cycles was 7%, and overall, was 17%, consistent with prior *nab*-P studies. Grade 3 PN was manageable by dose reduction or delay and reversible to grade $\leqslant$1 for almost half of those patients within a median time of approximately 1 month.

Compassionate use of everolimus in advanced neuroendocrine tumors

F. Panzuto[1], M. Rinzivillo[1], N. Fazio[2], F. De Braud[3], G. Luppi[4], E. Degli Uberti[5], L. De Marinis[6], P. Tomassetti[7], M. Falconi[8], G. Delle Fave[1]. *[1]Sapienza Università di Roma Ospedale Sant'Andrea, Digestive and Liver Disease, Roma, Italy; [2]Istituto Europeo di Oncologia, Medical Oncology, Milano, Italy; [3]Fondazione IRCCS Istituto Nazionale Tumori, Medical Oncology, Milano, Italy; [4]Azienda Ospedaliero-Universitaria di Modena, Medical Oncology, Modena, Italy; [5]Azienda Ospedaliero-Universitaria di Ferrara, Endocrinology, Ferrara, Italy; [6]Policlinico Gemelli Università Cattolica, Endocrinology, Roma, Italy; [7]Policlinico S.Orsola-Malpighi Università di Bologna, Internal Medicine, Bologna, Italy; [8]Università Politecnica delle Marche, Pancreatic Surgery, Ancona, Italy*

Background: Everolimus has been approved for treatment of advanced Pancreatic Neuroendocrine Tumors (pNETs). However, no data are available outside the setting of clinical trials designed for drug approval.
Aim: To determine, in a real world setting, tolerability and efficacy of Everolimus in advanced NET.
Patients and Methods: Retrospective analysis of patients (pts) treated with Everolimus given by compassionate use programme. Inclusion criteria: advanced, unresectable, sporadic NET, progression after failure of previous treatments, performance status $\leqslant$2, life expectancy >3 months. Safety assessed according with the CTCAE. Efficacy assessed by evaluation of best response rate during treatment, progression-free survival (PFS), overall survival (OS).
Results: 169 pts enrolled (55.5% male, median age 63 yr), including 85 PETs (50.3%), and 84 non-pancreatic NET (non-PETs) (49.7%). Tumor grading was: G1, 40 pts (23.7%); G2, 114 pts (67.4%); G3, 15 pts (8.9%). Most frequent prior treatments were peptide-receptors radionuclide therapy (PRRT) (50.3%) and systemic chemotherapy (49.7%); 38 pts (22.5%) received both treatments before Everolimus. During a median treatment period of 6 months (range 1−46), 109 pts (64.5%) reduced dose or temporarily discontinued treatment due to toxicity. 144 pts (85.2%) experienced adverse events (AEs), which were grade 3−4 in 78 of them (46.1%). Significantly higher proportion of pts previously treated with both PRRT and chemotherapy had grade 3−4 AEs when compared with other patients (33/38, 86.8% vs 45/131, 34.3%; p < 0.0001). Overall, most frequent grade 3−4 AEs were: pneumonitis, 14 pts (8.3%); thrombocytopenia, 13 pts (7.7%); anemia, 9 pts (5.3%). Tumor response was observed in 128 pts (75.7%) (stable disease: 67.4%, partial response 7.7%, complete response 0.6%). Overall, PFS was 12 months (11 and 12 months in PETs and non-PETs, respectively; p = 0.789). A total of 46 pts died during follow-up (27.2%). Median OS was 32 months (not reached and 32 months in PETs and non-PETs, respectively; p = 0.295).

Conclusions: In real world setting (clinical practice), Everolimus efficacy was similar to that reported by phase 3 trials, with equal results in both PETs and non-PETs. A two fold increase of severe toxicity incidence was observed in patients previously treated with PRRT and chemotherapy. These data rise the question on the influence of previous treatments on the severity of adverse events expectable during Everolimus treatment.
No conflict of interest.

Second-line chemotherapy for advanced biliary tract cancer: Results of a multicenter survey

E. Vasile[1], S. Di Girolamo[2], S. Cereda[3], S. Lonardi[4], F. Leone[5], M. Russano[6], N. Silvestris[7], C. Vivaldi[1], L. Fornaro[8], G. Brandi[2].
[1]Azienda Ospedaliero-Universitaria Pisana, Medical Oncology, Pisa, Italy; [2]Sant'Orsola Malpighi Hospital University of Bologna, Medical Oncology, Bologna, Italy; [3]San Raffaele Scientific Institute, Medical Oncology, Milano, Italy; [4]Istituto Oncologico Veneto, Medical Oncology, Padova, Italy; [5]Institute for Cancer Research and Treatment IRCC Candiolo University of Torino, Medical Oncology, Torino, Italy; [6]Campus Biomedico University, Medical Oncology, Roma, Italy; [7]Institute for Cancer Research and Treatment IRCCS Ospedale Oncologico, Medical Oncology, Bari, Italy; [8]Azienda USL 2, Medical Oncology, Lucca, Italy

Background: There is no established standard chemotherapy for second-line treatment of patients with advanced biliary tract cancer (BTC). However, with the improvement of first-line treatment, many patients remain in good clinical conditions and maintain a normal liver function after progression to first-line chemotherapy and therefore are suitable for second-line chemotherapy.
Material and Methods: We retrospectively reviewed data of consecutive patients who received second-line chemotherapy for BTC at 8 Italian institutions from 2006 to 2012, and described clinic-pathological characteristics of disease and the outcome of second-line treatment.
Results: A total of 247 evaluable patients were identified. At the beginning of second-line chemotherapy, median age was 65 years with a range of 28 to 85 years; 135 patients were of female sex and 112 male; ECOG performance status was 0 in 154 patients (64%), 1 in 66 (27%) and 2 in 23 patients (9%). The site of primary tumor was gallbladder in 44 patients (18%), intrahepatic in 129 (52%), extrahepatic in 55 (22%), ampullary in 19 patients (8%). The majority of patients had metastatic disease; the median number of metastatic site was 2.
The majority of patients had received a platinum-containing first-line chemotherapy (71%); 19.8% of patients responded to first-line chemotherapy with a median progression-free survival (PFS) was 6.3 months.
Second-line chemotherapy consisted of platinum-based combinations in 84 patients (34%), fluoropyrimidines in 50 patients (20%), gemcitabine in 16 (7%), combinations of fluoropyrimidines and gemcitabine in 41 patients (17%), taxanes containing regimen in 11 patients (4%), irinotecan containing regimen in 22 (9%), other regimens in the remaining 23 patients (9%).
Twelve partial responses (5%) and 77 stable diseases (31%) have been observed with a disease control rate of 36%; 7% of patients have not been evaluable for response.
Median PFS was 3.3 months (95% confidence interval-CI: 2.9−3.7) and median overall survival from the beginning of second-line was 8.2 months (95% CI: 6.8−9.6).
One hundred and thirteen patients (45%) received further local or systemic treatment after second-line therapy.
Conclusions: Second-line chemotherapy is active for a group of patients with advanced BTC progressed to first-line chemotherapy. Considering the moderate benefit of treatment, an analysis of prognostic and predictive factors is needed and prospective randomized trials are necessary.
No conflict of interest.

2586 POSTER

Dose delivery in a phase III trial (MPACT) of weekly nab-paclitaxel (nab-P) plus gemcitabine (G) vs G alone for patients with metastatic adenocarcinoma of the pancreas

W. Scheithauer[1], D.D. Von Hoff[2], R.K. Ramanathan[2], M. Moore[3], J. Tabernero[4], D. Goldstein[5], P. Hammel[6], V. Kunzmann[7], A. Ko[8], A. Romano[9]. *[1]Medizinische Universität Wien, Wien, Austria; [2]Scottsdale Healthcare/TGen, Scottsdale, USA; [3]Princess Margaret Hospital, Toronto, Canada; [4]Vall d'Hebron University Hospital, Barcelona, Spain; [5]Prince of Wales Hospital, Sydney, Australia; [6]Hôpital Beaujon, Clichy, France; [7]Universitätsklinikum Würzburg, Würzburg, Germany; [8]Celgene Corporation, Summit, USA; [9]Celgene Corporation, Boudry, Switzerland*

Background: *nab*-P + G demonstrated superior efficacy to G in the phase III MPACT trial for all endpoints. Here we present data on dose modifications, with an emphasis on their impact on overall treatment delivery.
Methods: 861 previously untreated patients (pts) with metastatic pancreatic cancer (PC) were randomized 1:1 to receive *nab*-P 125 mg/m^2 + G 1000 mg/m^2 days 1, 8, and 15 every 4 weeks or G alone 1000 mg/m^2 weekly for 7 weeks followed by 1 week of rest (cycle 1) and then days 1, 8, and 15 every 4 weeks (cycle $\geqslant$2).
Results: Pts in the *nab*-P + G arm received treatment for a longer duration (median, 3.9 vs 2.7 months), resulting in a higher number of total doses delivered (Table). The median cumulative dose of *nab*-P was 1425 mg/m^2, and the median cumulative doses of G were 11,400 and 9000 mg/m^2 in the *nab*-P + G and G arms, respectively. Furthermore, 71% of *nab*-P doses were delivered at the per-protocol dose of 125 mg/m^2, and the median relative dose intensities of *nab*-P and G in that arm were 81% and 75%, respectively. The overall incidence of treatment-emergent adverse events (AEs) leading to dose reductions (DRs) was higher in the *nab-P* + G (38% and 44%, respectively) vs G arm (31%), and more DRs and dose delays occurred in the *nab*-P + G vs G arm. Associations between DRs and efficacy outcomes will also be examined.

Table. Dose delivery (treated population)

	nab-P + G (n = 421)		G (n = 402)
	nab-P	G	
Total doses administered, n	5770	5888	4769
Per-protocol/total doses, %	71	63	79
Mean percentage of pts receiving per-protocol dose at week 1 by cycle, n/n (%)			
Cycle 3	180/255 (71)	160/258 (62)	144/193 (75)
Cycle 4	134/202 (66)	113/205 (55)	94/136 (69)
Cycle 6	70/131 (53)	57/140 (41)	39/66 (59)
Pts with $\geqslant$1 DR, n (%)	172 (41)	198 (47)	132 (33)
AEs leading to DR[a], n (%)			
Neutropenia	44 (10)	81 (19)	54 (13)
Thrombocytopenia	15 (4)	36 (9)	35 (9)
Peripheral neuropathy	26 (6)	26 (6)	0
Fatigue	18 (4)	19 (5)	9 (2)
Patients with $\geqslant$1 dose delay/omission, n (%)	300 (71)	295 (70)	230 (57)
AEs leading to dose delay/omission[a], n (%)			
Neutropenia	68 (16)	75 (18)	43 (11)
Thrombocytopenia	50 (12)	57 (14)	36 (9)
Peripheral neuropathy	32 (8)	12 (3)	0
Fatigue	34 (8)	33 (8)	15 (4)

[a] Most common treatment-emergent AEs that led to dose modification.

Conclusions: This regimen of *nab*-P + G can be effectively administered to pts with metastatic PC. The *nab*-P + G arm had a longer median treatment duration and higher cumulative dose of G than the G arm.

2587 POSTER

Phase III trial of a 3-weekly vs. 5-weekly schedule of S-1 plus cisplatin (SP) combination chemotherapy for first-line treatment of advanced gastric cancer (AGC): SOS study

K.H. Lee[1], E. Baba[2], M.H. Ryu[3], N. Boku[4], Y.I. Park[5], I. Hyodo[6], B.H. Nam[7], B.Y. Ryoo[3], E.K. Song[8], Y.K. Kang[3]. *[1]Yeungnam University Hospital, Department of Hemato-oncology, Daegu, South Korea; [2]Kyushu University, Department of Comprehensive Clinical Oncology, Fukuoka, Japan; [3]Asan Medical Center, Department of Oncology, Seoul, South Korea; [4]St. Marianna University School of Medicine, Department of Clinical Oncology, Kawasaki, Japan; [5]National Cancer Center, Center for Gastric Cancer, Goyang, South Korea; [6]University of Tsukuba, Division of Gastroenterology, Tsukuba, Japan; [7]National Cancer Center, Biometric Research Branch, Goyang, South Korea; [8]Chonbuk National University Medical School, Department of Internal Medicine, Jeonju, South Korea*

Background: 5-weekly S-1 plus cisplatin (SP5: S-1 80–120 mg/body/day on D1−21, cisplatin 60 mg/m^2 on D8, every 5 weeks) has become a standard first-line chemotherapy for AGC in Japan based on the SPIRITS trial (Lancet Oncol. 2008;9:215). To strengthen the low-dose intensity of cisplatin in this SP5 for greater efficacy, a 3-weekly S-1 plus cisplatin (SP3: S-1 80 mg/m^2/day on D1−14, cisplatin 60 mg/m^2 on D1, every 3 weeks) has been developed in Korea (Cancer Chemother Pharmacol. 2008;61:837).
Methods: This SOS study was a multi-center, randomized, open-label, phase III study to evaluate whether SP3 was non-inferior/superior to SP5 in terms of progression free survival (PFS) determined by a blinded central radiology review according to RECIST v1.1. Patients (pts) with metastatic or recurrent gastric or gastroesophageal junction adenocarcinoma and with

no prior chemotherapy were randomized 1:1 to receive either SP3 or SP5 until disease progression or unacceptable toxicities.
Results: Between February 2009 and January 2012, a total of 625 pts were randomized from 42 sites in Korea and Japan. Median age was 59.6 years. 99% of pts had ECOG performance status 0−1. 16% of pts had prior gastrectomy. 62% of pts had measurable lesions. With a median follow-up of 34.7 months (range, 14.2–48.8) in surviving pts, SP3 was significantly non-inferior and superior to SP5 in PFS (median 5.5 months vs. 4.9 months; HR 0.82, 95% CI 0.68–0.99, p = 0.0418). Overall response rate (ORR) was also better with SP3 than with SP5 (60% vs. 50%, p = 0.029). However, OS of both groups was equivalent (median 14.1 vs. 13.9 months; HR 0.99, 95% CI 0.81–1.21, p = 0.9068). Treatment was well tolerated in both arms, while SP3 was associated with more frequent G3/4 anemia (19% vs. 9%) and neutropenia (39% vs. 9%). Dose intensity was higher in SP3 than in SP5 for both agents (median 331 vs. 317 mg/m^2/week for S-1, p < 0.001; median 18 vs. 12 mg/m^2/week for cisplatin, p < 0.001).
Conclusion: SP3 was non-inferior and superior to SP5 in terms of PFS and ORR. However, considering the small benefit in PFS and no difference in OS, both SP3 and SP5 can be recommended for the first-line treatment of AGC.

2588 POSTER

Tolerability and quality-of-life (QoL) results from the phase 3 REGARD study: Ramucirumab versus placebo in patients with previously treated gastric or gastroesophageal junction (GEJ) adenocarcinoma

I. Chau[1], R. Passalacqua[2], J.R. Zalcberg[3], C.S. Fuchs[4], A.M. Liepa[5], Y. Hsu[6], J.D. Schwartz[7], M. Koshiji[8], J. Tabernero[9]. *[1]Royal Marsden Hospital, Department of Medicine, Sutton, United Kingdom; [2]Istituti Ospitalieri di Cremona, Medical Oncology Division, Cremona, Italy; [3]Peter McCallum Cancer Centre and University of Melbourne, Division of Hematology and Medical Oncology, Melbourne, Australia; [4]Dana-Farber Cancer Institute and Harvard Medical School, Department of Medical Oncology, Boston, USA; [5]Eli Lilly and Company, Global Health Outcomes, Indianapolis, USA; [6]ImClone Systems LLC (a wholly owned subsidiary of Eli Lilly and Company), Global Statistical Sciences, Bridgewater, USA; [7]ImClone Systems LLC (a wholly owned subsidiary of Eli Lilly and Company), Global Medical Sciences, Bridgewater, USA; [8]Eli Lilly and Company, Global Medical Sciences, Indianapolis, USA; [9]Vall d'Hebron University Hospital and Universitat Autònoma de Barcelona, Medical Oncology Department, Barcelona, Spain*

Background: Ramucirumab (RAM) was associated with significantly longer survival and progression-free survival (PFS) versus placebo (Fuchs et al, GI Cancer Symposium 2013). Here we present assessments of tolerability and QoL from REGARD.
Material and Methods: Patients (pts) with advanced gastric or GEJ adenocarcinoma who had previously been treated were randomized 2:1 to receive RAM 8 mg/kg IV or placebo every 2 weeks; both arms received best supportive care. Pts and investigators were blinded to treatment assignment. Pts were eligible if they had received prior fluoropyrimidine- or platinum-based combination therapy and had ECOG performance status (PS) of 0 or 1. PS was assessed prior to every cycle, at therapy discontinuation, and within 30 days after last dose. Time to PS deterioration was measured from randomization to first change in PS to ⩾2 and evaluated with Kaplan–Meier analysis and log-rank test. Pts completed the EORTC QLQ-C30 (v3) QoL instrument at baseline and on study at Cycles 4, 7, and 10. Scores were classified as improved or worsened if changed by a ⩾10-point difference relative to baseline, otherwise stable. Adverse events (AEs) and supportive therapies were collected while pts were on study.
Results: 355 pts were randomized (238 to RAM, 117 to placebo); 2 pts in each arm did not receive treatment. RAM pts received a median of 4 cycles (interquartile [IQ] range 3−8), while placebo pts received 3 cycles (IQ range 2−4). Treatment discontinuation rates for AEs were 10.5% for RAM and 6.0% for placebo. Time to PS deterioration was longer for RAM (median 5.1 months vs 2.4 months; hazard ratio=0.59 [95% confidence interval: 0.41–0.83], p = 0.002). While on study, QoL completion rates were >86% at all time points. Primarily due to disease progression, <50% of RAM and <25% of placebo pts provided post-baseline QoL data. For the randomized population, rates of improvement were 5−15% for RAM and 3−6% for placebo across the 15 QoL scales at Cycle 4. Rates of stability were 16−37% for RAM and 8−19% for placebo. Rates of worsening were 4−18% for RAM and 1−9% for placebo, with 54% of RAM and 78% of placebo pts providing no data, primarily due to disease progression by 6 weeks. Rates of serious AEs were similar (44.9% RAM, 44.3% placebo). The highest rate of any specific grade ⩾3 AE was <10% in the RAM arm. Select supportive care is summarized in Table 1.

Table 1. Select supportive care for treated pts

	RAM (N = 236)	Placebo (N = 115)
Hospitalizations due to any AE	33.9%	38.3%
Transfusions	11.4%	8.7%
Erythropoietin	2.1%	0.9%
G-CSF	0.8%	0.9%
Anti-hypertensive agents	42.8%	40.0%

Conclusions: In addition to improved survival and PFS for RAM versus placebo, RAM was well tolerated. Rates of serious AEs were similar between arms; for RAM, the incidence of any individual severe toxicity was low and supportive care requirements were modest. For pts who received at least 4 cycles of therapy, more pts maintained their QoL with RAM. Performance status was maintained for a significantly longer time with RAM.

'Pazonet': Single-arm multicentric phase II trial of pazopanib in patients with progressive gastroenteropancreatic neuroendocrine tumors (GEPNETs)

J. Capdevila[1], D.E. Castellano[2], R. Garcia-Carbonero[3], A. Teule[4], I. Duran[5], J. Fuster[6], I. Sevilla[7], P. Escudero[8], J. Sastre[9], E. Grande[10]. *[1]Vall d'Hebron University Hospital, Medical Oncology, Barcelona, Spain; [2]Hospital Universitario 12 de Octubre, Medical Oncology, Madrid, Spain; [3]Hospital Universitario Virgen del Rocio Instituto de Biomedicina de Sevilla (IBIS), Medical Oncology, Sevilla, Spain; [4]IDIBELL Institut Català d'Oncologia L'Hospitalet, Medical Oncology, Barcelona, Spain; [5]Centro Integral Oncológico Clara Campal, Medical Oncology, Madrid, Spain; [6]Hospital Son Espases, Medical Oncology, Palma de Mallorca, Spain; [7]Hospital Universitario Virgen de la Victoria, Medical Oncology, Malaga, Spain; [8]Hospital Clínico Universitario Lozano Blesa, Medical Oncology, Zaragoza, Spain; [9]Hospital Clínico San Carlos, Medical Oncology, Madrid, Spain; [10]Ramon y Cajal University Hospital, Medical Oncology, Madrid, Spain*

Background: Pazopanib is an oral multitargeted tyrosin kinase inhibitor of VEGFR-1, VEGFR-2, VEGFR-3, PDGFR-α/β and c-kit, with antitumoral and antiangiogenic properties. The aim of this study was to evaluate the clinical benefit rate (CBR), [defined as stable disease + response rate], after six months of Pazopanib in patients (pts) with advanced GEPNETs.
Methods: Pts with advanced GEPNETs who had failed chemotherapy, somatostatin analogs (SSAs) or molecular targeted therapies (MTT) received Pazopanib 800 mg qd. Efficacy was evaluated every 8 weeks following RECIST 1.0. A two-stage Simon's design was utilized and positivity defined as CBR>63% of the pts after 6 months on therapy.
Results: Forty-four pts were recruited from Jan 2011 to March 2012, 42 were evaluable. Twenty were women, mean age was 60 years, 44% were pancreatic and 20% had received previous MTT. Median time of Pazopanib treatment was 30 weeks (IQR 16−55). Thirty-six patients (86%) met the primary endpoint (4 partial responses, 32 stable disease). Median progression-free survival (PFS) was 10 months (95% CI 4.3–15.6). CBR

at 6 months was 100% in pts with no previous targeted therapy (9 pts), 80% in pts with previous mTOR inhibitors (8 pts), 87% in pts with previous antiangiogenics (13 pts) and 75% in pts with previous antiangiogenics and mTOR inhibitors (6 pts) respectively. Most frequent grade III−IV toxicities were asthenia (18%), hypertransaminasemia (13.6%) and diarrhea (9%). Concomitant treatment with SSAs ($p = 0.007$), no decrease in serum chromogranin A levels ($p = 0.024$) and pancreatic origin ($p = 0.013$) were associated with longer PFS.
Conclusion: Pazopanib showed remarkable activity in pts with advanced GEPNETs regardless previous MTT treatment. These results raise the hypothesis of non-cross resistance between MTT in this population and could justify the use of sequential targeted therapies. A phase III study of Pazopanib in progressive GEPNETs is planned.
Conflict of interest: *Other substantive relationships: GlaxoSmithKline*

Safety, efficacy, and immune analyses of a phase 2, randomized study of GVAX pancreas and CRS-207 immunotherapy in patients with metastatic pancreatic cancer

D. Le[1], A. Wang Gilliam[2], V. Picozzi[3], T. Greten[4], T. Crocenzi[5], G. Springett[6], M. Morse[7], H. Zeh[8], D. Brockstedt[9], E. Jaffee[1]. *[1]Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Oncology, Baltimore MD, USA; [2]Washington University, Medical Oncology, St. Louis, USA; [3]Virginia Mason Medical Center, Hematology Oncology, Seattle WA, USA; [4]National Cancer Institute, Medical Oncology, Bethesda MD, USA; [5]Providence Medical Group, GI Oncology, Portland OR, USA; [6]Moffitt Cancer Center, Oncology, Tampa FL, USA; [7]Duke University Medical Center, Oncology, Durham NC, USA; [8]University of Pittsburgh, Surgical Oncology, Pittsburgh PA, USA; [9]Aduro Biotech Inc, Immunology and Oncology, Berkeley CA, USA*

Background: GVAX is composed of GM-CSF-secreting allogeneic pancreas cancer cell lines and administered with low-dose cyclophosphamide (CY) to inhibit regulatory T cells. In prior studies, GVAX induced mesothelin-specific T cell responses that correlated with survival. CRS-207 is live-attenuated *Listeria monocytogenes* engineered to express human mesothelin. CRS-207 stimulates potent innate and adaptive immunity and has shown synergy with GVAX in mouse tumor models. Anecdotal survival benefit was observed in the CRS-207 phase 1 study in patients who received prior GVAX.
Material and Methods: Patients were enrolled with metastatic pancreatic ductal adenocarcinoma (PDA) who received or refused $\geqslant 1$ prior chemotherapy, had ECOG 0−1 and adequate organ function. Patients were randomized 2:1 to receive 2 doses of CY/GVAX followed by 4 doses of CRS-207 (Arm A) or 6 doses of CY/GVAX (Arm B) every 3 weeks. Clinically stable patients were offered additional 20-week courses. The primary endpoint was comparison of OS between arms. Secondary endpoints were to evaluate safety, clinical, and immune responses.
Results: 90 patients were treated (Arm A: 61, Arm B: 29). Thirty-four patients completed 1 course (A: 28, B: 6) and 19 patients (A: 17, B: 2) initiated a 2ndcourse. Median age was 63. Median number of prior regimens was 2. No treatment-related serious adverse events (SAEs) or unexpected toxicities were observed. The most frequent Grade (G) 3/4 related toxicities were fever, lymphopenia, hypophosphatemia, elevated liver enzymes, and fatigue after CRS-207 in <5% of subjects. Of 51 patients evaluated post-treatment, 34% had stable disease in Arm A vs. 19% in Arm B. OS for all patients treated was 6 months in Arm A vs. 3.9 months in Arm B (two-sided, $p = 0.0169$). Patients receiving $\geqslant 3$ doses had OS of 8.3 months in Arm A vs. 4.2 months in Arm B ($p = 0.0107$). Immune analyses will be reported.
Conclusions: Combined CY/GVAX pancreas and CRS-207 was generally well-tolerated with no treatment-related SAEs or unexpected G3/4 toxicities. The significant difference in OS between treatment arms met the criteria for early stopping and was confirmed at the primary analysis. This combination immunotherapy resulted in extended survival for metastatic PDA patients and should continue to be developed as an effective therapy.

2591 POSTER

Biweekly irinotecan plus cisplatin (BIRIP) versus irinotecan alone (IRI) after S-1-based chemotherapy failure in patients with advanced gastric cancer (AGC): Final analysis of a randomised phase III trial (TCOG GI-0801/BIRIP trial)

W. Koizumi[1], K. Higuchi[1], K. Shimada[2], H. Hosaka[1], E. Sasaki[3], N. Nakayama[1], K. Amagai[1], Y. Takeda[1], T. Moriwaki[1], T. Sekikawa[1]. *[1]The Tokyo Cooperative Oncology Group (GI Group), Gastroenterology, Tokyo, Japan; [2]The Tokyo Cooperative Oncology Group (GI Group), Internal Medicine, Tokyo, Japan; [3]The Tokyo Cooperative Oncology Group (GI Group), Chemotherapy, Tokyo, Japan*

Background: The optimal second-line chemotherapy for AGC remains uncertain, but favourable results have been obtained with irinotecan. Preclinical and clinical studies have reported that irinotecan acts synergistically with cisplatin. We tested the hypothesis that BIRIP is superior to IRI in terms of progression-free survival (PFS) as second-line chemotherapy in patients with AGC resistant to S-1-based chemotherapy (UMIN Clinical Trial Registration number: UMIN000001028).
Material and Methods: Patients with recurrent or metastatic gastric cancer resistant to S-1-based first-line chemotherapy were randomly assigned to receive irinotecan (60 mg/m^2 on day 1) plus cisplatin (30 mg/m^2 on day 1) every 2 weeks or irinotecan alone (150 mg/m^2 on day 1) every 2 weeks. The statistical design was based on a superiority hypothesis, assuming a median PFS of 110 days with BIRIP and 65 days with IRI (two-sided α=0.05; 1-β=0.8). Planned accrual was 130 patients.
Results: From April 2008 through July 2011, 130 patients were randomized to BIRIP ($n = 64$) or IRI ($n = 66$) at 21 sites in Japan. Patient characteristics were well balanced between the two groups. The primary endpoint was met. PFS with BIRIP was superior to that with IRI (median PFS, 3.8 m [95% CI 3.0−4.7] vs. 2.8 m [95% CI 2.1−3.3], respectively; HR = 0.68 [0.47–0.98], $p = 0.04$). The response rate as secondary endpoint was 21.9% with BIRIP and 15.9% with IRI ($p = 0.50$). The disease control rate with BIRIP was superior that with IRI (75.0% vs. 54.0%, respectively; $p = 0.02$). On exploratory subgroup analyses with a Cox proportional-hazards model, the effect of BIRIP on PFS was greater in patients with target tumors than in those without target tumors and in patients without peritoneal metastasis than in those with peritoneal metastasis. The most common grade 3/4 toxicities in BIRIP/IRI (%) were neutropenia, 39.1/36.4; diarrhoea, 1.6/6.1; and anorexia, 6.3/10.6.
Conclusions: BIRIP as second-line chemotherapy significantly prolongs PFS in patients with AGC resistant to S-1-based first-line chemotherapy.
No conflict of interest.

2592 POSTER

Prognostic factors in locally advanced pancreatic cancer (LAPC) treated with first line chemotherapy

R. Peixoto[1], C. Speers[1], Y. Yin[1], D.J. Renouf[1], H. Kennecke[1]. *[1]BC Cancer Agency, Medical Oncology, Vancouver BC, Canada*

Background: LAPC is defined as surgically unresectable disease without detectable metastases and is associated with a longer survival than metastatic disease. The natural history of LAPC may differ from metastatic disease and patients may succumb to locoregional tumor complications in the absence of metastatic disease. The aim of this study was to evaluate prognostic factors in LAPC and investigate whether development of metastatic disease conferred a worse overall survival (OS).
Material and Methods: The BC Cancer Agency is a multi-centre institution treating the majority of oncology patients for the province of BC. A total of 244 consecutive patients with LAPC who initiated palliative chemotherapy from 2001 to 2011 were identified using the pharmacy database. Clinicopathologic variables and treatment outcome were retrospectively collected and analyzed. Kaplan–Meier and Cox-regression survival analysis were performed. This study was approved by our Institutional Review Board.
Results: 244 patients (136 males and 108 females) with a median age of 65 years (range 36−88) were included. First-line chemotherapy regimens included single-agent Gemcitabine ($n = 230$), Gemcitabine doublet therapy ($n = 13$), and 5-Fluorouracil, Irinotecan and Oxaliplatin ($n = 1$). 35 (14.4%) patients received locoregional radiation and 128 (52.5%) developed distant metastatic disease. The most frequent sites were liver ($n = 53$), peritoneum/ascites ($n = 52$) and lungs ($n = 18$). Progression-free survival (PFS) and OS were 5.2 months (95% CI, 4.59–5.92) and 11.6 months (95% CI, 10.53–12.65), respectively. On univariate analysis, poor performance status (PS) at diagnosis (ECOG $\geqslant 2$) and high CA19-9 levels ($\geqslant 1000$) were significantly associated with worse OS ($p < 0.001$ and 0.004, respectively). Age, location of the tumor (head or body/tail) and development of metastatic disease were not significantly associated with worse OS. On multivariate analysis,

the only predictors of worse OS were PS (HR 1.67, p = 0.0002) and elevated CA19-9 (HR 1.46, p = 0.009).
Conclusion: On multivariate analysis, performance status and elevated CA 19.9 were the only significant prognostic factors and may be considered as stratification factors among patients enrolled in clinical trials. More than half of LAPC patients died without evidence of metastatic disease, highlighting the importance of locoregional tumor complications.
No conflict of interest.

HERBIS-1: A phase II study of tri-weekly S-1 and CDDP with trastuzumab regimen in HER2-positive advanced gastric cancer (updated data)

H. Okuda[1], N. Sugimoto[2], H. Miwa[3], Y. Murakawa[4], T. Shimokawa[5], D. Sakai[6], Y. Kurokawa[7], T. Tsujinaka[8], H. Furukawa[9]. *[1]Keiyukai Sapporo Hospital, Medical Oncology, Sapporo Hokkaido, Japan; [2]Osaka Medical Center for Cancer and Cardiovascular Diseases, Clinical Oncology and Gastrointestinal Oncology, Osaka, Japan; [3]Hyogo College of Medicine, Upper Gastroenterology, Hyogo, Japan; [4]Miyagi Cancer Center, Clinical Oncology, Miyagi, Japan; [5]University of Yamanashi, Graduate School of Medicine and Engineering, Kofu, Japan; [6]Osaka University Graduate School of Medicine, Frontier Science for Cancer and Chemotherapy, Osaka, Japan; [7]Osaka University Graduate School of Medicine, Gastroenterological Surgery, Osaka, Japan; [8]Kaizuka City Hospital, Surgery, Kaizuka, Japan; [9]Kinki University Faculty of Medicine, Surgery, Osaka-Sayama, Japan*

Background: S-1 plus cisplatin (SP) is one of the standard regimens as first-line for advanced gastric cancer. In patients with HER2-positive advanced gastric cancer, trastuzumab (T-mab) in combination with capecitabine or fluorouracil and cisplatin improved the overall survival in ToGA study. However, there was no study to evaluate the efficacy and the safety of T-mab in combination with SP regimen. Therefore, we conducted this study to evaluate the efficacy and the safety of the SP plus T-mab combination.
Material and Methods: Main eligibility criteria: gastric or esophagogastric junction adenocarcinoma; HER2-positive (IHC 3+ or IHC 2+ and FISH positive); unresectable or recurrent; measurable lesion; no history of chemotherapy or radiotherapy; age⩽75; ECOG PS of 0−1; and adequate organ function.
S-1 80/100/120 mg/day based on BSA, po, d1−14, q3w plus cisplatin 60 mg/m^2, iv, d1 plus T-mab 8 mg/ kg, iv, d1 (1st course), and 6 mg/ kg, iv, d1 (from 2nd course), was repeated until disease progression.
Primary endpoint was response rate (RR). Secondary endpoints were progression-free survival (PFS), overall survival (OS) and safety.
The threshold RR was defined as 35%, and the expected RR was set at 50% with 80% power and a 1-sided alpha value of 0.1 and the calculated sample size was 50 patients. Trial registration number is UMIN000005739. The primary sponsor is Osaka Gastrointestinal cancer chemotherapy Study Group (OGSG).
Results: A total of 56 patients (median age 66) were enrolled from July 2011 to May 2012. The efficacy and the safety analyses were conducted in the full analysis set of 53 patients. Two patients were excluded for ineligibility and one was for no treatment. The confirmed RR assessed by the independent review committee was 67.9% (95% CI: 53.7–80.1), and the disease control rate was 94.3%. The median PFS was 7.1 months (95% CI: 6.0–10.1). The median OS was not reached at the median follow-up time of 9.2 months. The main grade 3/4 adverse events (⩾5%) were as follows: neutropenia 34%, leucopenia 8%, anorexia 23%, diarrhea 8%, vomiting 6%, and increased creatinine 6%.
Conclusions: This tri-week regimen with SP plus T-mab was tolerable and showed high RR indicating promising results in patients with HER2-positive advanced gastric cancer. We will show the one-year survival rate in the meeting.

Final analysis of GIDEON (Global Investigation of therapeutic DEcisions in hepatocellular carcinoma and of its treatment with sorafeNib) in >3000 sorafenib-treated patients: Prognostic value of baseline characteristics and staging systems

J. Bronowicki[1], R. Lencioni[2], S.L. Ye[3], M. Kudo[4], C. Papandreou[5], K. Nakajima[6], A.P. Venook[7], J. Marrero[8]. *[1]INSERM U954 University Hospital University of Lorraine, Department of Gastroenterology and Hepatology, Nancy, France; [2]Pisa University Hospital and School of Medicine, Division of Diagnostic Imaging and Intervention, Pisa, Italy; [3]Liver Cancer Institute and Zhongshan Hospital Fudan University, Liver Cancer Institute, Shanghai, China; [4]Kinki University School of Medicine, Department of Gastroenterology and Hepatology, Osaka, Japan; [5]University Hospital of Larissa, Department of Medical Oncology, Larissa, Greece; [6]Bayer HealthCare Pharmaceuticals, Global Medical Affairs, Montville NJ, USA; [7]University of California, Division of Medical Oncology, San Francisco CA, USA; [8]University of Texas Southwestern Medical Center, Department of Internal Medicine, Dallas TX, USA*

Background: GIDEON (NCT00812175; Bayer), a large, global, prospective, non-interventional study conducted across 5 regions in 39 countries, is now complete. Over 3300 patients with unresectable hepatocellular carcinoma treated with sorafenib were enrolled.
Materials and Methods: Baseline characteristics were recorded at study entry; safety/outcomes data were collected during follow-up. The visit interval for patient evaluation was determined at physicians' discretion. Patient outcomes were evaluated according to baseline characteristics and staging/scoring systems.

AFP, alpha-fetoprotein; BCLC, Barcelona Clinic Liver Cancer; CLIP, Cancer of the Liver Italian Program; ECOG PS, Eastern Cooperative Oncology Group performance status; MELD, model for end-stage liver disease; TNM, tumor node metastasis.
[a]TTP defined as time (days) from start of sorafenib treatment to date of first documented disease progression (PD). Only radiologically documented PD of tumor considered as PD.
[b]At study entry; [c]ECOG PS 4 (n = 7); AFP other (n = 303); MELD ⩾40 (n = 2) not shown; [d]Patients with unknown status not shown; [e]Non-evaluable patients not shown.

Results: Prognostic values of baseline characteristics and various staging systems for median overall survival (OS) and time to progression (TTP) in the intent-to-treat population (n = 3213) are shown in the table.
The safety profile in the final analysis was consistent with that reported in the first and second interim analyses of GIDEON and in Phase III studies.
Conclusions: Consistent with previously reported studies, final data indicate that baseline characteristics and scoring/staging systems, including ECOG PS, Child-Pugh status, BCLC stage, and CLIP and MELD scores, appear to be useful prognostic factors for OS. However, BCLC also appears to be predictive of TTP. Further analyses will be presented.

2595 POSTER

Efficacy and safety of Gemcitabine plus S-1 treatment in locally advanced and metastatic pancreatic cancer: A pooled analysis of three randomized trials using updated individual patient data

T. Okusaka[1], T. Ikari[2], H. Isayama[3], J. Furuse[4], H. Ishii[5], Y. Nakai[3], S. Imai[6], S. Okamura[6], C. Hamada[6]. *[1]National Cancer Center Hospital, Hepatobiliary and Pancreatic Oncology, Tokyo, Japan; [2]Tobu Chiiki Hospital Tokyo Metropolitan Health and Medical Treatment Corporation, Internal Medicine, Tokyo, Japan; [3]The University of Tokyo Graduate School of Medicine, Gastroenterology, Tokyo, Japan; [4]Kyorin University School of Medicine, Medical Oncology, Tokyo, Japan; [5]Cancer Institute Hospital, Gastroenterological Medicine, Tokyo, Japan; [6]Tokyo University of Science, Faculty of Engineering Division1 Management Science, Tokyo, Japan*

Background: S-1 is an oral fluoropyrimidine derivative shown efficacy for advanced and resected pancreatic cancer (PC). Three randomized studies (Phase III: GEST, randomized phase II: JACCRO PC-01 and GEMSAP) were conducted to evaluate the efficacy of gemcitabine plus S-1 (GS) treatment compared with gemcitabine alone (GEM) for advanced PC in Japan. In this pooled analysis, the efficacy and safety of GS was evaluated according to the extent of disease (locally advanced or metastatic) and all population using individual patient data of these trials.
Material and Methods: Additional follow up was conducted and we used updated survival data in these three trials. On these updated individual patient data, Cox's proportional hazards model and log-rank test for overall survival (OS) and progression-free survival (PFS) were used to compare GS group to GEM group. Combined safety data was also evaluated. The sponsor for this pooled analysis is Taiho Pharmaceutical Co., Ltd.
Results: 770 patients (pts) were included in this pooled analysis (GEM: 389 pts, GS: 381 pts) and 738 events for OS were observed (95.8%). In patients with locally advanced disease, median survival time was 11.8 months in GEM group and 16.4 months in GS group (HR = 0.708, 95% CI: 0.527–0.951, p = 0.0220). GS also improved OS in all patients but not in patients with metastatic disease. Other results (HR of OS and PFS in locally, metastatic and all population) were shown in the table. Grade 3/4 toxicities (%) in GEM group and GS group were neutropenia 37.2/57.1, thrombocytopenia 8.9/15.1, vomiting 0.5/3.2, and diarrhea 0.8/4.0.
Conclusions: GS significantly improved OS in all patients and patients with locally advanced disease compared with GEM. The OS benefit from adding S-1 to GEM was more pronounced in patients with locally advanced disease. Toxicity of GS was higher than GEM but considered to be tolerable.

Trastuzumab in combination with different first-line chemotherapies for treatment of HER2-positive metastatic gastric or gastro-oesophageal junction cancer: Findings from the German non-interventional observational study HerMES

S. Al-Batran[1], H. Kroening[2], C.V. Hannig[3], T. Hamm[4], E. Moorahrend[5], V. Petersen[6], E. Eggers[7], D. Hempel[8], P. Thuss-Patience[9], S. Hegewisch-Becker[10]. *[1]Krankenhaus Nordwest, Frankfurt, Germany; [2]Schwerpunktpraxis für Hämatologie und Onkologie, Magdeburg, Germany; [3]Schwerpunktpraxis für Hämatologie und Onkologie, Bottrop, Germany; [4]Schwerpunktpraxis und Tagesklinik für Hämatologie und Onkologie Kloster Paradiese, Soest, Germany; [5]Onkologische Praxis, Porta Westfalica, Germany; [6]Praxis für Hämatologie und Onkologie, Heidenheim, Germany; [7]Kreiskrankenhaus "Johann Kentmann", Torgau, Germany; [8]Onkologisches Zentrum, Donauwörth, Germany; [9]Charité – Universitätsmedizin, Berlin, Germany; [10]Onkologische Schwerpunktpraxis Eppendorf, Hamburg, Germany*

Background: The international phase III study ToGA has shown that trastuzumab (Herceptin®) is effective in prolonging survival in HER2-positive metastatic gastric or gastro-oesophageal junction cancer (MGC). However, few data are available for trastuzumab as part of routine clinical practice.
Methods: This non-interventional observational study (NCT01220934) was conducted to evaluate the efficacy, safety and feasibility of trastuzumab in previously untreated pts with HER2-positive MGC.
Results: Between April 2010 and February 2013, data from 270 pts were collected. All pts were evaluable for safety. Baseline pt characteristics were as follows: median age 65 yrs (range 29–88); gender (male 74%; female 26%); ECOG PS (0: 28%; 1: 48%; 2: 13%; 3: 3%); distant mets (90%): liver (53%), lymph node (37%), peritoneal carcinomatosis (23%), lung (16%). The mean duration of trastuzumab treatment was 6.2 months. According to the schedule of chemotherapy trastuzumab was administered every 2–3 weeks in a median dose of 4–6 mg/kg BW with accordant loading doses. Only 27% of pts received trastuzumab according to the label in combination with cisplatin and 5-FU or capecitabine (see table). Most pts (52%) did not receive cisplatin-based therapy. 39 pts (14%) received trastuzumab for more than 12 months.

Trastuzumab containing regimen	n	(%)
+ 5-FU + cisplatin	55	(20)
+ 5-FU + cisplatin + leucovorin	41	(15)
+ 5-FU + oxaliplatin (+ leucovorin)	32	(12)
+ 5-FU + oxaliplatin + docetaxel	25	(9)
+ capecitabine + cisplatin	18	(7)
+ capecitabine	17	(6)
other combinations	71	(26)
trastuzumab monotherapy	11	(4)

Preliminary median progression-free survival was 6.8 months, thus comparable to the ToGA data. Most common AEs (all grades) were diarrhoea (7%), nausea (6%), vomiting (5%) and fatigue (4%). Most common grade 3/4 AEs were general physical health deterioration (2%), vomiting (2%), acute renal failure (1%) and fatigue (1%). Health-related quality of life as assessed by EORTC QLQ-C30 and QLQ-STO22 remained stable during observation time. An updated analysis of over 300 pts will be presented at the meeting.
Conclusions: Trastuzumab combined with diverse chemotherapies, including less toxic cisplatin-free schedules, is safe and effective in the routine treatment of MGC. Overall, the results are in line with those from the ToGA trial. Trastuzumab is the standard of care for pts with HER2-positive MGC.
Conflict of interest: *Advisory board: Roche*

Quality-of-life (QoL) assessments in patients (pts) with pancreatic neuroendocrine tumors (pNET) enrolled in the open-label, phase 3b, multicenter, expanded access study of everolimus in pts with advanced NET

M. Pavel[1], N. Unger[2], I. Borbath[3], S. Ricci[4], T.L. Hwang[5], T. Brechenmacher[6], X. Wang[7], S. Saletan[8], S.G. Stergiopoulos[9], O. Bechter[10]. *[1]Universitätsklinikum Charité, Campus Virchow-KlinikumHepatologie & Gastroenterologie, Berlin, Germany; [2]University of Duisburg-Essen, Department of Endocrinology and Division of Laboratory Research, Essen, Germany; [3]Université Catholique de Louvain, Cliniques Universitaires Saint-Luc, Brussels, Belgium; [4]Presidio Ospedaliero Santa Chiara, Dip. Scienze Oncologiche e Radiologiche, Pisa, Italy; [5]Chang Gung Memorial Hospital, Chang Gung University, Lin-Kou, Taiwan; [6]Novartis Pharma S.A.S., Rueil-Malmaison, France; [7]Novartis Pharmaceuticals Corporation, Worldwide Health Outcomes Value & Access, Florham Park, USA; [8]Novartis Pharmaceuticals Corporation, Onco Ex Dir Clinical Res Phys, Florham Park, USA; [9]Novartis Pharmaceuticals Corporation, Florham Park, USA; [10]Leuven Cancer Institute, University Hospital Leuven, Leuven, Belgium*

Background: Everolimus (EVE) improved median progression-free survival by 6.4 months in pts with advanced pNET (HR. 35, 95% CI. 27-.45, $P<0.001$) compared with placebo in the double-blind, placebo-controlled, phase 3 RADIANT-3 study. QoL was not measured. An expanded access protocol was launched to gather additional safety data, to provide access to EVE for pts with advanced NET while awaiting regulatory approval (EudraCT No: 2010–023032−17), and to incorporate pt-reported outcomes to understand the impact of EVE on QoL. Here we present an analysis of QoL in pts with pNET enrolled in this study.

Methods: Pts aged ⩾18 years with biopsy-proven NET, WHO performance status 0−2, and adequate bone, hepatic, and renal function were enrolled. Main exclusion criteria were poorly differentiated NET and cytotoxic therapy within 4 wks of enrollment. EVE (10 mg/d) was administered until disease progression, unacceptable toxicity, discontinuation, death, commercial availability of EVE, or until May 30, 2012. Pts were enrolled from April 21, 2011, to April 20, 2012. The primary objective was safety of EVE. Secondary objectives included health-related QoL values assessed by the EORTC QLQ-C30 and the EORTC QLQ-GINET21 at baseline; cycles 1, 2, and 3; and then every 3 cycles until end of treatment. The QLQ-C30 has 30 items in 15 subscales, including global health status. The QLQ-GINET21 is used with the QLQ-C30 and includes NET-specific symptom and treatment-related questions not covered in the QLQ-C30 along with social and emotional well-being assessment. The EQ-5D was also administered.

Results: The full analysis set included 246 pts; 126 had pNET. Safety was similar to that reported for RADIANT-3. Throughout the treatment period, QLQ-C30 global health status remained stable (change from baseline at end of treatment = −3.9 points, n = 86). At end of treatment, the functional cognitive, emotional, physical, role, and social functioning scales were similar to baseline. Fatigue had the greatest change in symptom score (change from baseline to end of treatment, 8.9 points, n = 86), which was not considered clinically meaningful (defined as change >10 points). Similarly, the NET-specific QLQ-GINET21 symptom and functional assessment changes from baseline to end of treatment were <9 points on all scores.

Conclusions: Throughout the treatment period, as reported by pts and assessed by by QLQ-C30 and QLQ-GINET21, EVE maintained QoL in pts with pNET.

A phase 1b study of gemcitabine plus PEGPH20 (pegylated recombinant human hyaluronidase) in patients with stage IV previously untreated pancreatic cancer

S.R. Hingorani[1], J. Thaddeus[2], B.A. Berdov[3], S.A. Wagner[4], E.M. Pshevlotsky[5], S.A. Tjulandin[6], O.A. Gladkov[7], R.F. Holcombe[8], J.H. Zhu[9], C.E. Devoe[10]. *[1]Fred Hutchinson Cancer Research Center, Clinical, Seattle WA, USA; [2]Highlands Oncology Group, Clinical, Fayetteville NC, USA; [3]Medical Radiological Research Center, Clinical, Obninsk, Russian Federation; [4]Indiana University Melvin and Bren Simon Cancer Center, Clinical, Indianapolis IN, USA; [5]Omsk Regional Budget Medical Institution: Clinical Oncological Center, Clinical, Omsk, Russian Federation; [6]Russian Oncology Research Center n.a.N.N. Blokhin, Clinical, Moscow, Russian Federation; [7]Chelyabinsk Regional Clinical Oncology Center, Clinical, Chelyabinsk, Russian Federation; [8]Mount Sinai School of Medicine, Clinical, New York NY, USA; [9]Halozyme Therapeutics, Clinical, San Diego CA, USA; [10]Monter Cancer Center, Clinical, Lake Success NY, USA*

Background: PEGPH20 is a PEGylated version of human recombinant hyaluronidase. In preclinical studies, PEGPH20 depleted pancreatic cancers of their high hyaluronan (HA) content. In a genetically engineered murine model of PDA, PEGPH20 + gemcitabine (Gem) significantly prolonged survival compared to Gem alone. In Phase 1 PEGPH20 monotherapy studies, the MTD was 3 μg/kg. The most common AEs were musculoskeletal events.

Materials and Methods: This was a dose-escalation study to find the recommended Phase 2 dose (RP2D) of PEGPH20 in combination with Gem in patients (pts) with Stage IV previously untreated pancreatic cancer. Pts received PEGPH20 at 1, 1.6, or 3 μg/kg IV twice a week for Wks 1−4, weekly for Wks 5−7, then 1 wk rest. Dose escalation was based on safety. Gem was given at 1000 mg/m^2 IV once a week for Wks 1−7, then 1 wk rest. Thereafter, PEGPH20 + Gem were given once a week for 3 wks in 4-wk cycles. Dexamethasone was given pre and post PEGPH20 doses.

Results: Of the 28 pts enrolled, the majority had a Karnofsky performance status ⩾80%. Median age was 59 yrs. Metastatic sites were liver (89% pts), visceral (36%), lung (21%), and lymph nodes (21%). Median CA19-9 was 1139 U/mL. Four pts received PEGPH20 at 1 μg/kg, 4 at 1.6 μg/kg, and 20 at 3 μg/kg. The RP2D was 3 μg/kg. Median PEGPH20 treatment was 68 days (1–271 days); 4 pts remain on study. Three pts had 1 PEGPH20 dose reduction (3 to 1.6 μg/kg). The majority of PEGPH20-related AEs were Grade 1/2. The most common related AEs were muscle spasm (43%), myalgia (32%), arthralgia (25%), and fatigue (25%). Objective response was assessed by an independent central radiologist using RECIST 1.1. Partial response (PR) was seen in 10/24 pts (1.6 and 3 μg/kg) for an overall response rate of 42% (22−61%, 95% CI), and 8 pts had stable disease (41–189 days). Tumor biopsies from 17 pts (1.6 and 3 μg/kg) were evaluated for HA staining. PR occurred in 7/11 pts (64%) with high HA staining and in 2/6 pts (33%) with low HA staining. HA data were not available for the last PR pt. CA19-9 reductions ⩾70% occurred in 6/14 pts with elevated baseline levels (1.6 and 3 μg/kg). CA19-9 reductions were generally associated with response. PK results showed dose-dependent exposure consistent with PEGPH20 monotherapy studies.

Conclusions: PEGPH20 in combination with Gem is generally well tolerated in advanced pancreatic cancer and shows promising efficacy, especially in pts with high intratumoral HA content.

Randomized phase III trial of irinotecan plus cisplatin versus irinotecan in patients with metastatic gastric cancer resistant to S-1 monotherapy: Survival analysis

S. Tamura[1], K. Nishikawa[2], M. Yamada[3], E. Hirai[4], T. Yasuda[5], Y. Makari[6], A. Nashimoto[7], S. Morita[8], J. Sakamoto[9], T. Tsujinaka[10]. *[1]Kansai Rosai Hospital, Surgery, Amagasaki Hyogo, Japan; [2]Osaka General Medical Center, Surgery, Osaka, Japan; [3]Gifu Municipal Hospital, Surgery, Gifu, Japan; [4]Tokyo Women's Medical University Yachiyo Medical Center, Digestive and General Surgery, Yachiyo, Japan; [5]Kinki University, Surgery, Osaka, Japan; [6]Minoh City Hospital, Surgery, Minoh, Japan; [7]Niigata Cancer Center Hospital, Surgery, Niigata, Japan; [8]Yokohama City University, Biostatistics and Epidemiology, Yokohama, Japan; [9]Tokai Central Hospital, Kakamigahara, Japan; [10]Kaizuka City Hospital, Surgery, Kaizuka, Japan*

Background: The standard second-line regimen for the treatment of metastatic gastric cancer remains to be established. We have implemented a phase III trial comparing combination therapy with irinotecan (CPT-11) and cisplatin (CDDP) to monotherapy with CPT-11 (TRICS trial). The results of the safety analysis have already been reported (Hasegawa et al. ESMO 2012). Here we report the results of the survival analysis.
Methods: Patients with metastatic gastric cancer resistant to S-1 monotherapy were randomly allocated to the CPT-11/CDDP arm (CPT-11−60 mg/m^2, CDDP 30 mg/m^2, Day 1, q2w) or the CPT-11 arm (150 mg/m^2, Day 1, q2w). The main eligibility criteria included disease progression after receiving S-1 monotherapy or recurrence within 6 months after or during S-1 adjuvant chemotherapy (discontinuation due to adverse events was not included). The primary endpoint was to compare overall survival (OS). The planned sample size was 200, including ineligibility or dropout.
Results: Between 2007 and 2011, 168 patients were randomly assigned to the CPT-11/CDDP or CPT-11 arm, respectively. The median follow-up was 59.0 months (M). Median OS was 13.9 M in the CPT-11/CDDP arm and 12.7 M in the CPT-11 arm (hazard ratio [HR] 0.834, 95% CI 0.596–1.167, p = 0.288). There were no significant differences in the secondary endpoints: progression free survival (4.6 M vs. 4.1 M, HR 0.860, p = 0.376), response rate (16.9% vs. 15.4%, p = 0.812) and time to treatment failure (3.3 M vs. 3.5 M, HR 1.009, p = 0.96). The incidence of grade 3−4 neutropenia (35.4% vs 27.2%, p = 0.259), anemia (15.9% vs 3.7%, p = 0.009) and LDH (5% vs. 0%, p = 0.04) was greater in the CPT-11/CDDP arm than in the CPT-11 arm. An exploratory subgroup analysis revealed that the CPT-11/CDDP arm was significantly more effective in intestinal type gastric adenocarcinoma (median OS 17.3 M vs. 14.0 M, HR 0.561, p = 0.021).
Conclusions: CPT-11/CDDP combination therapy was not statistically superior to CPT-11 monotherapy for the OS. But the combination regimen may be particularly effective for intestinal type tumors.
No conflict of interest.

2600 POSTER

No improvement in median survival for patients with metastatic gastric cancer despite increased use of chemotherapy

N. Bernards[1], G.J. Creemers[2], G.A. Nieuwenhuijzen[3], K. Bosscha[4], J.F.M. Pruijt[5], V.E.P.P. Lemmens[1]. *[1]Eindhoven Cancer Registry, Research, Eindhoven, Netherlands; [2]Catharina Hospital, Internal Medicine, Eindhoven, Netherlands; [3]Catharina Hospital, Surgery, Eindhoven, Netherlands; [4]Jeroen Bosch Hospital, Surgery, 's Hertogenbosch, Netherlands; [5]Jeroen Bosch Hospital, Internal Medicine, 's Hertogenbosch, Netherlands*

Background: Gastric cancer often presents late in an irresectable or metastasized stage. We conducted a population-based study to evaluate trends in systemic treatment and survival of metastatic non-cardia gastric cancer.
Method: All patients with non-cardia adenocarcinoma of the stomach, diagnosed between 1990 and 2011 in the Eindhoven Cancer Registry area in the Netherlands were included (N = 4797). We conducted multivariable logistic regression analysis to evaluate trends in administration of palliative chemotherapy and multivariable proportional hazards regression analyses to evaluate trends in crude overall survival.
Results: The proportion of patients presenting with metastatic gastric cancer, defined as stage IV according to the TNM classification in the respective period, increased from 25% in 1990 to 44% in 2011 (p < 0.0001). The use of palliative chemotherapy increased, from 5% in 1990 to 36% in 2011, with a strong increase in particular after 2006 (p < 0.0001). Younger patients aged <50 yrs (46%, (adjusted odds ratio (OR_{adj}) 4.3, p < 0.001) or between 50−59 yrs (23%, OR_{adj} 1.7, p = 0.02) and patients with a high socioeconomic status (25%, OR_{adj} 1.5, p = 0.02) more often received chemotherapy. In contrast, older patients aged between 70−79 yrs (10%, OR_{adj} 0.28, p < 0.001) or 80+ yrs (1%, OR_{adj} 0.02, p < 0.001), patients with comorbidity (17%, OR_{adj} 0.6, p = 0.02), linitis plastica (19%, OR_{adj} 0.6, p = 0.04) or multiple distant metastases (18%, OR_{adj} 0.5, p = 0.007) were less often treated with chemotherapy. A large hospital variation was observed in the administration of palliative chemotherapy (9−27%). Median overall survival remained constant between 16 (95% CI 12.3–18.6) and 18 (95% CI 15.4–21.1) weeks (p = 0.10). In addition, female sex (HR 0.8, p = 0.001), poor or undifferentiated tumor grade (HR 1.2, p = 0.001), liver metastases (HR 1.6, p < 0.001), multiple distant metastases (HR 1.5, p < 0.001) and administration of chemotherapy (HR 0.6, p < 0.001) had an independent effect on survival.
Conclusion: The increased administration of chemotherapy in patients with metastatic gastric cancer did not lead to an increase in population-based overall survival. Identification of the subgroup of patients which benefits from palliative chemotherapy is of utmost importance to avoid unnecessary treatment.
No conflict of interest.

2601 POSTER

Subgroup analysis of prognostic factors for overall survival in the SHELTER trial evaluating resminostat in advanced hepatocellular carcinoma (HCC) − the SHELTER Study Group

M. Bitzer[1], A. Mais[2], B. Hauns[2], J. Asche[2], T. Herz[2], S. Pegoraro[2], A. Ammendola[2], S. Henning[2], B. Hentsch[2]. *[1]University Tuebingen, Medical University Clinic, Tuebingen, Germany; [2]4SC AG, Clinical Development, Planegg-Martinsried, Germany*

Background: Previously published results of the phase I/II SHELTER study demonstrated efficacy and safety of the oral pan-HDAC inhibitor resminostat in second-line treatment of HCC patients, who had progressed under first-line sorafenib therapy. An analysis of the influence of patient baseline characteristics on overall survival (OS) was performed.
Methods: Patients with advanced-stage HCC and centrally confirmed radiologic progression under first-line sorafenib therapy were included in a multi-center, two-arm trial where resminostat was administered either alone or in combination with sorafenib. A Cox proportional-hazards model was used to evaluate the interaction between baseline characteristics and OS in both treatment groups.
Results: In the combination group, pts with Child-Pugh-A, ECOG 0 or absence of vascular invasion had a statistically significant lower risk of death compared to pts with Child-Pugh-B (HR 0.19, 95% CI 0.06–0.55), ECOG 1 (HR 0.15, 95% CI 0.05–0.44), or vascular invasion (HR 0.37, 95% CI 0.15–0.93), respectively. For pts with BCLC-B there was a strong trend, although not statistically significant, for a lower risk of death when compared to pts with BCLC-C (HR 0.43, 95% CI 0.13–1.49). Etiology, prior TACE therapy, extrahepatic spread and interval between first- and second-line treatment had no impact on overall survival in this study. Comparing the impact of these baseline characteristics in the combination and resminostat monotherapy, no statistically significant different influence on OS between both treatment groups was observed.
Conclusions: Resminostat in combination with sorafenib showed a substantial median OS of 8.1 months in second-line treatment of advanced HCC patients who had developed progressive disease under first-line sorafenib therapy. Subgroup analysis of patient baseline characteristics revealed a significant influence of Child-Pugh index, ECOG classification, and vascular invasion on overall survival, whereas e.g. the interval between first- and second-line treatment had no impact.

2602 POSTER

Safety of two different doses of pertuzumab (P) in combination with trastuzumab (T) and chemotherapy (CTx) in patients (pts) with HER2-positive advanced gastric cancer (aGC)

Y.K. Kang[1], S.Y. Rha[2], P. Tassone[3], J. Barriuso[4], R. Yu[5], T. Szado[5], A. Garg[5], Y.J. Bang[6]. *[1]Asan Medical Center, Division of Oncology, Seoul, Korea; [2]Yonsei University College of Medicine, Yonsei Cancer Center, Seoul, Korea; [3]Magna Graecia University, Medical Oncology Unit, Catanzaro, Italy; [4]Hospital Universitario La Paz, Medical Oncology Department, Madrid, Spain; [5]Genentech, South San Francisco, USA; [6]Seoul National University Hospital, Division of Hematology and Medical Oncology, Seoul, Korea*

Background: HER2 is overexpressed in 15−20% of aGC. Phase III results demonstrated that T + CTx significantly improved overall survival compared with CTx alone in pts with HER2-positive aGC and/or gastro-oesophageal junction (GEJ) cancer (Bang Lancet 2010). The most frequent grade 3/4

adverse events (AEs) reported in that trial in pts receiving T + CTx were neutropenia, anaemia, diarrhoea, nausea, anorexia and vomiting. The combination of P with T + docetaxel significantly improved progression-free survival (Baselga NEJM 2012) and overall survival (Swain SABCS 2012) compared with T + docetaxel in HER2-positive first-line (1L) metastatic breast cancer. P + T + CTx has the potential to improve survival outcomes in HER2-positive aGC. We therefore conducted a Phase IIa study to investigate the pharmacokinetics (PK) and safety of P in combination with T + CTx in HER2-positive inoperable locally advanced or recurrent and/or metastatic adenocarcinoma of the stomach or GEJ (JOSHUA, NCT01461057).

Materials and Methods: JOSHUA was a randomised, open-label, multicentre study evaluating two different doses of P in 1L treatment of pts with HER2-positive aGC or GEJ cancer. Pts received P 840 mg for Cycle 1 and 420 mg q3w for Cycles 2−6 (Arm A) or P 840 mg q3w for all 6 cycles (Arm B). Six cycles of T, cisplatin and capecitabine were also given, followed by T q3w until disease progression or unmanageable toxicity. Primary endpoints were P trough concentrations (C_{min}) at Day 43 (to identify the P dose giving a steady-state C_{min} of $\geqslant$20 μg/mL in $\geqslant$90% of pts), safety and tolerability.

Results: 15 pts were randomised into each arm and both arms were well balanced in terms of tumour stage and race. However, there were more males (93 vs. 67%), older pts (median age 67 vs. 59 years) and more pts with ECOG performance status 0 (67 vs. 40%) in Arm A than in Arm B. The mean C_{min} at Day 43 in Arms A and B was 40.0 μg/mL (CV 43.2%) and 57.9 μg/mL (CV 56.5%), respectively, and the estimated proportion of pts achieving the target C_{min} was 91.6% (95% CI 78.3–99.2) in Arm A and 98.3% (95% CI 91.4–99.97) in Arm B. At this interim safety assessment, treatment was well tolerated and there was no difference in AE profile between arms. The most common grade $\geqslant$3 AEs ($\geqslant$4 pts overall) were diarrhoea, neutropenia, anaemia, decreased appetite, fatigue, febrile neutropenia, hyponatraemia and stomatitis. Diarrhoea was the most frequent AE in both arms and occurred early during study treatment. Updated safety data and preliminary efficacy data will also be presented.

Conclusions: The safety profile was similar between arms, with diarrhoea being the most common AE. Based on the PK and safety data, the higher dose of P (840 mg q3w) has been selected for a Phase III study comparing the safety and efficacy of P + T + CTx vs. placebo + T + CTx in 1L HER2-positive metastatic gastric or GEJ cancer (JACOB, NCT01774786).

2603 POSTER

Comparison of aggressive gastric B-cell lymphoma patients according to HIV infection status in the era of combination antiretroviral therapy

S. Nakazuru[1], T. Uehira[2], A. Sugimoto[1], T. Iwasaki[1], R. Iwasaki[1], H. Hasegawa[1], Y. Sakakibara[1], T. Toyama[1], H. Ishida[1], E. Mita[1]. *[1]Osaka National Hospital, Department of Gastroenterology and Hepatology, Osaka, Japan; [2]Osaka National Hospital, AIDS Medical Center, Osaka, Japan*

Background: Human immunodeficiency virus (HIV)-associated non-Hodgkin lymphoma is the most common HIV-associated malignancy despite the advent of combination antiretroviral therapy (cART). The gastrointestinal (GI) tract is one of the most common extranodal sites, and the stomach is the most common site. This study investigated the clinical characteristics and survival outcomes of gastric lymphoma patients according to HIV infection status.

Material and Methods: We retrospectively analyzed the medical records of patients diagnosed with GI lymphoma and HIV-associated lymphoma at Osaka National Hospital from April 2000 to March 2013.

Results: Of 2,314 HIV-positive patients, 16 were diagnosed with GI lymphoma. The stomach was the most common site of GI involvement (n = 10, 63%), followed by the duodenum (n = 5, 31%). One patient was diagnosed upon autopsy with gastric diffuse large B-cell lymphoma (DLBCL). Of the 9 HIV-positive gastric lymphoma patients, 6 (67%) had Burkitt lymphoma and 3 (33%) had DLBCL according the WHO classification. One patient (11%) had stage I disease, 2 (22%) had stage II disease, and 6 (67%) had stage IV disease according to the Ann Arbor classification. At the time of diagnosis, the median CD4 lymphocyte count was 239/mm^3, and the HIV RNA viral load was 52,000 copies/mm^3. One patient (11%) had a prior AIDS-defining illness, and 2 (22%) had been previously treated with cART. Seven patients (78%) received systemic chemotherapy, and 1 (11%) received chemotherapy followed by locoregional radiotherapy. Five (56%) of the 9 patients have died within 6 months. Of the 49 HIV-negative gastric lymphoma patients evaluated, 24 (49%) were diagnosed with DLBCL. In total, 9 HIV-positive and 24 HIV-negative patients with aggressive gastric B-cell lymphoma were evaluated. Age at diagnosis was lower and LDH levels were higher in HIV-positive patients than in HIV-negative patients. After a median follow-up of 22 months (range, 0–138 months), the 2-year survival rates of patients with and without HIV infection were 44% and 72%, respectively. The overall survival rate differed significantly between HIV-positive and HIV-negative patients ($P = 0.049$).

Conclusions: Gastric aggressive B-cell lymphoma patients infected with HIV continue to experience higher mortality rates than those not infected with HIV, even in the era of cART. Better management and therapeutic approaches are needed to improve survival in HIV-infected patients who develop gastric lymphoma.

No conflict of interest.

2604 POSTER

Multivariate prognostic factor analysis in patients (pts) with advanced biliary tract cancer (aBTC) treated with second-line chemotherapy (CT)

L. Fornaro[1], S. Cereda[2], F. Bergamo[3], F. Leone[4], M. Russano[5], N. Silvestris[6], J. Corbelli[7], V. Rotella[1], C. Vivaldi[8], G. Brandi[7]. *[1]Azienda USL 2, Medical Oncology, Lucca, Italy; [2]San Raffaele Scientific Institute, Medical Oncology, Milano, Italy; [3]Istituto Oncologico Veneto, Medical Oncology, Padova, Italy; [4]Institute for Cancer Research and Treatment IRCC Candiolo University of Torino, Medical Oncology, Torino, Italy; [5]Campus Biomedico University, Medical Oncology, Roma, Italy; [6]Institute for Cancer Research and Treatment IRCCS Ospedale Oncologico, Medical Oncology, Bari, Italy; [7]Sant'Orsola Malpighi Hospital University of Bologna, Medical Oncology, Bologna, Italy; [8]Azienda Ospedaliero-Universitaria Pisana, Medical Oncology, Pisa, Italy*

Background: We retrospectively evaluated the impact of different clinico-pathologic factors on the survival of aBTC pts treated with second-line CT.

Material and Methods: Consecutive aBTC pts who received second-line CT at 8 Italian Institutions since 2004 were identified. The association between different clinico-pathological factors and progression-free survival (PFS) and overall survival (OS) was investigated by log-rank test and Cox model setting statistical significance at $P<0.05$. A prognostic score was calculated by assigning 1 point to each factor found significant at multivariate analysis.

Table 1.

Variable	PFS		OS	
	HR (95% CI)	*P*	HR (95% CI)	*P*
ECOG PS				
0	1		1	
1−2	1.550 (1.095–2.193)	0.013	2.675 (1.629–4.394)	<0.001
PFS after first-line				
$\geqslant$6 months	1		1	
<6 months	1.418 (1.047–1.919)	0.024	1.760 (1.099–2.819)	0.019
Leucocyte count				
$\geqslant$10000/μL	1		1	
<10000/μL	0.549 (0.355–0.851)	0.007	0.556 (0.321–0.964)	0.036
CA19.9 level				
$\geqslant$120 U/mL	1		1	
<120 U/mL	0.677 (0.501–0.914)	0.011	0.456 (0.292–0.711)	0.001
Lung metastases				
Yes	1		NS	
No	0.720 (0.524–0.989)	0.043		

NS: not significant

Results: 247 patients were identified: male, 45%; median age, 65 years (range 28−85); ECOG performance status 0/1−2, 64%/36%; disease site, intrahepatic 52%/extrahepatic 22%/ gallbladder 18%/ampullary 8%; previous surgery, 57%; previous adjuvant CT, 24%; first-line gemcitabine plus platinum, 61%; the majority of patients had metastatic disease; sites of metastases 1/>1, 46%/54%; second-line monotherapy/combination, 30%/70%. At a median follow up of 23 months, response rate with second-line CT is 5% (stable disease: 31%), while median PFS and OS are 3.3 months (95% CI: 2.9−3.7) and 8.2 months (95% CI: 6.8−9.6), respectively. The factors associated with PFS and OS at multivariate analysis are listed in the Table. By combining these factors, 204 pts with complete data were categorized into three risk groups: low (0 points), intermediate (1 to 2 points), and high (3 or more points). As regards PFS, median survival time for low, intermediate and high risk groups is 6.8, 3.5 and 2.4 respectively ($P<0.0001$). As regards OS, median survival time for low, intermediate, and high risk groups is 17.4, 8.0 and 3.1 respectively ($P<0.0001$).

Conclusions: aBTC is a heterogeneous disease for which no standard second-line CT has been established yet: easily available clinico-pathologic factors may help identifying aBTC pts with different prognosis, thus helping second-line treatment decision in each case.
No conflict of interest.

2605 POSTER

Comparison of three different docetaxel and cisplatin plus fluorouracil (DCF) as first-line therapy for advanced gastric cancer: A retrospective analysis of the two institution

A. Inal[1], D. Koca[2], M.A. Kaplan[3], M. Kucukoner[3], Z. Urakci[3], E. Dogan[4], A. Isikdogan[3]. *[1]Dicle University, Diyarbakir, Turkey; [2]Regional Training and Research Hospital, Department of Internal Diseases Division of Medical Oncology, Van, Turkey; [3]Dicle University, Department of Medical Oncology, Diyarbakir, Turkey; [4]van Yüzüncü Yil University, Department of Medical Oncology, Van, Turkey*

Background: We performed a retrospective analysis of the efficacy and side effects of three different docetaxel and cisplatin plus fluorouracil (DCF) in the advanced gastric cancer with first-line chemotherapy treated patients.
Patients and Methods: We retrospectively reviewed 202 locally advanced or metastatic gastric cancer patients. The standard DCF group was administered 75 mg/ m^2 docetaxel and cisplatin on day 1 and 750 mg/ m^2/day 5-fluorouracil infusion for 5 days, repeated every 3 weeks. The mDCF group received 60 mg/ m^2 docetaxel and cisplatin on day 1 and 600 mg/m^2 5-fluorouracil continuous infusion per day on days 1−5, every 3 weeks. The de Gramont regimen group consisted of 60 mg/ m^2 docetaxel and 50 mg/m^2 cisplatin on day 1 and bolus fluorouracil (400 mg/ m^2) on day 1, and continuous infusion of fluorouracil (2400 mg/ m^2) on two days, repeated every two weeks.
Result: The standard DCF arm 87 (M: 57, F: 30), The mDCF group arm 26 (M: 15, F: 11), de Gramont regimen arm 89 (M: 67, F: 22) are patients. Patients with the de Gramont regimen had a higher dose reduction ($p = 0.001$). Between treatment groups, gender, age, the number of cycles, histology, stage, second-line chemotherapy did not have a statistically difference (p >0.05). PFS and OS were more favorable in the de Gramont regimen in present study, while the differences were not statistically significant (p>0.05). The rate of response did not have a difference statistically. In spite of the fact that treatment efficacy were similar in between groups, grade III−IV neutropenia, febrile neutropenia, thrombocytopenia, anaemia, nausea and vomiting were higher in the standard DCF(table).

Table: Efficiency of the treatment and survival

Response	Group A (%)	Group B (%)	Group C (%)	*p*
Complete response	10.0	5.3	3.4	>0.05
Partial response	35.7	36.8	24.7	>0.05
Stable disease	32.9	36.8	39.3	>0.05
Progressive disease	21.4	21.1	32.6	>0.05
OS (months)	10.0 (6.9–13.0)	9.0 (7.4–10.6)	11.6 (10.7–12.4)	>0.05
PFS (months)	6.0 (4.7−7.2)	6.0 (3.0−8.9)	7.9 (6.8−8.9)	0.08

Conclusion: The response rate, median PFS and OS are similar in different DCF regimen, while the mDCF and de Gramont-based DCF regimens are more favourable than the DCF regimen for toxicity profile. mDCF and de Gramont-based DCF regimens may provide an alternative regimen to the standard DCF.
No conflict of interest.

2606 POSTER

Present status of screening of hepatitis B virus infection in patients who undergo chemotherapy in Japan

M. Ikeda[1], H. Ohshima[2], H. Yamamoto[2]. *[1]National Cancer Center Hospital East, Division of Hepatobiliary and Pancreatic Oncology, Kashiwa Chiba, Japan; [2]Japan Medical Data Center Co. Ltd., Statistical division, Tokyo, Japan*

Background: Reactivation of hepatitis B virus (HBV) has been often reported as a fatal complication, such as acute hepatitis, during or following chemotherapy. The Japanese HBV guideline for the prevention of HBV reactivation caused by immunosuppressive therapy or chemotherapy was published in 2009 by the research team of Ministry of Health, Labour and Welfare. This guideline recommends that the high risk patient group should be identified by measuring HBsAg, anti-HBc and anti-HBs before the commencement of chemotherapy. The aim of this study was to investigate the present status of screening of HBV in patients who underwent chemotherapy for malignancy.
Methods: This study was conducted through utilising the Claims Database which Japan Medical Data Center possesses. The study subjects abstracted from it were 1,995 patients who had been newly undergone chemotherapy for malignancy. They are abstracted from 28,087 patients with solid tumours and haematological malignancy among 1,154,774 insured people (individuals and families) who were member of multiple Health Insurance Association from Jan 2008 through Dec 2012. The proportion of patients who measured HBsAg (P-HBs) and HBsAg negative patients who measured anti-HBc or anti-HBs (P-HBc/HBs) before chemotherapy were investigated.
Results: Comparison P-HBs with P-HBc/HBs in all 1,995 patients were 64.2% and 15.7%, respectively. P-HBs and P-HBc/HBs in patients with solid tumours and haematological malignancy were 64.0% and 65.3% ($p = 0.89$), and 8.6% and 67.1% ($p < 0.0001$), respectively. P-HBs and P-HBc/HBs in patients on cancer center and non-cancer center were 64.6% and 63.3% ($p = 0.80$), and 21.2% and 8.7% ($p < 0.0001$), respectively. P-HBs and P-HBc/HBs in patients before and after the announcement of the Japanese guideline and haematological malignancy were 49.2% and 65.7% (p=24), and 6.7% and 16.5% ($p = 0.005$), respectively.
Conclusions: P-HBc was higher in patients with haematological malignancy and on cancer center, and this finding demonstrated that the oncologists charged in these patients were highly aware of HBV reactivation. However, the proportion was not sufficient, and the enlightenment for 'HBV reactivation by chemotherapy' was warranted.
No conflict of interest.

2607 POSTER

UK audit of sorafenib for advanced hepatocellular cancer

J. King[1], P. Johnson[2], D. Palmer[2], P. Ross[3], R. Hubner[4], J. Graham[5], S. Darby[6], C. Iwuji[7], D. Swinson[8], T. Meyer[1]. *[1]Royal Free London NHS Foundation Trust, Oncology, London, United Kingdom; [2]University Hospitals Birmingham NHS Foundation Trust, Oncology, Birmingham, United Kingdom; [3]Guys and St Thomas' NHS Foundation Trust, Oncology, London, United Kingdom; [4]The Christie NHS Foundation Trust, Oncology, Manchester, United Kingdom; [5]The Newcastle Upon Tyne Hospitals NHS Foundation Trust, Oncology, Newcastle, United Kingdom; [6]Sheffield Teaching Hospital NHS Foundation Trust, Oncology, Sheffield, United Kingdom; [7]Leicester Royal Infirmary, Oncology, Leicester, United Kingdom; [8]Leeds Teaching Hospitals NHS Trust, Oncology, Leeds, United Kingdom*

Background: Based on two randomised controlled trials, sorafenib is the current standard of care for patients with advanced hepatocellular carcinoma (HCC) and well compensated liver disease. In the SHARP trial, conducted in the western population including the UK, median survival was increased from 7.9 to 10.7 months (mo). Patients in SHARP had Child-Pugh (CP) score A (95%), and 54% had an ECOG performance status (PS) of 0. They received a mean daily dose of 710 mg/day for a median duration of 5.3 mo. We performed a retrospective national audit of patients treated with sorafenib in the UK to determine the outcome for patients treated outside a clinical trial.
Method: All UK centres that treat HCC were invited to participate. Patients with HCC who had received sorafenib between 1st Jan 2009 and 1st Jan 2013 were identified via the Cancer Drugs Fund records. Clinical, pathological and treatment data were collected from medical and pharmacy records. The primary outcome measure was overall survival which was estimated according to the Kaplan–Meier method.
Results: Data was received for 379 patients from 11 UK hospitals. Median age was 68 (range 17−89) and 78% were male. Background liver disease was known for 83% and was: alcohol 28%; none 23%; hepatitis C 16%; hepatitis B 12%; NASH 10%; other 16%. At baseline, ECOG PS was recorded for 84% of which: PS0 30%; PS1 47%; PS2 23%, and (CP) score was recorded for 83% of which: CPA 84% and CPB 16%. BCLC stage at baseline was reported for 85% of which: BCLC B 28% and BCLC C 71%. Previous loco-regional therapy had been given to 38%, and 38% had extra-hepatic metastases. At the time of analysis, 73% had completed treatment, with a median time on treatment of 3.2 mo, and an average daily dose of 585 mg. Dose was reduced in 43% of patients and 26% had a treatment interruption. The main reasons for stopping sorafenib treatment were toxicity (26%), radiological progression (24%) or clinical progression/death (41%). Median overall survival for 374 evaluable patients and 219 events was 8.5 mo (95% CI 7.4−9.7).
Conclusion: Clinical outcomes were compatible with those reported in other European audits. Overall, compared with the SHARP trial, patients had worse PS and background liver function, but also received a lower average dose and had a shorter time on treatment.
No conflict of interest.

2608 POSTER

Phase II open-label single-arm trial of combining the epitope peptide derived from Vascular Endothelial Growth Factor Receptor-2 with gemcitabine for patients with unresectable biliary tract cancer OTS102 Study202

J. Furuse[1], H. Ishii[2], S. Ohkawa[3], Y. Sasaki[4], H. Maguchi[5], N. Mizuno[6], Y. Ohashi[7], T. Tsunoda[8]. *[1]Kyorin University, Division of Hepatobiliary and Pancreatic Oncology, Mitaka, Japan; [2]Cancer Institute Hospital, Gastroenterological Medicine, Tokyo, Japan; [3]Kanagawa Cancer Center Hospital, Division of Hepatobiliary and Pancreatic Oncology, Yokohama, Japan; [4]Showa University School of Medicine, Division of Medical Oncology, Tokyo, Japan; [5]Teine-Keijinkai Hospital, Center for Gastroenterology, Sapporo, Japan; [6]Aichi Cancer Center Hospital, Department of Gastroenterology, Nagoya, Japan; [7]University of Tokyo, Department of Biostatistics School of Public Health, Tokyo, Japan; [8]Onco Therapy Science Inc., Kanagawa, Japan*

Background: Gemcitabine (GEM) is considered one of the standard therapies for advanced biliary tract cancer; however, due to still poor prognosis further improvement was needed. Vascular Endothelial Growth Factor Receptor-2 (VEGFR-2/Flk-1/KDR) is an essential target for tumor angiogenesis, which expression is also correlates to the progression of the biliary tract cancer. VEGFR2 peptide (OTS102, Elpamotide) specifically targets the cells expressing VEGFR-2/ KDR. Based on promising Phase I trial results on solid tumors, we conducted an open-label Phase II study to evaluate the efficacy and safety of the combination with OTS102 and gemcitabine.
Methods: This is a multi-center, single-arm, open-label, phase II study with the main eligibility criteria as unresectable and recurrent biliary tract cancer, with the status of human leukocyte antigen A*24:02, PS: 0−1, radiotherapy or chemotherapy naive. Patients received combination OTS102+GEM therapy by subcutaneous OTS102 injection on day 1, 8, 15 and 22 of each 28-day treatment cycles and GEM at a fixed dose of 1000 mg/m^2 on day 1, 8 and 15. Therapy was repeated for 18 months or termination criteria had been met. The primary endpoint was overall survival. Assuming 1-year survival as 15−30%, the increase of 1-year survival by OTS102 by 15%, one-sided significance level of 10%, and power of 80%, the sample size necessary was estimated as 50 patients. Kaplan–Meier method was used to draw survival curve, and 1-year survival and 95% CI of both sides were estimated. Historical data (GEM Historical) selected for the analysis of this report was a phase II single-agent GEM study (Okusaka et al. Cancer Chemother Pharmacol. 2006).
Results: From July 2009 to June 2011, 55 pts were registered from 14 facilities all over the Japan, and 54 were treated. For full analysis set of 54 pts, mean pt age was 62.9 years. Types of cancer pts had were: extrahepatic bile duct cancer, 13 pts; intrahepatic bile duct cancer, 20 pts; gallbladder cancer, 18 pts; and ampulla of Vater cancer, 3 pts. Mean survival time was 10.05 months (95% CI: 7.95–13.96) in OTS102+GEM group, whereas it was 7.6 months in GEM alone group (log-rank test, p = 0.043). 1-year survival rate, 44.4% vs 25.0%, respectively.
Conclusion: OTS102 added to GEM suggested to prolong OS compared to GEM alone. Further analysis with multiple historical data with adjustment to match the study population of this trial has been currently ongoing.

Overall survival of specific HCC patient subgroups in prospective, non-interventional INSIGHT study treated with sorafenib

R. Koschny[1], E. Schott[2], P.R. Galle[3], T. Göhler[4], P. Malfertheiner[5], R. Stauber[6], R. Buder[7], I. Bernard[8], G. Gerken[9]. *[1]Universitätsklinikum Heidelberg, Medizinische Klinik IV, Heidelberg, Germany; [2]Charité-Campus Virchow Klinikum, Medizinische Klinik Hepatologie und Gastroenterologie, Berlin, Germany; [3]Universitätsmedizin der Johannes Gutenberg-Universität, I. Medizinische Klinik und Poliklinik, Mainz, Germany; [4]Onkologische Praxis, Dresden, Germany; [5]Otto-von-Guericke Universität, Universitätsklinik für Gastroenterologie Hepatologie und Infektiologie, Magdeburg, Germany; [6]Univ.-Klinik für Innere Medizin, Klinische Abteilung für Gastroenterologie und Hepatologie Medizinische Universität, Graz, Austria; [7]Konventspital Barmherzige Brüder, Abteilung Innere Medizin, Linz, Austria; [8]Bayer HealthCare, MED Onkologie-Infektiologie, Leverkusen, Germany; [9]Universitätsklinik, Abteilung Gastroenterologie und Hepatologie, Essen, Germany*

Background: INSIGHT is a prospective, non-interventional study, conducted in pts with hepatocellular carcinoma at ~170 sites in Germany and Austria. The objectives of this study are the evaluation of safety and efficacy in daily clinical practice. Enrollment into INSIGHT is not restricted to a particular tumor stage.
Methods: Data are collected at the start of sorafenib treatment, then at intervals of approximately every 2−4 months. The time from start of sorafenib therapy until evidence of disease progression or unacceptable toxicities are defined as observation period. Documentation of tumor status evaluation, adverse events, changes of concomitant medication/treatments, and patient status is performed at each follow-up visit sorafenib therapy. In addition to baseline data the performance status, tumor status (clinical and/or radiological), and overall survival time are documented. This interim analysis (data cut-off 11 DEC 2012) evaluated overall survival and safety data in clinically relevant subgroups. Documentation of adverse events comprises relationship with drug, seriousness, grade (CTCAE version 3.0), and outcome.
Results: Until the data cut-off 781 pts have been enrolled; 778 of which were evaluated regarding efficacy and safety. The table summarises major baseline characteristics together with median overall survival (mOS) data for relevant subpopulations.

Table 1. Patient characteristics

	n	(%)
Patients recruited	778	
Male	667	(86)
ECOG PS		
0	243	(31)
1	403	(52)
2	123	(16)
BCLC stage		
A	100	(13)
B	192	(25)
C	389	(50)
D	14	(2)
Missing	83	(11)
Child Pugh stage		
A	322	(41)
B (7−9)	128	(17)
C (>9)	18	(2)
Missing	310	(40)

Table 2. Overall survival

Population	Overall survival (months)
mOS total population (Events n = 219)	15.8
mOS according to BCLC	
A	29.1
B	25.1
C	14.4
D	3.1
mOS according to age	(p = 0.4166)
<65 years	19.7
⩾65 years	15.6
mOS according to NASH at baseline	(p = 0.2610)
no/missing (n = 690)	15.8
yes (n = 88)	14.5
mOS according to diabetes at baseline	(p = 0.3302)
no/missing (n = 422)	18.6
yes (n = 356)	14.5

Conclusions: The efficacy of sorafenib therapy for HCC patients in German and Austrian hospitals and private practices under everyday clinical conditions is comparable with that reported in prospective, randomized clinical trials. The data suggest that the survival of elderly and HCC patients with risk factors (e.g. NASH and diabetes) is similar to the general study population.

2610 POSTER

Does timing of adjuvant chemotherapy for gastric cancer influence outcome?

M. Ahn[1], S. Kang[1], J. Choi[1], G. Song[1], H. Lee[1], Y. Cho[2], S. Han[2], H. Hur[2]. *[1]Ajou University Hospital, Hematology-Oncology, Suwon, South Korea; [2]Ajou University Hospital, Surgery, Suwon, South Korea*

Background: According to recent large phase III trials, adjuvant chemotherapy is currently established as standard treatment in patients with stage II, III gastric cancer. However, to the authors' knowledge, the effect of the interval between surgery and the start of chemotherapy on outcome has not been investigated.
Methods: A retrospective review was conducted of 716 patients who underwent adjuvant chemotherapy for stage IB−IIIC (AJCC 7th edition) gastric cancer after radical surgery with D2 dissection between 1994 and 2004 at the Ajou University Hospital. Overall survival (OS) was compared among patients grouped by time from surgery to start of adjuvant chemotherapy.
Results: In terms of chemotherapy regimens, 5-FU/mitomycin-C-based (61.3%) was the most commonly used regimen, followed by 5-FU/doxorubicin-based one (16.9%), oral fluoropyrimidines (10.3%) and others (11.4%). The median time from surgery to chemotherapy was 20 days (range: 4–105 days), while 114 patients (15.9%) began adjuvant chemotherapy >4 weeks after surgery. The median follow-up duration was 152 months (range: 97–222 months) for the survivors. There was no significant difference in 10 year-OS between patients starting chemotherapy ⩽20 days after surgery and those initiating later (51.2% vs. 48.5%, p = 0.896). Commencing chemotherapy 4 weeks, 6 weeks and 8 weeks after surgery was not associated with inferior OS, compared with earlier initiation at each time interval (p = 0.183, 0.739, 0.434, respectively). Even very early initiation of chemotherapy (⩽2 weeks after surgery) did not correlate with better outcome (p = 0.579).
Conclusion: This study did not demonstrate any significant survival benefit from early initiation of adjuvant chemotherapy after surgery.
No conflict of interest.

2611 POSTER

Placebo-controlled, double-blind, prospective, randomized study on the effect of octreotide LAR in the control of tumor growth in patients with metastatic neuroendocrine midgut tumors (PROMID): Results of long-term radiological follow-up

A. Rinke[1], K.J. Klose[2], B. Aminossadati[3], H.H. Müller[4], C. Schade-Brittinger[3], M. Wittenberg[3], T.M. Gress[1], R. Arnold[1]. *[1]Universitatsklinkum Giessen und Marburg, Gastroenterology, Marburg, Germany; [2]Universitatsklinkum Giessen und Marburg, Radiology, Marburg, Germany; [3]Philipps University Marburg, Coordinating Centre for Clinical Trials (KKS), Marburg, Germany; [4]LMU Munich, Institute of Medical Informatics Biometry and Epidemiologyl Trials (KKS), Munich, Germany*

Background: Octreotide LAR compared to placebo significantly lengthens the time to tumor progression (TTP) in patients with metastatic midgut neuroendocrine tumors (Rinke et al. 2009). The antiproliferative effect was pronounced in patients with low (⩽10%) hepatic tumor load (HL). Aim of this follow-up trial was to analyze the prognostic significance of HL on overall survival (OS) and to assess long term development of HL.
Patients and Methods: Between July 2001 and January 2008 42 and 43 treatment naive patients were randomly assigned to receive octreotide LAR and placebo, respectively. Post-study treatment was at the discretion of the local investigator. However, >90% of patients in the placebo group received octreotide LAR after progression. Up to January, 2013 HL was determined in CT or MRI scans by central review. HL was assessed semiquantitatively (HL groups: 0%, >0%- ⩽10%; >10%-⩽25%; >25%-⩽50%; >50%). OS was analyzed using the Kaplan–Meier method for patients with HL ⩽10% at study entry (low HL) vs those with HL >10% (high HL) and compared using the log-rank test.
Results: 26 of 64 patients (40.6%) (10 in the octreotide LAR vs 16 in the placebo arm) died in the low HL at baseline subgroup and 15 of 21 patients (71.4%) (9 in the octreotide LAR vs 6 in the placebo arm) in the high HL (p = 0.002, HR = 2.7). Cause of death was tumor-related in 33 of 41 cases. In 53 of 85 patients follow up scans for central review were available. 4 patients randomized to octreotide LAR were without progression at the last evaluation (50, 71, 100 and 107 months after randomization).
Patients in the octreotide LAR treatment group with low HL at baseline more often remained in this HL group up to the last evaluation than patients in the placebo group (octreotide LAR: 16/32; placebo: 8/32).
At the last evaluation a lower HL as compared to the baseline evaluation was rarely found (3/53 patients) and resulted from chemoembolization (n = 2) and resection (n = 1).
Most patients with available scans who died during follow up had an HL>10% at the last evaluation (16/19), 9 of them had HL >50%. In 2 of the 3 remaining patients death was not tumor-related. The only patient with low HL at last evaluation and tumor-related death developed progressive extrahepatic disease.
Conclusion: In patients with well differentiated midgut tumors low HL is predictive for better response to early octreotide LAR treatment. High HL is associated with a shorter overall survival.

2612 POSTER

Chemotherapy of metastatic or recurrent, locally advanced squamous cell carcinoma (SCC) of the anal canal: A multicenter study by the Association of Gastroenterologists Oncologists (AGEO) in 116 patients (pts)

A. Audrain[1], M. Faron[1], A. Lievre[2], W. Cacheux[2], M. Barret[3], D. Tougeron[4], F. Cvitkovic[2], J. Taïeb[4], M. Ducreux[1], D. Malka[1]. *[1]Institut Gustave Roussy, Médecine Oncologique, Villejuif, France; [2]Institut Curie − Ensemble Hospitalier, Oncologie Médcale, Paris- Saint Cloud, France; [3]Hopital Européen George Pompidou, Oncologie Digestive, Paris, France; [5]Centre Hospitalo-Universitaire de Poitiers, Gastro-entérologie, Poitiers, France*

Background: We sought to define the chemotherapy (CT) regimens used and their effectiveness in the treatment of recurrent or metastatic anal SCC in a retrospective multicenter study.
Material and Methods: Were eligible pts with histologically proven anal SCC and local recurrence after initial treatment or with metastases treated by CT between January 1991 and April 2012. Primary and secondary endpoints were progression-free survival (PFS) and overall survival (OS), respectively.
Results: We enrolled 116 consecutive pts (women, 84; median age, 57 years; range, 23−84; local recurrence, 16; and metastases with or without local recurrence, 100) in five french centers. Metastases were synchronous in 18 of 100 pts (18%). Previous treatment was radiochemotherapy (RCT) (n = 74), radiotherapy (RT) (n = 17) or surgery alone (n = 2). A salvage surgery after RT/RCT was performed in 43 pts including 37 abdomino-perineal resections. The median PFS was 5.1 months. It was 4.6 months with platinum-based CT vs 7.6 months with platinum-free CT (n = 22) (p = 0.62). The median OS was 15.5 months. It was 15.1 months with platinum-based CT vs 19.3 months with platinum-free CT (p = 0.99). The median PFS and OS were respectively 4.7 and 15.0 months for pts with metachronous metastases or local recurrence vs 12.7 and 46.2 months in pts with synchronous metastases (n = 18) (p = 0.039 and p = 0.0057, respectively). Among 116 pts, 81 (69%) received second-line CT, mostly platinum-based (n = 21).
Conclusions: In this retrospective multicenter study (the largest reported to date), there was no statistically significant difference in OS or PFS according to the type of CT(with or without platinum). Pts with synchronous metastases had median OS and PFS significantly higher than pts with metachronous metastases or local recurrence, suggesting a development of resistance to CT. The majority of pts received second-line CT.
No conflict of interest.

2613 POSTER

A retrospective analysis comparing the treatment outcomes of gemcitabine and S-1 combination therapy to gemcitabine and cisplatin combination therapy in patients with advanced biliary tract cancer

T. Sasaki[1], H. Isayama[1], Y. Nakai[1], N. Takahara[2], H. Yagioka[3], Y. Ito[4], S. Matsubara[5], N. Toda[6], K. Koike[1]. *[1]The University of Tokyo, Gastroenterology, Tokyo, Japan; [2]Kanto Central Hospital, Gastroenterology, Tokyo, Japan; [3]JR Tokyo General Hospital, Gastroenterology, Tokyo, Japan; [4]Japanese Red Cross Medical Center, Gastroenterology, Tokyo, Japan; [5]Tokyo Metropolitan Hospital, Gastroenterology, Tokyo, Japan; [6]Mitsui Memorial Hospital, Gastroenterology, Tokyo, Japan*

Background: Gemcitabine and cisplatin (GC) combination therapy became the standard of care for the treatment of advanced biliary tract cancer. In Japan, gemcitabine and S-1 (GS) combination therapy also showed good tumour efficacy in phase II setting, and a large phase III study comparing GS combination therapy to GC combination therapy are now planned. Before starting a prospective study, we conducted a retrospective analysis to compare the treatment outcomes of these two treatments.
Material and Methods: Advanced biliary tract cancer patients with performance status of 0 or 1 who were treated with GS combination

therapy or GC combination therapy were enrolled in this analysis. Treatment outcomes were compared between these two groups. Predictive factor for overall survival was also assessed using Cox proportional hazard model.
Results: One hundred eighteen patients were treated with GS combination therapy and thirty-nine patients were treated with GC combination therapy. Patient characteristics (age, sex, performance status, biliary site, disease status) were well balanced except age (median age; 68 for GS combination therapy, 73 for GC combination therapy; $p = 0.02$). Response rate of GS combination therapy was significantly higher than that of GC combination therapy (29% vs 8%; $p < 0.01$). Median time-to-progressions of GS and GC combination therapy were 5.7 months and 7.6 months, respectively ($p = 0.33$). Median overall survival of GS and GC combination therapy were 13.1 months and 9.7 months, respectively ($p = 0.13$). Based on the multivariate analysis, only performance status of one and gallbladder cancer were extracted as poor predictive factors of overall survival.
Conclusion: GS combination therapy showed better tumour shrinkage than GC combination therapy. Overall survival and time-to-progression were not statistically different between GS combination therapy and GC combination therapy. As previously reported, poor performance status and gallbladder cancer were extracted as poor predictive factors of prognosis.
No conflict of interest.

2614 POSTER

Multicentre randomized phase II trial of adjuvant imatinib for 6 versus 12 months in patients with intermediate or high risk GIST: Interim analysis results

K. Yamamoto[1], Y. Kurokawa[2], T. Tsujinaka[3], K. Muguruma[4], T. Nakai[5], J. Fujita[6], M. Hiramatsu[7], A. Takabayashi[8], S. Hirota[9], T. Nishida[10].
[1]Osaka National Hospital, Surgery, Osaka, Japan; [2]Osaka University Graduate School of Medicine, Gastroenterological Surgery, Osaka, Japan; [3]Kaizuka City Hospital, Surgery, Osaka, Japan; [4]Osaka City University Graduate School of Medicine, Surgical Oncology, Osaka, Japan; [5]Kinki University Graduate School of Medicine, Surgery, Osaka, Japan; [6]NTT WEST Osaka Hospital, Surgery, Osaka, Japan; [7]Osaka Medical College, General and Gastroenterological Surgery, Osaka, Japan; [8]Kitano Hospital, Surgery, Osaka, Japan; [9]Hyogo College of Medicine, Surgical Pathology, Hyogo, Japan; [10]Osaka Police Hospital, Surgery, Osaka, Japan

Background: Although the Z9001 study demonstrated that adjuvant imatinib for 1 year improved recurrence free survival (RFS) in GIST ($\geqslant$3 cm) patients and the SSGXVIII study showed that 3 years adjuvant imatinib improved RFS and overall survival (OS) for high risk GIST patients compared to 1 year adjuvant imatinib, there was no study to evaluate non-inferiority of shorter period of adjuvant imatinib than 1 year. We conducted a randomized phase II study to compare 6 months with 12 months adjuvant imatinib for intermediate or high risk GIST patients.
Material and Methods: Study design was an open-label randomized phase II trial conducted in 37 institutes in Japan. Eligibility criteria included ECOG-PS of 0 or 1, age between 20 and 79 years and histologically proven primary KIT-positive GIST with intermediate or high risk according to the Fletcher's risk classification. Patients were randomly assigned to the 6 or 12 months administration of imatinib 400 mg/day within 12 weeks after complete gross resection of a primary GIST, stratified by risk classification and primary site. The primary endpoint was RFS. We assessed non-inferiority of 6 months adjuvant imatinib compared with 12 months with a margin of hazard ratio 1.67, 1-sided alpha 0.2 and power 0.8.
Results: Ninety-two patients were randomly allocated into the 6 months group ($n = 45$) or the 12 months group ($n = 47$) between Dec 2007 and Aug 2011, which was well balanced for baseline characteristics. One patient was ineligible due to non-GIST (desmoid) tumor at a central review. The proportions of patients completed their assigned adjuvant treatment were 80% in the 6 months group and 70% in the 12 moths group. The first interim analysis was conducted at Sep 2012 with the median surveillance period of 33 months. Adjuvant imatinib was relatively tolerated, with one patient of Grade 4 rash and no treatment-related death. The 1- and 2-year RFS were 82% and 65% in the 6 months group and 96% and 86% in the 12 months group, respectively. Hazard ratio of recurrence was 1.81 (95% CI: 0.84–3.91), and the 2-sided log-rank p value was 0.12. A subset analysis according to the Fletcher's risk classification of primary GIST showed that Hazard ratio of recurrence in the 6 months group with intermediate and high risk was 1.15 (95% CI: 0.072–18.2) and 2.15 (95% CI: 0.96–4.81), respectively. Because of the lower efficacy of the 6 months adjuvant imatinib, the Data and Safety Monitoring Committee recommended the early release of first interim results.
Conclusions: Adjuvant imatinib for shorter period is not recommended at least for high risk GIST patients.
No conflict of interest.

2615 POSTER

Safety profile of erlotinib in a Japanese post-marketing surveillance study of pancreatic cancer patients (pts): Interim analysis of the first 313 pts of 855 pts enrolled

T. Okusaka[1], J. Furuse[2], A. Gemma[3], T. Hatori[4], W. Ichikawa[5], A. Seki[6]. *[1]National Cancer Center Hospital, Hepatobiliary and Pancreatic Oncology Division and Independent Advisory Board for Erlotinib, Tokyo, Japan; [2]Kyorin University School of Medicine, Department of Medical Oncology and Independent Advisory Board for Erlotinib, Tokyo, Japan; [3]Nippon Medical School Graduate School of Medicine, Department of Respiratory Medicine and Oncology and Independent Advisory Board for Erlotinib, Tokyo, Japan; [4]Tokyo Women's Medical University, Department of Gastroenterological Surgery and Independent Advisory Board for Erlotinib, Tokyo, Japan; [5]National Defense Medical College, Department of Clinical Oncology and Independent Advisory Board for Erlotinib, Saitama, Japan; [6]Chugai Pharmaceutical Co Ltd, Department of Pharmacovigilance, Tokyo, Japan*

Background: First-line erlotinib combined with gemcitabine is approved in Japan for the treatment of unresectable pancreatic cancer (PC). A surveillance study has been implemented to investigate erlotinib safety and efficacy in Japanese pts, focusing on the incidence of interstitial lung disease (ILD), highlighted in a Japanese Phase II study with an ILD incidence of 8.5% as an adverse drug reaction (ADR) of particular concern in this population.
Methods: Enrolment was from July 2011 to Aug 2012; observation period was 28 weeks. ADRs were defined as adverse events where erlotinib could not be ruled out as the cause. All events resembling ILD, excluding pts who did not have images available for analysis, were assessed by an independent committee. These interim safety analysis data are for pts enrolled prior to 28 Dec 2011.
Results: Of the 855 total enrolled pts, data from 313 pts with case report forms were obtained by 13 Apr 2013 for analysis. All pts were eligible for treatment of unresectable PC. Baseline characteristics included: male 56.2%; median age 65 yrs; any smoking history 41.8%; lung metastasis 18.0%; adenocarcinoma 97.9%; ECOG PS 0 69.7%. ADRs were reported in 82.7% of pts and the most common were skin disorders (64.5%), including rash (32.6%), and gastrointestinal disorders (31.6%), including diarrhoea (16.9%). 'ILD-like' events were experienced by 19 pts and ILD was confirmed by the independent ILD review committee in 18 pts (5.8% of the population), with a mortality rate of 0.64% (2 pts). 'ILD-like' events occurred throughout the observation period with an incidence of 21.1% within 4 weeks, 26.3% from 4−8 weeks, 31.6% from 8−12 weeks, and 21.1% >12 weeks from the start of therapy. This is in contrast to the highest ILD incidence occurring during the first 4 weeks (58.9%) in a Japanese post-marketing surveillance study (PMS) in non-small cell lung cancer (NSCLC) pts with a mortality rate of 1.54%. Data collection and analysis for this PC surveillance study are ongoing and further results for the 313 pts who have been registered as the interim safety evaluation population will be presented.
Conclusions: The interim safety profile of this surveillance study of erlotinib plus gemcitabine in Japanese PC pts was similar to previous clinical studies. In contrast to the PMS in NSCLC, ILD developed at various times during the observation period and showed a low mortality rate. This analysis provides the treatment profile of this population.

2616 POSTER

Intensified weekly paclitaxel, epirubicin, and cisplatin combination in neoadjuvant chemotherapy for resectable gastroesophageal cancer: A multicenter phase II trial (IPEC study)

S. Kim[1], F. Fein[2], T. Nguyen[1], M. Jacquin[3], M. Jary[1], D. Cleau[4], V. Nerich[5], V. Lorgis[6], F. Ghiringhelli[6], C. Borg[7]. *[1]University Hospital of Besançon, Oncology, Besancon, France; [2]University Hospital of Besançon, Gastroenterology, Besancon, France; [3]University Hospital of Besançon, Clinical Investigational Center CIC-Biotherapy-506, Besancon, France; [4]Hospital of Vesoul, Gastroenterology, Vesoul, France; [5]University Hospital of Besançon, Pharmacy, Vesoul, France; [6]Georges-Francois Leclerc Cancer Centre, Oncology, Dijon, France; [7]University Hospital of Besançon, Oncology INSERM Unit 1098, Besancon, France*

Background: Perioperative chemotherapy improves overall survival among patients with resectable, gastric and gastroesophageal adenocarcinoma

(GEA). However, more than 40% of the patients are not healthy enough to complete their post-operative chemotherapy.
Docetaxel demonstrated significant overall survival benefit in addition to cisplatin and 5FU in advanced GEA. The potential interest of taxanes in perioperative setting was recently suggested by two studies, providing an opportunity to optimize pre-operative chemotherapy in GEA. Then, we conducted a phase II trial to assess the feasibility of a dose-dense chemotherapy combining paclitaxel, epirubicin, and cisplatin as neoadjuvant treatment for resectable GEA (Trial registration: NCT01830270).
Material and Methods: GEA patients with>T1N0M0 disease were treated with eight preoperative cycles of intensified chemotherapy including paclitaxel 90 mg/m^2 Day 1, epirubicin 50 mg/m^2 Day 1, and cisplatin 30 mg/m^2 Day 1, every week. Primary prophylaxis by G-CSF was administered on day 3 to 5. Surgery was performed 4 to 6 weeks following the last cycle of chemotherapy. A complete resection rate higher than 79% was the primary endpoint. Secondary endpoints were safety, response rate, histological response rate (Becker score), PFS, and OS.
Results: 25 patients were analysed until the planned intermediate analysis. Median age was 64 (range, 43−83) and 6 patients (24%) presented signet-cell histology. Sixteen patients (64%) completed all 8 cycles and 80% received 7 or more cycles. Twelve patients (48%) experienced grade 3/4 neutropenia but only 1 patient had febrile neutropenia. Other grade 3/4 toxicities were rare. Twenty-three patients underwent surgery and a pathological complete response was observed for two of them, with nearly complete responses (Becker score 1b) for three other patients. A complete resection (R0 resection rate) was achieved for 82 % of the patients. PFS at 6 and 12 months were 94% and 74% respectively. 4 patients are died so far, including 2 disease-progression, a toxic death after surgery (pulmonary infection) and an angiocholitis-related sepsis diagnosed 4 months post-surgery.
Conclusions: Neoadjuvant, dose-dense, weekly paclitaxel-epirubicin-cisplatin regimen is feasible in resectable GEA and it met pre-planned criteria for intermediate analysis.
No conflict of interest.

Kitagawa[10]. *[1]Chiba Cancer Center, Clinical Trial Promotion Department, Chiba, Japan; [2]Shizuoka Cancer Center, Department of Esophageal Surgery, Shizuoka, Japan; [3]National Cancer Center, JCOG Data Center, Tokyo, Japan; [4]Kyushu Cancer Center, Department of Gastroenterological Surgery, Fukuoka, Japan; [5]Chiba University, Department of Frontier Surgery Graduate School of Medicine, Chiba, Japan; [6]Showa University School of Medicine, Deaprtment of Medicine, Tokyo, Japan; [7]Shikoku Cancer Center, Department of Gastrointestinal Medical Oncology, Matsuyama, Japan; [8]Osaka Medical College, Department of Internal Medicine II, Osaka, Japan; [9]National Cancer Center Hospital, Gastrointestinal Medical Oncology Division, Tokyo, Japan; [10]Keio University School of Medicine, Department of Surgery, Tokyo, Japan*

Background: Though a triplet chemotherapy of D plus CF (DCF) has shown superiority to CF in overall survival (OS), a high incidence of adverse events (AEs) especially in febrile neutropenia (FN) has been observed in previous trials (TAX324, 325). To reduce the incidence of AEs without reduction of efficacy, we conducted a multicenter open-label phase I/II study of a biweekly regimen of D plus CF for MEC and reported at ASCO2013 (S Hironaka et al). We herein report the results with subgroup analyses in OS.
Material and Methods: The main inclusion criteria included histologically proven MEC with measurable, metastatic or recurrent disease, age 20 to 75, and performance status (PS) 0 to 1. Patients (pts) received D (dose level (DL) 1: 30 mg/m^2, DL 2: 40 mg/m^2, on days 1, 15) combined with CF (cisplatin 80 mg/m^2 on day 1, fluorouracil 800 mg/m^2 on days 1−5) repeated every 4 weeks. The primary endpoint was dose limiting toxicity (DLT) in phase I part (P-I) and confirmed response rate (RR) defined by central peer review in phase II part (P-II). Based on a SWOG two stage design (p0=35%, p1=50%; one-sided α=0.1, β=0.2) at least 22 responders among 50 eligible pts should be observed to satisfy the primary endpoint. Subgroup analyses of OS were conducted with variables (recurrent, prior adjuvant chemotherapy (AC), number of baseline metastatic sites (No. of MS), only distant lymph node metastasis (DLN)).
Results: Between Feb 2009 and Jun 2011, 62 pts were enrolled in this study. In P-I, 10 pts were enrolled with DLT of 0/3 in DL1 and 2/7 in DL2. Considering DLT and treatment compliance, the recommended dose for P-II was determined as DL1. Then, 3 pts in P-I and 52 pts in P-II were analyzed: 53 for efficacy (excluding 2 ineligible) and 55 for safety. Pts characteristics were as follows: male/female 49/6, age median 61 (range 44−75), PS 0/1 39/16. The RR was 62% (95% confidence interval, 48−75%, p < 0.0001). Median OS and PFS were 11.1 and 5.8 months. No grade 3/4 FN was observed. Treatment related death occurred in one patient due to pneumonitis. In exploratory analyses, median OS was 11.5/9.2 months (metastatic/recurrent, p = 0.91), 9.2/11.5 months (AC +/−, p = 0.86), 14.0/9.3 months (No. of MS $\leqslant$1/2$\leqslant$, p = 0.010) and 13.3/10.5 months (DLN only/others, p = 0.14).
Conclusions: Biweekly D combined with CF showed promising efficacy and tolerability. A phase III study comparing DCF with CF is now planned and will also provide important information on these prognostic factors for MEC.
No conflict of interest.

2618 POSTER

Temozolomide plus capecitabine as salvage treatment for patients with advanced neuroendocrine tumors (NETs) in the community setting

C. Lopez Lopez[1], P. Jimenez Fonseca[2], G. Crespo Herrero[3], E. Grande Pulido[4], A. Custodio Carretero[5], M. Mangas Izquierdo[1], Q. Perez[2], M.J. Barrio Alonso[3], A. Soria[4], J. Bariuso Feijoo[5]. *[1]Marques Valdecilla, Medical Oncology, Santander, Spain; [2]Hospital Central de Asturias, Medical Oncology, Oviedo, Spain; [3]Hospital General Yague, Medical Oncology, Burgos, Spain; [4]Hospital Ramón y Cajal, Medical Oncology, Madrid, Spain; [5]Hospital La Paz, Medical Oncology, Madrid, Spain*

Background: Chemotherapy schemes based on streptozotocin and doxorubicin have been use widely in the past for the treatment of advanced NETs. Unfortunately, balance between efficacy and toxicity is clearly improvable. Novel combinations of cytotoxic agents like temozolomide and capecitabine, have shown promising antitumoral activity in retrospective series. We aimed to evaluate the efficacy and safety of this combination in patients with advanced NETs derived from the daily clinical practice.
Methods: We analyzed the clinical outcome of the 37 patients (pts) consecutively treated with temozolomide (150 mg/m^2 qo, days 10−14) plus capecitabine (1.000 mg/m^2 bid, days 1−14) every 28 days, between June-2008 and April-2013 in six referenced centers in Spain for the treatment of NETs under compassionate use.
Results: 24 pts (65%), were pancreatic primary NETs (pNETs). 10 pts (27%) were treated as first-line. 28 pts (77.7%) had ECOG 0 or 1 and 8 (22.3%) had ECOG 2. 1 pt (2.7%), 21 (56.8%), and 11 (29.7%) pts had low (G1), intermediate (G2) or high-grade (G3) respectively. Grade was not available in 4 pts (10.8%). Median administered cycles were 8 (range 1−26). At the time of the data cut-off (April-2013) 7 pts (18.9%) were still on treatment after a median follow up of 10.9 months. Fourteen of the 37 pts (37.8%) had partial response (PR) and 12 (32.4%) stable disease (SD) according to RECIST 1.1 criteria. Estimated median time to progression (TTP) was 9.4 months IC95% (5.3−13.6) in the intention to treat population. Thrombocytopenia was the most frequent toxicity found in grade 3 or more (8%). Other grade 3 toxicities according to CTCAE v4.0 were observed in less than 5% of pts. There were no toxicity-related deaths.
Conclusion: These encouraging results show a promising activity and a favorable safety profile of the combination of temozolomide and capecitabine in patients with advanced NETs of the daily clinical practice and deserves for further clinical research in the future.
No conflict of interest.

2619 POSTER

Sunitinib (S) and everolimus (E) in pancreatic neuroendocrine tumours (pNETs): A retrospective UKINETS study

L. Khoja[1], T. Meyer[2], J. Waters[3], J. Wadesley[4], Y. Ma[5], M. Eatock[6], H. Williams[7], P. Corrie[8], C. Thirlwell[2], J.W. Valle[9]. *[1]Christie Hospital NHS Foundation Trust, Medical Oncology, Manchester, United Kingdom; [2]University College London Hospital, Medical Oncology, London, United Kingdom; [3]Kent Oncology Centre, Medical Oncology, Maidstone, United Kingdom; [4]Sheffield Cancer Centre, Medical Oncology, Sheffield, United Kingdom; [5]Birmingham University Hospital, Medical Oncology, Birmingham, United Kingdom; [6]Belfast City Hospital, Medical Oncology, Belfast, United Kingdom; [7]Velindre Hospital, Medical Oncology, Cardiff, United Kingdom; [8]Addenbrookes University Hospital, Medical Oncology, Cambridge, United Kingdom; [9]The Christie NHS Foundation Trust, Medical Oncology, Manchester, United Kingdom*

Background: Two randomised phase III trials in patients (pts) with progressive metastatic well-differentiated pNETS reported benefit in progression free survival (PFS) with S (median 11.4 months, HR 0.42,

Raymond NEJM 2011) or E (median 11.0 months, HR 0.35, Yao NEJM 2011), over placebo. S and E were funded in the UK through the Cancer Drugs Fund (CDF) in Dec 2010 and Sept 2011, respectively. Use of these agents through the CDF will inform on benefit out with trials, in real-world clinical practice.
Methods: Pts diagnosed with pNET and treated with either S or E were identified through the CDF register at individual NET centres between Dec 2010 − Dec 2012. Data was collected on pts demographics, clinical characteristics and PFS.
Results: A total of 82 patients (51 (62%) males, median age 58) were treated with 88 courses of therapy (6 pts received sequential S then E). Tumour grade was well-differentiated in 72, poorly-differentiated in 3 and unknown in 7 pts. Median time from diagnosis was 3.5 years; median follow-up was 7 months. Treatment history and clinical outcome by agent is shown (table). Univariate analysis showed that age, sex, previous surgery, previous or current somatostatin treatment and time from diagnosis were not significant for outcome.

Characteristic	S (n = 57)	E (N = 25)
No prior treatment	5 (9%)	4 (16%)
Prior treatment	52(91%)	21(84%)
Surgery (curative)	19 (33%)	7 (28%)
Surgery (palliative)	11 (19%)	8 (32%)
Somatostatin analogue current	14 (25%)	8 (32%)
previous	7 (12%)	1 (4%)
Liver directed therapy (TACE/RFA)	5 (9%)	3 (12%)
Radionuclide therapy	8 (14%)	4 (16%)
Chemotherapy/immunotherapy	32 (56%)	14 (56%)
S /sorafenib (on trial)	0 (0%)	7 (28%)
E (on trial)	1 (2%)	0 (0%)
Median duration of treatment (months)	5	3
Reason for cessation Disease Progression	30 (53%)	4 (16%)
Toxicity	7 (12%)	10 (40%)
Median PFS (months)*	8.8	8.9
Median PFS all patients (months)*	8.8	

*Excluding patients with poorly-differentiated tumours (n = 3).

Conclusions: Real-world efficacy of S or E in more heavily pre-treated, non-study pNET pts is lower but approaching published data with either agent. Longer follow-up will determine the long term benefit and assess the effect of cross-over between S and E.
Conflict of interest: *Advisory board: Novartis (Valle),Pfizer (Waters, Valle). Corporate-sponsored research: novartis(Valle). Other substantive relationships: sponsorship for esmo conference attendence-novartis (Waters, Wadesley)*

2620 POSTER

A multicenter phase II study of gemcitabine plus S-1 chemotherapy for advanced biliary tract cancer

S. Arima[1], K. Shimizu[2], T. Okamoto[3], S. Toki[4], A. Kasuga[1], H. Kitamura[1], A. Takasu[1], F. Nagashima[1], M. Sugiyama[5], J. Furuse[1]. *[1]Kyorin University School of Medicine, Department of Medical Oncology, Tokyo, Japan; [2]Tokyo Women's Medical University, Institute of Gastroenterology, Tokyo, Japan; [3]The Jikei University School of Medicine, Department of Surgery, Tokyo, Japan; [4]Kyorin University School of Medicine, Third Department of Internal Medicine, Tokyo, Japan; [5]Kyorin University School of Medicine, Department of Surgery, Tokyo, Japan*

Background: Gemcitabine (GEM) plus cisplatin (CDDP) chemotherapy has been used worldwide as the first-line standard treatment for advanced biliary tract cancer (BTC). A previous phase II trial also suggested promising activity of *GEM plus S-1 chemotherapy* against advanced BTC.
The aim of this study was to evaluate efficacy and safety of GEM plus S-1 chemotherapy in patients with advanced BTC.
Methods: The eligibility criteria were as follows: histologically proven BTC, unresectable or recurrent disease, ECOG performance status (PS) of 0−1 regardless of pretreatment. Gemcitabine was administered intravenously at the dose of 1,000 mg/m^2 over 30 min on days 1 and 8, and S-1 was administered orally at the dose of 60/80/100 mg/day based on the BSA, from day 1 to day 14, every 3 weeks.
The primary endpoint was the response rate according to RESIST, ver. 1.1, and the secondary endpoints were the toxicity, progression-free survival (PFS) and overall survival (OS).
Results: A total of 38 patients were enrolled between August 2008 and November 2011. There were 19 men and 19 women, with a median age of 66 years (range, 44−81 years). Seven patients had a previous history of first-line or adjuvant chemotherapy after surgery. The PS was 0 and 1 in 30 and 7 patients, respectively. There were 6 cases with confirmed partial response (15.8%) and 18 patients (47.4%) with stable disease. The median PFS and OS were 5.8 and 15.9 months, respectively. The toxicity was generally mild, and the most common grade 3/4 toxicities were leukopenia (31.6%), neutropenia (36.8%), nausea and vomiting (2.6%) and diarrhea (2.6%). There was one treatment-related death due to interstitial pneumonia.
Conclusion: Gemcitabine plus S-1 chemotherapy was well-tolerated and exhibited favorable antitumor activity in patients with advanced BTC.
No conflict of interest.

2621 POSTER

Multicenter phase 2 study of TAS-102 monotherapy in patients with pretreated advanced gastric cancer

K. Muro[1], T. Doi[2], H. Bando[2], H. Yasui[3], T. Nishina[4], K. Yamaguchi[5], S. Takahashi[6], S. Nomura[7], A. Sato[7], A. Ohtsu[7]. *[1]Aichi Cancer Center Hospital, Department of Clinical Oncology, Nagoya, Japan; [2]National Cancer Center Hospital East, Department of Gastroenterology and Gastrointestinal Oncology, Kashiwa, Japan; [3]Shizuoka Cancer Center, Division of Gastrointestinal Oncology, Nagaizumi, Japan; [4]National Hospital Organization Shikoku Cancer Center, Department of Gastrointestinal Medical Oncology, Matsuyama, Japan; [5]Saitama Cancer Center, Department of Gastroenterology, Ina, Japan; [6]Cancer Institute Hospital of Japanese Foundation for Cancer Research, Division of Medical Oncology, Tokyo, Japan; [7]National Cancer Center, Exploratory Oncology Research & Clinical Trial Center, Kashiwa, Japan*

Background: TAS-102 is a novel oral nucleoside antitumor agent, which showed promising activity in a randomized phase 2 trial for pretreated colorectal cancer. Although a previous study of TAS102 for gastric cancer showed disappointing results (only one SD in 18 patients), the evaluated dose was lower than that recommended on Japanese phase 1 trial and used in phase 2 trial for colorectal cancer. Therefore, we investigated efficacy and safety of TAS-102 for gastric cancer patients with the same dose schedule as that for colorectal cancer.
Patients and Methods: We conducted a multicenter phase 2 study of TAS-102 monotherapy in patients with pretreated advanced gastric cancer. All the patients had a treatment history of fluoropyrimidine and platinum and a treatment history of taxane or irinotecan. TAS-102 of 35 mg/m^2 was orally administered twice a day in a 28-day cycle (2-week cycle of 5 days of treatment, followed by a 2-day rest period and then a 14-day rest period). The primary objective of this study was to evaluate the disease control (CR, PR, and SD) rate (DCR) at 8 weeks as the null hypothesis of 30%. The response rate (RR), PFS, OS, safety, and pharmacokinetic parameters were also evaluated as secondary objectives.
Results: A total of 29 patients (median age, 64 years; performance status 0/1 = 20/9) were assessable. One patient achieved PR, and other 18 patients had SD. DCR and RR was 67.9% (95% CI, 47.6% to 84.1%) and 3.6% (95% CI, 0.1% to 18.3%), respectively. Median PFS was 2.9 months (95% CI, 1.1 to 5.3 months). Common grade 3 or 4 adverse events included neutropenia, leukopenia, anemia, and anorexia, which were profiles similar to those of TAS-102 in patients with colorectal cancer. Only one case of febrile neutropenia was observed, and no treatment-related deaths occurred.
Conclusions: TAS-102 monotherapy resulted in a promising DCR and acceptable toxicity profile in patients with pretreated advanced gastric cancer. A higher dose of TAS-102 may have a positive effect on patients with advanced gastric cancer, and further confirmatory trials are required.
No conflict of interest.

2622 POSTER

Lack of association between ERCC1 expression in biliary tract malignancy and response to chemotherapy

M. Braghiroli[1], L. Dib[1], V. Miranda[1], S. Siqueira[1], P.M. Hoff[1], R. Riechelmann[1]. *[1]Instituto do Cancer do Estado de São Paulo, Oncologia Clinica, São Paulo, Brazil*

High tumor expression of the excision cross-complementing gene-1 (ERCC1) has been associated with resistance to platinum-based regimens in many solid tumors such as lung and colorectal cancer. The predictive and/or prognostic value of this biomarker in biliary tract malignancy (BTC) is unknown.
We retrospectively evaluated all consecutive patients (pts) with advanced/metastatic BTC who received first line gemcitabine and cisplatin (GC) at the Instituto do Cancer do Estado de São Paulo, Brazil, in a 3 year-period. Pts had their paraffin-embedded tumor tissues tested for ERCC1 immunohistochemistry (IHC) expression. Such expression was scored

based on its extension and its intensity of staining. Extension was scored from 0 to 4 (0: negative, 1: 0−25%, 2: 25−50%, 3: 50−75% and 4: 75–100%) and intensity, from 1 to 3 (1: weak, 2: moderate and 3: strong); the final score was the product of each result. Tumor response was measured by RECIST 1.1. The predictive value of ERCC1 was evaluated through comparison of the proportion of pts who responded to treatment with high/ positive ERCC1 expression vs low/negative, using the Chi-2 test. The prognostic effect of ERCC1 was explored by a Cox regression model, considering the ERCC1 expression as a continuous variable.
From June 2009 to June 2011, 75 pts received GC of whom 44 had their pathology material evaluable. Median age was 59 years [range: 32−80], and 59% were female. Nearly half (55%) of pts experienced clinical benefit (complete response [CR], partial response [PR] and stable disease [SD]) from GC treatment. 48% had positive ERCC1 IHC expression (score $\geqslant$2). ERCC1 expression was not associated with either clinical benefit or tumor response. The mean score of IHC expression was 2.65 for those who had PD and 4.0 for pts with clinical benefit (p = 0.28, OR 1.09 [IC − 95%: 0.93–1.26]). When comparing pts with PD and SD vs CR/ PR, the mean ERCC1 expression was also not different: 3.0 vs. 4.6 (p = 0.25, OR 1.1 [IC − 95%: 0.94–1.29]. ERCC1 expression did not influence pts survival (p = 0.349 HR 0.96 [IC − 95%: 0.88–1.05]).
Our results suggest that ERCC1 IHC expression in advanced BTC patients is neither a prognostic nor a predictive factor for the efficacy of CG regimen.
No conflict of interest.

2623 POSTER

A randomized phase II study of S-1 monotherapy or S-1 plus leucovorin as 2nd line chemotherapy in patients with advanced pancreatic cancer

J.M. Xu[1], F.J. Ge[1], N. Xu[2], Y.X. Bai[3], Y.Q. Zhang[3], Y. Ba[4], F. Li[5], Y. Wang[6]. *[1]Affiliated Hospital Academy of Military Medical Sciences, Digestive Oncology, Beijing, China; [2]The First Affiliated Hospital University of Zhejiang, Department of Oncology, Hangzhou, China; [3]The Cancer Hospital Medical University of Haerbin, Department of Medical Oncology, Haerbin, China; [4]The Cancer Hospital Medical University of Tianjin, Department of Medical Oncology, Tianjin, China; [5]The Xuanwu Hospital Capital Medical University, Department of Surgery, Beijing, China; [6]Academy of Military Medical Sciences, Affiliated Hospital Cancer Center, Beijing, China*

Background: Gemcitabine-based chemotherapy has been the standard treatment as 1st line for advanced pancreatic cancer. So far, the role of 2nd treatment after gemcitabine-based chemotherapy failure is unclear. S-1, as an oral fluoropyrimidine has shown comparable efficacy as compared with gemcitabine in 1st line setting, suggesting probable role of S-1 as a salvage therapy after gemcitabine failure. We conducted this randomized phase II study to verify the hypothesis the efficacy of the S-1 plus leucovorin (SL regimen) is superior to S-1 monotherapy as 2nd line therapy in patients with advanced pancreatic cancer.
Methods: Eligible patients had histologically or cytologically confirmed advanced pancreatic cancer, PS 0−2, previous gemicitabine-based regimen 1st line treatment failure, with adequate hematologic, hepatic and renal function. S-1 was administrated 40 mg/m ^{2} BSA twice a day on days 1−14 (Arm A) or plus LV 25 mg twice a day on days 1−14 (Arm B), followed by 7 days interval. The primary endpoint was overall survival (OS). Secondary endopints were progression-free survival(PFS), response rate(ORR), disease control rate (DCR), clinical benefit rate (CBR), safety, and quality of life (QoL).
Results: Eighty-one patients from 5 hospitals were enrolled between May 2010 and November 2012. Median OS and PFS were 5.7 and 3.1 months in Arm A and 7.1 and 3.8 months in Arm B (p = 0.571, HR 0.856 for OS, p = 0.884, HR 1.040 for PFS). ORR, DCR, and CBR were 5.3%, 55.2%, and 27.6% in Arm A and 6.1%, 66.7%, and 27.3% in Arm B (p = 0.638 for ORR, p = 0.211 for DCR, p = 0.978 for CBR). 7.1% patients in Arm A and 15.4% in Arm B discontinued treatment due to drug toxicities. All grade toxicities were 97.6% in Arm A and 100% in Arm B (p = 0.338). The major adverse events (AEs) were anorexia, stomatitis, fatigue, nausea, diarrhea, and neutropenia. Arm B had more grade 3/4 AEs than Arm A (30.9% vs 53.9%, p = 0.035). Biomarker research data was avaliable in 79 patients.
Conclusions: S-1 monotherapy or SL regimen is effective and tolerable as 2nd line therapy in patients with advanced pancreatic cancer. The addition of LV to S-1 resulted in a modest OS prolongation, but no significant difference(P = 0.571, HR 0.856). This study is still ongoing, and the biomarker research data will be presented also.
No conflict of interest.

2624 POSTER

A phase 1/2 study of S-1 with sorafenib in advanced hepatocellular carcinoma

Y. Ooka[1], S. Ogasawara[1], F. Kanai[1], K. Arai[2], E. Suzuki[1], A. Tawada[1], T. Chiba[1], T. Yamashita[2], S. Kaneko[2], O. Yokosuka[1]. *[1]Graduate School of Medicine Chiba University, Department of Gastroenterology and Nephrology, Chiba, Japan; [2]Kanazawa University Graduate School of Medical Science, Department of Gastroenterology, Kanazawa, Japan*

Background: Sorafenib was only drug, which was approved as effective systemic chemotherapy for patients with advanced hepatocellular carcinoma (HCC). But, the prognosis of advanced HCC patients is still poor. Development of more effective treatment is necessary for them. So, we conducted a phase 1/2 study of S-1with sorafenib in advanced HCC.
Method: S-1 was administered twice daily each day for day 1−14 and sorafenib was administered every day. This was repeated every 21 days. In part 1, we determined the maximum tolerated dose (MTD) and dose-limiting toxicities (DLTs). Dose of each drug was planned as follows: cohort 1: 48 mg/m^2/day/400 mg qd,2a: 48 mg/m^2/day/400 mg bid,2b: 64 mg/m^2/day/400 mg qd,3: 64 mg/m^2/day/400 mg bid,4: 80 mg/m^2/day/400 mg bid (S-1/sorafenib). In part 2, patients are being treated at the MTD to evaluate safety and efficacy.
Results: In part 1, 19 patients were enrolled. 1 in 6 patients at cohort 1 experienced DLT (increased transaminase). 0 in 3 patients at cohort 2a experienced DLT. 1 in 6 patients at cohort3 experienced DLT (bleeding). 3 in 3 patients at cohort 4 experienced DLT (2 hand foot skin reaction and 1 infection). So, cohort 3 was considered MTD. In part 2, 26 patients were enrolled. Most common grade 3/4 toxicities were aspartate aminotranspherase increased (38.5%), thrombocytopenia (23.1%), neutropenia (19.2%), blood bilirubin increased (15.4%), alanine aminotranspherase increased (15.4%), hyponatremia (11.5%), rash (11.5%) and hypophosphatemia (11.5%). Sudden death was occurred in one patient (3.8%). One (3.8%) was considered as PR, 15(57.7%) as SD and 10(38.5%) as PD. The median TTP and OS were 2.4 and 10.5 months, respectively.
Conclusion: The MTD of S-1 and sorafenib in patients with advanced HCC was 64 mg/m^2 /day and 400 mg bid, respectively. But, its toxicities were slightly severe and its effect does not seem to be improved than sorafenib alone.
Conflict of interest: *Other substantive relationships: O. Yokosuka: Research grants: Bayer*

2625 POSTER

A multicentre retrospective analysis of single agent nab-paclitaxel (nab-P) in heavily pretreated pancreatic cancer (aPDAC) patients (pts)

V. Vaccaro[1], E. Bria[2], M. Reni[3], I. Sperduti[4], A. Gelibter[1], E. Lucchini[2], S. Cereda[3], G. Tortora[2], F. Cognetti[1], M. Milella[1]. *[1]Regina Elena National Cancer Institute, Medical Oncology, Roma, Italy; [2]Azienda Ospedaliera Universitaria Integrata University of Verona, Medical Oncology, Verona, Italy; [3]San Raffaele IRCSS, Medical Oncology, Milano, Italy; [4]Regina Elena National Cancer Institute, Department of Biostatistics, Roma, Italy*

Background: No standard treatment exists in pretreated aPDAC pts, who have already received available active drugs. *nab*-P has shown to improve survival in combination with GEM in first line and to be active in GEM-resistant aPDAC pts.
Material and Methods: aPDAC pts who received off-label single agent *nab*-P (125 or 100 mg/m^2 over 30 minutes on days 1, 8, and 15 of a 28-day cycle) as 2nd or further line of treatment for metastatic disease in three Italian centers were retrospectively reviewed.
Results: 29 pts were identified (M/F: 16/13; median age: 66 yrs, range: 39−83); >50% of pts had an ECOG PS 2; median number of previous treatment lines: 2 (range 1−5); 7 pts had received Folfirinox as first line. *nab*-P starting dose was 125 mg/m^2 in 5 pts and 100 mg/m^2 in the others. A median of 2 cycles (range 1−10) were administered. Two partial responses (44 and 46-wk duration) were observed; 4 pts had stable disease SD (9, 16, 23, 28-wk duration, respectively); 5 pt are presently not evaluable. Median and mean progression free survival (PFS) were 8 (95% CI: 5−11) and 13 (95% CI: 7−18) wks, respectively; median and mean overall survival (OS) were 13 (95% CI: 9−17) and 25 (95% CI: 15−35) wks, respectively. Three- and 6-month PFS rates were 33% and 15%, respectively; 6- and 12-month OS rates were 36% and 22%, respectively. Toxicity was mild with G4 neutropenia in 1 pt and G3 neuropathy in 1 pts. With at least 10 out of 29 pts free from progression at 3 months (3-month PFS rate: 35%), our results satisfy the following post-hoc statistical hypothesis: p0: 15%, p1: 35%, a: 5%, 1-b: 80%, according to A'Hern exact single stage phase II design.

Conclusions: *nab*-P is well tolerated and moderately active, even in heavily pretreated aPDAC pts. Further analyses are warranted, especially to identify the small proportion of pts who derive exceptionally prolonged benefit from *nab*-P monotherapy.
No conflict of interest.

2626 POSTER

An open, multi-center, phase II clinical trial to evaluate efficacy and safety of S-1 plus split cisplatin in patients with advanced gastric cancer (AGC) − HGCSG0702 preliminary report

A. Ishiguro[1], S. Yuki[2], H. Fukushima[3], A. Sato[4], I. Iwanaga[5], T. Miyagishima[6], M. Kudo[7], K. Kato[8], Y. Sakata[9], Y. Komatsu[3]. *[1]Teine Keijinkai Hospital/Hirosaki University Hospital, Medical Oncology, Sapporo/Hirosaki, Japan; [2]Hokkaido University Hospital, Gastroenterology and Hepatology, Sapporo, Japan; [3]Hokkaido University Hospital, Cancer Center, Sapporo, Japan; [4]Hirosaki University Hospital, Medical Oncology, Hirosaki, Japan; [5]Japanese Red Cross Kitami Hospital, Gastroenterology, Kitami, Japan; [6]Kushiro Rosai Hospital, Internal Medicine, Kushiro, Japan; [7]Sapporo Hokuyu Hospital, Gastroenterology, Sapporo, Japan; [8]Iwamizawa Municipal General Hospital, Gastroenterology, Iwamizawa, Japan; [9]Misawa City Hospital, Medical Oncology, Misawa, Japan*

Background: From the results of SPIRITS trial, S-1 plus cisplatin has been regarded as standard first-line chemotherapy for patients with AGC in Japan (Koizumi W, et al. Lancet Oncol, 2008). However, conventional S-1 plus cisplatin regimen requires hospitalization for hydration. Therefore, in Hokkaido Gastrointestinal Cancer Study Group (HGCSG), to investigate the safety and efficacy, we conducted a multicenter phase II clinical trials of S-1 plus split cisplatin as a therapeutic strategy that can be administered in the outpatient clinic.
Methods: Eligibility criteria included pathologically confirmed AGC; no prior chemotherapy; Age 20 to 75, ECOG performance status (PS) of 0 to 1; adequate organ function; and written informed consent. S-1 (40−60 mg depending on patients' body surface area) was given orally, twice daily for 3 consecutive weeks, and 30 mg/m^2 cisplatin was given intravenously on day 1 and 15, followed by 2-week rest period, within a 5-week cycle. Primary endpoint was the response rate (RR), and secondary endpoints were progression-free survival, overall survival, safety profile, and duration of hospitalization.
Results: Between Mar 2008 and Mar 2012, 40 pts were enrolled. Patients characteristics were as follows: median age 63 years (range 41−75), Male: female 30:10, PS 0:1 33:7, diffuse: intestinal 23:17, initially unresectable: recurrent 31:9. Median no. of cycles was 3. The most common non-hematological adverse events (AE) were anorexia (70%), nausea (60%), fatigue (60%) and diarrhea (47.5%) and hematological AE were anemia (87.5%), neutropenia (82.5%), leukocytopenia (67.5%) and thrombocytopenia (60%). The main grade 3−4 AE were neutropenia (40%), anemia (30%), anorexia (30%) and fatigue (15%). These toxicities were safely managed. The median relative dose intensity of S-1 was 0.782, and cisplatin was 0.824. No treatment-related death was observed. Response rate was 57.5% (95% CI 42.2–72.8%) and disease control rate was 90.0%. Median progression-free survival was 6.1 months (95%C.I. 3.0−9.1 months).
Conclusions: We conclude that this S-1 plus split cisplatin regimen was highly active and tolerated in the treatment of AGC, and most patients could be administered in the outpatient clinic. Based on those result, we are planning the further study.

2627 POSTER

Safety and pharmacology of gemcitabine and capecitabine in patients with advanced pancreatico-biliary cancer and hepatic dysfunction

M. Joerger[1], A.D.R. Huitema[2], D. Koeberle[3], H. Rosing[2], J.H. Beijnen[2], D. Semela[4], T.H. Cerny[3], J.H.M. Schellens[5], S. Gillessen[3]. *[1]Cantonal Hospital, Medical Oncology, St Gallen, Switzerland; [2]Slotervaart Hospital, Pharmacy & Pharmacology, Amsterdam, Netherlands; [3]Cantonal Hospital, Medical Oncology, St.Gallen, Switzerland; [4]Cantonal Hospital, Gastroenterology, St.Gallen, Switzerland; [5]The Netherlands Cancer Institute, Clinical Pharmacology, Amsterdam, Netherlands*

Background: The study prospectively assessed the impact of hepatic dysfunction (HD) on the safety and pharmacology of gemcitabine and capecitabine in advanced pancreatico-biliary cancer, a condition that is of substantial clinical relevance (EKSG 08–087).
Materials and Methods: We included 12 patients with advanced pancreatico-biliary cancer receiving 3-weekly gemcitabine 1,000 mg/m^2/30min on day 1 and 8, and oral capecitabine 650 mg/m^2 b.i.d. over 2 weeks until disease progression or dose-limiting toxicity (DLT). Patients were included into one cohort with normal liver function (cohort 1, total bilirubin (TB) $\leqslant$15 μmol/L) and 3 cohorts with increasing HD, i.e. cohort 2 with a TB of 16−39 μmol/L, cohort 3 with a TB of 40−80 μmol/L and cohort 4 with a TB >80 μmol/L. Gemcitabine and dFdU were sampled at 15, 30, 60 and 90 minutes after the start of infusion on day 1 and 8. Intracellular gemcitabine triphosphates (dFdCTP) were measured in peripheral blood mononuclear cells 30 minutes after gemcitabine. Capecitabine (CAP), 5′-deoxy-5-fluorocytidine (DFCR), 5′-deoxy-5-fluorouridine (DFUR) and 5-fluorouracil (5FU) were sampled at 0.5, 1, 2, 3 and 4 hours after oral intake, as well as at steady-state on day 8. All compounds were analyzed using validated (HP)LC-MS/MS methodology, and submitted to population pharmacokinetic analysis using the NONMEM software version VII.
Results:: The reason for HD was intrahepatic cholestasis in 4 out of 8 patients (50%) and extrahepatic cholestasis in another 4 patients (50%). DLT was a further increase of TB (n = 2) and severe neutropenia (n = 2), but DLT resulting in dose reduction of any of the two drugs was not associcated with HD (Table). There was no significant increase of severe hematological or non-hematological toxicity with HD (Table). Gemcitabine clearance (CL) significantly decreased with increasing HD, but capecitabine CL did not (Table). Intracellular dFdCTP concentrations decreased with more severe HD (p = 0.001). One out of 3 patients with CCL<60 ml/min experienced DLT.
Conclusions: Gemcitabine/capecitabine can be given in patients with severe HD, but gemcitabine's activity is potentially limited due to poor intracellular activation. In patients with severe HD, initial monotherapy with capecitabine may be an option, followed by the addition of gemcitabine in case of improving hyperbilirubinemia.
No conflict of interest.

	Cohort 1 (n = 4)	Cohort 2 (n = 2)	Cohort 3 (n = 3)	Cohort 4 (n = 3)	p-value (ANOVA)

CL gemcitabine (L/h)	235	227	185	105	0.02
CL capecitabine (L/h)	340	243	169	163	0.41

2628 POSTER

Implementation of a nurse-driven educational program improves management of sorafenib's toxicities in hepatocellular carcinoma

A. Brunot[1], F. Le Roy[2], S. Lesourd[2], A. M'Sadek[3], M. Duval[3], L. Crouzet[1], A. Guillygomarc'h[2], E. Boucher[1], B. Laguerre[1], J. Edeline[1]. *[1]Centre Eugène Marquis, Oncology, Rennes, France; [2]CHU Pontchaillou, Hepatology, Rennes, France; [3]Centre Eugène Marquis, Supportive Care, Rennes, France*

Background: Sorafenib is the standard of care for advanced hepatocellular Carcinoma (HCC). This drug is orally-given and associated with substantial toxicity, emphasizing the need for proper supportive care. We aimed to improve usual care by adding an educational program (EP) driven by trained nurses.
Material and Methods: Since January 2011, after deciding treatment with sorafenib, gastrointestinal oncologists referred patients to the EP. Patients were seen by the clinical nurses before the first administration in a one-hour visit. The nurses also communicate with the general practitioner. Patients were followed with weekly phone calls and with a 30-minutes

interview before every oncologist visit. In this study, we retrospectively compared safety data from patients treated with sorafenib for HCC in 3 contexts: followed with the EP, with usual care (UC), or in clinical trials (CT). Comparisons were made by a Pearson's Chi-2 test.
Results: Since 2008, 129 patients were treated at our institution with sorafenib for HCC, 31 (24%) in the EP, 22 (17%) in CT and 76 (59%) with UC. Patients treated in the EP and in CT were more frequently treated for hypertension (19% and 23% respectively vs 0% for UC, $p < 0.001$ for both). Moreover, 71% of patients in the EP had toxicities identified during the phone call, which prompted symptomatic measures in 65% of patients and leaded to sorafenib dosing modification before the planned on-site visit in 29% of patients. Patients followed with the EP required less dose reductions (39% vs 61% for UC, $p = 0.04$). The median time to first dose reduction was shorter with EP than with UC (25 vs 45 days, $p = 0.04$). There was also a trend toward less treatment delay (19% vs 34%, $p = 0.13$) and toward less treatment discontinuation for toxicity (26% vs 36%, $p = 0.33$). These trends do not appear in patients in CT (dose reduction 46%, $p = 0.21$, treatment delay 36%, $p = 0.85$, cessation for toxicity 32%, $p = 0.75$). However, there was no difference in the incidence of severe toxicities (48% for EP vs 50% for CT vs 42% for UC, $p = 0.73$) or hospitalization for toxicity (7% for EP vs 18% for CT vs 11% for UC, $p = 0.40$).
Conclusion: Albeit retrospective, this study provides evidence for a clinical benefit of the EP, with a better management of toxicities leading to a quicker reaction and less dose reductions. These results represent meaningful improvement of patient tolerability of the treatment. However, this did not translate in decrease of major toxicities.
No conflict of interest.

2629 POSTER

Correlative study of mTOR inhibition with temsirolimus and tumour stathmin expression for unresectable hepatocellular carcinoma (HCC)

W. Yeo[1], J.H.M. Tong[2], A.W.H. Chan[2], S.L. Chan[1], F.K.F. Mo[1], E.P. Hui[1], J. Koh[1], L. Li[1], S.C.H. Yu[1], K.F. To[2]. *[1]Chinese University of Hong Kong, Clinical Oncology, Hong Kong, Hong Kong; [2]Chinese University of Hong Kong, Anatomical and Cellular Pathology, Hong Kong, Hong Kong*

Background: HCC is a common cause of cancer morbidity and mortality. The oncogenic PI3K/Akt/mTOR pathway is frequently activated in HCC. Preliminary studies on mTOR inhibitors such as temsirolimus show promising results but there is limited data on potential biomarker to predict clinical benefit of temsirolimus in HCC patients. It has been observed loss of PTEN, the negative regulator of PI3K, results in robust activation of this pathway. Stathmin, encoded by the signature gene STMN1, has been suggested to be an accurate IHC marker of the PTEN signature with a potential role as a prognosticator. Thus, evaluation of stathmin may be an effective way to quantitatively measure PI3K pathway. The objective of this study is to evaluate if stathmin overexpression is correlated with therapeutic efficacy of temsirolimus.
Materials and Methods: We have conducted a phase I/II study to examine temsirolimus in advanced HCC. Major eligibility criteria included histologically confirmed HCC that is not amenable to curative treatment. Pre-treatment tumour biopsies were collected. Phase I portion identified 25 mg weekly every 3 weeks to be the maximum tolerated dose. Phase II adopts a single arm design, the clinical endpoints were response rate, disease stabilization (PR/CR/SD $\geqslant$12 weeks), PFS and OS. Reassessment CT scans were done every 6 weeks. OS and PFS were calculated using the Kaplan–Meier method.
Results: A total of 36 patients were enrolled. The median follow-up was 17.0 months. 52.8% received $\geqslant$1 line of prior systemic therapies All had Child's A cirrhosis. 34 patients had pre-treatment HCC biopsies available for marker analysis. The PR and SD rates were 2.8% (1/35) and 57.1% (20/35) respectively. Disease stabilization rate was 38.9%. The median PFS and OS were 2.83 and 8.88 months respectively. Biomarker analysis for stathmin revealed that disease stabilization rates in tumors having high and low stathmin histoscores were 33.3% and 53.8%%, respectively ($p = 0.2376$). There was no difference in PFS and OS among pts with/without stathmin overexpression.
Conclusions: In this patient population, stathmin overexpression did not correlate with clinical outcomes. Further studies to identify patient subgroup that will benefit from this agent are warranted.

2630 POSTER

Phase II study of salvage mFOLFOX (5-fluorouracil, leucovorin, oxaliplatin) in patients with unresectable biliary tract cancer who had failed gemcitabine

I. Hwang[1], J.S. Jang[1], S.Y. Oh[2], J.M. Sun[3], E.M. Nam[4], H.R. Lee[5], H.J. Jun[6], K.C. Chi[7]. *[1]Chung-ang University Hospital, Internal Medicine, Seoul, Korea; [2]Dong-a University Hospital, Internal Medicine, Seoul, Korea; [3]Samsung Medical Center, Internal Medicine, Seoul, Korea; [4]Wha Womans University Hospital, Internal Medicine, Seoul, Korea; [5]Korea Cancer Center Hospital, Internal Medicine, Seoul, Korea; [6]Seoul Medical Center, Internal Medicine, Seoul, Korea; [7]Chung-ang University Hospital, Surgery, Seoul, Korea*

Background: We conducted a phase II trial of 5-fluorouracil and oxaliplatin combination chemotherapy as a second-line treatment in unresectable biliary tract cancer (BTC) patients who had failed gemcitabine-based chemotherapy.
Material and Methods: Patients treated with gemcitabine-based palliative treatment were enrolled in this study. Patients received oxaliplatin 85 mg/m^2 (2-hour intravenous infusion, Day 1) and leucovorin 30 mg intravenous (Day 1, 2) followed by 5-fluorouracil 1,500 mg/m^2 (23-h continuous infusion, Day 1, 2) every 2 weeks.
Results: Between March 2010 and June 2012, a total of 30 patients were enrolled in this study. Twenty-nine patients were evaluable for treatment response. One achieved complete response and no partial response was observed. By the intent-to-treat analysis, the overall response rate (ORR) was 3.3% (95% confidence interval [CI]: 0.08–17.2%). Stable disease was observed in 12 patients (40%), and 15 patients (50%) had progressive disease. The median follow-up duration was 4.2 months (range: 0.8–11.3 months). The median progression free survival (PFS) was 1.6 months (95% CI: 1.5−1.7 months), and the median overall survival (OS) time was 4.4 months (95% CI: 2.6−6.2 months). Grade 3/4 hematologic toxicities included neutropenia (20%), thrombocytopenia (10%) and anemia (3.3%) per patient. Grade 3 non-hematologic toxicities included hyperbilirubinemia (13.3%), increase of alkaline phosphatase (3.3%), diarrhea (6.6%), fatigue (3.3%) and vomiting (3.3%) per patient, respectively. One treatment-related death due to neutropenic infection was occurred.
Conclusions: Despite the first phase II study of salvage chemotherapy for patients with Gemcitabine refractory BTC, the results in terms of ORR, PFS, and OS were lower than expected. Together, we do not recommend further evaluation of this regimen as salvage treatment for patients with unresectable BTC who had failed gemcitabine.
No conflict of interest.

2631 POSTER

Extra- and Intra-hepatic biliary tract adenocarcinoma: Surgery alone versus surgery plus postoperative therapy

M. Kang[1], K.W. Kim[2], J.I. Park[2], Y.W. Kim[3], Y.J. Jeon[4], I.H. Kim[1], Y.J. Choi[5], H.Y. Lee[6], B.G. Seo[6], W.Y. Oh[7]. *[1]Inje University Haeundae Paik Hospital, Hemato-Oncology, Busan, Korea; [2]Inje University Haeundae Paik Hospital, Surgery, Busan, Korea; [3]Inje University Haeundae Paik Hospital, Otorhinolaryngology, Busan, Korea; [4]Inje University Haeundae Paik Hospital, Family Medicine, Busan, Korea; [5]Busan National University Hospital, Hemato-oncology, Busan, Korea; [6]Dongnam Institute of Radiological and Medical Sciences, Hemato-oncology, Busan, Korea; [7]Inje University Haeundae Paik Hospital, Radiation Oncology, Busan, Korea*

Background: Complete surgical resection provides the only possibility of cure in extra- and intrahepatic biliary tract adenocarcinoma. However, even in patients undergoing curative resection, the prognosis has remained poor. Given these poor outcomes, adjuvant therapy should be considered for these patients. However, the benefits of adjuvant therapy for those patients have remained unclear. The aim of this retrospective review was to evaluate the effect of adjuvant therapy versus surgery alone in patients with resectable biliary tract adenocarcinoma.
Material and Methods: The study involved 97 patients with biliary tract adenocarcinoma (BTA) undergoing curative resection between March 2010 and December 2012. The patients with BTA were included gall bladder cancer, intrahepatic bile duct cancer, perihilar bile duct cancer, distal bile duct cancer, and ampull of Vater cancer. Of the 97 patients, 49 received adjuvant chemoradiotherapy (CRT), chemotherapy, or radiotherapy (adjuvant therapy group) and 48 did not (surgery alone group). Recurrence-free survival (RFS) and overall survival (OS) was analyzed according to the presence of adjuvant therapy. Subgroup analyses were performed according to primary tumor sites.
Results: Baseline clinicopathologic characteristics were comparable between two groups, except age. The patients aged $\leqslant$65 years were more likely to have received adjuvant therapy than >65 years old ($p = 0.001$).

In adjuvant therapy group, CRT was 29 patients (59.1%), chemotherapy only was 19 patients (38.8%) and radiotherapy only was 2 patients (4.1%). With a median follow-up duration of 14 months for all patients, recurrence was developed in 21 patients (42.9%) of adjuvant therapy group, and in 25 patients (52.1%) of surgery alone group. For all patients, 1-year RFS and OS were 39.5% and 60.9%, respectively. The median RFS was 1-year survival rate were 14.5 months and 62.3% in adjuvant therapy group and 13.6 months and 57.4% in surgery alone group, respectively (p=o.623, $p = 0.279$). In subgroup analysis, the patients with distal bile duct cancer who received adjuvant therapy group tended to be higher 1-year RFS (57.7% versus 30.3%, $p = 0.06$) and OS (82.5% versus 61.4%, $p = 0.058$) than those who underwent surgery alone.
Conclusions: Adjuvant therapy might not be useful in patients with biliary tract adenocarcinoma after surgery. However, for those patients with distal bile duct cancer, adjuvant therapy deserves to consider after surgery.
No conflict of interest.

2632 POSTER

Capecitabine/5-fluorouracil and oxaliplatin (XELOX/FOLFOX): Suitable treatments for progressing G1-G2 neuroendocrine tumors

R. Marconcini[1], S. Ricci[2], L. Galli[1], A. Antonuzzo[2], L. Derosa[1], A. Farnesi[1], E. Biasco[1], E. Vasile[1], L. Ginocchi[1], A. Falcone[1]. *[1]S. Chiara Hospital, U.O. Oncologia Medica 2, Pisa, Italy; [2]S. Chiara Hospital, U.O. Oncologia Medica 1, Pisa, Italy*

Background: Beyond the usual regimens based on streptozocin and doxorubicin or 5-fluorouracil, no second-line therapy for metastatic neuroendocrine tumor (NET) has gained wide acceptance. Oxaliplatin plus 5-Fluorouracil (FOLFOX) or oral capecitabine (XELOX) have been evaluated in limited phase II studies in NET. We evaluate our experience in metastatic well differentiated G1 G2 NET patients (pt) treated with these chemotherapy regimens.
Materials and Methods: From October 2005 to February 2013, eighteen consecutive NET pt with progressive disease after failure of somatostatin analog (SSA) therapy and/or chemotherapy, targeted therapy, Peptide Receptor Radionuclide Therapy were treated with FOLFOX or XELOX. The primary tumor site was pancreas in 5 pt, gastrointestinal tract in 7 pt, lung in 3 pt, and unknown in 3 pt. Pt received oxaliplatin e.v. 130 mg/mq i.v. g1 and capecitabine 1000 mg/mq/die os gg1−14 (XELOX) or oxaliplatin e.v. 85 mg/mq i.v. g1 5-fluorouracil 2800 mg/mq ev 48 h gg1−3 q21 (FOLFOX). Patients were followed for evidence of toxicity, response assessed using RECIST criteria, and survival.
Results: Four (22.2%) out of 18 pt had a partial response, 9 pt (50%) showed stable disease, and 5 (27.8%) pt showed progressive disease; median progression-free survival was 8.23 months, 1 patient is still in treatment.
Median number of cycles was 5 (2−10). At a median follow-up of 46 months, median OS is 24 months (10 patient are still alive). G1-G2 toxicities were diarrhea, nausea, asthenia, neutropenia, neurotoxicity; main G3-G4 toxicities was neurotoxicity (5%) and diarrhea (11%).
Conclusions: XELOX or FOLFOX showed interesting activity and efficacy in pretreated patients with progressive NET, also after many previous treatments, with acceptable toxicity.
No conflict of interest.

2633 POSTER

Serum alpha-fetoprotein (AFP) level is a prognostic factor for advanced gastric cancer

H. Fukushima[1], Y. Komatsu[2], S. Yuki[3], T. Sasaki[3], Y. Kobayashi[3], K. Harada[3], Y. Kawamoto[4], H. Nakatsumi[5], M. Dazai[6], N. Sakamoto[7]. *[1]Hokkaido University Hospital, Cancer Center, Sapporo, Japan; [2]Hokkaido University, Cancer Center, Sapporo, Japan; [3]Hokkaido University, Gastroenterology and Hepatology, Sapporo, Japan; [4]Sapporo Medical Center NTT EC, Gastroenterology, Sapporo, Japan; [5]Wakkanai City Hospital, Internal Medicine, Wakkanai, Japan; [6]Kushiro Rosai Hospital, Internal Medicine, Kushiro, Japan; [7]Hokkaido University Hospital, Gastroenterology and Hepatology, Sapporo, Japan*

Backgrounds Gastric cancer is one of the most common AFP-producing cancers, reported having highly metastatic potent and a poor prognosis. Tissue AFP staining is not always evaluated in daily practice, and gastric cancer tissue has various degrees of heterogeneity. It is not clarified that the correlation between the serum AFP level and clinical outcome in advanced stage.
Objective: To explore the prognostic value of serum AFP in advanced gastric cancer.
Patients and Methods: Patients included that with histologically proven unresectable or recurrent gastric cancer, administered chemotherapy from January 2001 to Jan 2012 in Hokkaido University Hospital, and was obtained serum AFP level before treatment. The serum level of AFP was measured by using commercial kits with cut-off values of 10 ng/ml.
Survival analyses were performed with Kaplan–Meier method, log-rank test and Cox proportional hazards model.
Results: Of 153 pts were able to evaluate for this analysis. Patient's characteristics were as follows: male/female 114/39, median age 64 (range 24−85), ECOG PS (0 /1/ 2-) 93/39/21. Thirty-four patients were above normal upper limit of serum AFP. Elevated AFP group showed shorter survival time (MST 10.5 vs. 13.9 months, p = 0.03) than AFP normal group, but in Cox multivariate analysis, AFP elevation did not show independent prognostic impact (relative hazard: 1.36, 95% CI: 0.87–2.14, p = 0.18).
Conclusion: AFP elevation before treatment was not correlated to the poor prognosis for the patients with advanced gastric cancer in this analysis.

2634 POSTER

Gemcitabine after failure of cisplatin plus pemetrexed in patients with malignant peritoneal mesothelioma: A single-center experience

A. Takashima[1], T. Hamaguchi[1], Y. Honma[1], S. Iwasa[1], N. Okita[1], K. Kato[1], Y. Yamada[1], H. Tajiri[2], Y. Shimada[1], R. Sawada[2]. *[1]National Cancer Center Hospital, Gastrointestinal Medical Oncology Division, Tokyo, Japan; [2]The Jikei University School of Medicine, Department of Gastroenterology and Hepatology, Tokyo, Japan*

Background: Malignant peritoneal mesothelioma (MPeM) is an extremely rare cancer. No established standard treatment exists for this disease, and it is treated in the same way as malignant pleural mesothelioma (MPlM). For MPlM patients, cisplatin plus pemetrexed (CP) combination chemotherapy is the standard first-line chemotherapy, and gemcitabine (GEM) has been recommended by the National Comprehensive Cancer Network Guideline as a post-treatment option. However, as far as we know, there have been no reports of the use of GEM in MPeM. Here, we evaluated the efficacy and safety of GEM in MPeM patients who had failed CP therapy.
Materials and Methods: MPeM patients who had received GEM at our hospital after failure of CP therapy were reviewed retrospectively. GEM was given 1000 mg/m^2 weekly for 3 out of every 4 weeks until progressive or unacceptable toxicity occurred. Tumor response and adverse events were evaluated with RECIST ver. 1.1 and CTCAE ver. 4.0, respectively. Progression-free survival (PFS) and overall survival (OS) were estimated by using Kaplan–Meier methods.
Results: Between February 2007 and January 2013, 24 patients received CP as a first-line treatment. Seven of these 24 patients received GEM after failure of CP. The characteristics of these 7 patients were as follows: median age, 59 years (range 43−65 years); performance status, 0/1/2 = 2/4/1; pathologic diagnosis: epithelial/sarcomatoid/unknown = 4/2/1; and second-line/third-line treatment = 4/3. The response rate was 14% (partial response/stable disease/progressive disease = 1/3/3) and the disease-control rate was 57%. The median number of doses of GEM was 2 (range 2 to 106); all patients discontinued GEM because of progressive disease. Median PFS was 3.2 months (95% CI: 0.0−8.1 months) and median OS was 6.4 months (95% CI: 2.2–10.6 months). Grade 3 or more adverse events were observed in only 1 patient (Grade 3 anorexia).
Conclusion: GEM appears to have activity with mild toxicity in MPeM patients who fail CP therapy.
No conflict of interest.

2635 POSTER

JASPAC 02: A phase II study of gemcitabine and oxaliplatin (GEMOX) for gemcitabine-refractory advanced biliary tract cancer

I. Ohno[1], A. Fukutomi[2], J. Furuse[3], T. Okusaka[4], M. Asayama[5], S. Nakamori[6], H. Ishii[7], T. Okuno[8], T. Yamanaka[1], N. Boku[9]. *[1]National Cancer Center Hospital East, Kashiwa, Japan; [2]Shizuoka Cancer Center, Shizuoka, Japan; [3]Kyorin University School of Medicine, Tokyo, Japan; [4]National Cancer Center Hospital, Tokyo, Japan; [5]Saitama Cancer Center, Saitama, Japan; [6]Osaka National Hospital, Osaka, Japan; [7]Cancer Institute Hospital of JFCR, Tokyo, Japan; [8]Kobe University School of Medicine, Kobe, Japan; [9]St. Marianna University School of Medicine, Kawasaki, Japan*

Background: Gemcitabine (GEM) -based chemotherapy has been widely used in the first-line treatment for advanced biliary tract cancer (BTC). However, no standard second-line regimen after disease progression has been established and prognosis for such patients remains very poor with reported median survival times of 5.6−7.5 months. This study evaluated the

efficacy and safety of GEMOX, with a fixed dose rate of GEM combined with oxaliplatin (OX), for GEM-refractory BTC (UMIN000003650).
Patients and Methods: Patients with GEM-refractory BTC (gallbladder [GB], intrahepatic biliary duct [IHBD], extrahepatic biliary duct [EHBD], ampulla of Vater [AV]), an ECOG PS of 0−1, and adequate organ function, were eligible. Patients received GEM (1,000 mg/m^2 [10 mg/m^2/min]) followed by OX (100 mg/m^2) intravenously every 2 weeks until disease progression or unacceptable toxicity. The primary endpoint was objective response rate (ORR) by RECIST v1.1. Planned sample size of 40 provided 80% power to reject the ORR of 5% under the expectation of 15% with one-sided alpha of 0.1. Secondary endpoints included progression-free survival (PFS), overall survival (OS), and toxicity (CTCAE v3.0).
Results: From July 2010 to December 2011, 41 patients were enrolled from eight centers. Two patients received no study treatment. Of 39 evaluable for analysis, the median age was 67 years (range, 53−79); 20/19 males/females; 25/14 with PS 0/1; 12/15/7/5 with GB/IHBD/EHBD/AV. First-line GEM-based regimens consisted of GEM alone (22 patients), GEM+cisplatin (8 patients), GEM+S-1 (5 patients), and others (4 patients). The median treatment cycle was 5 (range, 2−18) and the median relative dose intensity of GEM/OX was 88%/86%. CR/PR/SD was confirmed in 0/4/15 patients with an ORR of 10.3% (95% CI, 2.9–24.2%, 80%CI corresponding to one-sided alpha of 0.1, 4.6–19.5%) and a disease control rate of 48.7% (95% CI, 32.4–65.2%). The median PFS and OS were 2.7 and 7.1 months, respectively. The most common grade 3 or 4 adverse events were leukopenia (10%), neutropenia (8%), hemoglobin decrease (8%), sensory neuropathy (8%), thrombocytopenia (5%), anorexia (5%), and hyponatremia (5%).
Conclusions: GEMOX regimen showed a promising anti-tumor activity with acceptable toxicity for GEM-refractory advanced BTC. Further considerations are warranted.

2636 POSTER

The effects of variability of mean erythrocyte corpuscular volume (MCV) in patients with advanced stage gastrointestinal stromal tumor (GIST) using imatinib on progression free survival

B. Cetin[1], D. Tastekin[2], B. Aktas[3], T. Guler[2], M.A. Kaplan[4], V. Berk[5], O. Gumusay[1], F. Dane[3], M. Ozkan[5], M. Benekli[1]. *[1]Gazi University Faculty of Medicine, Medical Oncology, Ankara, Turkey; [2]Necmettin Erbakan University Faculty of Medicine, Medical Oncology, Konya, Turkey; [3]Marmara University Faculty of Medicine, Medical Oncology, Istanbul, Turkey; [4]Dicle University Faculty of Medicine, Medical Oncology, Diyarbakir, Turkey; [5]Erciyes University Faculty of Medicine, Medical Oncology, Kayseri, Turkey*

Background: There is need for predictive factors to determine the reponses of patients with locally advanced and/or metastatic GIST to treatment. Imatinib increases in red blood cell size as measured by MCV and MCH via the KIT signaling pathway in bone marrow.

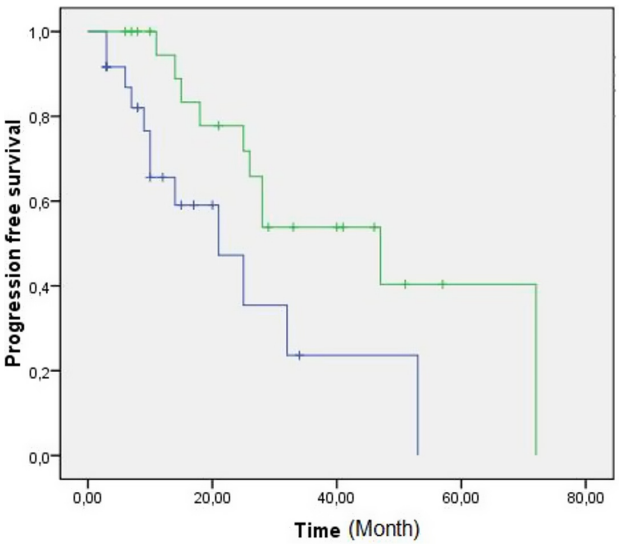

Figure 1. PFS according to the change that has occurred in MCV values.

Material and Method: In this study, we evaluated the relationship between MCV and MCH variability with progression free survival (PFS) three months after the start of the imatinib treatment. Patients with inoperable or metastatic GIST who were dignosed between the years 2000 and 2012 from five centers were included in the study. Blood parameters were evaluated before the start of imatinib treatment and three months after the treatment for the patients' MCV and MCH variability percentage change (?%: MCV 3 months after- MCV before treatment/ MCVX100 before treatment). Kaplan–Meier analysis was used for PFS and log rank was used for comparisons.
Results: A total of 49 patients, 19 female (% 38.8) and 30 male (% 61.2), were evaluated for analysis. Median age was 55 (24−80). Primary tumor locations were found to be stomach in 16 patients, small intestine 17 patients and sites of metastasis were liver in 26 patients. PFS exhibited a significant prolongation in patients with 5 % or more increase in MCV three months after the treatment (47 months versus 21 months respectively, p = 0.022). A PFS prolongation which was not statistically significant was observed in patients (11/49) who had 10 % or more increase in MCH values (28 months versus 26 months respectively, p = 0.968).
Conclusions: Changes in simple laboratory values of patients with locally advanced or metastatic GIST occur as a result of Imatinib pharmacokinetics and can be used in predicting clinical responses.
No conflict of interest.

2637 POSTER

Impact of prior chemotherapy (CT) and somatostatin analogues (SSAs) on clinical outcome in well differentiated pancreatic neuroendocrine tumors (pWDNETs) before treatment with Everolimus (EV)

S. Pusceddu[1], R. Buzzoni[2], V. Mazzaferro[3], P. Grassi[1], A. Damato[1], M. Vitali[1], P. Biondani[1], I. Testa[1], E. Verzoni[1], F. De Braud[1]. *[1]Fondazione IRCCS Istituto Nazionale Tumori, Medical Oncology, Milan, Italy; [2]Fondazione IRCCS Istituto Nazionale Tumori, Day Hospital/Ambulatorial, Milan, Italy; [3]Fondazione IRCCS Istituto Nazionale Tumori, Surgery and Liver Transplantation Unit, Milan, Italy*

Background: EV has been investigated in advanced pWDNETs patients (pts) whitin a large Phase III trial (RADIANT-3), showing a significant improvement of progression-free survival (PFS) of 6.4 months compared with placebo. This effect was long lasting (35% stable at 18 months) but tumor remissions were rare (5%). The most frequent adverse events included stomatitis (64%), rash (49%), diarrhea (34%), fatigue (31%), infections (23%) and pulmonary infiltrates (17%). Based on such results, EV was approved for the treatment of advanced pWDNETs by both FDA and EMA. The ESMO Clinical Practice Guidelines 2012, for diagnosis, treatment and follow up, recommended the use of EV in advanced pWDNETs G1/G2 pts. Aim of this study was to evaluate the disease control rate (DCR) at first radiologic assessment (12 week) defined as the proportion of the best radiological response achieved in pts with complete response (CR), partial response (PR) or stable disease (SD), as a measure of antitumor effect of EV on either pWDNETs naive pts or pts progressing after CT and/or SSAs.
Patients and Methods: We retrospectively analyzed 32 pWDNETs pts treated with EV, between 2010 to April 2013 at our institution.
Results: Median age was 55.5 years, male/female = 22/10. Overall, 22/32 pts received prior SSAs or CT (group A), and 10/32 were treatment naive (group B) before commencing EV. DCR was documented in both groups 12 weeks after EV treatment as follows: 90% (group A) and 70% (group B) respectively. Four out of 32 pts (2 pts in group A and 3 pts in group B) showed disease progression at first evaluation.
Although 13 pts are still on EV treatment, overall SD was achieved in 80% of pts, with a median duration of response of 10 and 13 mos for pretreated and naive patient respectively.
Conclusions: Despite median SD of EV is better in responder naive pts, the overall DCR at 12 weeks is worse when compared to pretreated pts. RADIANT III showed the benefit of EV in terms of PFS, but the therapeutic sequencing for advanced pWDNET remains still unclear. A comparative study is warranted to assess the best sequence strategy for EV in order to evaluate its role up front or following SSAs+/−CT in pWDNETs.
No conflict of interest.

2638 POSTER

Effects of single nucleotide polymorphisms on treatment outcomes and toxicity in patients treated with sunitinib for biliary tract and gastric cancers

C.H. Maeng[1], J.H. Yi[2], J. Lee[3], J.Y. Hong[3], M.K. Choi[3], H.A. Jung[3], J.O. Park[3], S.H. Park[3], Y.S. Park[3], H.Y. Lim[3]. *[1]Kyung Hee University Medical Center, Hemato-Oncology, Seoul, Korea; [2]Hanyang University Hospital, Hemato-Oncology, Seoul, Korea; [3]Samsung Medical Center, Hemato-Oncology, Seoul, Korea*

Background: We analyzed the efficacy and toxicity profile of sunitinib according to single nucleotide polymorphisms (SNPs) of *VEGFA* and *KDR* among the patients with gastric or biliary tract cancer.
Methods: We examined 8 known SNPs of *VEGFA* and 5 SNPs of *KDR* among patients with gastric or biliary tract cancer who were treated with sunitinib in our two previous phase II studies. We assessed time to treatment failure (TTF), overall survival (OS), and toxicity and their relationships to these SNPs.
Results: A total of 63 patients were evaluable. Among candidate SNPs, rs2010963, rs833068, and rs1870377 were associated with poor TTF (P =. 009,. 002, and. 029, respectively), while rs1870377 and rs7692791 were associated with poor OS (P =. 001 and 0.03, respectively). Multivariate analysis showed that only rs1870377 had significant effects on both TTF and OS. Toxicity evaluation indicated that rs1531289 was associated with grade 3−4 anemia. (P =. 021).
Conclusions: Certain SNPs of *KDR* may affect treatment outcome and toxicity of patients treated with sunitinib.
No conflict of interest.

2639 POSTER

Five-year outcomes of a phase II study of adjuvant chemotherapy with docetaxel, capecitabine, and cisplatin in stage IIIB-IV(M0) gastric cancer patients

S. Yoon[1], M.H. Ryu[1], B.Y. Ryoo[1], K.C. Kim[2], J.H. Yook[2], S.T. Oh[2], B.S. Kim[2], Y.K. Kang[1]. *[1]Asan Medical Center, Medical Oncology, Seoul, Korea; [2]Asan Medical Center, Gastric Surgery, Seoul, Korea*

Background: Postoperative adjuvant chemotherapy with S-1 or capecitabine/oxaliplatin combination is standard after D2 gastrectomy in patients with stage II−III (by AJCC 6th edition) gastric cancer. However, in patients with stage IIIB-IV(M0), despite apparently curative resection, more than 70% of patients have recurrence and die within 5 years. Therefore, we investigated the effect of more intensive adjuvant chemotherapy with triplet of docetaxel, capecitabine, and ciaplatin (DXP) for these patients.
Materials and Methods: This prospective, open label, single center phase II study was conducted for patients with histologically confirmed stage IIIB-IV(M0) gastric cancer who underwent D2 gastrectomy. Patients received adjuvant chemotherapy of six 3-week cycles of intravenous docetaxel (60 mg/m^2 on day 1), oral capecitabine (1,875 mg/m^2/day on days 1 to 14), and intravenous cisplatin (60 mg/m^2 on day 1). The primary end point was recurrence-free survival (RFS). The secondary end points were safety profiles, and overall survival (OS).
Results: From January 2007 to August 2008, a total of 46 patients (stage IIIB: 14, IV: 32) were included in this study. The median age was 53 years (29−70), and ratio of males to females was 0.44. Treatment was completed as planned in 40 (87%) patients. After a median follow-up of 56.1 months (range, 52.2–64.1), 28 patients had recurrence. The median RFS was 26.9 months (95% C.I. 7.5–46.4) and 5 year RFS rate was 39.1%. The median OS was 43.9 months (95% C.I. 29.2–58.7) and 5 year OS rate was 41.3%. Grade 3 or 4 toxicities included anemia (6.5%), leukopenia (23.9%), neutropenia (39.1%), thrombocytopenia (4.3%), febrile neutropenia (15.2%), fatigue (10.9%), anorexia (21.7%), nausea (10.9%), vomiting (4.3%), stomatitis (4.3%), diarrhea (4.3%), and myalgia (2.2%). There was no treatment-related mortality. Median relative dose intensity for docetaxel, capecitabine, and cisplatin were 87%, 75%, and 94%, respectively.
Conclusions: These results suggest that intensive adjuvant chemotherapy with triplet DXP combination is feasible and may be effective for patients with stage IIIB, IV (M0) gastric cancer.
Conflict of interest: *Advisory board: Sanofi, Roche. Corporate-sponsored research: Sanofi, Roche*

2640 POSTER

Somatostatin analogs (SSA) treatment in G1-G2 gastroenteropancreatic neuroendocrine tumors (GEP-NET): A single centre experience

R. Marconcini[1], S. Ricci[2], L. Galli[1], A. Antonuzzo[2], L. Derosa[1], A. Farnesi[1], E. Biasco[1], E. Vasile[1], S. Caponi[1], A. Falcone[1]. *[1]S.Chiara Hospital, U.O. Oncologia Medica 2, Pisa, Italy; [2]S.Chiara Hospital, U.O. Oncologia Medica 1, Pisa, Italy*

Background: In a recent study, 85 patients with advanced midgut neuroendocrine tumors (NETs) and predominantly low-volume disease were randomly assigned to receive treatment with octreotide long-acting release or placebo. Patients randomly assigned to the octreotide arm had a significantly longer median time to progression than patients assigned to the placebo arm (14.3 *v* 6 months, respectively; $P < 0.01$) at a planned interim analysis, leading to early termination of the study, giving the evidence of antitumor activity associated with SSA. In this study we analyze our experience with Octreotide LAR in metastatic G1-G2 GEP-NET.
Method: A retrospective analysis was conducted on 103 patients (pt) with advanced GEP-NETs treated upfront with Octreotide LAR (30 mg 1 fl every 28 days) or Lanreotide LAR (120 mg 1 fl every 28 days) until disease progression: 66 gastrointestinal (GI) NET pt (45 treated with Octreotide LAR, 21 with Lanreotide LAR), 37 pancreatic (P) NET pt (29 treated with Octreotide LAR, 8 with Lanreotide LAR).
Results: In 45 GI NET pt group treated with Octreotide LAR mPFS was 22.9 months: in this group, mPFS was 42.23 months in pt with a single metastatic organ and 19.67 months in pt with >1 metastatic organs.
In 21 GI NET pt group treated with Lanreotide LAR mPFS was 18.61 months: in this group, mPFS was 75.25 months in pt with a single metastatic organ and 16.08 months in pt with >1 metastatic organs.
In 29 P NET pt group treated with Octreotide LAR mPFS was 24.97 months: in this group, mPFS was 28.67 months in pt with a single metastatic organ and 21.78 months in pt with >1 metastatic organs.
In 8 P NET pt group treated with Lanreotide LAR mPFS was 25.10 months: in this group, mPFS was 22.28 months in pt with a single metastatic organ and 22.40 months in pt with >1 metastatic organs.

NET	Treatment	Patient number	mPFS (months)	mPFS in patients with 1 metastatic organ	mPFS in patients with >1 metastatic organs
GI	Octreotide LAR	45	22.9	42.23	19.67
	Lanreotide LAR	21	18.61	75.25	16.08
P	Octreotide LAR	29	24.97	28.67	21.78
	Lanreotide LAR	8	25.1	22.28	22.4

Conclusion: Octreotide LAR and Lanreotide LAR showed comparable efficacy in terms of PFS in both PNET and GI NET, especially in pt with limited metastatic involvement.
No conflict of interest.

2641 POSTER

Salvage chemotherapy of fixed dose rate gemcitabine and S-1 combination therapy (FGS) for gemcitabine-refractory advanced pancreatic cancer

A. Kasuga[1], N. Okano[1], D. Naruge[1], H. Kitamura[1], A. Takasu[1], F. Nagashima[1], J. Furuse[1]. *[1]Kyorin University School of Medicine, Department of Medical Oncology, Mitaka, Japan*

Background: No standard salvage chemotherapy regimen has been established for patients with advanced pancreatic cancer after failure of gemcitabine-based treatment. Although a phase I/II study of FGS was conducted in patients with gemcitabine-refractory advanced pancreatic cancer, the number of patients enrolled was small and efficacy and safety of FGS is still not well known.
Materials and Methods: We retrospectively reviewed 59 patients who received FGS as salvage chemotherapy at our institution from March 2009 to March 2013. The selection criteria in this study were progressive disease under gemcitabine-based chemotherapy, ECOG performance status 2 as a 120-min infusion on day 1 and S-1 was administered orally twice a day at a dose of 40 mg/m^2 on day 1 to 7. Cycles were repeated every 14 days.
Results: Fifty-eight patients were selected for the analysis. Fifteen patients of them had received second-line treatment before FGS. The overall response rate was 13.8% and the disease control rate was 50.0%. The median progression-free survival time was 2.7 months and the median overall survival time was 7.4 months. The common grade 3/4 toxicities were leukopenia (12%), neutropenia (16%), diarrhea (3%), anorexia (2%) and fatigue (2%). Univariate analysis showed that performance status of >0, presence of ascites, serum carcinoembryonic antigen level of >10 ng/ml, serum albumin level of 500 IU/L and serum C-reactive protein level of

>1.0 mg/dl were significantly associated with a poor prognosis. Multivariate analysis identified a performance status of >0 and serum C-reactive protein level of >1.0 mg/dl as factors independently associated with a poor prognosis.
Conclusion: FGS as salvage chemotherapy for patients with gemcitabine-refractory advanced pancreatic cancer is marginally effective and well tolerated in a practical setting. These results could be useful as reference data for optimizing treatment strategies and planning future clinical trials in patients with advanced pancreatic cancer after failure of the first-line treatment.
No conflict of interest.

2642 POSTER

Evaluation of polymorphisms as markers of pazopanib efficacy and toxicity in metastatic/advanced neuroendocrine tumors

E. Grande[1], M. Apellaniz-Ruiz[2], J. Capdevila[3], D.E. Castellano[4], R. Garcia-Carbonero[5], A. Teule[6], J. Garcia-Donas[7], M. Robledo[2], C. Rodriguez-Antona[2]. *[1]Ramon y Cajal University Hospital, Medical Oncology, Madrid, Spain; [2]Spanish National Cancer Research Centre (CNIO), Hereditary Endocrine Cancer Group, Madrid, Spain; [3]Vall d'Hebron University Hospital, Medical Oncology, Barcelona, Spain; [4]Hospital Universitario 12 de Octubre, Medical Oncology, Madrid, Spain; [5]Hospital Universitario Virgen del Rocio Instituto de Biomedicina de Sevilla (IBIS), Medical Oncology, Sevilla, Spain; [6]IDIBELL Institut Català d'Oncologia L'Hospitalet, Medical Oncology, Barcelona, Spain; [7]Centro Integral Oncológico Clara Campal, Medical Oncology, Madrid, Spain*

Introduction: Pazopanib is an anti-angiogenic tyrosine kinase inhibitor (TKI) that targets VEGFR-1, 2, and 3; PDGFR-α and β; and c-KIT. The PAZONET is a phase II clinical trial that aimed to determine the efficacy and safety and to identify predictive biomarkers of pazopanib in metastatic/advanced neuroendocrine tumor (NET) patients refractory to other systemic approaches. Within this study, here we evaluated the impact of single-nucleotide polymorphisms (SNPs), previously proposed as predictors of sunitinib outcome, on pazopanib response and toxicity.
Methods: Forty four NET patients were included, in the PAZONET trial. A blood sample for genomic DNA isolation was obtained from 29 of these patients. *VEGFR3* rs307821 (R1324L), *VEGFR3* rs307826 (T494A) and *CYP3A5* rs776747 (splicing defect) were genotyped using standard techniques. Cox regression was used to study genotype associations with progression free survival (PFS) and overall survival (OS), and logistic regression was used to study response and toxicity.
Results: The two *VEGFR3* missense polymorphisms were associated with reduced PFS in gastrointestinal NET (HR = 12.3, P = 0.042 for rs307821; HR = 6.9, P = 0.055 for rs307826). We did not find an association between *CYP3A5* rs776746 and pazopanib toxicity or response.
Conclusion: Polymorphisms in *VEGFR3* may define a subset of patients with decreased pazopanib response in gastrointestinal NET. These results confirm prior observations in kidney cancer, thus these SNPs could determine TKI resistance regardless of the tumor type.
Conflict of interest: *Other substantive relationships: GlaxoSmithKline*

2643 POSTER

The prognostic value of a trio of the EMT (tumour-mesenchymal transition) markers for patients with gastric cancer

J. Ji[1], S.Q. Jia[2], Y.N. Jia[3], W.G. Jiang[4]. *[1]Peking University Cancer Hospital, Gastroenterology, Beijing, China; [2]Cardiff University-Peking University Joint Cancer Institute, Cardiff University, Cardiff, United Kingdom; [3]Cardiff University-Peking University Joint Cancer Institute, Peking University Cancer Hospital, Beijing, China; [4]Cardiff University-Peking University Joint Cancer Institute, Cardiff University School of Medicine, Cardiff, United Kingdom*

Background: Gastric cancer is one of the leading cancers in the Far East and commonly seen in most part of the world. Despite the progress in the diagnosis and treatment options, it remains one of the tumour types with the highest mortality. The most frequently used methods in assessing the prognosis of the patients are the combined clinical and pathological information of the patients. EMT, Tumour-Mesenchymal Transition, is defined by a number of cellular function changes and characterised by a panel of specific biomarkers. EMT is a cellular process in cancer that is highly involved in the development and progression of cancer and cancer cells. In the present study, we have examined the expression of some of the key EMT molecules in gastric cancer and their value in assessing patients prognosis.
Materials and Methods: A cohort of 189 patients with gastric cancer who received gastrectomy entered the study. Tumour and normal gastric tissues were immediately obtained immediately after surgery. The paired samples were processed for histological and genetic based analyses. The gene transcript levels of a panel of recognised EMT markers were quantified in the paired tumour and normal tissues. The clinical and prognostic value of the expression of the EMT markers and the combined power of the markers were analysed against the clinical, histological, pathological and clinical outcome of the patients.
Results: Expression of Slug, Twist and cadherin-1 (CDH-1) were found to be aberrant in gastric cancer tissues when compared with normal tissues of the stomach. For examples, CDH1 was found to be markedly reduced in tumour compared with normal tissues ($p < 0.001$). Likewise, expression of Twist and Slug were also significantly different between tumour and normal tissues in that tumour had a markedly high level ($p < 0.0001$ and $p = 0.015$ respectively). Other EMT markers were found to be less aberrant in gastric cancers. The markers individually did not appear to be significantly correlated with the histological type nor the location of the tumour. However, the trio of the markers, namely, CDH1, Slug and Twist were significantly correlated with the incidence free survival ($p = 0.005$) and overall survival ($p = 0.008$), based on the Kaplan–Meier survival model. Likewise, patients with the Trio EMT marker abnormalities had a lower five-year survival rate.
Conclusions: A selective trio of the tumour-mesenchymal transition markers is an important indicator in the disease progression of gastric cancer and have prognostic value in predicting patients clinical outcome.
No conflict of interest.

2644 POSTER

Study of the expression of connective tissue growth factor (CTGF) and hypoxia-inducible-factor (HIF) in hepatocellular carcinoma (HCC)

A. Lamarca[1], M. Mendiola[2], E. Bernal[1], V. Heredia[3], E. Díaz[1], M. Miguel[1], E. Burgos[3], J. Feliú[1], J. Barriuso[1]. *[1]La Paz University Hospital, Medical Oncology, Madrid, Spain; [2]La Paz University Hospital, Medical Oncology/Pathology, Madrid, Spain; [3]La Paz University Hospital, Pathology, Madrid, Spain*

Background: CTGF is a matricellular protein involved in inflammation, tumour growth and angiogenesis. A hypoxic (HIF related) CTGF expression, independent of TGFβ, with implications in fibrosis and metastatic potential was described in renal cancer. The aim of this study is to clarify if this data could match in HCC.
Material and Methods: Patients (pts) diagnosed with HCC, with paraffin-embedded biopsy tissue and relapse and survival data available were eligible. A tissue microarray (TMA) was constructed from $\geqslant$70% tumoural sections and non-necrotic areas of the tumour foci. The expressions of CTGF, HIF1α and HIF2α were analysed by immunohistochemistry (IHC). The primary end point was relapse rate. Secondary end points were disease-free survival (DFS) and overall survival (OS). Univariate and multivariate analysis were performed.
Results: Fifty-three pts were analysed; 39 pts were eligible for this retrospective analysis. The median age at diagnosis was 66.9 years (range 36−82). 76.9% were men and 51.3% had hepatitis C related cirrhosis. Stage at diagnosis was as follows n(%): 10(25.6%) I, 14(35.9%) II, 6(15.4%) III, 2(5.1%) IV and 7(17.9%) unknown. Most of the pts were treated with surgery alone (84.6%) or combined with other treatment (10.3%). 5 pts (12.8%) died during the surgery or during the postoperative period. The median follow-up was 36.1 months (range 0–98.8). At the end of the follow up, 23(59%) pts relapsed [11(28.2%) locally, 4(10.3%) multicentric liver relapse and 3(7.7%) distant metastases)] and 27(69.2%) died; 8(20.5%) were alive and free of disease while 4(10.3%) were alive on treatment for HCC. Estimated median DFS was 23.4 months (95% CI 7.18–39.66) and median OS 38.6 months (95% CI 30.7–46.6). Expression of CTGF was: negative 9(23.1%), focal 19(48.7%) and diffuse 9(23.1%). Expression of HIF1α was positive 14(35.9%) and negative 16(41%) while expression of HIF2α was positive 11(28.2%) and negative 21(53.8%). 2 CTGF, 9 HIF1α and 7 HIF2α IHC were not evaluable. Non statistical significant relationship between expression of CTGF and HIF was shown (p0.93(HIF1α); p0.932(HIF2α)). CTGF expression was related to longer DFS (p0.028) and OS (p0.005) while expression of HIF2α was predictable of relapse (p0.034). Other prognosis factors were type of relapse ($p < 0.001$) and hepatic baseline disease (p0.022) for DFS and stage at diagnosis (p0.006) and type of relapse ($p < 0.001$) for OS. In the multivariable analysis, type of relapse (p0.09; HR 1.65; 95% CI 1.13–2.39) and CTGF expression (p0.016; HR 2.46; 95% CI 1.18–5.15) were independent factors related to OS.
Conclusions: Our results support that expression of CTGF is an independent factor related with OS in HCC. It would be worth performing further analysis of CTGF expression in larger series of HCC as prognostic biomarker and druggable target.
Conflict of interest: *Corporate-sponsored research: Jorge Barriuso participates in clinical trials sponsored by Roche, Novartis, Taiho, AstraZeneca and Pfizer. 2645 POSTER

Correlation between VEGF and VEGF-R polymorphisms, toxicity and clinical outcome in HCC patients receiving sorafenib

L. Faloppi[1], M. Scartozzi[2], M. Bianconi[1], C. Loretelli[1], G. Svegliati Baroni[3], A. Mandolesi[4], R. Giampieri[1], M. Del Prete[1], A. Benedetti[3], S. Cascinu[1]. [1]*Università Politecnica delle Marche, Department of Medical Oncology, Ancona, Italy;* [2]*AOU Ospedali Riuniti, Department of Medical Oncology, Ancona, Italy;* [3]*Università Politecnica delle Marche, Department of Gastroenterology, Ancona, Italy;* [4]*Università Politecnica delle Marche, Department of Pathological Anatomy, Ancona, Italy*

Background: The introduction of sorafenib for the treatment of advanced HCC radically changed patients' clinical outcome. However response to treatment as well as toxicity are still largely unpredictable in the single patient. We previously reported that VEGF and VEGFR polymorphisms may have a predictive and prognostic role in this setting, but little is known about the possible correlation with toxicity.
The aim of our study was to evaluate whether VEGF and VEGFR genotyping was able to correlate with toxicity in HCC patients receiving sorafenib.
Methods: 73 histological samples of HCC patients receiving sorafenib were tested for VEGF-A, VEGF-C and VEGFR-1,2,3 single nucleotide polymorphisms (SNPs). Patients time to progression (TTP), overall survival (OS) and toxicities were analysed.
Results: VEGF-A rs833061 T>C, rs699947 C>A and rs2010963 C>G polymorphisms were statistically significant associated with any grade global (respectively: $p = 0.031$; $p = 0.018$; $p = 0.003$) and cutaneous toxicities (respectively: $p = 0.043$; $p = 0.019$; $p = 0.025$). Furthermore patients with any grade global and cutaneous toxicities showed a better progression free survival and overall survival (global toxicity PFS: 7.0 vs 5.0 months, $p = 0.016$; OS: 26.8 vs 13.0 months, $p = 0.023$) (cutaneous toxicity PFS: 7.6 vs 5.1 months, $p = 0.033$; OS: 22.7 vs 13.3 months, $p = 0.014$).
Conclusions: In our analysis patients with polymorphism T at rs833061, C at rs699947 and C at rs2010963 showed a higher rate of toxicities and, accordingly to our previous report, this correlates with a better PFS and OS. Analysis of VEGF and its receptor genes polymorphisms represents a clinical tool to identify patients with favourable response to sorafenib presumably related to a more efficient control of tumour growth. The occurrence of toxicity could be an interesting clinical surrogate during sorafenib treatment and may help clinicians in a more cautious and aware management of HCC patients.

Prognostic impact of c-MET status on overall survival of patients with advanced gastric cancer treated with standard chemotherapy: A Japanese multicenter collaborative retrospective study

Y. Kuboki[1], N. Fuse[1], T. Kuwata[2], E. Shinozaki[3], N. Machida[4], S. Yuki[5], S. Kajiura[6], T. Yamanaka[7], A. Ochiai[8], A. Ohtsu[7]. [1]*National Cancer Center Hospital East, Department of Gastrointestinal Oncology, Chiba, Japan;* [2]*National Cancer Center Hospital East, Department of Pathology, Chiba, Japan;* [3]*Cancer Institute Hospital of JFCR, Department of Gastroenterology, Tokyo, Japan;* [4]*Shizuoka Cancer Center, Department of Gastrointestinal Oncology, Shizuoka, Japan;* [5]*Hokkaido University Hospital, Department of Gastroenterology and Hepatology, Hokkaido, Japan;* [6]*University of Toyama, The Third Department of Internal Medicine, Toyama, Japan;* [7]*National Cancer Center, Exploratory Oncology Research & Clinical Trial Center, Chiba, Japan;* [8]*National Cancer Center, Department of Pathology Research Center for Innovative Oncology, Chiba, Japan*

Background: c-MET overexpression has been reported in 18−82% of gastric cancer with immunohistochemistry (IHC) and was correlated with poor prognosis. However, the prognostic impact of c-MET status on overall survival (OS) of patients with advanced gastric cancer (AGC) treated with standard chemotherapy remains unclear. We investigated whether c-MET status is an independent prognostic factor for AGC patients.
Materials and Methods: Formalin-fixed paraffin-embedded tumor samples from 293 eligible patients were examined for c-MET by IHC. IHC staining was performed automatically with Ventana BenchMark® ULTRA using primary antibodies against rabbit anti-c-MET polyclonal antibody (SP44; Ventana). We used three separate IHC evaluation criteria to define c-MET+: (A) IHC 2+ or 3+ according to the DAKO HercepTest guideline; (B) $\geqslant$25% of tumor cells with any membrane staining intensity; and (C) a majority ($\geqslant$50%) of tumor cells with IHC 2+ or 3+ membrane staining intensity. Eligibility criteria included: 1) histology confirmed gastric or gastroesophageal junction adenocarcinoma, 2) unresectable or recurrent cancer, 3) treated with S-1 plus cisplatin as first-line chemotherapy, 4) age: $\geqslant$20, 5) ECOG performance status score: 0−2 and 6) with archived tumor sample.
Results: Of 293 patients, 142 (48.5%) were c-MET+ using criteria (A), 158 (53.9%) using (B), and 120 (40.9%) using (C). Under criteria (C), baseline patient characteristics between c-MET+ and c-MET− patients were significantly different by histology (intestinal/diffuse, 51.7%/48.3% vs. 36.4%/63.6%; $p = 0.012$), liver metastasis (41.7% vs. 29.5%; $p = 0.034$), and HER2 status (20.0% vs. 11.0%; $p = 0.043$). After median follow-up time of 48.9 months with 270 (92%) death events, there was significant difference in OS between c-MET+ and c-MET− patients using criteria (C) (median, 11.9 vs. 14.2 months; hazard ratio [HR] 1.282, 95% CI 1.004–1.636; log rank $p = 0.046$); whereas OS among c-MET+ and c-MET− groups selected by criteria (A) or (B) did not vary significantly. A multivariate Cox model with backward selection found c-MET+ using (C) was a marginal prognostic factor for OS (HR 1.283; 95% CI: 0.996–1.652; $p = 0.054$).
Conclusions: The present study suggested that c-MET+ AGC patients with $\geqslant$50% tumor cells with IHC 2+ or 3+ had a poor prognosis than those with c-Met−.

Prognostic impact of epidermal growth factor receptor status on overall survival of advanced gastric cancer patients treated with standard chemotherapy: A Japanese multicenter collaborative retrospective study

S. Kadowaki[1], N. Fuse[2], Y. Kuboki[2], T. Kuwata[3], T. Nishina[4], A. Ooki[5], T. Goji[6], T. Yamanaka[7], A. Ochiai[8], A. Ohtsu[7]. [1]*Aichi Cancer Center Hospital, Department of Clinical Oncology, Nagoya, Japan;* [2]*National Cancer Center Hospital East, Department of Gastrointestinal Oncology, Kashiwa, Japan;* [3]*National Cancer Center Hospital East, Department of Pathology, Kashiwa, Japan;* [4]*National Hospital Organization Shikoku Cancer Center, Department of Gastrointestinal Medical Oncology, Matsuyama, Japan;* [5]*Saitama Cancer Center Hospital, Department of Gastroenterology, Kitaadachi-gun, Japan;* [6]*The University of Tokushima Graduate School, Department of Gastroenterology and Oncology, Tokushima, Japan;* [7]*National Cancer Center, Exploratory Oncology Research & Clinical Trial Center, Kashiwa, Japan;* [8]*National Cancer Center, Research Center for Innovative Oncology, Kashiwa, Japan*

Background: Epidermal growth factor receptor (EGFR) overexpression, observed in 27−44% of gastric cancer patients, has been generally reported to be a poor prognostic factor in patients who underwent resection. The prognostic impact of EGFR status on overall survival (OS) of advanced gastric cancer (AGC) patients treated with standard chemotherapy remains unclear. We investigated whether EGFR status is an independent prognostic factor for AGC patients.
Patients and Methods: Formalin-fixed paraffin-embedded tumor samples from 293 eligible patients were examined for EGFR by immunohistochemistry (IHC). IHC staining was performed automatically with Ventana BenchMark® ULTRA using primary antibodies against EGFR (CONFIRM EGFR 3C6). An EGFR-positive sample was defined as IHC 2+ or 3+ according to the DAKO HercepTest guideline. Eligibility criteria included: 1) histology confirmed gastric or gastroesophageal junction adenocarcinoma, 2) unresectable or recurrent cancer, 3) treated with S-1 plus cisplatin as first-line chemotherapy between January, 2006 and March, 2010, 4) age: $\geqslant$20, 5) Eastern Cooperative Oncology Group performance status score: 0−2 and 6) with archived tumor sample.
Results: Of 293 patients, 79 (27.0%) were EGFR-positive. Baseline patient characteristics between EGFR-positive and -negative patients were significant different by disease status (unresectable/recurrent 91%/9% vs. 79%/21%; $p = 0.016$). After a median follow-up time of 48.9 months with 270 (92%) death events, there was no significant difference in OS between EGFR-positive and EGFR-negative patients (median, 11.9 vs. 14.2 months; hazard ratio 1.065, 95% CI 0.811–1.397; log rank $p = 0.650$). After adjusting other prognostic factors with Cox hazard model, EGFR status was still not prognostic factor for OS.
Conclusions: EGFR status has no significant prognostic impact on OS of AGC patients treated with S-1 plus cisplatin as a first-line treatment.

Plasma sVEGFR2 as predictor of efficacy of Pazopanib in patients with progressive neuroendocrine tumors: PAZONET biological Substudy

O. Casanovas[1], A. Figueras[1], R. Salazar[2], D. Castellano[3], J. Capdevila[4], R. García-Carbonero[5], A. Teulé[2], I. Durán[6], J. Fuster[7], E. Grande[8]. *[1]Catalan Institute of Oncology, Translational Research Laboratory, Barcelona, Spain; [2]Catalan Institute of Oncology, Medical Oncology Department, Barcelona, Spain; [3]Doce de Octubre University Hospital, Medical Oncology Department, Madrid, Spain; [4]Vall d'Hebrón University Hospital, Medical Oncology Department, Barcelona, Spain; [5]Virgen del Rocío University Hospital, Medical Oncology Department, Sevilla, Spain; [6]Centro Integral Oncológico Clara Campal, Medical Oncology Department, Madrid, Spain; [7]Son Espases Hospital, Medical Oncology Department, Mallorca, Spain; [8]Ramon y Cajal University Hospital, Medical Oncology Department, Madrid, Spain*

Background: The objective of this study is to evaluate the predictive role of plasma VEGF-A and sVEGFR2 in patients with progressive neuroendocrine tumors (NETs) treated with Pazopanib in the PAZONET clinical trial. As the trial allowed pre-treatment of patients with previous targeted therapies, the predictive value of these molecules was studied depending on pre-treatment.
Methods: Patients with advanced NETs progressing to prior chemotherapy, somatostatin analogs (SA) or targeted therapies (mTOR inhibitors or antiangiogenic drugs) were treated with Pazopanib 800 mg/day until progression or unacceptable toxicity in the PAZONET clinical trial (Grande et al, ESMO 2012; Grande et al, ASCO 2013). Blood samples were retrieved at baseline and after 12 weeks of treatment and plasma VEGF-A and sVEGFR2 were determined by ELISA. Disease was evaluated bimonthly with CT scans (RECIST1.0).
Results: Neither baseline VEGF-A (n = 39, median 108 pg/ml) vs on-treatment VEGF-A (n = 30, median 132 pg/ml), nor individual increase or decrease on VEGF-A levels demonstrated predictive value. Nevertheless plasma levels of sVEGFR2, demonstrated a significant decrease on treatment (baseline n = 41 median 8520 pg/ml; on-treatment n = 27, median 6561 pg/ml, $p < 0.0001$). Furthermore, the amplitude of sVEGFR2 decrease was associated with longer treatment duration ($p = 0.0046$), with −20% decrease in sVEGFR2 corresponding to 50 weeks of treatment.
PFS was longer for patients with greater decreases of sVEGFR2, with a median of 12.6 versus 9.1 for patients with decreases above or below the median, respectively ($p = 0.067$). This association was statistically significant among patients that had not received prior antiangiogenic therapy (n = 13, PFS of 20.1 versus 9.1 months respectively, $p = 0.028$), but not in the subset of patients with previous antiangiogenic therapy (n = 14, $p = 0.93$). As transient changes in pro-angiogenic factors have been described (Teulé & Casanovas 2012; Lieu et al. 2012), we subdivided patients according to time since previous antiangiogenic therapy and found sVEGFR2 to be predictive of PFS in past/older pre-treated patients compared to recent ones (median cutoff of 30 days since pre-treatment, n = 19 $p = 0.036$).
Conclusions: Pazopanib treatment is associated with a decrease in plasma levels of sVEGFR2. Stronger decrease of VEGFR2 is associated with improved PFS, especially in patients without prior antiangiogenic therapy and in those with a longer time elapsed since previous antiangiogenic therapy.

2649 POSTER

MutaGIST study: a prospective assessment of prognostic significance of the mutational status of KIT, PDGFRA, BRAF and expression of IGF-1, IGF-2, and S6k-phosphorylated in localized gastrointestinal stromal tumors (GIST). A molecular and clinicopathologic GIST study − preliminary results

J. Delgado[1], C. Valverde[2], A. López-Pousa[3], N. Laínez[4], C. Pericay[5], J. Cruz[6], A. Santón[7], M.E. Reguero[7], F. Ruiz-Cabello[8], E. Grande[9]. *[1]Hospital Universitario Virgen de las Nieves, Medical Oncology, Granada, Spain; [2]Hospital Valle Hebrón, Medical Oncology, Barcelona, Spain; [3]Hospital Sant Pau y Sta Creu, Medical Oncology, Barcelona, Spain; [4]Hospital de Navarra, Medical Oncology, Pamplona, Spain; [5]Hospital Parc Tauli, Medical Oncology, Sabadell, Spain; [6]Hospital Universitario de Canarias, Medical Oncology, Tenerife, Spain; [7]Hospital Ramón y Cajal, Pathology Department, Madrid, Spain; [8]Hospital Universitario Virgen de las Nieves, Molecular Biology Unit., Granada, Spain; [9]Hospital Ramón y Cajal, Medical Oncology, Madrid, Spain*

Background: There is a well-known correlation between tumor genotyping and clinical outcome of patients with metastatic GIST treated with imatinib. However, limited experience is available related to the role that GIST molecular subtype could play in the adjuvant setting. We aimed to prospectively assess the impact that mutational status could have in terms of time to relapse of patients with resected GIST and to obtain a better knowledge of early stage GIST.
Methods: A multicenter, prospective, observational study to establish the mutational status of KIT, PDGFRA and BRAF genes by sequencing exons and the expression level of the IGF1, IGF2 and pS6K proteins by immunohistochemistry in localized and resected GIST tumor samples at diagnosis. Patients will be followed for 24 months after inclusion and the same molecular analysis will be performed at relapse.
Results: 83 patients (pts) were included from 2011 to 2012. Median age was 66 yrs., 46 females and 35 males. The Stomach was the more frequent location, Median tumor size was 6 cm and median mitotic index was 5%. According to Miettinen criteria: 8.2% had very low risk, 26% low risk, 16.4% intermediate risk and 42.5% high risk. 48 pts received adjuvant therapy. 41 pts had spindle cell histology. Mutational showed that 21 (25.3%) exon 11 mutation (mut); 11 (13.2%) pts had KIT exon 9 mut; 2 (2.4%) pts exon 13 mut; and 2 (2.4%) exon 17 mut. PDGFRA mutational analysis showed that 13 (15.6%) pts had exon 18 mut (11 D842V). 46 pts were analyzed for BRAF and 1 (2.1%) patient had exon 15 mut. After a median follow-up of 16 months only 2 relapses have been identified.
Conclusions: This preliminary shows that there is a significant variations between the proportion of mutations in KIT, PDGFR, and BRAF genes in localized compared to advanced GIST samples. Exon 18 mutations were very frequent in primary GIST compared with metastatic GIST. A longer follow up will be needed to correlate the tumor genotyping with the benefit to imatinib in the adjuvant setting.
No conflict of interest.

Phase I study of vorinostat combined with capecitabine plus cisplatin as first-line chemotherapy in patients with advanced gastric cancer: The results of pharmacodynamic analysis

C. Yoo[1], M.H. Ryu[1], Y.S. Na[1], B.Y. Ryoo[1], C.W. Lee[1], J. Maeng[1], S.Y. Kim[1], D.H. Koo[1], I. Park[1], Y.K. Kang[1]. *[1]Asan Medical Center, Oncology, Seoul, Korea*

Background: Vorinostat is an oral histone deacetylase (HDAC) inhibitor. The purpose of this trial was to determine recommended phase II dose of vorinostat in combination with capecitabine plus cisplatin in patients with advanced gastric cancer. The results of dose-finding portion of study were previously presented (J Clin Oncol 30:2012; suppl 34; abstr 73). Here, we report the results of pharmacodynamic analysis in this patient cohort (NCT01045538).
Materials and Methods: Peripheral blood mononuclear cells (PBMCs) were obtained before the study treatment and 2 hours after ingestion of vorinostat capsules at post-treatment day 8 of cycle 1. HDAC2 expression and histone H3 acetylation were measured by Western blot analysis, and normalized to histone H3 expression. The correlations between the change of acetyl-H3 after treatment and covariates were analyzed by linear regression.
Results: Among 30 patients enrolled in this study, pre- and post- vorinostat PBMC samples were available in 29 patients. The vorinostat-induced change of histone acetyl-H3 was median 9.1% (95% confidence interval [CI], −10.3–224.1) over baseline ($p = 0.09$). Acetyl-H3 was significantly increased in patients who received vorinostat 400 mg/day (median 24.2%, $p = 0.02$), while not in those with 300 mg/day (4.0%, $p = 0.33$). The change of acetyl-H3 in PBMC was correlated with baseline acetyl-H3 ($p < 0.001$), but not with baseline HDAC2 expression ($p = 0.38$). Multivariate analysis was performed with inclusion of baseline HDAC2, baseline acety-H3, and vorinostat dose. In this analysis, baseline acetyl-H3 (beta = −0.71, $p < 0.001$) and vorinostat dose (300 vs 400 mg/day; beta=0.33, $p = 0.03$) were significantly correlated with the change of acetyl-H3 after study treatment.
Conclusions: In patients who received this combination regimen, baseline expression of histone acetyl-H3 was inversely correlated with the change in acetyl-H3 after treatment. Our finding suggests that baseline acetyl-H3 in PBMCs is a potential biomarker of vorinostat.

Gene expression characterization of gastroenteropancreatic neuroendocrine tumors (GEP-NETs) and their correlation with clinical factors and tumor behavior: initial molecular profile

P.J. Fonseca[1], J.A. Díaz Pérez[2], G. Crespo Herrero[3], C. Villabona[4], C. Blanco[5], C. González García[6], R. Garcia-Carbonero[7], R. Luque[8], J. Castaño[8], A. Martínez Fuentes[8]. *[1]Universitary Central Asturias Hospital, Medical Oncology Department, Oviedo, Spain; [2]Hospital Clínico de San Carlos Madrid, Endocrinology Department, Madrid, Spain; [3]Hospital Universitario de Burgos, Medical Oncology Department, Burgos, Spain; [4]Hospital Universitari de Bellvitge, Endocrinology Department, L'Hospitalet de Llobregat, Spain; [5]Hospital Universitario Príncipe de Asturias, Endocrinology Department, Alcalá de Henares, Spain; [6]Hospital Ramón y Cajal, Pathology Department, Madrid, Spain; [7]Hospital Universitario Virgen del Rocio/Instituto de Biomedicina de Sevilla (IBIS) [HUBVR CSIC US], Medical Oncology Department, Sevilla, Spain; [8]University of Cordoba and Reina Sofia University Hospital & Instituto Maimónides de Investigación Biomédica de Córdoba (IMIBIC) and CIBER Fisiopatología de la Obesidad y Nutrición, Department of Cell Biology Physiology and Immunology, Córdoba, Spain*

Background: Although distinctive biological features of GEP-NETs, such as somatostatin receptor expression, high vascularization and altered signal transduction activation, are currently being used as therapeutic tools, the development of specific therapies targeting GEP-NETs is impaired by their inherent heterogeneity, lack of a characteristic molecular profile and absence of adequate cellular or animal models.
Methods: A national multicenter study was initiated to characterize in GEP-NETs the molecular profile of 36 genes by quantitative real-time-PCR including somatostatin and dopamine receptors, VEGF pathway components, mTOR pathway components, and a number of tyrosine kinase receptors and adhesion molecules. Molecular information will be correlated with clinical factors such as localization of primary tumors, ploidy, Ki-67 index, stage of disease, and tumor functionality. 40 fresh-frozen tumor samples from patients with well differentiated gastrointestinal and pancreatic NETs (GI-NETs and pNETs) have been included.
Results: Initial analyses focused on somatostatin (sst1, sst2, sst3, sst5) and dopamine receptor expression (D2RT: total D2R isoform and D2RL: D2R long isoform). The first 15 patients analyzed (10 male, mean age 55 years) included 7 GEP-NETs of pancreatic origin (pNETs) and 8 GEP-NETs which originated in the bowel (GI-NETs). Of the 7 pNETs (G1, n = 3; G2, n = 4), 3 presented Stage IV at diagnosis and 1 was a secreting tumor. Of the 8 GI-NETs [foregut (G1, n = 1; G2, n = 2), midgut (G1, n = 2; G2, n = 1), hindgut (G2, n = 2)] 6 had Stage IV at diagnosis and 2 had secreting tumors.
Molecular data show that the sst1 mRNA transcript is the dominant sst isoform in pNET samples (1260±264 copies), followed by lower levels of sst2 (833±164 copies) and sst5 (713±277 copies) and negligible expression of sst3 (<100 copies). In GI-NET samples, sst1 (579±210 copies), sst2 (772±427 copies) and sst5 (455±197 copies) transcripts were expressed at similar levels; sst3 expression in GI-NETs was also very low (<100 copies). Sst1 transcript expression in GEP-NETs was significantly higher in non-functioning tumors compared with functioning tumors (1129±226 copies vs 312±199 copies, $p < 0.05$). Stage IV tumors had significantly lower sst1 transcript expression levels than earlier stages of disease (509±83 copies vs 1386±565 copies, $p < 0.02$). There were no significant differences of D2RT and D2RL isoforms between pNET and GI-NET samples, with limited mRNA expression levels in all samples (<50 copies).
Conclusion: Somatostatin receptor subtype transcriptional profile in GEP-NETs may substantially differ according to primary tumor type, functionality or stage of disease. Further analysis detailing the molecular phenotype of these tumors may help identify molecular targets of prognostic, diagnostic and/or therapeutic value, and shall ultimately improve stratification, diagnosis and management of patients with different types of GEP-NETs.

2652 POSTER

Personalized treatment of advanced pancreatic cancer based on a combined biomarker analysis: A feasibility targeted therapy study

J. Rodriguez-Pascual[1], J.C. Plaza[2], A. Cubillo[1], R. Alvarez[1], E. De Vicente[3], Y. Quijano[3], J.M. Cardenas[4], S. Angulo[4], F. Lopez-Rios[2], M. Hidalgo[1]. *[1]Centro Integral Oncologico Clara Campal, Medical Oncology, Madrid, Spain; [2]Centro Integral Oncologico Clara Campal, Laboratorio de Dianas Terapeuticas, Madrid, Spain; [3]Hospital Madrid Norte Sanchinarro, Surgical Oncology, Madrid, Spain; [4]San Pablo CEU University, Biostatistics, Madrid, Spain*

Background: Treatment options for patients (pts) with pancreatic cancer (PC) have increased in the last years, but there are no validated molecular markers in PC to select which agents are better to treat an individual case. The aim of this study was to determine the feasibility of implementing a molecular biomarker panel (MoBP) to guide treatment selection in PC.
Material and Methods: PC tumor samples were analyzed with a predefined set of 7 molecular targets, including: *KRAS* mutations, *EGFR* amplification (FISH), and thymidylate synthase (TS), thymidine phosphorylase (TP), ERCC-1, topoisomerase I (Topo I), and SPARC expression by IHC. Clinical characteristics and response to chemotherapy were registered. To establish the utility of this panel, we selected 3 groups of pts with completed clinical data: pts with MoBP determination that prospectively selected treatment (Group A), pts with MoBP determination but inconsistent treatment (Group B) and pts without MoBP and treated based on clinical guidelines (Group C).
Results: A total of 67 pts were studied. 63 pts were analyzed for overall survival. We determined MoBP in 35 (56%) Only 6 % required a repeated biopsy to obtain sufficient tumor for molecular analysis. In 47 % of pts was feasible to study 5/7 targets. There were 14/21 pts (67%) with *KRAS* mutant PC. TS was positive in 15/28 cases (54%), TP in 6/19 (32%), ERCC-1 in 7/28 (25%), Topo I in 7/15 (47%). SPARC was negative in tumoral and positive in stromal cells in 15/21 (71%). None of 20 pts had EGFR amplification. Clinical flow up was available in 67 pts (38 males, median age 66, 95% ECOG 0−1). 67, 47 and 16 pts received 1st, 2nd or 3rd line of chemotherapy respectively. Only TS and TP predicts response to treatment based on fluoropirimidines or capecitabine: PFS (months) in fluorpirimidine-treated group 6.9 (TS negative) vs. 2.2 (TS positive) $p = 0.015$; PFS (months) in Capecitabine-treated group 10.7 (TS negative and TP positive) vs 2.0 (TS positive or TP negative) $p = 0.036$. We selected 63 pts for overall survival, 23 pts in Group A, 12 in Group B and 28 in Group C. OS (months) in Group A (12) differs significantly from Group B (8.5) or Group C (7.6) $p = 0.013$. No significant differences between Group B and Group C were detected.
Conclusions: This MoPB is feasible to implement and should be explore to predict treatment response to PC.
No conflict of interest.

2653 POSTER

Clinical significance of CD151 expression in patients with advanced gastric cancer

B. Kang[1], J. Kim[1], S. Lee[1], Y. Chae[1], Y. Lee[1], D. Lee[2]. *[1]Kyungpook National University Hospital, Oncology, Daegu, Korea; [2]Kyungpook National University Hospital, Pathology, Daegu, Korea*

Background: Tetraspanin CD151 is known to be involved in cancer invasion and metastasis, and its overexpression appears to be associated with a poor prognosis in various types of cancers. CD151 is also implicated in the formation of signaling complexes between c-erbB2 and c-Met, modulating cancer cell motility and morphogenesis elicited by the activation of these molecules. However, the expression status of CD151 and its prognostic impact in gastric cancers has not been elucidated yet.
Methods: We investigated the expression of CD151, c-erbB2, and c-Met by immunohistochemistry in 160 cases of advanced gastric cancers. Clinicopathological and prognostic significance of these biomarkers was evaluated.
Results: Overexpression of CD151 was observed in a subset of advanced gastric adenocarcinomas (25.6%), while c-erbB2 and c-Met were overexpressed in 15% and 16.9% of our cohort, respectively. The expression of CD151 was not correlated with the expression of c-erbB2 and c-Met ($P = 0.666$ and $P = 0.969$). CD151 overexpression was more frequently observed in tumors from younger patients ($P = 0.028$). Interestingly, the expression rate of CD151 seemed to be gradually increased according to the depth of invasion (T stage) (x2 test for trend; $P = 0.082$), N stage ($P = 0.233$), and pathologic stage ($P = 0.133$), although they were not statistically significant. However, CD151 overexpression was closely associated with patients overall survival (OS; $P < 0.001$) and progression-free survival (PFS; $P < 0.001$). In multivariate analysis, CD151 overexpression was an independent prognostic factor for predicting worse

OS (P = 0.004) and PFS (P = 0.009) along with T stage and N stage. The expression status of c-erbB2 and c-Met did not exhibited a meaningful correlation with OS and PFS, respectively.
Conclusions: CD151 is a good tissue marker that has a powerful prognostic significance in advanced gastric cancers, and may become a new promising therapeutic target.
No conflict of interest.

2654 POSTER

A survey of MET overexpression and amplification in 287 patients with hepatocellular carcinoma

H. Lim[1], S.J. Lee[1], J. Lee[1], I. Sohn[2], C.K. Park[3], M. Mao[4], W. Kai[4]. *[1]Samsung Medical Center, Oncology, Seoul, Korea; [2]Samsung Medical Center, Samsung Cancer Research Institute, Seoul, Korea; [3]Samsung Medical Center, Pathology, Seoul, Korea; [4]Pfizer Inc., Oncology Research Unit, San Diego, USA*

Background: c-MET is a new potential drug target for treatment of hepatocellular carcinoma (HCC) patients, and a recent study of c-MET inhibitor in HCC patients has shown promising results. In the present study, we investigated the incidence of c-MET overexpression and its prognostic impact.
Methods: Tumor tissue microarrays were used to detect the expression of c-MET in samples from 287 HCC patients who underwent surgical resection at Samsung Medical Center. We explored the relationships between c-MET overexpression and clinicopathologic features of HCC and investigated recurrence-free survival (RFS) and HCC-specific survival according to the level of c-MET expression. Additionally, we explored the correlation between c-MET protein overexpression, MET mRNA expression and MET copy number variation.
Results: Most patients in this study were male (n = 297, 82.6%), with Child-Pugh class A liver function (n = 286, 99.7%) and hepatitis B viral infection (n = 217, 75.6%). c-MET overexpression was observed in 80 patients (27.9%), and it was not associated with Edmondson grade, tumor size, microvascular invasion, major portal vein invasion or AJCC stage. In addition, c-Met expression level did not affect RFS or HCC-specific survival. c-MET expression was weakly correlated with MET copy number variation (r = 0.255, $P<0.001$), but over half of patients with c-MET^{high} expression showed neutral copy number. c-MET IHC expression showed a very weakly but significantly positive correlation with its mRNA expression (r = 0.199, $P = 0.002$).
Conclusion: c-MET overexpression did not show a prognostic impact on recurrence or survival in HCC patients with surgical resection. However, 27.9% of HCC patients who had c-MET overexpression are candidates for treatment with c-MET inhibitor.
No conflict of interest.

2655 POSTER

ERCC1 codon 118 polymorphism as a predictive factor for pathologic complete response to S1/oxaliplatin combination chemoradiotherapy in patients with esophageal cancer

D. Yoon[1], J. Kim[2], Y. Kim[3], M. Woo[1], J. Kim[1], H. Kim[3], H. Jung[4], G. Lee[4], K. Cho[5], S. Kim[1]. *[1]Asan Medical Center, Oncology, Seoul, South Korea; [2]Asan Medical Center, Radiation Oncology, Seoul, South Korea; [3]Asan Medical Center, Thoracic Surgery, Seoul, South Korea; [4]Asan Medical Center, Gastroenterology, Seoul, South Korea; [5]Asan Medical Center, Pathology, Seoul, South Korea*

Background: DNA repair gene excision repair cross-complementing group 1 (ERCC1) polymorphism is known to be a predictive marker for response to the platinum-based chemotherapy. We aimed to investigate whether the single-nucleotide polymorphisms of ERCC1 at codon 118 affected clinical outcomes in patients with resectable esophageal cancer who underwent preoperative chemoradiotherapy with S1/oxaliplatin combination chemotherapy (Yoon DH et al., J Clin Oncol 30, 2012 suppl; abstr 4093).
Methods: A total 62 patients among those 97 patients who were enrolled in the clinical trial to evaluate the efficacy and safety of preoperative chemoradiotherapy with S1 and oxaliplatin doublets with or without induction chemotherapy with the same regimen underwent genotyping of ERCC1 with peripheral blood lymphocytes by the SNaPshot assay.
Results: Thirty five (56%) were homozygous for AAC codon (C/C genotype), 3 (5%) were homozygous for AAT codon (T/T genotype) and 24 (39%) were heterozygous (C/T genotype). Genotypes were not significantly different between the treatment arms (p = 0.725). Among those 45 patients who underwent esophagectomy after preoperative chemoradiotherapy, the pathologic complete response (pCR) rate was significantly lower in the C/C genotype compared with the C/T or the C/C genotype groups (34.6% vs. 68.4%, p = 0.025). With a median follow-up period of 31.0 mo (range, 17.8–47.8 mo) among surviving patients, 2-year progression-free survival (PFS) rate was 45.4% in the C/C genotype group and 70.8% in the C/T or the C/C genotype groups, respectively (p = 0.065). Two-year overall survival (OS) rate was 51.4% and 72.5%, respectively (p = 0.142). In the multivariate model with the treatment group (with or without induction chemotherapy), ERCC1 genotypes (C/C vs. C/T or T/T) were marginally correlated with PFS (HR = 2.2, p = 0.055) and OS (HR = 1.8, p = 0.169). Among those who underwent esophagectomy, 2-year PFS rate was significantly lower in the C//C genotype group (57.4% vs. 88.4%, p = 0.025).
Conclusions: pCR rate was significantly lower in the patients with ERCC1 118 C/C genotype treated by oxaliplatin-based chemoradiotherapy.
No conflict of interest.

2656 POSTER

NY-ESO-1 protein vaccine complexed with cholesteryl pullulan (CHP-NY-ESO-1) provides dose-dependent effects on immune responses and survival benefits for recurrent esophageal cancer patients

S. Kageyama[1], H. Wada[2], K. Muro[3], M. Niwa[4], S. Ueda[5], Y. Miyahara[6], T. Yamada[7], Y. Doki[2], H. Shiku[8]. *[1]Mie University Graduate School of Medicine, Immuno-Gene Therapy, Tsu Mie, Japan; [2]Osaka University Graduate School of Medicine, Gastroenterological Surgery, Suita Osaka, Japan; [3]Aichi Cancer Center Hospital, Clinical Oncology, Nagoya, Japan; [4]Aichi Cancer Center Hospital, Endoscopy, Nagoya, Japan; [5]Kitano Hospital, Gastroenterological Surgery, Osaka, Japan; [6]Mie University Graduate School of Medicine, Cancer Vaccine, Tsu Mie, Japan; [7]Mie University Graduate School of Medicine, Translational Medical Science, Tsu Mie, Japan; [8]Mie University Graduate School of Medicine, Cancer Vaccine/Immuno-Gene Therapy, Tsu Mie, Japan*

Background: Cancer vaccines using tumor-antigen proteins are expected to efficiently induce immune responses to multiple T cell epitopes. Cholesteryl pullulan (CHP) is a novel antigen-delivery system for cancer vaccines. NY-ESO-1 antigen is a cancer-testis antigen that is exclusively expressed in tumor tissues, except in testis and placenta. This antigen is considered an ideal target for cancer immunotherapy. We evaluated the safety and immune responses to the NY-ESO-1 antigen over the vaccination period, and explored the clinical impact on esophageal cancer patients with a poor prognosis.
Patients and Methods: Patients with advanced/metastatic esophageal cancer were enrolled and subcutaneously vaccinated with either 100 μg or 200 μg of CHP-NY-ESO-1. The primary endpoints were the toxicity and humoral immune responses, and the secondary endpoint was clinical efficacy.
Results: 25 patients were enrolled. Twelve and thirteen patients were repeatedly vaccinated with 100 μg or 200 μg of CHP-NY-ESO-1 with a median of 8 or 9.5 doses, respectively. No serious adverse events related to the vaccine were observed. In the 100-μg cohort, an antibody response was observed in 5 out of 10 pre-antibody-negatives patients, and the antibody levels were augmented in 2 pre-antibody-positive patients. In the 200-μg cohort, all 5 pre-antibody-negative patients became seropositive, and the antibody level was amplified in all 7 pre-antibody-positive patients. No tumor shrinkage was observed. No difference of time-to-progression was seen between 100-μg and 200-μg cohort. The patients who received 200 μg survived longer than patients receiving 100 μg, even those who exhibited unresponsiveness to previous therapies or had higher tumor burdens.
Conclusions: The safety and immunogenicity of CHP-NY-ESO-1 were confirmed. The 200-μg dose more efficiently induced immune responses and provided better survival benefits.
Conflict of interest: *Ownership: H Shiku is a stockholder of ImmunoFrontier, Inc., which provided CHP-NY-ESO-1 protein vaccine.*

EGFR expression, but not mutation of EGFR, KRAS, BRAF, PIK3CA and MSI is prognostic factor in gastric cancer after surgical resection

T. Lewandowski[1], E. Glodkowska-Mrówka[2], R. Biernacka[1], K. Roszkowska-Purska[3], M. Machnicki[2], J. Zielinski[4], P. Wlodarski[5], T. Stoklosa[2]. [1]*The Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology Warsaw Poland, Department of Chemotherapy, Warsaw, Poland;* [2]*Medical University of Warsaw Poland, Department of Immunology Center of Biostructure, Warsaw, Poland;* [3]*The Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology Warsaw Poland, Department of Pathology, Warsaw, Poland;* [4]*Medical University of Warsaw Poland, Department of Biophysics and Physiology, Warsaw, Poland;* [5]*Medical University of Warsaw Poland, Department of Histology and Embryology Center of Biostructure, Warsaw, Poland*

Background: Gastric cancer remains among leading cause of cancer death and the recurrence rate is still high even after curative surgical resection. Multidisciplinary treatment and novel targeted therapy could be potentially beneficial, however identification of new prognostic factors influencing such treatment is necessary. The existing molecular factors remain controversial.
We aimed at the evaluation EGFR expression, frequency and type of mutation in tyrosine kinase domain in *EGFR* gene (ex. 18−21) and also frequency and type of mutation of *KRAS* (ex.2,3,61), *BRAF* (ex.15), *PIK3CA* (ex.9,20) and microsatellite instability MSI status and their impact on prognosis after curative resection.
Material and Methods: We collected 107 tumor samples from pts. undergoing surgery because of adenocarcinoma of gastroesophageal junction (20) and stomach (89) between 2008–2011. Lauren type: intestinal-45, diffuse-38, mixed-22, unknown-2. 30 pts were treated multidisciplinary mainly with chemoradiotherapy. RNA and DNA was freshly isolated from tumor samples used concomitantly for routine histopathology examination and immunohistochemical staining for EGFR. Mutational status was examined by reverse transcription and polymerase chain reaction amplification (RT-PCR) followed by direct sequencing of its product. To detect microsatellite instability isolated DNA was amplified using the STR NGM kit and PCR. The PCR product was then sequenced and the results obtained were analyzed using GeneMapper 3.2.1.
Results: EGFR expression was detected in 73 samples (69.5% of evaluated samples) in the range from 1% to 100% cells. There were no *EGFR* mutations. However polymorphism 2361G>A, Gln787Gln was found in 80 samples (78.4%). 3 *KRAS* (2.8%), 2 *BRAF* (1.9%), 2 *PIK3CA* (2.2%) mutations and 12 MSI (12.9%) were detected. Median FU, DFS and OS were 910, 442, 520 days, respectively.
Conclusions: Neither mutations of *KRAS*, *BRAF*, *PIK3CA* and *EGFR* polymorphism nor MSI status were independent prognostic factors. EGFR expression was associated with shorter DFS and OS in the group with microsatellite instability and non-intestinal type ($p = 0.008$, $p = 0.06$ and $p = 0.04$ $p = 0.09$). Pts. who had microsatellite instability coexisted with lack of EGFR expression had a particularly good prognosis. There were no deaths in this group.
No conflict of interest.

2658 POSTER

Phosphorylated AMP-activated protein kinase and MAPK3/1 expression associated with prognosis for patients with gastric cancer

B. Kang[1], J. Kim[1], S. Lee[1], Y. Chae[1], Y. Lee[1], S. Oh[1], M. Kim[1], K. Kim[1], S. Kim[1]. [1]*Kyungpook National University Hospital, Oncology, Daegu, Korea*

Objectives: Phosphorylated AMP-activated protein kinase (pAMPK) plays a central role in cellular metabolic sensing and energy balance homeostasis, and interacts with various pathways [e.g., TP53, mTOR, NUAK2 (sucrose nonfermenting-like kinase), MAPK3/1 (ERK), and PDK]. Therefore, the present study analyzed the expression of pAMPK, NUAK2, MAPK3/1, and PDK-1 and their impact on the survival of patients with resected gastric cancer.
Methods: A total of 621 patients with surgically resected gastric adenocarcinoma and a curative intent were enrolled. Immunohistochemical staining for pAMPK, NUAK2, MAPK3/1, and PDK-1 was performed using tissue microarrays of operative specimens of gastric cancer.
Results: Positive pAMPK, NUAK2, MAPK3/1, and PDK-1 expression was observed in 379 (61.0%), 257 (41.4%), 327 (52.7%), and 67 (10.8%) cases, respectively. A multivariate survival analysis showed a significantly better survival for the patients with a positive pAMPK or MAPK3/1 expression than for the patients with a negative expression (pAMPK: disease-free survival [DFS], hazard ratio [HR]=0.750, 95% CI=0.568–0.970, p value=0.030; MAPK3/1: DFS, HR = 0.692, 95% CI=0.720–0.974, p value=0.021), while the expression of NUAK2 or PDK-1 had no effect on survival.
Conclusions: The expression of pAMPK or MAPK3/1 was found to be an independent prognostic marker for patients with resected gastric cancer.
No conflict of interest.

2659 POSTER

Iron-controlled cancer therapy: A new concept for anti-angiogenic drug (bevacizumab and sorafenib)

T. Ohara[1], K. Noma[1], S. Urano[1], R. Katsube[1], T. Ninomiya[1], S. Tanabe[1], Y. Tomono[2], H. Tazawa[1], Y. Shirakawa[1], T. Fujiwara[1]. [1]*Okayama University Hospital, Gastroenterological Surgery, Okayama, Japan;* [2]*Shigei Medical Research Institute, Molecular Cell Biology, Okayama, Japan*

Background: Iron is an essential element for both normal and cancer cells in humans. Iron overload is known to induce some kinds of cancer. Iron-depletion treatment is also known to suppress tumor growth in vivo. However iron-depletion mono-therapy has generally been thought to not be superior to ordinary chemotherapy and a standard therapeutic strategy in the treatment of cancer. We discovered that iron depletion inhibited the cancer cell proliferation and reciprocally induced angiogenesis in vitro and in vivo. Here we demonstrate that this new concept of iron controlled therapy induces a synergistic effect of anti-angiogenic drugs in the treatment of cancer.
Methods: A549, H1299 (lung cancer), TE4, TE8 (esophageal cancer), and HepG2, Hep3B (hepatocellular carcinoma: HCC) were used in this study. To stimulate iron depletion status, we used the iron depleted custom medium (passive iron depletion:PID) and deferasirox, an iron chilator, deferasirox (EXJADE® active iron depletion:AID). Bevacizumab and Sorafenib were used as anti-angiogenic drugs. We examined cell viability assay, flow cytometry, western blot analysis, and A549 and HepG2 subcutaneous tumor model in vivo.
Results: PID slightly inhibited proliferation of cancer cells, AID strongly inhibited them. Combination therapy (PID + Bevacizumab and AID + Sorafenib) -revealed a synergistic effect in vivo. In western blot analysis, AID affects the cancer cells as follows: increase VEGF expression via HIF-a, decrease N-cadherin expression. Moreover, AID + Sorafenib synergistically inhibited cyclin D1, cyclin E, CDK4 and CDK6, and induced apoptosis.
Conclusions: These results suggest that iron controlled cancer therapy has a potent synergistic anti-cancer effect with anti- angiogenic drugs.
No conflict of interest.

2660 POSTER

EGFR expression and prognosis in galbladder cancer

S.J. Martins[1], S.R. Pais-Costa[2], J.F.R. Farah[2], R. Artigiani-Neto[3], A. Goldenberg[3]. [1]*University of Brasilia, Medical Oncology, Brasília, Brazil;* [2]*São Paulo Civil Servants Hospital, Surgical Oncology, São Paulo, Brazil;* [3]*Federal University of São Paulo, Pathology, São Paulo, Brazil*

Background: Gallbladder carcinoma (GBC) is the most aggressive of the biliary cancers with the shortest median survival duration. There is a lack of biomolecular level studies on this disease and few data on prognostic biomarkers.
Material and Methods: We evaluate the prognostic value of laboratorial (albumin level, CA 19.9 and CEA), surgical (type of resection, bleeding, tumor clearance), morphological (necrosis, perforation, nodal status, lymphatic embolization, perineural invasion, tumor grade and tumor localization at gallbladder) and molecular characteristics (EGFR, E-cadherin, p53 protein and COX2 immunoexpression) in a series of 42 pts with GBC treated from Jan 1995 to Jan 2006 at a tertiary cancer center in São Paulo, Brazil. Survival analysis was performed using the Kaplan–Meier method and Cox regression.
Results: A multivariate analysis disclosed EGFR expression +2/+3 (HR = 8.9; 95% CI 2.6 to 29.9; $p = 0.001$), presence of necrosis (HR = 20.7; 95% CI = 3.8 to 111.0; $p = 0.001$) and low albumin level (HR = 21.9; 95% CI = 2.5 to 194.7; $p = 0.006$) as independent prognostic factors.
Conclusions: Immunoexpression of epidermal growth factor receptor identified a poor prognostic subgroup of GBC patients, eventual candidates suitable to treatments based on molecularly targeted agents that inhibit EGFR pathways.
No conflict of interest.

The role of LDH serum levels in predicting global outcome in HCC patients treated with sorafenib: Implications for clinical management

L. Faloppi[1], M. Scartozzi[2], M. Bianconi[1], C. Loretelli[1], G. Svegliati Baroni[3], S. De Minicis[3], R. Giampieri[1], M. Del Prete[1], A. Benedetti[3], S. Cascinu[1]. *[1]Università Politecnica delle Marche, Department of Medical Oncology, Ancona, Italy; [2]AOU Ospedali Riuniti, Department of Medical Oncology, Ancona, Italy; [3]Università Politecnica delle Marche, Department of Gastroenterology, Ancona, Italy*

Background: In many tumour types serum LDH levels proved to represent an indirect marker of tumour hypoxia, neo-angiogenesis and worse prognosis. As we reported previously LDH is an important factor in hepatocellular carcinoma (HCC) patients undergoing transarterial chemoembolization (TACE). Sorafenib is at present the therapeutic stronghold in HCC patients in advanced stage. As a TKI mainly directed against the angiogenetic pathway, the correlation of sorafenib administration with markers of hypoxia could be an important tool in patients management. Aim of our analysis was to evaluate the role of lactate dehydrogenase (LDH) pre-treatment levels and its variation post-treatment for HCC patients treated with sorafenib.
Methods: 78 patients were available for our analysis. For all patients LDH values were collected within one month before the procedure and after treatment end. For study purposes we divided our patients into two groups, according to LDH median serum concentration registered (first group: LDH $\leqslant$380U/l; second group: LDH >380U/l). Patients were, also, classified according to the variation in LDH serum levels pre- and post-treatment (increased patients vs decreased patients).
Results: Patients proved homogeneous for all clinical characteristics analyzed. In patients with LDH values under 380 U/l median progression free survival (PFS) was 7.6 months, whereas it was 2.9 months in patients above the cut-off ($p = 0.026$). Accordingly median overall survival (OS) was 14.9 months and 11.2 months ($p = 0.019$). In patients with decreased LDH values after treatment median PFS was 6.8 months, and median OS was 13.2 months, whereas PFS was 1.2 months and OS 7.3 months in patients with increased LDH levels (TTP: $p = 0.0014$; OS: $p = 0.0096$).
Conclusions: In our experience, LDH seemed able to predict clinical outcome in terms of TTP and OS for HCC patients treated with sorafenib. Given the correlation between LDH levels and tumour angiogenesis we can speculate that patients with high LDH pretreatment levels may be optimal candidates for other emerging therapeutic agents or strategies.
No conflict of interest.

2662 POSTER

The effects of XPD /ERCC2, RAD51 and hOGG1 gene polymorphisms on overall survival of Turkish gastric cancer patients

G. Gokoz Dogu[1], A. Kargi[2], O. Tanriverdi[3], H. Akca[4], A. Demiray[4], B. Yapar Taskoylu[5], G. Demiray[5], A. Yaren[5], C. Ozlu[6], A. Ergin[7]. *[1]School of Medicine University of Pamukkale, Department of Medical Oncology, Denizli, Turkey; [2]Medstar Hospital, Clinic of Medical Oncology, Antalya, Turkey; [3]Mugla University Education and Research Hospital, Department of Medical Oncology and Internal Medicine, Mugla, Turkey; [4]Department of Medical Biology School of Medicine University of Pamukkale, Department of Medical Biology, Denizli, Turkey; [5]School of Medicine University of Pamukkale, Department of Medical Oncology, Denizli, Turkey; [6]Denizli State Hospital, Department of Internal Medicine, Denizli, Turkey; [7]School of Medicine University of Pamukkale, Department of Public Health, Denizli, Turkey*

Aims: We assessed whether XPD /ERCC2, RAD51 and hOGG1 Gene Polymorphisms predicted clinical outcome in advanced gastric cancer patients.
Methods: DNA was isolated from parafin emedded tumor tissues and then SNPs analayses were done by MassARRAY® System (Sequenom). The data were statistically analyzed using SPSS software version 17.0 Statistical significance of the observed genotype frequencies was evaluated according to Hardy–Weinberg rule compared to the expected genotype frequencies.
Results: A total of 31 gastric cancer patients with locally inoperable or distant metastasis and performance status of 0−2 were enrolled in this study. We determined the XPD /ERCC2 Asp312Asn (rs1799793) single nucleotide gene polymorphism G23591A, RAD51(rs1801320) single nucleotide gene polymorphism G135C and hOGG1 Ser 326 Cys (rs1052133) single nucleotide gene polymorphism. Median age was 68 years: 74.2% male, 25.8% female. Docetaxel-based DCF regimen (docetaxel 75 mg/m(2) on day 1, cisplatin 75 mg/m(2) on day 1, and 5-fluorouracil 750 mg/m(2) for 5 days of continuous infusion every 21 days) with G-CSF were given to fourteen patients; all other patients received Mayo regimen.We found XPD /ERCC2 gene GA, GG, AA genotype and A, G allele frequencies in gastric cancer patients as 54.8%, 35.5%, 9.7% and 90.3%, 9.7%, respectively. Patients with GA genotype had a longer survival (11.96$\pm$2.177 months, 95% CI 7.69−16.23) than the other genotypes. However, this difference is not statistically significant ($p = 0.448$). We found that RAD51 gene GG, CG, CC genotype and G, C allele frequencies as 83.9%, 12.9%, 3.2%, 90%, 10%, respectively; for hOGG1 gene GC, CC, GG genotype and C,G allele frequencies as 48.4%, 45.2%, 6.5%, 69.4%, 30.6%, respectively. We didn't find any significant correlation between overall survival and genotype or allel for RAD51, hOGG1 genes ($p = 0.9$, $p = 0.307$, respectively). Cox regression analysis for overall survival showed that serum ALT level <33 IU/L (HR of ALT $\leqslant$33 IU/L vs >33 IU/Lis 2.705 $p < 0.001$);serum LDH level <214 IU (HR of LDH $\leqslant$214 IU/Lvs>214 IU/Lis1.247 $p = 0.007$) were the most important prognostic factors. The frequency of genotypes in these genes in patients did not show a significant deviation from Hardy–Weinberg equilibrium.
Conclusions: We could not find any significant association between the genotypes and clinicopathologic parameters; however, serum ALT and LDH levels were found to be the most important prognostic factors for overall survival.
No conflict of interest.

2663 POSTER

The changing of serum vitamin B12 and homocysteine levels after gastrectomy in patients with gastric cancer: Do they associate with clinicopathological factors?

A. Bilici[1], A. Sonkaya[2], S. Ercan[3], B.B. Ustaalioglu[4], M. Seker[4], M. Aliustaoglu[4], A. Orcun[3], M. Gumus[4]. *[1]Sisli Etfal Education and Research Hospital, Department of Medical Oncology, Istanbul, Turkey; [2]Dr.Lutfi Kirdar Kartal Education and Research Hospital, Department of Internal Medicine, Istanbul, Turkey; [3]Dr.Lutfi Kirdar Kartal Education and Research Hospital, Department of Biochemistry, Istanbul, Turkey; [4]Dr.Lutfi Kirdar Kartal Education and Research Hospital, Department of Medical Oncology, Istanbul, Turkey*

Bacground: After total or partial gastrectomy patients are at high risk of vitamin B12 (vit B12) deficiency, which results in elevation of homocysteine levels. However, the prevalence of the changing of serum vit B12 and homocysteine levels in patients with gastric cancer is not well investigated.
Methods: Sixty-two patients with gastric cancer who had undergone curative gastrectomy and fifty healthy controls were included. Serum vit B12 and homocysteine levels in gastric cancer patients were compared with those of healthy control subjects.
Results: Serum vit B12 level in gastrectomized patients was significantly lower than that of healthy controls (228.3$\pm$126.6 pg/mL vs. 309.9$\pm$174.3 pg/mL, $p = 0.002$), however, homocysteine levels were significantly higher in patients with gastric cancer compared with healthy controls (15.1 μmol/L vs. 12.5 μmol/L, $p = 0.016$). Mean serum folate level was found to be high in healthy controls (7.3 ng/mL) compared to patients (9.2 ng/mL, $p = 0.027$). Thirty-three (53.2%) patients received prophylactic vit B12 replacement after gastrectomy. Both serum vit B12 and homocysteine levels in patients receiving vit B12 treatment were similar with those in patients who are not receiving ($p>0.05$). When only patients who has not received vit B12 were analysed, we found significant low vit B12 and high homocysteine levels in gastrectomized patients compared to healthy subjects (231.8$\pm$97.2 pg/mL vs. 310$\pm$174.3 pg/mL, $p = 0.02$; 14.4 $\pm$6.1 μmol/L vs. 12.6$\pm$6.0 μmol/L, $p = 0.04$, respectively). Moreover, in patients transferin saturation was significantly found to be lower than controls ($p = 0.02$). There were no relationship iron parameters, vit B12 and homocysteine levels according to gastrectomy types ($p>0.05$).
Conclusions: Our results showed that gastric cancer patients who underwent total or subtotal gastrectomy had low vit B12 levels and hyperhomocysteinemia compared with healthy controls. In addition, the impact of vit B12 replacement on vit B12 and homocysteine levels could not be proved.
No conflict of interest.

2664 POSTER

Role of platelets in HCC cell growth: Clinical and experimental evidence

B.I. Carr[1], C. Messa[1], R. D'Alessandro[1], M.G. Refolo[1], C. Lippolis[1], A. Cavallini[1]. *[1]IRCCS, Medical Oncology, Castellana Grotte, Italy*

Background: Thrombocytopenia has been reported to be both a risk factor for HCC and a prognostic factor. Many HCCs also occur in presence of normal platelets. The relevance of platelets for HCC is unclear.
Materials and Methods: Records were examined of 634 biopsy-proven HCCs patients without thrombocytopenia. Pooled human donor platelet extracts were then examined for their growth effects on human HCC cell lines in culture.

Results: 52 patients were identified with thrombocytosis (platelet levels >400 x 10^9/L) and compared to 582 patients with normal platelet levels. Average tumour diameters were 13.1 vs. 8.8 cm, $p < 0.0001$ and average total bilirubin levels were 0.9 vs.1.5, $p = 0.02$. There were significant increases in tumour size with increased platelet levels and a significant trend. In presence of 1% serum, platelet extracts stimulated HCC cell growth and migration. In presence of growth-inhibitory concentrations of either sorafenib or regorafenib, platelet extracts antagonised inhibition of HCC cell growth. Both clinical observations and experimental findings suggest that platelet factors may influence HCC growth.
Conclusions: Thrombocytosis in association with HCC occurs in patients with larger tumour sizes and better liver function. Platelets stimulate HCC growth in vitro. They are a source of several known HCC mitogens and their antagonism offers a potential new avenue for therapy.
No conflict of interest.

Heterogeneous response and progression patterns of renal cell carcinoma metastases in individual patients reveal intra-tumour heterogeneity of anti-angiogenic drug resistance

S.M. Crusz[1], Y.Z. Tang[2], A. Sahdev[2], I. Kayani[3], L. Harris[4], L. Beltran[5], J. Peters[6], C. Swanton[7], T. Powles[4], M. Gerlinger[8]. *[1]Barts and The London NHS Trust, Medical Oncology, London, United Kingdom; [2]Barts and The London NHS Trust, Radiology, London, United Kingdom; [3]UCLH NHS Trust, Radiology − Nuclear Medicine, London, United Kingdom; [4]Queen Mary University of London, Barts Cancer Institute, London, United Kingdom; [5]Barts and The London NHS Trust, Histopathology, London, United Kingdom; [6]Barts and The London NHS Trust, Urology, London, United Kingdom; [7]CRUK London Research Institute, Translational Cancer Therapeutics Laboratory, London, United Kingdom; [8]CRUK London Research Institute and St Bartholomew's Hospital, Medical Oncology, London, United Kingdom*

Background: We recently demonstrated genetic and functional intra-tumour heterogeneity (ITH) in advanced clear cell renal cell carcinomas (ccRCC) (Gerlinger et al, N Engl J Med, 2013). We hypothesize that ITH may also lead to differences in drug sensitivity of different metastatic sites within individual patients. To investigate this, we longitudinally assessed multiple metastatic lesions in patients treated with VEGFR-TKI therapy.
Patients and Methods: Multiple metastatic lesions from each of 19 treatment naive patients with ccRCC were followed by contrast CT scans during first line VEGFR-TKI therapy with sunitinib or pazopanib in the context of clinical trials. The diameter of each measurable lesion was quantified before treatment initiation and at regular intervals during treatment until disease progression (RECIST criteria). Individual metastases were categorized based on their best response to treatment into responding (RL:$\geqslant$20% decrease in diameter), stable (SL:<20% change) and progressing (PL:$\geqslant$20% increase in diameter) lesions. A heterogeneous response was defined as the presence of metastases in at least two of these categories.
Results: A median of 4 metastatic lesions per patient (90 lesions in total) were assessed longitudinally by regular CT scans. Heterogeneous responses were found in 42% of patients ($n = 8$). RLs and PLs were detected simultaneously in 5 of these patients. Progressive disease by RECIST criteria occurred through progression of existing metastases in one patient and through the appearance of new metastases in the other 18 patients. Synchronous progression of existing metastatic sites was detected in 10 of these patients; however, 70% (63/90) of the existing metastases remained controlled (RL/SL) at the time of RECIST progression, indicating ITH of acquired resistance.
Conclusions: Heterogeneous radiological responses of metastatic sites were detected in 42% of patients with ccRCC treated with VEGFR-TKI therapy. At disease progression, 95% of patients had developed new metastases but the majority of existing lesions remained controlled. The simultaneous presence of sensitive and resistant metastases in a large proportion of ccRCC patients reveals clinically relevant ITH, potentially driven by the molecular heterogeneity previously identified. ITH of VEGFR-TKI sensitivity suggests that single biopsies are likely to miss resistant lesions, hindering the identification of resistance mechanisms or predictive biomarkers in metastatic ccRCC.

Prognostic significance of nephrectomy in patients with synchronous metastases from renal cell carcinoma (RCC) treated with 1st line sunitinib: A European collaborative study

A. Bamias[1], K. Tzannis[2], S. Oudard[3], B. Beuselinck[4], B. Escudier[5], R. Elaidi[3], M. Chrisofos[6], A. Papatsoris[6], M.A. Dimopoulos[1], C. Bamia[7]. *[1]University of Athens and Hellenic GU Cancer Group (HGUCG), Clinical Therapeutics, Athens, Greece; [2]University of Athens, Clinical Therapeutics, Athens, Greece; [3]Hopital Europeen Georges Pompidou, Medical Oncology, Paris, France; [4]University Hospitals Leuven Leuven Cancer Institute, General Medical Oncology and Laboratory for Experimental Oncology, Leuven, Belgium; [5]Institut Gustav Roussy, Medical Oncology, Paris, France; [6]University of Athens and Hellenic GU Cancer Group, 2nd Urology, Athens, Greece; [7]University of Athens and Hellenic GU Cancer Group (HGUCG), Hygiene Epidemiology & Medical Statistics, Athens, Greece*

Background: Nephrectomy was shown to be associated with improved outcome in patients with metastatic RCC (mRCC), treated with cytokines. Nevertheless, its role in the anti-VEGF targeted therapy era is controversial. This is the first study to evaluate the prognostic role of nephrectomy in patients with mRCC and synchronous metastases, treated with sunitinib.
Patients and Methods: Patients were selected from a multinational, multi-institutional database (Greece, France, Belgium), which includes 458 patients with histologically confirmed mRCC, treated with 1st-line sunitinib. Selection criterion for this analysis was the diagnosis of metastases prior to, at the time of or within 3 months from the diagnosis of RCC. Multiple Imputations were implemented for missing values. Correlations of baseline characteristics with OS were assessed through hazard ratios estimated from univariate Cox proportional hazards models. Significant factors were then included in a multivariate Cox proportional hazards model.
Results: 189 patients treated between 1/2006−3/2012, fulfilled the selection criteria. 38 patients (20%) did not undergo nephrectomy. Patients who had undergone nephrectomy were younger (<65 years 76% vs. 54%, $p = 0.011$), had better PS (PS 0 62% vs. 26%, $p < 0.001$), received IFN more frequently (40% vs. 10%, $p < 0.001$), had lower incidence of neutrophilia (45% vs. 73%, $p = 0.006$) and abnormal LDH (15% vs. 52%, $p < 0.001$) but had more frequently more than 2 metastatic sites (44% vs. 24%, $p = 0.02$). The location of metastases did not affect the decision of nephrectomy. Patients with nephrectomy lived significantly longer than those without nephrectomy (median OS 24 [95% CI: 20−28] vs. 10 [95% CI: 5−16] months, $p < 0.001$).
Multivariate analysis showed that age (<65 vs. >65), brain metastases, bone metastases and histology (clear cell vs. other) were independent prognostic factors. When nephrectomy was entered in a multivariate cox regression models including the above factors, it retained its significance (Table 1). When risk stratification according to IMDC or MSKCC was used in multivariate analysis, nephrectomy retained its independent prognostic significance.
Subgroup analyses suggested a more pronounced effect of nephrectomy in patients with clear cell histology or <2 metastatic sites, but these results are limited by the small number of patients included in each subgroup.

Table 1.

Model	Hazard ratio of nephrectomy after multiple imputation	95% CI	p
No risk stratification	0.478	0.297–0.771	.002
IMDC risk stratification	0.418	0.265–0.661	<0.001
MSKCC risk stratification	0.420	0.268–0.658	<0.001

Conclusions: In the targeted therapy era, nephrectomy is mainly offered to mRCC patients with synchronous metastases who have favourable prognostic features. Nevertheless, in this study nephrectomy retained its favorable prognostic significance independently of these factors. Information regarding the selection of patients likely to benefit from this approach may be derived by Prospective Phase III trials which are under way (CARMENA, SURTIME).

Tumor response is an independent prognostic factor in patients (pts) treated for metastatic renal cell carcinoma (mRCC)

V. Grünwald[1], X. Lin[2], D. Kalanovic[3], R. McKay[4], J. Perkins[5], R. Simantov[5], T. Choueiri[4]. [1]*Medical University Hannover, Hematology Hemostaseology Oncology and Stemcelltransplantation, Hannover, Germany;* [2]*Pfizer Oncology, Statistics, San Diego, USA;* [3]*Pfizer Pharma GmbH, Medical Oncology, Berlin, Germany;* [4]*Dana-Farber Cancer Institute, Medical Oncology, Boston, USA;* [5]*Pfizer Inc., Oncology Medical Affairs, New York, USA*

Background: Pts treated for mRCC may have different outcomes based on tumor response. To explore whether extent of tumor shrinkage correlates with distinct clinical outcomes and may represent an early indication of treatment benefit, we investigated these questions in a pooled clinical trial population.
Materials and Methods: Data from pts treated in phase II (NCT00054886, NCT00077974, NCT00267748, NCT00338884, NCT00137423) and phase III (NCT00083889, NCT00065468, NCT00678392) trials sponsored by Pfizer from 2003 to 2011 were included. Pts were characterized by maximal tumor shrinkage from baseline (⩽100% to <-60%, ⩽60% to <-30%, ⩽-30% to <0%, ⩽0 to <+20%, ⩾+20%). Pts without post-baseline scans were also included. A Cox proportional hazard analysis as well as a 6-month landmark analysis were performed for the evaluation of prognostic factors with progression free survival (PFS) and overall survival (OS); Kaplan–Meier (K-M) plots were utilized to estimate median PFS and OS.
Results: 2749 pts (71% male) with median age 60 (33% ⩾65) were treated (median 162 days) with sunitinib (n = 1059), interferon-alfa (IFN) (n = 560), axitinib (n = 359), sorafenib (n = 335), temsirolimus (TEM) (n = 208), or TEM + IFN (n = 208). Most pts had baseline ECOG PS of 0 (47%) or 1 (51%), clear cell histology (91%), and nephrectomy (84%). Multivariate analysis of prognostic factors including age, performance status, LDH, hemoglobin, and calcium, showed that maximal tumor shrinkage was an independent predictor of OS. Median OS was 54.5 months in patients with the highest maximal tumor shrinkage (−100% to −60%), and was 7.3 months in patients with ⩾+20% increase in tumor size. Overall, the degree of tumor shrinkage correlated with OS (Table).

Maximal tumor shrinkage	N	HR (95% CI)	Median OS (months)
⩽−100% to <−60%	283	0.267 (0.201–0.354) [a]	54.5
⩽−60% to <−30%	547	0.697 (0.589–0.825) [a]	26.4
⩽−30% to <0%	1155	*	16.6
⩽0 to <+20%	390	1.618 (1.383–1.893) [a]	10.4
⩾+20%	156	1.918 (1.540–2.389) [a]	7.3
No post-baseline scan	218	4.369 (3.607–5.292) [a]	2.0

[a] p < 0.0001. *Reference in Cox proportional hazards model.

Conclusions: Tumor shrinkage is an independent predictor of OS. Patients with maximal tumor shrinkage achieve marked clinical benefit with prolonged OS, independent of systemic therapy. Achievement of maximal tumor response should be a therapeutic goal in patients with mRCC.

Preliminary data on feasibility of vinflunine (VFL)-based combinations as 1st line in CDDP-unfit patients (pts) with advanced urothelial carcinoma (UC): VFL/gemcitabine vs. VFL/CBDCA in a randomised international phase II trial (JASINT1)

M. De Santis[1], P. Wiechno[2], C. Lucas[3], W.C. Su[4], L. Albiges[5], C.C. Lin[6], N. Vaissière[7], J.P. Burillon[8], S. Culine[9]. [1]*Kaiser Franz Josef Hospital, 3rd Med.Dept.-Oncology and LBI-ACR, Vienna, Austria;* [2]*Oncology Centre-Institute, Medical Oncology, Warsaw, Poland;* [3]*Pierre Fabre Research Institute, International Medical Affairs-Oncology, Boulogne Billancourt, France;* [4]*National Cheng Kung University Hospital, Medical Oncology, Tainan, Taiwan;* [5]*Institut Gustave Roussy University of Paris Sud, Department of Cancer Medicine, Villejuif, France;* [6]*National Taiwan University Hospital, Medical Oncology, Taipei, Taiwan;* [7]*Pierre Fabre Research Institute, Statistics, Boulogne-Billancourt, France;* [8]*Pierre Fabre Research Institute, International Medical Affairs-Oncology, Boulogne-Billancourt, France;* [9]*St Louis University Hospital, Medical Oncology, Paris, France*

Background: There is no standard treatment in patients unfit for a CDDP-based regimen as 1st line chemotherapy (CT) for advanced or metastatic UC. CBDCA-gemcitabine doublet or single agents are frequently used. VFL is a novel agent approved in the post-platinum setting that has shown to be safe in pts with impaired renal function. The aim of this study is to provide data of the benefit/risk ratio of two VFL combination CT regimens in UC.
Methods: The primary endpoint was to assess the disease control (DC) rate (CR + PR + SD by RECIST 1.1); 68 pts with a creatinine clearance (CrCl) <60 mL/min but ⩾30, PS 0/1, no prior systemic CT (except neoadjuvant or adjuvant CT if relapse occurred ⩾6 months after last dose) were to be randomised. Depending on CrCl, <40 or ⩾40 mL/min, pts received VFL 250 or 280 mg/m^2, plus Gemcitabine (Arm A) 750 mg/m^2, escalated to 1000 in cycle 2 (if no toxicity Grade (G) ⩾2) or plus CBDCA AUC 4.5 (Arm B). Other endpoints included safety, response rate, PFS, OS.
Results: We report on the safety data of the first 43 recruited pts (February 2011-February 2012), cut-off June 2012, median follow-up 7 months (21 arm A, 22 arm B). Median age was 70 yrs, PS 0 in 46.5% and PS 1 in 53.5%; 53% and 47% pts had bladder and upper tract primary sites, respectively; 14% had received prior CT. Pts characteristics were similar in both groups. The vast majority of pts had multiple co-morbidities, cardiac in 26%. Mean CrCl was 46.7 mL/min (<40 in 19%). Median [range] number of cycles was 5 [1−12] and the median VFL relative dose-intensity was 98% and 93% in arms A and B, respectively. Haematological G3/4 events were more frequent in arm B with neutropenia in 68% pts (vs. 43%) and febrile neutropenia in 9.1% (vs. 0%). Overall, most frequent possibly related non-haematological G3/4 adverse events were asthenia-fatigue (18.6%), infection (11.6%), and constipation (7.0%) without major difference between arms. The reason for treatment discontinuation was a non-haematological drug-related event in 9.5% and 18% pts, in arms A and B, respectively. DC was observed in 36/41 evaluable pts (17 A, 19 B) with ORR in 20/41 pts (confirmed in 16).
Conclusions: Preliminary data confirm that both doublets with VFL are feasible, safe and can be administered for ⩾5 cycles. The DC was similar between arms but haematological toxicity was more frequent with VFL-CBDCA. Collection of data on the whole cohort is ongoing.

Phase II study of eribulin in platinum-treated, tubulin naive advanced urothelial cancer (UC) − A California Cancer Consortium trial (NCI/CTEP 7435)

D.I. Quinn[1], P.W. Twardowski[2], Y.E. Wei[3], S.G. Groshen[4], T.B. Dorff[1], A.M. Aparicio[5], W.M. Stadler[6], D.R. Gandara[7], P.N. Lara[7], E.M. Newman[2]. [1]*University of Southern California, Norris Comprehensive Cancer Center, Los Angeles, USA;* [2]*City of Hope National Medical Center, Experimental Therapeutics, Duarte CA, USA;* [3]*City of Hope National Medical Center, Biostatistics, Duarte CA, USA;* [4]*University of Southern California, Biostatistics, Los Angeles, USA;* [5]*University of Texas, M.D. Anderson Cancer Center, Houston TX, USA;* [6]*University of Chicago, Medical Oncology, Chicago IL, USA;* [7]*UC Davis, Medical Oncology, Sacramento, USA*

Introduction: There is an unmet need for new agents in locally advanced and metastatic UC. Tubulin directed agents (vincas, taxanes) have activity in UC. We previously reported that eribulin, a microtubule modulator derived from the black Pacific sea sponge toxin, is active against UC in the frontline setting (D. Quinn, ASCO A4359, 2010). Here we report the initial results of a phase II study in UC patients (pts) with prior platinum-based therapy but with no prior anti-tubulin drug exposure, which has completed accrual. An ongoing parallel study is evaluating patients with prior anti-tubulin drug exposure.
Methods: Patients with a calculated CrCl ⩾20 mL/m, UC of any histological type & prior platinum-based cytotoxic therapy for advanced disease were eligible. Eribulin 1.4 mg/m^2 was given IV on d 1 & 8, q3 weeks. An overall response rate (RR) of >20% was considered promising for further study; 41 pts were required in a Simon 2-stage design. PFS and OS were Secondary endpoints.
Results: Of 46 pts entered, 39 were evaluable (7 too early).
Patient characteristics: Median age: 67 years (range: 25−86); Males: 87%; KPS ⩾90% in 64%, ⩽80% in 33%; Histology: Transitional 36 (92%), unclassified 2 (6%) adenocarcinoma 1 (2%); Bajorin risk groups: 0: 33%, 1: 62%, 2: 5%.
Overall RR was 36% (95% CI: 21, 53%), including 1 CR, 7 PR, and 6 unconfirmed PR. [Confirmed RR was 21% (95% CI: 9, 36%)]. Stable disease for ⩾12 weeks was seen in 12 pts (31%). PD was best response in 11 pts (28%). At median follow-up of 5.9 (1.4, 17.1) months, median PFS

was 4.1 months (2.6, 6.4). Median OS was 9.6 months (5.3, ∞) 16 pts dead). PFS was associated with Bajorin risk group (p = 0.005 for trend). Toxicities: 24 pts (62%) Gr 3/4 neutropenia, 3 pts (8%) Gr 3 febrile neutropenia, 14 pts (36%) and Gr 1/2 sensory neuropathy. Other non-hematologic toxicities: hyperglycemia (1 pts (3%) Gr 3), hyponatremia (8 pts (21%) Gr 1), alopecia (16 pts (41%) Gr 1/2), leg fatigue & aching (2 (5%) Gr1).

Conclusions: Eribulin has highly encouraging single agent activity in advanced UC pts with prior platinum-based chemotherapy and has the potential to improve outcomes in this disease. Phase III evaluation of eribulin in advanced UC is warranted. http://clinicaltrials.gov/show/NCT00365157 (U01 CA062505 P30 CA014089, P30 CA033572).

Risk of cardiovascular disease, diabetes and death in germ-cell cancer survivors in a large cohort

J. Lauritsen[1], M.S. Mortensen[1], M.G. Gundgaard[2], S.O. Dalton[2], C. Johansen[2], G. Daugaard[1]. [1]*Rigshospitalet, Oncology, Copenhagen, Denmark;* [2]*Danish Cancer Society, Survivorship, Copenhagen, Denmark*

Background: Treatment of germ-cell cancer (GCC) imposes a risk of secondary cardiovascular disease (CVD) and increased mortality. Through collation of hospital files with national registries we present the most complete analysis to date.

Material and Methods: Danish patients treated for GCC 1984–2007 were included (n = 4697) in this study. Data on cause of death, CVD and diabetes were obtained from national registries and collated with information from hospital files. Type of treatment was registered; cisplatin, etoposide and bleomycin (BEP), (n = 1525), radiotherapy (RT) (adjuvant (n = 298) or curative (n = 366)) or combinations hereof and surveillance only (n = 2314). Patients were excluded if they died of GCC (n = 179) or if they received other types of treatment (n = 53). Only tobacco use had missing values with data available on 2063 patients and missing on 2402. Hazard ratios (HR) were calculated adjusted for age and tobacco use and compared to surveillance only.

Results: Median observation time was: 15.3 years (IQR, 9.8–21.3 years). Treatment with PEB increased the risk of all major cardiovascular diseases independently (table). RT given with curative intent increased the risk of diabetes significantly. If tobacco use was omitted from the analyses, HR on CVD remained significant in the chemotherapy group, whereas HR on CVD remained insignificant in the RT group.

Conclusions: We confirm that treatment with BEP increases long-term risk of CVD in GCC survivors compared to patients treated on a surveillance program. CVD was not increased in patients treated with RT, but patients with disseminated seminoma treated with RT had an increased risk of developing diabetes. With the present observation time, development of diabetes had no impact on CVD-risk. Death due to CVD was not significantly increased. The present data will be compared to an age-matched control group without GCC and these data will be presented at the meeting.

2706 POSTER DISCUSSION

Open-label phase II trial of first-line everolimus monotherapy in patients with papillary metastatic renal cell carcinoma: RAPTOR final analysis

B. Escudier[1], S. Bracarda[2], J.P. Maroto[3], C. Szczylik[4], P. Nathan[5], S. Negrier[6], D. Castellano[7], C. Weiss[8], C. Porta[9], V. Grünwald[10]. [1]*Institut Gustave Roussy, Villejuif, France;* [2]*Ospedale San Donato, Arezzo, Italy;* [3]*Hospital de la Santa Creu i Sant Pau, Oncology Department, Barcelona, Spain;* [4]*Private practice, Warsaw, Poland;* [5]*Mount Vernon Cancer Centre, Northwood, United Kingdom;* [6]*University of Lyon, Centre L Berard, Lyon, France;* [7]*University Hospital 12 de Octubre, Madrid, Spain;* [8]*Novartis Pharmaceuticals Corporation, Nuernberg, Germany;* [9]*IRCCS San Matteo University Hospital Foundation Hospital, Pavia, Italy;* [10]*Medical School Hannover, Clinic for Hematology Haemostaseology Oncology and Stem Cell Transplantation, Hannover, Germany*

Background: Treatment options for patients with papillary metastatic renal cell carcinoma (mRCC) are limited. The RAPTOR (RAD001 in Advanced Papillary Tumor Program in Europe; ClinicalTrials.gov, NCT00688753) study evaluated first-line everolimus in patients with papillary mRCC. Preliminary results were presented at ESMO 2012.

Materials and Methods: RAPTOR is an open-label, multicenter phase II trial. Adult patients with type I or type II papillary mRCC, an ECOG performance status of $\leqslant$1, and no previous systemic therapy for RCC were enrolled. Central pathology review was performed for every patient. Patients received oral everolimus 10 mg once daily until disease progression or unacceptable toxicity. The primary end point was the proportion of patients progression free at 6 months. Secondary end points included progression-free survival (PFS), overall survival (OS), and safety.

Results: Study duration at time of analysis (Jan. 2013) was 3.5 years. The analysis included three populations: safety (N = 92, 100%), intention-to-treat (ITT, n = 83), and per protocol (PP, received $\geqslant$1 dose of study drug dose and had no major protocol violations; n = 63). Most patients were men (78%), most were white (92%), and mean age was 60 years (23−84 years). Among patients with papillary RCC per local review (99%), of whom 77% were confirmed centrally, 58% had type II and 16% had type I (25% missing) and per central review (76%), 59% had type II and 33% had type I (9% missing). In the PP population, the 6 month PFS rate was 58.7% per local review and 34.9% per central review. Median PFS was 7.8 months (95% CI: 5.5–10.8) per local review and 3.9 months (95% CI: 2.1−5.7) per central review in the PP population and 7.6 months (5.5−9.9) per local review and 3.7 months (2.3−5.5) per central review in the ITT population. Median OS was 21.0 months (95% CI: 15.4–28.0) in the ITT population and 20.0 months (95% CI: 11.1–28.0) in the PP population. Common grade $\geqslant$3 AEs included asthenia (10.9%), fatigue (5.4%), and anemia (5.4%); 27.2% of patients discontinued due to AEs.

Conclusions: These results demonstrated that everolimus provides clinical benefit with promising OS and is generally well tolerated by patients with papillary mRCC.

Sunitinib expanded-access trial in metastatic renal cell carcinoma (mRCC) − final Italian results

C. Sternberg[1], S. Bracarda[2], G. Carteni[3], G. Lo Re[4], E.M. Ruggeri[5], C. Masini[6], K. Fly[7], K. Zhang[8], S. Hariharan[9], B. Capaccetti[10], C. Porta[11]. *[1]San Camillo Forlanini Hospital, Medical Oncology Department, Rome, Italy; [2]San Donato Hospital Istituto Toscano Tumori (ITT), Medical Oncology, Arezzo, Italy; [3]Cardarelli Hospital, Division of Oncology, Naples, Italy; [4]Santa Maria Degli Angeli General Hospital, Department of Oncology, Pordenone, Italy; [5]Ospedale Belcolle AUSL Viterbo, Divisione di Oncologia, Viterbo, Italy; [6]Azienda Ospedaliero-Universitaria Policlinico di Modena, Dipartimento di Scienze Mediche e Chirurgiche Materno-Infantili e dell'Adulto, Modena, Italy; [7]Pfizer Oncology, Medical Oncology, Groton, USA; [8]Pfizer Oncology, Statistics, La Jolla, USA; [9]Pfizer Oncology, Medical Oncology, New York, USA; [10]Pfizer Oncology, Rome, Italy; [11]IRCCS San Matteo University Hospital Foundation, Medical Oncology, Pavia, Italy*

Background: Sunitinib is established as a reference standard of care and is approved globally for patients (pts) with mRCC based on a randomized, phase III trial (Motzer et al, 2007). Prior to regulatory approval, more than 4,500 patients were enrolled between 2005 and 2007 in a global mRCC expanded-access trial (ClinicalTrials.gov, NCT00130897; Pfizer) in which sunitinib was given to pts ineligible for other sunitinib trials. Sunitinib was shown to have a manageable safety profile and encouraging efficacy in this broad population of pts (Gore et al, 2009). Here we report final efficacy and safety results for pts in Italy who enrolled in this trial.

Material and Methods: 521 pts aged ⩾18 years with treatment-naive or previously treated mRCC received oral sunitinib at 50 mg/day on a 4-wk-on/2-wk-off schedule. Tumor measurements were scheduled per local standard practice and measured using RECIST. Safety was assessed regularly. Objective response rate (ORR), progression-free survival (PFS), overall survival (OS), and treatment-related adverse events (AEs) are reported. Analyses included all pts who received ⩾1 dose of sunitinib.

Results: Characteristics of 521 pts included 40% aged ⩾65 years, 14% with non-clear cell RCC, 11% with ECOG performance status (PS) ⩾2, and 11% with baseline brain metastases. Median treatment duration and follow-up were 7.4 and 12.3 months, respectively. 514 pts (99%) discontinued treatment; reasons included death (17%), lack of efficacy (46%), or AEs (13%). ORR was 12%, with ORR in subgroups of interest as follows: aged ⩾65 years, 8%; non-clear cell RCC, 7%; ECOG PS ⩾2, 2%; and baseline brain metastases, 4%. Median PFS and OS were 9.1 months (95% CI: 7.9–11.0) and 27.2 months (95% CI: 22.5–36.5), respectively. The most common any-grade treatment-related AEs were asthenia (44%; fatigue, 15%), thrombocytopenia and stomatitis (both 37%), diarrhea (36%), mucosal inflammation (29%), hypertension (26%), and dysgeusia (25%); the most common grade 3/4 treatment-related AEs were thrombocytopenia (10%), asthenia (9%; fatigue, 3%), neutropenia and stomatitis (both 6%), hypertension (5%), and hand–foot syndrome, mucosal inflammation, and diarrhea (all 4%).

Conclusions: Among 521 mRCC pts in Italy treated in the expanded-access trial, safety with sunitinib was comparable to, whereas OS was longer than, that of the overall population as previously reported.

2708 POSTER DISCUSSION

Characterizing prior nephrectomy patients with metastatic renal cell carcinoma (mRCC) treated with first-line sunitinib versus interferon-alfa

R.A. Figlin[1], T.E. Hutson[2], P. Tomczak[3], M.D. Michaelson[4], G.A. Bjarnason[5], X. Lin[6], S. Pitman Lowenthal[7], B. Korytowsky[8], E. Matczak[9], S. Oudard[10]. *[1]Cedars-Sinai Medical Center, Samuel Oschin Comprehensive Cancer Institute, Los Angeles, USA; [2]Baylor Sammons Cancer Center-Texas Oncology, GU Oncology Program, Dallas, USA; [3]Uniwersytet Medyczny, Klinika Onkologii, Poznan, Poland; [4]Massachusetts General Hospital Cancer Center, Hematology/Oncology, Boston, USA; [5]Sunnybrook Odette Cancer Centre, Medical Oncology, Toronto, Canada; [6]Pfizer Oncology, Biostatistics, La Jolla, USA; [7]Pfizer Oncology, Asia Pacific/Canada Medical Oncology, New York, USA; [8]Pfizer Global Pharmaceuticals, Oncology Health Economics Outcomes Research, New York, USA; [9]Pfizer Oncology, Medical Oncology, New York, USA; [10]Hôpital Européen Georges Pompidou Université Paris Descartes, Medical Oncology, Paris, France*

Background: In a randomized, phase III trial (Motzer et al, 2009), median progression-free survival (PFS; primary endpoint) was superior with sunitinib versus interferon-alfa (IFN-α) as first-line therapy of mRCC, 11 versus 5 months, respectively (P<0.001); median overall survival (OS) was 26.4 versus 21.8 months (P = 0.051). Prior nephrectomy was previously shown by multivariate Cox regression analysis to be an independent predictor of improved PFS with sunitinib in this trial (Patil et al, 2011). Here we report a retrospective analysis of the baseline characteristics and survival outcomes of patients in this trial with prior nephrectomy.

Material and Methods: 750 treatment-naive patients with mRCC were randomly assigned to sunitinib 50 mg/day on a 4-week-on-2-week-off schedule or IFN-α 9 MU subcutaneously thrice weekly. Median PFS (as assessed by central review of imaging studies) and OS were estimated by Kaplan–Meier method for the subset of patients with prior nephrectomy in each arm, with 95% confidence intervals (CIs) and hazard ratios (HRs) calculated for each. Median survival values were compared by 2-sided, unstratified log-rank test.

Results: Of 375 patients randomized to each arm, 90% had prior nephrectomy (sunitinib, n = 339; IFN-α, n = 335). Baseline characteristics were similar in each group; median age was 61 and 59 years, 71% and 72% were male, and the percentages of patients with ECOG performance status of 0/1 were 64%/36% and 64%/35%, respectively. Median PFS (95% CI) of sunitinib versus IFN-α in patients with prior nephrectomy was 11.5 months (10.7–13.6) versus 5.1 months (4.1−5.5), respectively (HR, 0.502; 95% CI, 0.407–0.618; P<0.0001). Median OS (95% CI) of sunitinib versus IFN-α in patients with prior nephrectomy was 30.0 months (23.7–not reached) versus 24.2 months (19.1–28.8), respectively (HR, 0.806; 95% CI, 0.650–1.000; P = 0.0496). Baseline characteristics and survival outcomes of patients with prior nephrectomy categorized by baseline ECOG performance status will also be presented.

Conclusions: In treatment-naive mRCC patients with prior nephrectomy, sunitinib maintained and improved upon its treatment effect over IFN-α in the overall population, with a statistically significant difference in median OS.

2709 POSTER DISCUSSION

An update of the Renal Cancer Appropriateness-based treatment toolkit (ReCATT) based on the validated semi-quantitative RAND UCLA methodology

M. Gore[1], J. Bellmunt[2], T. Eisen[3], B. Escudier[4], G.H. Mickisch[5], J. Patard[6], C. Porta[7], A. Ravaud[8], M. Schmidinger[9], P. Schoffski[10], C.N. Sternberg[11], C. Szczylik[12], S. Kirpekar[13]. *[1]Royal Marsden Hospital, London, United Kingdom; [2]University Hospital del Mar-IMIM, Department of Medical Oncology, Barcelona, Spain; [3]Cambridge University Health Partners, Department of Oncology, Cambridge, United Kingdom; [4]Institut Gustave Roussy, Department of Medical Oncology, Villejuif, France; [5]Centre of Operative Urology (COUB), Bremen, Germany; [6]Paris XI Bicetre University Hospital, Department of Urology, Paris, France; [7]I.R.C.C.S. San Matteo University Hospital Foundation, Department of Medical Oncology, Pavia, Italy; [8]Hôpital Saint André, Department of Medical Oncology, Bordeaux, France; [9]Medical University of Vienna, Department of Medicine I Clinical Division of Oncology and Comprehensive Cancer Center, Vienna, Austria; [10]University Hospitals Leuven Catholic University Leuven Leuven, Department of General Medical Oncology and Laboratory of Experimental Oncology, Brussels, Belgium; [11]Department of Medical Oncology, San Camillo Forlanini Hospital, Rome, Italy; [12]Department of Oncology, Military Medical Institute, Warsaw, Poland; [13]Double Helix Consulting, London, United Kingdom*

Background: Since we developed the RAND-UCLA appropriateness-based treatment toolkit for the treatment of patients with advanced/metastatic renal cancer in 2011 (Gore ME et al, Eur J Cancer. 2012 May;48(7):1038−47), there have been several clinical studies conducted in patients with metastatic renal cell carcinoma (RCC). These clinical data comprises RCTs and other non-controlled studies. To ensure that the treatment toolkit is up-to-date with available clinical evidence, especially in light of outputs of the COMPARZ trial (Motzer RJ et al. ESMO, 2012 October: Abstract LBA8), we have undertaken an update of prior published work.
Methods: The decision support toolkit was updated using the RAND/UCLA method and employed a panel of 11 EU RCC experts who evaluated treatment strategies in 36 different case scenarios. Cases and treatments were updated based on outputs of the updated systematic review. Elimination of the 'clinical trial' treatment option makes the toolkit more relevant to practice outside specialist centres. Individual panel members scored the appropriateness and their preferences of several interventions for each case and treatment, 1 (inappropriate) to 9 (most appropriate). This was followed by a panel meeting to reconcile disagreements as per the RAND methodology.
Results: Outputs of this update, while generally in-line with the published results in 2011, showed a greater specificity of appropriateness in general. Only 41 of the 575 total treatment options scored were seen as appropriate. There was higher concordance among the panel for the appropriateness/in-appropriateness of therapies in general, compared to the scoring from 2011. Areas in which there was discordance among the panel were those with the least- available data and include
– Use of pazopanib and sunitinib in the neo-adjuvant setting
– Possibility of nephrectomy with or without systemic targeted therapies in patients who have a high ASA score (3 or 4) and, thus, have been identified as having poor surgical risk

A significant change over the previous scoring exercise was that pazopanib and sunitinib are now considered equal by the panel in every situation. Of the 101 peer-reviewed publications concerning the treatment of RCC in the past 2 years, 24 had grade 1 evidence (SIGN grading criteria; SIGN, 2010). Further analysis will be conducted to explore the association between this new grade 1 evidence and the greater specificity of the outputs from the toolkit.
Conclusions: Apart from an update on the outputs of the decision toolkit, the update has objectively assessed more updated expert opinion in the treatment of RCC. Large studies have a rapid impact on experts, which may not be translated to general oncology practice. Areas of uncertainty and disagreement among RCC experts warrant further clinical research. Discordance around the role of surgery in high-risk patients may be because decision-making in such patients is best done only when actually seeing the patient.

2710 POSTER DISCUSSION

Baseline biomarker trend analysis of a randomized phase 2/3 study of naptumomab estafenatox plus IFN-a vs IFN-a in advanced renal cell carcinoma

T. Eisen[1], G. Hedlund[2], G. Forsberg[2], O. Nordle[2], R. Hawkins[3]. *[1]Addenbrooke's Hospital, University of Cambridge Department of Oncology, Cambridge, United Kingdom; [2]Active Biotech AB, Lund, Sweden; [3]University of Manchester and The Christie Hospital, Manchester, United Kingdom*

Background: Naptumomab estafenatox/ANYARA (Nap) is a fusion protein of an antibody (5T4) and a superantigen (SEA/E-120). After phase 1 studies a randomized phase 2/3 trial of Nap + IFN-α vs IFN-α was conducted. The main results were presented at ASCO 2013. The primary endpoint OS was not reached, HR = 1.08. In a subgroup of 130 patients (pts) having below median of baseline IL-6 and anti-SEA/E-120 antibodies (anti-S), prolonged OS (HR = 0.59, p = 0.02) was achieved. Plasma IL-6 was predictive of pazopanib and vaccine benefit in RCC pts.
Methods: 513 pts with RCC were treated. Baseline biomarkers IL-6 and anti-S were analyzed. Trend analysis (moving median, adapted STEPP) was performed for the biomarkers vs drug concentration, induced IL-2 (marker for drug induced T cell activation), PFS HR and OS HR (HR corrected by Heng risks).
Results: The STEPP analysis (see table) shows clear trends of decreasing HRs in pts with decreasing IL-6 and anti-S. The pts with IL-6 <3.24 pg/ml and anti-S <36.7 pmol/ml display an OS HR of 0.26. The pts defined by the three lowest anti-S blocks having IL-6 below median of the study display OS HRs $\leqslant$0.68. Pts with high anti-S or IL-6 have HRs >1, most pronounced at high anti-S and low IL-6. Similar trends are seen for PFS HRs. Plasma concentrations of Nap and induced IL-2 show matched trends.
Conclusions: The trend analysis clearly indicates that low baseline anti-S and IL-6 plasma levels independently predict anti-tumor efficacy after Nap + IFN treatment. The results warrant further studies with Nap in sequence or combo with e.g. TKIs in a biomarker IL-6/ anti-S defined subgroup. The results also emphasize the potential role of IL-6 as a predictive factor for the outcome on treatment with immunotherapies and TKIs in RCC.

c-MET is an active target across all papillary renal cell carcinoma (pRCC): Results from a large genomic French study

L. Albiges[1], J. Guegan[2], S. Gad[3], A. Le Formal[4], V. Verkarre[5], V. Molinie[6], M. Sibony[7], N. Rioux- Leclercq[8], J.J. Patard[9], B. Escudier[1]. *[1]Institut Gustave Roussy, Cancer Medicine − Inserm U753, Villejuif, France; [2]Institut Gustave Roussy, Functional Genomic Unit, Villejuif, France; [3]Institut Gustave Roussy, Inserm U 753 − EPHE, Villejuif, France; [4]Institut Gustave Roussy, Inserm U 753, Villejuif, France; [5]Hopital Necker − APHP, Pathology, Villejuif, France; [6]CHUM La Meynard Hospital, Pathology, Fort de France, Martinique; [7]Hopital Cochin − APHP, Pathology, Paris, France; [8]CHU de Rennes, Pathology, Rennes, France; [9]Hopital Bicêtre- APHP, Urology − Inserm U753, Kremlin Bicêtre, France*

Background: C-MET, is a tyrosine kinase receptor involved in tumor cell proliferation and migration. C- MET gene copy number alterations or somatic mutations have been reported in sporadic type I pRCC. MET pathway activation has not been investigated in type II (or non type I) pRCC. We used high-resolution oligonucleotide comparative genomic hybridization (CGH) arrays and matching gene expression array data on a large collection of pRCC to investigate c-MET as a potential deregulated gene across all pRCC subtypes.

Methods: 220 frozen pRCC were collected through French RCC Network, quality controlled for percentage of malignant cells >70% and subsequently RNA and DNA extraction were performed. Gene expression data generated with human whole genome Agilent 8x60K arrays was assessed on 98 pRCC (47 type I, 45 type II and 6 unclassified pRCC). Copy number alterations were analysed using Agilent Human 2x400K array for Type II pRCC and using comparative genomic microarray analysis (CGMA) method from gene expression data for Type I pRCC. C-MET gene sequencing was performed on type I pRCC.

Results:

- Ten somatic mutations of MET gene were identified amongst 51 type I pRCC (19.6%), including 8 mutations previously reported and 2 new mutations strongly predicted to be damaging.
- Copy Number alterations (Gain or Kr 7 polysomy) were identified by CGMA in 71% of type I and in 46 % of type II pRCC (69% gain in low grade type II and 38% gain in high grade type II).
- Correlation between DNA copy number alterations (CGH) and mRNA expression level was highly significant (Cor = 0.6, adjP=3.5e-02)
- c-MET expression level was high across all pRCC (Fold change = 5.8/ 3.1/ 1.8; $p=1.4x10^{-14}/p=1.8x10^{-4}/p = 0.1$) respectively for pRCC I /pRCC II /clear cell when compared each to normal kidney expression)
- LRRK2 is a known kinase required for MET downstream pathway activation. We found that LRRK2 overexpression specifically correlates with elevated c-MET mRNA expression across pRCC (Fold change = 7.4/3.6/1.5; $p= 1x10^{-11}/ p=8x10^{-6}/p = 0.2$) in pRCC I /pRCC II /clear cell respectively when compared each to normal kidney expression).

Conclusion: The present report expends the role of c-MET activation as a potential target across all pRCC subtypes. Further evaluation of MET downstream pathway activation according to c- MET status (somatic mutation, copy number alteration) is ongoing. These data support investigating c-MET inhibitors in phase II trials in correlation with MET activation status.

2712 POSTER DISCUSSION

Treatment and outcomes of non-transitional cell bladder cancer

S. Hafeez[1], J. Murray[1], M. Singhera[1], R. Huddart[1]. [1]*Institute of Cancer Research, Imaging and Radiotherapy, Sutton Surrey, United Kingdom*

Background: Non-transitional cell (non-TCC) bladder tumours are characterised by advanced stage and poor prognosis. Their relative infrequency and exclusion from bladder cancer trials means there is lack of evidence regarding ideal treatment approach. We report on the tumour characteristics and treatment outcomes of patients with non-TCC treated at our institution.

Material and Methods: Retrospective analysis between January 1990 and June 2011 identified 1269 patients with bladder cancer, of those 94 (46 male, 48 female) had confirmed non-TCC tumour on centralised pathological review. Variant TCCs were not included. The association between survival and tumour characteristics was examined using descriptive statistics.

Results: Median age at diagnosis was 70 years (range 22−96). Most patients presented with locally advanced disease. There was no significance difference between gender, stage at presentation and pathological subtype.

Pathological variant	Stage					Total
	T1N0	T2-T3N0	T4N0	TxN+	TxNxM+	
Squamous (SQ)	2	28	19	15	3	67
Adenocarcinoma (AD)		8	4	3	1	16
Neuroendocrine (NE)		4		2	2	8
Sarcomatoid (SA)		2	1			3
Total	2	42	24	20	6	94

67 patients were offered treatment with radical intent. 54 patients were treated with cystectomy, 11 with radical radiotherapy. 11/67 received neo-adjuvant chemotherapy, 1 progressed on chemotherapy and was not treated radically and 1 opted for experimental HIFU. Of the 27 who were treated with palliative intent, 18 had radiotherapy, 3 had surgery (including palliative cystectomy), 2 had chemotherapy and 4 received supportive care alone. After median follow-up of 8 months (range 0.2–106), 22 patients were alive with no disease, 68 had died (46 from metastatic bladder cancer). 3 were alive with active disease. Median time to disease progression following treatment was 7 months (range 1−76).

Overall 2 and 5 year survival were 31.4% and 23.5% respectively. There was no significant difference in overall survival rates between pathological variants (SQ vs AD p = 0.47, HR 1.26 95% CI 0.67–2.39; AD vs NE p = 0.99, HR 1.0 95% CI 0.34–2.95; SQ vs NE p = 0.28, HR 1.67 95% CI 0.66–4.20) and when stratified for stage (T1−4N0 vs N+ p = 0.54, HR 1.2 95% CI 0.67–2.14; T1-T4N0 vs M+ p = 0.08, HR 1.48 95% CI 0.96–2.28; N+ vs M+ p = 0.12, HR 2.18 95% CI 0.82–5.82).

Conclusion: Patients with non-TCC bladder cancer present at more advanced stage and have poor survival regardless of pathological subtype. Clinical trials are needed to determine whether multimodality treatment can improve outcome.

No conflict of interest.

2713 POSTER DISCUSSION

Disparities in predictors of genitourinary cancer in men

H.N. Tran[1], Y. Li[2], N. Udaltsova[3], M.A. Armstrong[3], G.D. Friedman[3], A.L. Klatsky[3]. [1]*Kaiser Permanente Oakland Medical Center, Internal Medicine, Oakland, USA;* [2]*Kaiser Permanente Oakland Medical Center, Hematology and Oncology, Oakland, USA;* [3]*Kaiser Permanente Oakland Medical Center, Division of Research, Oakland, USA*

Background: Almost half of all cancers in men are genitourinary cancers with prostate as the most common site, bladder 4th, and kidney 7th. Prospective data about risk factor disparities for these 3 cancer types are sparse leading us to study them in one large multiethnic cohort.

Material and Methods: In our study, 56,764 men supplied baseline data at health examinations from 1978 to 1985 and were followed through 2008 for tumor registry diagnoses. We performed Cox proportional hazards models adjusted for age, ethnicity, alcohol intake, smoking, BMI, and education to estimate hazard ratios (HR) and 95% confidence intervals (CI).

Results: Increasing age was related to higher risk of all 3 cancer types and alcohol drinking was unrelated to any. Statistically significant relationships (most with p < 0.001) included: (1) Compared to whites, black men had almost twice the risk of prostate cancer but 40% lower risk of bladder cancer while Asian men had lower risk of both prostate and bladder cancer. (2) Smokers had increased risk only of bladder cancer. (3) Obesity [BMI $\geqslant$30 kg/m^2] was related to increased risk of bladder and kidney cancer. (4) Higher educational attainment was related to increased risk for prostate cancer.

Conclusions: There are noteworthy disparities in risk factors for different GU cancers in men including race/ethnicity, smoking, BMI, and education.

No conflict of interest.

Table: Adjusted relationships* of traits to GU cancers in 56,764 men

Trait	Prostate cancer (n = 3,031)	Bladder cancer (n = 524)	Kidney cancer (n = 181)
Age (X10 years)	2.0 (1.9–2.0)[c]	2.5 (2.3–2.7)[c]	1.7 (1.5–1.9)[c]
Black/White	1.9 (1.8–2.1)[c]	0.6 (0.4–0.7) [c]	1.2 (0.8–1.7)
Asian/White	0.7 (0.6–0.8)[c]	0.5 (0.3–0.7) [c]	1.2 (0.7–2.0)
$\geqslant$1 pack per day smoking/none	1.0 (0.9–1.2)	3.6 (2.8–4.8) [c]	1.3 (0.8–2.2)
$\geqslant$3 alcohol drinks per day/none	1.1 (1.0–1.2)	1.0 (0.7–1.2)	1.1 (0.6–1.8)
BMI $\geqslant$30 kg/m^2/ <25 kg/m^2	1.0 (0.9–1.1)	1.4 (1.2–1.8)[a]	1.9 (1.2–3.0)[b]
College graduation/none	1.3 (1.2–1.4)[c]	1.0 (0.8–1.2)	1.0 (0.6–1.4)

p-values <0.05[a],<0.01[b], <0.001[c].
*HRs (95% CI).

2714 POSTER DISCUSSION

Historical data in real life from patients treated by vinflunine for an advanced or metastatic urothelial carcinoma: Results of the CURVE study

J. Médioni[1], A. Guillot[2], D. Spaeth[3], M. Di Palma[4], C. Théodore[5]. [1]*Hôpital Européen Georges Pompidou, Medical Oncology, Paris Cedex 15, France;* [2]*Lucien Neuwirth Cancerology Institute, Medical Oncology, Saint Priest En Jarez, France;* [3]*Gentilly Oncology Centre, Medical Oncology, Nancy, France;* [4]*Gustave Roussy Institute, Medical Oncology, Villejuif, France;* [5]*Foch Hospital, Medical Oncology, Suresnes, France*

Background: Vinflunine (VFL) is a chemotherapy (CT) registered as second line treatment of advanced or metastatic urothelial carcinoma (UC) after failure of a platinum-based CT. VFL was made available in France in September 2010. The purpose of the study was to collect data on the use of VFL in real life for a comparison with the phase 3 study results.

Material and Methods: The CURVE study is a retrospective data collection. 88 French centres where at least 4 patients (pts) had been treated during the year 2011 were asked to participate.

Results: From November 2012 to February 2013, 20 sites included 134 pts.

At the initiation of VFL, the mean age was 66 years and 89% of pts were males. The performance status (PS) was 0 or 1 in 72 % of pts. Most of them had a metastatic disease (75%) with visceral sites (liver and/or lung in 57%). Most pts underwent initial radical surgery (84%). All pts received prior chemotherapy with 95.5% for advanced disease intent; only one patient did not receive a platinum salt (99%).
The median duration of treatment by VFL was 3.1 months [0.03; 15.2] and the median number of cycles was 5 [1; 23]. The median initial dose of VFL was 280 mg/m^2 [120; 320] and the relative dose intensity reached the median value of 92.7% [19; 126]. 16% of pts experienced at least one dose reduction.
Most frequent grade 3−4 toxicities were asthenia and fatigue (20.9%), neutropenia (17.2%), anemia (8.2%) and constipation (8.2%). Prophylaxis against vomiting and constipation were prescribed in 92 and 86% of pts respectively.
The median overall survival (OS) was 8.2 months [6.5; 9.4]. The response rate was 22% with 5% and 17% of complete and partial responses respectively. The disease control rate was 51% with a median duration of 7.7 months [6.0; 9.4]. Median progression free survival was 4.2 months [2.8; 4.8]. Following VFL, 46% of pts received from 1 to 3 additional lines of chemotherapy.
Conclusion: The study reflects the current second line management of UC in France, pts exhibiting worse conditions than in real life and clinical trials.
The results are consistent with those of the phase 3 study, better for OS; toxicity is manageable with a higher number of cycles per patient and few dose reduction or delay. VFL brings a real benefit in some pts where there is no validated alternative.
Conflict of interest: *Advisory board: Pierre-Fabre Research Institute*

2715 POSTER DISCUSSION

Prognostic risk stratification of men with advanced penile squamous cell cancer (PSCC) receiving first-line systemic therapy

G. Sonpavde[1], G. Di Lorenzo[2], A. Necchi[3], B. Eigl[4], M. Kolinsky[5], R. Chacko[6], T. Dorff[7], L. Harshman[8], J. Goyal[9], G. Pond[10]. *[1]UAB (University of Alabama Birmingham) Cancer Center, Birmingham AL, USA; [2]University Federico II, Genitourinary Cancer Section and Rare-Cancer Center, Naples, Italy; [3]Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Oncology, Milan, Italy; [4]BC Cancer Agency, Medical Oncology, Vancouver, Canada; [5]University of Alberta, Medical Oncology, Edmonton, Canada; [6]Christian Medical College, Medical Oncology, Vellore, India; [7]University of Southern California, Medical Oncology, Los Angeles, USA; [8]Dana Farber Cancer Institute, Medical Oncology, Boston, USA; [9]UAB (University of Alabama Birmingham) Cancer Center, Medical Oncology, Birmingham, USA; [10]McMaster University, Biostatistics, Hamilton, Canada*

Background: Clinicopathologic factors are prognostic in men with PSCC undergoing surgery. The discovery of prognostic factors in men with for advanced (locoregional or metastatic) PSCC receiving primary systemic therapy may guide rational drug development in this orphan disease with substantial unmet needs.
Methods: We combined individual patient level data obtained from multiple institutions to study clinicopathologic prognostic factors in the context of first-line systemic therapy for advanced PSCC. Cox proportional hazards regression analysis was conducted to examine the independent prognostic impact of candidate factors on overall survival (OS). The candidate factors were age, stage, hemoglobin, neutrophil count, lymphocyte count, albumin, site of metastasis (visceral or non-visceral), smoking, circumcision, therapy (cisplatin or non-cisplatin), ECOG performance status (PS), lymphovascular invasion, precancerous lesion and surgery following chemotherapy. Statistical methods, including automated selection procedures and multiple imputation, along with expert knowledge to select an optimal model of prognostic factors.
Results: 147 men received first-line therapy for advanced disease. The number of patients with complete data on all candidate clinicopathologic factors was 96. There were no major differences in characteristics and outcomes between men with complete and incomplete data. Mean age across all men was 57.1 years; 10.2%, 21.8% and 68.0% had stage 2, 3 and 4 disease, respectively. 43.3% were ECOG PS $\geqslant$1, 41.0% had visceral metastases and 74.8% received cisplatin-based chemotherapy. On multivariable analysis, poor prognostic factors were visceral metastasis, treatment with non-cisplatin regimens and ECOG-PS $\geqslant$1. A risk stratification was constructed with 0, 1 and $\geqslant$2 poor prognostic factors which demonstrated moderate discriminatory ability (c-statistic=0.70).
Conclusion: In men with advanced PSCC receiving first-line systemic therapy, visceral metastases, non-cisplatin regimens and ECOG-PS $\geqslant$1 were independently prognostic for poor OS. A prognostic model including these factors exhibited moderate discriminatory ability. External validation of the risk model will enable interpretation of outcomes and guide rational drug development.
No conflict of interest.

Number of factors	N	Overall survival		
		Median (95% CI) months	6-month (%) (95% CI)	1-year (%) (95% CI)
0	36	Not Reached	94.4 (79.6–98.6)	70.4 (48.9–84.2)
1	39	9 (7−11)	88.0 (71.0–95.3)	7.2 (1.3–20.4)
$\geqslant$2	36	6 (5−8)	46.8 (28.6–63.0)	8.5 (1.5–23.5)

2716 POSTER DISCUSSION

Long-term platinum retention after treatment with cisplatin-based chemotherapy in testicular cancer survivors (TCSs)

L. Hjelle[1], P.O.M. Gundersen[2], J. Oldenburg[3], S.D. Fossâ[3], T. Tandstad[4], L. Slørdahl[2], M. Brydoy[5], R. Bremnes[1], H.S. Haugnes[1]. *[1]Universitetssykehuset I Nord-norge, Department of Oncology, Tromsø, Norway; [2]St. Olav Hospital, Department of Clinical Pharmacology, Trondheim, Norway; [3]Radium Hospital, Department of Oncology, Oslo, Norway; [4]St. Olav Hospital, Department of Oncology, Trondheim, Norway; [5]Haukeland, Department of Oncology, Bergen, Norway*

Background: Testicular cancer (TC) survivors treated with cisplatin-based chemotherapy have an increased risk for serious late effects as cardiovascular disease and second cancers. Apart from treatment burden, mechanisms explaining the increased risk are still unknown. To further elucidate possible mechanisms, we have evaluated long-term platinum (Pt) retention in TCSs treated with cisplatin-based chemotherapy.
Material and Methods: 456 men treated for unilateral TC (1980–1994) participated in a national follow-up study (2007–2008), with blood samples available for Pt analyses. Pt determinations in serum samples were carried out with high resolution inductively coupled plasma sector field mass spectrometry. The limit of quantification for this method was 15 ng/L. Patients were categorized in three treatment groups: Surgery (n = 134), and two chemotherapy groups: cumulative cisplatin dose $\leqslant$850 mg (cis$\leqslant$850; n = 269) and cisplatin dose >850 mg (cis>850; n = 53). The Pt plasma concentrations ([Pt]) were categorized into quartiles. Logistic regression was performed to evaluate the risk for having [Pt] in the highest quartile vs. the other quartiles, presented as odds ratio (OR) and 95% confidence intervals (CI).
Results: The median observation time was 20 years (range 13−28). The median level for the surgery group was 49ng/l (range 0–230 ng/l), for the cis<850 group 84ng/l (0–244 ng/l) and for the cis>850 group 112ng/l (21–247 ng/l). Only 5.2% of the surgery group had Pt levels in the highest quartile, while corresponding numbers were 27.5% and 62.3% for the cis$\leqslant$850 and cis>850 groups, respectively. There was a significant association between pt-level and both follow-up time and cisplatin dose ($p < 0.001$, both). The OR for having [Pt] in the highest quartile was positively associated with cisplatin dose (OR 1.31, 95% CI 1.22–1.41) per 100 mg increase in cisplatin dose), and negatively associated with follow-up time (OR 0.48, 95% CI 0.35–0.66 per every 5 year increase in follow-up time). Age, smoking and physical activity at follow-up were not associated with pt-level.
Conclusion: Our data suggest that pt is detectable in serum median 20 years after cytotoxic treatment. This is a novel finding, and future studieson the associations between Pt level, cisplatin dose and long-term toxicities as well as genetic factors are needed to identify those at increased risk for serious late effects.
No conflict of interest.

2717 POSTER DISCUSSION

Impact of testicular scatter radiation (TSR) on testosterone (T) and luteinizing hormone (LH) 11 and 18 years after abdominal radiotherapy for testicular cancer

M. Sprauten[1], H. Haugnes[2], M. Brydøy[3], S.D. Fossâ[1], J. Oldenburg[4]. *[1]Department of Clinical Cancer Research Oslo University Hospital, Oncology, Oslo, Norway; [2]University of Tromsø and University Hospital of North Norway, Oncology, Tromsø, Norway; [3]Department of Clinical Science University of Bergen, Oncology, Bergen, Norway; [4]Clinic for Cancer and Surgery Oslo University Hospital, Oncology, Oslo, Norway*

Background: Radiotherapy (RT) may compromise gonadal function in male cancer survivors (CSs). Testicular CSs are at increased risk of gonadal dysfunction after adjuvant abdominal RT as measured by declining

T and/or increasing LH. Testicular scattered radiation (TSR) dose is lower after abdominal RT for testicular cancer (<1 Gy), than after RT for rectal- or anal cancer (3−13 Gy). The long-term impact of low doses of TSR on gonadal function, has not been assessed in a longitudinal matter and may have consequences for planning of radiotherapy and follow-up of irradiated CSs.
Material and Methods: T and LH levels were retrieved from 111 testicular CSs median 11 and 18 years after adjuvant RT administered as a Dog Leg field (DL) in 96 CSs or Para aortal strip (PA) in 15 CSs. Differences in TSR between DL and PA were assessed by T-test. Hormone values were categorized into 6 scores according to cut off levels corresponding to quartiles and 2.5- and 97.5 percentiles from healthy controls matched for decadal age, yielding an ordinal score ranging from 1 to 6. The impact of TSR on hormone levels was assessed by ordinal logistic regression analysis with TSR dose as a continuous variabel.
Results: In general, the TSR dose was low (median 0.34 Gy, inter quartile range [IQR] 0.24–0.48 Gy) and significantly higher after DL (median 0.36 Gy, IQR 0.30–0.50 Gy) than after PA (median 0.09 Gy, IQR 0.08–0.12 Gy), $p < 0.001$. TSR dose was significantly associated with increasing LH scores 18 years after treatment, $p = 0.030$, whereas no significant associations emerged after 11 years. There were no significant associations between TSR and T scores at any of the time points.
Conclusion: Even small amounts of TSR may impair gonadal function in the long-term. The significant association between increasing scores of LH and TSR almost two decades after treatment may have implications for the follow-up of irradiated CSs in general, especially as the majority of patients receiving pelvic/abdominal radiation are exposed to higher scatter gonadal doses than testicular CSs. As a consequence, irradiated CSs should be screened for gonadal dysfunction in their follow up, since testosterone supplementation may prevent complications of hypogonadism.

Prognosis of screen failure for brain metastases in patients with metastatic renal cell carcinoma

C. Helissey[1], L. Albiges[1], C. Massard[1], Y. Loriot[1], E. Ileana[1], K. Fizazi[1], B. Escudier[1]. *[1]Institut Gustave Roussy, Cancer Medicine, Villejuif, France*

Background: Brain metastases (BM) are common exclusion criteria for clinical trials in metastatic Renal Cell Carcinoma (mRCC). However, real prognosis of asymptomatic BM, when discovered at screening is unknown. The goal of our study was to determine (i) if the prognosis of BM is different from that of other screen failure reasons, (ii) if the number of BM is an important prognostic factor.
Methods: We reviewed all the patients who signed an ICF for second and third line trials in mRCC in 8 different clinical trials at Institut Gustave Roussy (5 published trials: TARGET, RECORD-1, Sunitinib continuous dosing trial, AXIS, and INTORSECT; 3 ongoing: PIM, GOLD and BMS-CA209 025) and who failed screening. From each patient's chart, we reported: disease characteristics, reasons for screen failure and in case of brain mets: clinical and radiological features of BM, treatment received and overall survival (OS). The association between OS and these factors was evaluated by univariate analysis (Cox model).
Results: Among 283 pts screened, 55 pts had screen failure (19.4%) including 24pts (8.5%) for BM. All screen failure causes are reported in table 1.
Patients with BM had no neurological symptoms when signing ICF, but 12 of them developed symptoms during screening period while 12 remained symptom free. Median OS for all screen failure patients was 6 mths [20 days to 102 months], very similar to those with BM (5.7 mths). HR was 1.3, 95% CI [0.7−2.4], $p = 0.36$. Median OS was 6.9 mths and 3.7 mths for asymptomatic and symptomatic respectively, $p = 0.08$, HR = 0.47 95% CI [0.17–1.07]. Among the 12 asymptomatic patients, 7 had one BM, and 5 had multiple BM. Median OS in pts with unique BM vs multiple BM were respectively 6.9 mths vs 12.8 mths ($p = 0.44$), HR was 1.55, 95% CI [0.49−6.75].
Conclusions: Incidence of unknown BM during screening for 2nd line therapy in mRCC is not uncommon (8.1%) and this is the first cause of screen failure. Median OS is overall poor, even in asymptomatic patients with a unique BM, justifying excluding those patients from clinical trials.

Adjuvant radiotherapy with or without chemotherapy in patients with nonmetastatic stage III/IV transitional cell carcinoma of the upper urinary tract

E. Jwa[1], Y.S. Kim[1], H. Ahn[2], C.S. Kim[2], J.L. Lee[3], S.D. Ahn[1]. *[1]Asan Medical Center, Radiation Oncology, Seoul, South Korea; [2]Asan Medical Center, Urology, Seoul, South Korea; [3]Asan Medical Center, Oncology, Seoul, South Korea*

Background: The role of adjuvant radiotherapy still remains undefined in patients with transitional cell carcinoma of the upper urinary tract (UTTCC). To evaluate the role of adjuvant radiotherapy, we updated the prior review of clinical outcomes of patients with advanced stage III or IV UTTCC.
Material and Methods: From 2007 to 2012, 36 patients with nonmetastatic (M0) stage III or IV UTTCC underwent nephroureterectomy (NU) with bladder cuff excision followed by adjuvant radiotherapy (RT) with or without chemotherapy. As a historic control group, we reviewed 91 patients underwent NU and bladder cuff excision alone for the same stage UTTCC between 2000 and 2010. Patients in adjuvant RT group had significantly higher rate of involved resection margin (33% vs. 9%, $p = 0.001$) and higher tumor grade (grade 2, 9% vs. 30%; grade 3, 91% vs. 69%, $p = 0.017$). Adjuvant RT was delivered to tumor bed and regional lymph nodes with median dose of 46 Gy (range 45−60 Gy). Differences in risk-adjusted rates of treatment outcomes between 2 groups were assessed using multivariable Cox proportional-hazards model and the inverse-probability-of-treatment weighting (IPTW).
Results: Three-year actuarial locoregional recurrence (LR) free survival rates were 88% vs. 61% in adjuvant RT group and surgery alone group, respectively ($p = 0.017$). Three-year actuarial bladder recurrence (BR) free survival rate was 70 % in adjuvant RT group and 51% in surgery alone group ($p = 0.021$). After adjustment for differences in baseline risk factors, crude risk of LR (hazard ratio [HR]: 0.18; 95% confidence interval [CI]: 0.05 to 0.59, $p = 0.005$), the risk of BR (HR:0.39; 95% CI: 0.15 to 0.99, $p = 0.048$), and the risk of disease recurrence (HR:0.45; 95% CI: 0.22 to 0.92, $p = 0.029$) were significantly lower in the RT group. However, the rates of death were similar between 2 groups (HR: 1.14; 95% CI: 0.562 to 2.30, $p = 0.723$).
Conclusions: Despite the similar overall survival rate between 2 groups, current study shows that adjuvant radiotherapy may have benefit for reducing LR & BR, and improving disease free survival in patients with nonmetastatic stage III/IV UTTCC. Further prospective study will be required to confirm the role of adjuvant radiotherapy in patients with advanced stage UTTCC.
