U. Aksoy Ozcan[1], H. Ozveri[2], M.E. Yildiz[1], Y. Yildirim[3], Y. Saglican[4]. *[1]Acibadem University, Radiology, Istanbul, Turkey; [2]Acibadem University, Urology, Istanbul, Turkey; [3]Anadolu Medical Center Hospital, Medical Oncology, Gebze-Izmit-Kocaeli, Turkey; [4]Acibadem University, Pathology, Istanbul, Turkey*

Background: Testicular cancer is the most common solid neoplasia in men in the 20−40-year age group. Ultrasound (US) has so far been accepted as the gold standard for the evaluation of scrotal pathologies and is basically an extension of the physical examination. On the other hand, US can recognize testicular lesions only when they reach a certain size. It is important to know the presence of intratubuler germ cell neoplasia (ITGCN) in the contralateral testis for patients with testicular tumor, however, ultrasound cannot delineate ITGCN. The uncertain relation between the presence of testicular calcification, ITGCN, and testicular tumor needs further information. The booming advances in full field digital technology has enabled the use of this modality in the diagnosis of different malignant tumors. The objective of our study is to compare US and full field digital orchiography (FFDO) in the evaluation of testicular tumors with special emphasis on calcifications and discuss their clinical significance.
Materials and Methods: Between December 2011–2012, 12 orchiectomy specimens which were obtained from patients who underwent orchiectomy for testicular solid mass and 6 ram testicles which were selected to simulate normal testicular parenchyma, were evaluated with high resolution US and FFDO. Institutional review board approved the study protocol.
The digital orchiographic images of the specimens were obtained as magnification views without compression. Ultrasound was performed with 13−5 MHz. Two radiologists that were blinded to the histopathology results reviewed images in consensus. Calcification types and locations and mass on US and other US findings were recorded. Then the specimens were send to pathology department. The tumor types were identified and the presence of ITGCN was specifically sought for.
Results: Histopathologic findings revealed 4 seminoma, 8 non-seminomatous germ cell tumors and 6 normal testicular tissue (ram testicles). 10 out of 18 (55%) cases, calcifications were found on US. FFDO revealed calcifications in 13 (72%) of cases.
Small and faint microcalcifications were not detected by US. Orchiography performed better especially for the faint calcifications. Ultrasound was better in the detection of solid mass from the normal appearing adjacent testicular parenchyma. In 7 cases ITGCN was detected and both diagnostic modalities were able to detect calcifications.
Conclusion: Despite the findings that US provide, calcifications may need additional attention whether they may provide useful information in the diagnosis of testicular cancer. Our results had showed that FFDO was better in the detection and analysis of calcifications compared to US. On the other hand, we found that ultrasound was better in the detection of intrascrotal masses especially in delineation from the normal appearing adjacent parenchyma.

2721 POSTER

Treatment management of malignancy in end stage renal disease patients

B. Civelek[1], O. Yazici[1], H. Odabas[2], S. Aksoy[3], M.A. Sendur[1], N. Ozdemir[1], N. Zengin[1]. *[1]Ankara Numune Education and Research Hospital, Medical Oncology, Ankara, Turkey; [2]Haydarpasa Education and Research Hospital, Medical Oncology, Ankara, Turkey; [3]Hacettepe University Cancer Institute, Medical Oncology, Ankara, Turkey*

Background: End stage renal disease (ESRD) cancer patient have some difficulties in their treatment management. These are management of drug toxicities and side effects, providing effective dose intensity, electrolyte imbalance, hemodialysis procedure and balancing volume load. We retrospectively evaluated the patients on continuous hemodialysis program, who were admitted to our department and had administrated chemotherapy.
Methods: We evaluated the clinical features of patients on continuous hemodialysis program and administrated chemotherapy from March 2007 to December 2010 in our department.
Results: We retrospectively evaluated 10 cancer patient with ESRD, who were on continous hemodialysis program. Median age and hemodialysis duration of patient population was 55 years (32−67) and 36 (2−84) months, respectively. Six of patients were male and four of them were female. The primary diagnosis of patients as follows; 4 had lung, 2 had breast, 1 had ovarian, 1 had colon, 1 had bladder cancer and 1 had Ewing sarcoma. Six patients had metastatic disease at diagnosis. All of patients had systemic chemotherapy and 8 of them had up to 40 % dose reduction of chemotherapeutics. Eight patients had grade 3 or 4 side effects of chemotherapy. The most common side effects were hematological toxicities. In early period, two patients died due to toxic effects of chemotherapy and 1 patient had cardiomyopathy. Two patients had primary granulocyte stimulating factor prophylaxis. Partial, stable and progressive response was obtained in 5, 3 and 2 patients, respectively. Two patients, who had progressive disease, had second line chemotherapy. In follow up period 4 patients died.
Conclusion: There are no detailed data about the management of cancer in hemodialysis patients in literature. During treatment management in hemodialysis patients, fluid and electrolyte imbalance and increased risk of toxicity are difficulties encountered in clinical practice. Medical oncologist should have collaborated with nephrologists while treating these patients. The loss of chemotheurapeutic agents to dialysis solutions and fluid overload have to be considered in treatment planning and chemotherapeutic dose modifications have to be done. Therefore dialysis schedule should be programmed according to these properties of chemotherapeutics. In our small patient group, we observed 2 toxic deaths and 5 patients had partial response. Well recorded data of these patients, will contribute treatment management of other ESRD cancer patients. End stage renal failure is not contraindication for chemotherapy. However, further randomized controlled studies are needed in this patient group for more effective and safe chemotherapy administration.
No conflict of interest.

2722 POSTER

Retrospective multicenter French study of relapse after adjuvant carboplatin in 19 patients with clinical stage I testicular seminoma

N. Bonnin[1], P. Kerbrat[2], L. Dupuy[3], Y. Loriot[4], A. Thyss[5], G. Gravis[6], C. Chevreau[7], M. Laramas[8], H. Boyle[1], A. Fléchon[1]. *[1]Centre Régional Léon Bérard, Medical Oncology, Lyon, France; [2]Centre Eugène Marquis, Medical Oncology, Rennes, France; [3]Groupe Hospitalier Mutualiste, Medical Oncology, Grenoble, France; [4]Institut Gustave Roussy, Medical Oncology, Villejuif, France; [5]Centre Antoine Lacassagne, Medical Oncology, Nice, France; [6]Institut Paoli Calmettes, Medical Oncology, Marseille, France; [7]Institut Claudius Regaud, Medical Oncology, Toulouse, France; [8]Centre Hospitalier Universitaire, Medical Oncology, Grenoble, France*

Background: Stage I testicular seminoma is the most frequent presentation of Germ Cell Tumors (GCT) with a rising incidence. Surveillance or adjuvant treatment (radiotherapy or carboplatin AUC7) can be offered. The eatimated 5 year relapse rates are 15−20%, 4% and 5% respectively. There are no well-defined factor to predict relapse.
Material and Methods: We identified retrospectively, from 11 French institutions, patients (pts) who relapsed after adjuvant carboplatin AUC7 for clinical stage I seminoma since April 2008. We report here their characteristics, treatment and clinical outcome. Theoric carboplatin doses were checked and compared to administered doses.
Results: Nineteen pts were identified. Median age at GCT diagnosis was 39.6 years (23.6−68). All pts had a pure seminoma and were classified as stage I disease except one pt who must be reclassified as initial stage IIA disease. Median testicular tumor size was 50 mm (16−90) with 14 tumors $\geqslant$40 mm. Involvement of the rete testis was identified in 8/17 pts. The median time to relapse after carboplatin AUC7 was 15.1 months (mo) (1.7−46.5). Eighteen relapses occurred in the retroperitoneum, only one was located in the mediastinum. We have recalculated carboplatin doses from blood creatinin clearance for 18 patients: two patients received a dose that was more than 10% lower than the theorical dose. All pts received first line cisplatin-based chemotherapy (CT) (BEP, EP or VIP) at relapse. One patient progressed again one month after CT (3 BEP) and was treated with 3 TIP followed by retroperitoneal lymph node dissection. After a median follow-up of 26.0 mo (2.4–50.2) after first seminoma relapse, 18 pts are alive without disease and 1 is on CT.
Conclusions: In this study we couldn't identify factors that could predict relapse after carboplatin AUC7 for clinical stage I seminoma. Especially, there wasn't a difference between theoric and administered carboplatin doses. All patients at relapse were cured with cisplatin-based CT.
No conflict of interest.

2723 POSTER

Resection of post-chemotherapy residual masses (RMs) in patients with advanced non-seminomatous germ cell tumors (NSGCT): prediction of outcomes

M. Mediano Rambla[1], A. Thiery-Vuillemin[2], M. Alonso[1], E. Ocon[3], M. Conde[3], P. Sancho[1], I. Osman[3], C. Robles[1], R. Medina[3], I. Duran[1]. *[1]HHUU Virgen del Rocío, Medical Oncology, Sevilla, Spain; [2]CHU Minjoz, Medical Oncology, Besançon, France; [3]HHUU Virgen del Rocío, Urology, Sevilla, Spain*

Background: Multidisciplinary treatment of advanced NSGCT involves tumor resection of RMs following inductive chemotherapy. About 45% of RMs harbor necrosis/fibrosis (N/F), 40% teratoma (Te) and only 15% viable tumor (VT). The presence of Te in the primary tumor, the size of the RM and tumor marker values pre-chemotherapy have been proposed as predictive factors of RM histology. We analyze here the experience of two European tertiary hospitals and search for predictors of histology.
Methods: All NSGCT patients (pts) who underwent retroperitoneal lymph node dissection (RPLND) of RMs in the two institutions from 2004 to 2012 were reviewed. Histology of primary tumor, the size of RM as determined by CT and tumor marker values were analyzed as predictors of RM pathology. Three groups of pts according to RMs size were established for the analysis: (A) $\leqslant$2 cm, (B) >2-$\leqslant$5 cm, (C) >5 cm.
Results: 45 RPLND of RMs were performed in 40 pts. In 7 pts embryonal carcinoma was the only histology in the primary tumor. In those with mixed pathology (n = 27), 20 (74%) had teratoma components. According to the size of the RM (data available in 25) pts distributed in groups as follows: 3 in group A, 11 in group B and 11 in group C. The pathology of the RMs revealed VT in 0%, 27% and 0% respectively in groups A, B and C. All RMs in group A, 54.5% in group B and 63.6% in group C showed Te. The % of N/F ranged from 0% in group A to 18.2% and 36.4% in groups B and C respectively. When analyzed for correlation, only the presence of Te in the primary tumor approached statistical significance as a valid predictor for Te in the RM ($p = 0.064$).
Conclusions: No clinical or histological factor was able to predict with accuracy the pathology of RMs in our series. RPLND remains necessary even in minimal-size residual lesions in order to achieve long-term survival in this patient population.
No conflict of interest.

2724 POSTER

Sequential targeted therapy (TT) with sorafenib-sunitinib (SO-SU) versus sunitinib-sorafenib (SU-SO) in metastatic renal cell carcinoma (mRCC): Results from a case-series of patients

P. Biondani[1], V. Torri[2], E. Verzoni[1], L. Porcu[2], P. Grassi[1], I. Testa[1], S. Pusceddu[1], E. Garanzini[1], F. De Braud[1], G. Procopio[1]. *[1]Istituto Nazionale Tumori, Medical Oncology 1, Milan, Italy; [2]Istituto di Ricerche Farmacologiche Mario Negri, Methodology for Biomedical Research, Milan, Italy*

Introduction: Up to now, there is no clear consensus on the most appropriate sequencing of drugs following disease progression in mRCC. This study was performed to investigate correlation between progression free survival (PFS) and overall survival (OS) in a consecutive series of mRCC pts treated with the sequence SO-SU versus SU-SO.
Methods: Characteristics and outcomes of 125 pts affected by mRCC treated with SO-SU or SU-SO at the Istituto Nazionale Tumori of Milan were collected between November 2005 and January 2012. The Kaplan Meier curves were used to describe the survival distributions and the log-rank test to detect a statistical significance between survival distributions (p-value<0.05); correlation between PFS and OS was measured with the Kendall's Tau non parametric index.
Results: The main characteristics of 104 (83.2%) pts treated with the SO-SU sequence were: ECOG PS 0/1/2 56 (53.8%)/47 (45.2%)/1 (1 %); clear-cell histology 88 (84.6%); previous nephrectomy 98 (94.2%); according to Motzer criteria 38.5% were low risk, 53.9% intermediate risk and 7.7% poor risk. The main characteristics of 21 (16.8%) pts receiving SU-SO were: ECOG PS 0/1/2 10 (47.6%)/10 (47.6%)/1 (4.8%); clear-cell histology 17 (81%); previous nephrectomy 20 (95.2%); according to Motzer criteria 14.3% were low risk, 61.9% intermediate risk and 23.8% poor risk. Median follow-up was 66.6 months (range 6−84) in the SO-SU arm and 37.1 months (range 4–60.1) in the SU-SO treatment. At the time of analysis 88/125 (70%) pts were dead and 98/125 (78%) pts reached the disease progression. No statistical difference in PFS was observed for the two treatment groups: median PFS for SO-SU was 26.1 months (95% CI: 21.8–34.0), while for SU-SO was 20 months (95% CI: 10.0–33.0); no statistical difference in OS was observed for the two treatment groups: median OS for SU-SO was 27 (95% CI: 10.0-nd), while for SO-SU was 35.3 months (95% CI: 26–44.4). For both SO-SU and SU-SO treatment sequences a low positive correlation between PFS and OS was observed, respectively τ=0.13 and τ=0.15.
Conclusions: These data suggest that the sequence SO-SU compared to the sequence SU-SO has comparable efficacy in terms of PFS and OS. No strong evidence of a correlation between PFS and OS was demonstrated.

2725 POSTER

Cross-sectional observational study assessing the impact in daily clinical practice of the implementation of cooperative group (SOGUG) guidelines about management of targeted therapies in metastatic renal cell carcinoma (mRCC)(proTECT 2 Study)

N. Lainez[1], J. Puente[2], M.I. Sáez[3], L. León[4], S. Vazquez[5], A. Pinto[6], M. Lázaro[7], M.A. Climent[8], M. Morán[9], J. García-Donas[10]. *[1]Complejo Hospitalario de Navarra, Oncology Service, Pamplona, Spain; [2]Hospital Clinico Universitario San Carlos, Oncology Service, Madrid, Spain; [3]Hospital Universitario Virgen de la Victoria, Oncology Service, Malaga, Spain; [4]Complejo Hospitalario Universitario de Santiago de Compostela, Oncology Service, Santiago de Compostela, Spain; [5]Hospital Universitario Lucus Augusti, Oncology Service, Lugo, Spain; [6]Hospital Universitario La Paz, Oncology Service, Madrid, Spain; [7]Hospital Universitario Xeral de Vigo, Oncology Service, Vigo, Spain; [8]Instituto Valenciano de Oncologia, Oncology Service, Valencia, Spain; [9]Pfizer Oncology, Oncology, Madrid, Spain; [10]Instituto Oncológico Integral Clara Campal, Oncology, Madrid, Spain*

Background: Appropriate management of secondary effects has been proposed as a key factor for optimizing the outcome of patients (pts) with mRCC on targeted therapies. Aiming to improve such management the Spanish Oncology Genitourinary Group (SOGUG) launched in 2011 a program for the implementation of a clinical guide of recommendations for adverse event (AE) management. We report the impact of such program in the daily clinical practice of 32 Spanish hospitals.
Methods: This is a retrospective, cross-sectional, and multicenter study. Two populations were analyzed: A) pts with mRCC who initiated any targeted therapy before the guidelines were published (March 2010- March 2011) and B) pts who were treated after an educational program for the implementation of such guides was launched (Jan 2012- Dec 2012). The main objective of this study was to compare the adherence to the gold standard of care in the management of 10 key AEs in both populations. This study was approved by the Spanish Medicine Agency and Ethic Committees of each hospital.
Results: A total of 269 pts have been included: 54% received sunitinib (SU), 18% everolimus (EVE), 12% sorafenib (SO), 11% pazopanib (PAZ), 4% temsirolimus (TEM) and 1% bevacizumab (BEV). A total of 1231 cycles (605 before and 626 after the implementation program) were analyzed. The selected AEs were: Hypertension, cardiac, hepatic and cutaneous toxicity, hypothyroidism, diarrhea, proteinuria, hyperglycemia, dyslipaemia and neumonitis. Analisis was based on the adherence to the guides regarding baseline/follow up test performance, use of concomitant medication and policy for dose reduction/interruption or definitive suspension. After the implementation program there was a significant improvement in the adherence to recommendations regarding cardiac toxicity and diarrhea in pts treated with SU, 5.8% vs 12.9% ($p < 0.01$) and 84.8% vs 94.1% ($p < 0.001$) respectively. Also, there was a significant increase in guide overall compliance with EVE 36.8% vs 52.7% ($p < 0.05$). Regarding type of hospital, a significant improvement in management of toxicity was seen in those with higher number of renal cases per year and higher specialization after the program was launched 12.9% vs 34.6% ($p < 0.001$).
Conclusions: Educational programs focused on the implementation of clinical guidelines, may be of major help to the medical community in the therapy management and in the benefit of pts.
Conflict of interest: *Other substantive relationships: Dr. Morán is a Pfizer employee*

2726 POSTER

Residual masses in germ cell tumors and their impact in prognosis

E. Almagro-Casado[1], D. Pérez-Callejo[2], J. Rubio-Martinez[2], F.F. Franco[2], M. Palka[2], A. Ruiz-Valdepeñas[2], P. Ibeas[2], A. López-González[3], V. Calvo[4], M. Provencio[4]. *[1]Hospital Puerta De Hierro, Majadahonda Madrid, Spain; [2]Hospital Puerta De Hierro, Medical Oncology, Majadahonda Madrid, Spain; [3]Complejo Asistencial Universitario de León, Medical Oncology, León, Spain; [4]Hospital Puerta de Hierro, Medical Oncology, Madrid (Majadahonda), Spain*

Background: Residual masses (RM) are common in patients with germ cell tumors (GCT) treated with orchiectomy and chemotherapy. Those

masses may be positive for tumoral cells, necrosis or teratoma and might be implicated in the prognosis of the disease.
Patients and Methods: We analized retrospectively 161 male patients diagnosed of GCT treated between 1974 and 2012 in our hospital with a median follow up of 8.1 years (0.3−23.6). We compared the evolution of patients with RM with those without.
Results: Of the 161, 159 had testicular tumors and 2 extragonadal tumors at diagnosis. All of them but one underwent standart orchiectomy. 41.5% were seminomas and 84.5% nonseminomatous tumors (the most prevalent were embryonal carcinoma and teratocarcinoma). Of the nonseminomatous, 57.4% were mixed tumors whereas just 4.5% in seminomas. The median tumor size was 4.4 cm. Most of them (60.1%) were diagnosed at stage one, of these, 16% had RM, 15% in stage two, 50% in three and 46% in stage four ($p < 0.001$). The most frequent chemotherapy schemes used (53.4%) were BEP (Cisplatin, etoposide and bleomicine), other conteining platin (14%) and carboplatine alone (6%). 8.7% of the patients recived radiotherapy as part of the treatment.
The rate of complete responses (CR) was 89.4%, parcial responses (PR) with negative tumoral markers was 7.5% and with positive markers 1.9%.
A total of 27 (16.8%) of the 161 had RM detected in computed tomography. In 22 (81%) were resected, in 5 (19%) watchful waiting was decided. In 40%t the histology was malignant tumor, in 32% teratoma, in 27% necrosis or other findings. Analizing this subgroup of patients with RM, no histological differences (linfovascular, rete testis or albugineal invasion) were found in those with malignant tumor. ($p = 0.13$). The histology of teratoma in prmary tumor (PT) was not associated with the presence of RM ($p = 0.31$). The median time to diagnosis of PT in the group without RM was 1.2 months, and in the RM group 2.1 ($p = 0.04$).
According to the GCT risk classification, intermediate or bad prognosis at diagnosis was associated to the presence of RM (55% vs 11.3%, $p < 0.001$).
Of the 133 patients without RM, only 27 (20.3%) relapsed whereas 13 (48.1%) out of the 27 did it in the RM group ($p = 0.001$).
The rate of progression free survival (PFS) in both groups (without and with RM) after two and ten years was 83% and 57% and 77% and 33% respectively (logrank test $p < 0.001$) HR: 3.1 (95% CI 1.7−5.6). Ten-year overall survival (OS) was 92% and 81% respectively ($p = 0.07$) HR: 2.5 (95% CI 0.9−6.9).
Conclusions: Forty per cent of RM were malignant tumors but we did not find any histological marker that may predict this. Bad or intermediate prognosis and advanced stages as well as elapsed time to diagnosis of PT were associated with the presence of RM. These patients had a raised risk of relapse and a lower rate of PFS but no differences were found in OS. In this serie, the finding of teratoma in primary tumor was not a predictor of residual masses.
No conflict of interest.

2727 POSTER

Best response (BR) may be predictive of progression-free survival (PFS) in patients with metastatic renal cell cancer (mRCC) treated with tyrosine kinase inhibitors (TKI) in first line

S. Provenzano[1], M. Lo Mauro[2], G. Maltese[1], M. Spada[3], F. Fulfaro[1], G. Rinaldi[1], L. Incorvaia[1], F. Patti[1], N. Borsellino[2], G. Badalamenti[1]. *[1]University of Palermo, Department of Surgical and Oncological Sciences, Palermo, Italy; [2]A.O. Fatebenefratelli "Buccheri-LaFerla", Medical Oncology, Palermo, Italy; [3]A.O. G.Giglio, Medical Oncology, Cefalù, Italy*

Background: TKIs have quite recently brought innovation in the treatment of mRCC. Though TKIs' efficacy and tolerability has been proven in many trials, there is no current certain data about predictive markers (both clinical and biological) of response.
In this retrospective study we analyzed the correlation between BR and PFS in a cohort of patients subjected to first line TKI treatment for mRCC.
Patients and Methods: 36 patients affected by mRCC, stage IV, MSKCC good risk 6/36, moderate risk 21/36, poor risk 7/36, were treated since 2007 in three hospitals in Palermo, Sicily, Italy. Patients received the following treatment: 30 patients received sunitinib, 5 patients received sorafenib, 1 patient received pazopanib. Responses were evaluated using RECIST 1.1. Patients with a treatment follow-up longer than 24 months were included in the analysis, while patients with shorter follow-up were censored at the time of the last evaluation. Kaplan–Meier survival and log rank test were performed using MedCalc® software.
Results: 30/36 patients were evaluable for response and were included in the analysis. 6/30 patients did not respond to the treatment at the time of the first evaluation. Analysis showed Median PFS in PR group to be 22 months vs. 7 months in SD group ($p = 0.0003$).
Conclusions: In our study, patients affected by mRCC experiencing PRs to TKI treatment in first line appeared to have a better outcome in terms of PFS compared to patients experiencing SDs. These data do not reflect what we have seen in Gastro-Intestinal Stromal Tumors (GIST). Although the treatment approach to GIST is very similar to mRCC, patients who experience PR appear to have very similar outcome to patients who experience SD. Limits to these study are retrospectivity, small amount of cases, and short follow-up. Also, it is not clear whether a longer PFS is associated to a longer OS. Further studies will certainly follow.
No conflict of interest.

2728 POSTER

The preliminary result of combination of radiotherapy and cisplatin arterial infusion for bladder cancer

H. Yoshioka[1], T. Shinbo[1], N. Yoshikawa[1], K. Yoshida[1], Y. Uesugi[1], K. Yamamoto[1], Y. Narumi[1], H. Azuma[2]. *[1]Osaka Medical College, Department of Radiology, Takatsuki, Japan; [2]Osaka Medical College, Department of Urology, Takatsuki, Japan*

Background: To evaluate the effectiveness of combination with radiotherapy and balloon-occluded arterial infusion (BOAI) for bladder cancer, we analyzed our preliminary clinical experience.
Methods and Materials: We investigated 160 patients (Male : Female 123 : 37) and the median age was 71 (range; 38−98) years old. The median follow-up time was 16 months. Using the UICC classification, 10 stage I, 82 stage II, 46 stage III, and 22 stage IV were identified. Transurethral resection showed urothelial carcinoma for 153 patients and the other histological types for 7 patients. All patients received external beam radiation therapy (EBRT) with the prescribed dose of 50 Gy to the whole pelvis and 10 Gy to the bladder as a boost. During EBRT, BOAI of cisplatin (100 mg/body) was performed from bilateral internal iliac artery.
Results: Complete response rate was 73% on 2 months after treatment. The 2-year local control and overall survival rates were 87% and 78%. The 2-year bladder preservation rate was 93%. Grade 3 acute complication occurred in 20 patients (13%) (genitourinary: 17; gastrointestinal: 3) and Grade 4 acute complication was not observed.
Conclusions: The combination of radiotherapy and cisplatin arterial infusion for bladder cancer showed promising preliminary results.
No conflict of interest.

2729 POSTER

Biological toxicity as a predictive factor of efficacy in metastatic renal cell carcinoma (mRCC) treated with sunitinib

P. Guillabert[1], R.T. Elaidi[2], C. Teghom[2], J. Medioni[1]. *[1]Hospital Georges Pompidou, Medical Oncology, Paris, France; [2]Hospital Georges Pompidou, Medical Oncology ARTIC association, Paris, France*

Background: Sunitinib is the standard of care for mRCC in first-line. There are no established predictive factors of efficacy. We investigated retrospectively the relationship between biological toxicities and sunitinib efficacy.
Methods: Clinical data were retrospectively collected in all clear cell carcinoma patients treated with sunitinib for mRCC (except 3 pts for papillary carcinoma) at the European Georges Pompidou Hospital in Paris, France, who started between 2005 and 2012. Only patients having received sunitinib in first-line for at least one cycle were eligible. Platelets, neutrophils/granulocytes, leukocytes counts, cholesterolemia, triglyceridemia, hemoglobin and biological hypothyroidism were recorded with onset date and higher grade (NCI-CTC3.0).
Time to highest toxicity and time to best response were also recorded. Efficacy was assessed with objective response according to RECIST criteria 1.0 and progression-free survival. Statistical tests were chi square for categorical variables and log rank or Cox test for censored variables.
Results: 150 patients charts were reviewed. Data for biological toxicities were available for 42 patients. Median age=61.5 y (42−80), sex ratio=6/1 (M/F). ECOG-PS= 0 (50%). Objective response rate: CR=2, PR=18, SD=17, PD=2, NE=3. Median treatment duration= 23 months (11.4–28.5). Median treatment follow-up time= 36.3 m. Median survival = 51 m (30.7−64). Median PFS= 28.5 m (17.5–35.5).
Efficacy and toxicity were studied with several approaches. Relationship between grade toxicity and RECIST criteria, duration of treatment and time to best response were considered. All those relationship were non significant. Delay of highest toxicity was shorter for SD and PD responses ($p < 0.05$). Absolute decrease of leukocytes was related to delay of best response ($p < 0.05$). All other tests were non significant.
Conclusions: There is no clear relationship between biological toxicities and radiological response to sunitinib. But, other efficacy criteria such as delay of highest toxicity and delay of best response seem to be of interest for efficacy evaluation.
No conflict of interest.

2730 POSTER

Sunitinib in patients (pts) from Latin America: Final results of the expanded-access trial in metastatic renal cell carcinoma (mRCC)

C.H. Barrios[1], D. Herchenhorn[2], M. Chacón[3], P. Cabrera-Galeana[4], M. Monaco[5], P. Sajben[5], K. Zhang[6]. *[1]PUCRS School of Medicine, Department of Medicine, Porto Alegre RS, Brazil; [2]Instituto Nacional de Câncer, Department of Medical Oncology, Rio de Janeiro, Brazil; [3]Alexander Fleming Institute, Department of Medical and Surgical Oncology, Buenos Aires, Argentina; [4]ISSEMyM, Centro Oncológico Estatal, Toluca, Mexico; [5]Pfizer Oncology, Medical Oncology, New York, USA; [6]Pfizer Oncology, Statistics, La Jolla, USA*

Background: Sunitinib is approved multinationally for the treatment of mRCC. A global expanded-access trial (NCT00130897; Pfizer) confirmed the manageable safety profile and efficacy of sunitinib in a broad population of pts with mRCC (N = 4543; Gore et al, ESMO 2012). Using final data from this trial, we present sunitinib efficacy and safety results in pts from Latin America, the first such report from this region.
Material and Methods: Pts aged ⩾18 y with treatment-naive or previously treated mRCC received oral sunitinib at 50 mg/d on a 4-wk-on/2-wk-off schedule. Safety was assessed regularly, tumor measurements done per local practice, and survival data collected where possible. ORR, PFS, OS, and treatment-related (TR) AEs are reported. Analyses included all pts who received ⩾1 dose of sunitinib.
Results: 348 pts were the subject of this analysis (modified ITT [mITT] population), of whom 60% had received prior cytokine treatment. In the mITT population, 28% were aged ⩾65 y, 5% had non-clear cell RCC, 14% had an ECOG performance status ⩾2, 9% had baseline brain metastases, and 75% had ⩾2 sites of metastatic disease; 89% had prior nephrectomy. Median treatment duration and follow-up were 8.0 and 15.1 mo, respectively. 326 pts (94%) discontinued study participation for reasons including death (41%), lack of efficacy (22%), or AEs (13%). Among 311 pts with RECIST tumor assessments, the ORR was 17% (19% and 15% in pts with or without prior cytokine treatment, respectively). The clinical benefit rate (CR + PR + SD ⩾3 mo) was 57%. Median response duration among responders was 26.7 mo. Median PFS was 12.1 mo for the 311 pts with RECIST tumor assessments and for pts with or without prior cytokine treatment. Median OS was 16.9 mo (95% CI: 15.1–20.2) in the mITT population, and 16.6 mo (95% CI: 14.7–19.5) and 19.3 mo (95% CI: 13.8–28.5) among pts with or without prior cytokine treatment (P = 0.46). The most common TRAEs of any grade were mucosal inflammation (54%), diarrhea (53%), asthenia (41%), and decreased appetite (33%); the most common grade 3/4 TRAEs were asthenia (12%), neutropenia (10%), fatigue (9%), and thrombocytopenia (9%). Further analyses of pt subgroups with and without prior cytokine treatment, as well as other subgroups of interest, will be presented.
Conclusions: In this expanded-access trial, the efficacy and safety profile obtained with sunitinib in pts with mRCC in Latin America was comparable to that of the overall population as previously reported.

2731 POSTER

Taxanes in salvage and high-dose chemotherapy and autologous peripheral blood stem cell transplantation in patients with advanced germ cell tumors

I. Korenkova[1], A. Sakalo[2], V. Sakalo[2], P. Yakovlev[3]. *[1]Kiev Bone Marrow Transplantation Center, Kiev, Ukraine; [2]State Institution "Institute of Urology of AMS of Ukraine", Oncology, Kiev, Ukraine; [3]Kiev Municipal Clinical Oncology Center, Urology, Kiev, Ukraine*

Paclitaxel-based combination became the standard in salvage settings and incorporated in high-dose regimens prior autologous stem cell transplant (ASCT). We report on docetaxel use in salvage regimen prior to high-dose chemotherapy (HDCT).
Materials and Methods: 44 procedures of HDCT and ASCT were performed in 28 relapsed or refractory germ cell cancer patients, judged to be incurable by standard salvage therapy. Two patients had seminoma and 26 nonseminomatous germ cell tumors.
50% of patients were heavily pretreated with ⩾2 lines of previous systemic therapy and median of 7.5 cycles of cisplatin-based chemotherapy (CT). 22 patients were cisplatin refractory and 9 patients had relapse. Treatment plan consisted of 2−3 cycles of salvage CT and two sequential cycles of high-dose (HD) etoposide (1500 mg/m^2) and carboplatin 1800 mg/m^2 (24 AUC). Salvage regimens were docetaxel (160 mg), ifosfamide (6 g/m^2) and cisplatin (100 mg/m^2) in 13 patients, standard TIP − in 4, VIP − in 5 and GOP (gemcitabine, oxaliplatin and paclitaxel) in 6 patients, depending on previous therapy or drug availability. Totally 36 taxanes-based salvage CT blocks were conducted.
Stem cells were successfully collected in all patients, but 5 of them required second mobilization. 14 patients received 2 HD regimens, 13 patients − one, and 1 patient received 3 cycles of HDCT. HD-paclitaxel was included in HD regimen in 7 cases.
Results: The median patients' age was 27.5 years (range 14−41 years). Response was achieved in 23 (82%) patients: partial in 19, complete − in 4 patients, 4 had stable disease and 1 progressed before HDCT.
The most frequent non-hematological toxicities of HDCT were nausea and vomiting, mucositis (Grade 3 mainly in patients receiving paclitaxel in HD regimen), ototoxicity and hepatic toxicity.
Transplant-related mortality was 3.57% (1/28), 1 patient died due to renal insufficiency after HDCT (ifosfamide was included in HD regimen). At a median follow-up of 2.3 years (range 2–141 mo.) a continuously disease-free status was achieved in 14 (50%) patients, in 7 patients residual tumor was removed. 12 patients died because of disease profession, one − from other reason.
Conclusion: Incorporation of docetaxel and paclitaxel in salvage treatment and HDCT appear to benefit patients with resistant germ cell tumors with manageable toxicity.
No conflict of interest.

2732 POSTER

Effect of adjuvant chemotherapy on survival in patients with urothelial bladder cancer undergoing radical cystectomy

P. Yakovlev[1], V. Mrachkovskiy[1], A. Kondratenko[1], I. Khimich[2], V. Sakalo[3]. *[1]Kiev City Clinical Oncology Center, Urology, Kiev, Ukraine; [2]Kiev City Clinical Oncology Center, Chemotherapy, Kiev, Ukraine; [3]State Institution "Institute of Urology of AMS of Ukraine", Oncology, Kiev, Ukraine*

Patients with urothelial bladder cancer (BC) scheduled for radical cystectomy (RC) often are candidates for systemic therapy. Administration of chemotherapy in postoperative regimen requires additional evidence of its effect, as EAU guidelines do not provide proof of its benefit. We ran retrospective single center study on effect of adjuvant chemotherapy (CT) on 3- and 5-years cancer-specific survival (CSS) in series of patients after RC for BC.
Materials and Methods: 286 patients with BC underwent RC with pelvic lymph node dissection and subsequent urinary diversion from 2000 through 2011. Males were 259 (90.2%). Median age at surgery was 60.6±15 years (range: 30−79 years). Orthotopic intestinal urinary diversion was performed in 130 (45.5%) patients, heterotopic intestinal urinary diversion − in 30 (10.5%), and on-skin diversion of urine was done in 126 (44%) patients.
Patients with locally advanced or lymph node positive disease underwent adjuvant platinum-based chemotherapy in one of the selected modes (methotrexate with vinblastine, doxorubicin and cisplatin; or gemcitabine with cisplatin).
Logistic regression method was applied for data analysis. Statistical significance of independent variables (clinical stage pT, sex, age at surgery, adjuvant CT) on 3- and 5-yr. CSS was determined.
Results: Forty-six (15.8%) patients after RC received adjuvant CT: 38 (82.6%) patients with N+, 3 (6.5%) − with pT3a disease, and 5 (10.9%) − with M+.
Thirty (65.0%) patients died due to progression, with median survival of 14.8 months (range 3.4–55.3 mo., 95% CI: 5.0–36.7). At final follow-up only 3 out of 16 survived patients after CT are free from disease.
Among 174 patients who did not receive CT after RC 108 (62.1%) patients died due to all reasons including progression of cancer. Median survival was 34.3 mo. (12.9–88.6 mo., 95% CI: 13.4–82.7).
Logistic regression analysis revealed significant factors for 3-years CSS with AUC=0.847 to be age at surgery ($p < 0.00001$), pT ($p < 0.0001$), insignificant factors were: sex ($p = 0.259$) and adjuvant CT ($p = 0.233$). For 5-years CSS with the AUC = 0.784 significant factors were pT ($p < 0.0001$), age ($p = 0.001$), insignificant factors were adjuvant CT ($p = 0.127$) and sex ($p = 0.221$).
Conclusion: Adjuvant chemotherapy does not affect cancer specific survival in bladder cancer patients after radical cystectomy.
No conflict of interest.

2733 POSTER

Patience is a virtue: "wait and see" strategy for metastatic or recurrent renal cell carcinoma

I. Park[1], J.L. Lee[2], J.H. Ahn[2], I.G. Jeong[3], C. Song[3], B. Hong[3], J.H. Hong[3], C.S. Kim[3], H. Ahn[3]. *[1]Gil Medical Center, Internal Medicine, Incheon, South Korea; [2]Asan Medical Center, Oncology, Seoul, South Korea; [3]Asan Medical Center, Urology, Seoul, South Korea*

Background: Metastatic renal cell carcinoma (MRCC) often presents with very indolent course without any symptom, and treatment (Tx) for MRCC is mostly palliative rather than curative in a molecular target agents era. There exist several Tx options for MRCC, but all available agents have considerable toxicities, cause economic burden to patients (pts), and impair quality of life. For some cancers like indolent lymphoma, 'wait and see' strategy (W&S) is adopted for asymptomatic pts. We retrospectively evaluate clinical outcomes of W&S for asymptomatic MRCC pts.
Methods: We enrolled MRCC pts who was followed-up with deferred treatment for the purpose of W&S in our institution between 2000 and 2012. Clinical characteristics, response to W&S, predictive factor for time-to-progression (TTP), and response to succeeding first line Tx were analyzed.
Results: Of 44 pts found, 30 pts had recurrent disease and 13 pts initially metastatic disease. Most pts had good Karnofsty PS (KPS), 100% for 26 pts and 90% for 13 pts. Lung (38 pts), lymph nodes (16 pts), kidney (6 pts) were most common site of metastasis. During W&S, stable disease (SD) and progressive disease (PD) were the best overall response for 36 (82%) and 8 (18%) pts, respectively, and 37 pts had PD finally. With a median F/U period of 24.7 months, median TTP and OS were 12.5 months (95% CI, 6.7–18.4) and 91.1 months (95% CI, 41.3–141.0). After univariate and multivariate analysis for TTP, KPS <100, liver metastasis, time from diagnosis to W&S <1 year, and neutrophilia were found to be predictive factors for TTP during W&S. After PD, 27 pts proceeded to systemic treatment (13 sunitinib, 10 pazopanib, 3 immunotherapy, and 1 temsirolimus). Objective response rate were 54% for sunitinib, and 50% for pazopanib.
Conclusions: This study suggests that W&S could be a viable treatment option for the first-line approach in asymptomatic MRCC pts, especially for those who have good performance status without neutrophilia or liver metastases.
No conflict of interest.

2734 POSTER

Demographic and clinical data on nonseminomatous germ cell tumours and long-term (1993–2011) results: GATA experience

N. Karadurmus[1], S. Ataergin[1], G. Erdem[1], M. Cakar[2], O. Kuzhan[3], T. Turker[3], S. Ozaydin[3], M. Ozturk[3], F. Arpaci[3]. *[1]Gulhane School of Medicine, Medical Oncology, Ankara, Turkey; [2]Gulhane School of Medicine, Internal Medicine, Ankara, Turkey; [3]Gulhane School of Medicine, Public Health, Ankara, Turkey*

Introduction: Male nonseminomatous germ cell cancers are frequently seen tumors in young patients between the ages of 20−40. Approximately 95% of them involve testes and 5% are extragonadal.
Methods and Patients: Demographic and clinical characteristics of 248 patients who applied to section of Medical Oncology, Gulhane Military Medical Academy between February 1993-December 2011were retrospectively reviewed and evaluated.
Results: Median age of patients was 26 (19−45 years) and 74 patients (29.8%) were living in Central Anatolia; Eastern Anatolia region drew attention to be the least one of living area (n = 14, 5.6%). 54 cases (21.7%) had noticed an asymptomatic testicular mass themselves and 39 percent of these cases (72.2%) were higher educated. In evaluation of body-mass indexes; 156 cases (62.9%) were normal weight, 45 (18.1%) were overweight, and 38 (15.3%) were obese. Two patients (008%) had testicular intraepithelial neoplasia, 32 patients (12.9%) were stage I, 126 patients (50.8%) were stage II, 88 patients (35.4%) had stage III disease. The primary place of tumor was as follows; 189 patients (76.2%), testis, 59 patients (23.8%) extragonadal [retroperitoneal in 38 patients (15.3%), mediastinal in 21 patients (8.4%)]. Histopathologically, embryonal carcinoma, yolk-sac and choriocarcinoma components accompanied mixt-germ cell components in the frequencies of 73%, 22%, 17% respectively. As first line therapy, PVB or BEP chemotherapy in all cases was performed. Number of patients who needed retroperitoneal lymph node dissection because of a residual mass after standard chemotherapy for stage II and stage III disease were 21 (8.4%) and 7 (2.8%), respectively. Median follow-up was 94 months (range: 19–228), 69 months (14 −176) and 31 months (11–134) for stage I, II and III patients, respectively. 10-year overall survival rate of patients with testicular tumors were 99%, 79% and 43% for stage I, II and III patients, respectively.
Conclusion: Germ cell cancers have high response and survival rates with conventional chemotherapy although they have heterogeneous characters in terms of histologic type and clinical behavior.
No conflict of interest.

2735 POSTER

Response to second line chemotherapy (Ctx) in advanced urothelial carcinoma: A pooled retrospective analysis of combination versus monotherapy

A. Jayaram[1], M.Y. Teo[1], S.R. Mc Dermott[1]. *[1]Adelaide Meath & National Children's Hospital, Medical Oncology, Dublin, Ireland*

Introduction: Second line ctx for advanced urothelial carcinoma (UC) constitutes a substantial unmet need. There are a number of agents used however with marginal activity in advanced UC. We examined the effectiveness of chemotherapy in the 2nd-line setting along with the effect on reported overall survival (OS). We also determined whether responses differed between combination and monotherapy regimens.
Methods: Published 2nd-line studies were identified from PubMed between 1997 and 2012. Manuscripts were reviewed for data extraction. Pooled weighted objective response rate (ORR), disease control rate (DCR), progression-free survival (PFS) and median overall survival (OS) were calculated. Using Fisher's exact we determined the difference between the ORR and DCR of combination versus monotherapy.
Results: Twenty-five prospective studies of second-line ctx for progressive advanced UC were identified (22 non-randomised, 3 randomised) (n = 1297). The majority of studies (88%) were phase II. Twelve studies investigated combination regimens while 13 studies examined monotherapy. All studies allowed adjuvant and primary chemotherapy as 1st-line but only 12 reported breakdown while only 7 studies reported median time from last chemotherapy. The pooled ORR was 17.0% (95% CI 12.7–21.3%) and DCR was 47.7% (95% CI 36.8–58.6%). In terms of median PFS, the pooled median is 3.0 mos (range 1.6–11.0 mos) while the median pooled OS was 6.9 mos (range 3.0–14.4 mos). When we compared the combination regimens to monotherapy the ORR was 27.7% versus12.3% ($p < 0.001$) and DCR was 44.3% versus 32.3% ($p < 0.001$). There was numerical difference in PFS between combination and monotherapy, at3.9 mos (range 1.6−3.8 mos) versus 2.7 mos (range 2.6−11 mos), and in OS at 7.5 mos (range 4–14.4) versus 6.6 (range 3−1.8 mos). No formal comparison was performed.
Conclusion: The pooled analysis revealed that 2nd-line ctx for advanced UC can induce a response and good disease control. Combination ctx is still superior in 2nd-line and is an appropriate approach in patients with a good performance status. This may help relief symptomatic patients. However larger prospective study is needed to confirm this.
No conflict of interest.

Experience with Sunitinib in metastatic renal cell carcinoma (mRCC) patients: Pool analysis from 3 Spanish observational prospective studies

D. Castellano[1], P. Maroto[2], E. Espinosa[3], E. Esteban[4], A. Gonzalez de Alba[5], M.A. Climent[6], J.A. Arranz[7], M.J. Méndez-Vidal[8], M.V. Bolós[9], J. García-Donas[10]. *[1]Hospital 12 de Octubre, Medical Oncology, Madrid, Spain; [2]Hospital Santa Creu i Sant Pau, Medical Oncology, Barcelona, Spain; [3]Hospital Universitario La Paz, Medical Oncology, Madrid, Spain; [4]Hospital General de Asturias, Medical Oncology, Oviedo, Spain; [5]Hospital Son Espases, Medical Oncology, Palma de Mallorca, Spain; [6]Instituto Valenciano de Oncologia, Medical Oncology, Valencia, Spain; [7]Hospital General Universitario Gregorio Marañón, Medical Oncology, Madrid, Spain; [8]Hospital Reina Sofia, Medical Oncology, Cordoba, Spain; [9]Pfizer, Oncology, Madrid, Spain; [10]Centro Integral Oncológico Clara Campal, Medical Oncology, Madrid, Spain*

Background: Sunitinib is a standard of care for favorable and intermediate risk mRCC patients (pts) in the firts-line setting. Here we report efficacy and safety results from a pooled analysis of 3 observational prospective studies involving 33 Hospitals.
Material and Methods: 224 evaluable pts who were enrolled between 2007 and 2011 and received Sunitinib in the 1st line setting following routine clinical practice were analyzed. 49 pts from SUT-IIG-09 study; 94 from SUT-REN-07 and 81 from MAR-SUT-2008−01. The primary objective of these studies was to evaluate the predictive value of different biomarkers in terms of PFS.
Results: 42% pts were metastatic at diagnosis and 93% were clear cell or showed a clear cell component. 81% had prior nephrectomy. 36% only one site of metastasis, 37.5% two sites, 25.5% $\geqslant$3 sites and 1% locally advanced disease. 25%, 63% and 12% were ECOG PS 0, 1 and

⩾2 respectively; 6%, 83% and 11% showed intermediate and poor risk (MKSCC criteria) respectively.
Time from diagnosis to Sunitinib interval was ⩽1 year in 58% of pts. 59% of pts had at least one dose reduction. Median treatment duration was 7.7 months (m) (95% CI: 9.3–11.3). At the time of the analysis 171 pts (76%) had discontinued treatment: 68% due to progressive disease (PD) and 20% due to toxicity. With a median time of follow up of 13.07 m (95%IC: 6.97–22.20) median PFS was 11.60 m (95% CI: 9.92–13.28) for the favorable-intermediate risk group. 208 pts were evaluable for response. As a best response: 5% complete responses (CR), 38.5% partial response (PR), 38.5% stable disease (80% lasting >6 m) and PD 17.8%. Objective response rate (CR+PR) was 43.5% (95% CI: 36.8–50.7). Median time to PR was 3.8 m (95% CI: 3.86–5.99) and to CR 8.2 (95% CI: 4.75–9.77). Median duration of response was 7.43 m (95% CI: 8.9–12.3). At the time of the analysis 102 pts had died and median overall survival was 21.9 m (95% CI: 17.2–26.6).
The most common related AEs were asthenia (72%), mucosal inflammation (56%), diarrhea (41.5%), neutropenia (36%), hypertension (HTN) (36%), hand food syndrome (HFS) (35%) and hypothyroidism (24%); the most common grade 3 toxicities (more than 10% of patients) were asthenia (25.5%), HFS (18%), HTN (16%) and neutropenia (12.5%). Only 3 cases of grade 4 toxicities were reported.
Conclusions: Efficacy and safety with Sunitinib in pts treated within an observational prospective study were comparable to those previously reported in clinical trials.
Conflict of interest: *Other substantive relationships: MV Bolos works at Pfizer*

2737 POSTER

Outcome of metastatic renal cell carcinoma (mRCC) patients in the era of new targeted therapies

A.L. Ruíz[1], M.V. Bolós[2], A. Viqueira[2], E. Esteban[1]. *[1]Hospital Universitario Central de Asturias, Oncology, Oviedo, Spain; [2]Pfizer, Oncology, Madrid, Spain*

Background: Targeted therapies have improved the outcome in patients (pts) with mRCC in terms of progression-free survival (PFS) and overall survival (OS).
Material and Methods: A retrospective analysis from pts treated with targeted therapies between 2007 and 2011 in a single institution was carried out. The primary objective was to evaluate the efficacy of treatment with sunitinib and the different treatment sequences.
Results: 102 pts with mRCC were included, 84% had prior nephrectomy and most of the tumors were clear cell or showed a clear cell component (98%); 35%, 48% and 16% showed an ECOG PS of 0, 1 and 2 respectively; 48%, 27.5% and 24.5% were favorable, intermediate and poor risk, respectively, according to MSKCC criteria. 79% received sunitinib as a 1st line, 16% as a 2nd line and 5% in subsequent lines. 37% were treated only with Sunitinib (n = 38), 19% received 2 lines of treatment (n = 19), 26% 3 lines (n = 27) and 18% ⩾4 lines (n = 18), including sunitinib. 9 pts were rechallenge with sunitinib. 33% of pts were treated with a VEGF (vascular endothelial growth factor) inhibitor followed by a VEGF inhibitor (n = 34); 19% of pts (n = 19) received the sequence VEGF-mTOR inhibitors and 7% the sequence mTOR-VEGF inhibitors (n = 7). Sunitinib starting dose and schedule was 50 mg/day 4-wk-on-2-wk-off (4/2) in 75.5% of cases. 46.5% of pts experienced at least one dose reduction during sunitinib treatment. Median time of follow up was 19.32 months (m) (95% CI: 8.63–34.67). 93% of patients had discontinued sunitinib at the time of this analysis: 68% due to progressive disease and 19% due to toxicity. Best response: 5% complete response, 33% partial response and 38% stable disease (61% lasting >6 months). Median PFS was 9.5 m (95% CI: 6.73–12.21) in the favorable-intermediate risk group and 3.8 m (95% CI 1.4−6.2) in the poor risk group. Median OS for the favorable-intermediate risk group was 33.9 m (95% CI: 26.9–40.9) and 11.7 m (95% CI: 2.7–20.7) for the poor risk group. The 3 yrs OS rate was 22.6%. An exploratory analysis to evaluate the efficacy in terms of PFS and OS of different treatment sequences is underway.
Conclusion: The outcome of mRCC has improved markedly with targeted therapies. Multiples lines of treatment have increased survival to close to 3 years in patients with good-intermediate prognosis. Patients with poor prognosis also obtain a survival improvement when compared to historical data.
Conflict of interest: *Other substantive relationships: Mari Victoria Bolós and Andrea Viqueira are Pfizer employees*

2738 POSTER

Hand–foot syndrome (HFS), a potential biomarker of efficacy in patients (pts) with metastatic renal cell carcinoma (mRCC) treated with sunitinib (SU)

A. Bensalem[1], A. Ammari[2], A. Dahdouh[3], A. Saadi[3], K. Bouzid[4]. *[1]Chu Dr Benbadis Constantine Algeria, Chu Dr Benbadis Constantine, Cne, Algeria; [2]Chu Annaba, Medical Oncology, Annaba, Algeria; [3]Ehs Daksi, Urology, Constantine, Algeria; [4]Medical Oncology, Cpmc, Algiers, Algeria*

Background: HFS and related skin toxicities are common side effects of tyrosine kinase inhibitors such as SU, a multitargeted inhibitor of VEGF and PDGF receptors plus other receptor tyrosine kinases. In the treatment of naive mRCC pts, SU showed superior progression-free survival (PFS) and objective response rate (ORR) over interferon-alfa, with a median PFS of 11 mo and median overall survival (OS) of 26.4 mo, establishing SU as a reference standard of care (Motzer et al, 2009). In this analysis, correlations between SU-associated HFS and efficacy endpoints were investigated in mRCC pts from January 2009 to January 2011 in the first- and second-line treatment settings.
Methods: A total of 23 patients who received single-agent SU as 50 mg/d on a 4-week-on/2-week-off schedule (n = 17; 73.9%) or 37.5 mg (n = 6; 26%). Median PFS and OS were estimated and compared between pts with vs without HFS. Adverse events were recorded regularly.
Results: Of 23 pts, 9 (39%) developed any-grade HFS, compared with 14 (60.8%) who did not. Most HFS (58%) initially occurred during the first 3 treatment cycles. Pts who developed HFS had significantly better ORR (55% vs. 32%), PFS (12 vs. 8 mo), and OS (23 vs. 11 mo) than pts who did not develop HFS.
Conclusions: In mRCC pts, SU-associated HFS was significantly and independently associated with improved clinical outcomes. Overall, pts who did not develop HFS still had substantial benefit from SU. However, the presence of HFS identified a subset of pts that manifested highly favorable efficacy results with SU. This is suggesting that development of HFS may serve as a predictive biomarker of SU efficacy.
No conflict of interest.

2739 POSTER

SUVmax evaluated by FDG-PET/CT predict survival for patients with advanced renal cell carcinoma

N. Nakaigawa[1], M. Yao[1], U. Tateishi[2], K. Kobayashi[3], T. Kishida[4], K. Kondoh[1], K. Makiyama[1], T. Inoue[2], Y. Kubota[1]. *[1]Yokohama City University Graduate School of Medicine, Department of Urology, Yokohama, Japan; [2]Yokohama City University Graduate School of Medicine, Department of Radiology, Yokohama, Japan; [3]Yokosuka Kyosai Hospital, Department of Urology, Yokosuka, Japan; [4]Kanagawa Cancer Center, Department of Urology, Yokohama, Japan*

Background: Recently, various molecular targeting therapeutics were developed and improved the prognosis of patients with advanced renal cell carcinoma (RCC). When molecular targeting therapies have become the mainstay of treatment, assessment of the biological activity of cancer becomes important. Because the antitumor action of targeting therapeutics is not cytotoxic, like classical antitumor therapeutics, but rather cytostatic, suppressing biological activity by inhibiting critical biological pathways. ^{18}F-2-fluoro-2-deoxyglucose positron emission tomography (FDG PET/CT) is a useful non-invasive tool to evaluate glucose metabolic status, which can be the index of biological activity of cancer. We evaluated the impact of the maximum standardized uptake value (SUVmax) from pretreatment FDG PET/CT, which was a semiquantitative simplified measurement of the tissue FDG accumulation, on survival for patients with advanced RCC.
Material and Methods: A total of 71 patients with advanced RCC were enrolled in this study. The impact of pretreatment SUVmax from FDG PET/CT (Aquiduo 16; Toshiba Medical Systems, Tokyo, Japan) on patient survival was analyzed prospectively.
Results: The SUVmax of 71 patients ranged between undetectable level and 16.6 (median 8.1). The patients with RCC tumors showing high SUVmax demonstrated poor prognosis ((P<0.001 hazard ratio 1.289, 95% CI 1.161–1.430). The SUVmax of 36 patients (51%) were <7.0 and their median overall survival (OS) was 1218±248 days. The SUVmax of 24 patients (34%) were 7.0⩽and <12.0 and their median OS were 676±291 days. The SUVmax of 11 patients (15%) were 12.0⩽and their median OS were 129±43 days. The OS for these patient subgroups were statistically different (<7.0 vs. 7.0⩽<12.0: $P = 0.0257$, 7.0⩽<12.0 vs 12.0⩽: $P = 0.0181$).
Conclusions: The survival of patients with advanced RCC can be predicted by evaluating their pretreatment SUVmax using FDG-PET/CT. In the era of molecular targeting therapy, FDG-PET/CT has potency as an

'imaging biomarker' to provide helpful information for the clinical decision-making.
No conflict of interest.

Health-related quality of life among patients with metastatic renal cell carcinoma in daily clinical practice

P. Kellokumpu-Lehtinen[1], T. Purmonen[2], T. Turpeenniemi-Hujanen[3], A. Jekunen[4], T. Reunamo[5], N. Paunu[1], V. Kataja[6], H. Sintonen[7]. *[1]Tampere University Hospital, Department of Oncology, Tampere, Finland; [2]University of Eastern Finland, Kuopio, Finland; [3]Oulu University Hospital, Department of Oncology, Oulu, Finland; [4]Vaasa Central Hospital, Department of Oncology, Vaasa, Finland; [5]Turku University Central Hospital, Department of Oncology, Turku, Finland; [6]Kuopio University Hospital, Department of Oncology, Kuopio, Finland; [7]Helsinki University, Helsinki, Finland*

Background: Real-life data on mRCC patients' health-related quality of life (HRQoL) have not been available. It is recognized that the every-day patient population may differ from those in clinical trials. Sunitinib is normally administered in 6wk cycles including a 2wk rest period. Previous studies have indicated an improvement in the HRQoL during the 2 weeks off the treatment.
Materials and Methods: A prospective follow-up study of patients using sunitinib as the first line mRCC treatment (N = 54) was carried out. The data were collected in 5 oncology clinics in Finland. The patients were asked to fill in the generic 15D HRQoL questionnaire at baseline, at day 28 of the 1st sunitinib treatment cycle, 1st day of 2nd cycle, and thereafter in 3 month intervals. The 15D produces a HRQoL score on a 0−1 (dead-full health) scale. After exclusion due to missing HRQoL questionnaires, data from 49 patients were available for final analysis. The mean age among the responders was 65.3 years [range: 46.4–80.5], and 73% were men.
Results: At baseline the mRCC patients' mean 15D score was slightly lower than that of the age-standardized general population (0.854 vs. 0.865). The difference was neither statistically significant nor clinically important. The patients were statistically significantly worse off than the general population on the dimensions of usual activities, mental function, distress, and sexual activity. The mean 15D score declined from the baseline level by 0.040 when a full 28 days of sunitinib was administered (a statistically significant and clinically important decline), and returned back to the baseline level (0.860) after the 2 week rest period. The HRQoL fluctuated during later phases of treatment, but this was not clinically important in magnitude. No trend was observed between the time on sunitinib and HRQoL.
Conclusions: The 2wk rest period included in the 6wk treatment cycle is relevant from the perspective of patients' HRQoL. The decline in HRQoL during treatment days was clinically important and could be captured with the generic 15D instrument.
Conflict of interest: *Other substantive relationships: The data collection was partly supported by Pfizer*

Validation of imaging biomarker in multi-centric study to predict PFS in mRCC treated with sunitinib

N. Lassau[1], S. Taieb[2], J. Lacroix[3], R. Aziza[4], A. Sarran[5], F. Joly[6], C. Chevreau[7], S. Negrier[8], G. Gravis[9], B. Escudier[10]. *[1]Institut Gustave Roussy, Département d'Imagerie, Villejuif, France; [2]Centre Oscar Lambret, Imaging Department, Lille, France; [3]Centre François Baclesse, Imaging Department, Caen, France; [4]Centre claudius Regaud, Imaging Department, Toulouse, France; [5]Centre Paoli Calmettes, Imaging Department, Marseille, France; [6]Centre François Baclesse, Oncology Department, Caen, France; [7]Centre Claudius Regaud, Oncology Department, Toulouse, France; [8]Centre Leon Berard, Oncology Department, Lyon, France; [9]Centre Paoli Calmettes, Oncology Department, Marseille, France; [10]Institut Gustave Roussy, Oncology Department, Villejuif, France*

Background: Tyrosine kinase inhibitors including sunitinib are the most effective treatments of metastatic renal cell carcinoma (mRCC). A multi-centric study of 539 patients (different tumors treated anti-angiogenic treatments) evaluating dynamic contrast-enhanced ultrasound (DCE-US), showed that a decrease of AUC (Area under the curve) correlated to the blood volume at one month is predictive of response. Our objective was to validate the correlation between this parameter and the PFS in a sub-group of mRCC treated with Sunitinib.
Material and Methods: Each Patient had CT-scan every 2 months in order to evaluate the Response assessment using the Response Evaluation Criteria in Solid Tumors (RECIST 1.1).
DCE-US were performed at baseline and at D30. At each examination, we quantified 7 DCE-US parameters after bolus injection of contrast agent and mathematical modelization of raw linear data recorded during 3 minutes. We also estimated the variation between baseline and D30. The main endpoint was progression free survival assessed according to RECIST. We first selected the best parameters. We studied the trend between the parameter value and freedom from progression. After, the best cut-points were searched through a grid search. The best single cut-point was that with the lowest P-value for progression free survival. We performed this analysis in the sub-group of patients with mRCC treated with sunitinib.
Results: A total of 81 mRCC patients treated with sunitinib were selected. All had DCE-US at baseline and one month. The median of follow-up was 18 months. For DCE-US, the decrease of 90 % of AUC at D 30 was correlated to the PFS (p = 0.01). The difference of PFS between the groups defined by this cut-point was 4 months (bad responders) and 14 months (good responders).
Conclusions: The decrease of more than 90% of AUC with DCE-US at one month is a potential predictive biomarker of response in mRCC patients treated with sunitinib.
No conflict of interest.

Important differences for fatigue and quality of life questionnaires in advanced renal cell carcinoma patients

J. Beaumont[1], K. Kaiser[1], J. Diaz[2], F. Mehmud[3], D. Cella[1]. *[1]Northwestern University, Department of Medical Social Sciences, Chicago, USA; [2]GlaxoSmithKline Pharmaceuticals, Global Health Outcomes − Oncology, Uxbridge, United Kingdom; [3]GlaxoSmithKline Pharmaceuticals, Medical Affairs, Uxbridge, United Kingdom*

Background: The Functional Assessment of Chronic Illness Therapy − Fatigue (FACIT-F) is a widely used 13-item questionnaire assessing fatigue that is validated for use in the general population, cancer patients, and other chronic disease populations. Past analyses suggest 3−4 points constitute an important difference. A Supplementary Quality of Life Questionnaire (SQLQ) assessing mouth/throat, hand, and foot soreness and limitations due to soreness was created for use in PISCES, an ongoing trial in advanced renal cell carcinoma (RCC) patients (NCT01064310). The FACIT-F and SQLQ were administered at baseline and every 2 weeks thereafter. This project evaluates important differences on the FACIT-F and SQLQ in 168 advanced RCC patients enrolled in PISCES.
Material and Methods: We used distribution- and anchor-based approaches to estimate important differences. We compared baseline mean scores across levels of baseline ECOG performance status. Effect sizes (ES) were calculated as the mean group difference/pooled standard deviation (SD). Mean change from baseline to Week 8 was calculated for patient subgroups defined by worst fatigue (or hand–foot syndrome) adverse event (AE) grade during that period. ES was calculated as mean change/SD of change. Distribution-based measures, 1/3 SD and 1/2 SD, were also calculated at each assessment.

Table: Score changes by AE grade

Worst grade	N	Mean score change	ES
FACIT-F (fatigue grades)			
0	81	−0.52	−0.07
1	17	−4.68	−0.59
2	19	−9.21	−0.93
3	9	−10.22	−1.29
Limitations due to mouth and throat soreness (hand–foot syndrome grades)			
0	94	0.36	0.27
1	13	0.77	0.62
2−3	13	0.77	0.45
Limitations due to foot soreness (hand–foot syndrome grades)			
0	92	0.15	0.08
1	13	0.38	0.34
2−3	13	1.31	0.62

Results: ECOG 0 and 1 patients differed by 8.6 FACIT-F points (ES=1.06), 0.45 points for SQLQ limitations due to mouth/throat soreness (ES=0.45), and 0.94 points for limitations due to foot soreness (ES=0.48). Change for patients categorized by worst fatigue or hand–foot syndrome AE are summarized in the table. For the FACIT-F, 1/3−1/2 SD equaled 3−5.6 points, 0.3−1.0 points for limitations due to mouth/throat soreness, and 0.2−0.3 points for limitations due to foot soreness.
Conclusions: In advanced RCC patients, FACIT-F and SQLQ are valid and responsive measures. Group differences on clinical anchors range from small to large in magnitude, and are therefore often larger than one would

consider 'minimally' important. These results inform future judgments of the clinical relevance of group differences on these measures.

2743 POSTER

First-line treatment in the management of advanced renal cell carcinoma: Systematic review and network meta-analysis

J. Larkin[1], A. Paine[2], G. Foley[3], S.A. Mitchell[2], C. Chen[4]. *[1]Royal Marsden NHS Foundation Trust, London, United Kingdom; [2]Abacus International, Systematic Review, Bicester, United Kingdom; [3]Pfizer Ltd, Surrey, United Kingdom; [4]Pfizer Inc, New York, USA*

Background: A systematic review (SR) and network meta-analysis (NMA) were conducted to assess the efficacy and safety of first-line treatments for advanced renal cell carcinoma (RCC) building on previous published analyses.
Materials and Methods: Database searches (accessed November 2012) were conducted to systematically identify randomised controlled trials (RCTs) in the first-line treatment of RCC. Indirect comparisons using a fixed-effect Bayesian model were used to assess the relative effectiveness of treatments, reported as hazard ratio (HR) and 95% credible intervals (CrI). All eligible studies were included in the model to minimise the introduction of potential bias.
Results: Seventy-nine publications of 43 RCTs met the pre-specified criteria for inclusion in the SR. Hand-searching of conference proceedings identified efficacy results from three additional RCTs. Eight RCTs were eligible for inclusion in the basecase NMA. In terms of progression-free survival (PFS) sunitinib was superior compared with sorafenib, bevacizumab + IFN and temsirolimus + bevacizumab (see table). Sunitinib also showed benefit over pazopanib and tivozanib, though these results were not significant. Sensitivity analysis based on re-estimating the HR from one study was performed, which impacted the results of the NMA. A robust analysis of overall survival (OS) was not performed due to difficulties in identifying OS data for individual treatments when many results include post-study treatment.
Conclusions: Based on available comparative clinical trial data the analysis results suggest that sunitinib continues to be an important treatment option to extend PFS in the management of advanced RCC in the first-line setting. While results from the current analysis can guide clinicians regarding the relative efficacy of currently available treatments, the results should be interpreted with the following caveats. Due to the lack of individual patient level data it was difficult to test the validity of the proportional hazards assumption. Also, as each treatment pair is connected by just one study, the results can be sensitive to changes in a single trial result.

Treatment comparison [a]	Mean HR	Median HR	95% CrI
Sunitinib vs. Pazopanib	0.94	0.93	0.80–1.08
Sunitinib vs. Bevacizumab + IFN	0.79	0.78	0.64–0.96
Sunitinib vs. Sorafenib	0.57	0.56	0.40–0.78
Sunitinib vs. Tivozanib	0.76	0.74	0.48–1.13
Sunitinib vs. Temsirolimus + bevacizumab	0.74	0.73	0.56–0.96

[a] Results include independently assessed data (where available).

Prospective, multicenter and epidemiological study to determine prognostic factors in patients with renal cell carcinoma: A stroma-related SNP located at FGFR2 as a potential prognostic biomarker

M.J. Méndez-Vidal[1], N. Lainez[2], I. García-Carbonero[3], M.L. Gonzálvez[4], D. Castellano[5], E. Esteban[6], M.I. Sáez[7], Y. Martín[8], A. Viqueira[9], J. García-Foncillas[10]. *[1]Hospital Universitario Reina Sofía, Oncology, Córdoba, Spain; [2]Complejo Hospitalario de Navarra, Oncology, Pamplona, Spain; [3]Hospital Virgen de la Salud, Oncology, Toledo, Spain; [4]Hospital Clínico Universitario Virgen de la Arrixaca, Oncology, Murcia, Spain; [5]Hospital Universitario 12 de Octubre, Oncology, Madrid, Spain; [6]Hospital Universitario Central de Asturias, Oncology, Asturias, Spain; [7]Hospital Universitario Virgen de la Victoria, Oncology, Málaga, Spain; [8]Trial Form Support, Oncology, Madrid, Spain; [9]Pfizer Oncology, Oncology, Madrid, Spain; [10]Fundación Jiménez Díaz, Oncology, Madrid, Spain*

In renal cell carcinoma (RCC) the MSKCC criteria are the most widely used classification for stratifying patients (pts) into different risk categories. Although generated from pts treated with cytokines, this classification is still widely used in the era of molecular targeted therapy. Moreover, there is little information on non-clinical characteristics that might have a prognostic significance; recently the role of stroma has been reported as crucial to define the patient outcome. This study evaluates the role of the MSKCC prognostic classification in pts treated with targeted therapies and explores the prognostic potential of some molecular, genetic and stroma-associated biomarkers.
A prospective, observational and multicenter study in pts with treatment naive RCC was carried out. Baseline clinicopathological characteristics were recorded; a baseline blood sample was extracted from all pts in order to evaluate the molecular, genetic and stromal factors. The primary objective of the study was to identify the pre-treatment prognostic factors associated with progression free survival (PFS) in pts with RCC.
From May 2009 to September 2010, a total of 145 pts (137 evaluable) were included. Pts had a median age of 64 years, 65% were male, 72% had clear cell RCC and 75% had a prior nephrectomy. According to MSKCC criteria, 23% had a favorable prognosis, 56% an intermediate prognosis and 21% a poor prognosis. All pts were treated with targeted therapies: 71% with sunitinib, 23% with temsirolimus and 6% with sorafenib. Median PFS according to prognostic group were: not yet reached, 10.9 and 4.1 months for pts with good, intermediate and poor prognosis, respectively, with statistically significant differences between the 3 categories. In a multivariate analysis, non-clear histology, Karnofsky performance status and time from diagnosis to treatment were shown to be independent prognostic factors of poor PFS. Regarding stroma-associated factors, a SNP located at FGFR2 gene at position 906C>T (rs2981582) provides independent prognostic information identifying two clinical patterns ($p = 0.009$) regardless of other significant clinicopathological variables.
MSKCC criteria are still a valid tool for stratifying pts into prognostic categories. Additionally, non-clear histology, Karnofsky performance status, time from diagnosis to treatment and FGFR2 SNP at 906-nt (C>T) were shown to be independent prognostic factors that might be useful to classify pts with RCC.

2745 POSTER

Smoking habit and its impact on the efficacy and safety of sunitinib in metastatic renal cell carcinoma (mRCC) patients

A.L. Ruiz[1], B. Suárez[2], J. Llinares[2], E. Esteban[1]. *[1]Hospital Central de Asturias, Medical Oncology, Oviedo, Spain; [2]Trial Form Support, Oncology, Madrid, Spain*

Background: Sunitinib is a tyrosin kinase inhibitor with proven efficacy in mRCC. The impact of the smoking habit on the efficacy and safety of novel anti-angiogenic agents is not still clear.
Material and Methods: We conducted a retrospective analysis on 102 mRCC patients (pts) who received Sunitinib in a single Institution (Hospital Universitario Central de Asturias) with a high incidence of mRCC. The main objective of the study was to explore the impact of the smoking habit on treatment response in terms of progression free survival (PFS) and overall survival (OS).
Result: 42% of pts ($n = 43$) were never-smokers, 38% ($n = 39$) former-smokers and 20% ($n = 20$) current-smokers. Most of the pts showed clear cell tumors (83%) or with a clear cell component (15%). 74.5% ($n = 76$) of pts were male, median age was 62 (range 58−62).
Although different groups according to smoking habit were not well-balanced in terms of ECOG PS, prior nephrectomy, sites of metastatic

Table (abstract 2747): Clinical outcome by AUC_{study} threshold

	AUC_{study} threshold (ng·h/ml)							
	⩾200	<200	⩾300	<300	⩾400	<400	⩾273*	<273*
n	123	44	73	94	49	118	82	85
ORR	53%	34%	48%	48%	53%	46%	52%	44%
mPFS, mo	14.5	11.5	12.2	16.6	12.2	16.3	13.8	14.6
HR† (95% CI); *P*	0.719 (0.478–1.08); 0.111		1.1 (0.751–1.62); 0.621		1.01 (0.662–1.53); 0.975		0.94 (0.642–1.38); 0.751	

*Median AUC_{study}; †Hazard ratio ⩾ vs < threshold.

disease, MSKCC risk groups and number of patients under 1st line Sunitinib, these differences were not statistically significant.
Statistically significant differences in terms of PFS were found among never-smoker, former-smoker and current-smoker groups: a median PFS of 5.9 months (95%IC: 4.1 −7.65), 10.2 months (95%IC: 7.7–12.6) and 10.2 months (95%IC: 2.2 −18.1) $p < 0.05$ was found respectively. Although an improvement in PFS was found in those patients with any smoking history, a multivariant analysis doesn't confirm it as independent factor for achieving a longer PFS. Non significant differences in terms of clinical benefit rate (complete and partial responses+ disease stabilizations) were found among these groups: 69% in never-smoker and former-smoker groups and 85% in the current smoker one ($p = 0.286$).
At the time of the analysis 93% of pts had discontinued Sunitinib. Reasons for discontinuation were: progression disease (68%), toxicity (19%) and others (17%).
Incidence of adverse events (AEs) with Sunitinib was as expected, with asthenia, hand food syndrome and mucosal inflammation as main toxicities (more than 40% of patients). Incidence of most Sunitinib associated AEs was greater in patients with any smoking history, although these differences were not statistically significant.
Conclusions: Additional prospective studies in well-balanced populations of patients are required to confirm if the smoking habit really impacts on the efficacy and safety with anti-angiogenic agents in mRCC.
No conflict of interest.

2746 POSTER

Determination of chromosome aberration as a factor of prognosis in treatment of bilateral renal cell carcinoma

N. Rahimov[1], M.N. Tillyashaykhov[2]. *[1]Samarkand Medical Institute, Oncology, Samarkand, Uzbekistan; [2]Tashkent Medical Academy, Oncology, Tashkent, Uzbekistan*

Background: To study cytogenetic features of peripheral blood lymphocytes in patients with bilateral renal cell carcinoma (RCC) in order to determine the degree of tumor aggressiveness.
Material and Methods: The results of examination and treatment of 37 patients with bilateral RCC have been studied in urological departments National center of oncology, regional center of oncology. There were 23 (62.1%) males and 14 (37.9%) females. The age of patients ranged from 22 to 83 years, mean 59.5±4.2 years. In order to determine chromosome changes in peripheral blood lymphocytes metaphase plate were studied in the corporative aspect.
Result: Analysis of the research results according to the number of metaphase plate with aberrations showed that in patients with local bilateral RCC metaphase plate with single chromosome aberrations are revealed more often (in 91.7% of cases), metaphase plates with plural aberrations are revealed more seldom (in 8.3% of cases) differences are statistically reliable ($p < 0.05$).
In patients with primary generalized form of bilateral RCC metaphase plate with plural chromosome aberrations occur on the contrary more often (in 57.1% of cases) than single ones (in 42.9%of cases), differences are statistically reliable ($p < 0.05$).
Conclusion: Marked tumor aggressiveness and chromosome disturbances in peripheral blood lymphocytes are specific for patients with bilateral RCC. The study of genetic alterations in lymphocytes in bilateral RCC due to discovery of their qualitative and quantitative changes is the method of early diagnostics and screening for cancer and it probably reveals the cause of bilateral RCC.
No conflict of interest.

2747 POSTER

Randomised phase II trial of axitinib with or without dose titration in first-line metastatic renal cell carcinoma (mRCC): Efficacy and pharmacokinetic (PK) analyses

B.I. Rini[1], B. Melichar[2], T. Ueda[3], M.N. Fishman[4], Y. Pithavala[5], Y. Chen[5], G. Andrews[5], A.H. Bair[5], S. Kim[5], V. Grünwald[6]. *[1]Cleveland Clinic Taussig Cancer Institute, Department of Solid Tumor Oncology, Cleveland, USA; [2]Palacky University Hospital, Olomouc, Czech Republic; [3]Chiba Cancer Center, Urology, Chiba, Japan; [4]H. Lee Moffitt Cancer Center, Tampa, USA; [5]Pfizer Oncology, San Diego, USA; [6]Hannover Medical School, Hannover, Germany*

Background: Prior PK analyses suggest higher axitinib exposure correlates with efficacy in mRCC. Dose titration based on tolerability may optimise axitinib exposure and improve outcome.
Material and Methods: In a phase II trial (NCT00835978; sponsor: Pfizer), patients with treatment-naive mRCC received axitinib 5 mg BID for 4 wk (cycle 1). Patients with blood pressure ⩽150/90 mmHg, no axitinib-related toxicities grade >2, no dose reduction, and ⩽2 antihypertensive medications were randomised (double-blind) to axitinib 5 mg BID + dose titration to 10 mg BID maximum (n = 56) or placebo titration (n = 56). Those ineligible for randomisation continued ⩽5 mg BID (n = 91). Primary endpoint was objective response rate (ORR) in active vs placebo titration arms. Axitinib exposures (AUC 0−24 h) prior to randomisation (AUC_{cycle1}) and throughout treatment (AUC_{study}) were estimated by population PK analyses.
Results: ORR was significantly higher (1-sided *P*=.019) with active (54%) vs placebo (34%) titration. Patients eligible for dose titration had lower mean AUC_{cycle1} (active vs placebo titration: 248 vs 214 ng·h/ml) at 5 mg BID vs those not eligible (382 ng·h/ml). Mean AUC_{study} was 300 ng·h/ml with active titration, due to dose increases, and 207 ng·h/ml with placebo titration. Exploratory analyses indicated that progression-free survival (PFS) and AUC_{study} were not strongly correlated across the range of observed exposures. AUC_{study} thresholds (Table) showed the largest difference in ORR and PFS hazard ratio in patients ⩾ vs <200 ng·h/ml. When retrospectively grouped by AUC_{study} quartiles, patients in quartile 2 (199–272 ng·h/ml) had longer median PFS (mPFS; 22.2 mo) vs other quartiles (11.5–13.9 mo).
Conclusions: Axitinib titration significantly improved ORR vs placebo titration. Patients eligible for titration had lower AUC_{cycle1} at 5 mg BID, which increased with active titration, indicating the dose titration scheme identified patients with lower exposures at the starting dose. Results suggest PK is not the only driver of clinical outcome; pharmacodynamic and/or patient-specific factors likely contribute to axitinib efficacy in mRCC.

2748 POSTER

Long-term safety with sunitinib (SU) in metastatic renal cell carcinoma (mRCC)

C. Porta[1], M.E. Gore[2], B.I. Rini[3], B. Escudier[4], L.P. Charles[5], L. Chen[6], S. Hariharan[6], R.J. Motzer[7]. *[1]IRCCS San Matteo University Hospital, Medical Oncology, Pavia, Italy; [2]Royal Marsden Hospital NHS Trust, Medical Oncology, London, United Kingdom; [3]Cleveland Clinic Taussig Cancer Institute, Department of Solid Tumor Oncology, Cleveland, USA; [4]Institut Gustave Roussy, Medical Oncology, Villejuif, France; [5]Pfizer Oncology, Safety Surveillance and Risk Management, New York, USA; [6]Pfizer Oncology, Medical Oncology, New York, USA; [7]Memorial Sloan-Kettering Cancer Center, Genitourinary Oncology Service, New York, USA*

Background: SU is approved globally for mRCC. Here we report long-term safety with SU in mRCC patients (pts) using pooled data from 11 prospective clinical trials.
Material and Methods: Pts received SU 50 mg/d on a 4-wk-on/2-wk-off schedule or 37.5 mg/d continuous dosing. Three analyses of treatment-related adverse events (TRAEs) were conducted, both in pts on SU $\geqslant$2 y and in all pts: (1) interval analysis, in which AEs were evaluated over successive 6-month intervals, with each AE counted once per interval; (2) cumulative analysis, in which each successive interval was defined from the start of treatment plus an additional 6 months; and (3) time to onset of common TRAEs.
Results: At the data cutoff, 5,292 pts had received SU, including 189 (4%) for $\geqslant$2 y ('long-term' pts), whose mean treatment duration was 964 days. Among long-term pts, most AEs initially occurred in the first 6 mo to 1 y and were stable and/or decreased in frequency over time in the interval analysis (table), except for hypothyroidism. There were minor differences in AE patterns between long-term pts and all pts in the interval analysis; however, the cumulative analyses showed that new occurrences of AEs plateaued in both groups. Most common TRAEs occurred within the first 6 mo, except for hypothyroidism, for which median time to onset was 9.4 mo. Among long-term pts, most common grade $\geqslant$3 TRAEs, except leukopenia, were stable or decreased in frequency in the interval analysis. No new grade $\geqslant$3 TRAEs were reported in the cumulative analysis of long-term pts, and there were no clinically significant differences between the grade $\geqslant$3 TRAE profiles of long-term pts and all pts. Most cardiovascular TRAEs occurred during $\leqslant$1 y, with the most common, hypertension, reported within 3 mo. Among long-term pts, only one new cardiovascular TRAE was reported after 2 y, ventricular dilation.
Conclusions: Prolonged SU treatment was not associated with new types or increased severity of TRAEs in mRCC pts. Only hypothyroidism appeared to be cumulative and delayed, possibly due to increased awareness of this TRAE.

Table: Most common TRAEs in long-term pts by 6-mo interval (N = 189)

	0–<6 mo	6 mo–<1 y	1–<1.5 y	1.5–<2 y	2–<2.5 y	⩾2 y

A prospective phase II study of pemetrexed in combination with cisplatin in patients with advanced urothelial cancer: PECULIAR study

Y.J. Choi[1], J. Lee[2], J. Ahn[2], D.H. Lee[2], C. Song[3], B. Hong[3], J.H. Hong[3], C. Kim[3], H. Ahn[3]. *[1]Korea University Anam Hospital, Oncology, Seoul, South Korea; [2]Asan Medical Center University of Ulsan College of Medicine, Oncology, Seoul, South Korea; [3]Asan Medical Center University of Ulsan College of Medicine, Urology, Seoul, South Korea*

Background: Pemetrexed has demonstrated a favorable response at the rate of about 30% with minimal toxicity when used as single agent as first-line and second-line treatment for advanced urothelial carcinoma. This trial was performed to evaluate the efficacy and safety of pemetrexed plus cisplatin in advanced urothelial carcinoma.
Methods: Eligible criteria included chemotherapy-naive advanced urothelial carcinoma, ECOG PS 0−2 and measurable disease. Pemetrexed 500 mg/m^2 on day 1 with cisplatin 70 mg/m^2 on day 1 were administered every 3 weeks till disease progression or a maximal of 8 cycles. Primary endpoint was response rate (RR), and secondary endpoints were progression-free survival (PFS), overall survival (OS) and toxicities. Response was evaluated every 6 weeks according to the RECIST critieria v.1.0 and toxicities were assessed with NCI CTCAE v.3.0 (ClinicalTrials.gov identifier NCT01490437).
Results: At the time of this analysis, a total of 40 patients were enrolled and 34 patients (median age 66.5 years, ECOG 0−1 100%, visceral metastasis 70.6%) were evaluable; 6 patients were too early to assess. Two received one or fewer cycles leaving 32 evaluable for outcomes. Nineteen partial responses and five complete responses for an overall response rate of 75% [95% confidence interval (CI) 60.5–89.6%] were documented. Three patients had stable disease. The median PFS was estimated to be 7.0 months [95% CI 6.2−7.8 months]. The median OS was 14.4 months [95% CI 9.1–19.7 months]. The most common grade 3 or 4 toxicities were neutropenia in 35% of patients. No one experienced febrile neutropenia. Other grade 3 or 4 hematological and non-hematological toxicities were rarely observed (thrombocytopenia 6%, anemia 6%, LFT elevation 6%, nausea 3%, anorexia 3%, edema 3%, dyspnea 3%).
Conclusion: The combination of pemetrexed and cisplatin is clinically very active, with an overall response rate of 75% and well tolerated in patients with advanced urothelial cancer who have not been previously treated.
No conflict of interest.

2750 POSTER

Methods of immunocorrection as accompanying therapy in patients with ovarian and cervical cancer

S. Navruzov[1], D. Pulatov[2], S. Kamishov[2], L. Salimova[2]. *[1]National Cancer Center of Uzbekistan, Coloproctology, Tashkent, Uzbekistan; [2]National Cancer Center of Uzbekistan, Chemotherapy Department, Tashkent, Uzbekistan*

Background: Chemoradiation therapy in cancer patients often leads to immunosuppression, reflected in the inhibition of the cellular and humoral immunity, which leads to an increase in complications of the treatment. Modern methods allow immunocorrection greatly reduce the side effects of chemotherapy by increasing immunological reactivity.
Material and Methods: There were evaluated the results of treatment of 183 patients with cervical cancer and 97 patients with ovarian cancer of stages $T_{2-3}N_{0-2}M_0$. All patients with cervical cancer received concomitant radiotherapy in split course, systemic and intraarterial chemotherapy. Patients with ovarian cancer had a combined therapy, including chemotherapy (cisplatin and cyclophosphamide for 4−6courses), as well as surgical treatment. 87 (47.5%) patients with cervical cancer and 43 (44.3%) patients with ovarian cancer were treated by methods of immunotherapy. Methods of extracorporeal immunepharmacotherapy (EIPhT) was carried out by exfusion of 200–250 ml of autologous blood, incubation with thimalin a total dose of 30 mg (for 3treatments) followed by reinfusion of the conjugate. The method of intermittent plasma exchange included exfusion of 500–1000 ml autologous blood followed by centrifugation and incubated with thimalin.
Results: The severity of the general condition of patients on a scale of ECOG(WHO) in patients with plasma exchange followed by EIPhT was very minimal incomparison with other groups of patients. Patients with EIPhT without plasma exchange had significantly reduced indicator in comparison with patients without immunocorrective therapy. In the study of quality of life of patients after treatment, which was conducted according to the questionnaire SF-36showed that the scores of physical health component in patients with plasma exchange followed by EIPhT was 284.5$\pm$39.1, in patients with EIPhT without plasma exchange − 362.7$\pm$41.0, and in the control group − 162.4$\pm$30.2 ($p < 0.01$). The total score of mental health component in these groups of patients, respectively, amounted

to 258.5±43.8, 234.0±46.1 and 196.3±35.9($p < 0.01$). Chemoradiation therapy led to an acceleration of erythrocyte sedimentation rate (ESR) in patients, decreased number of erythrocytes, leukocytes, development of lymphopenia with a predominance of suppressor cells, there is marked increase in IgG. CD4/CD8 parameter decreased from 1.257±0.03 to 1.08±0.02 ($p < 0.05$). In evaluating the hematological parameters after EIPhT there is observed their positive trend with an increase in the number of erythrocytes and leukocytes, ESR is decreasing to 17.3±1.27 mm/h (at the level of 24.2±1.46 mm/h). At the same time patients had an increase in CD4/CD8 immunoregulatory index to1.38±0.01, reduced level of IgG and a decrease in disimmuneglobulinemia, some increase in the level of phagocytosis.

Conclusions: Studies have shown that the methods EIPhT are highly effective in reducing the side effects of chemotherapy and radiation in combined treatment of patients with cervical cancer and ovarian cancer of III stage by improving the blood, normalization of the immune system and improvement of the life quality of patients.

No conflict of interest.

2751 POSTER

Early results of a phase 2 study of neoadjuvant cisplatin and gemcitabine plus sorafenib (S-CG) for patients with muscle-invasive transitional cell carcinoma of the bladder (INT52/10, NCT01222676)

A. Necchi[1], E. Fina[2], P. Giannatempo[1], L. Mariani[3], N. Nicolai[4], D. Raggi[1], M. Maffezzini[4], M. Colecchia[5], V. Cappelletti[2], R. Salvioni[4].
[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Medical Oncology, Milan, Italy; [2]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Experimental Oncology, Milan, Italy; [3]Fondazione IRCCS Istituto Nazionale dei Tumori, Epidemiology and Trials Organization Unit, Milan, Italy; [4]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Surgery-Urology Unit, Milan, Italy; [5]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Pathology, Milan, Italy

Background: Despite surgery with curative intent, about 50% of patients (pts) with muscle-invasive transitional cell carcinoma of the bladder (MIBC) die for distant metastases. Improvements with neoadjuvant chemotherapy are still limited. A rationale exists for inhibiting the RAF/MEK/ERK pathway, the VEGFR1−3, and PDGFR in urothelial cancer. The S-CG combination is being investigated in an ongoing open-label, single-group, single-center, Phase 2 trial.

Methods: Chemonaive pts with T2−4N0 MIBC were given 4 cycles of cisplatin 70 mg/m^2 on day 1 and gemcitabine 1000 mg/m^2 on day 1 and 8, every 3 weeks. Sorafenib 400 mg q12 h was administered daily from day 1 until surgery (radical cystectomy). Pts were staged with computed tomography (CT) and positron emission tomography (PET)/CT scan at baseline and after treatment, and with CT after 2 cycles. An optimal 2-stage Simon's design is applied whereby 6 pathologic complete responses (pT0, primary endpoint) should be observed in 24 patients before moving to full enrollment of 45 cases. Residual carcinoma in situ with no evidence of concurrent invasive tumor (T1-T4) was considered as pT0. Intention-to-treat analysis was applied. 10 mL blood samples were collected at baseline and at each cycle for exploratory circulating tumor cell (CTC) analysis adapting the AdnaTest Prostate Cancer Select kit (AdnaGen®) and testing for gene expression of EPCAM and some other selected markers (5 ml blood) and for filtration on the ScreenCell®Cyto device (2x2.5 mL blood samples).

Results: 21 pts were enrolled from 04/11 to 03/13. Thus far, 17 completed the treatment and are evaluable. Median age was 61 yrs (IQR: 54−66). 11 had T2, 9 T3, and one a T4 disease. 6 pts had hydronephrosis at presentation. 15 pts underwent radical cystectomy. Six pts (35.3%, 95% CI: 14.2–61.7) had a pT0 and 3 pts a residual pT1. G1−2 hand–foot syndrome (HFS) occurred in 4 pts, rash in 2, and diarrhoea, increase of liver transaminases, fatigue and hypertension in one patient each. Grade 3 adverse events were thrombocytopenia in 7 pts (41.2%), fatigue in 2 pts (11.7%), HFS, anemia and hypertension in one pt each (5.8%).

CTC evaluations were carried out in 11 pts. The two methods used for CTC evaluation likely recognized different CTC populations and additional data are necessary to fully evaluate the correlation with clinical outcomes for each type of CTC measure. However, in 4 pts with pT<2 evaluable by the ScreenCell method (range 7−21 cells) a stepwise reduction prior to cystectomy was observed.

Conclusions: S-CG combination is tolerable and endowed of substantial antitumor activity that justifies full study enrollment in pts with muscle-invasive bladder cancer. Preliminary results on the contribution of sorafenib were obtained and warrant further investigation on a larger sample size. Mature results on the CTC and further biomarker analyses with longer follow up will be available in September 2013.

No conflict of interest.

2752 POSTER

Phase II study of dovitinib in first line metastatic or (non resectable primary) adrenocortical carcinoma (ACC) − SOGUG study 2011−03

J. Garcia-Donas[1], S. Hernando[2], M. Guix[3], M. Climent[4], M.J. Mendez[5], P. Jimenez[6], N. Lainez[7], L. Leon[8], D. Castellano[9], F. Moreno[10]. *[1]Centro Integral Oncologico Clara Campal, Oncology, Madrid, Spain; [2]Hospital Universitario Fundacion Alcorcon, Oncology, Madrid, Spain; [3]University Hospital del Mar-IMIM, Oncology, Barcelona, Spain; [4]Fundacion Instituto Valenciano de Oncología, Oncology, Valencia, Spain; [5]Hospital Reina Sofia, Oncology, Cordoba, Spain; [6]Hospital Universitario Central de Asturias, Oncology, Oviedo, Spain; [7]Complejo Hospitalario de Navarra, Oncology, Pamplona, Spain; [8]Complejo Hospitalario Universitario de Santiago, Oncology, Santiago de Compsotela, Spain; [9]University Hospital 12 de Octubre, Oncology, Madrid, Spain; [10]Hospital Clínico Universitario San Carlos, Oncology, Madrid, Spain*

Background: Dovitinib is a novel targeted therapy that inhibits the fribroblast growth factor receptor(FGFR). Preclinical studies have pointed to a major role of this pathway in adrenocortical carcinoma (ACC) thus we aimed to test its clinical efficacy in this tumor.

Methods: A phase II proof of concept trial was designed. Since this is an extremely infrequent disease sample size calculation was done taking as a basis the first stage of a two-stage Gehan model. Thus 15 patients needed to be included to show a treatment efficacy of at least 15% (probability of Type I error α = 0.05, power [1 − β] = 0.8). Main inclusion criteria was advanced non-resectable ACC, histologically confirmed, with no prior therapy other than mitotane. Primary endpoint was response rate (RR) by RECIST 1.1 assessed by an independent radiologist. Secondary endpoints included clinical benefit (RR plus stable disease), progression free (PFS) and overall survival (OS). Dovitinib was administered at 500 mg daily dose 5 days on 2 days off for 6 months. Continuation of therapy was permitted at physician criteria.

Results: From January 2012 to August 2012, 17 patients (5 male and 12 female) have been included in 7 institutions. Median age was 53 years (range 26−72); ECOG was 0−1 in 15 patients, 2 in one patient and N/A in one patient. 77 cycles, defined as one month on treatment, have been administered with dose reductions in 6 (7.8%). Grade 3−4 adverse events deemed as related to the drug were: rash (6%), asthenia (12%), diarrhea (6%), GGT elevation (18%), nausea (6%),hypertriglyceridemia (6%), hypertension (6%), hyperkalemia (6%). 13 patients withdrew treatment because of disease progression and 4 remain on dovitinib. No toxic death was reported. After a median follow-up of 5.2 months (range 2.27−9.7) no objective response has been observed. Median PFS was 1.8 months (95% CI [1.35–2.25]), median OS has not been reached and clinical benefit has been achieved in 30% of patients with long lasting stable disease (>6 months) in 23%.

Conclusions: Though no objective response was observed, a significant number of long lasting stabilizations have been achieved with an acceptable toxicity. These encouraging results and merit further study.

2753 POSTER

Phase II trial of bevacizumab and erlotinib in patients with advanced hereditary leiomyomatosis and renal cell cancer (HLRCC) or sporadic papillary renal cell carcinoma

L. Stamatakis[1], E.A. Singer[1], M.M. Siddiqui[1], B. Shuch[1], J.W. Nix[1], J.C. Friend[1], J.H. Shih[2], P.L. Choyke[3], W.M. Linehan[1], R. Srinivasan[1].
[1]National Institutes of Health/National Cancer Institute, Urologic Oncology Branch, Bethesda, USA; [2]National Institutes of Health/National Cancer Institute, Biometric Research Branch, Bethesda, USA; [3]National Institutes of Health/National Cancer Institute, Molecular Imaging Program, Bethesda, USA

Background: There are no standard systemic options for patients with advanced papillary renal cell carcinoma (pRCC). Hereditary Leiomyomatosis and Renal Cell Cancer (HLRCC) is a familial syndrome that results from germline mutations in the gene for the Krebs cycle enzyme fumarate hydratase and is associated with an aggressive variant of pRCC. Recognition of hypoxia inducible factor upregulation in HLRCC and reliance of these tumors on aerobic glycolysis suggests that therapy targeting these pathways may be beneficial in this population. Herein, we report interim results from an ongoing phase II trial of bevacizumab plus erlotinib in patients with advanced HLRCC-associated or sporadic pRCC (ClinicalTrials.gov Identifier: NCT01130519).

Materials and Methods: Subjects with advanced pRCC (Cohort 1 − HLRCC-associated; Cohort 2 − sporadic) were enrolled on an IRB-approved protocol for treatment with bevacizumab 10 mg/kg IV q2 weeks,

and erlotinib 150 mg daily until disease progression or unacceptable toxicity. Eligibility included ECOG performance status $\leqslant 2$ and no more than 2 prior VEGF-pathway antagonists. The primary endpoint was overall response rate (ORR) assessed by RECIST 1.1. Secondary endpoints included evaluation of progression-free survival (PFS) and disease control rate (DCR) at 24 weeks.
Results: To date, a total of 34 subjects have been enrolled, including 14 in cohort 1 and 20 in cohort 2. Sixteen subjects had received at least one prior systemic therapy. The majority of subjects (24/34, 70%) belonged to the MSKCC intermediate risk category. ORR was 32.4% (11/34) in the entire cohort with a DCR (PR plus SD at 24 weeks) of 64.7% (22/34); 6/14 (42.9%) with HLRCC and 5/20 (25.0%) with sporadic pRCC had a partial response, respectively. With a median follow-up of 10.7 months, median PFS was 10.5 months (95% CI, 7.4–18.6 months). Median PFS was not reached at the time of this analysis in cohort 1, and was 7.3 months in cohort 2; several durable responses were observed in both groups. Most adverse events (AEs) were grade 1−2, with the most frequent grade 3−4 AEs being hypertension (17.6%) and proteinuria (8.8%). One subject died of gastrointestinal hemorrhage, possibly related to bevacizumab.
Conclusions: The combination of bevacizumab and erlotinib demonstrates significant activity in patients with advanced pRCC, particularly in those with HLRCC, and is associated with an acceptable toxicity profile. This regimen should be evaluated further as a possible standard of care option in pRCC.
No conflict of interest.

2754 POSTER

Liver toxicity in patients with metastatic renal cell carcinoma treated with pazopanib therapy

L. Lim[1], J. Mathias[2], M. Lampron[3], M. Fehr[4], V. Gruenwald[5], M. Khan[6], S. Crabb[4], T. Choueiri[3], T. Powles[1], B. Rini[2]. *[1]Queen Mary University of London, Experimental Cancer Centre, London, United Kingdom; [2]Cleveland Clinic, Solid Tumour Oncology, Cleveland, USA; [3]Harvard Medical School, Solid Tumour Oncology, Boston, USA; [4]Southampton University, Medical Oncology, Southampton, United Kingdom; [5]Hannover Medical School, Clinic for Haematology Hemostasis Oncology and Stem Cell Transplantation, Hannover, Germany; [6]The Beatson Institute, Solid Tumour Oncology, Glasgow, United Kingdom*

Background: Pazopanib is a vegf tyrosine kinase inhibitor used in the treatmnet of metastatic renal cell carcinoma. It is associated with liver toxicity, athough timing, severity management and consequences of this toxicity is not known.
Material and Methods: Sequential patients who were treated with first line pazopanib for their metastatic renal cell cancer were identified from a prospective database. Four weekly liver monitoring occurred. Specific protocols for the management of grade 1−4 toxicity were followed. Toxicity was graded based on the clinical toxicity criteria (CTC) grading classificaion, but only patients who develped clinically significant grade 2 or more toxicity had a structured treatment interruption and dose reduction according to local policy.
Results: 125 patients were identified as having received pazopanib treatment as first line therapy between 2009–2012, 44 (35%) of whom developed clinically siginificant liver toxicity (grade 2 and above) as evidence by either a raise in bilirubin and alkaline transaminase levels [maximum CTC grade 2 = 16 (21%], 3 = 23 (31%), 4 = 5 (7%), 5 = 0 (0%). Maximum toxicity occurred a median 6.0 weeks after commencing therapy ((IQR 3.6–10.2 weeks). Resolution occured in all but 5 patients (grade 1 or less after stopping treatment for a median 2.0 weeks (IQR 1.0−4.0).
68% patients restarted pazopanib treatment, with 22% having a dose reduction. Recurrence of raised liver function occured in 27% of patients [maximum CTC grade 2 = 4 (18%), 3 = 2 (9%)].
114 patients progressed after 42 days, 44 patients (39%) had no liver toxicity, 29 (44%) patients developed grade 1 liver toxicity and 41 (36%) patients developed clinically significant liver toxicity (grade 2 and above). Patients who developed grade 1 liver toxicity had an improved progression free survival ($p = 0.011$, HR 0.43 (0.23–0.82), whereas patients who developed clinically significant liver toxicity had no significant survival benefit ($p = 0.459$, HR 0.81 (0.47–1.41).
Conclusions: Patients who developed only grade 1 liver toxicity was associated with an improved progression free survival, most likely secondary to the fact that these patients did not have any treatment interruptions or dose reductions.
Conflict of interest: *Corporate-sponsored research: GSK − Prof Tom Powles, Prof Brian Rini*

2755 POSTER

Treatment sequencing following first-line sunitinib in patients (pts) with advanced renal cell carcinoma (RCC)

M.E. Gore[1], T.E. Hutson[2], X. Lin[3], B. Korytowsky[4], M.J. Lechuga[5], E. Matczak[6], R.A. Figlin[7], R. Bukowski[8], R.J. Motzer[9]. *[1]Royal Marsden Hospital NHS Trust, Department of Medicine, London, United Kingdom; [2]Baylor Sammons Cancer Center-Texas Oncology PA, GU Oncology Program, Dallas, USA; [3]Pfizer Oncology, Biostatistics, La Jolla, USA; [4]Pfizer Global Pharmaceuticals, Oncology Health Economics Outcomes Research, New York, USA; [5]Pfizer Oncology, Medical Oncology, Milan, Italy; [6]Pfizer Oncology, Medical Oncology, New York, USA; [7]Cedars-Sinai Medical Center, Samuel Oschin Comprehensive Cancer Institute, Los Angeles, USA; [8]Cleveland Clinic Taussig Cancer Institute, Medical Oncology, Cleveland, USA; [9]Memorial Sloan-Kettering Cancer Center, Genitourinary Oncology Service, New York, USA*

Background: In a randomized phase III trial, sunitinib had superior progression-free survival over interferon-alfa (median, 11 vs. 5 mo; $P<0.001$) as first-line metastatic RCC therapy with a median overall survival (OS) of 26.4 mo (Motzer et al, 2009). In a randomized phase II study of advanced RCC pts, time to tumor progression was compared between sunitinib intermittent versus continuous daily dosing as first-line therapy (median, 9.9 vs. 7.1 mo; $P = 0.090$) and median OS was more than 23 mo in both arms (Motzer et al, 2012). Here we report a retrospective analysis of post-study treatment using pooled data from pts in both trials to determine the optimal treatment sequence following first-line sunitinib.
Material and Methods: Data were pooled from 213 treatment-naive advanced RCC pts who received sunitinib 50 mg/d on a 4-wk-on-2-wk-off schedule and any post-study treatment. Pts were divided into 4 groups based on the following post-study treatment regimens: (1) a single tyrosine kinase inhibitor (TKI; n = 129); (2) a single mammalian target of rapamycin (mTOR) inhibitor (n = 35); (3) multiple TKIs (n = 11); and (4) a combination of TKI/mTOR inhibitors (n = 38). Median OS was estimated by Kaplan–Meier method for each group with 95% confidence intervals (CIs) calculated.
Results: Baseline characteristics were similar in each group; median age ranged from 59−61 yr, 71−82% were male, and 82−97% were white. Post-study treatments used in each group were as follows: single TKI: sorafenib (57%) and sunitinib (43%); single mTOR inhibitor: sirolimus (43%), temsirolimus (37%), everolimus (20%), and SGN-75 (3%), a humanized anti-CD70 monoclonal antibody used in combination with mTOR inhibitors; multiple TKIs: sorafenib and sunitinib (both 100%); and TKI/mTOR inhibitors: sorafenib (82%), sunitinib (39%), sirolimus (58%), temsirolimus (29%), and everolimus (21%). Median OS (95% CI) in each group was as follows: single TKI: 32.2 mo (26.9–not reached); single mTOR inhibitor: 34.6 mo (22.3–39.0); multiple TKIs: 25.5 mo (20.2–45.3); and TKI/mTOR inhibitors: 32.9 mo (28.8–42.7).
Conclusions: In a subgroup analysis of sunitinib-treated pts with advanced RCC, post-study treatment with a single TKI or regimens containing mTOR inhibitors showed similar prolonged OS. Pts who received multiple TKIs appeared to have shorter OS; however, these findings require further investigation due to sample size limitations and potential differences in disease aggressiveness and/or durations of therapy.

2756 POSTER

Use of bisphophonates in combination with sunitinib in renal cell cancer patients with bone metastases from the Expanded Access Study

E. Vrdoljak[1], C. Szczylik[2], J. Mardiak[3], A. Sella[4], G. Kharkevich[5], S. Leyman[6], K. Zhang[7], L. Torday[8]. *[1]Clinical Hospital Split, Center of Oncology, Split, Croatia; [2]Department of Oncology Central Clinical Hospital, Military Institut of Medicine, Warsaw, Poland; [3]National Cancer Institute, Department of Medical Oncology, Bratislava, Slovak Republic; [4]Asaf Harofeh Center Zerefin, Department of Oncology, Tel Aviv, Israel; [5]NN Blokhin Russian Cancer Research Center, Biotherapy Department, Moscow, Russian Federation; [6]Pfizer Inc, Brussels, Belgium; [7]Pfizer Inc, La Jolla, USA; [8]Albert Szent-Gyorgyi Medical University, Department of Pharmacology, Szeged, Hungary*

Background: Evidence suggests that bone metastases in metastatic renal cell cancer (mRCC) patients are a negative prognostic factor for survival and a negative predictive factor on the outcome of VEGF-targeted therapy (TKI). Common practice in these patients is bone-directed therapy with bisphosphonates (BPS) that showed a potentially synergistic effect with TKIs. More osteonecrosis of the jaw (ONJ) was reported when combining TKIs and BPS.
Materials and Methods: This retrospective study investigated the clinical effects of BPS in sunitinib treated mRCC patients with bone metastases. Patients enrolled into the sunitinib expanded access protocol were divided into 3 groups: those with bone metastases without BPS (group 1, n = 1147) or with BPS (group 2, n = 446) and those without bone metastases nor BPS (group 3, n = 2817).
Results: The groups were well balanced in terms of age, sex, histology, cancer surgery, sunitinib exposure and dose reductions. Group 2 seemed to have more advanced disease and be more heavily pretreated. The median overall survival (OS) of group 1 and 2 was 14.1 months (95% CI; 12.1, 15.6) and 12.9 months (95% CI; 11.4, 15.0) respectively. In a univariate analysis the hazard ratio (HR) for OS was 1.2243 (p = 0.0025) favoring group 1 over group 2. However, when adjusted for covariates like age, histology, prior cytokines, prior angiogenic therapy and MSKCC risk in a Cox Proportional Hazards analysis the results were not statistically significant (HR 1.132, p = 0.082). Group 3 showed superior OS over group 1, namely 22 months (95% CI; 20.8, 23.5) vs 14.1 months (95% CI; 12.1, 15.6). Univariate analysis showed HR = 0.7004 (p < 0.0001). This statistically significant difference was maintained in a multivariate analysis with a HR = 0.841 (p value <0.001).
The percentage of patients with ⩾1 adverse event or ⩾1 serious adverse event was similar between group1 and group 2. ONJ was reported in 18 (4%) patients in group 2 and 2 (<1%) in group 1.
Conclusion: Our study shows that having bone metastases is a predictor for worse clinical outcome. BPS treated mRCC patients with bone metastases had inferior OS in a univariate analysis compared to patients with bone metastases without BPS. When adjusted for covariates there was no statistical difference.

2757 POSTER

Adverse events among patients treated for metastatic renal cell carcinoma (mRCC): Data from a real world, multicenter registry

B. Hirsch[1], M.R. Harrison[2], M.S. Walker[3], L. Roe[1], C. Chen[4], B. Korytowsky[4], E.J. Stepanski[3], D.J. George[2], A.P. Abernethy[1]. *[1]Duke University, Duke Clinical Research Institute, Durham NC, USA; [2]Duke University, Duke Cancer Institute, Durham NC, USA; [3]ACORN Research, Memphis TN, USA; [4]Pfizer, New York NY, USA*

Background: Data on the experience and rate of adverse events (AEs) among mRCC patients treated in routine practice (RP) are lacking. It is postulated that AEs in randomized clinical trials (RCTs) may vary considerably from those in RP. Data on these differences are critical to understanding and optimizing care delivery.
Methods: A retrospective, multicenter registry of mRCC patients treated in RP in the U.S. was developed between academic (Duke) and community (ACORN) partners. Data were collected on 466 patients between 2007–2011. 270 patients received 1st line sunitinib (SU), 53 sorafenib (SO), and 25 pazopanib (PA). AEs meeting the threshold of identification in the medical record (MR) were abstracted. Rates of AEs occurring in >10% of patients were contrasted with all grades of AEs reported on the package insert (PI), focusing on SU in 1st line therapy because of the large number of patients who received it.
Results: The AEs identified in the MR are reported in the Table. For some AEs the event rates were consistent between the MR and all grade AEs on the SU PI including fatigue (56% in MR vs 62% in PI), vomiting (42% vs 39%), and hand foot syndrome (24% vs 29%), while others varied widely such as diarrhea (37% vs 66%), mucositis (26% vs 47%), and hypertension (18% vs 34%). Variations were also noted between alternative first line agents and respective PIs.
Conclusions: These data shine light on the patient experience in RP. There are multiple potential explanations for the variations seen between RP and the PI including inconsistent clinician reporting of AEs, differences in dosing and real world management of AEs, and variations in patient populations between RP and RCTs. As these data reveal, we must first understand patterns of AEs in RP and their real-world clinical management, in order to provide guidance and optimize care. Prospective capture of AEs in RP is a critical first step.
Conflict of interest: *Corporate-sponsored research: Pfizer, Novartis, Bristol-Myers Squibb, Exelixis, Prometheus, Bayer, Genentech/Roche, AVEO, Astellas, Alexion, Amgen, Biovex, DARA. Other substantive relationships: Pfizer (employees)*

Adverse events (AEs) by age: data from a real world, multicenter registry of patients treated for metastatic renal cell carcinoma (mRCC)

M. Harrison[1], B.R. Hirsch[2], M.S. Walker[3], L. Roe[2], C. Chen[4], B. Korytowsky[4], E. Stepanski[3], D.J. George[1], A.P. Abernethy[2]. *[1]Duke University, Duke Cancer Institute, Durham NC, USA; [2]Duke University, Duke Clinical Research Institute, Durham NC, USA; [3]ACORN Research, Memphis, USA; [4]Pfizer Inc., New York, USA*

Background: There is no data on the experience of elderly patients (⩾65 yrs) treated with targeted therapies for mRCC in routine practice (RP) across multiple treatment lines. Patients in randomized clinical trials (RCTs) are younger than patients who do not go on RCTs and may experience different rates of AEs. Do AEs vary by age in RP?
Material and Methods: A retrospective, multicenter registry of mRCC patients treated in RP was developed between academic (Duke) and community (ACORN) partners. Treatment data was collected on 462 patients who received systemic therapy for mRCC from 2007–2011. AEs across 3 lines of therapy deemed clinically significant were abstracted from the medical record and broken down by age (<65 or ⩾65 yrs), organ system class, and AE term. P values were calculated using the Fisher Exact test.
Results: There was no difference (P = 0.39) in the fraction of patients with ⩾1 AE between those <65 (n = 242, 90.6%) and ⩾65 yrs (n = 182, 93.3%). However, there were significant differences between age groups for some organ systems, with the <65 group having higher AE rates in these systems (Table). AE numbers were small.

Table: Significantly different AEs by age group

Organ system (n)	Lines 1, 2, and 3		
	Age <65 (%)	Age ⩾65 (%)	P value
Skin (207)	50	38	P = 0.004
Nervous system (64)	17	10	P = 0.035
Respiratory (52)	37	15	P = 0.009
Musculoskeletal (43)	9	4	P = 0.002
Endocrine (16)	5	2	P = 0.045
Hepatobiliary (9)	3	0.5	P = 0.029

Conclusions: These data provide reassurance that elderly patients do not experience more AEs in RP. Although overall frequency of AEs was not significantly different by age group (<65 or ⩾65), the <65 group had

increased rates of AEs in several organ systems. Since toxicity may be a surrogate for dose intensity, we hypothesize that elderly patients may be subject to lower dose intensity; the <65 group may also have been preferentially selected as 'healthier' individuals, thereby better tolerating therapy. Limitations include the retrospective approach and physician reporting of AEs. A strength is the real world population (vs RCTs). Prospectively captured patient reported outcomes in addition to physician-assessed AEs are needed improve understanding of the patient experience in RP.

Impact of antiangiogenic treatment on cognitive functions and fatigue in metastatic renal cancer patients

F. Joly[1], S. Noal[2], N. Heutte[3], I. Léger[4], B. Duclos[5], M. Lange[6], N. Longato[7], S. Dauchy[8], B. Clarisse[9], B. Escudier[10]. *[1]Centre Francois Baclesse, Unité de Recherche clinique Centre François Baclesse Département d'Oncologie Méd, France; [2]Centre Francois Baclesse, Unité de Recherche clinique Centre François Baclesse Département d'Oncologie Médicale Centre François Baclesse, Caen Cedex 5, France; [3]Centre Francois Baclesse, Unité de Recherche clinique Centre François Baclesse Equipe "Cancers et populations", Caen Cedex 5, France; [4]Institut Gustave Roussy, Département de Psycho-oncologie, Villejuif, France; [5]Hôpitaux Universitaires, Département d'Hématologie et d'Oncologie, Strasbourg, France; [6]Centre François Baclesse, Unité de Recherche Clinique Centre François Baclesse Equipe "Cancers et populations" ERI3 INSERM UFR de Médecine Université de Caen Basse-Normandie Caen, Caen cedex 5, France; [7]Hôpitaux Universitaires, Département de Neurologie, Strasbourg, France; [8]Institut Gustave Roussy, Département de Psycho-Oncologie, Villejuif, France; [9]Centre François Baclesse, Unité de Recherche Clinique Centre François Baclesse, Caen, France; [10]Institut Gustave Roussy, Département d'Oncologie Médicale, Villejuif, France*

Purpose: Antiangiogenic treatments (AT) are currently standard in metastatic renal cancer (mRCC). Although these therapies improve outcome, they can induce some important, but commonly underreported adverse effects such as fatigue, concentration and attention disorders. Our goal was to assess the incidence of cognitive impairments and severe fatigue induced by AT and their evolution over time.

Methods: mRCC patients starting AT were eligible. Episodic, working memory, executive functions, information processing speed, cognitive complaint, anxiety, depression and fatigue were assessed with neuropsychological tests and self-reported questionnaires before AT(T0), 3 and 6 months later (T3, T6). Cognitive impairment was defined as a score <1.5 standard deviation (SD) of normative data on $\geqslant$2 tests, or <2 SDs on $\geqslant$1 test. Severe fatigue was defined if at least one score was $\geqslant$40 at the MFI20. Levels of hormones dosage, albuminemia, hemoglobinemia, CRP and cytokines were correlated with cognitive impairment and fatigue.

Results: Results concern 75 patients (63$\pm$10 years): males/females were 49/26 and 80% of the patients had good and intermediate prognostic. Brain imaging was normal in all the patients. A majority of patients received sunitinib (41 patients, 75%), and most of them were enrolled during first line treatment (55 patients,73%). At baseline, 38 (51%) patients had cognitive disorders (episodic memory and executive functions mainly impaired), independent from the line of treatment. Severe fatigue was expressed in 45 patients (67%). Only 3 and 1 patients experienced anxiety and depression, respectively.

Among the 58 patients with evaluations at T0 and T3 or T6, 18 (31%) had $\geqslant$1 domain of cognitive functions that became pathological over AT (mainly executive functions and episodic memory). Among these 18 patients, 13 (72%) had no initial cognitive disorder. Severe fatigue appeared in 41% of patients and an increase of fatigue was observed in 50% of patients with initial severe fatigue. Cognitive complaint was not related to objective cognitive performances but was associated to fatigue. Correlations with biologic parameters will be presented at the meeting.

Conclusions: Our study is the first to prospectively describe the incidence of both cognitive impairments and fatigue and their deterioration over AT. More than half of mRCC patients report cognitive impairments and severe fatigue before AT. In addition, AT induces cognitive decline and severe fatigue.

No conflict of interest.

Metastatic chromophobe renal cell carcinoma: Outcome with targeted agents

E. Colomba[1], L. Albiges[1], C. Saldana[2], G. Verhoest[3], E. Vauléon[4], P. Bigot[5], S. Lheureux[6], J. Berger[7], P. Barthelemy[8], B. Escudier[1]. *[1]Institut Gustave Roussy, Cancer Medicine, Villejuif, France; [2]Hôpital Henri Mondor, Medical Oncology, Creteil, France; [3]CHU de Rennes, Urology, Rennes, France; [4]Centre Eugène Marquis, Medical Oncology, Rennes, France; [5]CHU d'Angers, Urology, Angers, France; [6]Centre François Baclesse, Medical Oncology, Caen, France; [7]CHU Dupuytren, Urology, Limoges, France; [8]CHRU de Strasbourg, Medical Oncology, Strasbourg, France*

Introduction: Chromophobe renal cell carcinomas (ChRCC) represent less than 5% of all RCC, and are commonly excluded from large clinical trials. Localized ChRCC have been communly reported to be associated with better outcome and a lower risk of metastases compared to clear cell RCC. However, little is known about the outcome of metastatic ChRCC in the era of targeted therapies.

Patients and Methods: A retrospective analysis performed amongst the French Kidney Group and the GETUG group was conducted to establish a clinical database of metastatic ChRCC. Data recorded included date of diagnosis, age at diagnosis, sex, date of first metastases, number and location of metastatic sites, prognostic factors, systemic and focal treatments performed and associated response.

Results: We report the preliminary results of 23 patients treated between 2005 and 2013 centers. Median age at diagnosis was 55. 3 years (24−78), with a majority of men (60%). Most of patients had nephrectomy (83%) and only 8/23 (35%) had synchronous disease; in overall population median time from diagnosis to metastasis was 25.6 months (range 0–122). Number of metastatic sites in the metastatic setting was >1 in 74 % of the patients, abdominal lymph nodes being the most common site of metastasis (70%), while lung (39%) and (35%) liver metastases, appeared to be less common than in ccRCC. Overall survival (OS) for the entire population from metastatic disease was 28.8 months. Median follow up for entire population was 3.7 years [0.3–12.4]. Nine patients received VEGFR TKI as first line (7 sunitinib, 2 sorafenib) with a medain PFS of 9.2 months; 6 patients received mTOR inhibitors (5 temsirolimus, 1 everolimus) with a median PFS of 8.1 months. Four patients received different therapy (roferon, vinfluinine, IFbevacizumab and bevacizumab alone). Eleven patients received second line (5 TKI, 3 mTOR inhibitors, 3 another therapy), and three received a third line. Interestingly, first line systemic therapy could be delayed more than 6 months in 7/19 pts (37%) thanks to focal treatment such as metastasectomy.

Conclusion: Metastatic ChRCCs is a rare situation and prognosis as well as specific therapeutic results in the era of targeted therapies remain scarce. We report the largest cohort of mChRCC to date and investigate PFS and OS with VEGFR-TKI and mTOR inhibitors treatments.

What is the best treatment option for second-line in long-responders to the first line TKI in metastatic renal cell carcinoma (mRCC) patients (pts): TKI-TKI or TKI-mTORi? Final results of a European retrospective study

R.T. Elaidi[1], A.H. Harbaoui[2], B. Beuselinck[3], J.C. Eymard[4], A. Bamias[5], E. De Guillebon[6], C. Porta[7], C. Linassier[8], P. Debruyne[9], S. Oudard[10]. *[1]Association ARTIC, HEGP Medical Oncology, Paris, France; [2]Hôpital Saint André. CHU de Bordeaux, Medical Oncology, Bordeaux, France; [3]UZ Leuven, Medical Oncology, Leuven, Belgium; [4]CLCC Reims, Medical Oncology, Reims, France; [5]University Hospital of Athens, Medical Oncology, Athens, Greece; [6]CH Poitiers, Medical Oncology, Poitiers, France; [7]San Matteo University Hospital, Medical Oncology, Pavia, Italy; [8]CHU Tours, Medical Oncology, Tours, France; [9]AZ Groeninge Hospital in Kortrijk, Medical Oncology, Kortrijk, Belgium; [10]European Georges Pompidou Hospital, Medical Oncology, Paris, France*

Background: Benefit of a TKI rechallenge versus switch to an mTOR inhibitor (mTORi) in mRCC pts who responded to a previous line of TKI is still debated. We report final results of a multicenter retrospective study.

Methods: This study retrospectively investigated Progression Free Survival and Time to Treatment Failure (PFS/TTF) in mRCC pts treated with sequence TKI-TKI or TKI-mTORi. Eligibility criteria: TKI in 1st line (L1)

followed by TKI or mTORi in 2nd line (L2), ongoing L2>6m. Prior L1 immunotherapy was allowed but no L1-L2 intermediate line (any drug). Pts characteristics and MSKCC/Heng risk group (RG) were collected at L1 L2 initiation. Long Response was defined as PFS/TTF>6m with objective response upon RECIST (OR) =SD/PR/CR. L2 PFS/TTF was analyzed with time to event and categorical analysis of L1 PFS/TTF at 6−12, 12−18, 18−24, 24−36, >36m. Cox model covariates: center, age, RG, Fuhrman, number of metastatic sites, presence of bone mets, L1 PFS/TTF, prior L1 and L2 ECOG, L1 best OR, interaction L2 therapy X prior L2 RG. Model was subject to sensitivity analysis (SA) with C-index (Ci) at cut-off 6, 12, 18, 24 and 36m. Analysis was performed both with case deletion and multiple imputations to deal with RG related missing data. Corrections for multiple testing were applied.
Results: Data for 313 pts from 10 European centers were collected and 242 were eligible. L2 therapy: 118 pts received a TKI and 123 a mTORi. Prior L2 Favorable + Intermediate RG (MSKCC): TKI=70%, mTORi=54%. Median L2 PFS (m, 95% CI): TKI=7.4 (5.5−9.5), mTORi=5.3 (3.8−6.5). Benefit of a 2nd TKI vs mTORi increased with L1 TKI PFS/TTF (p = 0.02, Mann-Whitney), largest difference being observed for L1=12−18m interval. Despite prior L2 unbalanced RG, interaction RG x L2 therapy was not significant. Among all covariates, only L2 therapy and prior L2 ECOG were predictive factors for PFS/TTF: HR (TKI/mTORi)=0.64 (0.45–0.90) and 0.62 (0.45–0.85) for PFS and TTF, respectively; stratified HR across 6−12, 12−18, 18−24, 24−36, >36 =0.55 (0.38–0.81) and 0.55 (0.39–0.77) for PFS and TTF. SA(TTF): HR L2 therapy(Ci): 12m=0.65(0.67), 18m=0.54(0.69), >18m=NS.
Conclusions: These results suggest a benefit of TKI rechallenge in patients with long response to a 1st line TKI.
No conflict of interest.

2762 POSTER

DILIGENCE-1: Dovitinib in 1st-line renal cell carcinoma, an investigation into tumour gene status and correlation with efficacy − 1st exploratory study

R. Broom[1], S. Duffey[1], K. Thompson[1], C. Fraser-Browne[1], G. Wilson[1], F. Hanning[1], L.J. Zwi[2], G. Dranitsaris[3], P. Oei[4], P. Fong[1]. *[1]Auckland City Hospital, Medical Oncology, Auckland, New Zealand; [2]Auckland City Hospital, Anatomical Pathology, Auckland, New Zealand; [3]Consultant, Statistics, Toronto, Canada; [4]IGENZ Ltd., Cytogenetics, Auckland, New Zealand*

Background: Dovitinib is a multi-targeted tyrosine kinase inhibitor which, in addition to VEGFR blockade, also has affinity to FGFR-1,-2,-3 and PDGFRβ. We sought to evaluate the activity of dovitinib as first-line therapy in patients with metastatic clear-cell renal cell carcinoma (mCCRCC) and correlate this activity with the status of genes relevant to its mechanism-of-action.
Material and Methods: 30 treatment-naive patients with mCCRCC have enrolled in this single-arm, single-site, phase II study (DILIGENCE-1, ACTRN12612000140853, sponsor Auckland City Hospital). Dovitinib was administered at 500 mg 5 days on/2 days off until progression. An optional post-treatment biopsy is also being offered to patients. The primary endpoint is PFS using RECIST 1.1. Secondary endpoints include response rate (RR) and efficacy by FGFR gene status (FISH and DNA sequence using Sequenom ® OncoCarta™ panel) by Spearman's rho correlation coefficient.
Results: The 1st patient was enrolled in March 2012 and the 30th in February 2013. Median patient age was 64 years and 72% were male. ECOG PS was 0 in 45% and 1 in 55%. Heng prognostic group was in favourable-risk in 38%, intermediate-risk in 52% and poor-risk in 10%. 38% of subjects had bone metastases (an adverse prognostic feature). Four patients discontinued treatment because of toxicity and one further patient was withdrawn (investigator decision), therefore target accrual was increased to 31 patients and is expected to be complete by May 2013. 93%, 59% and 51% of study patients have tumour tissue available for analysis from primary, metastatic and both sites respectively. As of April 2013, 15 primary and 12 metastatic pre-treatment samples have been assessed for FGFR gene status by FISH. Samples from16% of patients showed FGFR-1 or −3 amplification (when defined as a target:control >2.0 and FGFR copy number >6) and 21% showed loss of FGFR-1. Discordance in FGFR-1 status between primary and metastatic samples was seen in 3 patients (of 7 matched pairs). Polysomy for FGFR was also frequently seen, especially for FGFR-3.
Conclusions: 30 patients with mCCRCC have been treated 1st-line with dovitinib. Abnormal FGFR-1 and −3 gene status has been seen in a reasonable proportion of tumour samples and analysis continues. RR and correlational data with gene status including PDGF/PDGFRβ will be presented.

2763 POSTER

Clinical practice outcomes of patients treated with pazopanib for metastatic renal cell cancer (mRCC) − 6 year experience at a referral centre in Manchester, UK

V. Galvis[1], S. Chow[2], F.C. Thistlethwaite[2], D. Lawrence[2], R.E. Hawkins[2]. *[1]Christie Hospital NHS Foundation Trust, Manchester, United Kingdom; [2]Christie Hospital NHS Foundation Trust, Medical Oncology, Manchester, United Kingdom*

Background: Pazopanib is the most recently licensed first-line therapy for patients with mRCC. While there is good evidence of the efficacy and safety of Pazopanib within clinical trials, there is little evidence of treatment outcomes among the wider population. Here we characterize and present the outcomes of Pazopanib treated patients in routine clinical practice.
Methods: We identified 104 patients who commenced treatment with Pazopanib within the licensed indications from July 2006 to October 2012 with follow up to January 2013. The demographic data was extracted from the Christie kidney cancer database and clinical information was obtained from the patient's records. No patient was lost to follow-up. We explored the clinical features of the patients who receive this treatment. Median OS and PFS were estimated using the Kaplan–Meier method.
Results: 23% of patients were 75 years or older (range 42−87 median 66), 60% male and 29% performance status of 2 or more. A high proportion of patients had metastatic sites carrying an adverse prognosis at start of treatment (7% brain, 22% liver, and 25% bone metastases; half of these were spinal) and significant co-morbidities were frequent (13% mild, 22% moderate, 27% severe according to the ACE 27 Comorbidity Index), 69% had a Nephrectomy. All patients experienced side effects from treatment but 16 patients (15%) discontinued Pazopanib as a result of treatment toxicity. There was no statistical difference in the discontinuation rate due to toxicity in the different prognostic groups.
Table 1 shows the efficacy outcomes by MSKCC and Heng prognostic factors.

Table 1.

	%	PFS (mo)	OS (mo)
All Patients		13	19
MSKCC (ver 2)			
Favorable	19	NR*	25
Intermediate	63	12	17
Poor	18	6	6
Heng			
Favorable	17	NR	NR
Intermediate	51	12	25
Poor	32	6	7

*NR, Not Reached.

Conclusions: The population treated reflects the nature of patients with mRCC (often frail, elderly and with comorbidities) but these poorer prognosis groups tend to be under-represented in clinical trials. The patients that we see in clinical practice are challenging not only due to disease burden but due to existing severe pre-existing ilnesses, altough this is a familiar problem to the clinicians it is not often explored in the literature, often these patients are ofered Pazopanib as first line treatment due to the toxicity profile reported in large trials.
It was therefore encouraging that OS and PFS for the favorable/intermediate prognostic groups were similar to that reported in trials. Whilst the PFS in patients with poor prognosis is short, a proportion of patients appeared to benefit from Pazopanib; it was encouraging to see that treatment was generally well tolerated with rate of discontinuation due to toxicity not being different from the trial population.
No conflict of interest.

2764 POSTER

Pre-treatment neutrophil to lymphocyte ratio as an independent prognostic factor in patients with advanced urothelial cancer

L. Rossi[1], M. Santoni[2], E. Scarpi[3], L. Burattini[2], E. Bianchi[1], A. Savini[2], R. Berardi[2], D. Amadori[1], S. Cascinu[2], U. De Giorgi[1]. *[1]IRCCS Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (I.R.S.T.), Medical Oncology, Meldola, Italy; [2]Ospedali Riuniti-Università Politecnica delle Marche, Medical Oncology, Ancona, Italy; [3]IRCCS Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (I.R.S.T.), Biostatistics Unit, Meldola, Italy*

Background: Increased pre-treatment neutrophil to lymphocyte ratio (NLR), an index of systemic inflammation, is associated with poor outcome

for various types of cancers. We aimed to assess the association between pre-treatment NLR and progression free survival (PFS) and overall survival (OS) of patients with advanced urothelial cancer (UC) treated with first-line chemotherapy.
Materials and Methods: We retrospectively reviewed the records of 149 patients with advanced UC treated with first-line chemotherapy between January 2003 and December 2012 in our two Institutions. The NLR cut-off value was defined as ⩽3 (group 1) vs >3 (group 2). PFS and OS were estimated using Kaplan–Meier method. After univariate analysis a multivariate analysis was carried out by Cox regression model and included the following variables: Eastern Cooperative Oncology Group (ECOG) performance status (⩾2 vs 0−1), visceral disease (present vs absent), hemoglobin (<12 g/dL vs. ⩾12 g/dL), and NLR (>3 vs ⩽3).
Results: The median age was 68.8 years (range, 46.9–86.6) and 124 (83.2%) were male. The primary site was bladder in 123 cases (82.6%), renal pelvis in 20 (13.4%) and ureter in 6 (4%). First-line chemotherapy consisted of a platinum-based regimen in 105 cases (69.8%). The median PFS was 4.8 months (95% confidence interval (CI) 3.8−5.3) and the median OS was 9.7 months (95% CI 8.6–11.1). The median PFS was 3.8 months (95% CI 3.2−4.8) in the group 1 and 6.2 months (95% CI 4.5−8.1) in the group 2 ($p = 0.0002$). The median OS was 7.9 months (95% CI 5.7−9.1) in the group 1 and 15.9 months (95% CI 11.2–19.2) in the group 2 ($p < 0.0001$). In multivariate analysis, ECOG performance status, hemoglobin and NLR were predictors of PFS (hazard ratio (HR) = 1.78 (1.18–2.69) $p = 0.006$, HR = 1.48 (1.04–2.10) $p = 0.027$ and HR = 1.85 (1.28–2.68) $p = 0.001$, respectively) and OS (1.79 (HR = 1.16–2.76) $p = 0.008$, HR = 1.56 (1.07–2.28), $p = 0.022$, and HR = 2.70 (1.79–4.07) $p < 0.0001$, respectively).
Conclusions: Increased pre-treatment NLR is an independent prognostic factor for patients with advanced UC treated with first-line chemotherapy.
No conflict of interest.

2765 POSTER

Prognostic factors of patients treaded by vinflunine for an advanced or metastatic urothelial carcinoma: Results of the CURVE study

M. Di Palma[1], D. Spaeth[2], A. Guillot[3], J. Médioni[4], C. Théodore[5].
[1]Gustave Roussy Institute, Medical Oncology, Villejuif, France; [2]Gentilly Oncology Centre, Medical Oncology, Nancy, France; [3]Lucien Neuwirth Cancerology Institute, Medical Oncology, Saint Priest en Jarez, France; [4]Georges Pompidou Hospital, Medical Oncology, Paris, France; [5]Foch Hospital, Medical Oncology, Suresnes, France

Background: Vinflunine (VFL) is a chemotherapy (CT) registered as second line treatment of advanced or metastatic urothelial carcinoma (UC) after failure of a platinum-based CT. Based on the phase 3 data, performance status (PS), haemoglobin level and liver metastasis had been identified as predictors for overall survival (OS). The CURVE study included a search for prognostic factors.
Material and Methods: The CURVE study is a retrospective data collection involving 20 French centres where at least 4 patients (pts) had been treated during the year 2011.
Several potential pre-treatment prognostic factors for OS were investigated in univariate and multivariate analyses: PS (⩽1 or >1), hepatic function (normal or abnormal), previous history of pelvic radiotherapy (yes or no), haemoglobin level (⩽10 or >10 g/dl), creatinine clearance (⩽60 or >60 ml/min), previous lines of CT (⩽1 or >1), metastases at diagnosis (yes or no), visceral metastases (yes or no), liver metastases (yes or no), lung metastase (yes or no), previous treatment by cisplatin (yes or no), previous treatment by versus carboplatin (yes or no), progression free interval before VFL (<3 or ⩾3 months), previous surgery (bladder or kidney/ureter), relative dose intensity (⩽90 or >90 %), initial dose of VFL (<280 or ⩾280 mg/m^2), further lines of CT (post VFL) (0 or ⩾1), neutropenia (yes or no), asthenia/fatigue (yes or no),nausea (yes or no), constipation (yes or no) and PS at the end of VFL (⩽1 or >1).
Results: From November 2012 to February 2013, 134 pts were included. The median OS was 8.2 months [6.5; 9.4]. The study population and the main results are presented in a separate abstract.
The main identified prognostic factors were PS, haemoglobin level and hepatic function. In addition, four subgroups were formed based on the presence of zero, one, two, or three prognostic factors; the median OS times for these groups were 11.0, 5.7, 2.7, and 1.1 months (P<.001), respectively.
Conclusion: The CURVE study reflects the current second line management of UC in France, pts exhibiting worse conditions (age, PS) than in daily practice.
The current analysis of prognostic factors for OS is consistent with the data published from the phase 3 study. PS, haemoglobin and hepatic function appear to be the prominent parameters to take into account for the identification of patients having a potential higher benefit from VFL.
Conflict of interest: *Advisory board: Pierre-Fabre Research Institute*

2766 POSTER

Biological processes after discontinuation of VEGFR TKI in metastatic renal cell cancer (mRCC)

M.J. Boers-Sonderen[1], I.M.E. Desar[1], J.J. Fütterer[2], S.F. Mulder[1], L.F. De Geus-Oei[3], P.F. Mulders[4], W.T.A. Van der Graaf[1], W.J.G. Oyen[3], C.M.L. Van Herpen[1]. *[1]Radboud University Nijmegen Medical Centre, Medical Oncology, Nijmegen, Netherlands; [2]Radboud University Nijmegen Medical Centre, Radiology, Nijmegen, Netherlands; [3]Radboud University Nijmegen Medical Centre, Nuclear Medicine, Nijmegen, Netherlands; [4]Radboud University Nijmegen Medical Centre, Urology, Nijmegen, Netherlands*

Background: In mRCC there is no definite proof of the optimal treatment in case of PD during treatment with a VEGFR TKI. After discontinuation of a VEGFR TKI an accelerated growth is described in some patients and reintroduction of (the same) VEGFR TKI is sometimes effective. This study was performed to gain more insight into the biological mechanisms of this phenomenon.
Methods: mRCC pts on treatment with sorafenib or sunitinib with PD, were randomized to either directly stop the VEGFR TKI or to continue for two weeks. At baseline (*i.e.* at the moment of PD) and after two weeks VEGF plasma levels, CRP, D-dimer and regulatory T cells were measured and FDG-PET/CT and functional-MRI were performed. Differences between both groups were assessed by using the Mann-Whitney test. The association between parameter changes were tested using Spearman's correlation test.
Results: 16 mRCC pts (13M, 3F) were included and randomly assigned to direct stop (n = 9, 6 sunitinib, 3 sorafenib) or continue treatment (n = 7, 4 sunitinib, 3 sorafenib). Median age was 61.5 (range 48−79 yrs). Before PD occurred pts were treated for a median of 86 weeks (range 10–219). Overall the median change in tumor size according to RECIST in two weeks was +6% (range −5 to +19%). No significant difference in tumor size change was found between pts who stopped and pts who continued treatment (7 vs 1%, $p = 0.35$).
A median rise in K^{trans} of 1.6s^{-1} (range −0.9 to +4.2s^{-1}) was observed in pts who stopped versus a decrease of 1.1s^{-1} (range −34.6 to +0.6s^{-1}) in pts who continued ($p = 0.03$). A negative correlation between the change in VEGF and change in K^{trans} ($r = -0.70$, $p = 0.036$) and K_{ep} ($r = -0.72$, $p = 0.030$) was observed. In pts who stopped therapy the median decrease in LDH was 18.6% versus an increase of 11.7% in patients who continued ($p = 0.008$). Hemoglobin levels decreased in both groups, but more in the group who stopped treatment (−10.3 vs −1.1% $p = 0.005$). Results of PET, CRP, D-dimer and Tregs were not significantly different between both groups.
Conclusion: Within two weeks after VEGFR TKI discontinuation because of PD, a rise in K^{trans} accompanied by a decrease in LDH and a negative correlation with VEGF was observed.
This indicates a higher perfusion or permeability, denoting an increase in tumor vascularization. Although all pts had PD, only the pts who stopped showed increased perfusion and permeability, implying that at the moment of PD the effect of the VEGFR TKI is not completely exhausted.
No conflict of interest.

2767 POSTER

Efficacy and safety of first-line sunitinib in patients with late recurrence (>5 years) of clear cell renal cell carcinoma: Results from LateR study

M. Santoni[1], C. Porta[2], G. Procopio[3], L. Cerbone[4], U. Basso[5], U. De Giorgi[6], M. Rizzo[7], F. Massari[8], R. Iacovelli[9], S. Cascinu[1]. *[1]Polytechnic University of the Marche Region AOU Ospedali Riuniti, Department of Medical Oncology, Ancona, Italy; [2]I.R.C.C.S. San Matteo University Hospital Foundation, Medical Oncology, Pavia, Italy; [3]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Medical Oncology, Milan, Italy; [4]San Camillo and Forlanini Hospital, Department of Medical Oncology, Rome, Italy; [5]Istituto Oncologico Veneto-IOV IRCCS, Division of Medical Oncology, Padova, Italy; [6]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori-IRST, Department of Oncology, Meldola, Italy; [7]Cardarelli Hospital, Department of Medical Oncology, Napoli, Italy; [8]Azienda Ospedaliera Universitaria Integrata (A.O.U.I.) University of Verona, Medical Oncology, Verona, Italy; [9]Sapienza University of Rome, Department of Radiology Oncology and Human Pathology Oncology Unit, Rome, Italy*

Background: The effect of vascular endothelial growth factor receptor (VEGFR) tyrosine kinase inhibitors (TKIs) in patients (pts) with late recurrence of clear cell renal cell carcinoma (ccRCC) is not well-known. Aim of this retrospective study was to investigate the efficacy and safety of first-line sunitinib in late-relapsing metastatic ccRCC pts.
Material and Methods: Data were collected from 11 Italian centers involved in the treatment of mRCC. MSKCC prognostic categories were assessed before starting first-line treatment with sunitinib. Overall survival

(OS) and progression free-survival (PFS) were estimated with the Kaplan-Meyer method with 95% CI and curves were compared with log-rank test.
Results: A total of 2021 pts were screened and 151 pts (7%) were included in this retrospective analysis. The median age was 64 years (range 43−87) and 119 (78%) of pts were male. Median time to recurrence was 7.6 years (range 5.3–23.4). Motzer prognostic categories were good in 59%, intermediate in 36% and poor in 5% of these pts. Median OS of these groups were 52.9, 40.6 and 16.9 months, respectively. Median PFS was 37.3, 16.4 and 3.6 months in the three groups. In the good risk group, pts relapsed >7.6 vs <7.6 yrs had a PFS of 40.2 and 15.3 months, respectively ($p = 0.009$). No differences were observed in terms of OS or in the other prognostic groups. Fifty-five percent of pts had a partial response, 36% stable disease and 9% progressive disease. The most commonly reported grade 3 adverse events were hand–foot syndrome (9%), hypothyroidism (8%), hypertension (7%), fatigue (6%), neutropenia (6%), thrombocytopenia (4%) and diarrhea (4%). Eighty-five pts (56%) underwent a second-line treatment with a VEGFR-TKI (46%) or a mTOR inhibitor (54%). Sunitinib-related PFS was significantly associated with the OS of these patients (p <0.001).
Conclusion: Patients with late relapsing ccRCC treated with first-line sunitinib showed consistently longer PFS and OS than reported in previous studies with sunitinib. Our data should be considered before enrolling these patients in randomized clinical trials.
No conflict of interest.

2768 POSTER

Vinflunine maintenance therapy vs best supportive care after platinum combination in advanced bladder cancer: A phase II, randomized, open label, study (MAJA study), SOGUG 2011−02

B. Perez-Valderrama[1], J.C. Villa[2], M.A. Climent[3], N. Lainez[4], S. Hernando[5], A. Font[6], A. Gonzalez del Alba[7], B. Mellado[8], D. Castellano[9], J. Garcia-Donas[10]. *[1]Hospital Universitario Virgen del Rocio, Medical Oncology Service, Sevilla, Spain; [2]Hospital General Universitario de Ciudad Real, Medical Oncology Service, Ciudad Real, Spain; [3]Instituto Valenciano de Oncologia, Medical Oncology Service, Valencia, Spain; [4]Complejo Hospitalario de Navarra, Medical Oncology Service, Pamplona, Spain; [5]Fundación Hospital Universitario de Alcorcon, Medical Oncology Service, Alcorcon, Spain; [6]Institut Català d'Oncologia − Hospital Germans Trias i Pujol, Medical Oncology Service, Badalona, Spain; [7]Hospital Universitario Son Espases, Medical Oncology Service, Palma de Mallorca, Spain; [8]Hospital Clinic, Medical Oncology Service, Barcelona, Spain; [9]Hospital Universitario 12 de Octubre, Medical Oncology Service, Madrid, Spain; [10]Hospital Sanchinarro, Medical Oncology Service, Madrid, Spain*

Background: Vinflunine (VFL) is a novel microtubule inhibitor currently approved by EMA as treatment after platinum progression, in metastatic bladder cancer. It is distinguished from the other vinca-alkaloids because it binds relatively weakly to tubulin, suggesting an improved tolerance profile as a result of less neuropathy. Based on the fact that no cumulative toxicity is expected and the results reported in second-line, we aim to test the role of vinflunine in first-line therapy, as maintenance treatment for patients who obtain clinical benefit after platinum.
Material and Methods: Multicenter, randomized, open label, proof-of-concept study that is being performed in 21 institutions members of the Spanish Oncology Genitourinary Group (SOGUG). Subjects are randomized to receive VFL 320 mg/m^2 (280 mg/m^2 for patients with PS=1, age $\geqslant$75 years, prior pelvic radiotherapy or creatinine clearance Cr <60 ml/min) every 21 days plus best supportive care (BSC) vs BSC alone until disease progression. Main inclusion criteria: Subjects $\geqslant$18 and<80 years of age with histological diagnosis of transitional cell carcinoma of the urothelial tract and measurable disease whith radiological response or stabilization after 4 to 6 cy of a cisplatin-containing doublet for metastatic/advanced disease (carboplatin allowed on cy 5−6). Primary objective: progression free survival (PFS). A sample size of 86 patients allocated in a 1:1 ratio is planned. Recruitment started on April 2012. A pharmacogenomic translational study will be conducted.
Results: To March 2013, 29 pts have been enrolled, 14 in the VFL+BSC group (VFL dose 320 mg/m^2, 36%; 280 mg/m^2, 64%), 15 in the BSC group. Median age 65 years (range 47−78, 41.4% under 65); PS 0/1, 48.3%/51.7%; CrCl <60 ml/min 20.7%; liver metastasis 20.7%; prior pelvic RT 6.9%. Median time from the initial diagnosis to study entry was 8.2 months. Primary tumour location: bladder 85.7%, upper urinary tract 9.5%, urethra 4.8%. Pure transitional cells 90.5%. Metastatic/locoregional disease, 76.2%/23.8%. We analyzed 32 cy in the chemotherapy arm. Hematological toxicities (% cy): Anemia g2, 16.7%; leucopenia g2, 6.7%, neutropenia g3−4, 10%. Non-hematological toxicities (% cy): alopecia, 15.6%, constipation g3−4, 12.5%, fatigue g3, 6.2%.
Conclusions: These preliminary data show a good safety profile with low myelosupression for vinflunine as maintenance therapy for patients with advanced TCCU who obtained clinical benefit after platinum. Recruitment is ongoing, interim analysis will be presented.
No conflict of interest.

2769 POSTER

Long-term progression-free-survival (PFS) under sunitinib (SU) treatment for metastatic renal cell carcinoma (Sulong study): Analysis of two populations − long term responders (LR) vs. primary refractory (PR) patients

J. Puente[1], N. Laínez[2], D.E. Castellano[3], L. Basterretxea[4], L. León[5], B. Pérez-Valderrama[6], J. Lambea[7], S. Vázquez[8], L. Antón-Aparicio[9], E. Esteban[10]. *[1]Hospital Clinico Universitario San Carlos, Oncology Service, Madrid, Spain; [2]Complejo Hospitalario de Navarra, Oncology Service, Pamplona, Spain; [3]Hospital Universitario 12 de Octubre, Oncology Service, Madrid, Spain; [4]Hospital de Donostia, Oncology Service, San Sebastian, Spain; [5]Complejo Hospitalario Universitario Santiago de Compostela, Oncology Service, Santiago de Compostela, Spain; [6]Hospital Universitario Virgen del Rocio, Oncology Service, Sevilla, Spain; [7]Hospital Clínico de Zaragoza, Oncology Service, Zaragoza, Spain; [8]Hospital Universitario Lucus Augusti, Oncology Service, Lugo, Spain; [9]CHUAC, Oncology Service, A Coruña, Spain; [10]Hospital Universitario Central de Asturias, Oncology Service, Oviedo, Spain*

Background: It would be useful for the management of patients (pts) with renal cancer to identify factors at the time of diagnosis that would enable us to identify prognostic groups and select the optimal therapeutic approach of the disease. We look at clinical and tumor characteristics in two extremely different groups: those with the highest benefit and those who show drug resistance.
Methods: Retrospective, observational and multicenter study of pts treated with SU under clinical practice. Two groups were included: pts with metastatic renal carcinoma (mRCC) who achieved PFS $\geqslant$22 months, and pts who showed progressive disease at first radiological evaluation. The objectives were to compare the clinical and molecular characteristics at tumor level (activation status of cancer stem cell signaling pathways) in LR vs. PR pts. This study was approved by the Spanish Medicines Agency and Ethic Committees of each hospital.
Results: A total of 82 pts in 12 centers were included, 70 were LR and 12 were identified as PR. Clinical factors that showed statistical significance between LR vs. PR are shown in Table 1.
In the LR cohort, median PFS was 45 months. Median time to best response was 10.2 months for complete response (CR) and 4.42 months for partial response (PR). CR and PR rates were 21% and 59% respectively. Median duration of response was 27 months. No differences in PFS between pts who received prior cytokines and those who did not. Significantly longer PFS was seen in LR who developed hypertension (36 vs.52, $p < 0.05$) and hypothyroidism (50 vs. 61, $p < 0.05$). 38 pts discontinued treatment: 8% due to toxicity, 41% progression and 3 pts for other reasons. Molecular assessment is still ongoing and will be presented.

Table 1 (abstract 2769).

Clinical factors	LR (70 patients)	PR (12 patients)	p-value
Metastasis at the time of 1st diagnosis, pts (%)	23	58.3	0.05
Age of diagnosis, median (years)	57	63	<0.05
Time from primary to metastatic diagnosis, median, months	38.17	2.07	<0.01
LDH value, median (U/L)	254	355	<0.01
Hemoglobin value, median (g/dL)	13.90	12.55	<0.05
Time from primary diagnosis to treatment, median, months	39	3.8	<0.01
Initial dose of Sunitinib, mg/day (% pts)	37.5 (3%) 50.0 (97%)	37.5 (17%) 50.0 (83%)	<0.01
Dose reductions, pts (%)	83.6	45.5	<0.01

Conclusions: Sunitinib achieves long-term response in a subset of pts with mRCC. MSKCC risk criteria, hypertension and hypothyroidism were confirmed as prognostic factors. Treatment initiation with 50 mg/day of SU and better drug management may improve clinical outcomes.
No conflict of interest.

2770 POSTER

Treatment outcome and relevance of palliative chemotherapy in urachal cancer

H. Jung[1], J.M. Sun[1], S.M. Kim[1], M.J. Kim[1], W.J. Jang[1], M.K. Choi[1], J.Y. Hong[1]. *[1]Samsung Medical Center Sungkyunkwan University School of Medicine, Division of Hematology-Oncology Department of Medicine, Seoul, Korea*

Objective: Urachal cancer is rare malignancy accounting for less than 1% of bladder cancer and is no consensus in diagnosis and management of urachal cancer. Especially in unresectable, recurrent urachal cancer, there were few reports on the use of palliative chemotherapy. We delineate clinical feature and treatment outcome of resectable urachal cancer and relevance of palliative chemotherapy in recurrent, metastatic urachal cancer.
Methods: Between January 1996 to December 2010, 29 patients were diagnosis of urachal cancer. We collected clinicopathologic variables and treatment outcome were retrospectively.
Results: Among 29 patients, 25 patients were localized disease, 3 patients were metastatic disease at initial diagnosis. Among patients of localized disease, 21 patients got curative PC(partial cystectomy) or RC(radical cystectomy), 4 patients got curative tumor excision, 1 patients were followed up loss. The median overall survival in resectable disease and in unresectable disease were 110.0 months and 7.8 months (p value=0.001). Lung was the most common metastatic site in 5 (17.2%) patients followed by liver, bone, peritoneal seeding. Among patients of localized disease, 13 patients were no recurrence, 2 patients were follow up loss, 10 patients recurred disease. 9 patients who recurred disease after curative operation and 1 patient who presented metastatic disease at initial were received palliative chemotherapy. Fluropyrimidine(5-FU) based regimens, taxane based regimen and gemcitabine based regimen were most commonly used. The response of chemotherapy was poor (16.6%), but fluropyrimidine(5-FU) based regimens had most favorable response activity. One patients who had mucious mixed with small cell component adenocarcinoma showed partial response both etoposide based regimen and taxane based regimen.
Conclusions: In urachal cancer, curative operation is significantly associated with better overall survival. Fluropyrimidine based regimen could be considered as chemotherapy for metastatic, recurrent disease.
No conflict of interest.

2771 POSTER

Targeted therapies (TTs) in metastatic renal cell carcinoma (MRCC): Role of metastatic site as a prognostic and predictive factor

G. Procopio[1], P. Grassi[1], L. Porcu[2], E. Verzoni[1], I. Testa[1], E. Garanzini[1], P. Biondani[1], S. Pusceddu[1], F. De Braud[1]. *[1]Fondazione IRCCS Istituto Nazionale Tumori, Medical Oncology, Milan, Italy; [2]Mario Negri Institute for Pharmacological Research, Milan, Italy*

Background: The prognostic/predictive role of metastatic sites in mRCC patients (pts) treated with TTs is not clearly understood. Aim of this study was to investigate whether metastatic sites were statistically associated to progression-free survival (PFS) and overall survival (OS).
Patients and Methods: We retrospectively collected data of consecutive mRCC pts treated with TTs at Istituto Nazionale Tumori of Milan. All pts received at least one targeted agent including: sunitinib, sorafenib, bevacizumab plus interferon-alfa, pazopanib, everolimus, temsirolimus or axitinib. Multivariate Cox regression models were used to estimate hazard ratios (HRs) and to test the association between predictors and PFS and OS. In the first model metastatic sites categorized into liver, lung, brain, bone, lymphnode and other site were contemporary introduced as binary predictors; in the second model the previous predictors and the Motzer score were evaluated. Statistical significance was reached when p value was less than 5%. Survival was estimated through the Kaplan–Meier method.
Results: From January 2004 to October 2012 a total of 366 mRCC pts were treated with TTs at our centre and a total of 358 (97.8%) pts were evaluated. After a median follow-up of 56.1 months (range: 1.0–93.2 months) median PFS was 11 months (95% CI: 8.1–12.0) and median OS was 24.2 months (95% CI: 20–27.8). Metastatic sites were associated to the PFS as follows: lymphnodes (HR: 1.43; 95% CI: 1.12–1.83, p = 0.004); liver (HR: 1.41; 95% CI: 1.05–1.90, p = 0.021); bone (HR: 1.26; 95% CI: 0.96–1.65, p = 0.091); brain (HR: 0.81; 95% CI: 0.46–1.43, p = 0.474); other sites (HR: 1.07; 95% CI: 0.83–1.38, p = 0.589). Number (n) of metastatic site were statistically associated to the PFS (HR: 1.16; 95% CI: 1.04–1.29, p = 0.008). Metastatic sites were associated to the OS as follows: lymphnodes (HR: 1.73; 95% CI: 1.31–2.29, p < 0.001); liver (HR: 1.71; 95% CI: 1.23–2.37, p = 0.002); bone (HR: 1.48; 95% CI: 1.10–1.98, p = 0.009); brain (HR: 1.21; 95% CI: 0.64–2.28, p = 0.568); other sites (HR: 1.09; 95% CI: 0.81–1.47, p = 0.568). Number of metastatic sites were statistically associated to the OS (HR: 1.27; 95% CI: 1.13–1.44, p=<0.001).
Conclusions: mRCC pts with liver, lymphnodes and bone metastases treated with TTs had poorer outcome than pts with metastases to other sites. Liver, lymphnodes and bone metastases may be considered independent negative prognostic factors.

2772 POSTER

Sunitinib expanded-access trial in metastatic renal cell carcinoma (mRCC) − final results from Spain

D. Castellano[1], X. Garcia del Muro[2], M.A. Climent[3], P. Maroto[4], J.L. Pérez-Gracia[5], G. López-Vivanco[6], K. Zhang[7], K. Fly[8], S. Hariharan[9], L. Antón-Aparicio[10]. *[1]Hospital Universitario 12 de Octubre, Medical Oncology, Madrid, Spain; [2]Instituto Catalán de Oncología, Medical Oncology, Barcelona, Spain; [3]Instituto Valenciano de Oncología, Medical Oncology, Valencia, Spain; [4]Hospital de la Santa Creu i Sant Pau, Medical Oncology, Barcelona, Spain; [5]Clínica Universitaria de Navarra, Medical Oncology, Pamplona, Spain; [6]Hospital Universitario Cruces, Medical Oncology, Barakaldo, Spain; [7]Pfizer Oncology, Statistics, La Jolla, USA; [8]Pfizer Oncology, Medical Oncology, Groton, USA; [9]Pfizer Oncology, Medical Oncology, New York, USA; [10]Complejo Hospitalario Universitario A Coruña, Medical Oncology, A Coruña, Spain*

Background: Between 2005 and 2007, more than 4,500 patients (pts) were enrolled in a global mRCC expanded-access trial (NCT00130897; Pfizer) in which sunitinib was given to pts ineligible for other sunitinib trials. Sunitinib was shown to have a manageable safety profile and encouraging efficacy in this broad population (Gore et al, 2009). Here we report final results for pts in Spain who enrolled in this trial.
Material and Methods: Pts $\geqslant$18 years of age with treatment-naive or previously treated mRCC received sunitinib 50 mg/d on a 4-wk-on/2-wk-off schedule. Tumor measurements were scheduled per local standard practice and measured using RECIST. Safety was assessed regularly. Objective response rate (ORR), progression-free survival (PFS), overall survival (OS), and treatment-related adverse events (AEs) are reported. Analyses included all pts who received $\geqslant$1 dose of sunitinib.
Results: 231 pts received treatment, including 36% aged $\geqslant$65 years, 16% with non-clear cell RCC, 8% with baseline brain metastases, and 16% with Eastern Cooperative Oncology Group performance status (ECOG PS) $\geqslant$2 (29% and 47% had ECOG PS 0 and 1, respectively). 61% and 12% had received prior cytokine and antiangiogenic therapy, respectively, and 84% had prior nephrectomy. The proportions of pts classified as favorable, intermediate, or poor risk based on published MSKCC data were 29%, 35%, and 9%, respectively (data missing, 27%). Median treatment duration and follow-up were 6.6 and 12.8 months, respectively. 193 pts (84%) discontinued treatment; reasons included death (43%), lack of efficacy (15%), or AEs (6%). ORR was 16%. Median PFS was 9.7 months (95% CI: 7.3–12.2) overall and 17.9 months (95% CI: 11.6–22.7), 7.2 months (95% CI: 4.3−8.6), and 2.3 months (95% CI: 1.4−2.6) in favorable, intermediate, and poor risk groups, respectively. Median OS was 15.1 months (95% CI: 11.6–19.4) overall and not reached (95% CI: 22.5–not reached), 9.4 months (95% CI: 6.8–13.8), and 3.2 months (95% CI: 1.5−5.0) in favorable, intermediate, and poor risk groups, respectively. The most common grade 3/4 treatment-related AEs were asthenia (21%), neutropenia (10%), thrombocytopenia (10%), mucosal inflammation (8%), hand–foot syndrome (8%), diarrhea (6%), and hypertension (5%).
Conclusions: Among 231 mRCC pts in Spain treated in the expanded-access trial, efficacy and safety with sunitinib were favorable for a non-selected population and comparable to that of the overall population as previously reported.

2773 POSTER

The difference in adverse event profiles between the mammalian target of rapamycin inhibitors, everolimus and temsirolimus, in advanced renal cell carcinoma

M. Nozawa[1], S. Tamada[2], F. Hongo[3], S. Anai[4], K. Fujimoto[4], T. Miki[3], T. Nakatani[2], H. Uemura[1]. *[1]Kinki University Faculty of Medicine, Department of Urology, Osaka-Sayama, Japan; [2]Osaka City University Graduate School of Medicine, Department of Urology, Osaka, Japan; [3]Kyoto Prefectural University of Medicine, Department of Urology, Kyoto, Japan; [4]Nara Medical University, Department of Urology, Kashihara, Japan*

Background: Everolimus and temsirolimus have proven their efficacy and are used for patients with advanced renal cell carcinoma (RCC). They both are rapamycin derivatives and are categorized as mammalian target of rapamycin (mTOR) inhibitors. There have been few reports that examined the difference between these two agents regarding adverse events. Our objective was to investigate the difference in the safety of both agents on the basis of our real-world clinical experience.
Material and Methods: We identified patients with advanced RCC who had been treated with everolimus or temsirolimus at four major Japanese medical centers. Treatment duration, relative dose intensity, laboratory data, and adverse events during treatment with each agent were evaluated.
Results: A total of 176 patients were evaluable. 118 of those had been treated with everolimus and 58 with temsirolimus. There was no significant difference in age, gender, histological type, number of metastatic sites, and Memorial Slone-Kettering Cancer Center (MSKCC) risk between the two treatment groups. Median treatment durations of the everolimus and temsirolimus groups were 17.4 weeks and 12.1 weeks, respectively ($P = 0.192$). Relative dose intensities of the everolimus and temsirolimus groups were 75.4% and 80.5%, respectively ($P = 0.990$). Interstitial pneumonia ($P = 0.010$), stomatitis ($P = 0.010$), and increased serum aspartate aminotransferase ($P = 0.015$) of all grades were detected with significantly higher frequency in the everolimus group. Grade 3 or higher interstitial pneumonia was reported in 11.9% of the everolimus group and 1.7% of the temsirolimus group ($P = 0.022$). Frequencies of any adverse events of grade 3 or higher in the everolimus and temsirolimus groups were 45.8% and 22.4%, respectively ($P = 0.003$).
Conclusions: Adverse event profiles of everolimus and temsirolimus may differ from each other. Interstitial pneumonia may occur more frequently and severely in patients treated with everolimus than temsirolimus. These findings suggest that the difference in the pharmacodynamics, pharmacokinetics, and treatment regimen of these two agents may result in different adverse events even though they target the same molecule.
No conflict of interest.

2774 POSTER

Bleomycin lung toxicity in patients with male germ cell cancer

M. Alexandre[1], A. Luis[1], I. Duarte[2], S. Esteves[3], A. Guimarães[1], A. Moreira[1], M. Brito[1]. *[1]Instituto Oncologia Lisboa, Medical Oncology, Lisboa, Portugal; [2]Instituto Oncologia Lisboa, Thoracic Radiologist, Lisboa, Portugal; [3]Instituto Oncologia Lisboa, Research Department, Lisboa, Portugal*

Background: Germ cell cancer is a highly curable disease and the most common solid malignancy in young men. Combination of bleomycin, etoposide and cisplatin (BEP) remains the standard chemotherapy. The use of BEP is limited by the lung toxicity of bleomycin (BLT). Some probable predictive factors of BLT have been described.
Methods: Retrospective analysis of all consecutive patients (pts) treated with BEP regimen for germ cell cancer in our cancer center (Jan 2000-Aug 2012). Our aim was to evaluate the incidence of BLT during BEP up to six months after completion. BLT was defined by chest CT features (reviewed by expert) with or without symptoms, in the absence of other causes. Secondary aim was to validate in our population the risk factors reported for BLT: age, clearance creatinine (ClCr), lung metastases, smoking habits, bleomycin dose, lung disease, mediastinal primary and use of G-CSF.
Results: Of the 114 pts treated with BEP, 37 (32%) had seminoma, 77 (68%) non-seminoma. Median age at beginning of BEP was 29 years (range 15−61). Clinical stage was I in 32 pts (28%), II in 40 (35%), III in 36 (32%); 6 pts (5%) had mediastinal primary; 31 pts had multiple lung metastases; Prognostic staging (IGCCCG) was good in 71%, intermediate in 13% and poor in 16%; 45 pts had smoking habits. Median ClCr was 131 ml/min (range 39–231); 15% pts did G-CSF during BEP. Eight pts had underlying lung disease. Eighty-nine pts (78%) completed 3 or more BEP cycles. Median dose of bleomycin administered was 270U (range 30–360). BLT occurred in 17 pts (15%; 95% CI: 9−23%), in 6 pts during treatment and in 11 immediately after BEP completion. BLT radiologic patterns were interstitial pneumonia in 12 pts, organizing pneumonia in 3 pts and fibrosis in 2 pts. BLT symptoms were dyspnea in 8 pts and dry cough in 8 pts. Six pts were asymptomatic. Carbon monoxide diffusing capacity (DLCO) was done in 14 of the 17 BLT pts. Of these, only 6 pts had a reduction of at least 40%, all were symptomatic. Five pts needed hospitalization. Nine (53%) received steroids. All BLT pts had a full radiological and clinical recovery. BLT pts were older (median age 33 and 29 yrs, respectively; $p = 0.021$). In our data we couldn't demonstrate association between the other evaluated risk factors and BLT.
Conclusion: Our BLT incidence is in accordance with literature (3−14%). Despite age, the described risk factors were not useful for predict BLT. DLCO was not a relevant parameter for the diagnosis of BLT. Valid BLT predictive markers are needed.
No conflict of interest.

2775 POSTER

Evaluation of safety, tolerability and activity of temsirolimus in patients with advanced or metastatic renal cell carcinoma (a/mRCC) in routine clinical practice

M. Woike[1], L. Bergmann[2], T. Steiner[3], D. Kalanovic[4]. *[1]Pfizer, Karlsruhe, Germany; [2]Universitätsklinikum Frankfurt, Medizinische Klinik II, Frankfurt am Main, Germany; [3]HELIOS-Klinikum, Urologie, Erfurt, Germany; [4]Pfizer Pharma GmbH, Berlin, Germany*

Background: Temsirolimus (TEMS), an i.v. mTOR inhibitor, is approved in the EU for the first-line treatment of patients with a/mRCC who have at least 3 of 6 prognostic risk factors. A pivotal study demonstrated significantly increased overall survival with TEMS in poor risk patients compared to the former standard Interferon (10.9 vs. 7.3 mo; $p = 0.0078$). To evaluate the safety profile and efficacy of TEMS in a clinical routine setting, collection of data in a post-approval non-interverntional trial is useful.
Methods: A German multicenter registry for a/mRCC patients treated with TEMS was started in Jan 2008 (NCT00700258). Objectives are evaluation of safety, tolerability and anti-tumor activity of TEMS, patients' profile, and sequence of systemic therapies. Inclusion criteria are histologically confirmed a/mRCC treated with TEMS and written informed consent.
Results: From Feb 2008 to Mar 2013, 122 active study centers recruited 466 patients. Preliminary data are available for 464 patients: 68.6% male, median age 66.8 years, median Karnofsky index 80%. Histological subtype: 73.5% clear cell, 11.6% papillary, and 2.8% chromophobe RCC. According to modified MSKCC criteria 94.9% of the patients were classified as poor risk and 5.1% as intermediate risk (n = 353). Adverse events (AE) and drug-related serious adverse events (SAE) were observed in 41.6% and 9.9% of the patients, respectively. Most common AEs of any grade were skin disorders, fatigue, nausea, stomatitis, anemia, thrombocytopenia, and mucosal inflammation. Median progression-free survival for the total patient population was 4.9 months, for the subgroup of 1st line patients 5.1 months, and for patients $\geqslant$65 years 5.1 months. Median overall survival for all patients was 11.4 months.
Conclusions: The population in our registry represents the expected pattern in a/mRCC patients regarding distribution of age, sex, and histology. Safety profile and clinical efficacy of TEMS in routine clinical practice confirm the phase III data. Besides, safety and clinical efficacy of TEMS for patients $\geqslant$65 years of age are comparable to the results for the overall study population.

2776 POSTER

Real world experience with axitinib in renal cell carcinoma at Institut Gustave Roussy (IGR)

M. Matias[1], L. Albiges[2], C. Ablard[3], N. Lassau[4], B. Benatsou[4], B. Escudier[2]. *[1]Institut Gustave Roussy, Medical Oncology, Villejuif, France; [2]Institut Gustave Roussy, Medical Oncology, Villejuif, France; [3]Institut Gustave Roussy, Pharmacie Clinique, Villejuif, France; [4]Institut Gustave Roussy, Villejuif, France*

Background: Axitinib has shown activity in metastatic renal cell carcinoma (mRCC) in a large phase III, and has been approved in patients (pts) who failed sunitinib. It is available in France since mid November 2012, with recommended starting dose of 5 mg bid, and dose titration every 2 weeks up to 10 mg bid in pts without hypertension or grade >2 toxicity.
Material and Methods: We report IGR preliminary real world experience with axitinib in mRCC. Each time possible, Dynamic Contrast Enhanced ultrasonography (DCE-US) was performed at baseline, days 15 and 30. CT scans will be performed at month 2, and every 2−3 months thereafter.
Results: From 14 November 2012, 21 mRCC pts were treated with Axitinib for second or subsequent line. ECOG performance status was 0/1/>1 in

6/11/4 pts. Patients were classified as good (n = 6), intermediate (n = 6) or poor prognostic (n = 9) by Heng criteria. The number of prior therapies was 1 (n = 9), 2 (n = 4), or ⩾3 (n = 8), varying from 1 to 6 and included prior antiangiogenic therapy and/or immunotherapy. 18 pts (86%) had prior nephrectomy. The number of pts that had surgery, radiotherapy and radiofrequency/cryotherapy for metastases was 12, 9 and 4 respectively. The number of metastatic sites was 1/2/⩾2 in 3/2/16 pts. Dose titration could be performed in 29% pts at 2 weeks (7 mg bid) and in 16% pts at 4 weeks (10 mg bid). Hypertension was the most common adverse event (AE) according to CTC, with 9% grade 3. No other grade 3−4 AEs have been observed so far. The incidence of Grade 2 AEs was 52% and included hypertension (24%), fatigue (14%), diarrhea (5%), dysphonia (15%), abdominal pain (10%) and articular pain (10%). Efficacy: 76% of pts have been currently evaluated at 2 months. 5 patients progressed within 8 weeks. 11 pts had stable disease with tumor shrinkage ranging from −7 to −27%. DCE-US was performed in 9 pts. In 6 pts blood volume was evaluated in days 0, 15 and 30 through AUC quantification. In 5 pts vascularization decreased both in D15 (−55% to −92%) and D30 (−68% to −99%) and in 1 patient increased in D15 (+33%) and D30 (+152%). When compared to RECIST criteria all 6 pts presented SD. Data about efficacy will be updated, as well as correlation between DCE US and efficacy/toxicity.
Conclusions: Dose titration of axitinib is possible in only 29% of pts at 7 mg bid, and 16% at 10 mg bid in real world experience. Efficacy of Axitinib is observed, even in late line of treatment.
No conflict of interest.

2777 POSTER

Treatment-induced hyperlipidemia and pneumonitis could be meaningful clinical biomarkers during treatment with mTOR inhibitors (everolimus, temsirolimus) in metastatic renal cell cancer

J. Obertova[1], M. Mego[2], Z. Sycova-Mila[2], P. Palacka[2], J. Rajec[2], M. Chovanec[2], J. Mardiak[2]. *[1]Narodny Onkologicky Ustav, Bratislava, Slovak Republic; [2]Narodny Onkologicky Ustav, 2nd Department of Medical Oncology, Bratislava, Slovak Republic*

Objective: Objective of this analysis was to evaluate both, efficacy and toxicity of mTOR inhibitors in metastatic renal cell carcinoma patients and evaluate of treatment outcome predictive biomarkers.
Methods: This is a retrospective analysis of metastatic renal cell carcinoma patients treated with at least one regimen with mTOR inhibitor from December 2008 to November 2012 at the 2nd Oncology Department in National Cancer Institute in Bratislava. Therapy with mTOR inibitor was according usual standard guidelines and was conducted by a treating physician. Median PFS and OS were estimated using Kaplan–Meier method and compared with log-rank test. We perfomed univariate analysis of correlation of treatment-induced adverse events and treatment outcomes.
Results: We identified 69 patients that fulfill study inclusion criteria. Among them 65 patients were treated with everolimus and 4 with temsirolimus. mTOR inhibitor was given as 2nd line therapy in 50 patients, and as 3rd line in 17 patients, 1 patient received everolimus as 5th line and 1 patient as first line because of heart transplantation. We observed one patient (1.5%) who achieved partial remission and 26 patients (37.7%) had disease stabilisation. Median PFS and OS were 3.4 months and 10.2 months, respectively. There were the most frequent adverse event hyperlipidemia in 41 (59.4%) of patients (19 pts grade 1, 15 patients grade 2, 7 patients grade 3/4), presence of asymptomatic CT radiographic changes in 8 (11.6%) patients and non-infectious pneumonitis grade 3 in 6 (8.7%) patients. In patients treated with everolimus or temsirolimus, there was observed a positive association among treatment-induced plasma lipids elevation (any grade) and the significant prolongation of median PFS 6.3 vs 2.1 months [HR 0.37 95% CI(0.20–0.69); p = 0.00005] as well as median OS [13.4 vs 2.9 months (HR 0.33 95% CI(0.18–0.62); p = 0.00002]. Median time to onset hyperlipidemia was 1.1 months. The outcome of patients was not affected, when hypolipidemic therapy was administered. Similarly, significantly positive correlation was observed among patients who developed any grade of non-infectious pneumonitis with median PFS 15.0 vs 3.0 months [HR 0.42 95% CI(0.25–0.72); p = 0.0026] and median OS 17.4 vs 8.2 months [HR 0.40 95% CI(0.23–0.70); p = 0.0036]. Median onset was 3.1 months.
Conclusion: Hyperlipidemia and pneumonitis might be considered to be the meaningful clinical biomarkers of better treatment outcome in patients with metastatic renal cell cancer treated with mTOR inhibitors. This observation need to be validitate in prospective trial with larger number of patients.
No conflict of interest.

2778 POSTER

Clinico-pathological features and prognosis of patients with late-relapsing (>5 years) renal cell carcinoma after curative surgery: Results from LateR study

M. Santoni[1], C. Porta[2], G. Procopio[3], L. Cerbone[4], M. Maruzzo[5], U. De Giorgi[6], M. Rizzo[7], G. Di Lorenzo[8], D. Santini[9], S. Cascinu[1]. *[1]Polytechnic University of the Marche Region AOU Ospedali Riuniti, Department of Medical Oncology, Ancona, Italy; [2]IRCCS San Matteo University Hospital Foundation, Medical Oncology, Pavia, Italy; [3]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Medical Oncology, Milan, Italy; [4]San Camillo and Forlanini Hospital, Department of Medical Oncology, Rome, Italy; [5]Istituto Oncologico Veneto-IOV IRCCS, Division of Medical Oncology, Padova, Italy; [6]IRCCS Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (I.R.S.T.), Department of Oncology, Meldola, Italy; [7]Cardarelli Hospital, Department of Medical Oncology, Napoli, Italy; [8]University of Federico II of Napoli, Department of Oncology, Napoli, Italy; [9]University Campus Bio-Medico, Department of Medical Oncology, Rome, Italy*

Background: Late relapse of renal cell carcinoma (RCC) after radical initial nephrectomy is not a rare event. The aim of this study was to describe the late relapse of RCC, defined as 5 or more years after the primary tumour's excision in a series of RCC patients (pts).
Material and Methods: Pts who developed metastatic RCC over 5 years after curative surgery were enrolled in this retrospective analysis. Data were collected from 11 Italian centers involved in the treatment of RCC. MSKCC risk class was assessed before starting first-line treatment with sunitinib. Overall survival (OS) was estimated with the Kaplan-Meyer method with 95% CI.
Results: A total of the 2021 pts were screened and 232 pts (11%) experienced a late relapse (>5 yrs) and were included in this analysis. The median age was 66 yrs (range 29−88) and 172 pts (74%) were male. Median time to recurrence was 7.8 yrs (range 5.1–25.8). Pathological subtypes of the 232 eligible pts were clear cell RCC in 219 pts (94%) and non-clear cell RCC in 13 pts (6%), including 9 with papillary RCC (4%). At first diagnosis, Fuhrman's nuclear grade was grade (G)1 in 8 pts (3%), G2 in 153 pts (66%), G3 in 64 pts (28%), G4 in 7 pts (3%); micro-vascular and fatty infiltration were present in 28 (12%) and 29 (13%) pts, while sarcomatoid differentiation was identified in 11 pts (5%). In 16 pts (7%) the first relapse of disease was a single metastasis that was treated with surgery. The main sites for late relapse was lung (58%), followed by lymph nodes (26%), bone (19%), adrenal gland (16%), pancreas (15%), kidney (14%), liver (14%), soft tissue (9%), brain (7%), and thyroid (3%). Median OS from relapse was 38 (4.6–87.9) months. Prognostic categories using MSKCC score were good in 62%, intermediate in 32% and poor in 6% of pts. For each group median OS were 71.4, 43.5 and 16.9 months, respectively. One hundred and eight (47%) and 86 (37%) pts received a second and third-line treatment, respectively.
Conclusion: Pts with late relapsing RCC present a different metastatic spread of disease and a consistently favorable prognosis. These data should be considered in the long-term therapeutic strategy and management of these pts.
No conflict of interest.

2779 POSTER

Outcomes of unselected patients with metastatic renal cell carcinoma treated with front-line pazopanib therapy

M. Matrana[1], A. Shetty[2], P. Teegavarapu[2], S. Kalra[2], L. Xiao[3], B. Atkinson[2], P. Corn[2], E. Jonasch[2], N.M. Tannir[2]. *[1]M.D. Anderson Cancer Center, Division of Cancer Medicine, Houston Texas, USA; [2]M.D. Anderson Cancer Center, Genitourinary Medical Oncology, Houston Texas, USA; [3]M.D. Anderson Cancer Center, Department of Biostatistics, Houston Texas, USA*

Background: Pazopanib is an approved tyrosine kinase inhibitor (TKI) shown to prolong progression-free survival (PFS) compared to placebo in treatment-naive and cytokine-refractory clear cell metastatic renal cell carcinoma (mRCC). Outcomes and safety data on its use in the front-line setting in unselected patients (pts) are limited. Likewise, outcome data are limited regarding subsequent therapies after front-line pazopanib therapy and in pts with non-clear-cell mRCC.
Materials and Methods: We reviewed records of consecutive pts with mRCC treated at MD Anderson Cancer Center with front-line pazopanib between 11/09−11/12. PFS and overall survival (OS) times were estimated by the Kaplan–Meier method. Univariate and multivariate Cox proportional hazards models were fitted to evaluate the association of PFS and OS with pt co-variables.
Results: 100 pts (median age 65 years, 68% male, 87% clear-cell, 78% with prior nephrectomy) met inclusion criteria. 21% had Karnofsky PS<80%. 48% had intermediate-risk and 11% had poor-risk disease by

MSKCC criteria. 42 pts have died. Median OS for all pts is 32.3 mos (95% CI: 23.3−NA). Median PFS for all pts is 11.5 mos (95% CI: 8.13–17.1) and 13.7 mos (95% CI: 8.16–18.3 m) for clear-cell pts. PFS for all pts was associated with serum LDH level >1.5xULN (HR = 5.055; 95% CI: 1.755–14.56, p value = 0.0027).
32% of pts were still receiving pazopanib at analysis. 48% discontinued pazopanib due to progressive disease. 9% discontinued due to adverse events (AEs): 7% due to increased LFTs, 1% hypertension, 1% vomiting. There were no treatment related deaths. Common AEs included fatigue (55%), diarrhea (36%), hypertension (26%), nausea/vomiting (25%), anorexia (20%), and increased LFTs (16%). 88% of AEs were grade 1/2.
66% received one or more therapies after pazopanib: 33% received everolimus, 26% sunitinib, 14% axitinib, 13% temsirolimus, 10% chemotherapy, 8% cytokines, 8% sorafenib, 4% bevacizumab, and 16% received other therapies in the second-and-subsequent-line settings.
Conclusions: In this retrospective study, pazopanib confirmed its efficacy and safety in mRCC in a real-world front-line setting. AEs were mild/moderate and manageable. Objective response rates and efficacy data on post-pazopanib sequence outcomes will be provided at meeting presentation.
No conflict of interest.

2780 POSTER

Vinflunine in routine practice for the treatment of advanced or metastatic urothelial cell carcinoma in Germany

A. Hegele[1], P. De Geeter[2], P. Goebell[3], U. Matz[4], W. De Schultz[5], M. Retz[6]. *[1]Philipps University, Urology and Pediatric Urology, Marburg, Germany; [2]Klinikum Kassel, Urology, Kassel, Germany; [3]Friedrich-Alexander-University, Urology, Erlangen, Germany; [4]Medical Urology Praxis, Urology, Döbeln, Germany; [5]Medical Urology Praxis, Urology, Leipzig, Germany; [6]Technische Universität, Urology, Munich, Germany*

Background: Vinflunine is recommended by European guidelines for the treatment of advanced or metastatic urothelial cell carcinoma (UCC) after failure of platinum-based chemotherapy. In a phase III study (Bellmunt et al., JCO, 2009, 27(27):4454−61) vinflunine treated patients had a median survival of 6.9 months with moderate toxicities. The non-interventional trial investigated the effectiveness and safety of vinflunine in routine practice.
Material and Methods: Data were prospectively collected on 77 patients with advanced or metastatic UCC undergoing vinflunine treatment in 39 German hospitals or outpatient units. Dosing of vinflunine, tumor assessments and concomitant medications were performed according to physician's usual practice. The planned observation period was limited to six cycles.
Results: The patient population was representative for the specified indication (male: 82%, median age: 67 years, median Karnofsky-Index: 80, tumor location: 82% lower urinary tract, visceral metastasis: 60%). Vinflunine starting dose of 320 mg/m^2 was chosen in 48% of all patients and 280 mg/m^2 in 39%. All patients received prior systemic chemotherapy (CT), mostly cisplatin (82%) as perioperative or first line CT. Vinflunine was predominantly administered as second line CT (66%) or in subsequent treatment lines (21%). One third of the patients received more than six cycles of vinflunine and the average number of cycles was 4.7.
The frequency of treatment related hematological toxicities with minimum grade 3 was low with leukopenia 16.9%, neutropenia: 1.3%, neutropenic infections 2.6%, anemia 6.5% and thrombocytopenia 1.3%. Non-hematological toxicities with minimum grade 3 were reported with constipation 5.2%, elevated liver enzymes 5.2%, nausea 2.6%, vomiting 2.6% and fatigue 1.3%. Prophylaxis of emesis and constipation was administered in 84% and 71% of the patients, respectively.
The objective response rate was 23.4% (complete response 5.2% and partial response 18.2%) on vinflunine treatment and the median survival was 7.7 months. Patients receiving a starting dose of 320 mg/m^2 tended to benefit most of the therapy with a median survival of 10.5 months (p = 0.054).
Conclusions: This prospective non-interventional study confirmed that vinflunine is an active agent with low toxicites in an unselected population of real life experience through a large number of German centres. The treatment was manageable in daily practice with simple gastrointestinal prophylaxis.
Conflict of interest: *Other substantive relationships: AH and MR worked as consultant for Pierre Fabre Pharma GmbH within the scope of this project.*

2781 POSTER

Final results of a non-interventional study of everolimus in mRCC after exactly one previous VEGFR-TKI

L. Bergmann[1], P.J. Goebell[2], E. Herrmann[3], S. Weikert[4], A. Jakob[5], F. Overkamp[6], T. Steiner[7], C. Doehn[8], G. Guderian[9], M. Staehler[10]. *[1]University Hospital Frankfurt, Tumor Center Rhein-Main, Frankfurt a.M, Germany; [2]University Hospital Erlangen, AURONTE (Department of Urology), Erlangen, Germany; [3]University Hospital Muenster, Department of Urology, Muenster, Germany; [4]Charité Campus Mitte, Department of Urology, Berlin, Germany; [5]Private practice for Oncology, Oncology, Offenburg, Germany; [6]Private practice for Oncology and Hematology, Oncology and Hematology, Recklinghausen, Germany; [7]Helios Hospital Erfurt, Department of Urology, Erfurt, Germany; [8]Urologikum Luebeck, Urology, Luebeck, Germany; [9]Novartis Pharma GmbH, Solid Tumors & Early Clinical Development, Nuremberg, Germany; [10]University Hospital Munich-Großhadern, Department of Urology, Munich, Germany*

Background: Everolimus (Afinitor®) is approved for the treatment of metastatic renal cell cancer (mRCC) after failure of VEGF-targeted therapy. Despite seven approved agents for the treatment of mRCC, data beyond clinical trials is limited. In addition, data on VEGFR-TKI − mTORi sequences warrant further detailed investigation. In order to ascertain prospective data on the routine use of everolimus after a first VEGFR-TKI in patients with mRCC, a non-interventional study was conducted (NIS CHANGE, CRAD001LDE27).
Material and Methods: Patients with mRCC treated with everolimus after failure of a first VEGFR-TKI were documented in a prospective, single-armed, non-interventional study at 132 sites in Germany. Between October 2009 and December 2011, 382 patients were documented and followed until 31 December 2012, discontinuation of therapy or withdrawal of consent − whichever occurred first. Goals of the study were assessment of safety and effectiveness (as time from first everolimus intake to progression due to any cause, TTP) of everolimus in routine use.
Results: Baseline documentation had been recorded for 327 patients, with a cut-off at Dec 31st 2012. At baseline, median age of patients was 68 years and median Karnofsky Performance Status was 80%. 76% of patients were male and 92% of patients had been diagnosed with histologically proven clear-cell RCC. MSKCC risk score at start of first-line therapy was favorable in 35%, intermediate in 56%, and poor in 9% of patients. Median treatment duration with everolimus after failure of one VEGFR-TKI was 6.7 months (95% CI, 5.1−8.8 months). Median time to progression (TTP) for patients who received everolimus after failure of one VEGFR-TKI was 7.4 months (95% CI, 6.4−9.1 months). Median overall survival had not yet been reached.
Conclusions: These data represent preliminary results from a large prospective non-interventional study on the routine use of everolimus in mRCC after exactly one previous VEGFR-TKI. These data provide additional evidence for the role of everolimus in routine use after failure of one VEGFR-TKI.
Conflict of interest: *Advisory board: Novartis, GlaxoSmithKline, Roche, Astellas, Sanofi-Aventis, Pfizer, Amgen, Janssen-Cilag, Bayer. Corporate-sponsored research: Novartis. Other substantive relationships: Novartis*

2782 POSTER

Baseline peripheral blood immune cells and inflammatory molecules predict progression free survival in metastatic renal cell carcinoma patients treated with first-line sunitinib

G. Kimura[1], R. Mizuno[2], T. Ueda[3], T. Kondo[4], H. Hara[5], S. Shoji[6], H. Nakazawa[7], K. Tanabe[4], S. Horie[8], M. Oya[2]. *[1]Nippon Medical School, Urology, Tokyo, Japan; [2]Keio University School of Medicine, Urology, Tokyo, Japan; [3]Chiba Cancer Center, Urology, Chiba, Japan; [4]Tokyo Women's Medical University, Urology, Tokyo, Japan; [5]Kyorin University Hospital, Urology, Tokyo, Japan; [6]Tokai University Hachioji Hospital, Urology, Tokyo, Japan; [7]Tokyo Women's Medical University Medical Center East, Urology, Tokyo, Japan; [8]Juntendo University, Urology, Tokyo, Japan*

Background: Predicting the efficacy of tyrosine kinase inhibitors (TKI) would be of clinical value in patients with metastatic renal cell carcinoma (mRCC). We tested the hypothesis that peripheral blood immune cells and serum inflammatory markers are associated with clinical outcome in mRCC patients at favorable or intermediate prognostic risk treated with first-line sunitinib.
Material and Methods: Ninety mRCC patients were prospectively monitored at baseline (day 0) during sunitinib treatment. Serum interleukin-6 and 8 levels were determined by CLEIA and ELISA, respectively. A high-sensitivity C-reactive protein (hs-CRP) levels were measured using laser nephelometry. The immunological parameters, including proportion of

type-1 (Th1) and type-2 (Th2) cells, regulatory T cells (Treg), monocytes, mature dendritic cells and Th1/Th2 ratio, were assessed by flow cytometric analysis. Correlations between those baseline variables and progression-free survival (PFS) were examined.
Results: Median PFS was 12.6 months. Clinical benefit rate (CBR; percent complete responses+partial responses +stable disease 24 weeks) was 57.3%. In univariate analyses, baseline interleukin-8, hs-CRP and proportion of Th1 were correlated with PFS, respectively. In multivariate Cox proportional analysis, hs-CRP ($p = 0.0110$) and proportion of Th1 ($p = 0.0140$) were independent indeces to predict PFS.
Conclusion: Baseline peripheral blood immune cells and serum inflammatory markers could be of clinical interest in sunitinib-treated mRCC patiens to predict outcome. Baseline hs-CRP serum levels as well as proportion of Th1 warrant further study.
No conflict of interest.

2783 POSTER

Addition of bevacizumab as salvage treatment in patients with metastatic renal cell carcinoma

H. Boyle[1], A. Daste[2], A. Jouinot[3], A. Ravaud[2], S. Oudard[3], N. Oussaid[4], S. Négrier[1]. *[1]Centre Régional Léon Berard, Department of Medical Oncology, Lyon, France; [2]Hôpital Saint André, Department of Medical Oncology, Bordeaux, France; [3]Hôpital Européen Georges Pompidou, Department of Medical Oncology, Paris, France; [4]Centre Léon Bérard, Department of Biostatistics, Lyon, France*

Background: Treatment of metastatic renal cell carcinoma (mRCC) is based on VEGF inhibitors and mTOR inhibitors. However resistance occurs. A previous study showed interesting results with a bevacizumab (bev) − sunitinib combination in sunitinib-refractory patients (pts). We report on our experience on pts who were progressing on a anti-VEGF inhibitor or a m-TOR inhibitor and were given the same drug plus bevacizumab.
Population and Methods: The study population was described (pts demographics, initial tumour characteristics, treatments etc). Overall survival (OS) from the beginning of the 1st combination was estimated by Kaplan–Meier method and prognostic factors were explored using a Cox model.
Results: Twenty-nine pts were treated with such a combination: 23 men and 6 women. Twenty four pts had undergone surgery. Eleven pts (37.9%) had metastatic disease at initial diagnosis. Eighteen pts had clear cell histology, 8 had clear cell + another component (sarcomatoid or eosinophil), 2 had papillary tumours. For 1 pt the precise histology was not available.
Most patients received sunitinib as first antiangiogenic drug for metastatic RCC (93.1%). The 2 other pts were in a clinical trial and received respectively AMG-sorafenib and pazopanib+bevacizumab. Only 6 pts had received prior immunotherapy. Ten pts received the combination as 2nd line treatment, 7 as 3rd line, 8 as 4th line and 4 as 5th line.
Fifteen pts received sunitinib+ bev, 9 everolimus+ bev and 5 temsirolimus+ bev. All pts but 1 received full-dose bev (10 mg/kg). Full dose sunitinib of 50 mg 4w/6 was given to 8/15 pts. Four patients received full dose everolimus (10 mg/day) and temsirolimus (25 mg/weekly) respectively.
Main toxicities were hypertension, proteinuria, hand–foot syndrome, mucositis and haematological toxicity. Two pts had grade 3 proteinuria,3 had grade 3 hypertension and 3 grade 3 hand–foot syndrome.
More than a third of pts had improvement in their symptoms. Best radiological response was stable disease in 15 pts and partial response in 2.
With a median follow-up of 18 months (range: 1−35 mo), 2 pts are still on treatment. Fifteen pts discontinued treatment because of progression and 9 because of toxicity.
The median duration of the 1st combination was 4 months (95% IC=2−5 mo). Median OS from 1st combination was 8 months (95% IC=4−26 mo). There was no statistical difference according to the type of combination, the line of treatment and the histological subgroup.
Conclusions: Adding bevacizumab to another antiangiogenic therapy at progression can benefit some pts. Side effects should be monitored closely. However selecting which pts should receive such a treatment is not defined yet.
Conflict of interest: *Ownership: no. Advisory board: Pfizer, Bayer, Novartis, Janssens, Keocyt, Takeda, Roche. Board of directors: No. Corporate-sponsored research: Bayer, Novartis. Other substantive relationships: No*

2784 POSTER

Everolimus in clinical practice, which patients benefit?: A study of outcomes, tolerability and quality of life in an early cohort of patients

L. Pennant[1], C. Boon[1], A. Zarkar[1]. *[1]University Hospital Birmingham, Clinical Oncology, Birmingham, United Kingdom*

Background: Following a phase III trial suggesting benefit, Everolimus gained approval for second line treatment for renal carcinoma. Trial data shows a PFS benefit of 3 months, and sustained quality of life. We aimed to assess outcomes in clinical practice, comparing to those expected, and investigated factors predicting increased benefit.
Methods and Materials: Patients commencing Everolimus between August 2009 and January 2012 were found via applications to the West-midlands cancer drugs fund. Data was extracted from electronic records of patient demographics and outcomes: OS and PFS, treatment length, toxicity. An adapted version of the EORTC QLQ-C30 assessed quality of life in patients on follow up.
Results: Of 47 patients identified 3 were lost to follow up. Of 44, 27 patients had died, 17 were alive. Patient characteristics were compared to trial patients: gender and age were similar, performance status was lower (0=2% vs 28%, 1=66% vs 36%), as was MSKCC risk (favourable= 18% vs 29%, poor 30% vs 15%). Median treatment time was 70 days vs 95. Discontinuation due to toxicity was higher (28% vs 10%), and increased with disease burden, $\geqslant$4 sites of metastasis (OR 2.01, $P = 0.28$). Best objective response was stable disease in 57% (vs 63%). Median PFS was 3 months (vs 4.9). PFS was reduced by poor MSKCC (0= 5, 1= 3 and 2= 2.3 months Chi-Square=1.72, $P = 0.4$), PS (0 or 1= 177 days, 2= 112, $P = 0.09$), younger age (age <60=132, $\geqslant$60= 174, $P = 0.2$) and increased disease burden (PS, 1−3 sites=194, $\geqslant$4=112, $P = 0.04$). Median OS was 8 months, and similarly reduced with poor PS, MSKCC score, increased disease burden and younger age. Of 7 patients completing the EORTC QLQ-C30, only 1 reported deterioration in QOL.
Conclusions: Poorer PS, lower MSKCC and higher disease burden were seen, and resulted in worse outcomes in Everolimus treated patients. Unexpectedly younger age was also a poor prognostic factor and disease burden appeared to reduce ability to tolerate treatment. Although benefit in PFS is lower, maintained objective response and moderate PFS advantage was seen. These factors should be considered in decisions to commence Everolimus treatment.
No conflict of interest.

2785 POSTER

Clinical significance of Ezrin and Neuropilin-2 expression in advanced renal cell carcinoma

B. Cetin[1], I.I. Gonul[2], S. Buyukberber[1], B. Afsar[3], O. Gumusay[1], M. Benekli[1], U. Coskun[1]. *[1]Gazi University Faculty of Medicine, Department of Internal Medicine Division of Medical Oncology, Ankara, Turkey; [2]Gazi University Faculty of Medicine, Department of Pathology, Ankara, Turkey; [3]Konya Numune State Hospital, Department of Internal Medicine Division of Nephrology, Konya, Turkey*

Background: The identification of prognostic factors in patients with renal cell carcinoma (RCC) represents an area of increasing interest. This study used a cohort of patients treated for RCC to provide information about biomarkers and prognosis. The purpose of this study was to evaluate prognostic factors in patients with RCC.
Materials and Methods: The expression of several biomarkers were measured by immunohistochemistry (IHC) in 45 patients with advanced RCC treated with second-line vascular endothelial growth factor (VEGF) targeted tyrosine kinase inhibitors (TKIs) after failure of interferon-alpha between January 2007 and June 2012. Kaplan–Meier and log-rank analyses were employed on PFS and OS and multivariate Cox proportional hazard model analyzed clinical parameters for their prognostic relevance.
Results: Age, ezrin and neuropilin-2 overexpression were statistically significant factors ($P < 0.05$) for PFS in the univariate analysis. Ezrin and neuropilin-2 overexpression, hemoglobin and albumin were statistically signifiant factors ($P < 0.05$) for OS in the univariate analysis. Multivariate analysis revealed that low expression of ezrin and neuropilin-2 were a favorable prognostic factor independent of PFS and OS. Median PFS was 4 versus 11 months in patients with overexpression neuropilin-2 versus low expression neuropilin-2 ($p = 0.033$). The median OS was 13 months versus 26 months, in patients with overexpression neuropilin-2 versus low expression neuropilin-2, respectively ($p = 0.023$). Increased expression of ezrin was related to poor prognosis with VEGF targeted TKI treatment (PFS, 3 vs. 7 months $p = 0.012$).
Conclusions: Neuropilin-2 and ezrin in particular are useful prognostic factors in patients with advanced RCC.
No conflict of interest.

A retrospective analysis of treatment efficacy of primary mediastinal germ-cell tumours

K. Nietupski[1], W. Michalski[1], P. Wiechno[1], T. Demkow[1], M. Ligaj[2], P. Peczkowski[3], M. Pilichowska[3], G. Poniatowska[1], M. Sadowska[1], I. Skoneczna[4]. *[1]Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Urooncology, Warsaw, Poland; [2]Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Pathology, Warsaw, Poland; [3]Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Radiotherapy, Warsaw, Poland; [4]Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Warsaw, Poland*

Background: Primary germ-cell tumours of the mediastinum are rare. Treatment algorithms do not differ from those for testicular germ-cell tumours. However, extragonadal origin in the chest is an independent factor of poor prognosis.
This paper summarizes treatment results in our centre.
Material and Methods: Data of 20 patients treated in our centre in the years 1998–2012 were retrospectively analysed.
Results: Median age of the patients was 24.8 years. In 13 patients (65%), the diagnosis was established after mediastinoscopy and biopsy; 4 patients (20%) underwent partial or complete tumour resection, 1 patient had a transbronchial biopsy, 1 patient − biopsy of the supraclavicular mass; in 1 case the clinical picture (computed tomography, serum markers) was sufficient to establish the diagnosis. 19 patients received chemotherapy, 1 did not due to poor compliance. Of these, 9 (45%) had one line of chemotherapy, 8 (40%) − two lines, and 2 (10%) − three lines. Resection of residual masses was conducted in 12 (60%) patients, whereas 1 patient (5%) underwent radiotherapy to the mediastinum. The median follow-up was 16.5 months. 8 patients (40%) died of their disease; the median survival from the end of first-line chemotherapy in this subgroup was 11.3 months. 1 patient was lost to follow-up. In the subgroup of patients followed up for over 5 years, 5 of 14 (35.7%) are still alive.
Conclusions: The data confirmed a moderate efficacy of systemic treatment in primary mediastinal germ-cell tumours. The prognosis was particularly poor in patients who did not achieve remission during the first-line treatment.
No conflict of interest.

2787 POSTER

Second line treatment in metastatic patients with non-clear cell renal carcinoma (Ncc-RCC): Retrospective analysis of a 22 patients cohort

L. Derosa[1], L. Galli[1], E. Biasco[1], A. Farnesi[1], R. Marconcini[1], R. Viglialoro[1], C. Cianci[1], A. Antonuzzo[2], S. Ricci[2], A. Falcone[3]. *[1]Azienda Ospedaliera Universitaria Pisana, Oncologia Medica 2 Universitaria, Pisa, Italy; [2]Azienda Ospedaliera Universitaria Pisana, Oncologia Medica 1 Ospedaliera, Pisa, Italy; [3]Dipartimento di Oncologia dei Trapianti e delle Nuove Tecnologie in Medicina-Azienda Ospedaliera Universitaria Pisana, Oncologia Medica 1 Ospedaliera, Pisa, Italy*

Background: Renal cell carcinoma (RCC) more than one single disease consists of various tumor types, each one with a different histology and clinical course. Histologies include clear cell, papillary types I/II, chromophobe, collecting duct and unclassified renal carcinoma. Sarcomatoid Variant (SV) represents a phenotype of RCC that can be present in any subtype, usually showing an aggressive biological behavior. Patients with SV or Ncc-RCC have been included in RCC clinical trials, although such patients represent minority components. There is no specific recommendation for Ncc-RCC. First line prospective dedicated studies are on going. No second line data have been reported.
Material and Methods: All pts with metastatic Ncc-RCC treated in first line from 2007 to 2013 at our Institution, were retrospectively analysed. Clinical data, prognosis classifications and treatments were assessed; PFS after first and second line and OS were calculated.
Results: 22 pts with metastatic Ncc-RCC were identified. Median age at diagnosis was 62, sex ratio 16M/6F. Histological subtypes were: papillary type I/II (39%), chromophobe (18%), unclassified (13%) and sarcomatoid(30%). Nephrectomy had been performed in 18 pts (82%). Most pts presented with synchronous metastatic disease (82%). Metastatic sites were: 12 lung (55%), 17 LN (77%), 5 bone (23%), 6 liver (27%). Prognostic classification by MSKCC was good in 9, intermediate in 5 and poor in 8 pts. Median OS was 16.0 months, 9/22 pts are still alive. As first line treatment, pts received: sunitinib (9), temsirolimus (7), sorafenib (3), pazopanib (1), bevacizumab based regimen (2). Median first line PFS is 13.0 months [1−17]. Median PFS in papillary type I/II and chromophobe is 7 months and in unclassified and SV is 6 months. 11(50%) pts received a second line treatment after first line failure. Second line treatment included sunitinib (6), sorafenib (3) or mTOR inhibitor (2). Median second line PFS is 16 months [1−34]. Median PFS in papillary type I/II and chromophobe is 18 months and in unclassified and SV is 2 months.
Conclusions: This is a report of second line data in Ncc-RCC. Median second line PFS is better in papillary or chromophobe (16 months) than unclassified and SV (2 months). The optimal treatment for pts with Ncc-RCC remain to be fully explored. Definitive recommendations will require subtype specific clinical trials or, lacking that, a registry of treatment results for pts with these relatively uncommon tumors.
No conflict of interest.

Vinflunine (VFL) as second-line chemotherapy for patients with transitional cell carcinoma of the urothelium (TCCU): A multicenter retrospective study

I. Chirivella[1], E. Grande[2], P. Lopez-Criado[3], B. Gonzalez-Grajera[4], O. Fernandez[5], C. Santander[6], J.A. Arranz[7], N. Mohedano[8], A. Pinto[9], G. De Velasco[10]. *[1]Hospital Clínico Universitario, Medical Oncology Service, Valencia, Spain; [2]Hospital Universitario Ramón y Cajal, Medical Oncology Service, Madrid, Spain; [3]MD Anderson Cancer Center, Medical Oncology Service, Madrid, Spain; [4]Fundación Hospital Son Llatzer, Medical Oncology Service, Palma de Mallorca, Spain; [5]Complexo Hospitalario Universitario, Medical Oncology Service, Ourense, Spain; [6]Hospital Universitario Miguel Servet, Medical Oncology Service, Zaragoza, Spain; [7]Hospital General Universitario Gregorio Marañon, Medical Oncology Service, Madrid, Spain; [8]Hospital Universitario de Guadalajara, Medical Oncology Service, Guadalajara, Spain; [9]Hospital Universitario La Paz, Medical Oncology Service, Madrid, Spain; [10]Hospital Universitario 12 de Octubre, Medical Oncology Service, Madrid, Spain*

Background: VFL is the standard chemotherapy in second-line advanced TCCU in Europe (EMA approval 21/09/2009). We set up a multicenter retrospective study to evaluate the efficacy and toxicity of VFL in patients (pts) with advanced TCCU after platinum failure within the framework of routine practice.
Material and Methods: Descriptive and retrospective study in pts who had demonstrated prior progression to a platinum-containing chemotherapy regimen at 9 centers. VFL standard dose (280–320/m^2 every three weeks) was administered until progression or unacceptable toxicity. Objective response was evaluated according to RECIST criteria v.1.1.
Results: Between April 2010 and February 2013, a total of 66 pts with median age of 67 years (range 47−83) were analyzed. Main characteristics: ECOG 0−1−2 in 21pts (31.8%), 40pts (60.6%), 5pts (7.6%). Mean creatinine clearance was 59 ml/min. Primary sites of disease were bladder 54pts (81.78%), renal pelvis 9pts (13.16%), ureteral 2pts (3%) and prostatic urethra 1pt (1.5%). All pts had previously received platinum-based chemotherapy as a first-line treatment (cisplatin in 42.4% of pts). Metastatic locations were: 42pts (63.6%) lymph nodes, 26pts (39.3%) lung, 18pts (27.2%) bone and 17pts (25.7%) liver. The median number of cycles of VFL was 5 (1−18). All pts were assessed for response, one (1.5%) patient presented complete response (CR), 17pts (25.8%) partial response (PR), 28pts (42.4%) stable disease (SD) and 20pts (30.3%) progressive disease (PD). Median progression-free survival was 3.96 months (95% CI, 3.11−4.8). Median overall survival (OS) was 10.4 months (95% CI, 6.25–14.5). OS at 6 months was 58%. Liver metastasis ($p = 0.013$) and ECOG ($p = 0.023$) was confirmed as prognostic factors for OS. Grade 3/4 adverse events included neutropenia 6pts (9%), constipation 4pts (6%), abdominal pain 4pts (6%) and nausea/vomiting 4pts (6%).
Conclusions: This retrospective analysis confirm VFL as an active agent in pts progressing after platinum-based combination for advanced TCCU in a daily clinical practice in Spain. As ESMO (Bellmunt J, 2011) and Spanish (Castellano D, 2012) guidelines recommend vinflunine, it should be offered in this setting or alternatively, treatment within a clinical trial.
No conflict of interest.

2789 POSTER

New chemotherapeutic regimens in patients (pts) with mediastinal nonseminomatous germ cell tumors (MNSGCT): Do we still need BEP as a standard?

M. Fedyanin[1], A. Tryakin[1], I. Pokataev[1], A. Bulanov[1], T. Zakharova[2], B. Polockii[3], A. Garin[1], S. Tjulandin[1]. *[1]Blokhin's Russian Cancer Research Center, Clinical Pharmacology and chemotherapy, Moscow, Russian Federation; [2]Blokhin's Russian Cancer Research Center, Pathomorphology, Moscow, Russian Federation; [3]Blokhin's Russian Cancer Research Center, Toracoabdominal Surgery, Moscow, Russian Federation*

Background: Pts with MNSGCT belong to the poor prognostic group by IGCCCG. BEP regimen is still a gold standard of treatment. We

retrospectively compared efficacy of different chemotherapeutic regimens which were used in our center in phase II trials.
Material and Methods: We analyzed data of 61 pts with MNSGCT, who were treated in our department during 1986–2011. Median age was 23 years (range, 18−44). Median follow-up time was 60 months (range, 4–180). Induction chemotherapy BEP was accomplished in 23/61 (37.8%), TBEP − in 17/61 (27.8%), CBOP − in 17/61 (27.8%), accelerated (dose-dense) BEP − in 4/61 (6.6%) pts. Surgery resection of residual tumor was performed in 28/61 (45.9%) pts.
Results: Based on similar efficacy of CPOB and TBEP regimens we combined pts to a single 'CPOB/TBEP' group and compared with 'BEP' group. Pts in both groups were similar according main prognostic factors, including size of the primary tumor, number metastatic sites, lungs and nonlungs metastases, age, mean levels of AFP, HCG, LDH. Marker-negative objective response obtained in 40/61 (65.6%) pts. Median OS was 24 months and 3-year OS − 46% for all pts. Marker-negative objective response rate was higher in pts in CPOB/TBEB group: 26/34 (76.5%) vs. 14/27 (51.8%), p = 0.08. Surgery resection of residual tumor was performed in 20/34 (58.8%) pts of CPOB/TBEB group vs. 8/27 (29.6%) pts of BEP group, p = 0.04. Overall survival was also higher in pts in CPOB/TBEB group: 2- and 5-years OS were 63% and 55% vs. 35% and 21% (p = 0.009, HR 2.8, 95% CI 1.30−6.1), respectively.
Conclusions: CBOP and TBEP regimens are associated with better outcome in pts with MNSGCT. These data should be confirmed in prospective trials.
No conflict of interest.

2790 POSTER

Efficacy and safety of sequential use of everolimus (EVE) in patients (pts) with metastatic renal cell carcinoma (mRCC) previously treated with bevacizumab (BEV) +/− interferon (INF) therapy − updated results from the European AVATOR retrospective study

A. Thiery-Vuillemin[1], C. Theodore[2], L. Jacoabsh[3], J. Schmitz[4], A. Guillot[5], C. Papandreou[6], C. Emmanouilides[7], S. Kim[1], N. Kelkouli[8], T. Nguyen[1]. *[1]Jean Minjoz Hospital, Oncology, Besançon, France; [2]Foch Hospital, Oncology, Suresnes, France; [3]Private Practice, Oncology/Hematology, Dresden, Germany; [4]Fachklinik Lindenberg/Ried, Oncology, Lindenberg, Germany; [5]Cancerology Institute, Oncology, Saint Priest en Jarez, France; [6]University Hospital of Larissa, Oncology, Larissa, Greece; [7]Interbalkan Hospital, Oncology, Thessaloniki, Greece; [8]Novartis Pharma, Oncology, Rueil-Malmaison, France*

Background: EVE (Afinitor®) has demonstrated activity in the treatment of mRCC after failure of VEGF-targeted tyrosine kinase inhibitors. To this date, there is no published data evaluating its activity/safety after failure of first line BEV-based therapy.
Methods: Our non-interventional multicenter international study reports retrospective data on EVE in routine use. Eligible patients had mRCC; were given EVE after 1 prior first-line systemic therapy with BEV +/− INF. The data were provided by each center and centralized.
Results: Twenty sites included 43 pts between 2011 and 2012, with 42 evaluable patients. Baseline patient characteristics included median age of 69 [38−90] years old; 64.3% male; 97.5% with prior nephrectomy. First-line therapy was BEV + INF in 69% of patients, BEV only for 31%. Prognostic groups at the time of EVE initiation according to Heng [1] and to MSKCC [2] were respectively: (1) good 25%, intermediate 59.4% and poor prognosis 15.6% and (2) good 28.1%, intermediate 56.3% and poor 15.6%. Median duration of treatment with first line therapy was 7.5 months, and it was discontinuated for disease progression in 61.9% of pts.
After initiation of first line 53.3% of patients were alive at 32 months. Median OS was not reached for the second line. Median progression free survival (PFS) for EVE was 17 [5.0-not reached] months. Overall response rate was 9.5% and disease stabilization rate was 50%. At least one adverse event (AE) occurred in 73.8% of pts with 13 serious AEs. All grade common AEs were consistent with the toxicity profile of EVE with 31 % of stomatitis, 16.7% of pneumonitis, 31 % of fatigue.
Conclusions: This study provided encouraging results for the activity and safety profile of EVE in this second line mRCC setting after 1 prior first-line therapy with bevacizumab-based regimen. Further studies with larger numbers of pts are planned based on these novel findings.
Conflict of interest: *Corporate-sponsored research: Novartis − Pfizer*

2791 POSTER

Sequential assessment by FDG-PET/CT of patients with advanced renal cell carcinoma treated with tyrosine kinase inhibitors

N. Nakaigawa[1], M. Yao[1], U. Tateishi[2], K. Kobayashi[3], T. Kishida[4], K. Makiyama[1], K. Kondoh[1], T. Inoue[2], Y. Kubota[1]. *[1]Yokohama City University Graduate School of Medicine, Department of Urology, Yokohama, Japan; [2]Yokohama City University Graduate School of Medicine, Department of Radiology, Yokohama, Japan; [3]Yokosuka Kyosai Hospital, Department of Urology, Yokohama, Japan; [4]Kanagawa Cancer Center, Department of Urology, Yokohama, Japan*

Background: Tyrosine kinase inhibitors (TKIs) which target vascular endothelial growth factor receptors improved the prognosis of patients with advanced renal cell carcinoma (RCC). The antitumor activity of TKIs is not cytotoxic, like classical antitumor therapeutics, but rather cytostatic, suppressing biological activity. It has been suggested that a new assessment focusing not only on the volume of the tumors, but also biological activities to evaluate the antitumor activity of TKIs is necessary. FDG PET/CT is a useful non-invasive tool to evaluate glucose metabolic status, which can be the index of biological activity of cancer. From 2008, we have been investigating the usefulness of FDG PET/CT as biological biomarker to assess the status of advanced renal cell carcinoma (RCC) as a clinical study and previously reported that the RCC which FDG accumulation decreased more or 20% on 1 month after tyrosine kinase inhibitors (TKIs) treatment started showed good prognoses (BMC Cancer 2012). In this time, we investigated the sequential FDG accumulation change during TKI treatment.
Material and Methods: Of 71 patients with advanced RCC who were enrolled in this study, we focused on the 26 patients, who were treated with TKIs (13 sunitinib and 13 sorafenib) and evaluated by FDG PET/CT (Aquiduo 16; Toshiba Medical Systems, Tokyo, Japan) before treatment, 1 month after treatment started, and following every 3 months until their RCC demonstrated progression disease (PD) defined by RECIST criteria. The standardized uptake value (SUV), which is a semiquantitative simplified measurement of the tissue FDG accumulation rate was measured sequentially during TKI treatments.
Results: The median of progression free survival (PFS) of all 26cases was 159 days. Maximum SUV (SUVmax) in 17 cases (65%) was decreased by TKI treatment and that in 9 cases (35%) were increased. The median PFS of 19 cases with decreasing SUVmax was 211 days and that of 9 cases with increasing SUVmax was 110 days. There was statistic difference (P = 0.005). In 19 cases with decreasing SUVmax, the median date when SUVmax reached to nadir was 67 days. The median decreasing ratio of SUVmax at the nadir compared with that before treatment was 30%. The SUVmax increased after nadir in 14 cases (82%) and the SUVmax in 11 cases increased before cancer showed PD defined by RECIST criteria. The time lag between SUVmax increase and PD were 0−98 days (median 63 days). Interestingly, the SUVmax at PD was higher than that before TKI treatment in 12cases (46%).
Conclusions: FDG PET/CT could evaluate the biological response of advanced RCC to TKI treatment on real time and the increase in SUVmax before RCC showed progression suggested that acceleration of glucose metabolism was one of the mechanism how RCC acquired the resistance to TKI treatments.
No conflict of interest.

2792 POSTER

Safety and efficacy of vinflunine in long-time therapy of metastatic bladder cancer

L.A. Aparicio[1], R. Campelo[1], S. Antolin[1], M. Reboredo[1], M. Quindós[1], A. Figueroa[2], V. Chantada[3], L. Leon[4]. *[1]La Coruña University Hospital, Medical Oncology, La Coruña, Spain; [2]Tranlational Cancer Research Lab, Inibic, La Coruña, Spain; [3]La Coruña University Hospital, Urology, La Coruña, Spain; [4]Hospital Clinico Universitario, Santiago de Compostela, Spain*

Background: Vinflunine(VFL) has shown activity in second line metastatic bladder cancer patients. Culine et al have reported long-duration responses ranging from 4.2 to 15 months (median 9.1 months) in this setting. We performed an analysis to study clinical characteristics of long term responders to vinflunine.
Material and Methods: Patients with partial or complete response to first line treatment with platinum and gemcitabine were included. Patients had a performace status of 0 or 1, measurable disease by RECIST criteria, age >18 years, a life expectancy of a least 12 weeks, and an adequate organ function and bone marrow reserve. Patients received vinflunine 320 mg/m^2 IV day 1 every 21 days until disease progression or unacceptable toxicity.
Results: Data from 10 patients receiving an initial dose of VFL 320 mg/m^2 every 21 days show that the most frequent toxicity of vinflunine is

neutropenia (grade 1−2). Neutropenia is reversible and non-cumulative; severe anemia and thrombocytopenia were rarely observed. Constipation (any grade) was observed in 50% of patients. All patients in our serie presented site local patin related to vinflunine administration.
A total of 5 patients are still receiving vinflunine at the cut-off date; two of them have received 27 and 28 cycles of treatment. Median overall survival was not reached wtih a median follow-up of 10.5 months (range 8 to 19 months).
Conclusion: Single-agent vinflunine is safe and active as maitenance chemotherapy of patients with advanced transitional cell bladder carcinoma who have responded to a prior platinum-containing regimen, with minor toxicity and a good tolerance.
No conflict of interest.

2793 POSTER

Phase II clinical trial of sorafenib plus interferon-alfa treatment for patients with metastatic renal cell carcinoma in Japan

M. Eto[1], Y. Wada[1], Y. Hirao[2], K. Mita[3], Y. Arai[4], G. Kimura[5], N. Shinohara[6], S. Hinotsu[7], K. Tatsugami[8], S. Naito[8]. *[1]Kumamoto University, Urology, Kumamoto, Japan; [2]Nara Medical University, Urology, Nara, Japan; [3]Hiroshima City Asa Hospital, Urology, Hiroshima, Japan; [4]Tohoku University, Urology, Sendai, Japan; [5]Nippon Medical School, Urology, Tokyo, Japan; [6]Hokkaido University, Urology, Sapporo, Japan; [7]Okayama University, Urology, Okayama, Japan; [8]Kyushu University, Urology, Fukuoka, Japan*

Background: Much attention has been paid to molecular target-based drugs including tyrosine kinase inhibitors and mTOR inhibitors, which were approved by FDA for advanced renal cell carcinoma (RCC). Recently, however, we have already known their limitations in the treatment of patients with metastatic RCC (mRCC). To improve the antitumor effects of molecular target-based drug, sequential or combination therapy with these drugs has been advocated. In combination therapy, the additional effect of interferon (IFN)-α on sorafenib has been recently reported in mRCC patients (J Clin Oncol 25:3288, 2007) and in our murine model (J Urol 184:2549, 2010). Furthermore, the prognosis of mRCC patients in Japan was good in the cytokine era (Eur Urol 57:317, 2010). We have thus conducted a phase II clinical trial of sorafenib plus IFN-α for untreated mRCC patients in Japan (UMIN000002466).
Methods: In this multicenter, prospective study, provisionally registered patients with histologically confirmed clear cell RCC that was metastatic, measurable disease, age ⩾20 years, ECOG PS 0−1 and adequate organ function received 3 dosages of 3 million U per week of natural IFN-α treatment for 2 weeks. Then, only patients tolerable to IFN-α treatment were registered to this trial, and oral administration of sorafenib (400 mg, bid) was added to IFN-α treatment. The primary end point of the study was to evaluate response rate (CR + PR) of sorafenib plus IFN-α treatment for mRCC patients using RECIST v1.0. The secondary end point was to evaluate disease control rate (CR + PR + SD), progression free survival (PFS), overall survival (OS), and safety of the combined treatment.
Results: From July 2009 to July 2012, 53 untreated patients were provisionally registered, and 51 patients were finally registered to this trial of sorafenib plus IFN-α treatment. Nine patients were excluded because of violation of eligibility criteria. Among 42 eligible patients, 35 patients were male. Median age of patients was 64.5 years old (range 37−78). Thirty seven and 5 patients were PS 0 and 1, respectively. One patient pathologically demonstrated around 5% of spindle cell components. Response rate of the combined therapy was 26.2% (11/42) (CR 1, PR 10). Frequent adverse effects (AE) were hand–foot syndrome, fatigue, dermatitis, and diarrhea, which were well-known as common AE caused by either IFN-α or sorafenib. Neither increase of the incidence of AE nor unexpected AE due to the combined therapy was observed.
Conclusions: Our results have clearly demonstrated that sorafenib plus IFN-α treatment is safe and effective, and can be a therapeutic option for mRCC patients as a first line treatment.

2794 POSTER

Central and Eastern European experience with sutent from the expanded-access mRCC trial

E. Vrdoljak[1], I. Bodrogi[2], J. Mardiak[3], T.E. Ciuleanu[4], V. Gorbunova[5], S. Leyman[6], K. Zhang[7], L. Torday[8]. *[1]Clinical Hospital Split, Center of Oncology, Split, Croatia; [2]Orszagos Onkologiai Intezet, Budapest, Hungary; [3]National Cancer Institut, Department of Medical Oncology, Bratislava, Slovak Republic; [4]Institut of Oncology, Cluj Napoca, Romania; [5]NN Blokhin Russian Cancer Research Center, Moscow, Russian Federation; [6]Pfizer Inc, Brussels, Belgium; [7]Pfizer Inc, La Jolla, USA; [8]Albert Szent-gyorgyi Medical University, Department of Pharmacology, Szeged, Hungary*

Background: The international, open-label, expanded-access protocol (EAP) of sunitinib including 4371 patients with mRCC between June 2005 and December 2007 reported its final results of extended follow-up in 2012. This retrospective study presents results of patients from Central and Eastern European countries (CEE) including Slovakia, Serbia, Slovenia, Bulgaria, Croatia, Hungary, Russia, Romania, Czech Republic.
Materials and Methods: We analyzed safety, overall survival (OS), progression free survival (PFS) and objective response rate (ORR) in the subgroup of patients from CEE countries. Toxicity was assessed on days 1, 14 and 28 of cycle 1 and 28 of subsequent cycles. Tumor assessments were guided by the Response Evaluation Criteria in Solid Tumors (RECIST, version 1.0) but were not scheduled in the study protocol and were performed according to local standard of care, with data on response, PFS, and OS collected when possible. (Survival data collected up to July 15, 2008.)
Results: The CEE data set comprised 401 patients (8.8% of total population). 85.3% of the patients had ECOG performance status 0 or 1 and 86.5% had a favorable or intermediate risk according to the MSKCC risk criteria. The median duration of treatment of CEE group was 9.6 months (95% CI; 8.1–11.1) and the median number of treatment cycles was 7 (range 1−57). 159 (39.6%) patients had a dose reduction. The median PFS and OS results are presented in table 1.

Table 1. The median PFS and OS results in CEE mRCC patients in general and divided by prior cytokine use

	CEE population n = 378 (PFS) n = 401 (OS)	No prior cytokines n = 161 (PFS) n = 172 (OS)	Prior cytokines n = 217 (PFS) n = 229 (OS)
Median PFS (months; 95% CI)	11.6 (10.3; 12.8)	12.2 (9.3; 16.5)	11.0 (8.8; 12.6)
Median OS (months; 95% CI)	30.7 (23.3; −)	60.8 (26.3; −)	27.5 (20.9; 36.6)

The mPFS in patients with good, intermediate or poor risk according to MSKCC was 16.2 months (95% CI; 13.3; 18.5), 9.3 months (95% CI; 8.1; 11.9) and 5.2 months (95% CI; 2.3; 6.6) with a HR for the comparison of poor vs favorable or intermediate of 3.21 ($p < 0.0001$).
46 patients (11.5%) discontinued the study due to adverse events. 143 patients (35.7%) had at least one serious adverse event. The adverse event profile was comparable to the known profile of sunitinib.
Full comparison with global data set will be disclosed.
Conclusions: Results from this subanalysis of EAP confirm the safety and efficacy of sunitinib in patients treated in CEE.
Conflict of interest: *Advisory board: Pfizer. Corporate-sponsored research: Pfizer*

Safety and efficacy of second-line axitinib versus sorafenib in metastatic renal cell carcinoma by duration of prior therapy: Subanalyses from a phase III trial

B. Escudier[1], R.J. Motzer[2], H.Y. Lim[3], E. Porfiri[4], P. Zalewski[5], G. Kannourakis[6], J. Tarazi[7], B. Rosbrook[7], S. Kim[7], B.I. Rini[8]. *[1]Institut Gustave Roussy, Medical Oncology, Villejuif, France; [2]Memorial Sloan-Kettering Cancer Center, New York, USA; [3]Samsung Medical Center, Suwon, Korea; [4]Queen Elizabeth Hospital Birmingham, Birmingham, United Kingdom; [5]Durham Regional Cancer Centre, Oshawa, Canada; [6]Fiona Elsey Cancer Research Institute and Ballarat Oncology and Haematology Services, Ballarat, Australia; [7]Pfizer Oncology, San Diego, USA; [8]Cleveland Clinic Taussig Cancer Institute, Cleveland, USA*

Background: In the phase III AXIS trial (NCT00678392; sponsor: Pfizer), 723 patients with clear cell metastatic renal cell carcinoma, progressive disease after 1 systemic therapy and Eastern Cooperative Oncology Group performance status (PS) 0 or 1 were stratified by PS and prior therapy and randomised 1:1 to axitinib or sorafenib. Axitinib significantly improved

progression-free survival (PFS; primary endpoint) vs sorafenib in patients previously treated with sunitinib (n = 389) or cytokines (n = 251).
Material and Methods: In post-hoc analyses, investigator-assessed PFS, overall survival (OS), and safety of axitinib vs sorafenib by duration of 1st-line sunitinib or cytokines were evaluated.
Results: Median duration of prior sunitinib and cytokines was 9.7 and 6.5 months, respectively. Among patients with ⩾ vs <9.7 months of prior sunitinib treatment, median PFS (mPFS; 95% CI) was 6.6 (5.2−8.3) vs 6.4 (4.6−8.3) months with axitinib (*P*=.996) and 4.5 (3.0−6.5) vs 3.5 (1.9−4.7) months with sorafenib (*P*=.431); median OS (mOS; 95% CI) was 18.1 (14.8–23.0) vs 11.7 (9.3–15.2) months with axitinib (*P*=.220) and 19.0 (15.0–23.9) vs 14.9 (10.5–18.0) months with sorafenib (*P*=.018). Among patients with ⩾ vs <6.5 months of prior cytokine treatment, mPFS (95% CI) was 15.7 (12.2–22.1) vs 8.6 (6.5–13.8) months with axitinib (*P*=.002) and 8.4 (7.2–10.2) vs 6.7 (5.6−9.5) months with sorafenib (*P*=.580); mOS (95% CI) was not estimable (NE; 28.0−NE) vs 26.3 (18.8–31.6) months with axitinib (*P*=.017) and 34.5 (27.8–34.5) vs 23.1 (17.3–31.9) months with sorafenib (*P*=.014). In both arms, grade ⩾3 hypertension was more common (⩾5% difference) in patients who had received 1st-line cytokines for ⩾ vs <median duration; grade ⩾3 hand–foot syndrome was more common in patients who had received 1st-line sunitinib for < vs ⩾median duration (Table).
Conclusions: Longer prior treatment with sunitinib or cytokines was associated with longer OS with 2nd-line axitinib or sorafenib. Safety profile of 2nd-line axitinib or sorafenib differed modestly by duration of prior therapy.

Comprehensive activated kinase profiling to identify novel therapeutic targets in metastatic clear cell (cc)-renal cell carcinoma (RCC)

G. Sonpavde[1], J.C. Anderson[2], K. Welaya[2], D. Chen[3], A. Mehta[4], P. Ghatalia[5], S. Sudarshan[6], W.E. Grizzle[7], T.K. Choueiri[8], C.D. Willey[2].
[1]UAB (University of Alabama Birmingham) Cancer Center, Birmingham AL, USA; [2]UAB (University of Alabama Birmingham) Cancer Center, Radiation Oncology, Birmingham AL, USA; [3]UAB (University of Alabama Birmingham) Cancer Center, Biostatistics, Birmingham AL, USA; [4]UAB (University of Alabama Birmingham) Cancer Center, Hematology-Oncology, Birmingham AL, USA; [5]UAB (University of Alabama Birmingham) Cancer Center, Medicine, Birmingham AL, USA; [6]UAB (University of Alabama Birmingham) Cancer Center, Urology, Birmingham AL, USA; [7]UAB (University of Alabama Birmingham) Cancer Center, Pathology, Birmingham AL, USA; [8]Dana Farber Cancer Institute and Harvard Medical School, Medical Oncology, Boston MA, USA

Background: Kinase inhibitors have yielded therapeutic advances in cc-RCC. We hypothesized that determining differential kinase activity between primary and metastatic renal tumors may identify critical drivers of progression and relevant therapeutic targets in metastatic disease.
Methods: Fresh frozen RCC with a clear cell component were provided by the Cooperative Human Tissue Network (funded by U.S. National Cancer Institute). Kinomic profiling of tumor lysates was performed using the PamStation®12 high-content phospho-peptide substrate microarray system (PamGene International). The protein tyrosine kinome (PTK) and serine/threonine kinome (STK) PamChips® were used to measure global kinase activity. The degree of phosphorylation on each peptide probe was measured kinetically using Evolve software (PamGene), that measured FITC labeled anti-phosphotyrosine (or anti-phosphoserine/threonine) antibody binding to each phosphorylated peptide substrate during the 60 min assay and were further analyzed using BioNavigator software (PamGene). Advanced network modeling of altered phosphopeptides was performed using MetaCore (Thompson Reuters). All peptides in the metastatic and primary renal tumors were compared using an unpaired students t-test. Peptides were uploaded to Metacore as source-protein Uniprot ID's and a Djikstras shortest path networking algorithm with 2 steps maximum between nodes was used to generate a network model.
Results: Among 96 available tumor samples, 92 met quality control criteria for kinase activity. Frozen cc-RCC tumor was available from 79 patients from the primary site, 11 patients from the metastatic site and 1 patient from both the primary and metastatic site. When comparing the profiles of primary and metastatic tumors, 8 phosphopeptide probes were significantly altered ($p < 0.005$): 7 PTK peptides had increased phosphorylation in metastases including peptides derived from FGFR1, FAK1, MBP, EPHB4, K2C8, ACHD and EGFR; the PGYL STK peptide phosphorylation was decreased in metastases. Network modeling also identified CEBPB as a key transcription factor.
Conclusion: Comprehensive kinase profiling of fresh frozen cc-RCC tumors identified 7 tyrosine kinase substrates showing elevated phosphorylation in metastatic tumors compared to primary tumors. Further validation is warranted since these kinases may represent novel targets for the therapy of metastatic disease as well as adjuvant therapy following extirpation of localized tumors.

2797 POSTER

Preclinical activity of CEP9722, a PARP inhibitor, in urothelial carcinoma (UC)

G. Sonpavde[1], W. Jian[2], Z. Xu[3], H. Xu[3], J. Chen[3], S. Yang[4], S.P. Lerner[2].
[1]UAB (University of Alabama Birmingham) Cancer Center, Birmingham AL, USA; [2]Baylor College of Medicine, Urology, Houston, USA; [3]UAB (University of Alabama Birmingham) Cancer Center, Oncology, Birmingham, USA; [4]UAB (University of Alabama Birmingham) Cancer Center, Radiation Oncology, Birmingham, USA

Introduction: Somatic loss of DNA repair proteins ERCC1 and BRCA1 is common in UC. A rationale can be made to evaluate the preclinical activity of a PARP inhibitor, CEP9722 and its active metabolite, CEP8983, to exploit synthetic lethality.
Methods: The activity of CEP8983 alone and with cisplatin after 72 hrs was evaluated in vitro by MTT assay against human UC cell-lines: 5637, TCC-SUP, T24, and RT4. FACS for Annexin-V/PE-FITC was performed to assess apoptosis/necrosis. Alkaline COMET assay was performed post 24-hr exposure to CEP8983, cisplatin or both to assess DNA damage. Western Blot was done to examine proteins involved in DNA repair (LKB1, MRE11, BRCA1, CHK1, CHK2, RAD50, RAD51, ATM) and PAR on untreated cell-lines to identify biomarkers predictive of sensitivity. Subcutaneous RT4 xenografts were treated with placebo or CEP9722 100 mg/kg/day or 200 mg/kg/day orally for 5 days a week for 4 weeks (5 mice per group). Xenografts underwent immunohistochemistry (IHC) for apoptosis (cleaved caspase [cc]-3) and angiogenesis (CD31).
Results: CEP8983 1 μM reduced the viability of RT4 and T24 cells by 20% compared to controls (sensitive), but did not reduce viability of 5637 and TCC-SUP cells (resistant). At 10 μM, RT4 viability was reduced by 39% and 5637 viability by 18%. The combination of cisplatin and CEP8983 in vitro did not yield additive activity. FACS demonstrated apoptosis plus necrosis in 9.7 and 9.1% of RT4 and 5637 cells, respectively. RT4 cells exhibited greater DNA damage compared to 5637 by COMET assay. COMET assay also showed increased DNA damage with combination versus either CEP8983 or cisplatin alone in RT4 and 5637 cells. Western Blot did not demonstrate consistent differences for DNA damage repair proteins and PAR between resistant or sensitive cells. CEP9722 showed antitumor activity in RT4 xenografts compared to controls and dose response was observed; 200 mg/kg daily was statistically better than control ($p = 0.04$) and 100 mg/kg was not ($p = 0.26$). IHC of xenografts showed significant increase in cc-3 and decrease in CD31 with both doses ($p < 0.05$).
Conclusion: Selected UC cells are preclinically sensitive to PARP inhibition by CEP9722 and its active metabolite CEP8983. CEP8983 did not enhance the activity of cisplatin and no biomarkers predictive for activity were identified. Further investigation of PARP inhibitors as single agents and genome wide profiling to identify a signature predictive for activity may be warranted.

2798 POSTER

Body composition as a predictor of dose limiting chemotherapy toxicity in patients with renal cell carcinoma treated with sunitinib

S. Cushen[1], D. Power[2], M.Y. Teo[3], P. McEneaney[4], P. McLaughlin[4], F. Fitzpatrick[1], R. McDermott[3], A. Ryan[1]. [1]*University College Cork, Food and Nutritional Sciences, Cork, Ireland;* [2]*Mercy University Hospital, Medical Oncology, Cork, Ireland;* [3]*Medical Oncology, St Vincents Hospital, Dublin, Ireland;* [4]*Mercy University Hospital, Radiology, Cork, Ireland*

Background: Predicting toxicity to chemotherapy is often difficult because of patient variation in drug metabolism and the narrow therapeutic window of most chemotherapeutic agents. Body composition is a prognostic factor in cancer patients (pts) and sarcopenia (i.e. muscle wasting) is associated with performance status, treatment toxicity and survival. Sunitinib is a standard first line oral chemotherapy for metastatic renal cell carcinoma (mRCC) that is associated with significant dose limiting toxicities. We investigated if body composition by computed tomography (CT) scan predicted dose limiting toxicity (DLT) from sunitinib in mRCC.
Methods: Pts with mRCC receiving sunitinib 50 mg as first line therapy between 2007–2012 were included. Ethical approval was obtained and prospectively maintained databases analysed. Skeletal muscle cross-sectional area at L3 was measured by CT, which had been done previously for diagnostic purposes. Sarcopenia was defined using published cut offs. Toxicity was assessed after 4 cycles of drug, according to Common Terminology Criteria for Adverse Events (CTCAE, v 4.0).
Results: 55 pts (43 male), mean age 64 yrs were included. 67% were overweight/obese (Body Mass Index [BMI] >25 kg/m^2). Sarcopenia was present in 33% (56% of normal BMI, 44% of overweight groups). Overall 40 pts (73%) experienced DLT (51% M, 100% F, p = 0.016. DLT occurred in <6 months in 53% (44% M vs 83% F, p = 0.016) and these pts who experienced DLT were older (mean 68 yrs vs 60 yrs, p = 0.01), had lower skeletal muscle mass (SMM) (51.8 cm^2/m^2 vs 59.4 cm^2/m^2, p = 0.012), and fat free mass (FFM) (51.4 kg vs 57.7 kg, p = 0.03), and received higher drug dose in mg/kg FFM (1.01 vs 0.89, p = 0.02). There was no difference in weight, BMI, fat mass or the drug dose (mg/kg). Common toxicities were gastrointestinal (65%) and fatigue (47%). 92% pts with SMM <25th centile experienced DLT compared to 57% pts with SMM >75th centile (p = 0.05). Pts <25th centile had an average of 5 toxicities vs 2 in those >75th centile (p = 0.003). All toxicities were more common in muscle wasted patients (p = 0.05). 77% (n = 10) of pts receiving a drug dose >75th centile (1.105 mg/FFM) experienced DLT in <6 months vs 44% (n = 17) receiving a dose <75th centile (<1.099 mg/FFM; p = 0.037).
Conclusions: Sarcopenia is prevalent in patients with mRCC, is an occult condition in pts with normal/high BMI, and is a significant predictor of DLT in pts receiving first line sunitinib. Our results highlight the potential use of baseline body composition to predict toxicity. There is an urgent need for validated biomarkers to help clinicians identify pts who may develop unnecessary toxicity from ineffective therapy. The role of sarcopenia in targeted therapy is evolving and its potential to predict toxicity should be further studied.
No conflict of interest.

Truly resistant patients with advanced renal cell carcinoma receiving first line sunitinib: Analysis of VEGF and VEGFR polymorphisms

M. Bianconi[1], M. Scartozzi[2], L. Faloppi[1], C. Loretelli[1], A. Zizzi[3], R. Giampieri[1], M. Del Prete[1], L. Burattini[2], R. Montironi[3], S. Cascinu[1]. [1]*Università Politecnica delle Marche, Department of Medical Oncology, Ancona, Italy;* [2]*AOU Ospedali Riuniti, Department of Medical Oncology, Ancona, Italy;* [3]*Università Politecnica delle Marche, Department of Pathological Anatomy, Ancona, Italy*

Background: Metastatic renal cell carcinoma treatment has radically changed. At present, therapeutic strongholds are TKIs directed against the angiogenetic pathway, such as sunitinib. Although in mRCC sunitinib demonstrated a huge activity profile, a large proportion of patients, ranging from 60−70%, is still refractory to such treatment approach. This latter group of patients is then exposed to potentially relevant toxicities without any hope for clinical benefit. We previously reported the predictive role of VEGF and VEGFR polymorphisms in mRCC patients treated with first-line sunitinib. The aim of our study was to evaluate the role of VEGF and VEGFR polymorphisms, in identifying a subgroup of patients truly resistant to treatment with sunitinib.
Methods: 84 formalin-fixed paraffin-embedded tissue blocks from mRCC patients receiving first-line sunitinib were tested for VEGF-A, VEGF-C and VEGFR-1,2,3 single nucleotide polymorphisms (SNPs). SNPs were correlated with PFS. Patients with a PFS under 3 months were considered truly resistant.
Results: 84 patients with metastatic renal cell carcinoma were available for our analysis, 19 of this were considered truly resistant (23%). Truly resistant patients express a TT polymorphism of rs833061 (p = 0.017), a CC polymorphism of rs699947 (p = 0.011) and a CC+CG polymorphism of rs2010963 (p = 0.009).
Conclusions: In our analysis patients with TT polymorphism of rs833061, a CC polymorphism of rs699947 and a CC+CG polymorphism of rs2010963 seemed to be truly resistant to sunitinib treatment. This subgroup of patients may, thus, be averted from unnecessary toxicities and could be considered for treatment with a different agent.

MicroRNA profiling differentiates between urine samples from prostate cancer patients, kidney cancer patients, and patients without a cancer diagnosis

T. Lautenschlaeger[1], W. Meng[1], H.J. Alder[2], K.H. Maclean[3], S. Kirste[4], P. Stegmaier[5], A.L. Grosu[4], A. Chakravarti[1]. [1]*The Ohio State University, Radiation Oncology, Columbus OH, USA;* [2]*The Ohio State University, Nucleic Acid Shared Resource, Columbus OH, USA;* [3]*Nanostring Technologies, Nanostring Technologies, Seattle WA, USA;* [4]*University of Freiburg, Radiation Oncology, Freiburg, Germany;* [5]*University of Freiburg/The Ohio State University, Radiation Oncology, Freiburg/Columbus OH USA, Germany*

Background: Screening biomarkers to identify asymptomatic patients with prostate or kidney cancer are not established. MicroRNAs are known to be a particularly robust species of RNA. We have performed microRNA profiling to identify biomarker candidates potentially useful as screening or recurrence biomarkers. To this end we have gathered clinical information and urine specimens from a cohort of 240 individuals: 80 patients with prostate adenocarcinoma, 80 patients with renal clear cell carcinoma, and 80 normal control individuals.
Material and Methods: Urine samples from prostate adenocarcinoma patients (no prostate massage performed; 4% Gleason score (GS) 6, 76% GS 7, 20% GS 8 or higher, 98% intermediate or high risk, 5% with N1 disease), renal clear cell carcinomas patients (63% stage I, 10% stage II, 19% stage III, 7% stage IV, 1% unknown), and normal control individuals (34% diverticulosis, 15% bariatric surgery, 14% diverticulitis, 15% hernia surgery, 10% hemorrhoids, 12% other non-cancer conditions) were collected. 10 urine samples of a single patient group were pooled. MicroRNAs from exfoliated cells and circulating microRNAs in 1 ml of urine were extracted together using the Norgen Biotek urine microRNA purification kit. The nCounter human miRNA assay kit, v2 (800 human mature miRNAs), was used according to manufacturer's guidelines with 100 ng RNA input. Data was log2 transformed, normalized using the global sum method, and analyzed using nSolver (nanoString Technologies).
Results: Here we present data of our pooled urine sample nanoString analysis representing 240 individuals. Several microRNAs were differentially expressed between prostate cancer, kidney cancer, and control patients. Consistent with previous data miR-21 was expressed higher in urine from either prostate cancer or kidney cancer patients compared to normal controls. Similarly, let-7a, miR-25, or miR-30d, all known tumor suppressors or oncomirs in various cancers, were identified in our comparisons. MiR-1268a, a microRNA not previously reported to be involved with kidney or prostate cancer biology, was found at high concentrations in urine from kidney or prostate cancer patients compared to normal controls. MicroRNA MiR-387e expression could differentiate between urine from kidney cancer patients and urine from prostate cancer patients.
Conclusions: Urine microRNA signatures are potentially useful as prostate adenocarcinoma and renal clear cell carcinoma screening biomarkers.
No conflict of interest.

2801 POSTER

Modulation of Regulatory T cells in long responsive patients with metastatic renal cell carcinoma (mRCC) treated with everolimus (EVE)

A. Thiery-Vuillemin[1], L. Mansi[1], C. Laheurte[2], T. Maurina[1], V. Nerich[3], T. NGuyen Tan Hon[1], U. Stein[1], P. Montcuquet[1], F. Kleinclauss[4], O. Adotevi[5]. [1]*Universitary Hospital Jean Minjoz, Medical Oncology, Besançon, France;* [2]*Universitary Hospital Jean Minjoz, CIC-BT506, Besançon, France;* [3]*Universitary Hospital Jean Minjoz, Pharmacy Unit, Besançon, France;* [4]*Universitary Hospital Jean Minjoz, Urology, Besançon, France;* [5]*INSERM UMR1098 Besançon, UMR1098, Besançon, France*

Background: EVE has demonstrated activity in the treatment of mRCC after failure of VEGF-targeted tyrosine kinase inhibitors. mTOR inhibition

can also facilitate the induction of immunosuppressive regulatory T cells (Treg).
Methods: Our observational study reports retrospective data on EVE in routine use. Eligible patients (pts) had mRCC; were given EVE after prior first-line systemic therapies comprising anti-angiogenic agents. Blood Treg cells were evaluated by measuring CD4+CD25+Foxp3+ T cells by flow cytometry. The data were provided by each center and centralised. The focus was on immunologic assessment, the oncologic outcome and the clinical safety.
Results: Ten pts have been followed between Sept 2011 and March 2013. Baseline patient characteristics included median age of 66 [51−83] years old; 90% male; 100% with prior nephrectomy. Prognostic groups at the time of EVE initiation according to Heng classification were: good 60%, intermediate 20% and poor prognosis 20%. After initiation of EVE 75 % of patients were alive and 32 % free from disease progression at 24 months respectively. Overall response rate was 30 % and disease stabilization rate was 70%. At least one adverse event (AE) occured in 100 % of pts with 2 serious AEs. All grade common AEs were consistent with the toxicity profile of EVE. Treg cells number decreased significantly in the 3 (30%) patients who experienced the longer PFS (progression free survival). Stable Treg cells were found in 6 (60%) patients and increased in only one patient. In contrast, these cells greatly increased above 10% of total blood lymphocyte in one patient who progressed on EVE therapy.
Conclusions: These preliminary data suggest that everolimus could shape host immune responses, which in turn could contribute to the efficacy of the anti-mTOR therapy. Thus, we believe that it could be interesting to take into account the immunomodulatory effect of anti-mTOR drugs for the management of mRCC patients.

2802 POSTER

Wilms' tumor gene 1 (WT1) expression in testicular germ cell tumors (TGCTs)

L. Boublikova[1], K. Kramarzova[1], V. Bakardjieva-Mihaylova[1], T. Buchler[2], P. Dusek[3], M. Grega[4], B. Rosova[5], J. Abrahamova[2], J. Trka[1]. *[1]2nd Faculty of Medicine and University Hospital Motol, Dept. of Pediatric Hematology and Oncology, Prague, Czech Republic; [2]1st Faculty of Medicine and Thomayer Hospital, Dept. of Oncology, Prague, Czech Republic; [3]2nd Faculty of Medicine and University Hospital Motol, Dept. of Urology, Prague, Czech Republic; [4]2nd Faculty of Medicine and University Hospital Motol, Dept. of Pathology and Molecular Medicine, Prague, Czech Republic; [5]Thomayer Hospital, Dept. of Pathology and Molecular Medicine, Prague, Czech Republic*

Background: Wilms' tumor gene 1 (WT1) is a zinc-finger transcription factor essential for normal development of the urogenital system and male gonadal differentiation. Alterations in this gene have been found in a number of malignancies as well as in testicular dysgenesis syndromes. We studied WT1 expression and mutations to address its function in TGCT tumorigenesis and its possible clinical applications.
Material and Methods: Fresh-frozen samples of testicular germ cell tumors (TGCTs) and controls (9 seminomas, 18 non-seminomas, 2 stromal tumors, 27 non-malignant controls) were collected on a prospective basis. Expression of total WT1 and its isoforms was quantified by qPCR of our own design. Mutations in WT1 exons 7 and 9 (where the hot-spots are clustered) were detected by direct sequencing. The presence and distribution of WT1 protein was evaluated by standard immunohistochemistry (IHC) staining.
Results: The total WT1 expression was significantly lower in TGCTs than in non-malignant testicular tissues and stromal tumors − median 2 505 (range 219−32 584) WT1/ABLx10 000 in TGCTs vs. 23 200 (range 1 598−46 659) in non-malignant controls (Kruskal-Wallis, $p < 0.0001$). Of the four main WT1 isoforms, isoforms A and C missing the exon 5 (EX5[-]) were highly overexpressed in a proportion of TGCTs and both stromal tumors in comparison with controls − the mean EX5[+]/EX5[-] ratio was 2.19 (95% CI 1.88–2.50) for TGCTs vs. 4.05 (3.59–4.51) for non-malignant controls (Kruskal-Wallis, $p < 0.0001$). No WT1 mutation was found, the most common SNP (rs16754) with unknown clinical significance was present in 6/23 (26%) analyzed patients. Staining for WT1 protein was highly positive in the nuclei of Sertoli cells of control samples and undetectable in TGCT cells, corresponding well with the expression data on mRNA level.
Conclusion: Although the finding of total WT1 down-regulation in TGCTs we would interpret with caution (due to the lack of highly WT1-expressing Sertoli cells in TGCTs comparing to the control samples), the alteration of isoform expression pattern with a pronounced shift to [EX5-] variants in TGCTs and stromal tumors suggests that WT1 probably acts as a local tumor-suppressor gene in testicular tissues. Dysregulation of WT1 functions may be therefore associated with the process of malignant transformation and TGCT development.

Looking for predictive biomarkers for sunitinib in metastatic renal clear cell carcinoma (mRCC)

P. Maroto[1], E. Esteban[2], M.J. Méndez-Vidal[3], E.M. Fernández-Parra[4], L. León[5], B. Pérez-Valderrama[6], M. Domenech[7], V. Calderero[8], J.L. Perez-Gracia[9], F. Algaba[10]. *[1]Hospital Santa Creu i Sant Pau, Oncology, Barcelona, Spain; [2]Hospital General de Asturias, Oncology, Oviedo, Spain; [3]Hospital Reina Sofía, Oncology, Córdoba, Spain; [4]Hospital Nuestra Señora de Valme, Oncology, Seville, Spain; [5]Hospital Clinico Universitario de Santiago de Compostela, Oncology, Santiado de Compostela, Spain; [6]Hospital Virgen del Rocío, Oncology, Seville, Spain; [7]Althaia- Xarxa Assitencial de Manresa, Oncology, Manresa, Spain; [8]Hospital Miguel Servet, Oncology, Zaragoza, Spain; [9]Clínica Universitaria de Navarra, Oncology, Pamplona, Spain; [10]Fundación Puigvert- UAB, Pathology, Barcelona, Spain*

Background: Properly validated molecular predictors of response to targeted agents are still lacking. Different molecular subtypes of clear cell RCC have been proposed by Gordan et al. It has been suggested that c-Myc may be driving proliferation in HIF2α expressing tumors in a growth factor independent manner. The predictive value of Focal Adhesion Kinase (FAK), a key signaling protein, has not been explored yet.
Material and Methods: An observational prospective study involving 9 hospitals was designed to evaluate in formalin-fixed tumor samples the predictive value of different biomarkers. We enrolled clear-cell mRCC patients (pts). Eligible pts were treated with Sunitinib in the 1st line setting following routine clinical practice.
Results: 81 pts were included, 34.5% were metastatic at diagnosis and time from diagnosis to Sunitinib was $\leqslant$1 year in 39.5%. 36% of pts had only one site of metastasis. 7%, 76.5% and 16% were ECOG PS 0, 1 and $\geqslant$2 and 18.5%, 58% and 12.5% favorable, intermediate and poor risk (MSKCC criteria). Median time of follow up was 21.02 months (m) (95% CI: 14.70–24.53). Median PFS (mPFS) was 11.5 m (95% CI: 7.2–14.8) in the favorable-intermediate risk group. Tumor samples were available for 69 pts. 10% were FAK positive (+) (any score: 1−3), 20% were PTEN+ and 27.5% were c-Myc+ (8% were c-Myc and HIF2a+). Both pts groups (+ and -) were well balanced, with the exception of differences in terms of MSKCC risk groups ($p > 0.05$) between FAK- and + pts and significant differences ($p < 0.05$) in terms of ECOG PS between PTEN- and + pts. A trend toward a lower mPFS was found in pts bearing tumours with FAK+ staining: 5.5 m vs.11.5 in -tumors (HR = 2.1275; 95% CI: 0.82–5.55; $p = 0.1136$); tumors with PTEN+ staining: 7.2 m vs. 11.5 in -tumors (HR = 1.8822; 95% CI: 0.98−3.6; $p = 0.0531$) and tumors with c-Myc+ staining: 5.9 m vs.10.9 in -tumors (HR = 1.4361; 95% CI: 0.76–2.72; $p = 0.2630$). Greater differences were found in the favourable-intermediate risk group: 5.9 m vs. 12.7 in C-Myc- tumors (HR = 1.7147; 95% CI: 0.85−3.5; $p = 0.128$) and a statistically significant worse mPFS was found in those pts with doble c-Myc/HIF2a+ staining: 4.3 m vs. 11.5 (HR = 2.6445; 95% CI: 1.027–6.8056; $p = 0.036$). A similar trend was also found in terms of overall survival.
Conclusions: These preliminary results suggest that predictive subgroups might be defined based on biomarkers such as cMyc/HIF2a, FAK and PTEN. Further validation with more pts will help to define their role in mRCC pts treated with Sunitinib.
No conflict of interest.

2804 POSTER

PI3K/AKT/mTOR and Wnt/β-catenin signaling components as a prognostic and predictor factors in patients with renal cell carcinoma treated with everolimus after anti-angiogenic therapy failure

L. Bodnar[1], R. Stec[1], S. Cierniak[2], A. Synowiec[1], M. Cichowicz[2], R. Koktysz[2], W. Kozlowski[2], C. Szczylik[1]. *[1]Military Institute of Medicine, Dep. of Oncology, Warsaw, Poland; [2]Military Institute of Medicine, Dep. of Pathology, Warsaw, Poland*

Background: Everolimus, an inhibitor of mTOR, has been approved for the treatment of patients with metastatic renal cell carcinoma (mRCC) The mTOR pathway can be activated by different proteins, including Wnt. The aim of this study was to search for predictive and prognostic factors in patients with mRCC treated with everolimus among the components of PI3K/AKT/mTOR and Wnt/β-catenin pathways.

Methods: Patients with mRCC after anti-angiogenic therapy failure were included in a prospective, one-arm, phase II study. Patients received everolimus 10 mg/day. A prospectively planned evaluation of potential biomarkers of PI3K/AKT/mTOR and Wnt/β-catenin pathway activation was conducted, focusing on VEGF in peripheral blood plasma, soluble E-cadherin (sE-cadherin) in serum and phosphorylated AKT 473, p70S6, Wnt-1, β-catenin, E-cadherin, cyclin D1, and p53 in the primary tumor. Additionally, 13 single nucleotide polymorphisms (SNP) of four genes were assessed, i.e. *AKT1, AKT2, PI3KCA* and *FRAP1*.
Results: The median age of the 58 patients included in the study was 60 years (range 41−78). In the univariate analysis, we found that the PIK3CA gene variant rs6443624 was significantly important [hazard ratio (HR): CC vs. AA = 2.08, 95% CI: 1.11–3.89, p = 0.0215 and HR: CC vs. AC + AA = 1.87, 95% CI 1.02–3.44, p = 0.0452). Expression of proteins involved in the PI3K/AKT/mTOR and Wnt/β-catenin pathways in primary RCC tumor tissues did not have a statistically significant association with progression free survival (PFS) and overall survival (OS). In the multivariate analysis, the independent favorable predictors for everolimus therapy were histological grade G3/4 [HR: 0.44 (95% CI 0.21–0.93, p = 0.0324)], normal LDH level before treatment [HR: 0.26 (95% CI 0.13–0.54, p = 0.0003)], a high concentration of sE-cadherin before treatment (above 66.74 pg/mL) [HR: 0.49 (95% CI 0.27–0.91, p = 0.0233)], the toxicity of the treatment regarding hypercholesterolaemia [HR: 0.40 (95% CI 0.21–0.76, p = 0.0054)] and neutropenia [HR: 0.31 (95% CI 0.14–0.67, p = 0.0032)]. In multivariate analysis, we observed that the favorable independent prognostic factors were normal LDH levels before qualifying for this treatment [HR: 0.41 (0.21–0.79, p = 0.0077)], previous therapy with sorafenib [HR: 0.36 (95% CI, 0.17–0.75, p = 0.0065)], and a neutropenia [HR: 0.19 (95% CI, 0.07–0.52, p = 0.0054)].
Conclusions: Serum sE-cadherin and LDH may be new simple tests which, together with monitoring toxicity such as neutropenia and hypercholesterolemia, could predict improved outcomes with everolimus therapy. Therapy with sorafenib and assessments of the LDH level and the incidence of neutropenia could predict the prognosis of patients with metastatic RCC. Encouraging results of our study should guarantee the need for further studies planned prospectively in patients with RCC.

2805 POSTER

Prognostic significance of FDG-PET/CT after two cycles of first-line chemotherapy in advanced transitional cell carcinoma

P. Giannatempo[1], R. Miceli[2], F. Crippa[3], D. Raggi[1], N. Nicolai[4], A. Alessi[3], M. Maffezzini[4], A.M. Gianni[1], R. Salvioni[4], A. Necchi[1].
[1]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Medical Oncology, Milan, Italy; [2]Fondazione IRCCS Istituto Nazionale dei Tumori, Epidemiology and Trials Organization Unit, Milan, Italy; [3]Fondazione IRCCS Istituto Nazionale dei Tumori, Nuclear Medicine-PET Unit, Milan, Italy; [4]Fondazione IRCCS Istituto Nazionale dei Tumori, Department of Surgery-Urology Unit, Milan, Italy

Background: A risk-adapted treatment for advanced transitional cell carcinoma (TCC) is still lacking and it may guide new trial designs with novel agents/combinations for early-recognized unresponsive patients (pts). [18F]fluorodeoxyglucose Positron Emission Tomography/computed tomography (FDG-PET/CT) is increasingly used by many centers for (re)staging in TCC. We prospectively assessed the value of FDG-PET/CT after 2 cycles of upfront chemotherapy.
Methods: In a single-center trial, pts with newly-diagnosed advanced/metastatic TCC receiving first-line MVAC underwent CT and FDG-PET/CT at baseline, a restaging with FDG-PET/CT after 2 cycles only, and a CT and/or FDG-PET/CT at the end of treatment (4−6 cycles). A CT scan every 3 months was done in the follow up (FUP) period. EORTC criteria for metabolic response were applied. The end-points were progression-free (PFS) and overall survival (OS). PFS and OS rates were estimated with the Kaplan–Meier method; univariable (UVA) and multivariable (MVA) Cox models were also fitted. Pre-specified prognostic variables were presence of visceral metastases, nodal/soft tissue disease, and early PET/CT response.
Results: 31 pts were accrued in the time-frame 05/2010−10/2012. All of them received MVAC regimen and had an ECOG-PS 0, 9 pts had an upper tract TCC, 15 had a visceral and 29 a nodal or soft-tissue disease. After 2 cycles of MVAC, 6 pts (19.3%) had a complete (CR) and 17 (54.8%) a partial metabolic response (PR), 4 pts had stable disease (SD). Median FUP was 18 months (IQR: 10−47). Those with metabolic response (CR+PR) had a median (95% CI) PFS=8.0 (7−11) mos compared to 3.0 (2−5) mos in patients without response (p = 0.024). Those with prior response had a median OS of 19.0 (9−21) mos, compared with 9.5 (6−11) mos for those without response (p = 0.813). A significant association was observed between early PET response and PFS in both UVA and MVA (p = 0.027 and p = 0.023, respectively, [Table]).
Conclusion: PET response after 2 cycles of first-line MVAC in pts with TCC seemed to confer an independent prognostic impact on PFS, similarly to the presence of visceral metastases. An international cooperation to corroborate the role of early metabolic response in advanced TCC is warranted.
No conflict of interest.

Table: Cox models for progression-free survival

	Univariable			Multivariable		
	HR	95% CI	p	HR	95% CI	p

Angiopoietin 2 (Ang-2) as prognosis biomarker in clear cell renal cell carcinoma (ccRCC) patients

G. Boggio[1], M.E. Knott[2], J. Grasselli[1], M.N. Gandur Quiroga[3], L. Pasik[4], G. Gueglio[5], C. Pulero[6], A. Alvarez[3], L. Puricelli[2], M.G. Pallotta[1].
[1]Hospital Italiano de Buenos Aires, Clinical Oncology, Buenos Aires, Argentina; [2]Institute of Oncology "Ángel H. Roffo", Molecular Biology, Buenos Aires, Argentina; [3]Institute of Oncology "Ángel H. Roffo", Clinical Oncology, Buenos Aires, Argentina; [4]Institute of Oncology "Ángel H. Roffo", Urology, Buenos Aires, Argentina; [5]Hospital Italiano de Buenos Aires, Urology, Buenos Aires, Argentina; [6]Institute of Oncology "Ángel H. Roffo", Pathology, Buenos Aires, Argentina

Background: Tumor progression and metastasis are critically dependent on the tumor's sustained ability to induce the growth of new blood vessels to nourish the growing tumor and to remove metabolic waste products. The angiopoietins Ang-1 and Ang-2 have critical role in tumor angiogenesis. Ang-2 acts in concert with the vascular endothelial growth factor and receptor (VEGF/VEGFR) to control vessel assembly during tumor progression.
ccRCC, the most common histological type of RCC, is a heterogeneous group of entities with variable clinical outcomes, is characterized by deregulation of angiogenic pathways. Up to now no useful prognostic biomarker has been developed in ccRCC, so our aim was to determine the value of tissular tumor Ang-2 expression in the outcome of these patients.
Material and Methods: Antigen expression was analyzed by immunohistochemistry on formalin fixed paraffin embedded ccRRC primary tumors [men: n = 22, age: Md 54 years (range 46−72); women: n = 23, age: 65 (44−82)], from patients who underwent a surgical resection as first treatment. A case was considered positive when more than 50% of the tumor cells presented specific staining. The relationships between the expression of the antigen and the known prognostic factors in ccRCC were analyzed by Chi-square test. Prognostic evaluation was analyzed with the log rank test and the multivariate Cox model.
Results: We observed that 80% of ccRCC tumors expressed Ang-2 at membrane level and more than 90% of the cases also expressed the antigen at cytoplasmic level. No association was observed between the expression of Ang-2 and other prognosis factors like ionized calcium and hemoglobin circulating levels, clinical stage and histological grade. Kaplan–Meier curves and Log rank test showed that positivity for Ang-2 was associated with a lower overall survival at five years. Multivariate analysis indicated that Ang-2 expression was not influenced by other clinico-pathological prognostic parameters.
We conclude that tumor positivity for the expression of Ang-2 in this group of ccRCC patients can be considered as an independent prognostic marker associated to a worse outcome.
Conclusions: We conclude that tumor positivity for the expression of Ang-2 in this group of ccRCC patients can be considered as an independent prognostic marker associated to a worse outcome.
No conflict of interest.

Expression of CD47 in bladder cancer

U. Demirci[1], E.U. Bagriacik[2], C. Irkkan[3], D.S. Dede[4], E. Yaman[2], S. Altinova[5], G. Gulnur[6], B. Yalcin[4]. *[1]Dr Abdurrahman Yurtaslan Ankara Oncology Training and Research Hospital, Medical Oncology, Ankara, Turkey; [2]Gazi University Faculty of Medicine, Immunology, Ankara, Turkey; [3]Dr Abdurrahman Yurtaslan Oncology Training and Research Hospital, Pathology, Ankara, Turkey; [4]Atatürk Training and Research Hospital, Medical Oncology, Ankara, Turkey; [5]Atatürk Training and Research Hospital, Urology, Ankara, Turkey; [6]Atatürk Training and Research Hospital, Pathology, Ankara, Turkey*

Background: CD47, a member of immunoglobulin superfamily, is expressed by various cancers. It has been reported that CD47 expression protects tumor cells from phagocytosis by transmitting an inhibitory signal to macrophages.
Material and Methods: The present study aimed at studying CD47 expression by bladder cancer. We performed immunohistochemical analysis to eveluate CD47 expression levels in three groups; subjects undergone to transurethral bladder resection (TUR-B) outside of malignancy (tumor negative, control group), superficial bladder cancer (BC) and invazive BC.
Results: Between 2006 and 2012, 88 subjects were evaluated in superficial BC (n = 41), invazive BC (n = 14) and control groups (n = 33), retrospectively. Immunohistochemical stainning was performed on paraffin-embedded tissue sections. Median age of the patients and control were 61.5 (range, 22−91) and 55 (range, 16−77), respectively. Fourteen patients were high grade and 10 patients had lymph node positive disease. We found that CD47 expression increased significantly (Kruskal Walls test, p = 0.02,) on bladder cancer. The three groups of patients were compared according to Mann-Whitney U test. The significance of difference between each group was calculated ((the superficial BC and control (p = 0.003), invazive BC and control (p = 0.005) and superficial BC and invazive BC (p = 0.301)). Expression of CD47 was elevated significantly in BC.
Conclusions: Overexpression of CD47 may be a critical for bladder cancers in escaping from immunesurveillance.
No conflict of interest.

2808 POSTER

Prognostic significance of apoptotic marker in non muscle invasive bladder cancer treated by bacillus Calmette Guerin immunotherapy

F. Ajili[1], A. Daruiche[2], M. Chebil[2], S. Boubaker[1]. *[1]Pasteur Institute of Tunis, Laboratory of Human and Experimental Pathology, Tunis, Tunisia; [2]Charles Nicolle Hospital Tunis Tunisia, Department of Urology, Tunis, Tunisia*

Background: A critical hallmark of cancer cell survival is evasion of apoptosis. This is commonly due to overexpression of anti-apoptotic proteins such as Bcl-2 which bind to the pro-apoptotic proteins and inhibit their function. It has been reported previously that Bcl-2 is overexpressed in a variety of cancers and is associated with treatment resistance. However, its impact on superficial bladder cancer recurrence after bacillus Calmette Guerin (BCG) immunotherapy has yet to be investigated. The aim of the present study was to assess the prognostic significance of Bcl-2 expression in terms of recurrence after BCG immunotherapy in superficial bladder cancer.
Material and Method: Bcl-2 positivity was detected by immunohistochemical analysis on frozen pre-treatment biopsies obtained transurethrally from 28 patients, having superficial bladder cancer. All patients were treated with BCG immunotherapy and followed up during 26 months. The prognostic significance of tumour stage, grade, loci number, tumour size, age and Bcl-2 in determining the risk for recurrence was studied with both univariate and multivariate methods of analysis.
Result: According to univariate analysis of the prognostic significance for tumour stage, grade, tumour size, loci number, age and bcl-2 expression in patients, the pT1 stage and high grade seem to be associated in a statistically significant manner with higher risk for recurrence (P = 0.004, P = 0.004, respectively). In the other hand, multivariate Cox regression's analysis selected the model involving stage, age and Bcl-2 expression as quasi-independent predictor of recurrence after BCG immunotherapy (p = 0.005, p = 0.020, p = 0.020, respectively).
Conclusion: The expression of Bcl-2 seems to offer prognostic information in predicting those patients with high risk superficial bladder cancer who may recur in a short follow-up period. These findings require further investigations on larger cohort in order to ascertain new molecular markers of the response to BCG immunotherapy.
No conflict of interest.

CA184-043: A randomized, multicenter, double-blind phase 3 trial comparing overall survival (OS) in patients (pts) with post-docetaxel castration-resistant prostate cancer (CRPC) and bone metastases treated with ipilimumab (ipi) vs placebo (pbo), each following single-dose radiotherapy (RT)

W.R. Gerritsen[1], E.D. Kwon[2], K. Fizazi[3], A. Bossi[4], A. Van den Eertwegh[5], C. Logothetis[6], H.I. Scher[7], T.M. Beer[8], M.B. McHenry[9], P. Gagnier[10], C.G. Drake[11]. *[1]Radboud University Nijmegen Medical Centre, Department of Medical Oncology, Nijmegen, Netherlands; [2]Mayo Clinic, Urology and Immunology, Rochester, USA; [3]Institut Gustave Roussy University of Paris Sud, Department of Cancer Medicine, Villejuif, France; [4]Institut Gustave Roussy, Department of Radiation Oncology, Villejuif, France; [5]VU University Medical Center, Department of Medical Oncology, Amsterdam, Netherlands; [6]The University of Texas M. D. Anderson Cancer Center, Department of Genitourinary Medical Oncology, Houston, USA; [7]Memorial Sloan-Kettering Cancer Center, New York, USA; [8]Oregon Health & Science University Knight Cancer Institute, Hematology & Medical Oncology, Portland, USA; [9]Bristol-Myers Squibb Company, Global Biometric Sciences, Wallingford, USA; [10]Bristol-Myers Squibb Company, Clinical Research Oncology Global Research, Wallingford, USA; [11]Johns Hopkins Sidney Kimmel Comprehensive Cancer Center, Department of Oncology, Baltimore, USA*

Background: Ipi boosts anticancer immunity by targeting cytotoxic T-lymphocyte antigen-4 (CTLA-4) to deplete regulatory T cells and activate cytotoxic T cells by inhibiting negative signaling associated with CTLA-4. In metastatic melanoma, ipi demonstrated 4-year OS rates of 19−36% in phase 2 studies and significant OS prolongation in phase 3 studies. Clinical antitumor activity was also seen in phase 1/2 studies in CRPC.
Study Design: Following 1:1 randomization, pts with post-docetaxel CRPC received bone-directed RT at 8 Gy before either 10 mg/kg ipi (N = 399) or pbo (N = 400) every 3 weeks x 4, with every-3-month maintenance for eligible pts. The primary endpoint was OS.
Results: Baseline characteristics were balanced across arms and were indicative of advanced disease (48% had baseline pain of $\geqslant$4 per BPI). In the intent-to-treat analysis (N = 799), the HR for OS numerically favored ipi (HR = 0.85; 95% CI=0.72–1.00; p = 0.053). Median OS for ipi was 11.2 months (95% CI=9.5–12.7) vs 10.0 months (95% CI=8.3–11.0) for pbo. Respective 1- and 2-year OS rates for ipi vs pbo were 47% vs 40% and 26% vs 15%. Median progression-free survival (PFS) also favored ipi over pbo (HR = 0.70; 95% CI=0.61–0.82), as did prostate-specific antigen (PSA) declines of $\geqslant$50% in evaluable pts (13.1% vs 5.3%, respectively). Pre-specified subset analyses suggest that ipi may be most active in pts with no visceral disease and favorable laboratory prognostic factors (eg, decreased alkaline phosphatase, elevated hemoglobin). A post hoc analysis in pts who received treatment (N = 779; N = 387 for ipi vs N = 392 for pbo) showed an improvement in OS which favored ipi (HR = 0.84; 95% CI=0.71–1.00; p = 0.0498).
Treatment-related adverse events (AEs) were common and mostly immune-related AEs (irAEs). Grade $\geqslant$3 irAEs in the ipi vs pbo arms, respectively, were GI (18% vs 1%), liver (5% vs 1%), endocrine (2% vs 1%) and dermatologic (1% vs 0%); most were reversible using standard ipi management algorithms. Incidences of drug-related death and GI perforation were 1% and 0.6%, respectively.
Conclusions: This phase 3 study supports activity of ipi in advanced CRPC by showing a numerical improvement in OS, although statistical significance was not achieved. Drug-related AEs were similar to those reported in melanoma. Pre-specified subset analyses suggest CRPC pts with lower disease burden may experience the most benefit. An ongoing phase 3 study in chemotherapy-naive CRPC is prospectively evaluating this population.

A validated prognostic model for predicting overall survival in patients with metastatic chemotherapy naive castrate-resistant prostate cancer

S. Halabi[1], C.Y. Lin[1], W.K. Kelly[2], K. Fizazi[3], J.W. Moul[4], E. Kaplan[1], M.J. Morris[5], E.J. Small[6]. *[1]Duke University, Biostatistics and Bioinformatics, Durham NC, USA; [2]Thomas Jefferson University, Medical Oncology and Urology, Philadelphia PA, USA; [3]Institut Gustave Roussy, Cancer Medicine, Paris, France; [4]Duke University, Surgery, Durham NC, USA; [5]Memorial Sloan-Kettering Cancer Center, Medical Oncology and Urology, New York NY, USA; [6]University of California, Medical Oncology and Urology, San Francisco CA, USA*

Background: Although several prognostic models for overall survival (OS) have been developed for patients (pts) with mCRPC, they are outdated and not applicable to contemporary pts. This work sought to develop and validate a contemporary prognostic model that can be used to predict OS in metastatic chemotherapy naive castrate-resistant prostate cancer (mCRPC) pts.

Materials and Methods: Data from a phase III trial of 1,050 chemotherapy naive mCRPC pts randomized to bevacizumab plus docetaxel or placebo plus docetaxel were used (CALGB 90401). The CALGB 90401 data was randomly split into training (n = 705) and testing (n = 345) sets. A separate data set from the ENTHUSE 33 phase III trial, consisting of 942 men randomly assigned to either zibotentan plus docetaxel or placebo plus docetaxel, served as a second testing set used for independent external validation. Adaptive least absolute shrinkage and selection operator (LASSO) selected eight baseline factors prognostic for OS in the training set. A predictive score was computed from the estimated regression coefficients and used to classify patients into low and high risk groups in the two testing sets. The model was assessed for its predictive accuracy using the area under the curve (AUC) on the two testing sets.

Results: The final model included: ECOG performance status, extent of disease (categorized as lymph node only; bone or bone+lymph node; or any visceral metastases), LDH (defined as > upper limit of normal), opiate use, albumin, hemoglobin, PSA, and alkaline phosphatase. The median OS values in the high and low risk groups, respectively, in the internal testing set (CALGB 90401) were 17 and 30 months with a hazard ratio (HR) = 2.2 (p-value<0.0001); and in the external testing set (ENTHUSE 33) were 14 and 26 months (HR = 2.9, p < 0.0001).

The AUC for the model with the risk score as a continuous variable was 0.73 (95% CI 0.70–0.73) and 0.76 (95% CI 0.72–0.76) on the two testing sets (CALGB 90401 and ENTHUSE 33, respectively).

Conclusions: A contemporary prognostic model for OS in chemotherapy naive mCRPC pts was developed and validated on internal and independent external data set. This model can be used to counsel pts, as well as select pts to participate in clinical trials on the basis of their prognosis.

No conflict of interest.

Evaluation of a composite biomarker panel including circulating tumor cell (CTC) enumeration as a surrogate for survival in metastatic castration-resistant prostate cancer (mCRPC)

H.I. Scher[1], G. Heller[2], A. Molina[3], G. Attard[4], R. McCormack[5], R. Riisnaes[6], T. Kheoh[7], M. Fleisher[8], M. Buyse[9], J.S. De Bono[10]. *[1]Memorial Sloan-Kettering Cancer Center Sidney Kimmel Center for Prostate and Urologic Cancers, Genitourinary Oncology Service, New York NY, USA; [2]Memorial Sloan-Kettering Cancer Center, Epidemiology & Biostatistics, New York NY, USA; [3]Janssen Research & Development, Oncology, Los Angeles CA, USA; [4]The Institute of Cancer Research and Royal Marsden Hospital, Drug Development Unit, Sutton, United Kingdom; [5]Veridex, Technology Innovation, Raritan NJ, USA; [6]The Institute of Cancer Research, Cancer Biomarkers Team, Sutton, United Kingdom; [7]Janssen Research & Development, Biostatistics & Programming, Los Angeles CA, USA; [8]Memorial Sloan-Kettering Cancer Center, Department of Laboratory Medicine, New York NY, USA; [9]International Drug Development Institute, (IDDI), Louvain-la-Neuve, Belgium; [10]The Institute of Cancer Research and Royal Marsden Hospital, Urology Unit and Drug Development Unit, Sutton, United Kingdom*

Background: Multiple new therapies prolong survival for mCRPC, making demonstration of a survival benefit with newer agents more difficult. Qualified surrogate biomarkers for survival benefits are a critical unmet need. CTC number is prognostic pre- and post-treatment and showed a 34% and 41% conversion rate from unfavourable (⩾5 cells/7.5 mL) to favourable (⩽4 cells/7.5 mL) in phase 2 trials of abiraterone acetate (AA) +/− prednisone (P). We explored CTC enumeration as a potential surrogate for survival in the phase 3 registration trial of AA+P in mCRPC post-chemotherapy (COU-AA-301; clinicaltrials.gov NCT00638690).

Material and Methods: Biomarkers, including CTC count (CellSearch®; Veridex, Raritan, NJ) and lactate dehydrogenase (LDH) levels, were assessed as a secondary objective in COU-AA-301 at baseline, 4, 8, and 12 weeks; prostate-specific antigen was recorded every 12 weeks. Biomarker data at each fixed time point, differences from baseline, relative differences from baseline, and conversion from unfavourable to favourable (for CTC) were analyzed. A trichotomous surrogate biomarker panel based on 12-week landmark data categorized patients as low-risk (CTC ⩽4), intermediate-risk (CTC ⩾5, LDH ⩽250 IU/L), or high-risk (CTC ⩾5, LDH >250 IU/L). Individual level surrogacy was assessed using Prentice criteria and trial level surrogacy by measuring the association between the treatment effect on the surrogate and survival within each country and randomly generated pseudo substudies.

Results: Complete biomarker data at 12 weeks were available from 711 of 1195 patients; some study sites/countries were unable to assess CTCs. All Prentice criteria were satisfied at the individual level: survival differed between the AA and placebo arms (p = 0.034); surrogate distribution differed by treatment (p < 0.001); the surrogate had strong discriminatory power to distinguish low- and high-risk patients (concordance probability estimate [CPE] = 0.79); and the treatment effect on survival was explained by the surrogate. There was only a weak association between the surrogate and survival at the trial level, potentially related to the small sample sizes of the groups studied.

Conclusions: In COU-AA-301, the 12-week CTC number and LDH level biomarker panel demonstrated survival surrogacy at the individual patient level in mCRPC progressing post chemotherapy. Individual and trial level surrogacy will be further explored in other fully accrued phase 3 trials in this patient population.

Enzalutamide (ENZA) monotherapy in hormone naive prostate cancer (HNPC): Complete analysis of a phase 2 study

M. Smith[1], M. Borre[2], P. Rathenborg[3], P. Werbrouck[4], H. Van Poppel[5], A. Heidenreich[6], P. Iversen[7], E. Baskin-Bey[8], F. Perabo[8], D. Phung[9], B. Tombal[10]. [1]*Massachusetts General Hospital Cancer Center, Department of Hematology/Oncology, Boston, USA;* [2]*Aarhus University Hospital, Department of Urology, Skejby, Denmark;* [3]*Herlev Hospital, Department of Urology, Herlev, Denmark;* [4]*AZ Groeninge Kortrijk, Department of Urology, Kortrijk, Belgium;* [5]*UZ Leuven, Department of Urology, Leuven, Belgium;* [6]*Universitätsklinikum der RWTH Aachen, Department of Urology, North.-Rhine Westphalia, Germany;* [7]*Rigshospitalet University of Copenhagen, Department of Urology, Copenhagen, Denmark;* [8]*Astellas Pharma Global Development Inc., Global Medical Science, Staines, United Kingdom;* [9]*Astellas, Global Data Science, Leiderdorp, Netherlands;* [10]*Cliniques Universitaires Saint-Luc, Service d'Urologie, Brussel, Belgium*

Background: Compared with castration therapy (LHRHa), monotherapy with bicalutamide (Bic) maintains quality of life (QoL) but has lower efficacy. ENZA, a US FDA-approved oral androgen receptor (AR) inhibitor with higher AR-binding affinity than Bic, increases overall survival for patients (pts) with post-docetaxel metastatic castration-resistant PC. This phase 2 open-label study assessed ENZA monotherapy in pts with HNPC and noncastrate testosterone (T; ⩾230 ng/dL).
Materials and Methods: Pts with any stage HNPC requiring hormonal therapy received ENZA 160 mg/d for 25 wks. Primary endpoint was prostate-specific antigen (PSA) response (⩾80% decline at wk 25). Other endpoints were endocrine levels, pharmacokinetics, safety, metabolic changes, and QoL. Analyses were performed after pts completed 25 wks of ENZA.
Results: 67 pts were treated. Median age was 73.0 y; 38.8% had metastatic disease, and 35.8% and 23.9% had prior prostatectomy and radiation, respectively. Plasma ENZA levels reached steady state after ~4 wks. The primary endpoint (PSA decline ⩾80%) was reached in 62 pts (92.5%; 95% CI, 86.2–98.8%); median PSA decrease was −99.6% (95% CI, −100.0 to −86.5).
Table 1 shows results in metastatic (M1) vs non-metastatic (M0) disease. Mean serum T and estradiol levels increased by 114.3% and 71.7%, respectively. Mean femoral neck bone mineral density (BMD) increased by 0.4±2.3%. Mean lean body mass decreased by 4.2±3.4%, and fat body mass index increased by 6.9±12.1%. Insulin sensitivity (measured by HOMA-IR) increased by 45.1±192.5%. Frequent treatment-emergent AEs were grade 1: gynecomastia (35.8%), fatigue (34.3%), nipple pain (19.4%), and hot flush (17.9%). There were no serious drug-related AEs. Sexual function AEs (4.5%) were grade 1 and considered possibly or not related to study drug. Per EORTC QLQ-C30, global health status was maintained from baseline to wk 25.
Conclusions: ENZA monotherapy is associated with a high PSA response rate, rapid PSA decline regardless of metastatic disease, and stable BMD and QoL. Endocrine changes and AEs were consistent with AR inhibition. Top-line results regarding 1-year persistence of PSA response will be discussed.
Funded by Astellas Pharma Global Development, Inc. and Medivation, Inc.; NCT01302041, active/not recruiting.

Table 1.

	M0 (n = 41), n (%)	M1 (n = 26), n (%)	Total (n = 67), n (%)
PSA decline ⩾80%	38(92.7)	24(92.3)	62(92.5)
PSA decline ⩾90%	37(90.2)	24(92.3)	61(91.0)
PSA ⩽4 ng/mL	38(92.7)	24(92.3)	62(92.5)
PSA ⩽0.1 ng/mL	20(48.8)	10(38.5)	30(44.8)

An open-label, phase I/II safety, pharmacokinetic, and proof-of concept study of ODM-201 in patients with progressive metastatic castration-resistant prostate cancer (CRPC)

K. Fizazi[1], P. Bono[2], R.H. Jones[3], V. Kataja[4], N. James[5], J. Garcia[6], A. Protheroe[7], A. Vuorela[8], L. Mattila[8], M.V.J. Mustonen[8]. [1]*Institut Gustave Roussy University of Paris, Department of Cancer Medicine, Villejuif, France;* [2]*Helsinki University Hospital, Department of Oncology, Helsinki, Finland;* [3]*Cardiff University, Velindre Hospital, Cardiff, United Kingdom;* [4]*Kuopio University Hospital, Department of Oncology, Kuopio, Finland;* [5]*Birmingham University Hospital NHS, Queen Elizabeth Hospital, Birmingham, United Kingdom;* [6]*Cleveland Clinic, Oncology, Cleveland Ohio, USA;* [7]*Churchill Hospital, Oncology, Oxford, United Kingdom;* [8]*Orion Corporation Orion Pharma, R&D, Espoo, Finland*

Background: ODM-201 is a new generation androgen receptor (AR) inhibitor with higher binding affinity for the AR and a superior anti-cancer activity in prostate cancer xenograft models compared to enzalutamide. ODM-201 and its major metabolite ORM-15341 inhibit the AR nuclear translocation.
Methods: The phase I part explored six ODM-201 dose levels ranging from 200 mg to 1800 mg given orally divided in 2 daily doses, with a parallel pharmacokinetic analysis, in patients (pts) with metastatic CRPC (mCRPC). The phase II expansion part randomly explored three dose levels (200 mg, 400 mg, 1400 mg) in four cohorts of pts defined according to whether they had received chemotherapy and a CYP17 inhibitor (CYP17i) (mostly abiraterone) or not. The accrual is completed.
Results: Overall, 136 pts were recruited in the study (phase I: 24; phase II: 112). No dose-limiting toxicity was found in the phase I part. The pharmacokinetic data indicated that ODM-201 has linear kinetics up to 1400 mg with T1/2 of 5.5−8.7 h on Day 1. 78/108 (70%) currently evaluable pts experienced a PSA decline during the first 12 weeks, including a >50% PSA drop in 44/108 (41%). In chemotherapy and CYP17i naive pts, 28/43 pts (65%) experienced a >50% PSA decline, and the median PSA change was −62% during 12 weeks (200 mg −55%, 400 mg −79% and 1400 mg −85%). In chemotherapy pretreated but CYP17i naive pts, 14/33 pts (42%) experienced a >50% PSA decline, and the median PSA change was −43% during 12 weeks (200 mg −53%, 400 mg −16% and 1400 mg −51%). In the post-CYP17i group 13/32 (41%) pts experienced a PSA decrease. Median PSA change in these pts was −26%. In the meeting the radiological progression free survival, circulating tumor cell data and exploratory biomarkers will be presented. ODM-201 was well tolerated with no treatment-related SAEs. The most common AEs included grade 1−2 back pain (16 pts) (one grade 3), fatigue (14 pts), arthralgia (13 pts) (one grade 3), nausea (11 pts), constipation (10 pts), musculoskeletal pain (9 pts), pain (9 pts), diarrhea (8 pts), peripheral edema (8 pts), decreased appetite (8 pts), headache (7 pts), insomnia (7 pts) and asthenia (7pts). No seizures were observed at any of the dose levels.
Conclusion: ODM-201 is well tolerated and is associated with a high activity in pts with mCRPC, including pts with progression after docetaxel and a CYP17i.
Studies are registered as NCT01317641 and NCT01429064.

The effects of enzalutamide (ENZA) in combination with abiraterone acetate (AA) in patients with bone metastatic castration resistant prostate cancer (mCRPC)

E. Efstathiou[1], M. Titus[1], A.S. Wen[1], A. San Miguel[1], A. Hoang[1], A. De Haas-Amatsaleh[2], F. Perabo[3], D. Phung[4], P. Troncoso[1], C. Logothetis[1]. [1]*The University of Texas M. D. Anderson Cancer Center, Genitourinary Medical Oncology, Houston, USA;* [2]*Astellas Global Development, Uro-Oncology, Northbrook, USA;* [3]*Astellas Global Development, Global Medical Science, Northbrook, USA;* [4]*Astellas Global Development, Global Data Science, Northbrook, USA*

Background: Co-targeting the androgen receptor and paracrine androgen biosynthesis in mCRPC may result in a more potent androgen signaling inhibition than either approach alone. We conducted this study to determine the safety, effects on androgen signaling and steroid metabolome and screen for efficacy of ENZA with AA (plus prednisone).
Material and Methods: Study patients (pts) had progressive mCRPC with serum testosterone (S-T) ⩽50 ng/dL, bone metastases and agreed

to serial Bone Marrow biopsy. Pts received oral ENZA 160 mg QD in combination with AA 1g QD plus prednisone 5 mg bid. Pts were monitored at 4 week intervals with liver function, electrolytes, CBC, ECG and physical examinations. Modulation of tumor microenvironment is assessed by immunohistochemistry and of the androgen metabolome by LC Mass Spectrometry (blood and bone marrow). mCRPC was assessed clinically, by serum markers (PSA, alkaline phosphatase) and by imaging (bone scan, CT scan).

Results (preliminary): Since July 2012, 41 of 60 men have been enrolled with median age 65 yrs (range 40−82), PS-ECOG 1 (range 0−2) and baseline PSA concentration 23.3 ng/ml (range 1–606.3). Gleason Score (GS) at diagnosis was ⩾8 in 28/37 (76%), [GS ⩾9 21/37 (57%)/4 pts not available]. Seventeen (41%) had ⩾20 bone lesions, 14 (34%) lesions in lymph nodes and 2 (5%) visceral metastases while 6 (15%) had received prior chemotherapy.

To date PSA changes in pts on treatment ⩾12 weeks: maximum PSA decline ⩾50% [21/29 (72%)], ⩾90% [14/29 (48%)], to PSA ⩽1ng/ml level [3/29 (10%)] and PSA rise above baseline [5/29 (17%)].

Eleven pts had Grade 3 adverse events including 4 pts with liver function test increases which normalized after AA discontinuation,1 pt with hypokalemia, 1 pt with cardiac disorders and 1 pt with femoral neck fracture. No Grade 4 adverse events.

Median baseline Serum Testosterone (S-T) was 8.5 pg/ml (range <1–47.7) and Bone Marrow T (BM-T) was 6.5 pg/ml (range <1–33.6). Following 8 weeks treatment S-T and BM-T were undetectable (<1pg/ml) in 19/23 evaluable pts.

Conclusions: ENZA+ AA combination has a favorable safety profile and depletes androgens in the blood and marrow in pts with mCRPC. Promising PSA response profile was observed: 72% of pts achieved a ⩾50% PSA decline, 48% achieved ⩾90% decline and 3 pts have undetectable PSA, following ⩾12 weeks of treatment.

Degarelix versus luteinising hormone-releasing hormone (LHRH) agonists: Safety outcomes from six comparative randomised clinical trials

B. Tombal[1], K. Miller[2], T.M. De Reijke[3], B.E. Persson[4]. [1]*Cliniques Universitaires Saint-Luc, Service d'Urologie, Bruxelles, Belgium;* [2]*Charité-Universitätsmedizin Berlin, Department of Urology, Berlin, Germany;* [3]*Academic Medical Center, Department of Urology, Amsterdam, Netherlands;* [4]*Ferring Pharmaceuticals, Urology/Oncology, Saint-Prex, Switzerland*

Background: LHRH agonists, used to treat men with hormone-dependent advanced prostate cancer, are associated with an increased risk of cardiovascular disease (CVD) and death. The antagonist degarelix has a distinct mechanism of action and comparative trials have shown differences in disease control between these agents. The comparative incidence of disease-related adverse events (AEs) and CVD have now been analysed.

Materials and Methods: Data were pooled from 6 prospective, comparative randomised trials (sponsored by Ferring Pharmaceuticals) of degarelix vs. LHRH agonists (n = 2328). 1686 patients received 1 year of treatment and 642 patients had 3 to 7 months of treatment. Events were analysed using Kaplan Meier plots, a log-rank test for homogeneity and adjusted for common baseline factors (Cox proportional hazard model).

Results: Baseline characteristics including age, testosterone, PSA, disease stage and CVD history were balanced between groups. 1491 patients received degarelix and 837 a LHRH agonist (goserelin, n = 458; leuprolide, n = 379). Overall probability of any urinary tract AE ($p < 0.0001$) and of a urinary tract infection ($p = 0.001$) were significantly lower in patients on degarelix. The overall probability of joint related signs and symptoms was significantly reduced in the degarelix group vs. the LHRH agonist group (5.3% vs. 8.1%, respectively; $p = 0.0116$). Overall probability of fracture (<1% vs. 2%, $p = 0.0234$) was significantly reduced in men receiving degarelix. Fracture risk in men >70 years old was also lower in the degarelix group (HR = 0.264, 95% CI 0.091–0.761; $p = 0.0137$). The risk of a CV event was significantly lower in patients receiving degarelix (HR = 0.597, 95% CI 0.380–0.938; $p = 0.0253$). In patients with CVD history the findings remained significant (HR = 0.476, 95% CI 0.260–0.871; $p = 0.0160$). The risk of a serious CV event was also significantly lower in patients with CVD history receiving degarelix (HR = 0.367, 95% CI 0.174–0.775; $p = 0.0086$).

Conclusions: This analysis of 2328 men demonstrates that, during the first year of treatment, those treated with degarelix had a reduced occurrence of disease-related side effects including urinary tract symptoms and fractures. The risk of a CV event or serious CV event was significantly lower for men receiving degarelix vs. a LHRH agonist.

Poster Discussion Session and Poster Session (Mon, 30 Sep)
Genitourinary Malignancies − Prostate Cancer

2856 POSTER DISCUSSION

Going beyond age for comorbidity evaluation in prostate cancer patients treated with radiation

S. Ng[1], G. Duchesne[1], K.H. Tai[1], F. Foroudi[1], S. Williams[1]. [1]*Peter MacCallum Cancer Institute, Radiation Oncology, Melbourne, Australia*

Introduction: Prostate cancer management involves a balance between the risks of cancer death against those from other causes. This study evaluates the potential value of several simple comorbidity indices in a large radiotherapy cohort.

Methods: 1956 men with localised prostate cancer treated with radical radiotherapy between 2000–2007 were studied. Tumour features, androgen deprivation usage, age, number of prescription medications and Adult Comorbidity Evaluation 27 Index (ACE-27) were recorded. Death from prostate cancer (DPCa) and death from other causes (DOthC) were analysed as competing causes of death using a competing risks model, with discrimination assessed using the concordance index.

Results: Patients were treated with external beam radiation only (73%) or with high-dose-rate brachytherapy boost (21%) or low-dose-rate brachytherapy (6%). Median age was 70 (95% CI 53−79). 48% had ACE-27=1, 16.5% had ACE-27=2, and 3% had ACE-27=3. ACE-27 scores correlated with patient's number of prescription medications (median number of prescriptions=2, 95% CI 0−7). Tumour features were independent of ACE-27 scores. Median follow up was 66.5 months.

Estimated cumulative incidence of DOthC at 10 years was 30.3% (95% CI 24.1–37.4%), and for DPCa was 18.0% (95% CI 13.0–24.4%). In the low/intermediate risk group (n = 1026) there was a 3.4-fold predominance of DOthC inside 10 years, with a cumulative incidence of 33.5% (95% CI 23.7–45.1%) of DOthC compared to 9.8% (95% CI 4.9%-16.1%) risk of DPCa. High risk men had approximately equal rates of DPCa and DOthC at 10 years.

Multivariable analysis showed age, ACE-27 score of one or more and number of medications to have significant associations with DOthC ($p < 0.002$ for all). No tumour related variables had an impact on DOthC. The discriminatory performance (C-Index) of univariable models of age, ACE-27 or medication number was 0.589, 0.612 and 0.608 at 10 years respectively. A multivariable model incorporating all 3 variables resulted in C-Index of 0.644. A simple prognostic score incorporating these variables facilitates usage.

Conclusion: Age, ACE-27 score and number of medications act as independent prognostic factors for DOthC in prostate cancer patients and can be considered in clinical setting to aid in predicting a patient's life expectancy and treatment decisions. Objective assessment of comorbidity can potentially reduce the rate of radiotherapy that will ultimately be futile due to comorbid deaths.

No conflict of interest.

2857 POSTER DISCUSSION

Mortality rate 60 days following radical prostatectomy in France

M. Boniol[1], A. Koechlin[1], P. Autier[1], A. Ruffion[2], P. Perrin[2], P. Boyle[1]. [1]*International Prevention Research Institute, Lyon, France;* [2]*Centre Hospitalier Universitaire de Lyon, Service d'Urologie, Lyon, France*

Background: The increasing use of PSA testing for prostate cancer screening, in particular in ageing populations, leads to a rise in the number of overdiagnosed prostate cancers and associated overtreatment. A major element of treatment is radical prostatectomy (RP). It is of utmost importance to rely on good statistics on demographics of patients and mortality associated with this procedure.

Material and Methods: RP in men aged 40 and over conducted in France between 2007 and 2011 were retrieved from the French Technical Agency for Information on Hospitalization (ATIH) database. 637 hospitals (public and non-profit private) performing RP were included. Basic patient data such as age, place of residence, type of surgery (open/laparotomy vs. laparoscopy) and Charlson comorbidity index were available. For each patient, vital status 60 days following surgery was retrieved. Income of patients was estimated using the median income of the 'commune' of residence of patients.

Results: In the study period, 120,333 RP were performed. 68,106 were open RP and 52,227 were laparoscopic RP. The number of RP per year was stable during the study period. Patients undergoing laparoscopy were significantly younger than patients undergoing laparotomy (62.94 vs. 63.31 years, p<2.2*10−16). At 60 days following RP, a total of 183 deaths were registered, corresponding to a crude mortality rate of 0.15%. The major factor associated with mortality was age: death rate increased exponentially with age. A significant proportion of RP (18%) were conducted in patients aged over 70 years of age. In this latter group, the mortality rate was 0.36% as compared to 0.11% for patients younger than 70. Other factors associated with mortality were the type of intervention (open, ASR=0.18%; laparoscopy, ASR=0.06%), Charlson index (Charlson=0, ASR=0.10%; Charlson>0, ASR=0.59%) and socioeconomic status.
In a sensitivity analysis, the survival curve at different points in time was evaluated. Survival falls rapidly until around 60 days; afterwards death rate is more stable. This indicates that the bulk of risk following RP is within 60 days and further follow-up reflects the background risk of death.
Conclusions: In a large cohort of men, the risk of death 60 days post RP is 0.11% for men aged 40−69. RP performed after the age of 70 is associated with a tripling of risk of death. RP should be discouraged in this older population.
No conflict of interest.

2858 POSTER DISCUSSION

Which is the best radiation treatment for low risk prostate cancer? A comparison of stereotactic body radiotherapy, standard external beam radiotherapy or low dose rate brachytherapy

A. Loblaw[1], P. Sethukavalan[1], P. Cheung[1], G. Morton[1], L. D'Alimonte[1], A. Deabreu[1], A. Mamedov[1], L. Zhang[2], H. Chung[1], R. Nam[3].
[1]Sunnybrook Health Sciences Centre, Radiation Oncology, Toronto, Canada; [2]MacroStat Inc, Biostatistics, Toronto, Canada; [3]Sunnybrook Health Sciences Centre, Surgery, Toronto, Canada

Background: Stereotactic body radiotherapy (SBRT) is an emerging radiotherapy technique that appears to be efficacious, well tolerated and convenient. However, outcomes for patients treated with SBRT are unknown compared to more conventional radiation options for patients with prostate cancer. The purpose of this study is to evaluate and compare late toxicities and biochemical disease-free survival (bDFS) of low risk prostate cancer patients treated SBRT (35 Gy/5 fractions), standard external beam radiotherapy (STND; median 76 Gy/38 fractions) or low-dose brachytherapy (LDR; iodine-125, 145 Gy) at the Odette Cancer Centre.
Material and Methods: Consecutive patients with low risk prostate cancer treated with radiation from 2006–2008 were analyzed. Patients treated with SBRT were part of a phase 2 prospective clinical trial; patients treated with STND or LDR had data abstracted from medical charts retrospectively. Patients treated with neoadjuvant androgen deprivation therapy were excluded from biochemical analyses. bDFS was defined by time to Phoenix-failure (nadir + 2ng/ml). Univariate (UVA) and multivariate analyses (MVA) of Cox proportional hazard model were conducted to identify significant covariates predicting bDFS.
Results: A total of 357 low-risk prostate cancer patients were identified (84 SBRT, 81 STND and 192 LDR). The median follow-up was 57, 62, and 59 months, respectively. At baseline, 85% of patients were T1c, 15% T2a; 100% had GS 6; median PSA 5.9 ng/ml. There were more patients in the STND and LDR cohort who had T2a disease (6%, 21% and 16%, p = 0.013) and the mean PSA was higher in the STND cohort (6.08, 6.69, and 6.02, p = 0.017). Patients who received LDR experienced more late hematuria (0%, 1.23% and 11.98%, p < 0.0001); otherwise there were no significant differences in late toxicities observed. There were no significant differences in bDFS (97.4% vs 96.9% vs 97.2% at 60 months, p = 0.94). There was 79−89% power to detect a one-sided 7% difference in bDFS between cohorts. There were no covariates identified predicting bDFS on UVA or MVA, including treatment type.
Conclusions: SBRT, STND and LDR show equivalent effectiveness and both external beam techniques showed less hematuria than LDR. However, SBRT and LDR are more convenient and less costly than STND. Further prospective studies of SBRT are ongoing.
No conflict of interest.

2859 POSTER DISCUSSION

Denosumab in men with nonmetastatic castration-resistant prostate cancer (CRPC) at high risk for bone metastases

M.R. Smith[1], K. Fizazi[2], K. Miller[3], B. Egerdie[4], J. Morote[5], T.L. Tammela[6], S. Wong[7], Z. Ye[8], A. Braun[8]. *[1]Massachusetts General Hospital Cancer Center, Boston, USA; [2]Institut Gustave Roussy, University of Paris Sud, Villejuif, France; [3]Charité Berlin, Berlin, Germany; [4]Urology Associates/Urologic Medical Research, Kitchener, Canada; [5]Hospital Vall d'Hebron, Barcelona, Spain; [6]Tampere University Hospital, Tampere, Finland; [7]Western Hospital, Footscray, Australia; [8]Amgen Inc., Thousand Oaks, USA*

Background: In a double-blind, placebo-controlled, multi-center, phase 3 study of men with non-metastatic CRPC at risk for bone metastasis (based on PSA ⩾8.0 ng/mL and/or PSADT ⩽10 months), denosumab significantly increased bone metastasis-free survival (BMFS) (HR 0.85, 95% CI 0.73–0.98, *P* = 0.028) (Smith et al, *Lancet*, 2012). PSA doubling time (PSADT) is a key prognostic factor for progression in men with CRPC. In this post-hoc analysis, we compare the treatment effect of denosumab in patients with PSADT ⩽6 months vs PSADT >6 months. This trial was sponsored by Amgen Inc., ClinicalTrials.gov, NCT00286091.
Material and Methods: A total of 1432 men with non-metastatic CRPC at risk for bone metastasis (PSA ⩾8.0 ng/mL and/or PSADT ⩽10 months) were randomized 1:1 to receive 120 mg subcutaneous denosumab or placebo every 4 weeks. The primary endpoint was BMFS, defined as the time to first bone metastasis (BM; symptomatic or asymptomatic) or death from any cause. Secondary endpoints included the time to first BM (symptomatic or asymptomatic, excluding death), time to symptomatic BM, and overall survival. Analyses of the primary and secondary endpoints were performed in the subset of patients with PSADT ⩽6 months who were enrolled based on aggressive PSA kinetics (short PSADT). The blinded treatment phase of the trial has been completed. The primary analysis has been reported previously.
Results: Approximately 80% of the entire study population had a baseline PSADT ⩽10 months (N = 1154). In the placebo group, men with PSADT ⩽6 months had decreased BMFS and time to BM vs men with PSADT >6 months by 17.4 months and 14.9 months, respectively. Denosumab demonstrated a greater improvement in BMFS and delay in both the time to BM (Table 1) and time to symptomatic BM in these higher risk patients. Survival was similar between treatment groups.

Table 1. PSADT ⩽10 months at baseline subset

Endpoints	Denosumab median months	Placebo median months	HR (95% CI)	p-value
BMFS				
PSADT ⩽6 months	25.9	18.7	0.77 (0.64–0.93)	0.006
PSADT >6 months	33.3	36.1	1.13 (0.81–1.57)	0.469
Treatment-by-PSADT interaction				0.054
Time to BM				
PSADT ⩽6 months	26.5	22.1	0.80 (0.65–0.97)	0.026
PSADT >6 months	33.7	37.0	1.08 (0.74–1.56)	0.698

Conclusion: Men with CRPC and aggressive PSA kinetics (PSADT ⩽6 months) are at significant risk of BM and death. The treatment effect of denosumab is greatest in these patients.

2860 POSTER DISCUSSION

A Phase 2 trial of sipuleucel-T in combination with concurrent or sequential abiraterone acetate (AA) in patients (pts) with metastatic castrate-resistant prostate cancer (mCRPC)

E. Small[1], R. Lance[2], T.A. Gardner[3], L.I. Karsh[4], A. Stubbs[5], C. McCoy[5], T. DeVries[5], C.H. Redfern[6], N.D. Shore[7]. *[1]University of California, San Francisco, CA, USA; [2]Eastern Virginia Medical School, Norfolk, VA, USA; [3]Indiana University School of Medicine, Indianapolis, IN, USA; [4]The Urology Center of Colorado, Denver, CO, USA; [5]Dendreon Corporation, Seattle, WA, USA; [6]Sharp Healthcare, San Diego, CA, USA; [7]7Carolina Urologic Research Center, Myrtle Beach, SC, USA*

Background: Sipuleucel-T and AA + prednisone (P) are FDA-approved for asymptomatic or minimally symptomatic mCRPC. Suppression of the androgen axis via AA can be immunostimulatory, suggesting AA

plus sipuleucel-T may be synergistic. However, P (used with AA) could impair sipuleucel-T production and/or immune responses if administered concurrently with sipuleucel-T. P11-3 (NCT01487863) is the first study to assess the combination of sipuleucel-T and AA + P.

Material and Methods: Pts with asymptomatic/minimally symptomatic mCRPC were co-administered sipuleucel-T (3 infusions at wks 0, 2 and 4) with concurrent or sequential AA + P (AA 1000 mg QD + P 5 mg BID for ⩽26 wks). Pts were randomised 1:1 to AA + P starting either 1 day (concurrent) or 10 wks (sequential) after the 1st sipuleucel-T infusion. The primary endpoint was antigen presenting cell (APC) activation; secondary/tertiary endpoints included APC and total nucleated cell (TNC) counts (sipuleucel-T product potency measures), immune responses, adverse events (AEs) and efficacy.

Results: As of March 2013, 64 pts have been enrolled. 30/32 pts in the concurrent arm and 31/32 pts in the sequential arm had received all 3 sipuleucel-T infusions. Median AA duration (range) was 25.4 wks (0.1–26.0) in the concurrent arm and 18.3 wks (7.9–26.0) in the sequential arm. Median cumulative APC activation and APC and TNC counts did not differ between arms (p>0.05). Indicative of a prime-boost effect, APC activation increased with the 2nd and 3rd sipuleucel-T infusions in both arms. No differences were seen between arms in the robust peripheral antibody and T cell responses observed (p>0.05). Overall AE incidence was 96.9% in the concurrent arm and 87.5% in the sequential arm; however, most AEs were infusion-related, occurring within 1 day of infusion (53.1% and 65.6% of total population, respectively). The most common AEs (incidence ⩾20% in either arm) included muscle spasms (concurrent arm, 40.6%; sequential arm, 25.0%), cough (21.9%; 15.6%), back pain (9.4%; 25.0%) and extremity pain (9.4%; 21.9%). The incidence of drug-related grade ⩾3 AEs was 3.1% (concurrent arm) and 6.3% (sequential arm). There was no difference in clinically significant laboratory toxicities between arms.

Conclusions: These data suggest sipuleucel-T can be successfully manufactured during concurrent AA + P without affecting product potency and immunological prime-boost responses. AEs were similar in both arms and generally mild to moderate in severity.

Assessing the impact of prior treatments on the efficacy of enzalutamide (ENZ): A subanalysis of the phase 3 AFFIRM trial

J. De Bono[1], K. Fizazi[2], N. Shore[3], M. Taplin[4], R. De Wit[5], A. Stenzl[6], M. Hirmand[7], B. Franks[8], H. Scher[9]. *[1]Institute of Cancer Research, Drug Development Unit, London, United Kingdom; [2]Institut Gustave Roussy University of Paris Sud, Department of Cancer Medicine, Villejuif, France; [3]Grand Strand Urology, Carolina Urologic Research Center, Myrtle Beach, USA; [4]Dana-Farber Cancer Institute, Medical Oncology/Solid Tumor Oncology, Boston, USA; [5]Erasmus University Medical Center, Department of Medical Oncology, Rotterdam, Netherlands; [6]University Clinic Tübingen, Department of Urology, Tübingen, Germany; [7]Medivation Inc, Clinical Development, San Francisco, USA; [8]Astellas, Scientific and Medical Affairs, Northbrook, USA; [9]Memorial Sloan-Kettering Cancer Center, Department of Medicine Sidney Kimmel Center for Prostate and Urologic Cancers Genitourinary Oncology Service, New York, USA*

Background: AFFIRM trial data showed a 4.8-mo survival benefit for patients (pts) with metastatic castration-resistant prostate cancer post-docetaxel (Doc) who took ENZ vs placebo (PBO; Scher et al, 2012). This posthoc analysis evaluated the correlation between ENZ response and prior therapy duration.

Material and Methods: AFFIRM randomized 1199 pts. The primary endpoint was overall survival (OS); secondary endpoints included radiographic progression-free survival (rPFS) and prostate-specific antigen (PSA) response. We assessed ENZ response by duration of exposure to A) prior Doc (time from start to end of prestudy Doc), B) any prior hormone therapy, and C) prior LHRH analogs only (calculated as the time from start of first therapy to end of last prestudy therapy or start of Doc, whichever was first; time excluded if overlapping with prestudy Doc, and continuous treatment assumed if hormone therapy changed). Data were divided into tertiles based on duration of exposure to prior therapy.

Results: All pts showed better OS, rPFS, and PSA response from ENZ vs PBO (Table).

Conclusions: In this analysis, ENZ showed consistent benefit across tertiles of exposure time for each prior therapy. Pts progressing more rapidly on previous LHRH analogs or any hormone therapy, but not on Doc, had inferior OS.

AFFIRM (NCT00974311) is sponsored by Medivation and Astellas, and is ongoing (not recruiting).

Prognostic index for progression-free survival in metastatic castration-resistant prostate cancer patients without previous chemotherapy: An analysis of the COU-AA-302 abiraterone acetate study

C.J. Ryan[1], T. Kheoh[2], A. Molina[3], J. Carles[4], E. Efstathiou[5], P.W. Kantoff[6], P.F.A. Mulders[7], F. Saad[8], T. Griffin[9], K.N. Chi[10]. *[1]University of California San Francisco (Helen Diller Family Comprehensive Cancer Center), Hematology/Oncology, San Francisco CA, USA; [2]Janssen Research & Development, Biostatistics & Programming, Los Angeles CA, USA; [3]Janssen Research & Development, Oncology, Los Angeles CA, USA; [4]Vall d'Hebron University Hospital, Medical Oncology, Barcelona, Spain; [5]MD Anderson Cancer Center, Genitourinary Medical Oncology, Houston TX, USA; [6]Dana-Farber Cancer Institute and Harvard Medical School, Medical Oncology, Boston MA, USA; [7]Radboud University Medical Centre, Department of Urology, Nijmegen, Netherlands; [8]University of Montreal, Division of Urology, Montreal QC, Canada; [9]Janssen Research & Development, WC Clinical Oncology, Los Angeles CA, USA; [10]BC Cancer Agency, Oncology, Vancouver BC, Canada*

Background: COU-AA-302 was a multinational, randomized, placebo-controlled, phase 3 trial of abiraterone acetate (AA) + prednisone (P) versus placebo + P in asymptomatic/mildly symptomatic metastatic castration-resistant prostate cancer (mCRPC) patients without prior chemotherapy and no visceral metastases (clinicalTrials.gov NCT00887198). Using readily assessable routine clinical and laboratory parameters at baseline,

we developed a prognostic index model for the primary end point of radiographic progression-free survival (rPFS) in patients treated with AA.
Material and Methods: The analyses used data from patients treated with AA in the COU-AA-302 trial. Assessment of rPFS was based on Prostate Cancer Working Group 2 criteria with required confirmatory bone scans. Baseline variables were assessed for association with rPFS through a univariate Cox proportional hazards model. Accepted values for lower (LLN) and upper (ULN) limits of normal were used to dichotomize most of the laboratory parameters; baseline median was used to dichotomize prostate-specific antigen (PSA) levels. Independent prognostic factors for rPFS were identified by multivariate Cox modeling with a stepwise procedure; internal validation was undertaken. Model accuracy was estimated by the C-index.
Results: In the model from the stepwise procedure, the following risk factors were associated with poor prognosis: presence of lymph node metastasis (HR = 1.76, p < 0.0001), lactate dehydrogenase > ULN (234 IU/L) (HR = 1.71, p = 0.0001), 10 or more bone metastases (HR = 1.71, p = 0.0015), hemoglobin < LLN (12.7 g/dL) (HR = 1.47, p = 0.0030), and PSA >39.5 ng/mL (HR = 1.42, p = 0.0078). Patients were categorized into 3 risk groups (good prognosis, n = 230; intermediate prognosis, n = 152; poor prognosis, n = 164) based on number of risk factors, and the median rPFS was calculated for each group (table). The C-index of 0.83 (95% CI, 0.73–0.91) indicated high model accuracy.

Number of risk factors	Median rPFS, months (95% CI)	HR (95% CI)[a]
0 or 1 (good)	27.6 (19.1–33.1)	–
2 (intermediate)	16.6 (13.8–21.9)	1.58 (1.17–2.12)
3–5 (poor)	8.3 (8.1–11.0)	3.08 (2.33–4.08)

[a]Versus patients with good prognosis.

Conclusions: This prognostic index associates readily available parameters to rPFS, which was positively associated with overall survival in a prior analysis of this trial. External validation is required before integrating this model into standard clinical practice and the design of future risk-stratified clinical trials.

2864 POSTER DISCUSSION

Sensitivity analyses for radiographic progression-free survival (rPFS): Results from the phase 3 AFFIRM trial comparing enzalutamide to placebo

H. Scher[1], K. Fizazi[2], C.N. Sternberg[3], A. Armstrong[4], S. Bhattacharya[5], M. Hirmand[6], J. De Bono[7]. *[1]Memorial Sloan-Kettering Cancer Center, Department of Medicine Sidney Kimmel Center for Prostate and Urologic Cancers Genitourinary Oncology Service, New York, USA; [2]Institut Gustave Roussy University of Paris Sud, Department of Cancer Medicine, Villejuif, France; [3]San Camillo-Forlanini Hospitals, Department of Medical Oncology, Rome, Italy; [4]Duke University, Oncology, Durham, USA; [5]Medivation Inc., Biometrics, San Francisco, USA; [6]Medivation Inc., Clinical Development, San Francisco, USA; [7]Institute of Cancer Research, Drug Development Unit, London, United Kingdom*

Background: Enzalutamide (ENZA) inhibits multiple steps in the androgen receptor signaling pathway (Tran et al, Science 2009). In the phase 3 AFFIRM trial, ENZA increased median overall survival (OS) by 4.8 months (P<0.001; HR, 0.63) vs placebo (PBO) in patients (pts) with metastatic castrate-resistant prostate cancer (mCRPC) progressing after docetaxel (Scher et al, NEJM 2012). We performed sensitivity analyses to assess the robustness of the ENZA benefit and the impact of different sources of progression on the pre-specified rPFS analysis.
Materials and Methods: AFFIRM was a phase 3 multinational, randomized, double-blind trial of 1199 post-docetaxel mCRPC pts. Randomization was 2:1 to ENZA 160 mg/day or PBO. The primary endpoint was OS; rPFS was a secondary endpoint. In the pre-specified analysis, rPFS was defined as time from randomization to the earliest objective evidence of radiographic progression or death due to any cause. Patients were assessed at regular intervals. Radiographic progression was defined by the appearance of 2 or more new bone lesions on bone scan as assessed per the PCWG2 guidelines or by RECIST 1.1 for soft tissue disease. Three sensitivity analyses (SA1–3) on rPFS assessed the impact of types of progression and other potential confounding factors. SA1 censored potential confounding factors; SA2 and SA3 added a factor (see Table) to the rPFS definition used for the primary analysis. Correlations between rPFS and OS were evaluated.
Results: As previously reported, the primary analysis for rPFS favored ENZA. The results of the 3 SA were statistically significant in favor of ENZA vs PBO treatment.

Analysis	Modifications from Primary Analysis	Total Events	Hazard Ratio* (95% CI)
Primary	None	861	0.40 (0.35–0.47)
SA1	Additional censoring criteria: • Unconfirmed bone PD • Initiation of new anti-neoplastic treatment • Incidence of SRE • Surgery/radiation for prostate cancer or bone disorders beyond first SRE	455	0.42 (0.34–0.53)
SA2	• Added: clinical progression as event	930	0.36 (0.32–0.42)
SA3	• Deleted: soft tissue PD events Added: first SRE	841	0.41 (0.36–0.48)

PD: progressive disease; SRE: skeletal-related event.
*All nominal P-values <0.0001.

Conclusions: Sensitivity analyses of rPFS, a key secondary endpoint of the AFFIRM trial, demonstrated a consistent and robust treatment benefit with ENZA. Endpoint correlations will be presented.
AFFIRM is co-sponsored by Medivation, Inc. and Astellas. The trial (NCT00974311) is ongoing, but not recruiting.

2865 POSTER DISCUSSION

New prognostic score for metastatic castration-resistant prostate cancer with incorporation of neutrophil to lymphocyte ratio

A.J. Templeton[1], C. Pezaro[2], A.G. Omlin[2], M.G. McNamara[1], R. Leibowitz-Amit[1], F.E. Vera-Badillo[1], G. Attard[2], J.S. De Bono[2], I.F. Tannock[1], E. Amir[1]. *[1]Princess Margaret Hospital, Medical Oncology, Toronto, Canada; [2]The Royal Marsden NHS Foundation Trust, Insitute of Cancer Research, Sutton Surrey, United Kingdom*

Background: Prognostic information is important to patients, physicians, and for stratification in clinical trials. Most prognostic nomograms for men with metastatic castration-resistant prostate cancer (mCRPC) are derived from patients treated in clinical trials. Here we develop a simple prognostic score for men with mCRPC treated in daily practice. Inflammation may play an important role in cancer progression, and a high neutrophil to lymphocyte ratio (NLR) has been reported to be a poor prognostic indicator in several malignancies.
Methods: In the training cohort, NLR was added to known prognostic variables identified from published nomograms for all chemotherapy-naive patients treated with 3-weekly docetaxel at *Princess Margaret Cancer Centre* (PMCC). Cut-offs for significant variables on univariable Cox regression were evaluated by the area under the receiver operating characteristic (ROC) curves. Multivariable Cox regression with forward elimination was then used to derive a prognostic score where one risk point was assigned for each significant variable. The model was tested in an external validation cohort of patients treated at *Royal Marsden* (RM).

	PMCC (training cohort)				RM (validation cohort)			
Risk points	0	1	2	3–5	0	1	2	3–5
Prevalence, %	8	25	30	37	10	31	31	29
Median OS, months	31.5	22.5	15.7	9.8	37.6	23.7	20.2	13.6
2 year OS, %	43	37	12	3	57	39	30	15
Hazard ratio for death	1 (ref)	1.9	3.1	6.4	1 (ref)	1.7	3.0	4.6
AUC*	0.78 (95% CI 0.72–0.84)				0.66 (95% CI 0.58–0.74)			

*AUC, area under ROC curve (discriminatory accuracy for predicting 2-year survival).

Results: 357 patients from PMCC were analyzed. Median age was 71 years, 26% had ECOG performance status (PS) ⩾2, 12% had liver metastasis (LM), 12% were treated in clinical trials and median overall survival (OS) was 14.7 months. LM (HR 1.9, P = 0.03), hemoglobin <12 g/dL (HR 1.8, P<0.01), ALP >2.0 x ULN (HR 1.6, P = 0.04), LDH >1.2 x ULN (HR 2.5, P<0.01), NLR >3 (HR 1.9, P<0.01) were associated with worse OS in the multivariable model thereby leading to a score of 0 to 5

points. Four risk categories were established with 0, 1, 2, and 3−5 points. For 215 patients in the RM validation cohort, median age was 67 years, 7% had PS $\geqslant$2, 4% had LM, 16% had prior treatment with abiraterone, 64% were treated in clinical trials and median OS was 19.6 months. Prognostic and discriminatory accuracy for the training and validation sets are shown in the table.
Conclusion: This simple risk score provides good prognostic and discriminatory accuracy for men with mCRPC.
No conflict of interest.

Leupaxin mediates actin cytoskeletal remodeling by regulating the phosphorylation status of the actin-binding protein caldesmon in prostate cancer cells

S. Dierks[1], S. Von Hardenberg[1], T. Schmidt[1], P. Burfeind[1], S. Kaulfuß[1]. [1]*University Medical Center Goettingen, Human Genetics, Goettingen, Germany*

Background: Prostate cancer is claiming a high number of deaths every year making prostate cancer a serious health problem. Recently, we could identify the focal adhesion protein leupaxin (LPXN) to be overexpressed in approximately 20% of prostate carcinomas (PCa) and that this overexpression leads to the progression of prostate carcinomas. In the present study, we analyzed the LPXN-mediated adhesive and cytoskeletal changes during PCa progression and report a novel mechanism for the LPXN-mediated regulation of cytoskeletal rearrangements during migration and invasion of PCa cells.
Methods: We performed siRNA studies to analyze LPXN function in the PCa cell lines PC-3 and DU 145. Yeast-Two-Hybrid-Screen, co-immunoprecipitation, and GST-pulldown assays identified interaction of LPXN and the actin-binding protein caldesmon (CaD). Relevance of interaction between LPXN and CaD during migration was examined using proximity ligation assays.
Results: Downregulation of LPXN expression resulted in a reduced adhesion of the PCa cells PC-3 and DU 145 to different substrates. To identify candidate proteins that could mediate the LPXN-induced cytoskeletal changes necessary for adhesion we performed a Yeast-two-Hybrid screen and identified CaD as a putative interaction partner of LPXN. CaD stabilizes actin structures thereby inhibiting migration and invasion. Using proximity ligation assays we could show that during migration of PCa cells LPXN interacts with CaD and more interestingly with its phosphorylated form which detaches from the actin leading to highly dynamic cytoskeletal structures. Furthermore, siRNA knockdown of CaD in these cell lines resulted in an increased migration and invasion, whereas proliferation stayed unaffected. Interestingly, we found decreased phosphorylation levels of CaD after downregulation of LPXN, whereas total CaD levels remained equal, indicating that the loss of CaD-mediated actin stabilization is the underlying cause of the observed impediments of adhesion and invasion. In addition, specific kinase inhibitors helped us to identify the extracellular signal-regulated kinase (ERK) as the kinase responsible for LPXN-induced CaD phosphorylation during migration. Moreover, we could show similar interaction patterns of LPXN and ERK during migration of PC-3 and DU 145 cells.
Conclusion: These results suggest that LPXN acts as an adapter protein that mediates the phosphorylation status of the actin-binding protein caldesmon (CaD) by interaction with the extracellular signal-regulated kinase (ERK) during migration and invasion of PCa cells.
No conflict of interest.

High lysophosphatidylcholine acyltransferase 1 expression independently predicts high risk for biochemical recurrence in prostate cancers

K. Grupp[1], S. Sanader[2], H. Sirma[2], R. Simon[2], K. Prien[2], C. Hube-Magg[2], J. Izbicki[1], G. Sauter[2], T. Schlomm[3], M. Tsourlakis[2]. [1]*University Medical Center Hamburg-Eppendorf, General Surgery, Hamburg, Germany;* [2]*University Medical Center Hamburg-Eppendorf, Institute of Pathology, Hamburg, Germany;* [3]*University Medical Center Hamburg-Eppendorf, Martini Clinics and Department of Urology, Hamburg, Germany*

Background: Lysophosphatidylcholine acyltransferase 1 (LPCAT1) has been suggested to play a role in cancer.
Material and Methods: To assess its role in prostate cancer, LPCAT1 expression was analysed on a tissue microarray containing samples from 11,152 prostate cancer patients.
Results: In benign prostate glands, LPCAT1 immunostaining was absent or weak. In prostate cancer, LPCAT1 positivity was found in 73.8% of 8,786 interpretable tumours including 29.2% with strong expression. Increased LPCAT1 expression was associated with advanced tumour stage (p <0.0001), high Gleason score (p <0.0001), positive nodal involvement (p = 0.0002), positive surgical margin (p = 0.0005), and early PSA recurrence (p <0.0001). High LPCAT1 expression was strongly linked to *ERG*-fusion type prostate cancer. Strong LPCAT1 staining was detected in 45.3% of ERG positive but in only 16.7% of ERG negative tumours (p <0.0001). Within ERG negative cancers, LPCAT1 staining was strongly increased within the subgroup of *PTEN* deleted cancers (p <0.0001). Further subgroup analyses revealed that associations of high LPCAT1 expression with PSA recurrence and unfavourable tumour phenotype were largely driven by ERG negative cancers (p <0.0001) while these effects were substantially mitigated in ERG positive cancers (p = 0.0073).
Conclusions: The prognostic impact of LPCAT1 expression was independent of histological and clinical parameters. It is concluded, that LPCAT1 measurement, either alone or in combination, may be utilised for better clinical decision-making. These data also highlight the potentially important role of lipid metabolism in prostate cancer biology.
No conflict of interest.

A role for activated leukocyte cell adhesion molecule (ALCAM) in the growth and matrix adhesion of prostate cancer cells

A.J. Sanders[1], A. Sobkowicz[1], S. Owen[1], L. Ye[1], M.D. Mason[2], W.G. Jiang[1]. [1]*Cardiff University School of Medicine, Surgery, Cardiff, United Kingdom;* [2]*Cardiff University School of Medicine, Oncology & Palliative Medicine, Cardiff, United Kingdom*

Background: Prostate cancer is one of the most common cancers in men in the UK and Europe, accounting for close to a quarter of all diagnosed male cancers. Mortality and morbidity is commonly associated with the metastatic spread of the primary cancer which frequently occurs to the bone. Activated Leukocyte Cell Adhesion Molecule (ALCAM) is a glycoprotein of the immunoglobulin superfamily that has been linked to various human cancers where it frequently displays aberrant expression patterns. It has also been shown to be involved in the development of bone metastasis. The current study aimed to explore the functional role of ALCAM in human prostate cancer cells.
Materials and Methods: Human prostate cancer cell lines, PC-3 and LNCaP were used. ALCAM expression was targeted in prostate cancer cells by way of genetic manipulation, namely transfecting the cells with anti-ALCAM hammerhead ribozyme transgenes, to specifically cleave ALCAM transcripts (PC-3^{ALCAMKO}). Successful knockdown of ALCAM expression, in comparison to control PC-3 cells transfected with a closed pEF6 plasmid (PC-3^{pEF6}), was verified using quantitative PCR. The impact of targeting ALCAM on an array of biological functions were tested, including cell growth and cell-matrix adhesion, using *in vitro* functional assays.
Results: Transfection of PC-3 cells with the ALCAM ribozyme transgene brought about a substantial reduction in the levels of ALCAM transcript within this cell line. Suppression of ALCAM expression resulted in an enhanced growth rate. PC-3^{ALCAMKO} cells had a significantly increased growth rate at both three day and five day incubation periods compared to control PC-3^{pEF6} cells ($P < 0.05$). However, following ALCAM suppression, PC-3 cells displayed a reduced adhesive capacity to an artificial Matrigel basement membrane and the number of adherent PC-3^{ALCAMKO} cells was notably reduced compared to control PC-3^{pEF6}.
Conclusions: Targeting of ALCAM in PC-3 cells enhanced growth rates but reduced the capacity of the cells to adhere to an artificial matrix. The current data suggests that ALCAM may play an important role in regulating these processes in PC-3 cells and may thus be an important factor in prostate cancer progression.
No conflict of interest.

2869 POSTER

ODM-201 − new generation antiandrogen with excellent antiandrogenic and antitumor activity in nonclinical models of CRPC

A. Moilanen[1], R. Riikonen[1], R. Oksala[1], L. Ravanti[1], E. Aho[1], G. Wohlfahrt[2], O. Törmäkangas[1], P.J. Kallio[1]. [1]*Orion Corporation, Research & Development, Turku, Finland;* [2]*Orion Corporation, Research & Development, Espoo, Finland*

Background: Activation of androgen receptor (AR) signaling is crucial for prostate cancer growth at all stages of the disease. Also castration resistant

prostate cancer (CRPC) is still dependent on AR and is often characterized by AR overexpression and resistance to conventional antiandrogens such as bicalutamide. ODM-201 is a novel, new generation antiandrogen that has unique properties and superior efficacy in preclinical models.
Methods and Results: Receptor binding studies indicated that ODM-201 and its major metabolite bind to wild-type AR with excellent selectivity and superior affinity (9 nM) when compared to known second generation antiandrogens. In functional cell-based assays, ODM-201 and its metabolite function as full AR antagonists with improved potency over clinically tested antiandrogens. In highly AR overexpressing cells, ODM-201 functions as an antagonist unlike bicalutamide which shows significant agonism. Most importantly, ODM-201 and its metabolite were found to inhibit testosterone-induced nuclear translocation in AR overexpressing cells whereas bicalutamide fails to block testosterone-induced AR nuclear translocation. W741L (tryptophan to leucine) mutation of AR has been shown to have a role in the mechanism of bicalutamide resistance. In this mutation, both ODM-201 and its metabolite functioned as antagonists, whereas bicalutamide was a pure agonist, as previously shown. In VCaP cell line derived from a bone metastasis of a patient with CRPC and containing endogenous AR gene amplification and AR overexpression, ODM-201 dose-dependently suppressed androgen-induced cell proliferation. In a VCaP xenograft model designed to mimic the castration resistant state of prostate cancer, ODM-201 potently ($p < 0.05$ over treatment time) inhibits tumor growth with superior efficacy when compared to MDV3100.
Conclusion: In summary, ODM-201 is a new generation AR antagonist found to possess excellent antiandrogenic as well as antitumor activity both in the in vitro and in vivo models of CRPC. These results suggest that ODM-201 is a promising new therapeutic for treatment of CRPC.

Association of WAVE (WASP verprolin homologous) proteins with the Arp2/3 complex in prostate cancer metastasis

H. Weeks[1], A.J. Sanders[1], H.G. Kynaston[1], W.G. Jiang[1]. [1]*Cardiff University School of Medicine, Metastasis and Angiogenesis Research Group, Cardiff, United Kingdom*

Background: Metastasis is the main cause of cancer related death in prostate cancer patients. Acquisition of an increased migratory phenotype drives metastatic potential of cancer cells. Cell locomotion is driven by actin polymerisation which is regulated by the Arp2/3 complex which itself requires activation which can be brought about by the WAVE (WASP verprolin homologous) protein family. With the discovery of elevated WAVE 1 and 3 expression in metastatic prostate cancer cell lines, this study aims to gain a better understanding of the association between WAVE expression and prostate cancer metastasis as well the relationship with the Arp 2/3 complex.
Material and Methods: The metastatic prostate cancer cell line, PC-3 was transfected with ribozyme transgenes to target WAVE 1 and 3 expression to generate knockdown sub-lines named PC-$3^{WAVE1KO}$ and PC-$3^{WAVE3KO}$, respectively. Control cell line, PC-3^{pEF6} was generated via transfection with a closed plasmid. Once expression knockdown was confirmed, a series of assays were conducted to evaluate the effects of WAVE 1 and 3 knockdown on cell growth, invasion and motility. Treatment of cells with the Arp2/3 inhibitor, 8012–5102 was also carried out in parallel.
Results: Growth of PC-$3^{WAVE1KO}$ cells was significantly reduced compared to PC-3^{pEF6} cells, whilst there was no change in cell invasion and motility. There was a significant decrease in cell growth, invasion and motility in PC-$3^{WAVE3KO}$ cells relative to PC-3^{pEF6} cells. Treatment of PC-3^{pEF6} cells with 8012–5102 saw an increase in cell growth and little change in cell invasion, whilst both PC-$3^{WAVE1KO}$ and PC-$3^{WAVE3KO}$ cells exhibited reduced cell growth and little change in invasiveness compared to untreated cells.
Conclusions: This present study demonstrates the impact of WAVE on several cell functions in the prostate cancer cell line, PC-3. Whilst knockdown of either WAVE 1 or 3 displayed a reduction in cell growth, decreased invasiveness and motility was only seen with WAVE 3 knockdown. Some aspects of cell function were affected in response to Arp2/3 inhibition in these cells and provides some insight into the relationship between WAVE and Arp2/3. It is clear expression aberrations in WAVE 1 and 3 could be a contributing factor in prostate cancer metastasis, however, functional differences between WAVE 1 and 3 highlight subtle distinctions between these proteins.
No conflict of interest.

Effects of amniotic membrane proteins on mitochondrial activity, protein synthesis, cell viability and DNA of prostate cancer cell lines: Preliminary results

A.C. Mamede[1], M. Laranjo[2], S. Moreira[2], M.J. Carvalho[3], A.M. Abrantes[2], A.S. Pires[2], J.E. Casalta-Lopes[2], C.J. Maia[1], M.F. Botelho[2]. [1]*CICS − Health Sciences Research Centre, University of Beira Interior, Covilhã, Portugal;* [2]*Biophysics Unit − IBILI, Faculty of Medicine of University of Coimbra, Coimbra, Portugal;* [3]*Gynaecology and Obstetrics Service, University Hospitals of Coimbra, Coimbra, Portugal*

Background: Amniotic membrane (AM) is a thin tissue on the inner side of placenta. AM is already used in several clinical areas due to its attractive properties. In fact, AM has anti-inflammatory, anti-bacterial, anti-viral, anti-angiogenic, pro-apoptotic and immunological characteristics. Although these properties are already identified, little is known about AM active protein content. Due to its characteristics, AM has recently drawn attention as an upcoming therapy in oncologic disease. Regarding the strategies already implemented, nothing is known about the effect of AM proteins in cancer cells.
Material and Methods: AM tissue was obtained from healthy women (after approval by Ethics Committee) after vaginal delivery or caesarean section, washed with phosphate buffered solution and subjected to mechanical actions in order to extract proteins. Proteins were quantified using Nanodrop®. To study the effect of AM proteins in prostate cancer (PCa), studies were performed in two cell lines obtained in ATCC: LNCaP (androgen/estrogen dependent) and PC3 (androgen/estrogen independent). Cells were incubated with 1 or 3 μg/μL of AM proteins during 72 h. After this period, MTT and SRB assays were performed to assess mitochondrial activity and protein synthesis of PCa cells, respectively. Trypan blue and comet assay were used to respectively analyze cell viability and DNA damage.
Results: LNCaP mitochondrial activity decreases 31.01% and 58.13% after treatment with 1 or 3 μg/μL, respectively. Regarding PC3 mitochondrial activity, there is a decrease of 48.69% (1 μg/μL) and 95.87% (3 μg/μL) relatively to control. Through SRB assay, it was found a decrease of 17.92% and 71.03% in LNCaP protein synthesis after incubation with 1 or 3 μg/μL. AM induced a decrease of 14.19% (1 μg/μL) and 34.25% (3 μg/μL) of protein synthesis ability in PC3. Through trypan blue we found that LNCaP viability is reduced after treatment, being this response dose-dependent in both cell lines. Preliminary results of comet assay allowed to verify DNA damage in LNCaP, being these most evident when cells were exposed to 3 μg/μL. When exposed to 1 μg/μL, PC3 DNA does not seem to be affected. However, the DNA damage is apparent after 3 μg/μL treatment.
Conclusion: Our preliminary results indicate that AM proteins have a promising role in the PCa therapy. Mitochondrial activity, protein synthesis, cell viability and DNA of PCa cell lines under study appear to be affected by AM treatment, being the effects in hormone dependent PCa cell line more evidenced.
No conflict of interest.

2872 POSTER

Paxillin in the prostate cancer cell models

A. Sobkowicz[1], A. Sanders[1], M.D. Mason[1], W.G. Jiang[1]. [1]*Cardiff School of Medicine Cardiff University, Metastasis & Angiogenesis Research Group, Cardiff Wales, United Kingdom*

Introduction: Prostate cancer is characterised by its unique but not entirely understood prevalence of osteoblastic metastasis. Cells migration and adhesion are involved in cancer metastasis and the direct result of the dynamic changes in the extracellular matrix environment, i.e. stimulation with growth factors or bone matrix proteins. Paxillin, being one of the proteins involved in integrin-dependent cell attachment may aid the colonisation of bone marrow.
Objectives: The present study uses a variety of prostate cancer cell lines (generating osteolytic, mixed osteolytic/osteoblastic and osteoblastic metastasis) with significantly down-regulated expression of *PAXILLIN* gene and investigates their response to hepatocyte growth factor (HGF) or/and bone matrix extract (BME) stimulation. An aggressive human breast cancer cell line (MDA-MB-231) was used to establish any organ-related differences.
Methods: Three prostate cancer cell lines PC-3, LNCaP, MDA-PCa-2b and a breast cancer cell line MDA-MB-231 were transfected with specifically generated anti-paxillin ribozymes to obtain the *PAXILLIN* gene knock-down. Knock-down cell lines were treated with 40 ng/ml HGF and/or 50 μg/ml BME and growth, migration, adhesion and invasion assays were performed.
Results: Up to date 2 knock-downs of PC-3 (Rib1 Col3 and Rib2 Col6) were confirmed using PCR and Real-Time RT PCR (with GAPDH gene expression as a normalization factor throughout the experiments) as well

as by Western blotting. Low level of paxillin exhibited by both cell lines seems to contribute not only to their morphology changes but also to the significant decrease in their adhesion and invasion abilities comparing to the control PC-3 pEF6 cell line. Migration abilities of PC-3 Rib2 Col6 cell line are impaired when untreated or non existing upon HGF stimulation while migration of untreated PC-3 Rib1 Col3 cells remains on the level of the control, is slightly slower when stimulated with HGF or slightly faster upon BME treatment. The lack of any viable MDA-PCa-2b cells with *PAXILLIN* knock-down may suggest that its lack is fatal hence necessary for their adhesion and survival.
Conclusions: Our preliminary results into the role of paxillin in the metastasis of prostate cancer suggest that the environment of HGF or bone matrix influences its expression which might contribute to metastasis in prostate cancer.
No conflict of interest.

2873 POSTER

Continued excess mortality for long-term prostate cancer survivors

O. Husson[1], L.N. Van Steenbergen[2], E.L. Koldewijn[3], P.M. Poortmans[4], J.W.W. Coebergh[2], M.L.G. Janssen-Heijnen[5]. *[1]Tilburg University, Tilburg, Netherlands; [2]Comprehensive Cancer Centre South, Eindhoven Cancer Registry, Eindhoven, Netherlands; [3]Catharina Hospital, Urology, Eindhoven, Netherlands; [4]Institute Verbeeten, Radiation Oncology, Tilburg, Netherlands; [5]Viecuri Medical Centre, Clinical Epidemiology, Venlo, Netherlands*

Background: Many cancer patients want to know their actualized prognosis after having survived cancer for some time. We estimated population-based conditional 5-year relative survival rates for prostate cancer patients.
Material and Methods: All 98,672 patients diagnosed in the Netherlands with prostate cancer stage I−III in 1989–2008 aged 45−89 years were selected from the Netherlands Cancer Registry and followed until 2010. Conditional 5-year relative survival was estimated for every subsequent year of survival up to 15 years after diagnosis.
Results: Conditional 5-year relative survival decreased with time of survival since diagnosis. Excess mortality (conditional 5-year relative survival <95%) for patients with clinical T1 stage started 5 years after diagnosis and increased to almost 10% after 10 years. Patients with more advanced disease (cT2-cT4) exhibited an excess mortality of 6−12% at diagnosis which increased up to 15−22% after 10 years. Excess mortality occurred earlier for the older age groups. Five-year relative survival at diagnosis was <90% for all age groups of patients with cT3/cT4 and excess mortality for this group increased to over 20% for those who had already survived for 5 years since diagnosis.
Conclusions: Excess mortality was found for prostate cancer patients at some point within 10 years after diagnosis, being earlier for more advanced stage and older age groups. Quantitative insight into conditional survival is useful for caregivers to help planning optimal cancer treatment and surveillance and to inform patients about their actual prognosis during follow-up, taking the current condition of the patient into account.
No conflict of interest.

Feasibility of assessing quality of prostate cancer care by means of Patient Reported Outcome Measures (PROMS): Results from the population-based PROFILES registry

L.V. Van de Poll-Franse[1], R.H. Verhoeven[1], P.J. Kil[2], V.E. Lemmens[1]. *[1]Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands; [2]Elisabeth Hospital, Urology, Tilburg, Netherlands*

Background: In the past years attention has increasingly been paid to Patient Reported Outcomes Measures (PROMs) for measuring and benchmarking the performance of oncological health care providers. Our aim was to investigate the feasibility of using the EORTC QLQ-C30 and QLQ-PR25 as measures of health related quality of life (HRQoL) and prostate cancer specific symptoms to assess potential variation in health care performance on hospital level among patients treated for localized prostate cancer.
Methods: We estimated to minimally need 65 patients with localized prostate cancer (cT1/cT2) per hospital to be able to find clinically meaningful differences in HRQoL between hospitals. We therefore randomly selected 150 patients per hospital diagnosed with prostate cancer between 2006 and 2009. In total, 1050 prostate cancer patients from 7 hospitals as registered in the Eindhoven Cancer Registry were asked to complete a questionnaire 2−6 years after diagnosis. The questionnaire included a survey on HRQoL (EORTC QLQ-C30) and prostate cancer specific symptoms (EORTC QLQ-PR25). Analyses of covariance were conducted, correcting for differences in case mix, to investigate the variation in HRQoL and symptoms between hospitals.
Results: A total of 698 patients (66%) responded to the invitation. For this analysis we selected 532 (76%) patients with cT1 or cT2 disease. Despite similar age, stage and comorbidity distribution of participating patients in the different hospitals, treatment at diagnosis varied between hospitals. Overall, 34% was treated with prostatectomy (varying between hospitals from 23% to 51%), 17% was treated with external radiotherapy (11%-24%), 18% received brachytherapy (3%-33%), and 30% was treated with hormonal therapy only (20%-41%).
As expected, patients treated with prostatectomy reported clinically meaningful higher incontinence scores compared to other treatment groups (20 vs. 6−15), but also best physical functioning (89 vs. 80−87) and most sexual activity (33 vs. 22−30), whereas patients treated with external radiotherapy reported most bowel symptoms (9 vs. 2−4). When comparing HRQoL or prostate cancer symptoms between hospitals we only observed a statistically significant and clinically meaningful difference regarding incontinence scores, ranging from 8−23 points. No significant differences were observed regarding all other symptoms.
Conclusions: Despite the strong association between prostate cancer treatment and outcomes and the large treatment variation between hospitals, we did not observe clinically meaningful differences in PROMS (HRQOL and symptoms) between hospitals, except for urinary incontinence. This might imply that although variation in treatment is large the ultimate hospital outcome performance is almost similar. Or, using PROMS to measure and benchmark hospital performance is less sensitive than we thought.
No conflict of interest.

2875 POSTER

Tolerability and reproducibility of a novel rectal obturator to localise the prostate and spare the rectum during radical prostate radiotherapy

E. Alexander[1], H.A. McNair[2], S. Landeg[2], V. Hansen[3], D.P. Dearnaley[1]. *[1]Institute of Cancer Research, Academic Radiotherapy, Sutton, United Kingdom; [2]Royal Marsden NHS Foundation Trust, Radiotherapy, Sutton, United Kingdom; [3]Royal Marsden NHS Foundation Trust and Institute of Cancer Research, Joint Physics Department, Sutton, United Kingdom*

Background: ProSpare® is a daily disposable rectal obturator designed to localise the anterior rectal wall on X-Ray image-guidance radiotherapy (IGRT) and increase sparing of rectal tissue during radical prostate radiotherapy. A previous clinical trial documented inadequate reproducibility of the device in the superior-inferior (SI) direction which led to design modifications. We have re-assessed the modified ProSpare® device.
Materials and Methods: We designed a clinical trial (ProSpare II, UKCRNID 11814) in two parts. Part I assessed feasibility, patient tolerance and accuracy. The primary endpoint had to be met to continue to part II: 80% of measured displacements were required to be 6 mm or less in the superior-inferior direction in at least 6 out of 9 patients (66.7%). Part II will subsequently assess treatment accuracy using an intra-patient randomised design treating men sequentially with and without ProSpare®. Patients planned for radical radiotherapy to the prostate and seminal vesicles were eligible for the study. Three intra-prostatic gold seed fiducial markers (FMs) were implanted in each patient. ProSpare® was inserted by the patient before patient set-up to skin marks. Daily cone-beam CT (CBCT) scans were obtained and the patient shifts were determined online using co-registration of the intra-prostatic FMs and the planning CT. ProSpare® displacements were analysed offline. Reproducibility was assessed by calculating the ProSpare® displacement after bony alignment. Planning target volume (PTV) margins were calculated using the Van Herk equation. Tolerability was assessed using an in-house questionnaire.
Results: Eleven men were enrolled into the study between September 2012 and November 2012. All patients successfully completed treatment using ProSpare® for all fractions. A total of 365 treatment fractions were analysed with 3285 displacements measured. Eight out of the 11 patients (83%) had more than 80% of SI displacements of 6 mm or less.

Table 1. Reproducibility displacement errors, systematic and random errors and consequent PTV margins required using ProSpare for prostate IGRT.

	Right–Left (n = 365)	Superior–Inferior (n = 365)	Anterior–Posterior (n = 365)
Total no. of reproducibility errors >6 mm	0	66	23
% of fractions with reproducibility errors ⩽6 mm	100%	82%	94%
Systematic Error (Σ) Prospare IGRT (mm)	1.28	3.15	0.83
Random Error (σ) Prospare IGRT (mm)	1.05	2.94	1.21
Prostatic PTV margin required for online Prospare IGRT (mm)	3.9	9.9	2.9

Conclusions: The device was tolerable in 100% of patients. The primary endpoint was met. The localising ability of ProSpare is promising in the lateral and vertical axes although certain limitations remain in the longitudinal direction. Hybrid CBCT co-registration techniques will allow maximal benefit to be gained from ProSpare IGRT.

2876 POSTER

Time to first skeletal-related event (SRE) with radium-223 dichloride (Ra-223) in patients with castration-resistant prostate cancer (CRPC) and bone metastases: ALSYMPCA trial stratification factors analysis

R. Coleman[1], S. Fossa[2], A. Chodacki[3], S. Wedel[4], O. Bruland[5], K. Staudacher[6], J. Garcia-Vargas[7], O. Sartor[8]. [1]*Weston Park Hospital, Sheffield, United Kingdom;* [2]*Radiumhospitalet, Oslo, Norway;* [3]*Hospital Kochova, Chomutov, Czech Republic;* [4]*Ortenau Klinikum Offenburg Gengenbach Klinik für Urologie und Kinderurologie, Offenburg, Germany;* [5]*Norwegian Radium Hospital and Faculty of Medicine University of Oslo, Oslo, Norway;* [6]*Algeta ASA, Oslo, Norway;* [7]*Bayer HealthCare, Montville NJ, USA;* [8]*Tulane Cancer Center, New Orleans LA, USA*

Background: Ra-223, a novel alpha-emitting pharmaceutical, targets bone metastases (mets) with high-energy, short-range (<100 μm) alpha-particles. In the phase 3 ALSYMPCA trial, Ra-223 significantly improved overall survival in CRPC patients (pts) with bone mets by 3.6 months vs placebo (pbo) (median OS: 14.9 vs 11.3 mo; HR = 0.695; 95% CI, 0.581–0.832; $P = 0.00007$) with a highly favorable safety profile. Analyses of time to first SRE with and without Ra-223, and impact of trial stratification factors on Ra-223 effects on time to first SRE are presented.

Methods: SREs were a key secondary endpoint, including use of external beam radiation therapy to relieve skeletal symptoms, new clinically detected pathologic bone fractures, spinal cord compression, and tumor-related orthopedic surgical intervention. Time to first SRE was assessed for the entire ITT population (n = 921) and by trial stratification factors (baseline alkaline phosphatase levels [ALP: <220 or ⩾220 U/L], current bisphosphonate use [yes/no], and prior docetaxel [yes/no]).

Results: Ra-223 significantly prolonged time to first SRE vs pbo (median time to first SRE: 15.6 vs 9.8 mo; HR = 0.658; 95% CI, 0.522–0.830; $P = 0.00037$). Treatment effect on time to first SRE favored Ra-223 over pbo regardless of current bisphosphonate use, with a trend toward even greater Ra-223 effect in pts given bisphosphonates. Similarly, time to first SRE was significantly prolonged vs pbo regardless of baseline ALP level (<220 or ⩾220 U/L). Pts with prior docetaxel had a significantly longer time to first SRE with Ra-223; there is a trend toward risk reduction for time to first SRE with Ra-223 vs pbo (HR = 0.74) in pts with no prior docetaxel (Table).

Conclusions: Ra-223 prolonged time to first SRE in pts with CRPC and bone mets, irrespective of baseline stratification factors. Time to first SRE may be prolonged for pts given Ra-223 who had concurrent bisphosphonate use.

Group	n	Time to 1st SRE (median, mo)	Hazard Ratio (95% CI)	*P* Value*
Overall				
Ra-223	614	15.6	0.66 (0.52, 0.83)	0.00037
Pbo	307	9.8		
Total ALP <220 U/L

Hematologic safety of radium-223 dichloride (Ra-223) in the phase 3 ALSYMPCA trial in castration-resistant prostate cancer (CRPC) patients with bone metastases: Baseline prognostic factor subgroup analysis

J. O'Sullivan[1], D.C. Johannessen[2], A. Widmark[3], I. Syndikus[4], N. James[5], M. Dall'Oglio[6], I. Haugen[7], A. Cross[8], J. Garcia-Vargas[9], N. Vogelzang[10]. [1]*Centre for Cancer Research and Cell Biology Queen's University Belfast, Belfast, Ireland;* [2]*Ullevål University Hospital, Oslo, Norway;* [3]*Umeå University, Umeå, Sweden;* [4]*Clatterbridge Center for Oncology, Wirral, United Kingdom;* [5]*Cancer Research UK Clinical Trials Unit School of Cancer Sciences, Birmingham, United Kingdom;* [6]*Hospital das Clínicas Faculdade de Medicina da USP Instituto do Câncer do Estado de São Paulo, São Paulo, Brazil;* [7]*Algeta ASA, Oslo, Norway;* [8]*Sheffield Hallam University, Sheffield, United Kingdom;* [9]*Bayer HealthCare, Montville NJ, USA;* [10]*Comprehensive Cancer Centers of Nevada, Las Vegas NV, USA*

Background: Ra-223 is a targeted alpha-emitter that selectively binds to bone metastases (mets) and emits ionizing radiation as high-energy, short-range (<100 μm) alpha-particles. In ALSYMPCA, Ra-223 significantly prolonged overall survival compared to placebo (pbo) in patients (pts) with CRPC and bone mets with a highly favorable safety profile. Incidence of grade 3 and 4 hematologic adverse events (AEs) was low in both Ra-223 and pbo groups: anemia in 13% of both groups; neutropenia (NP) in 2% and 1% and thrombocytopenia (TCP) in 6% and 2% of Ra-223 and pbo groups, respectively. Here we report a post hoc analysis of hematologic AEs in both treatment (tx) arms based on ALSYMPCA baseline prognostic factors. Since the incidence of grade 3 and 4 events was low, this analysis included grade 2−4 hematologic AEs.

Methods: Pts with progressive, symptomatic CRPC with ⩾2 bone mets were randomized 2:1 to Ra-223 (50 kBq/kg IV) q4wk (n = 600) or matching pbo (n = 301). The relationships of hematologic toxicity and 6 baseline factors (study tx, current bisphosphonate use, prior docetaxel use [pDoc], extent of disease >6 mets including superscan, prior external beam radiotherapy [EBRT] for bone pain, and total alkaline phosphatase [ALP]) were assessed at baseline, week 24, and follow-up (40 weeks after the first study drug dose) using multivariate Cox regression analysis.

Results: In the regression analysis of grade 2−4 hematologic AEs, tx with Ra-223 (vs pbo) and pDoc (vs no pDoc) were associated with a greater risk for NP (Ra-223: HR = 4.10, $P = 0.0207$; pDoc: HR = 2.81, $P = 0.0254$) and TCP (Ra-223: HR = 2.17, $P = 0.0118$; pDoc: HR = 2.31, $P = 0.0035$). Risk of anemia was significantly increased with pDoc (HR = 1.41, $P = 0.0087$) and more extensive disease (>6 mets) (HR = 4.50, $P < 0.0001$). Pts with lower baseline ALP levels (<220 U/L) had a significantly lower risk of TCP (HR = 0.56, $P = 0.0166$) and anemia (HR = 0.36, $P < 0.0001$) independent of tx group. No differences were seen in risk of hematologic AEs with bisphosphonate use or prior EBRT for bone pain. Blood transfusions were required for 137/614 (22%) and 69/307 (22%) of Ra-223 and pbo pts, respectively. Each tx group had 1 case of sepsis.

Conclusions: Ra-223 tx is associated with a low incidence of myelosuppression. Both Ra-223 and pDoc treatment are strong prognostic factors for grade 2−4 NP and TCP. Lower baseline ALP <220 U/L is a strong prognostic factor for lower risk of TCP and anemia.

2878 POSTER

Effects of radium-223 dichloride (Ra-223) on health-related quality of life (QOL) outcomes in the phase 3 ALSYMPCA study in patients with castration-resistant prostate cancer (CRPC) and bone metastases

C. Parker[1], D. Heinrich[2], D. Bottomley[3], P. Hoskin[4], L. Franzén[5], A. Solberg[6], V. Pawar[7], J. Reuning-Scherer[8], C.G. O'Bryan-Tear[9], S. Nilsson[10]. [1]*The Royal Marsden NHS Foundation Trust and Institute of Cancer Research, Sutton, United Kingdom;* [2]*Akershus University Hospital, Lørenskog, Norway;* [3]*St James Hospital, Leeds, United Kingdom;* [4]*Mount Vernon Hospital Cancer Centre, Middlesex, United Kingdom;* [5]*Länssjukhuset Sundsvall-Härnösand County Hospital Sundsvall and Umeå University Hospital, Umeå, Sweden;* [6]*St Olavs Hospital, Trondheim, Norway;* [7]*Bayer HealthCare, Montville, NJ, USA;* [8]*Yale University, New Haven, CT, USA;* [9]*Algeta ASA, Oslo, Norway;* [10]*Karolinska University Hospital, Stockholm, Sweden*

Background: Ra-223, a first-in-class alpha-emitter, significantly improved overall survival (OS) by 3.6 mo vs placebo (HR = 0.695; 95% CI, 0.581–0.832; $P = 0.00007$) in CRPC patients (pts) with bone metastases and was well tolerated (Parker et al, ASCO 2012). Ra-223 was also shown to have a positive impact on pain; it significantly delayed time to external beam radiation therapy and reduced pain and opioid use (Nilsson et al, ASCO GU 2013). Reported here is a post hoc analysis assessing treatment effect on QOL including pain-related score and time to deterioration in QOL over the entire treatment and follow-up phases.
Methods: QOL was assessed at weeks 16, 24, and follow-up visit 2 (week 44) using the Functional Assessment of Cancer Therapy for Patients with Prostate Cancer (FACT-P) questionnaire. Mixed-effect linear regression models were used to assess the average treatment effect in terms of change from baseline in FACT-P total score and subscales. The time to deterioration in QOL analysis defined deterioration as a $\geqslant$10-point reduction in FACT-P total score.
Results: For the entire trial period (weeks 16, 24, and 44), deterioration in mean FACT-P total score from baseline was significantly greater in the placebo group compared to the Ra-223 group (mean: −8.7 vs −4.8; $P = 0.004$). The results for 4 of the 5 FACT-P subscales indicate that Ra-223 pts had significantly higher QOL than placebo pts, the exception being the Social/Family Well-being Subscale (interactions with friends and family), which was not affected by treatment. Within the Prostate Cancer Subscale, the mean pain-related score improved with Ra-223 but declined with placebo; the treatment difference was statistically significant (mean: 0.6 vs −0.2; $P < 0.001$). In addition, Ra-223 was associated with significantly longer time to deterioration in QOL vs placebo (median: 6.3 vs 5.6 mo; HR = 0.75; 95% CI: 0.59–0.95; $P = 0.016$).
Conclusions: Ra-223 was associated with a significantly longer time to deterioration in QOL than placebo, with better preservation of QOL on most FACT-P subscales. Ra-223 is a well-tolerated agent that not only has a proven survival benefit, but also has a positive impact on QOL in patients with CRPC and bone metastases.

Acute toxicity of hypofractionated IMRT with simultaneous integrated boost in high-risk prostate cancer patients

M. Lecavalier-Barsoum[1], S. Faria[1], R. Ruo[2], F. Cury[1], M. David[1], M. Duclos[1], L. Souhami[1]. [1]*McGill University Health Centre, Radiation Oncology, Montreal, Canada;* [2]*McGill University Health Centre, Medical Physics, Montreal, Canada*

Background: McGill has over 10 years of successful experience with hypofractionation in favorable risk prostate cancer (PCa) where only the prostate has been irradiated. We have now expanded the use of this regimen to a phase II study involving high-risk PCa patients where the prostate and the pelvic nodes receive hypofractionated intensity-modulated radiotherapy (IMRT) with a simultaneous integrated boost. We report the acute toxicity found with this new approach.
Material and Methods: 69 high-risk PCa patients (stage T3, or PSA $\geqslant$20 ng/ml, or Gleason score of 8−10) entered in the study. Patients received androgen suppression before, during and after radiotherapy. IMRT plans were designed to deliver 60 Gy in 20 fractions of 3 Gy over 4 weeks to the prostate and base of seminal vesicle (PTV60), while simultaneously delivering 44 Gy in 20 fractions of 2.2 Gy to the pelvic lymph nodes (PTV44). All patients had daily image guidance with ultrasound and/or cone-beam. PTVs were CTVs with a 7 mm margin. Whole bladder and rectum constraints were as follows: V56 Gy<25%; V48 Gy<50% for the rectum and V60 Gy<25%; V52 Gy<50% for the bladder. Acute gastro-intestinal (GI) and genito-urinary (GU) toxicity were recorded prospectively, weekly during treatment and every 2−6 months post IMRT, using the NCI-CTCv3 scoring system. Correlation between acute toxicities and various dosimetric parameters including mean and maximum doses to the target volumes and to organs at risk (bladder and rectum) was performed, using the Wilcoxon test.
Results: Median age is 73 years (54−85). All patients, except one, completed IMRT without interruption, and were followed for more than 3 months. The exception was an 80 year-old patient who interrupted treatment at 54 Gy due to medical reasons diagnosed prior to IMRT. Acute toxicity is summarized in the table below and compared to the only phase III study (Pollack et al. 2006) comparing standard fractionation (arm I with 76 Gy in 38 fractions) to hypofractionation (arm II with 70.2 Gy in 26 fractions) for high-risk PCa patients treated with IMRT to the prostate and pelvic nodes. There was no grade $\geqslant$4 acute toxicity. in our study, acute toxicity did not correlate with any of the dosimetric parameters examined, and this analysis will be presented in details.
Conclusions: Hypofractionated IMRT to the pelvis with simultaneous integrated boost to the prostate is feasible with acute GI and GU toxicity rates similar to standard fractionation. The trial is continuing to accrue. Longer follow-up is critical to accurately assess long term toxicity and disease control.
No conflict of interest.

Association between VEGF-A gene variants and clinical outcome in prostate cancer patients treated with definitive radiotherapy

T. Langsenlehner[1], E.M. Thurner[1], S. Krenn-Pilko[1], A. Ehammer-Rosenkranz[1], W. Renner[2], A. Gerger[3], K.S. Kapp[1], U. Langsenlehner[4]. [1]*Medical University of Graz, Department of Therapeutic Radiology and Oncology, Graz, Austria;* [2]*Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria;* [3]*Medical University of Graz, Department of Internal Medicine, Graz, Austria;* [4]*GKK Outpatient Department, Division of Internal Medicine, Graz, Austria*

Purpose: Vascular endothelial growth factor-A (VEGF-A), a key regulator of tumor-induced angiogenesis, is a critical factor in tumor growth and metastatic tumor spread. The present study was aimed to analyze the role of VEGF-A polymorphisms and haplotypes for the development of biochemical recurrence and distant metastases in prostate cancer patients treated with definitive radiotherapy.
Methods and Materials: The association of VEGF-A genetic variants was analyzed in a prospective study including 496 prostate cancer patients recruited from 2004 to 2007. Seven polymorphisms were selected for analysis and determined by 5′-nuclease (TaqMan) assays. Haplotypes and linkage disequilibrium were analyzed using the Haploview program.
Results: Within a median follow-up time of 80 months, 118 patients (23.8%) developed biochemical recurrences (defined according to the 'Phoenix Definition') and 41 patients (8.3%) distant metastases, respectively. In univariate analysis, the ATTGC haplotype formed by the −2578A, −2489T, −1498T, −634G, −7C alleles was significantly associated with distant metastases-free survival (hazard ratio (HR)=2.035; 95% CI 1.165–3.556; p = 0.013). In multivariate analysis, the HR for the development of distant metastases was 2.143 for carriers of the ATTGC haplotype (95% CI 1.161–3.956; p = 0.015). Furthermore, univariate analysis revealed a trend toward decreased biochemical recurrence-free survival for carriers of the CG haplotype formed by the 936C and 1612G alleles (HR = 1.292, 95% CI 1.101–1.669, p = 0.05). In multivariate analysis, the HR for the development of biochemical recurrence was 1.329 for carriers of the CG haplotype (95% CI 1.014–1.743; p = 0.04).
Conclusions: We conclude that VEGF-A gene polymorphisms and haplotypes may influence clinical outcome in prostate cancer patients undergoing definitive radiotherapy.
No conflict of interest.

2881 POSTER

Impact of high dose to the prostate in IGRT on patient outcome

K. Gnep[1], J.B. Delobel[1], R. Mathieu[1], V. Beckendorf[2], E. Le Prisé[3], C. Chira[3], S. Guerif[4], J.D. Ospina Arango[5], R. De Crevoisier[6]. *[1]Centre Eugene Marquis, Ille et Vilaine, Rennes, France; [2]Centre Alexis Vautrin, Lorraine, Nancy, France; [3]Centre Eugène Marquis, Ille et Villaine, Rennes, France; [4]CHU Poitiers, Vienne, Poitiers, France; [5]LTSI INSERM1099, Ille et Vilaine, Rennes, France; [6]Centre Eugène Marquis, Ille et Vilaine, Rennes, France*

Background: The clinical benefit of prostate IGRT is not yet fully demonstrated. The objective of the study was to compare the biochemical failure and the late urinary and rectal toxicity risks in high dose prostate cancer 3DCRT, with or without IGRT.
Material and Methods: A total of 302 patients (pts) received a 3DCRT for localized prostate cancer. Median age was 69 years (52−81). History of abdominal or pelvic surgery, anticoagulant therapy (ACT) and diabetes were observed in 29%, 24% and 8% of pts, respectively. D'Amico risk groups were: good (10%), intermediate (64%) and bad (26%). Total dose in the prostate was: 78 Gy (13%) or 80 Gy (87%), 2 Gy/fraction, without any pelvis lymph nodes irradiation. The RT technique did not include any IGRT for 66% of pts (58% receiving 'standard' 3DCRT and 8% IMRT). IGRT (fiducials or CBCT) was combined with IMRT in 34% of pts. The data were prospectively collected for all the pts. Digestive and urinary toxicities were analyzed according to the SOMALENT classification (⩾ Grade 2). The impact of pts characteristics and RT techniques on pts outcome were assessed by univariate and multivariate analysis.
Results: The median follow-up was 60 months (range: 6 to 152). The 5 year grade ⩾2 rectal and urinary toxicity rates were: 17% (95% CI: 12−22%) and 22% (95% CI: 17−27%), respectively. The 5 year biochemical failure rates by risk group were: good: 0%, intermediate: 21% (95% CI: 14−28%) and bad: 38% (95% CI: 26−50%) (RR = 2.5; p < 0.0001).
IGRT combined with IMRT decreased the risk of grade ⩾2 rectal toxicity:
– compared to 'standard' 3DCRT without IGRT (RR:0.54; p = 0.02)
– compared to IMRT without IGRT (RR = 0.26; p = 0.05).
IGRT was not associated with a significant decrease of the risk of GU toxicity or biochemical failure.
Conclusion: Prostate IGRT is associated with a significant decrease of the risk of late rectal toxicity, without any obvious benefit on late urinary toxicity and biochemical failure.
No conflict of interest.

2882 POSTER

Salvage stereotactic body radiotherapy in radio-recurrent prostate cancer − what dose is feasible?

A.C. Tree[1], V.S. Khoo[2], N.J. Van As[1]. *[1]Royal Marsden NHS Foundation Trust, Radiotherapy, London, United Kingdom; [2]Royal Marsden NHS Foundation Trust and the Institute of Cancer Research, Radiotherapy, London, United Kingdom*

Background: Although the last decade has seen great improvements in radiotherapy techniques in prostate cancer, 10−20% of patients with organ-confined prostate cancer will experience PSA failure. For a subset of these patients, disease recurrence occurs exclusively within the prostate, most commonly at the site of dominant disease nodule at original presentation. The optimum treatment in this scenario is unknown but with stereotactic radiotherapy techniques we can dose-paint to target solely the area of recurrence.
Methods: This planning study selected 16 patients with dominant nodules at presentation, as a surrogate for intraprostatic recurrence. Planning target volume was defined as dominant tumour nodule plus 5 mm, except where this volume extended posteriorly towards the rectum when it was clipped at 3 mm posteriorly.
Planning objectives were to deliver 30 Gy in 5 fractions to cover 95% of the PTV whilst respecting a rectal constraint of D1% <22.5 Gy, based on published HDR re-irradiation constraints. The plans were calculated using Multiplan ®, the planning system for Cyberknife®.
Results: 30 Gy in 5 fractions could be delivered within rectal D1% constraint in 9/16 cases despite the PTV overlapping with the rectum in 9/16 cases. Keeping within this constraint a mean dose of 28.6 Gy was deliverable (range 22.9–30.3 Gy).
To deliver 30 Gy, mean dose to 1% of the rectum was 21.4 Gy but ranged from 5.1 to 30.9 Gy. Mean dose to 50% of the rectum was 2.8 Gy (range 0.85−8.1 Gy) and mean dose to 40% of the bladder was 2.4 Gy (0.9 to 6.0 Gy).
Ability to deliver 30 Gy within constraints was strongly correlated with distance from the anterior rectal wall to the GTV (p < 0.0001) If the distance from the GTV to the rectum was <2 mm 8/9 plans exceeded the rectal constraint, compared to 1/7 if this distance was ⩾2 mm.
The relationship between GTV volume (which ranged from 0.46 cc to 12.35 cc) and dose to 1% rectum was also significant (p = 0.04).
Conclusion: 30 Gy in 5 fractions (which delivers a BED of 150 Gy if a/b ratio = 1.5 Gy) can be delivered within rectal constraints likely to be safe in 56% of cases. The ability to achieve this is strongly correlated with distance between GTV and the anterior rectal wall and is also significantly related to GTV size. This study will aid case selection for future clinical trials examining the role of SBRT in radio-recurrent prostate cancer.

Radium-223 dichloride (Ra-223) efficacy and safety in patients with castration-resistant prostate cancer (CRPC) with bone metastases: Phase 3 ALSYMPCA study findings stratified by age group

P. Wiechno[1], S.I. Helle[2], J. Logue[3], S. Nilsson[4], O. Sartor[5], R.E. Coleman[6], J. Kliment[7], F. Fang[8], C. Parker[9]. *[1]Centrum Onkologii-Instytut im Sklodowskiej-Curie, Warsaw, Poland; [2]Haukeland University Hospital, Bergen, Norway; [3]Christie Hospital, Manchester, United Kingdom; [4]Karolinska University Hospital, Stockholm, Sweden; [5]Tulane Cancer Center, New Orleans LA, USA; [6]Weston Park Hospital, Sheffield, United Kingdom; [7]Jessenius School of Medicine University Hospital, Martin, Slovak Republic; [8]Bayer HealthCare, Montville NJ, USA; [9]The Royal Marsden NHS Foundation Trust and Institute of Cancer Research, Sutton, United Kingdom*

Objective: Ra-223, a novel alpha-emitting pharmaceutical, targets bone metastases (mets) with high-energy, short-range (<100 μm) alpha-particles. In ALSYMPCA, Ra-223 significantly improved overall survival (OS) in CRPC patients (pts) with bone mets (median OS: 14.9 vs 11.3 mo; HR = 0.695; 95% CI, 0.581–0.832; *P* = 0.00007) compared to placebo, and had a highly favorable safety profile. Here we present age group analyses of efficacy and safety.
Methods: Eligible pts had progressive, symptomatic CRPC with ⩾2 bone mets and no known visceral mets; were receiving best standard of care; and were post-docetaxel, or were unfit for or declined docetaxel. Pts were randomized 2:1 to 6 injections of Ra-223 (50 kBq/kg IV, n = 614) q4wk or matching placebo (n = 307). Primary endpoint was OS; secondary endpoints included skeletal-related events, time to ALP progression, and safety. OS, secondary efficacy endpoints, and safety were analyzed for age groups <65 y and ⩾65 y.
Results: Baseline characteristics are shown in the Table. Ra-223 significantly prolonged median OS versus placebo in both age groups. Median times to first SRE and ALP progression were significantly prolonged with Ra-223 versus placebo regardless of age. As observed in the overall population, grade $\frac{3}{4}$ neutropenia and thrombocytopenia were reported more frequently with Ra-223 versus placebo in both age groups. However, the incidence of grade $\frac{3}{4}$ hematological adverse events was lower in the ⩾65 years age group than in the <65 years age group.

Age group	<65 years		⩾65 years	
Treatment	Ra-223	Placebo	Ra-223	Placebo
Baseline Characteristics (%)				
n	158	73	456	234
ECOG ⩾2	10	15	14	13
Prior docetaxel	75	69	51	53
Extent of disease (>20 mets/superscan)	48	33	38	42
Primary Endpoint				
n	158	73	456	234
OS, Median (mo)	16.9	11.4	14.1	11.3
HR (95% CI)	0.53 (0.36–0.78)		0.77 (0.62–0.94)	
P value	<0.01		<0.01	
Secondary Endpoints				
n	158	73	456	234
Time to 1st SRE, Median (mo)	12.1	6.6	17.1	11.2
HR (95% CI)	0.58 (0.38–0.90)		0.67 (0.51–0.89)	
P value	<0.05		<0.01	
Time to ALP progression, Median (mo)	7.4	4.0	NE	3.7
HR (95% CI)	0.21 (0.13–0.35)		0.16 (0.12–0.22)	
P value	<0.00001		<0.00001	
Grade 3/4 Adverse Event Incidence (%)				
n	153	71	447	230
Anemia	14	20	12	11
Neutropenia	3	0	2	1
Thrombocytopenia	10	3	5	2

Conclusions: Regardless of pt age, Ra-223 prolonged survival and showed consistent efficacy with a favorable safety profile in CRPC with

bone mets. Older pts (⩾65 y) can benefit from and tolerate Ra-223 as well as younger pts.

2884 POSTER

Up-to-date results of a clinical trial of carbon-ion radiotherapy for prostate cancer: Analysis of 1,144 patients

T. Nomiya[1], H. Tsuji[1], K. Maruyama[1], T. Kamada[1]. [1]*National Institute of Radiological Sciences, Radiation Oncology, Chiba, Japan*

Background: The carbon ion radiotherapy (C-ion RT) for the prostate cancer was started in 1995 using the Heavy-Ion Medical Accelerator in Chiba (HIMAC) at the National Institute of Radiological Sciences (NIRS), Japan. After preceding phase I/II dose escalation studies of 20 fractions over 5 weeks, a phase II study was initiated in April 2000 using the treatment techniques and the recommended dose fractionation established by the phase I/II studies. This study was also successfully completed in October 2003 when the C-ion RT for the solid tumors including the prostate cancer was approved as 'Advanced Medicine' from the Ministry of Health, Labor, and Welfare.

Materials and Methods: A phase II study of C-ion RT (9904[1]−[3]) for localized prostate cancer (T1b–T3bN0M0) was started from April 2000. A C-ion RT schedule of 66.0 GyE/20fr./5 weeks, 63.0 GyE/20fr./5w and 57.6 GyE/16fr./4w were used in 9904[1], 9904[2] and 9904[3] trials, respectively. The patients with low-risk prostate cancer were treated with C-ion RT alone, and the patients with intermediate-risk and high-risk prostate cancer were treated with C-ion RT combined with hormonal therapy of 6 months and ⩾24 months, respectively. Biochemical failure was defined as PSA increase of 2.0ng/ml above nadir after the treatment.

Results: A total of 1,144 patients were enrolled to the clinical study. Out of 1,144 patients, more than 50% patients were categorized as high-risk group with T3 clinical stage, Gleason's score of 8 or higher, or PSA of 20 or higher. The 5-year overall survival rate and biochemical relapse free rate of the entire group was 95.7% and 91.0%, respectively. Biochemical relapse free rates of low-, intermediate- and high-risk patients were 90.1%, 94.2% and 89.7%, respectively. T-stage, Gleason score was significant prognostic factors for both the biochemical control and patient survival and initial PSA was also a predictive factor for survival. Regarding the late radiation toxicity, incidence of rectal toxicity of grade 2 or worse was 1.1% and that of genitourinary toxicity was 6.5%, respectively. In addition, incidence of the toxicity in the patients treated with more hypofractionated C-ion RT of 16 fractions over 4 weeks were lower than those of 20 fraction-treatment.

Conclusions: These favorable outcomes can be thought as apparent evidence of physical and biological advantages of the hypofractionated C-ion RT.

No conflict of interest.

2885 POSTER

Prostate cancer stem cells are involved in radioresistance

M. Cojoc[1], C. Peitzsch[1], I. Kurth[1], V. Lukiyanchuk[1], L. Kunz-Schughart[2], M. Baumann[3], A. Dubrovska[1]. [1]*Oncoray, Biomarkers for the Individualised Radiotherapy, Dresden, Germany;* [2]*Oncoray, Tumour Pathophysiology, Dresden, Germany;* [3]*Oncoray, Experimental Radiotherapy and Radiobiology of Tumours, Dresden, Germany*

Background: Prostate cancer is one of the leading death causes among men and its relapse is driven by a small population of malignant cells resistant to conventional therapies. Preclinical and clinical findings suggest that a higher proportion of cancer stem cells (CSC), or tumour progenitor cells, which are responsible for tumour initiation and growth, correlate with higher cancer radioresistance. Therefore, the identification and validation of novel biomarkers for the early CSC detection and CSC-targeted therapy is essential for the optimisation of treatment strategies.

Material and Methods: We used global gene expression and proteomics analysis to identify novel biomarkers indicative of CSC population radioresistance and the signalling pathways involved in its maintenance. The morphological and functional changes in radioresistant prostate cancer cell populations were compared to bulk tumour cells and analysed using Western blot analysis, immunofluorescence microscopy, proliferation and migration assays. To measure the efficiency of DNA-double strand break (DSB) repair and the level of reactive oxygen species (ROS) in CSCs and non-CSCs populations after irradiation, γ-H2A.X foci formation assay and flow cytometry analysis were applied. To verify the results and to assess the role of the identified biomarkers in prediction and regulation of prostate cancer radiosensitivity, we used NMRI nu/nu murine models.

Results: Our work showed that aldehyde dehydrogenase (ALDH) activity is indicative of tumorigenic cells with increased radioresistance. Purified ALDH-positive prostate cancer cells possess higher tumour stem cell properties *in vitro*, including high clonogenic potential and sphere forming ability, and high tumorigenic potential in nude mice. ALDH- positive cancer progenitor cells are more resistant to irradiation and conventional chemotherapeutic drugs as compared to ALDH- cell population. Our data suggest that high ALDH activity could define a chemo- and radioresistant cancer cell progenitor population.

Furthermore, we established the radioresistant prostate cancer cell lines, which showed more efficient DSB repair, lower ROS level and enhanced expression of stem cell markers, including CD133, ABCG2, CXCR4, Oct-4 and NANOG, as compared to their parental cell lines. Moreover, they showed an increased activation of survival signalling pathways, elevated expression of EMT signatures and enhanced migratory potential.

Conclusions: Taken together, our results suggest that CSC markers can be used for the identification and isolation of radioresistant prostate cancer cell populations. Further validation of the clinical relevance of CSC based biomarkers and their characterisation as potential therapeutic targets will be beneficial in the development of individualized chemo- and radiotherapy.

No conflict of interest.

2886 POSTER

Stereotactic body radiation therapy (SBRT) for prostate cancer in men with large prostates (>50 cm^3)

E. Janowski[1], L. Chen[1], S. Uhm[1], J. Kim[1], S. Lei[1], S. Suy[1], B. Collins[1], J. Lynch[2], A. Dritschilo[1], S. Collins[1]. [1]*Georgetown University, Radiation Oncology, Washington DC, USA;* [2]*Georgetown University, Urology, Washington DC, USA*

Background: Patients with large prostate volumes have been shown to have higher rates of genitourinary and gastrointestinal toxicities after definitive IMRT treatment for prostate cancer. Stereotactic body radiation therapy (SBRT) delivers fewer high-dose fractions of radiation which may be radiobiologically favorable to the conventional low-dose IMRT fractions commonly used for prostate cancer radiotherapy. However, the efficacy and toxicity of SBRT treatment for prostate cancer in patients with large prostate volumes remain unclear. We report our early experience using SBRT for localized prostate cancer in patients with prostate volumes greater than or equal to 50 cm^3.

Methods: Patients treated with SBRT from February 2008 to February 2013 at Georgetown University Hospital for localized prostate carcinoma were included in this retrospective review of data that was prospectively collected in an institutional database. 57 patients were identified as having prostate volumes ⩾50 cm^3 prior to treatment with a minimum follow up of two years. Treatment was delivered using Cyberknife with doses of 35–36.25 in 5 fractions. Biochemical control was assessed using the Phoenix definition. Toxicities were recorded and scored using the CTCAE v.4. Quality of life was assessed before and after treatment using the American Urological Association Symptom Score (AUA) and the Expanded Prostate Cancer Index Composite (EPIC)-26. Late urinary symptom flare was defined as having both an AUA score ⩾15 with an increase of ⩾5 points above baseline six months after the completion of SBRT.

Results: 57 patients (23 low-, 25 intermediate- and 9 high-risk according to the D'Amico classification) at a median age of 69 years (range 54−83) received SBRT with a median follow up of 2.9 years. The median prostate size was 62.9 cm^3 (range 50–138.7 cm^3). 33.3% patients received ADT. The median pre-treatment prostate-specific antigen (PSA) was 6.5 ng/ml, and, at 2 years, the median PSA decreased to 0.4 ng/ml (p<0.0001). A median baseline AUA symptom score of 7.5 significantly increased to 13 at 1 month (p = 0.001) and returned to baseline at 3 months (p = 0.21). 23% of patients experienced a late transient urinary symptom flare in the first two years following treatment. Mean baseline EPIC bowel scores of 95.8 significantly decreased to 78.1 at 1 month (p <0.0001), but subsequently improved to 93.5 at three months (p = 0.08) and 94.7 two years (p = 0.32). The 2-year actuarial incidence rates of GU and GI toxicity ⩾ grade 2 were 49.1% and 1.8%, respectively. 2 patients (3.5%) experienced a grade 3 urinary toxicity, and no patient experienced grade 3 gastrointestinal toxicity.

Conclusions: SBRT for clinically localized prostate cancer was well tolerated in men with large prostates. Late GI and GU toxicity rates were comparable to conventionally fractionated radiation therapy. Late symptom flares were observed but the majority resolved with conservative management.

Conflict of interest: *Corporate-sponsored research: S Collins and B Collins serve as clinical consultants to Accuray Inc. The Department of Radiation Medicine at Georgetown University Hospital receives a grant from Accuray to support a research coordinator.*

2887 POSTER

Low PSA values by hormonal intervention do not guarantee biochemical control in the salvage radiotherapy for prostate cancer after radical prostatectomy

S. You[1], C.G. Lee[2]. [1]*Yonsei University Wonju College of Medicine, Radiation Oncology, Wonju, South Korea;* [2]*Yonsei University College of Medicine, Radiation Oncology, Seoul, South Korea*

Background: To identify the influence of preferential hormone use in the postoperative salvage radiotherapy for prostate cancer after radical prostatectomy by analyzing radiotherapeutical survival (RTS), which was defined as 2nd biochemical failure (BCF)-free survival after radiotherapy.
Material and Methods: A total of consecutive 34 prostate cancer patients were treated with postoperative salvage radiotherapy after radical prostatectomy between July 2004 and March 2011. On retrospective review, median age at diagnosis was 65.5 years and 19 patients (55.9%) had PSA level of more than 10 ng/mL. After radical prostatectomy, the patient number of T3-T4 stage, Gleason score 8−10, and positive resection margin was 11 (32.4%), 10 (29.4%), and 17 (50.0%), respectively. PSA reached below 0.2 ng/mL within 2 months without hormonal intervention in 19 patients (55.9%), which rose above 0.2 ng/mL again afterwards. For the other 15 patients (44.1%), PSA fell below 0.2 ng/mL not by surgery alone but by additional hormone use due to initial high PSA level or poor surgical pathology findings. No gross loco-regional or metastatic lesion was detected after surgery and radiotherapy was performed by median dose 64.8 Gy (range, 52.9–70.0 Gy) with 1.8−2.3 Gy fractionations. 2nd BCF was defined as a PSA level of >0.4 ng/mL or hormonal intervention due to steep PSA increase after radiotherapy. The timing of hormone and radiation was decided at physician's discretion and the median follow-up period after radiotherapy was 32.5 months (range, 10–118 months).
Results: All patients had their PSA values reached below 0.2 ng/mL median 4 months (range, 0−25 months) after radiotherapy and it was done within 1 month in 13 patients (38.2%). The 3-year rates of RTS were 60.3%. On univariate analysis, preferential hormone use ($p = 0.022$), persistent PSA after surgery ($p = 0.047$), higher PSA at radiotherapy ($p = 0.005$), shorter surgery to 1st BCF interval ($p = 0.033$), and higher PSA at 2 months after surgery ($p = 0.003$) were related to shorter RTS. High PSA at diagnosis ($p = 0.070$) and less radiation dose ($p = 0.062$) showed a tendency to poor RTS. On multivariate analysis, RTS benefit was associated with lower PSA at radiotherapy ($p = 0.016$), higher radiation dose ($p = 0.007$), and non-preferential hormone use ($p = 0.046$).
Conclusions: Fundamentally, lower PSA value is correlated with better prognosis in postoperative salvage radiotherapy. However, PSA decreased by hormonal intervention is not always reliable and should not be underestimated in radiotherapy planning. Therefore, this aspect should be considered in randomized trials together with proper radiotherapy timing as a salvage treatment.
No conflict of interest.

2888 POSTER

Interfractional variability in patients with prostate cancer treated with intensity-modulated radiotherapy with or without pelvic thermoplastic immobilization

J.A. Lee[1], D.S. Yang[1], C.Y. Kim[1], Y.J. Park[1], W.S. Yoon[1], S. Lee[1], N.K. Lee[1]. [1]*Korea University College of Medicine, Department of Radiation Oncology, Seoul, South Korea*

Background: To determine the variability of patient positioning errors associated with intensity-modulated radiotherapy (IMRT) for prostate cancer, and to assess the impact of pelvic thermoplastic immobilization on these errors using kilovoltage (KV) cone-beam computed tomography (CBCT).
Materials and Methods: From February 2012 to June 2012, the records of 314 sessions of 19 patients with prostate cancer treated with IMRT with or without immobilization at two different facilities of Korea University Hospital were analyzed. The KV CBCT images were matched with simulation computed tomography (CT) images to determine simulation-to-treatment variability. The shifts along x-(lateral), y- (longitudinal), z- (vertical) axes and the 3D vector were measured.
Results: The measured systematic errors of immobilized group during the treatment were 0.46±1.75 mm along the x-axis, −0.35± 3.83 mm along the y-axis, 0.20±2.75 mm along the z-axis, and 4.05± 3.02 mm in 3D vector. Those of non-immobilized group were −1.45± 7.50 mm along the x, 1.89±5.07 mm along the y, 0.28± 3.81 mm along the z, and 8.90± 4.79 mm in 3D vector. The immobilized group with pelvic thermoplastics showed lesser interfractional variability in x- axis, y-axis, and 3D vector compared to non-immobilized group($p<0.05$).
Conclusions: IMRT with pelvic thermoplastic immobilization in patients with prostate cancer appears to be useful in stabilizing interfractional variability during the planned treatment course.
No conflict of interest.

2889 POSTER

Urinary toxicity in high risk prostate cancer patients treated with whole pelvis intensity modulated radiotherapy (WP-IMRT) with cone beam ct (CBCT) for image guidance

S.P. Pavamani[1], S. Balukrishna[1], S.S. Varghese[1], B.P. Ravindran[1]. [1]*Christian Medical College Hospital, Radiation Oncology, Vellore, India*

Background: In India, the incidence of prostate cancer is low & patients are usually diagnosed in the advanced stages of the disease. Patients with localized high risk prostate cancer undergo androgen deprivation therapy (ADT) and whole pelvic radiation. This study aimed to assess the impact of radiation dose escalation on urinary toxicity in Indian men undergoing treatment for prostate cancer with WP-IMRT utilizing CBCT image guidance.
Material and Methods: In 2010, radiation dose escalation with WP-IMRT was initiated in our centre following the acquisition of a linear accelerator with CBCT. Between 2010 and 2013, patients with localized high risk prostate cancer were treated with ADT and WP-IMRT. WP-IMRT (4680 cGy) was followed by an IMRT boost (2520 to 2880 cGy) to the prostate, based on the tolerance of organs at risk. Image guidance was done by Daily CBCT. Urinary symptoms of the patients were assessed by the International Prostate Symptom Score (IPSS) prior to starting radiation and during each follow up. The initial scores were analyzed and compared with the scores on follow up.
Results: Twelve patients with localized high risk prostate cancer were treated with WP-IMRT with CBCT image guidance. The median prescription radiation dose was 7380 cGy. The planned radiation dose to the urinary bladder was within the accepted tolerance limits. The median follow up time after completion of radiation was 9.5 months with a range of 3 to 23 months. IPSS scores improved in 5 patients at the time of the first follow up and in 9 by the second follow up. Only one patient had a 10 point increase in his IPSS at his first follow up, but the score improved to below his baseline by the second follow up. There was no clinically significant worsening of urinary symptoms in the patients by the second follow up. No patient suffered urinary incontinence or obstruction.
Conclusion: IMRT delivered with image guidance is a relatively new treatment modality in India. Patients undergoing WP-IMRT experience urinary toxicity.However, this resolves within a year and the majority of patients do not experience any significant long term urinary toxicity.
No conflict of interest.

Preliminary results of combining external beam radiotherapy with Cs-131 brachytherapy implantation in patients with prostate cancer

M.B. Bernstein[1], A. Davarifar[1], R. Yaparpalvi[1], H. Kuo[1], J.M. Glanzman[1], R. Kabarriti[1], S. Patel[1], W.F. Mourad[1], S. Kalnicki[1], C. Guha[1]. [1]*Montefiore Einstein Center for Cancer Care, Radiation Oncology, Bronx NY, USA*

Background: Combining external beam radiation therapy (EBRT) with brachytherapy to treat prostate cancer offers several therapeutic advantages compared to the use of either treatment modality alone. Utilizing a prostate 'boost' with brachytherapy allows increased intraprostatic dose that cannot be achieved with EBRT alone. Further, EBRT can deliver dose to the periprostatic region that would otherwise not be reached with brachytherapy. Prior studies have reported excellent biochemical control rates with combination therapy using I-125 or Pd-103 as the brachytherapy source. However, using Cs-131, a source with higher energy, shorter half-life, and a lower total dose of radiation has also gained attention. Here, we report the initial results of prostate cancer patients treated at our institution with 45 Gy EBRT and Cs-131 brachytherapy implant.
Materials and Methods: We retrospectively analyzed prostate cancer patients treated with combination therapy of EBRT plus Cs-131 brachytherapy from 2006–2011. EBRT was delivered with the intensity modulated radiotherapy (IMRT) technique to a total dose of 45 Gy in 1.8 Gy fractions. The prescribed dose of the Cs-131 implant was 90 Gy. Acute and late gastrointestinal (GI) and genitourinary (GU) toxicity was determined using the Common Terminology Criteria for Adverse Events (CTCAE) 4.0 scale. Biochemical failure was defined both by the ASTRO consensus guidelines and the ASTRO-Phoenix criteria.
Results: A total of 34 patients were included in the final analysis; 19 of whom received EBRT prior to Cs-131 implant. The median age of the patients included was 67 years old with a median follow-up of 31 months. Patients had a median tumor stage of T1, Gleason score of 7 and pre-treatment PSA of 7.14ng/mL. To date, only 1 patient experienced acute

grade 2 GI toxicity with no grade 3−4 toxicity reported. No patient suffered late grade 2−4 GI toxicity. Twelve patients experienced acute grade 2 GU toxicity, mainly consisting of increased frequency and nocturia. There was no acute grade 3−4 GU toxicity noted. Eight patients reported late grade 2 GU toxicity, but no late grade 3−4 toxicity. Only one patient has suffered biochemical failure based on the ASTRO consensus guidelines (but did meet the ASTRO-Phoenix criterion for failure) 36 months after completion of therapy.
Conclusions: Combining EBRT with brachytherapy affords the possibility of dose escalation to the prostate while treating the periprostatic region. We show here that using a source with a short half-life and high energy, such as Cs-131, is well-tolerated with acceptable rates of acute GI and GU toxicity. Albeit short follow-up, no patient has experienced late grade 3−4 GI or GU toxicity with a current biochemical control rate of 97%.
No conflict of interest.

2891 POSTER

Salvage dose escalated prostate fossa radiotherapy for eMRI detected recurrence

S. Fenig[1], L. Tsvang[1], O. Portnoy[2], S. Appel[1], S. Felder[1], J. Leshem[1], J. Goldstein[1], D. Alezra[1], Z. Symon[1]. *[1]Sheba Medical Center- Tel Hashomer, Radiation Oncology, Ramat-Gan, Israel; [2]Sheba Medical Center- Tel Hashomer, Radiology, Ramat-Gan, Israel*

Background: Radiation therapy is effective treatment for rising PSA following prostatectomy. Patients that present with undetectable disease have potentially curable disease, however reported outcomes for patients with gross recurrence are poor. Imaging of the prostate fossa with eMRI can identify patients with macroscopic disease who may benefit from targeted dose escalation. This series reports outcomes for men with rising PSA and eMRI detected recurrent disease treated with prostate fossa radiation and dose escalation.
Patients and Methods: Data of 270 men treated between 2009–2012 with salvage RT following radical prostatectomy was reviewed using an IRB approved database. Twelve men who had eMRI detected recurrences were identified for analysis of outcomes and treatment parameters were extracted from the TPS.
Positive surgical margins were reported in four (33%) patients. Pathological Gleason scores were 6 in two pts, 7 in six pts and $\geqslant$8 in four pts. The median PSA level before radiotherapy was 1.2 ng/ml (range 0.13−6.5).
The GTV was contoured using eMRI recurrence and the CTV was defined using the EORTC guidelines for post prostatectomy radiation. Radiotherapy was delivered using IMRT technique with rapid arc (n = 9) or stationary beams (n = 3). Since radiation was delivered in either 2 Gy (n = 10) or 2.3 Gy (n = 2) fractions, dose will be reported as EQD2 Gy.
Results: The mean dose to the GTV was 73.2 Gy (range 70−80). The mean dose delivered to the prostatic bed CTV was 70.2 Gy (range 66−76). Radiotherapy to the pelvic lymph nodes (46 Gy) was delivered to four (33%) patients. Six months of concomitant androgen deprivation therapy was administrated to 10 (83%) of the patients.
At median follow up of 30 months (12−65) biochemical freedom from failure survival was 75%. The mean post treatment PSA nadir was 0.157ng/ml (0.01−0.8). The treatment was well tolerated with grade I gastrointestinal toxicity in four pts. (33%), grade 1−2 urinary toxicity in 6 (50%) of the patients, and one patient with grade 3 urinary toxicity (stricture).
Conclusions: Radiation treatment using IMRT/IGRT and eMRI to define gross prostatic fossa recurrence is associated with minimal toxicity and can safely allow for dose escalation in selected patients. This approach when combined with short term androgen deprivation is associated with excellent outcomes in this small series.
No conflict of interest.

2892 POSTER

Genetic variants in DNA repair genes and radiation-induced late toxicity in prostate cancer patients

E.M. Thurner[1], S. Krenn-Pilko[1], W. Renner[2], A. Gerger[3], U. Langsenlehner[4], K.S. Kapp[1], T. Langsenlehner[1]. *[1]Medical University of Graz, Department of Therapeutic Radiology and Oncology, Graz, Austria; [2]Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria; [3]Medical University of Graz, Department of Internal Medicine, Graz, Austria; [4]GKK Outpatient Department, Division of Internal Medicine, Graz, Austria*

Background: Homologous recombination (HR) is one of the two major mechanisms to repair DNA double-strand breaks (DSB), the most deleterious form of radiation-induced DNA damage, and the polymerization of RAD51 onto single-stranded DNA ends of a DSB is a limiting factor in HR. BRCA1 and 2 interact and co-localize with RAD51 in the process of double-strand break repair. A down-regulation of RAD51, BRCA1 and 2 has been associated with increased radiosensitivity. The purpose of the present prospective study was to analyze the role of RAD51, BRCA1 and 2 in the development of severe side effects after radiotherapy for prostate cancer.
Material and Methods: A total of 607 patients from the Austrian PROCAGENE study were included for further analysis. All eligible patients received a three dimensional conformal radiotherapy with high energy photons (18MV) five times a week to a total dose of 66–70.4 Gy. Late genitourinary and rectal toxicity was graded according to standard RTOG criteria. 38 SNPs located in important regulatory regions (promoter region, 5′UTR) of the RAD51, BRCA1 or BRCA2 genes, as well as functional polymorphisms, haplotype-tagging SNPs and intronic SNPs if their minor allele frequency was >0.05 were selected for further analysis and genotyped with the Applied Biosystem's 'TaqMan OpenArray'System.
Results: After a median follow-up time of 82 months, radiation induced severe urinary or rectal toxicity, classified as EORTC/RTOG grade$\geqslant$2 was observed in 133 (22%) and 73 (12%) patients. After correction for multiple testing, none of the investigated polymorphisms was significantly associated with late rectal or urinary toxicity grade $\geqslant$2.
Conclusion: We conclude that the presence of the analyzed single nucleotide polymorphisms is not associated with a higher risk of radiation-induced severe urinary or rectal late toxicity in prostate cancer patients.
No conflict of interest.

2893 POSTER

PTV margins in prostate cancer

L.A. Quiñones Rodríguez[1], I.J. Castro Ramirez[1], C. Salas Buzon[2], A. Ureña Llinares[1], M.A. Iborra Oquendo[1], E. Angulo Pain[1], L.J. Ramos Caballero[1], A. Seguro Fernandez[1], R. Mora Melendez[1]. *[1]Hospital Puerta Del Mar, Ugc Radiofisica, Cadiz, Spain; [2]Hospital Puerta Del Mar, Ugc Atención Integral Al Cáncer, Cadiz, Spain*

Background: It is Known that radiotherapy is affected by geometrical accuracy: target delineation error, intrafraction and interfraction target movement or calibration errors. In prostate treatments the most important one is interfraction movement, to manage it one possible solution is the implantation of fiducial gold markers within the prostate. With them, daily set-up error, which comprises a random and a systematic component, is solved. The first one would lead to a blurring of the dose distribution around the CTV whereas the second would shift the dose distribution, what could lead to underdose the CTV. Analyzing daily set-up displacements of patients with gold markers allow as to calculate CTV to PTV margins for prostate patients with no fiducial markers.
Material and Method: Thirty seven patients with prostate cancer were treated in a Siemens Oncor LINAC equipped with a Megavoltage Cone Beam Imaging system based on Si detectors. Immobilization during radiotherapy was made with alpha cradle molds. We get two orthogonal images in all sessions to override systematic and random set-up errors. Shift between treatment isocenter an simulation isocenter is automatically calculated by Siemens Syngo Therapyst system, comparing fiducial markers between planning system DRRs and Portal Imanging.
We calculated the population systematic error (Σ) and the population random error (σ), and finally we composed the PTV margin using Van Herk formula:
Margin = $2.5\,\Sigma + 0.7\,\sigma$
Results: Table 1 presents a summary of random (σ), systematic (Σ) error and CTV to PTV margins. The largest value of error and margin is seem in the vertical direction and can be correlated to rectum and bladder filling. Moreover, this margin should be taken carefully because involve rectal toxicity.
Conclusion: Systematic and random set-up errors are now known for our prostate cancer patients. Further, this has allowed us to obtain 'Ad hoc' CTV to PTV margins to treat with the required accuracy patients with no fiducial markers.
No conflict of interest.

Table 1.

	Vertical (mm)	Lateral (mm)	Longitudinal (mm)
Random error (σ)	3.8	2.4	2.4
Systematic error (Σ)	4.4	3.8	3.1
Van Herk margins (M)	13.7	11.2	9.4

2894 POSTER

A pathology verified, innovative method to predict nodal (N) status using an artificial intelligence (AI) approach in prostate cancer (PC) patients (pts): Beyond the Roach formula?

M. Buglione[1], B. De Bari[1], M. Vallati[2], R. Gatta[1], G. Girelli[3], I. Meattini[4], M. Krengli[5], U. Ricardi[6], F. Bertoni[7], S.M. Magrini[1]. *[1]Brescia University, Radiation Oncology, Brescia, Italy; [2]University of Huddersfield, School of Computing and Engineering, Huddersfield, United Kingdom; [3]Ivrea Hospital, Radiation Oncology, Ivrea, Italy; [4]Florence University, Radiation Oncology, Florence, Italy; [5]Piemonte Orientale University, Radiation Oncology, Novara, Italy; [6]Turin University, Radiation Oncology, Turin, Italy; [7]Modena Hospital, Radiation Oncology, Modena, Italy*

Aim: We already presented an innovative AI-based method to predict N status in PC, integrating several pre-treatment variables (Gleason Score/sum, age, initial PSA, neoadjuvant hormonal therapy vs no hormonal therapy − HT). We now present an independent test of the predictor in a population of 204 operated pts, classified as cN0 preoperatively and with a well-defined pN status (187 pN0 and 17 pN1).
Material and Methods: 1804 pts from a National Italian multicentre database with a known cN0−1 status were analyzed. Cases (N = 55) with node-positive pelvic MRI and/or CT scan and/or showing a nodal only relapse after RT (none received pelvic RT), were considered N+. Using Roach formula with a cut-off of >15%, >10% and >5%, the individual risk of N involvement was calculated. 3 AI methods, based on decision trees (J48, Forrest Tree and Random Tree) combined with 3 techniques of manipulation of imbalanced samples (oversampling, undersampling and combined under/oversampling) were created to predict the N status. Accuracy of the classical and of the AI based approaches was calculated. Finally, the results of the AI metodhs were tested on an independent population of 204 operated Brescia patients, not treated with HT, submitted to postoperative RT, classified as cN0 preoperatively, with a known pN status (187 pN0 and 17 pN1 pts. To that end, new algorithms without HT as input variable were generated.
Results: The AI methods perform better than the Roach formula. The classic approach showed an accuracy rate (i.e. true positives + true negatives/whole population) ranging, depending on the cut-off, between 19% and 42% in the test sample of 204 pts and between 34% and 52% in the whole series of 1804 pts. The accuracy of the 3 AI methods ranged between 19% and 86% in the test sample of 204 pts and between 56% and 98% in the whole series of 1804 pts. Concerning the specificity, the Roach Formula showed rates ranging, depending on the cut-off, between 12% and 32% in the test sample of 204 pts and between 32% and 51% in the whole series of 1804 pts. The specificity of the 3 AI methods ranged between 12% and 91% in the test sample of 204 pts and between 61% and 96% in the whole series of 1804 pts.
Conclusions: Non-linear relationships with more than two variables influence the N status of the patients and the Roach formula has suboptimal predictive performances. New approaches considering more variables could possibly improve these performances.
No conflict of interest.

2895 POSTER

Cabazitaxel for metastatic castration-resistant prostate cancer: Safety data from the Spanish Early Access Programme

L.A. Aparicio[1], A. Sanchez-Hernandez[2], E. Esteban[3], J.R. Germá[4], N. Batista[5], P. Maroto[6], B. Pérez-Valderrama[7], R. Luque[8], A. Garcia Palomo[9], D.E. Castellano[10]. *[1]Hospital Juan Canalejo, Oncology, A Coruña, Spain; [2]Hospital Provincial de Castellón, Oncology, Castellón, Spain; [3]Hospital General de Asturias, Oncology, Oviedo, Spain; [4]Hospital Duran i Reynals. ICO, Oncology, Barcelona, Spain; [5]Hospital Universitario de Canarias, Oncology, Canarias, Spain; [6]Hospital de la Santa Creu i Sant Pau, Oncology, Barcelona, Spain; [7]Hospital Universitario Virgen del Rocío, Oncology, Seville, Spain; [8]Hospital Virgen de las Nieves., Oncology, Granada, Spain; [9]Hospital General de León, Oncology, León, Spain; [10]University Hospital 12 de Octubre, Oncology, Madrid, Spain*

Background: Based on the results observed in the TROPIC trial, cabazitaxel (Cbz) has been recently approved for the management of metastatic castration-resistant prostate cancer (mCRPC) in patients who have progressed during or after treatment with a docetaxel-containing regimen. This single arm multicentre, open-label study (NCT01254279) provided early access to Cbz for use in patients similar to those evaluated in the TROPIC trial to further evaluate the Cbz safety profile in clinical practice. Results in Spain are reported here.
Patients and Methods: Eligible patients received Cbz 25 mg/m^2 iv every 3 weeks, in combination with oral prednisone or prednisolone 10 mg daily until disease progression, death, unacceptable toxicity, Investigator's decision, or up to 10 cycles and until it was commercially available. Safety assessments were performed before each cycle. A descriptive safety analysis was performed.
Results: A total of 153 patients were included. Median age was 70 (IQR: 65−75) years; 26.8% were aged over 75 years; 94% (n = 144) had bone metastasis and 51% had visceral (n = 78) metastasis. Most patients (136 [88.9%]) had an ECOG PS $\leqslant$1. Patients had previously received a median of 8.0 (IQR: 6.0–10.0) cycles of docetaxel and 59.5% (n = 91) had experienced disease progression $\geqslant$3 months from last docetaxel dose. Patients received a mean number of 6.2$\pm$2.9 cycles of Cbz and a mean cumulative dose of 149.2$\pm$72.1 mg/m^2. Adverse events (AEs) considered related to the study drug were experienced by 143 (93.5%) patients. The most common clinically significant grade 3 or higher AEs were neutropenia (25 [16.3%] patients) and asthenia (11 [11.1%] patients). Febrile neutropenia was reported in 5.2% of the patients. Grade 3 or 4 diarrhoea was identified in 5.2% of the patients. Incidence of grade $\geqslant$3 peripheral neuropathy (1 [0.7%]) was low. There were 5 (3.3%) treatment-related deaths, mainly infection-related. Granulocyte colony-stimulating growth factors were used in 114 (74.5%) patients mostly as preventive treatment (n = 107; 69.9%).
Conclusions: In clinical practice the treatment of mCRPC with Cbz is tolerable with manageable AEs, especially in a real-world Spanish population with poor prognostic factors (aged >70; with visceral metastasis). Proactive management of AEs, especially in >65 and ECOG>2 patients, might have a role for minimisation of haematological AEs.

Anti-angiogenic and Immuno-modulatory effects of metronomic cyclophosphamide treatment in prostate cancer patients with PSA failure

O. Adotevi[1], T. Maurina[2], F. Calcagno[2], G. Crehange[3], S. Kim[4], M. Jary[2], T. Nguyen[2], P. Bontemps[5], A. Thierry-Vuillemin[2], C. Borg[1]. *[1]University Hospital of Besançon, Oncology-INSERM-UMR 1098, Besancon, France; [2]University Hospital of Besançon, Oncology, Besancon, France; [3]University Hospital of Besançon, Clinical Investigational Center CIC-Biotherapy-506, Besancon, France; [4]University Hospital of Besançon, Oncology-Clinical Investigational Center-Biotherapy-506, Besancon, France; [5]University Hospital of Besançon, INSERM-UMR 1098, Besancon, France*

Background: After curative local therapy, patients (pts) will experience rising PSA as an early indicator of recurrent prostate cancer and no standard of care exists. Previous studies demonstrated the clinical interest of cyclophosphamide metronomic chemotherapy (CMC) in several cancers. Multifactorial modes of action including immunological and anti-angiogenic effects have been well described by Kerbel *et al* and Ghiringhelli *et al* (Cancer Research 2006 and European Journal of immunology 2004, respectively). In the current study, we investigated the safety and immuno-modulatory effects of CMC in prostate cancer patients with PSA failure (biochemical relapse).
Methods: We conducted a prospective phase II study to characterize the clinical and immunological interest of CMC in histologically proven prostate cancer patients previously treated by prostatectomy and with biochemical relapse (defined as PSA >1 and <20ng/mL and progressive PSA level on 3 different measures). CMC was administered *per os,* at daily dose of 50 mg during 6 months. PSA level, serum VEGF and immune parameters were monitored every month in blood samples.
Results: Thirty-four consecutive pts were enrolled in this study and all received CMC. The median age was 68.3 (range, 56.9−82.1) and all pts had good performance status (ECOG-PS = 0). Gleason Score was 7 in 58%, $\leqslant$6 in 13%, and $\geqslant$8 in 13%. No serious adverse events (grade 3−5) were observed. The most common drug-related adverse event was grade 1 lymphopenia. Baseline PSA was 2.92 ng/mL (range, 1.1–9.35). Twenty-two pts presented stable PSA (64.7%), one patient had partial response defined by >50% decline in the serum PSA (3%), and 11 pts (32%) had PSA progression before 6 months. The immuno-monitoring performed in all pts who completed 6 months of CMC. A decrease of immunosuppressive regulatory T cells (Treg) was observed in 56% (12/23). In addition, high rate of activated HLA-DR+ cytotoxic CD8 T cells was also detected in these cohort. Furthermore, serum VEGF level decreased at month 1 but it returned to baseline level at the end of treatment in 9/17 pts evaluated (52%). In some patients the correlation was observed between the control of PSA level, the decrease of Treg and VEGF parameters.
Conclusions: This study demonstrated the clinical benefit and the ability of CMC to promote the blockage of angiogenesis and immuno-modulatory effect in prostate cancer patients treated for a biochemical relapse. It will be of interest to combine CMC to vaccination in these patients.
No conflict of interest.

2897 POSTER

Impact of prior antiandrogen exposure on clinical outcomes in patients (pts) receiving abiraterone acetate (AA): Results from a randomized study (COU-AA-301) in metastatic castration-resistant prostate cancer (mCRPC) post-docetaxel (D)

J. Bellmunt[1], M.K. Yu[2], T. Kheoh[3], M.E. Taplin[4], I.D. Davis[5], D. Schrijvers[6], A. Protheroe[7], A. Molina[8], J.S. De Bono[9], H.I. Scher[10]. *[1]Dana-Farber Cancer Institute, Bladder Cancer Center, Boston MA, USA; [2]Janssen Research & Development, WC Clinical Oncology, Los Angeles CA, USA; [3]Janssen Research & Development, Biostatistics & Programming, Los Angeles CA, USA; [4]Dana-Farber Cancer Institute, Genitourinary Oncology, Boston MA, USA; [5]Monash University and Eastern Health, Eastern Health Clinical School, Victoria, Australia; [6]ZNA Middelheim Oncology Clinic, Medical Oncology, Antwerp, Belgium; [7]Churchill Hospital, Oncology, Oxford, United Kingdom; [8]Janssen Research & Development, Oncology, Los Angeles CA, USA; [9]The Institute of Cancer Research and Royal Marsden Hospital, Urology Unit and Drug Development Unit, Sutton, United Kingdom; [10]Memorial Sloan-Kettering Cancer Center Sidney Kimmel Center for Prostate and Urologic Cancers, Genitourinary Oncology Service, New York, USA*

Background: AA is a potent androgen biosynthesis inhibitor approved for treatment of mCRPC. Since AA is not a potent antiandrogen, minimal cross-resistance would be expected after prior antiandrogen exposure. A post hoc exploratory analysis was conducted to determine whether prior first-generation antiandrogens would have an impact on overall survival (OS), radiographic progression-free survival (rPFS), and prostate-specific antigen (PSA) response in mCRPC pts post-D.

Material and Methods: COU-AA-301 is a randomized double-blind study of AA (1 g) + prednisone (P) (5 mg po BID) vs P only in mCRPC post-D (N = 1195) with biochemical/surgical castration. The primary end point was OS. Pts who received prior antiandrogens bicalutamide (BIC), nilutamide (NIL), and flutamide (FLT) were examined here. Secondary end points included rPFS (based on modified RECIST [target lesion $\geqslant$2 cm] or bone scan [$\geqslant$2 new lesions not consistent with bone flare]) and PSA response ($\geqslant$50% decrease from baseline). Cox model was used to obtain the hazard ratio (HR) and associated 95% CI, with statistical inference by logrank statistic.

Results: 65%, 15%, and 2% of pts received 1, 2, or 3 antiandrogens, respectively. Pts received prior BIC (893 [74.7%]), NIL (84 [7.0%]), FLT (202 [16.9%]) for a median duration of 12.5 m, 6.0 m, or 9.3 m, respectively (any prior antiandrogen combination, AA+P: 15.3 m [95% CI: 0.2–192]; P: 12.2 m [0.3–166]). Baseline disease characteristics in pts with and without prior BIC, NIL, and FLT were similar. Pts receiving AA+P with prior BIC or FLT had a statistically significant reduction in risk of death and radiographic progression vs P as in pts without prior use (Table). Statistically significant benefit to AA+P was not observed for pts with prior NIL; this may be related to the low n's. PSA response was observed in all pts with prior antiandrogens (AA+P vs P: BIC: 30% vs 6%; NIL: 25% vs 3%; FLT: 31% vs 13%).

+/− = with or without antiandrogen exposure; *AA+P vs P.

Conclusions: As shown in this exploratory analysis of COU-AA-301, prior antiandrogen exposure does not appear to impact clinical benefit of AA+P vs P in mCRPC pts post-D. This suggests little cross-resistance to AA after prior BIC and FLT.

ARN-509 in men with high risk non-metastatic castration-resistant prostate cancer

M.R. Smith[1], E.S. Antonarakis[2], C.J. Ryan[3], W.R. Berry[4], N.D. Shore[5], G. Liu[6], J.J. Alumkal[7], C.S. Higano[8], E. Chow Maneval[9], D.E. Rathkopf[10]. *[1]Harvard Medical School Massachusetts General Hospital, Genitourinary Oncology, Boston, USA; [2]Sidney Kimmel Comprehensive Cancer Center Johns Hopkins University, Genitourinary Medical Oncology, Baltimore, USA; [3]UCSF Helen Diller Family Comprehensive Cancer Center, Genitourinary Medical Oncology, San Francisco, USA; [4]Cancer Centers of North Carolina, Prostate Cancer Medical Oncology, Raleigh, USA; [5]Carolina Urologic Research Center, Urology Oncology, Myrtle Beach, USA; [6]University of Wisconsin Carbone Cancer Center, Genitourinary Medical Oncology, Madison, USA; [7]OHSU Knight Cancer Institute, Genitourinary Medical Oncology, Portland, USA; [8]University of Washington Seattle Cancer Care Alliance, Genitourinary Medical Oncology, Seattle, USA; [9]Aragon Pharmaceuticals, Oncology Clinical Development, San Diego, USA; [10]Memorial Sloan-Kettering Cancer Center, Genitourinary Medical Oncology, New York, USA*

Background: ARN-509 is a novel second-generation anti-androgen that binds directly to the ligand-binding domain of the androgen receptor, impairing nuclear translocation and DNA binding. In the Phase II portion of a multicenter Phase I/II study, we evaluated the activity of ARN-509 in 3 distinct patient populations of men with castration-resistant prostate cancer (CRPC): high risk non-metastatic CRPC, metastatic treatment-naive CRPC, and progressive disease after abiraterone acetate. Here we present updated results for the high risk non-metastatic CRPC cohort.

Methods: All patients had CRPC, no radiographic evidence of metastases (pelvic lymph nodes <3 cm below the iliac bifurcation were allowed), and high risk for disease progression based on PSA value $\geqslant$8 ng/mL within 3 months of enrollment and/or PSA doubling time $\leqslant$10 months. Patients received ARN-509 at the recommended Phase II dose of 240 mg/day, previously established in Phase I (Rathkopf et al, ASCO GU 2012). The primary endpoint was PSA response rate at 12 weeks according to the Prostate Cancer Working Group 2 Criteria. Secondary endpoints included safety, time to PSA progression and 1-year metastasis-free survival. PSA assessments were collected every 4 weeks and tumor scans were performed every 16 weeks.

Results: Forty-seven patients were enrolled between November 2011 and June 2012. The median age was 71 years (range 51 to 88) and at baseline, patients presented with ECOG performance status 0 (77%), Gleason Score 8−10 (32%), and median PSA of 12.2 ng/mL. Twenty-six (55%) patients had PSA doubling time $\leqslant$10 months at baseline. All patients received prior treatment with a LHRH analog with or without a first-generation anti-androgen. At a median follow-up of 13.4 months, 10 (21%) patients discontinued the study. The most common treatment-related adverse events (AE) were fatigue (40%), diarrhea (34%), nausea (21%), abdominal pain (17%), and rash (11%). No seizures have been observed to date. As previously reported (Smith et al, ASCO GU 2013), the PSA response rates at 12 and 24 weeks were 91% and 91%, respectively. Median metastasis-free survival has not been reached, however among 34 patients with 1-year follow-up, 3 have developed metastases.

Conclusion: In men with high risk non-metastatic CRPC, ARN-509 is safe and well tolerated with promising preliminary activity based on durable PSA response and disease control.

Background: Prostate cancer is a major problem in the aging male population. Docetaxel, the first-line reference treatment in castration-resistant prostate cancer (CRPC) induces a prostate-specific antigen (PSA) response in 45% of patients and an objective tumor response in 12%. Preclinical studies suggested that curcuminoids inhibit tumor metastasis, invasion and angiogenesis and reverse drug resistance. We wanted to potentiate docetaxel by curcuminoids (CCM) in CRPC first line. Our previous phase I study showed the safety and the tolerability of CCM associated to docetaxel for advanced breast cancers. We have conducted in 2009–2010 a phase II study to assess the response of CRPC to this combination.
Methods: Patients (n = 30) with progressing CRPC and rising PSA were enrolled to receive the experimental treatment. Docetaxel was given in standard conditions (75 mg/m^2, 1 h i.v infusion every 3 weeks for 6 cycles + prednisolone) with CCM orally at the dose of 6gr/day (7 days by cycle: d-4 to d+2). The primary endpoint was response rate assessed by biological and paraclinical examinations. The secondary endpoints included safety, time to progression and compliance. Twenty nine patients were evaluable on PSA assessment and 15 on RECIST criteria.
Results: 26 patients received the treatment totality and 4 withdrew prematurely. No patient withdrew for toxicity (2 deaths and 2 PSA progressions). A PSA response was observed in 17/29 patients (59%) (4 complete and 13 partial) observed rapidly (before the 3rd cycle) for 15 patients. The median time to subsequent PSA progression (TTP) was 5.8 months. Six patients (40%) had a partial objective response and 9 (60%) a stable disease. The median TTP on targets was 7.85 months (n = 13/15). The regimen was well tolerated, with uncommon grade 3/4 toxicity; no adverse event was attributed to CCM. Of 169 cycles, 150 (89%) were completed with perfect compliance. Overall survival was 19 months (mean) and 24 months (median) with 17 events as of december 2012.
Conclusions: These results are promising in improving the response rate to docetaxel in terms of both PSA decrease and objective response, with good tolerability and acceptability of CCM. A randomized trial is necessary to confirm this results.
No conflict of interest.

2900 POSTER

Preliminary product parameters from P11-1, a Phase 2, open-label trial of sipuleucel-T in European men with metastatic castrate-resistant prostate cancer (mCRPC)

P. Mulders[1], M. De Santis[2], K. Fizazi[3], J. Whitmore[4], N. Sheikh[4], C. McCoy[4], A. Stubbs[4], T. Powles[5]. *[1]Radboud University Nijmegen Medical Centre, Department of Urology, Nijmegen, Netherlands; [2]Kaiser Franz Josef Hospital, Center for Oncology and Hematology, Vienna, Austria; [3]Institut Gustave Roussy University of Paris, Department of Cancer Medicine, Paris, France; [4]Dendreon Corporation, Seattle WA, USA; [5]Barts and the London School of Medicine and Dentistry, Department of Experimental Cancer Medicine, London, United Kingdom*

Background: Sipuleucel-T is an autologous cellular immunotherapy approved in 2010 by the FDA for the treatment of asymptomatic or minimally symptomatic mCRPC. Sipuleucel-T is designed to stimulate an immune response against prostate cancer. In the pivotal Phase 3 IMPACT trial, sipuleucel-T showed a 22.5% reduction in risk of death (HR = 0.775 [95% CI: 0.614–0.979]; p = 0.032), and a 4.1-month improvement in median overall survival (25.8 months vs. 21.7 months). P11-1 (NCT01477749) is a Phase 2, open-label, multicentre trial enrolling in Europe. The main aim of the study is to demonstrate that sipuleucel-T can be successfully manufactured for patients (pts) with mCRPC at a European manufacturing facility.
Materials and Methods: Pts enrolled into the study receive sipuleucel-T at approximately 2-week intervals for a total of 3 infusions. Sipuleucel-T is manufactured from autologous PBMCs isolated by leukapheresis prior to each infusion, and activated with PA2024 (a recombinant fusion protein composed of prostatic acid phosphatase [PAP] linked to GM-CSF). The primary endpoint is summarisation of the product parameters and product viability. The product parameters include antigen presenting cell (APC) activation as measured by CD54 upregulation and APC (large CD54$^+$ cells) and total nucleated cell (TNC) counts (x10^9).
Results: As of March 2013, 11 pts have been enrolled into the study across three sites in Austria, the Netherlands and the United Kingdom. APC activation was elevated at infusion 2 (median 16.20; range 6.00–23.50) and infusion 3 (median 14.90; range 7.80–21.20) compared with infusion 1 (median 8.90; range 5.40–16.60), indicative of an immunological prime-boost effect. APC counts did not differ between infusion 1 (median 0.62; range 0.18–1.32), infusion 2 (median 0.49; range 0.16–1.03) or infusion 3 (median 0.61; range 0.19–0.93). In addition, TNC counts remained stable between infusions: infusion 1 (median 4.74; range 1.40–9.80), infusion 2 (median 4.31; range 0.97–12.11) and infusion 3 (median 4.37; range 1.61–7.98).
Conclusions: These preliminary data from the P11-1 trial show that sipuleucel-T can be successfully manufactured by a European manufacturing facility that services multiple nations within the EU. The product parameter profiles are similar to those observed when sipuleucel-T is manufactured for mCRPC pts in the US, and provide evidence of an immunological prime-boost effect.

2901 POSTER

Evaluation of continuous abiraterone acetate (AA) plus prednisone (P) dosing in fasting and fed states in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC)

K.N. Chi[1], J. Spratlin[2], C. Kollmannsberger[1], S. North[2], C. Pankras[1], C. Chien[3], M. Gonzalez[4], L. Peng[5], M.K. Yu[6], N.P. Tran[6]. *[1]BC Cancer Agency, Oncology, Vancouver BC, Canada; [2]Cross Cancer Institute, Oncology, Edmonton AB, Canada; [3]Janssen Research & Development, Clinical Pharmacology, Titusville NJ, USA; [4]Janssen Research & Development, Clinical Pharmacology, Raritan NJ, USA; [5]Janssen Research & Development, Biostatistics Oncology, Raritan NJ, USA; [6]Janssen Research & Development, WC Clinical Oncology, Los Angeles CA, USA*

Background: AA plus P is approved for treatment of pts with mCRPC. A single oral dose of AA in healthy subjects in fed vs an overnight fasted state resulted in a 5- to 10-fold increase in abiraterone exposure. Prescribing guidelines recommend that AA+P is taken orally on an empty stomach with no food consumed at least 2 h before and 1 h after dosing (modified fasting). Pharmacokinetic (PK) exposure and food effect may differ in pts with mCRPC. Here we examined the short-term safety and PK profile of pts with mCRPC treated with AA+P in modified fasting and fed states.
Material and Methods: In this open-label, multi-centre study (NCT01424930), mCRPC pts received oral AA 1 g daily + P 5 mg bid. On Days 1−7, all pts (N = 25) received AA+P in the modified fasting state. On Days 8−14, AA+P was administered within 0.5 h after a standardized low-fat (Group 1, n = 6) or high-fat meal (Group 2, n = 18). Pts then continued AA+P therapy in the modified fasting state until disease progression. Serial 24 h PK sampling was done on Days 7 and 14 (to allow for intrasubject comparison under modified fasting vs fed state), and on Days 8 and 11 at 2 h post dose. Safety was assessed via clinical evaluations and laboratory testing.
Results: Geometric mean (GM) area under the plasma concentration–time curve (AUC) of abiraterone was ~2-fold higher when dosing occurred after high-fat meals compared with the modified fasting state (GM [SD]: 1992 [720] vs 973 [667] ng*h/mL). There was minimal difference in AUC between dosing after low-fat meals vs the modified fasting state (GM [SD]: 1264 [963] vs 1271 [1279] ng*h/mL). Subgroup analysis of modified fasting data revealed that pts who took AA at $\geqslant$2 h after food intake appeared to have higher AUCs compared to those who took AA at $\geqslant$1 h before a meal (GM [SD]: 1466 [1145] vs 843 [541] ng*h/mL). During cycle 1, treatment-emergent adverse events(TEAE) were all grade $\leqslant$3 and similar across pt groups 1 and 2 or AA dosed in a modified fasting or fed state. Grade

3 TEAEs: hypertension, hypokalaemia, hypocalcaemia, vomiting; 1 each occurring in 3 pts.
Conclusions: In pts with mCRPC, repeated dosing of AA+P with high-fat meals resulted in ~2-fold higher mean exposure to abiraterone compared with the modified fasting state. There was negligible change in abiraterone exposure after repeated dosing with low-fat meals. The short-term dosing of AA with food does not alter the safety profile of abiraterone. Taken together, abiraterone exposure associated with food intake does not appear to be clinically relevant.
Conflict of interest: *Advisory board: Janssen. Corporate-sponsored research: Janssen. Other substantive relationships: Janssen, Janssen R&D, Johnson & Johnson*

2902 POSTER

Updated safety results from a cohort compassionate-use programme (CUP) and early access programme (EAP) with cabazitaxel (Cbz) plus prednisone (P; Cbz + P) in patients (pts) with metastatic castration-resistant prostate cancer (mCRPC) previously treated with docetaxel (D)

Z.I. Malik[1], G. Di Lorenzo[2], A. Ardavanis[3], M. Basaran[4], P. Parente[5], W. De Schultz[6], F. Saad[7], I. Van Oort[8], S. Hitier[9], A. Heidenreich[10]. *[1]Clatterbridge Cancer Centre NHS Foundation Trust, Clinical Oncology, Merseyside, United Kingdom; [2]University Federico II, Medical Oncology GU Cancer Section, Naples, Italy; [3]St. Savas Anticancer Hospital, Department of Medical Oncology, Athens, Greece; [4]Istanbul University, Institute of Oncology, Istanbul, Turkey; [5]Box Hill Hospital Monash University, Medical Oncology, Melbourne, Australia; [6]Asklepios Klinik, Klinik für Urologie, Weissenfels, Germany; [7]Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), Division of Urology, Montreal, Canada; [8]Radboud University Nijmegen Medical Centre, Department of Urology, Nijmegen, Netherlands; [9]Sanofi, Biostatistics, Chilly-Mazarin, France; [10]University Hospital Aachen, Department of Urology, Aachen, Germany*

Background: Cbz + P significantly improved survival versus mitoxantrone + P in pts with mCRPC previously treated with D in the TROPIC trial (NCT00417079; de Bono, et al. Lancet 2010). A Sanofi-sponsored CUP and EAP were established to provide access to Cbz + P ahead of commercial availability and to document safety in a real-world population.
Materials and Methods: The CUP and EAP are expected to enrol 1600 pts at 250 centres worldwide. Pts receive Cbz 25 mg/m^2 IV Q3W + P 10 mg QD until disease progression, death, unacceptable toxicity or physician/pt decision. In some countries, commercial availability also requires discontinuation. Pts are followed for 30 days after treatment. Granulocyte colony-stimulating factor (G-CSF) use in pts with factors predisposing to neutropenic complications is recommended per ASCO guidelines (Smith, et al. J Clin Oncol 2006).
Results: We report data from 1301 pts in 37 countries. Pts (mean age: 68 years) had received a median of 1 prior line of therapy with D (range: 1−5). Most pts (90.8%) had an ECOG PS of $\leqslant$1, and 60.4% had $\geqslant$2 metastatic sites. Median time from last D dose to first Cbz + P dose was 5.3 months. In 16.6% of pts, disease progression had occurred during the last D line. A total of 697 pts (53.6%) received $\geqslant$6 cycles of Cbz + P. Disease progression was the most common reason for discontinuation (44.0%). The most frequent Grade 3−4 adverse events (AEs; NCI-CTCAE v4.03) possibly related to Cbz + P (total: 42.8%) were neutropenia (18.2%), febrile neutropenia (6.9%), leukopenia (6.8%), anaemia (4.9%), fatigue (4.3%) and diarrhoea (3.9%). In pts with prophylactic G-CSF use at Cycle 1 (n = 571, 44.0%), clinical neutropenia (all Grades) and febrile neutropenia occurred in 11.4% and 2.3% of pts, respectively. These values were similar to those observed in pts not receiving G-CSF at Cycle 1 (11.2% and 2.7%, respectively).
Conclusions: Data from CUP/EAP programmes with Cbz + P show a manageable tolerability profile consistent with results from the TROPIC trial. The similar incidence of neutropenic complications in pts with prophylactic G-CSF use and in pts without G-CSF use at baseline suggests that adequate risk mitigation of such haematological AEs can be achieved with G-CSF in pts at risk of developing neutropenia.

2903 POSTER

Metastatic disease detection is an important cause of screen failures in a phase II trial evaluating the optimal sequence of androgen deprivation therapy and sipuleucel-T in hormone-naive patients with biochemically-recurrent prostate cancer (BRPC)

A. Kibel[1], C. Drake[2], E. Yu[3], G. Adams[4], L. Karsh[5], A. Elfiky[6], N. Vogelzang[7], N. Shore[8], R. Tyler[9], E. Antonarakis[10]. *[1]Dana-Farber Cancer Institute, Urology, Boston, USA; [2]Johns Hopkins Medicine, Oncology Immunology and Urology, Baltimore, USA; [3]University of Washington, Oncology, Seattle, USA; [4]Urology Centers of Alabama, Urology, Birmingham, USA; [5]The Urology Center of Colorado, Clinical Research Department, Denver, USA; [6]Dana-Farber Cancer Institute, Genitourinary Oncology, Boston, USA; [7]Comprehensive Cancer Centers of Nevada, Medical Oncology, Las Vegas, USA; [8]Atlantic Urology Clinics, Urology, Myrtle Beach, USA; [9]Dendreon Corporation, Medical Affairs, Seattle, USA; [10]Johns Hopkins Medicine, Oncology, Baltimore, USA*

Background: The management of biochemical failure after definitive local therapy is controversial. Androgen deprivation therapy (ADT) is a standard treatment for this patient (pt) population. An ongoing, randomized phase 2 trial (NCT01431391; P10−2) explores the role of sipuleucel-T in combination with ADT in pts with biochemical failure in order to improve outcomes. It is commonly believed that radiographically-detected metastatic disease is rare in this population. However, a high frequency of metastatic disease (32%) has recently been reported in men with presumed non-metastatic castration resistant prostate cancer screened for the phase 3 ENTHUSE M0 trial (Yu et al., J Urol 2012). Here, we report the rate and characteristics of screen failures for hormone-naive pts who attempted to enroll on the P10−2 study.
Methods: Inclusion criteria are: prior primary therapy (radical prostatectomy [RP], radiation [XRT], or both) for prostate cancer, non-metastatic disease, rising prostate-specific antigen (PSA; $\geqslant$0.5ng/mL for RP, nadir plus 2ng/mL for XRT), PSA doubling time $\leqslant$12 months, testosterone $\geqslant$200ng/dL, and total prior ADT $\leqslant$6 months. We describe the characteristics of pts who did not meet the protocol-specified eligibility criteria (i.e., screen failures).
Results: A total of 99 pts were screened over a 9-month period, with 68 pts randomized into the study and 31 who failed screening (31.3%). Radiographic metastatic disease was detected in 11.1% (11/99 pts) of the total screened population, and was one of the leading reasons for screening failure (35.5%; 11/31 pts). Other reasons for screening failure included PSA doubling time >12 months (35.5%), testosterone levels <200ng/dL (16.1%), no rising PSA (9.7%), and ADT for >6 months prior to registration (3.2%). Compared to enrolled study pts, those with radiographic metastatic disease demonstrated a trend towards higher baseline median PSA (4.3 ng/mL [range: 1.7–141.7; n = 7] versus 2.4 ng/mL [range: 0.3–47.8; n = 68]) and median lactate dehydrogenase (174 U/L [range: 147–599; n = 7] versus 161 U/L [range: 103–248; n = 65]), and shorter median PSA doubling times (3.5 months [range: 1.1−7.6; n = 10] versus 5.1 months [range: 1.0–16.4; n = 68]).
Conclusions: We report a high frequency of radiographic metastatic disease in the earlier setting of hormone-naive BRPC. Pts at high risk for metastatic disease generally had worse prognostic factors. These results highlight the importance of screening for metastases in this population.

2904 POSTER

A retrospective study on cabazitaxel and abiraterone acetate sequential treatment (CAST) in docetaxel treated metastatic castrate-resistant prostate cancer patients

M.D. Wissing[1], J.L.L.M. Coenen[2], P. Van den Berg[3], I.M. Van Oort[4], R. De Wit[5], A.M. Bergman[6], H.M. Westgeest[7], P. Hamberg[8], M. Los[9], H. Gelderblom[1]. *[1]Leiden University Medical Center, Medical Oncology, Leiden, Netherlands; [2]Isala Clinics, Internal Medicine, Zwolle, Netherlands; [3]Tergooi Hospital, Internal Medicine, Hilversum, Netherlands; [4]Radboud University Nijmegen Medical Center, Urology, Nijmegen, Netherlands; [5]Erasmus Medical Center, Medical Oncology, Rotterdam, Netherlands; [6]Netherlands Cancer Institute, Medical Oncology, Amsterdam, Netherlands; [7]VU University Medical Center, Medical Oncology, Amsterdam, Netherlands; [8]Sint Franciscus Gasthuis, Internal Medicine, Rotterdam, Netherlands; [9]Sint Antonius Hospital, Internal Medicine, Nieuwegein, Netherlands*

Background: The European Association of Urology considers both cabazitaxel and abiraterone acetate first-choice options for patients with metastatic castrate-resistant prostate cancer (mCRPC) progressing during or after docetaxel. No scientific evidence exists for the preferred second-line therapy. In the CAST-study, the outcome in mCRPC patients treated with cabazitaxel and abiraterone is evaluated retrospectively, with the objective to establish a first scientific indication to the preferred second-line therapy in patients whose condition allows treatment with both compounds.
Patients and Methods: Twelve Dutch hospitals participated in the CAST-study. mCRPC patients were included when having disease progression during or after docetaxel therapy, and when cabazitaxel or abiraterone therapy was initiated before November 3rd, 2012. Patients received standard abiraterone (oral 1000 mg daily) and cabazitaxel treatment (intravenous 25 or 20 mg/m^2 q3w) plus prednisone (10 mg daily). Patients' characteristics were compared between the group that received cabazitaxel first (CA) to patients who received abiraterone first (AC). Primary outcome was median overall survival (OS). Secondary outcomes were progression-free survival (PFS) and biochemical PFS. All data were collected retrospectively; this study did not have any influence on the treatment of mCRPC patients. Therefore these results depict the outcome of cabazitaxel and abiraterone treatment in a representative clinical setting.
Results: In this interim analysis, 48 and 42 patients treated with CA or AC have been included; their median age was 65 and 69 years, respectively. Both treatment groups had on average 2 metastatic sites. Median treatment duration of cabazitaxel plus abiraterone was 10.0 months in the CA-treated group and 7.8 months in the AC-treated group. Median follow-up was 21.2 and 21.0 months; 45.8% and 59.5% of CA- and AC-treated patients had died, respectively. Median OS was 1.48 and 1.19 years in CA- and AC-treated patients, respectively. In CA-treated patients, total PFS was 7.7 and total biochemical PFS was 9.6 months, whereas total PFS and biochemical PFS were 5.5 and 6.4 months in patients treated with AC.
Conclusion: In this interim analysis of the CAST-study, there was a slight survival advantage for patients treated with CA. Further studying is needed to ensure that the results are not biased. At ECCO 2013, an updated analysis will be presented.
Conflict of interest: *Advisory board: Sanofi (Coenen, Gerritsen, Van Oort)*

2905 POSTER

Outcomes with different sequences of cabazitaxel and abiraterone acetate following docetaxel in metastatic castration-resistant prostate cancer (mCRPC)

G. Sonpavde[1], M. Bhor[2], D. Hennessy[3], D. Bhowmik[2], L. Shen[3], L. Nicacio[3], D. Rembert[4], M. Yap[4], R. Dhanda[4], I. Schnadig[5]. *[1]UAB (University of Alabama Birmingham) Cancer Center, Birmingham AL, USA; [2]McKesson Specialty Health, Outcomes, The Woodlands Texas, USA; [3]Sanofi-Aventis, Bridgewater NJ, USA; [4]McKesson Specialty Health, Outcomes, McKesson Specialty Health, USA; [5]Compass Oncology and The US Oncology Network, Hematology-Oncology, Tualatin OR, USA*

Background: The feasibility and outcomes with different sequencing of cabazitaxel (C) and abiraterone acetate (A), following docetaxel (D) in a real world setting in men with mCRPC is unclear. To better understand this research question, we evaluated treatment patterns overall survival (OS), and time to treatment failure (TTF) among post-D mCRPC patients receiving both A and C.
Methods: A retrospective analysis of the US Oncology network iKnowMed electronic health records (EHR) was conducted. with post-D mCRPC patients received both C and A: C followed by A (DCA) and A followed by C (DAC) from April 2011 to May 2012 with $\geqslant$2 visits, excluding clinical trial patients. Median time to OS and TTF were analyzed by Kaplan–Meier method from the start of 2nd line therapy post-D to the end of 2nd line (TTF1) and for the combined 2nd and 3rd line therapy (TTF2). Cox proportional hazard models were used to evaluate impact of age, PCWG2 subtype, Charlson comorbidity index (CCI), PSA/100 ng/ml, hemoglobin (Hb), narcotic use, and 2nd and 3rd line treatment duration on OS and TTF.
Results: 113 evaluable patients were identified (DCA n = 77, DAC n = 36). Baseline characteristics were similar. The median OS and TTF2 were significantly better in the DCA group vs. DAC group (Table). The median number of cycles of C therapy in DCA was greater than in DAC (6 vs. 4) while the duration of A was similar in both DCA and DAC.
Conclusions: In men with mCRPC receiving both C and A post-D, more men received the sequence of DCA compared to DAC and longer exposure to C was observed in the DCA sequence. Given the favorable impact of DCA on OS, we hypothesize that DCA may be a more optimal sequence due to better feasibility of C preceding A. Results from this study are exploratory and a randomized trial may provide definitive results.

2906 POSTER

Enzalutamide (ENZA) in heavily pretreated patients with bone metastatic castration resistant prostate cancer (mCRPC) resistant to androgen biosynthesis inhibitor (ABI) treatment − the Hellenic experience of the Name Patient Access Program (NPAP)

E. Bournakis[1], R. Gyftaki[1], E. Kafantari[1], E. Razis[2], G. Rigakos[1], K. Stravodimos[3], D. Mitropoulos[3], A. Bamias[1], M.A. Dimopoulos[1], E. Efstathiou[1]. [1]*The University of Athens Medical School, Dept of Clinical Therapeutics, Athens, Greece;* [2]*Hygeia Hospital, Third Department of Medical Oncology, Athens, Greece;* [3]*The University of Athens Medical School, Dept of Urology Athens, Athens, Greece*

Background: The novel antiandrogen Enzalutamide following its FDA approval for docetaxel treated mCRPC patients (pts) was made available in the European Union through a Name Patient Program. This is a preliminary report of the Hellenic Experience in far advanced mCRPC patients focusing on those resistant to ABIs in an effort to identify and target 'androgen signaling addicted' disease.
Material and Methods: Patients have progressive mCRPC with serum testosterone⩽50 ng/dL. Pts receive oral ENZA 160 mg QD. Pts are monitored at 4 week intervals with liver function, electrolytes, CBC, and physical examinations and agreed to serial Bone Marrow biopsy and use of archived tissue for molecular characterization by immunohistochemistry [Androgen Receptor (AR)- N, AR-C19, ARV7,CYP17, ERG, Glucorticoid receptor, pSrc, pmet,Ki67] and qPCR for AR copy number assessment. Disease is assessed clinically, by serum markers (PSA, alkaline phosphatase) and by imaging (bone scan, CT scan).
Results (preliminary): Since July 2012, 25/35 men who have initiated ENZA treatment within the NPAP had received prior ABIs [Abiraterone Acetate 20, Orterenol 7, (Both 2)]. Median age is 77 yrs (range 66−90), PS-ECOG 2 (range 0−3), baseline PSA concentration 120 ng/ml (range 3.6–649) and LDH > normal limit in 8/25 (32%). Gleason Score (GS) at diagnosis was ⩾8 in 15/20 (75%), [5 pts not evaluable]. Twenty (75%) had ⩾20 bone lesions, 16/25 (64%) lesions in lymph nodes, 4/25 (16%) visceral metastases and 6/15 (40%) had confirmed bone marrow infiltration. All but one pts have received prior chemotherapy [14 (56%) ⩾2 lines]. To date maximum PSA decline ⩾50% is observed in 6/15 (40%) evaluable pts (on treatment ⩾12 weeks and primarily refractory if discontinued earlier. Self-reported PS improvement 4/12 (33%) evaluable pts. No Grade ⩾3 adverse events are reported.
Conclusions: ENZA is well tolerated in a cohort of heavily pretreated far advanced m-CRPC patients and appears in this preliminary report to benefit a subset of pts resistant to prior ABI treatment. Further follow up and a planned molecular characterization of archived bone marrow infiltrating tumors will help guide selection of this population.

2907 POSTER

NeuACT, a Phase 2 randomised, open-label trial of DN24-02 in patients (pts) with surgically resected HER2+ urothelial cancer (UC) at high risk for recurrence: updated analysis of product parameters and safety

D. Bajorin[1], P. Sharma[2], P.H. O'Donnell[3], R. Sims[4], T. DeVries[4], N. Sheikh[4], L.G. Gomella[5]. [1]*Memorial Sloan-Kettering Cancer Center, New York NY, USA;* [2]*University of Texas MD Anderson Cancer Center, Houston TX, USA;* [3]*The University of Chicago, Chicago IL, USA;* [4]*Dendreon Corporation, Seattle WA, USA;* [5]*Jefferson Medical College and Kimmel Cancer Center, Philadelphia PA, USA*

Background: DN24-02 is a HER2-targeted autologous cellular immunotherapy (ACI) consisting of antigen presenting cells (APC) cultured with BA7072, a recombinant HER2-derived antigen (HER500) linked to GM-CSF. DN24-02 is based on the same manufacturing platform as sipuleucel-T, an ACI approved for asymptomatic or minimally symptomatic metastatic castrate resistant prostate cancer. NeuACT (N10−1; NCT01353222) is an open-label, randomised Phase 2 trial comparing adjuvant DN24-02 to surveillance in HER2+ UC pts at high risk of relapse following cystectomy or nephroureterectomy. The primary endpoint is overall survival. Enrolment is ongoing. Here we report a preliminary analysis of product potency and safety.
Methods: Pts randomised to DN24-02 underwent leukapheresis followed by infusion of DN24-02 for a total of 3 infusions at 2 week intervals. Product potency was assessed by measuring CD54 molecules on APCs; APC activation was defined as the ratio of the average number of CD54 molecules on post-culture cells compared with the number observed on pre-culture cells. Adverse events (AEs) were assessed using CTCAE v4.03.
Results: As of March 2013, 16 pts finished their DN24-02 infusions and were assessed for product potency. APC activation was observed on all 3 infusions but was typically greater at infusions 2 (median 15.25; range 10.19–23.97) and 3 (median 14.63; range 9.70–21.80) compared with infusion 1 (median 7.67; range 4.73–14.34). Of the 22 pts who had received ⩾1 leukapheresis, the most commonly reported AEs in >15% of pts were chills (45.5%), nausea (40.9%), fatigue (36.4%), vomiting (27.3%) and headache (18.2%). Most of these AEs were considered infusion-related, occurring within 1 day of infusion: chills, 40.9%; nausea, 27.3%; fatigue, 22.7%; vomiting, 18.2%; headache, 13.6%. No grade ⩾3 DN24-02-related AEs have been reported. One serious AE (grade 2 pyrexia) was considered treatment-related. No clinically significant left ventricular ejection fraction (LVEF; defined as an LVEF <40% or an absolute reduction in LVEF of ⩾20%) findings have been reported.
Conclusions: This preliminary analysis suggests that DN24-02 product potency (APC activation) is indicative of an immunological prime-boost effect comparable to that observed with sipuleucel-T. The majority of AEs were infusion-related and mild to moderate in severity. Preliminary assessment of safety suggests DN24-02 is well tolerated in UC pts.

2908 POSTER

Clinical outcomes (CO) evaluation of very old (⩾80 years) castration resistant prostate cancer (CRPC) patients (pts) treated with docetaxel (DOC): Updated results of an Italian multicenter retrospective study (cooperative group for DELPHI study)

O. Caffo[1], L.S. Burgio[2], G. Di Lorenzo[3], C. Ortega[4], F. Scognamiglio[5], R. Mattioli[6], G. Mansueto[7], G. Facchini[8], F. Zustovich[9], F. Maines[10]. [1]*Santa Chiara Hospital, Medical Oncology, Trento, Italy;* [2]*IRCCS Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori, Medical Oncology, Meldola, Italy;* [3]*University Federico II, Medical Oncology, Naples, Italy;* [4]*Institute for Cancer Research and Treatment, Medical Oncology, Candiolo, Italy;* [5]*Cardarelli Hospital, Medical Oncology, Naples, Italy;* [6]*Santa Croce Hospital, Medical Oncology, Fano, Italy;* [7]*Civil Hospital, Medical Oncology, Frosinone, Italy;* [8]*National Cancer Institute, Medical Oncology, Naples, Italy;* [9]*Istituto Oncologico Veneto IOV, Medical Oncology, Padua, Italy;* [10]*Santa Chiara Hospital, Medical Oncology, Trento, Italy*

Background: Since prostate cancer is mainly diagnosed in pts over 65 yrs of age, castration resistance is usually observed in older pts. In the case of very old pts (⩾80 years), fear of high toxicity degree limit chemotherapy use due to both pts frailty and several comorbidities occurrence. Moreover, if treated these pts usually receive an adapted chemotherapy, often with a weekly schedule, which in TAX327 trial failed to show survival advantage compared to mitoxantrone. The present retrospective study is aimed to assess CO in this very elderly CRPC population.
Methods: In this multicentric retrospective study, after Ethical Committee approval, we have reviewed the clinical records of all ⩾80 yrs CRPC pts from participating institutions, treated with DOC in clinical practice, recording the pre and post-DOC clinical history, the DOC treatment details and outcomes.
Results: To date we collected a consecutive series of 95 pts from 22 Italian hospitals. The median age was 83 yrs (range 80−90). The median baseline PSA was 124 ng/ml (range 3–1597); 83% of the pts had bone metastases, while nodal, lung and liver metastases were observed in 38%, 5%, and 6% of the pts, respectively. Median Cumulative Illness Rating Scale score was 3 (range 0−11), median Activity Daily Living index score was 0 (range 0−5), median Instrumental Activities of Daily Living score was 0 (range 0−5). The DOC was administered on 3-week or weekly schedule basis (40%/60%). A PSA reduction >50% and an objective response were observed in 76% and 10% of the pts, respectively. Grade 3−4 toxicities were: neutropenia (11%), fatigue (9%), diarrhea (1%), renal (2%), and febrile neutropenia (1%). The median PFS and OS were 7.5 mos and 21.5 mos, while the 1-year PFS and OS rates were 18.6% and 44.2%, respectively.
Conclusions: This data suggests that DOC treatment, both on 3-week or weekly schedule, is able to produce good survival outcomes, comparable to pivotal trials (18 mos), also in highly selected very older (⩾80 yrs) CRPC pts. Data collection is ongoing from other Hospitals.
No conflict of interest.

2909 POSTER

P10−1, an open-label, multicenter study of sipuleucel-T in men with metastatic castrate-resistant prostate cancer (mCRPC) previously treated with sipuleucel-T: Analysis of immunological data

T. Beer[1], M. Glode[2], R. Lance[3], R. Greengold[4], H. Haynes[5], R. Sims[5], Y. Wang[5], N. Sheikh[5], J. Corman[6]. *[1]Oregon Health & Science University Knight Cancer Institute, Portland OR, USA; [2]University of Colorado Denver, Aurora CO, USA; [3]Eastern Virginia Medical School, Norfolk VA, USA; [4]South Orange County Medical Research Center, Laguna Hills CA, USA; [5]Dendreon Corporation, Seattle WA, USA; [6]Virginia Mason Medical Center, Seattle WA, USA*

Background: Sipuleucel-T is an autologous cellular immunotherapy shown to improve survival in men with asymptomatic or minimally symptomatic mCRPC. P10−1 (NCT01338012) is an open-label, multicenter study of sipuleucel-T in men with mCRPC who previously received sipuleucel-T in the androgen-dependent setting in the Phase 3 PROTECT study (NCT00779402). This analysis of P10−1 evaluates antigen presenting cell (APC) activation, cellular immune responses and cytokine responses in patients (pts) retreated with sipuleucel-T.
Materials and Methods: Pts who had previously received at least one infusion of sipuleucel-T in PROTECT and had progressed to mCRPC will be retreated with up to three infusions of sipuleucel-T in P10−1. APC activation was assessed by CD54 upregulation (expressed as the ratio of the average number of CD54 molecules on post- vs pre-culture cells). Cellular immune responses were assessed before retreatment and at weeks 2, 4 and 6 by enzyme-linked immunospot (ELISPOT) assays. Serum cytokine levels were measured at baseline, after each sipuleucel-T infusion, and at week 6.
Results: As of March 2013, 7 pts have been enrolled and have received at least one infusion of sipuleucel-T. The median years from the last treatment on PROTECT was 8.6 years (range 5.5–10.0). APC activation was higher with the 1st sipuleucel-T infusion in P10−1 (median 19.8; range 11.7–26.2) compared with the 3rd infusion in PROTECT (median 13.2; range 6.4–19.0). Antigen-specific ELISPOT responses were detected at baseline, and elevated after the 1st infusion. IL-2 was the only cytokine significantly increased following the 1st sipuleucel-T infusion compared with baseline ($p = 0.005$). T cell activation-associated cytokines (IL-4, IL-5, IL-10 and IFN-γ) were significantly elevated after either 2nd or 3rd sipuleucel-T infusions vs baseline ($p < 0.05$).
Conclusions: P10−1 is the first study of pts retreated with sipuleucel-T after treatment in an earlier disease setting. Higher APC activation in the 1st treatment in P10−1 and detection of antigen-specific ELISPOT responses before retreatment indicate an underlying immunological memory response several years after initial treatment. Elevation of antigen-specific ELISPOT responses after the 1st infusion is a hallmark of memory immune response. Further studies are required to determine whether increased serum IL-2 levels following the 1st infusion of retreatment with sipuleucel-T is unique to pts previously treated with sipuleucel-T.

2910 POSTER

Impact of news drugs in the median overall survival of patients with metastatic castration resistant prostate cancer (mCRPC)

N. Chaumard-Billotey[1], M. Aitichou[1], H. Boyle[2], S. Chabaud[3], B. Favier[1], Y. Devaux[2], J.P. Droz[2], A. Fléchon[2]. *[1]Centre Leon Bérard, Pharmacy, Lyon, France; [2]Centre Leon Bérard, Oncology, Lyon, France; [3]Centre Leon Bérard, Biostatistic, Lyon, France*

In the past 3 years new therapies, such as cabazitaxel (C): a novel taxane, enzulatamide (E): a new androgen receptor signaling inhibitor and abiraterone acetate (A): an inhibitor of androgen synthesis, have been developed in the treatment of post-docetaxel métastatic castration resistant prostate cancer (mCRPC) patients. This study assessed the clinical impact of these new drugs, comparing the outcomes of two historical cohorts of patients with mCRPC.
Methods: We retrospectively reviewed the data of all patients with mCRPC treated by first line chemotherapy with docetaxel (D) at the Centre Léon Bérard. Based on the timing of the development of new drugs, we defined two cohorts based on two time periods depending on drugs available on the market: group 1: 2006–2009 corresponding to the period when only conventional drugs (D, mitoxantrone) were available; group 2: 2009–2012 corresponding to the period when new drugs like C, E, A could be used post docetaxel.
Outcome evaluated was overall survival (OS). OS was defined as the time from date of D introduction to date of death or date of last follow-up for patients alive at last contact. Survival distributions were estimated by the Kaplan–Meier method and compared between groups using Log-Rank test.
Results: One-hundred and thirty five patients were included: 66 patients in group 1 and 69 patients in group 2. Median age was 64 years in both groups. Karnofsky score was $\geqslant$80% for 67.7% of patients in group 1 and 81.8% in group 2. Gleason score was $\geqslant$9 for 38.7% and 31.4% of patients, respectively. In group 1, 47% of patients had node metastases when started on chemotherapy *vs* 40.6% in group 2. The weekly schedule of D (25 mg/m^2) was significantly more frequently used in group 1 than in group 2 (53% *vs* 15%, $p < 0.001$). Median cumulative doses of D as first line treatment were significantly higher in group 2: 643 mg/m^2 *vs* 454 mg/m^2 ($p < 0.001$).
Median overall survival was 10.6 months (95% CI 7.8–15.7) in group 1 *vs* 32.5 months (95% CI 25–42.4) in. group 2 ($p<0.0001$).
Conclusions: This study reflects how the management of mCRPC patients has evolved over the last 7 years. Survival has improved especially through an earlier management, a more intensive schedule of D and the impact of these new drugs.
Conflict of interest: *Other substantive relationships: Pfizer, Sanofi, Janssen, Novartis, Roche*

2911 POSTER

Quality of life (QoL) in patients with metastatic castration resistant prostate cancer (mCRPC) treated with cabazitaxel: Interim analysis of a prospective non-interventional trial (QoLiTime)

R. Hofheinz[1], S.E. Al-Batran[2], P. Hammerer[3], C. Kienitz[4], S. Kloss[5], C. Lange[6]. *[1]University Hospital Mannheim, Mannheim, Germany; [2]Krankenhaus Nordwest, Oncology/Hematology, Frankfurt, Germany; [3]Academic Hospital Braunschweig, Urology, Braunschweig, Germany; [4]Sanofi-Aventis Germany, Oncology, Berlin, Germany; [5]DRK Hospital Luckenwalde, Urology, Luckenwalde, Germany; [6]Medical Practice for Urology and Oncology, Urology/Oncology, Luckenwalde, Germany*

Background: Cabazitaxel (Caba) combined with Prednisone or Prednisolone is approved for second-line treatment of mCRPC after Docetaxel. Potential toxicity of chemotherapy may impact on patients' QoL and counterbalance treatment benefits. Thus QoL data are becoming more important from patients and regulatory perspective.
Material and Methods: Patients with mCRPC receiving Caba are asked to fill in EORTC QLQ C30 QoL questionnaires every three weeks. Here we describe QoL results of the first 131 patients of 480 planned in total.
Results: 131 patients who had finished 4 cycles of Caba treatment are evaluated. Median age was 72 years with generally good performance status (ECOG 0, n = 51; ECOG 1, n = 70). Bone metastases (n = 106 (82%)) and lymph node metastases (n = 66 patients (51%)) are most common. 114 patients have been pretreated with Docetaxel (6 cycles mean). Mean baseline functioning scales were (n = 119 patients): cognitive 80, emotional 65, physical 64, social 63, role 53. QoL questionnaire compliance was excellent: 114 patients (96%) reporting QoL data in cycle 4. Mean functioning values and global health status remained unchanged during the first 12 weeks of treatment. Mean baseline values for symptom scales are: fatigue 50, pain 42, sleep disturbance 39, appetite loss 32, dyspnea 31, constipation 24, financial difficulties 15, diarrhea 13, nausea/vomiting 9. A significant improvement of pain between baseline and cycle 4 (mean 35) ($p = 0.03$) and a trend regarding improvement of sleeping disturbance (cycle 4 mean 33) ($p = 0.15$) were noticed, while diarrhea significantly increased (cycle 4 mean 21; $p < 0.01$). Other parameters remained unchanged.
Conclusions: This interim analysis is the largest prospective non-interventional analysis of QoL in patients receiving Cabazitaxel for mCRPC. QoL questionnaire compliance was excellent. A significant improvement of pain and a trend for improved sleep quality were shown, for the price of increased diarrhea. Importantly, mean global health status was maintained during the 12-week observation period. Results need to be confirmed by final analysis.
Conflict of interest: *Advisory board: Sanofi-Aventis Germany. Other substantive relationships: Sanofi-Aventis Germany*

2912 POSTER

Does testosterone breakthrough impact biochemical failure in prostate cancer patients?

T. Niazi[1], B. Bahoric[2], L. Azoulay[3], T. Vuong[2]. *[1]McGill, Montreal, Canada; [2]McGill, Radiation Oncology, Montreal, Canada; [3]McGill, Oncology, Montreal, Canada*

Background: Androgen deprivation therapy (ADT) has been shown to play an important role in earlier stages of prostate cancer. Indeed, in patients with locally advanced or high-risk localized disease, the addition of neoadjuvant and adjuvant hormone therapy is now considered the

standard of care for those men treated with radical radiotherapy. Although luteinizing hormone-releasing hormone (LHRH) agonists have been used for many years as ADT, they may be associated with clinical testosterone breakthroughs. The question, however, remains if these testosterone breakthroughs impacts disease progression. This study will analyzed the breakthrough rates above castrate levels of testosterone, in a population-based series of men undergoing LHRH agonist therapy with curative radiation therapy and further correlated this with the rate of biochemical failure at 5 years.
Methods: Prostate cancer patients treated between 2000 and 2011 with curative radiation therapy were potentially eligible (n = 1442). Of these, 542 patients fulfilled the eligibility criteria with at least 3 months of LHRH agonist therapy and serial testosterone and PSA measurements during and after continuous LHRH therapy. Breakthrough rates of 0.7−1.1 nmol/L, 1.1−1.7 nmol/L and >1.7 nmol/L were calculated for each patient course. Various factors influencing the PSA failure and testosterone suppression were identified, and early surrogates of oncological outcome (clinical stage, Gleason score and pretreatment PSA) were determined for multivariate analysis.
Results: The risk of any breakthrough >0.7 nmol/L was 25%. Breakthrough 1.1−1.7 nmol/L occurred in 4.5% of the patients and >1.7 nmol/L in 5.6%. During 2334 person-years of follow-up, 92 patients experienced a biochemical relapse, yielding an overall rate of 3.94% per year. In multivariate analysis (adjusting for clinical stage, pretreatment PSA, Gleason score, age and smoking) neither overall biochemical failure (bNED = Nadir + 2) nor survival were compromised, although subgroup analysis showed a trend towards inferior 5-year bNED in those with breakthroughs of >1.7 nmol/L vs those without, with an adjusted HR: 1.74 (0.98–3.10). Furthermore, there were no differences in testosterone breakthrough amongst the commonly prescribed LHRH agonists (Goserelin, Leuprolide i.m, Leuprolide s.c and triptorelin).
Conclusion: Testosterone breakthrough above 0.7 nmol/L occurs in, at least, one quarter of these patients treated with curative radiation therapy and LHRH agonist. Breakthrough levels above 1.7 nmol/L appear to be associated with higher rates of biochemical failure. As such, it is imperative to monitor testosterone levels and PSA during LHRH agonist therapy.
No conflict of interest.

2913 POSTER

Predictors of outcome to post-docetaxel abiraterone acetate (AA) in metastatic castration-resistant prostate cancer (mCRPC) patients (p)

M. Ochoa de Olza[1], A. Font[2], N. Sala[3], M. Beltran[3], P. Barretina[3], O. Etxaniz[2], A. Indacoechea[2], A. Hernández[4], V. Navarro[5], J.R. Germà[1]. *[1]Catalan Institute of Oncology, Medical Oncology, Hospitalet del Llobregat, Spain; [2]Catalan Institute of Oncology, Medical Oncology, Badalona, Spain; [3]Catalan Institute of Oncology, Medical Oncology, Girona, Spain; [4]Insular University Hospital, Medical Oncology, Las Palmas, Spain; [5]Catalan Institute of Oncology, Clinical Research Unit, Hospitalet del Llobregat, Spain*

Background: AA is a standard treatment in mCRPC p both pre- and post-docetaxel treatment, but there is no recognized predictive marker of outcome. We have performed a retrospective analysis of mCRPC p treated with AA after progressing to docetaxel at the three hospitals of the Catalan Institute of Oncology.
Material and Methods: Data on p characteristics, upfront therapy, treatment outcomes and toxicity were collected. Multivariate analyses were performed using cox regression with stepwise algorithm to identify markers of progression-free survival (PFS) and overall survival (OS).
Results: From August 2011 to March 2013, 49 mCRPC p who had progressed to docetaxel were treated with AA. Median age, 74 years (y) (49−86); performance status (PS) 0, 1, 2 in 11 (22%), 25 (51%) and 13 (26%) p, respectively; Gleason score, 6−7/10 in 14 (29%) p and 8−10/10 in 27 (55%). Bone, nodal and visceral metastases were present in 39 (80%), 25 (51%) and 3 (6%) p, respectively. Median time on hormonal treatment (LHRH analogues) before starting docetaxel was 3 y. Before starting AA treatment, 30 (61%) p had received only docetaxel, and 19 (39%) had received docetaxel followed by $\geqslant$1 other chemotherapy regimens. Median number of cycles of docetaxel was 8. 4 (8%) p progressed during docetaxel treatment or within 3 months (m) after receiving their last dose; the remaining p progressed later. Median time on AA treatment was 7.5 m (0.5−12). Median PSA doubling-time at AA start was 1.5 m. On AA treatment, 21 (43%) p had $\geqslant$50% PSA decline, and 16 (33%) p had no PSA decline. 5 (10%) p attained partial response (RECIST), and 9 (18%) had stable disease. 17 (35%) p had clinical improvement. Median follow-up was 7 m (1−18). Median PFS was 7.5 m. Median OS was not reached. Only grade 1 toxicity was observed in 11 (22%) p. In the multivariate analyses, time on hormonal treatment (HR, 1.0; P = 0.007), PS (HR, 7.6; P = 0.036) and PSA nadir on AA treatment (HR, 2.9; P = 0.013) were markers of PFS, and time on hormonal treatment (HR, 0.995; P = 0.03) and PSA nadir (HR, 3.98; P = 0.01) were markers of OS.
Conclusions: This is the largest cohort of mCRPC p treated with AA post-doc outside a clinical trial setting in Spain. Treatment outcomes are in line with results of clinical trials and confirm the effectiveness of AA in an unselected population. Time on hormonal treatment, PS and PSA nadir have emerged as potential predictors of outcome to AA.
No conflict of interest.

2914 POSTER

Temsirolimus (TEM) maintenance therapy benefits patients with castration-resistant prostate cancer (CRPC) after response to docetaxel (TAX)

U. Emmenegger[1], C.M. Booth[2], S.R. Berry[1], S.S. Sridhar[3], N. Bandali[1], R.S. Kerbel[1], Y.J. Ko[1]. *[1]Sunnybrook Odette Cancer Centre, Medical Oncology, Toronto, Canada; [2]Cancer Centre of Southeastern Ontario, Medical Oncology, Kingston, Canada; [3]Princess Margaret Cancer Centre, Medical Oncology, Toronto, Canada*

Background: There is no standard therapy for men with CRPC who have responded to TAX and have not yet progressed. Aside from androgen receptor signaling, the mTOR pathway is amongst the most relevant contributors to CRPC progression. Given significant preclinical anti-CRPC activity of mTOR inhibitors, we designed a single-arm, multicenter phase II trial to explore whether therapy with TEM has the potential to maintain the response to TAX without compromising quality of life.
Methods: From 2009 until 2012 we recruited 21 CRPC pts with documented response to 6 to 10 cycles of TAX (75 mg/m^2 q3wks) by PSA (>50% decline from baseline) or RECIST (1.0) criteria. Pts received weekly TEM (25 mg iv x 4/cycle). The primary endpoint was time to treatment failure (TTF; RECIST or symptomatic progression). Secondary endpoints included safety (NCI-CTCAE v3.0), quality of life (FACT-P, PPI), PSA parameters, tumor response rate, and overall survival (OS). We also collected serum, plasma and peripheral blood mononuclear cells at baseline and 3-monthly thereafter for correlative studies such as the measurement of angiogenic factors.
Results: The mean ($\pm$SD) age of pts was 68 ($\pm$7.7) years. 8 pts had undergone prostatectomies, 17 pts had received local radiation therapy. After a median of 7 cycles of TAX (range 6−10) pts presented with a median baseline PSA of 17.3 μg/L (0.02–380.7). 18 pts had bone, 9 visceral and 10 nodal metastases. Pts received a median of 7 cycles of TEM (2−28), resulting in a median TTF of 6 months (95% CI 4.2−9.2), considered meaningful based on shorter treatment-free intervals observed during intermittent TAX therapy. 11 pts achieved SD and 1 patient a PR by RECIST, but no PSA responses were seen (median time to PSA progression 2.8 months). While the median OS is not yet reached, the 6, 12 and 24 month survival rate was 100%, 94% and 75%, respectively. TEM-associated grade 3 events were infrequent, and quality of life was not adversely affected by TEM. 13 pts discontinued treatment because of treatment failure (symptomatic 9, RECIST 3, combined 1); 4 pts for other reasons, including TEM-associated lymphedema in 1 pt; and 4 pts remain on TEM. Biological samples are currently being analyzed.
Conclusions: TEM maintenance therapy in CRPC pts that have responded to TAX is feasible, does not adversely affect their quality of life, and it results in meaningful prolonged TTF. Further study of TEM may be warranted in the rapidly changing post-TAX treatment space.
No conflict of interest.

2915 POSTER

Phase I trial of fractionated-dose 177Lutetium radiolabeled anti-prostate-specific membrane antigen (PSMA) monoclonal antibody J591 (177Lu-J591) for metastatic castration-resistant prostate cancer (CRPC)

S.T. Tagawa[1], N.H. Akhtar[1], A. Nikolopoulou[2], S. Vallabhajosula[2], J. Osborne[3], H. Beltran[1], R. Kahn[1], S.J. Goldsmith[2], D.M. Nanus[1], N.H. Bander[4]. *[1]Weill Cornell Medical College, Medicine, New York, USA; [2]Weill Cornell Medical College, Radiology, New York, USA; [3]Memorial Sloan Kettering Cancer Center, Radiology, New York, USA; [4]Weill Cornell Medical College, Urology, New York, USA*

Background: A phase II trial of single-dose ^{177}Lu-J591 in men with metastatic (met)CRPC demonstrated efficacy with acceptable toxicity and a dose-response relationship. Dose fractionation may decrease toxicity while maintaining or increasing efficacy.
Methods: In the dose-escalation phase, cohorts of 3−6 men with progressive metCRPC received 2 fractionated doses of ^{177}Lu -J591 2 weeks apart: Cohort 1 (20 mCi/m^2 x2), dose escalation 5 mCi/m^2 per dose per cohort up to 45 mCi/m^2 x2 to determine dose limiting toxicity

and cumulative maximum tolerated dose (MTD) of fractionated ^{177}Lu -J591. Expansion of recommended phase II dose (RP2D) cohorts was performed for preliminary efficacy data. ^{177}Lu -J591 planar imaging with semi-quantitative scoring was performed.

Results: 28 men in the dose-escalation phase received up to 45 mCi/m^2 x2; 12 additional in expansion cohorts (total n = 40). Median age 75.4 years (range 55−95), median baseline PSA 44.7 (2–766.5). 85% had bone mets, 65% LN mets and 47.5% lung/liver mets. All had progressed after 1−4 hormonal therapies and 40% after 1−4 lines of chemotherapy including docetaxel. Despite cumulative doses exceeding the single-dose MTD (70 mCi/m^2, a dose at which 41% receive platelet transfusions), during the dose-escalation phase only 6 men receiving up to 90 mCi/m^2 experienced Gr 4 thrombocytopenia (plts); 2 received transfusion. 3 experienced Gr 4 neutropenia (ANC) without fever or growth factors. Gr >1 non-hematologic toxicity was rare. 24 men were treated at RP2Ds (40 mCi/m^2 x2 or 45 mCi/m^2 x2 with allowable WBC growth factor); 12 (50%) had Gr 4 plts (10 with transfusion), 8 (33%) had Gr 4 ANC without fevers (2 received growth factor). By planar imaging, accurate targeting of known sites of PC mets was seen in 87%. Including all cohorts, 50% had any PSA decline, 30% with ⩾30% decline, 20% with ⩾50% decline. At RP2Ds, 58.3% had any PSA decline, 41.7% with ⩾30% decline, 29.2% with ⩾50% decline. Those with stronger PSMA expression by semi-quantitative imaging had more PSA declines (53% vs 20%, p = 0.18) and PSA responses (34% vs 0%; p = 0.29). 10 of 13 with baseline elevated circulating tumor cell counts (CTCs, CellSearch methodology) decreased by 6 weeks and 3 additional with 0 CTCs at baseline remained 0. Median survival is 25.3 mo [95% CI 17.3, 33.4] for all, 43.5 mo [95% CI, 26.5, 60.5] at RP2D. Survival was longer for those with PSA decline (32.7 vs 23.0 mo, p = 0.03).

Conclusions: Fractionated dose ^{177}Lu-J591 is well tolerated, with reversible myelosuppression and better tolerance of higher cumulative doses than single-dose ^{177}Lu-J591. Non-invasive assessment of PSMA expression might be a predictive biomarker.

2916 POSTER

Testosterone defining prognosis and predicting response in castration-resistant prostate cancer (CRPC)

A. Gómez de Liaño[1], O. Reig[2], B. Mellado[2], C. Martín[1], G. Sancho[3], J. Palou[4], G. Anguera[1], C. Arqueros[1], D. Condori[1], P. Maroto-Rey[1].
[1]Hospital de la Santa Creu i Sant Pau, Medical Oncology, Barcelona, Spain; [2]Hospital Clinic, Medical Oncology, Barcelona, Spain; [3]Hospital de la Santa Creu i Sant Pau, Radiation Oncology, Barcelona, Spain; [4]Fundació Puigvert, Urology, Barcelona, Spain

Background: New second line treatments in CRPC have emerged in the last 3 years. Lack of prognostic and predictive factors has arised the question of who benefits most from a chemotherapy (CT) or a salvage hormonal treatment (HT) after docetaxel failure. We analyzed the role of testosterone in this setting.

Material and Methods: We retrospectively analyzed 101 patients with CPRC included in 9 different first line CT phase II−III trials in two single institutions in Spain, since August 2006 until October 2012. Inclusion criteria required castration levels of testosterone(<50 ng/dL). Baseline testosterone level (TL) was determined by automated immunoassay. We also analyzed patients who received a hormonal maneuver after first line CT. Response was measured by PSA (PSAR). Survival times were analyzed using a Kaplan–Meier model. A Cox regression model was used to analyze prognostic factors for survival. Multivariate analysis was performed on those variables that were significant on the univariate analysis.

Results: Median TL was 11.53 ng/dL. First line CT was docetaxel in 70% of the patients. Testosterone baseline levels had impact in overall survival (OS), Disease Free Survival (DFS) and time to death since 1st line CT progression (TTD) (table 1). Other prognostic factors shown to be significant were: Baseline PSA (Lower vs Higher, HR 0.48, p = 0.0062), age (<65 vs ⩾65 years old, HR 0.48, p = 0.0259) and anemia (No vs Yes, HR 0.40, p = 0.0015).

After first line CT failure, 41/101 patients were treated with hormonal treatment. There were more responders in the High TL group than in the Low TL group (56% vs 21%, p = 0.0196). Responders to HT had a higher OS when testosterone was high (60.9 vs 20.6 months, p = 0.0092).

Conclusions: Lower than median testosterone levels, higher than median PSA levels, >65 years and anemia were significant prognostic factors for a worse survival in patients with metastatic CRPC. Higher baseline testosterone levels predicted a better response to salvage hormonal therapy after CT failure. This response translated into a better survival. Baseline testosterone could help us in treatment decision after first line chemotherapy failure.

No conflict of interest.

Table 1. Survival times depending on testosterone levels

Survival (months)	All patients (N = 101)	TL < median value (N = 49)	TL > median value (N = 52)	P log-rank	Cox-Prop HRR
OS	24.5	22.4	32.7	0.0162	HR 0.52 p = 0.018
DFS	5.1	4.9	5.7	0.0010	HR 0.484 p = 0.0014

2917 POSTER

Impact on abiraterone pharmacokinetics (PK) and safety: Open-label drug–drug interaction (DDI) studies with ketoconazole and rifampicin

C. Chien[1], A. Bernard[2], N. Vaccaro[3], M. Acharya[2], J. Jiao[4], J. Monbaliu[5], R. De Vries[6], H. Stieltjes[6], M.K. Yu[7], N.P. Tran[7]. *[1]Janssen Research & Development, Clinical Pharmacology, Titusville NJ, USA; [2]Janssen Research & Development, Clinical Pharmacology, Raritan NJ, USA; [3]Janssen Research & Development, Clinical Pharmacology, San Diego CA, USA; [4]Janssen Research & Development, Biometrics and Reporting, Raritan NJ, USA; [5]Janssen Research & Development, Preclinical Project Development, Beerse, Belgium; [6]Janssen Research & Development, Bioanalysis, Beerse, Belgium; [7]Janssen Research & Development, WC Clinical Oncology, Los Angeles CA, USA*

Background: Abiraterone acetate (AA) is a prodrug of abiraterone, an androgen biosynthesis blocker, which specifically inhibits CYP17. AA + prednisone or prednisolone therapy improves overall survival or radiographic progression-free survival in patients with metastatic castration-resistant prostate cancer with and without prior chemotherapy. In vitro, abiraterone is a substrate of CYP3A4, a key enzyme involved in metabolism of many prescribed drugs. These DDI studies evaluate the impact of a strong CYP3A4 inhibitor, ketoconazole (K), and a strong inducer, rifampicin (R), at steady state on the PK exposure and safety of abiraterone.

Material and Methods: Data from 2 (NCT01588782, NCT01655147) single-center, open-label DDI studies conducted in healthy men to evaluate the effects of K (Group A) and R (Group B) are presented. Subjects in both groups received 1000 mg of AA on Days 1 and 14. Group A (n = 20) received 400 mg K on Days 11−16. Group B (n = 19) received 600 mg R on Days 8−13. Serial PK sampling was done on Days 1 and 14 and safety was assessed via clinical and laboratory test and adverse event (AE) reporting.

Results: Based on geometric mean ratios (GMR), abiraterone exposure was increased by 9% for C_{max} (90% CI, 90.0–131.1) and 15% each for AUC_{last} (90% CI, 97.9–134.3) and AUC_{∞} (90% CI, 98.3–134.4) for AA+K vs AA alone. Mean (SD) values of abiraterone PK parameters for AA+K vs AA alone: C_{max} (137 [48] vs 131 [60] ng/mL), AUC_{last} (739 [274] vs 672 [332] h*ng/mL) and AUC_{∞} (753 [277] vs 682 [335] h*ng/mL).

Based on GMR, abiraterone exposure was reduced to 45% each for C_{max} (90% CI, 35.0–57.0) and AUC_{∞} (90% CI, 38.0–53.9) and to 42% for AUC_{last} (90% CI, 35.2–50.6) for AA+R vs AA alone. Mean (SD) values of abiraterone PK parameters for AA+R vs AA alone: C_{max} (61 [43] vs 138 [72] ng/mL), AUC_{last} (294 [169] vs 727 [433] h*ng/mL) and AUC_{∞} (332 [170] vs 747 [438] h*ng/mL).

Treatment-emergent AEs were reported in 8 (40%) patients in Group A and 13 (68%) in Group B; most were grades 1−2. No serious AEs, deaths, or discontinuations due to AEs were reported.

Conclusions: Ketoconazole had no clinically meaningful impact on abiraterone exposure. Rifampicin, however, decreased abiraterone exposure by half. Hence, clinical efficacy should be carefully evaluated when administering AA with known strong CYP3A4 inducers. The safety profile of adult men who received a single dose of AA was similar to previous studies of healthy adult men.

2918 POSTER

Tumor responses after steroid switch of prednisolone (P) to dexamethasone (D) in castration-resistant prostate cancer (CRPC) patients (pts) on abiraterone acetate (AA)

D. Lorente[1], K. Weatherstone[2], A. Omlin[1], C. Pezaro[1], R. Ferraldeschi[1], C. Parker[3], D. Dearnaley[3], S. Harland[2], J. De Bono[1], G. Attard[1]. [1]*Royal Marsden NHS Foundation Trust and the Institute of Cancer Research, Prostate Cancer Targeted Therapy Group, Sutton (Surrey), United Kingdom;* [2]*University College London NHS Foundation Trust, Cancer Services, London, United Kingdom;* [3]*Royal Marsden NHS Foundation Trust, Academic Urology Unit, Sutton (Surrey), United Kingdom*

Background: AA is an effective treatment for CRPC. AA has been combined with P 5 mg twice daily to minimize side-effects of secondary mineralocorticoid excess. Long-term use of P could select for androgen receptor (AR) mutations activated by P and we therefore hypothesized that a change in steroid regimen could result in secondary PSA declines in pts progressing on AA and P.
Material and Methods: We prospectively performed a 'steroid switch' from P to D 0.5 mg on 20 pts with a rising PSA (>25% from nadir confirmed after >3 weeks) on AA at the Royal Marsden and University College London Hospitals between January 2011 and February 2013. PSA was measured monthly after switch and restaging scans performed every 3 months or when clinically indicated.
Results: Nine of 20 pts currently continue treatment on AA and D. Eleven pts were discontinued, five (25%) due to PSA progression exclusively and six (30%) due to clinical or radiological progression. Five of 20 patients (25%) had a ⩾50% PSA reduction, confirmed by a second PSA 1 month later in 4 pts and 1 pt had a confirmed ⩾90% decline in PSA (Table 1). The median duration of treatment on AA and D after switch was 2.8 months. Steroid switch was well tolerated with no increase in side-effects from mineralocorticoid excess.
Conclusion: This is the first report of maintained PSA declines after a steroid switch in pts treated with AA and P. Next-generation sequencing of the AR in samples from patients undergoing a switch is currently ongoing. Steroid switch could represent a reasonable and well-tolerated therapeutic intervention in pts progressing on AA and P.

2919 POSTER

Impact of comorbidity on outcome in men with metastatic castrate-resistant prostate cancer (mCRPC)

A. Zist[1], E. Amir[2], A. Ocana[3], B. Seruga[4]. [1]*Institute of Oncology Ljubljana, Sector of Medical Oncology, Ljubljana, Slovenia;* [2]*Princess Margaret Cancer Center, Division of Medical Oncology and Haematology, Toronto, Canada;* [3]*Albacete University Hospital, Medical Oncology Department and Translational Research Unit, Albacete, Spain;* [4]*Institute of Oncology Ljubljana, Sector of Medical Oncology, Ljubljana, Slovenia*

Background: Based on randomized data showing survival improvements, three-weekly docetaxel is the gold standard treatment for patients with mCRPC. Despite this, some patients do not receive treatment, likely due to the assumption of poor tolerability due to comorbid conditions. Here we explore the impact of comorbidity on outcome in men with mCRPC in a population-based observational study.
Material and Methods: Men with mCRPC who were treated with docetaxel at the Institute of Oncology Ljubljana between 2005 and 2012 were eligible. Comorbidity was assessed by using Adult Comorbidity Evaluation (ACE-27) [score 0, 1, 2 or 3] and age-adjusted Charlson Comorbidity Index (aaCCI) [score 0, 1−2, 3−4 or >4]. Accordingly, comorbidity was categorized as none, mild, moderate and severe with higher score indicating a higher level of comorbidity. The association between comorbidity and overall survival (OS) was tested using Cox proportional hazards analysis. Comorbidity was analyzed as both categorical and dichotomous (score 0 vs. ⩾1) variable.
Results: Two hundred and eight men with a median age of 69.9 years were included. At baseline median PSA, Hb and alkaline phosphatase were 217 ng/ml (0->5000 ng/ml), 124 g/l (52–163 g/L) and 2.9U/L (0.57–146 U/L), respectively. Visceral metastases were present in 16% (n = 34) and 44% (n = 91) received opioid analgesia. No, mild, moderate and severe comorbidity was present in 2%, 32%, 53% and 13% using ACE-27 and in 27%, 35%, 29% and 8% when assessed by aaCCI. Ninety six percent (n = 199) of men received three-weekly and 4% (n = 9) received weekly docetaxel. After docetaxel 20% of patients (n = 41) received abiraterone acetate and 8% (n = 17) cabazitaxel. After median follow-up of 14 months, 133 men died. In univariate analysis a higher level of comorbidity was not associated with worse OS (ACE-27: HR 0.96; [95% confidence interval (CI) 0.79–1.17], p = 0.69; aaCCI HR 0.99; [CI 0.87–1.13], p = 0.93). Similarly, when analyzed as dichotomous variable a higher level of comorbidity was not associated with worse OS (ACE-27: HR 0.75 [CI 0.51–1.08], p = 0.12; aaCCI: HR 1.48 [CI 0.37−6.0], p = 0.58). Anemia, a weekly docetaxel schedule, no use of abiraterone and/or cabazitaxel and presence of visceral metastases were significant independent predictors of poor OS in multivariate analysis.
Conclusions: Despite comorbidities, men with mCRPC can have a substantial benefit from docetaxel and other systemic therapies in everyday clinical practice.
No conflict of interest.

2920 POSTER

Docetaxel response after 3 cycles as a predictor of survival in patients with metastatic castration resistant prostate cancer

A. Pinto[1], G. Casado[2], B. Castelo[1], P. Zamora[1], A. Redondo[1], B. Martínez[1], E. Espinosa[1]. [1]*La Paz University Hospital, Medical Oncology, Madrid, Spain;* [2]*La Paz University Hospital, Pharmacy, Madrid, Spain*

Background: The treatment of metastatic castration resistant prostate cancer (mCRPC) has changed in the last few years, with docetaxel still remaining as standard first-line chemotherapy. Nevertheless, we don't have factors able to predict which patients are going to derive the greater benefit from available therapies. Neither we have tools to estimate this benefit when patients have alredy begun therapy. We analyzed PSA response after 3 and 6 cycles of therapy with docetaxel, and tried to find a relationship with survival in these patients.
Material and Methods: We prospectively included consecutive patients with mCRPC that had been treated with at least 3 cycles of docetaxel. Patients with less than 3 cycles were excluded, as well as patients treated with other chemotherapy drugs before docetaxel.

Results: 64 patients were included, with a median age of 72.5 years (range 46−86). 27 patients had a Gleason score >7, 22 patients had a Gleason score ⩽7 and 15 patients had an unknown score. Median PSA at the initiation of docetaxel was 130 ng/ml (range 8.3–3355). 90.6% of patients had bone metastases, 32.8% had nodal metastases, and 4.7% had visceral metastases.
Patients with a reduction of PSA levels higher than 50% of baseline levels had a better progression-free survival (PFS), statistically significant (11 vs 7 months, p = 0.01). Overall survival (OS) results showed also a benefit for this group of patients (24 vs 16 months, p = 0.022).
Conclusions: In our group of patients, reduction of PSA levels above 50% respect to baseline levels could be a surrogate marker for better survival in patients with mCRPC treated with docetaxel. This could help us predict which patients are going to achieve a greater benefit from chemotherapy at an early phase of treatment. Updated data with longer follow-up will be presented at the meeting.
No conflict of interest.

2921 POSTER

A multicenter Phase 1−2 study of enzalutamide in Japanese patients with castration-resistant prostate cancer (CRPC), who had received combined androgen blockade (CAB)

H. Akaza[1], H. Uemura[2], T. Tsukamoto[3], S. Ozono[4], O. Ogawa[5], H. Sakai[6], M. Oya[7], M. Namiki[8], Y. Ohashi[9], S. Naito[10]. *[1]University of Tokyo, Department of Strategic Investigation on Comprehensive Cancer Network Research Center for Advanced Science and Technology, Tokyo, Japan; [2]Kinki University Faculty of Medicine, Department of Urology, Osaka, Japan; [3]Sapporo Medical University School of Medicine, Department of Urologic Surgery & Andrology, Sapporo, Japan; [4]Hamamatsu University School of Medicine, Department of Urology, Hamamatsu, Japan; [5]Kyoto University Graduate School of Medicine, Department of Urology, Kyoto, Japan; [6]Nagasaki University Graduate School of Biomedical Sciences, Department of Nephro-Urology, Nagasaki, Japan; [7]Keio University School of Medicine, Department of Urology, Tokyo, Japan; [8]Kanazawa University Graduate School of Medical Science, Department of Integrative Cancer Therapy and Urology, Kanazawa, Japan; [9]University of Tokyo Graduate School of Medicine, Department of Biostatistics School of Public Health, Tokyo, Japan; [10]Kyushu University Graduate School of Medical Sciences, Department of Urology, Fukuoka, Japan*

Background: Enzalutamide (formerly MDV3100) is a novel androgen receptor inhibitor, which has been proven to prolong survival of men with CRPC who have previously received docetaxel (AFFIRM study; Scher et al, NEJM.2012;367:1187−97). While CAB is commonly used in Japan as a primary androgen deprivation therapy, the treatment options after failure of CAB are currently limited to chemotherapy. Therefore, we conducted a dose escalation and expansion Phase 1−2 study to investigate the safety, tolerability, pharmacokinetics (PK), and anti-tumor activity of enzalutamide in Japanese patients with CRPC.
Methods: In the dose-escalation Phase 1, patients with progressive metastatic CRPC were sequentially assigned to receive single, then multiple doses of 80, 160 or 240 mg/day of enzalutamide, with 3 patients at each dose level to assess PK and safety, except for patients at the 240 mg/day who received a single dose of 240 mg then multiple doses of 160 mg/day. We enrolled 38 post-docetaxel CRPC patients with measurable disease as defined by RECIST into the dose-expansion Phase 2 at a dose of 160 mg/day.
Results: 47 patients were investigated in total: 9 in the Phase 1, and 38 in the Phase 2 at a dose of 160 mg/day. Enzalutamide PK parameters were similar to the non-Japanese population. In Phase 2, patients were heavily pre-treated with 84.2% of patients having 2 or more prior hormonal treatments and 78.9% having 2 prior chemotherapy regimens. 42.1% had 10 or more bone metastases and all patients had measurable disease by RECIST. The clinical benefit rate (Complete Response, Partial Response, or Stable Disease) by week 12 was 47.4% (18/38). Maximal PSA declines (>50% from baseline) were observed in 28.9% (11/38) patients. Treatment-emergent adverse events reported in >20% of patients in Phase 2 were decreased weight, decreased appetite, and constipation. No seizures were observed.
Conclusions: This is the first demonstration of the safety, tolerability, and anti-tumor activity of enzalutamide in the Japanese post-docetaxel CRPC patient population, who had received CAB. Enzalutamide at a dose of 160 mg/day was well tolerated, with similar pharmacokinetic, adverse-event, and anti-tumor activity profile to the non-Japanese population.

2922 POSTER

Docetaxel in combination with Temsirolimus in patients with advanced castration resistant prostate cancer (CRPC): A phase II trial of the Spanish Oncology Genitourinary Group

I. Durán[1], J.F. Rodríguez-Moreno[2], N. Lainez[3], M.A. Climent Durán[4], L. León[5], I. García-Carbonero[6], J. García-Donas[2], A. Viqueira[7], J. Bellmunt[8]. *[1]Hospital Universitario Virgen del Rocío, Oncology, Sevilla, Spain; [2]Centro Integral Oncológico Clara Campal, Oncology, Madrid, Spain; [3]Complejo Hospitalario de Navarra, Oncology, Pamplona, Spain; [4]Fundación Instituto Valenciano de Oncología, Oncology, Valencia, Spain; [5]Complejo Hospitalario Universitario de Santiago, Oncology, Santiago de Compostela, Spain; [6]Hospital Virgen de la Salud, Oncology, Toledo, Spain; [7]Pfizer Oncology, Oncology, Madrid, Spain; [8]Hospital del Mar − IMIM, Oncology, Barcelona, Spain*

Background: Mechanisms of resistance to Docetaxel (D) are not fully understood. Several lines of evidence suggest that mTOR is a potential target in CRPC and preclinical work revealed that combined treatment with Temsirolimus (T) and D had a greater therapeutic effect than monotherapy, both in vitro and in vivo (Fung AS et al. Clin Cancer Res 2009). We previously determined that the combination of these compounds is feasible at reduced doses of both agents and has anticancer activity in patients (pts) with a variety of solid tumors including CRPC. [Duran et al. J Clin Oncol 30, 2012]. The current study aims to evaluate the efficacy of this drug combination in a selected cohort of pts with CRPC after progression to D.
Material and Methods: Pts aged ⩾18, with advanced CRPC progressing after D treatment, ECOG <2, PSA >= 2 ng/ml, testosterone <50 ng/dl, adequate bone marrow, hepatic, pulmonary and renal function were eligible. D was given at 50 mg/m^2 on day 1 together with T 15 mg on days 2 and 16 in a 3 week-cycle. PSA response was evaluated according to PSAWG criteria and toxicity according to NCI-CTCAEv3.0. A two-stage Simon's design was applied.
Results: To date 14 pts have been included in this phase II cohort and full data are available from 11. Median age was 66 (range 55−76), 5 pts had ECOG 0 and all of them had bone metastases. Forty-seven cycles were administered (median: 4; range: 2−10). Mean dose intensity was D 98% and T 90%. The most frequent related adverse events (AEs) of all grades as % of cycles were: anemia (81%), neutropenia (60%) and asthenia (49%). Grade 3−4 AEs as % of cycles were: neutropenia (25%), leucopenia (13%), and febrile neutropenia (6%). Of those pts with sequential PSA data, 44% achieved a PSA response [decline greater than 50%]. Two pts received 8 and 10 cycles of treatment respectively showing sustained clinical benefit. Given these results the study is proceeding to stage II and active recruitment is ongoing.
Conclusions: The addition of Temsirolimus to Docetaxel could revert resistance to the latter in CRPC. This combination seems clinically tolerable with a manageable toxicity profile and promising activity.

Maximal androgen blockade versus castration alone in patients with metastatic prostate cancer

A. Abdalla[1], E. El Sharawy[2], M. El Bassiouny[2], R. Ghali[2]. *[1]Electricity Hospital, Clinical Oncology, Cairo, Egypt; [2]Ain Shams University, Clinical Oncology, Cairo, Egypt*

Background: Maximum androgen blockade (MAB) consisting of an anti-androgen plus either a luteinizing hormone-releasing hormone agonist (LHRHA) or orchiectomy, is widely used in the treatment of metastatic prostate cancer patients. Although clinical trials failed to prove any significant advantage in favor of MAB over castration alone and MAB has been the subject of considerable controversy.
Material and Methods: This prospective randomized trial was designed to compare MAB using orchiectomy or LHRHA (Goserelin 3.6 mg depot every 28 days) and Bicalutamide 50 mg once daily versus castration alone (orchiectomy or LHRHA) in previously untreated metastatic prostate cancer regarding PSA response, progression free survival (PFS), overall survival (OS) and treatment related toxicity.
This study included 100 eligible patients previously untreated pathologically proven metastatic prostate cancer with ECOG performance status 0−3, adequate hematologic, hepatic and renal function. An informed consent was taken from every patient before study entrance.

Results: This study took place during the period from January 2010 to January 2013, with a median follow up of 18 months (range 6 to 24 months). At three months, there were 35 patients (70%) had PSA normalization (⩽4 mg/dl) in MAB group versus 17 patients (34%) in castration alone group *(P = 0.001)*.
PSA normalization at 6 months, 9 months, 12 months was 90%, 92%, 97.6% respectively in MAB group while it was 82%, 86%, 89.7% respectively in castration only group ($p > 0.005$).
The median progression free survival for MAB was 22.18 months (95% CI, 19.7 to 24.2 months) while the median progression free survival for castration alone was 22 months (95% CI, 18 to 25.9 months) ($p = 0.045$).
The survival rate for MAB group was 82% at 18 month and 70.6% at 24 months while for castration alone group was 80% at 18 month and 70% at 24 months with no statistically significant difference between the two groups. The median overall survival was not reached in either group.
Regarding treatment toxicities. Anemia was seen in 4 patients (8%) in MAB group versus 3 patients (6%) in castration alone group and all were grade 1−2. Hepatic toxicity was recorded in 10 patients (20%) in MAB group where 5 patients were grade 1 and 5 patients were grade 2,while only 9 patients (18%) had hepatic toxicities in castration alone group where 7 patients were grade 1 and two patients were grade 2. Hot flushes was seen in 6 patients (12%) in MAB group versus 3 patients (6%) in castration only group.Impotence was relevant in 11 patients (22%) in MAB versus 5 patients (10%) in castration alone group where all of them were grade 1 (p > 0.005).
Conclusion: MAB as first-line treatment for metastatic prostate cancer, significantly improves the PSA normalization rate at 12 weeks and improves PFS compared to castration alone with no significant difference in overall survival in both treatment groups and with comparable acceptable toxicities. Further studies and longer duration of follow up periods are needed to document such findings.

2924 POSTER

Clinical outcomes (CO) and predictive factors (PRE) evaluation of young (<60 years) castration resistant prostate cancer (CRPC) patients, treated with docetaxel (DOC): Updated results of an Italian multicenter retrospective study (cooperative group for CYCLOP study)

O. Caffo[1], C. Ortega[2], G. Di Lorenzo[3], F. La Russa[4], L.S. Burgio[5], C. Messina[6], G. Spizzo[7], G. Facchini[8], G.L. Pappagallo[9], F. Maines[1].
[1]Santa Chiara Hospital, Medical Oncology, Trento, Italy; [2]Institute for Cancer Research and Treatment, Medical Oncology, Candiolo, Italy; [3]University Federico II, Medical Oncology, Naples, Italy; [4]University of Verona, Medical Oncology, Verona, Italy; [5]IRCCS Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori, Medical Oncology, Meldola, Italy; [6]Civil Hospital, Medical Oncology, Bergamo, Italy; [7]Civil Hospital, Medical Oncology, Merano, Italy; [8]National Cancer Institute, Medical Oncology, Naples, Italy; [9]Civil Hospital, Epidemiology & Clinical Trial, Mirano, Italy

Background: Prostate cancer is mainly diagnosed in pts over 65 yrs of age, so CRPC is rare in pts ⩽60 yrs. Clinical outcomes of these pts are not clearly defined but there is a common feeling of a worse prognosis for such younger pts. The present study is aimed to assess CO and PRE in this specific population.
Methods: In this multicentric retrospective study, after Ethical Committee approval, we have reviewed the clinical records of all ⩽60 yrs CRPC pts from participating institutions, treated with DOC, both in clinical trials and in clinical practice. We recorded the pre and post-DOC clinical history, the DOC treatment details and outcomes. We have also assessed the ability of a series of selected 18 clinical factors to predict DOC response through a logistic regression analysis. Continuous variables were categorized by quartiles and chosen for the initial model after a univariate chi-square analysis.
Results: To date we have collected a consecutive series of 113 pts from 19 Italian hospitals. The median age was 56.5 yrs (range 41−60). The median baseline PSA was 122 ng/ml (range 2–2721); 93% of the pts had bone metastases while 49%, 10%, and 13% showed nodal, liver and lung metastases, respectively. All but 8 pts received DOC with a 3-week standard schedule: the median number of received DOC courses was 8 (range 1−14). The main grade 3−4 toxicities were anemia (4 pts), neutropenia (15 pts), febrile neutropenia (1 pt), peripheral neuropathy(1 pt). A PSA reduction >50% was observed in 63.2% of the pts while 14% and 7% of the cases showed a partial and complete response, respectively. Having a Gleason score (GS) <8 [(exp(beta) 3.561; p = 0.031], a hemoglobin initial value >12 [(exp(beta) 2.991; p = 0.050], no nodal involvement [(exp(beta) 1.864; p = 0.107], resulted to be independently predictive of a PSA reduction >50%. The median PFS and OS were 8 mos and 19 mos, while the 1-year PFS and OS rates were 18.4% and 70.3%, respectively.
Conclusions: From these preliminary results, we failed to confirm a worse prognosis for younger CRPC since their survival outcomes are similar to those observed in the pivotal trials. Low GS, absence of nodal involvement and good hemoglobin levels are the only predictive factors. Data collection from other Hospitals is ongoing.
No conflict of interest.

2925 POSTER

Survival, efficacy and safety of weekly docetaxel (35 mg/m^2) plus prednisolone chemotherapy for metastatic hormone-refractory prostate adenocarcinoma

N. Berdjis[1], G. Rodemer[1], S. Ehlers[2], T. Wismann[2], Y. Rodemer[2].
[1]Medical Office, Urology, Wilhelmshaven, Germany; [2]Medical Office, Oncology, Wilhelmshaven, Germany

Background: The optimal timing of docetaxel-based chemotherapy for patients with castrate-resistant prostate cancer (CRPC) is of constant debate. Most studies started chemotherapy for rising PSA. The benefits of chemotherapy has to be weighed against its risks. A randomised trial (Tannock et al. 2004) demonstrated improved overall survival (OS) with docetaxel chemotherapy in a 3-week schedule (75 mg/m^2) compared with docetaxel given at the dose 30 mg/m^2 weekly or with with the mitoxantrone-prednisolone combination. However, the 3-week schedule was associated with a significantly higher incidence of grade 3 and 4 neutropenia. Only few studies examined the safety and efficacy of weekly docetaxel regimen. In the current retrospective study our data for weekly docetaxel with 35 mg/m^2 are demonstrated and compared to the results of the TAX 327 study.
Patients and Methods: We reviewed the medical records from 33 patients (median age 71 years; 57−80) with CRPC and a weekly scheduled docetaxel-regimen (35 mg/m^2 day 1 + day 8 + day 15 q3W) + prednisolone 2x5 mg. Chemotherapy was only initiated in cases of symptomatic tumor progression (e.g. pain, hydronephrosis, cachexia etc.). OS, efficacy and safety were assessed.
Results: Median six cycles (1−8 cycles) of docetaxel chemotherapy were delivered. Median PSA at baseline was 163.3 ng/ml (10.1–3190.2) and decreased during therapy in 24 patients (72.7%) for >50% from baseline. Our data show a higher PSA response rate compared to the 45% rate in the 3-weekly arm or 48% in the 1-weekly arm of the TAX327 study. OS from time of CRPC in median was 26 months (6−80 months) and OS from time of initiation of the chemotherapy was 16 months (5−75 months). In one patient the therapy was not tolerated and had to be stopped. In two other cases the dose of docetaxel was reduced for 25% because of neutropenia respectively intolerance. The overall occurence of grade 3 and 4 adverse events was 24.2% (anaemia, neutropenia, diarrhoea, nausea,vomiting) and for neutropenia alone 9.1% (TAX 327 study: 32% for the 3-weekly and 2% for the 1-weekly schedule).
Conclusions: The current 1-weekly docetaxel-chemotherapy schedule with 35 mg/m^2 shows higher PSA response rates compared to both docetaxel regimen of the TAX 327 study. In addiaiton the incidence of grade 3 and 4 neutropenia was much lower than in the 3-weekly arm of TAX 327. However, the OS rate of 16 months in our study was lower than in the 3-weekly arm (18.9 months) and in the 1-weekly arm (17.4 months) of TAX 327, which is likely due that the initiation of chemotherapy was done only in case of symptomatic tumor progress and therefore was started later than in TAX327 study. A prospective randomised study with comparison of the weekly and 3-weekly arm would be useful to answer the question for the optimal chemotherapy regimen.
No conflict of interest.

2926 POSTER

Low-dose metronomic oral cyclophosphamide plus prednisone for metastatic castration resistant prostate cancer (mCRPC) patients

N. Martinez Lago[1], U. Anido[1], M. Vieito[1], R. Varela-Ponte[2], M. Carmona[1], C. Rodriguez[1], A. Cortegoso[1], S. Candamio[1], R. Lopez-Lopez[1], L. Leon[1]. *[1]Hospital Clinico Universitario, Medical Oncology, Santiago de Compostela, Spain; [2]Hospital Clinico Universitario, Radiology, Santiago de Compostela, Spain*

Background: Although the introduction of new agents in recent years has allowed an improvement in overall survival in mCRPC, the treatment of elderly and poor performance status patients remains a therapeutic challenge. There are few data on the use of cyclophosphamide in this context, so we designed this protocol to evaluate the efficacy and toxicity of the metronomic oral administration of cyclophosphamide and prednisone in patients with mCRPC, not candidates for docetaxel or after progression to it.

Methods: We retrospectively evaluated the medical records of patients with metastatic mCRPC treated with prednisone and cyclophosphamide in our institution. Patients had been previously treated with a docetaxel-containing regimen or were not considered candidates for taxanes, because of important comorbidities or poor Performance Status (PS).
Results: Data from 48 patients treated with cyclophosphamide 50 mg/day vo plus prednisone 5 mg bid from January 2010 to February 2013 have been analyzed. Baseline characteristics of the patients are listed in the Table 1. 46 patients were evaluable for efficacy and toxicity. The PSA response rate (RR) was 26%; clinical benefit (stabilization disease + RR) was obtained in 60% of patients. Median progression-free survival and overall survival was 27 weeks (95% CI 18.9–35.8) and 60 weeks (95% CI 44.7–75.6), respectively. The overall 1-year and 2-year survival rate was 32% and 6%. The treatment was safe and well tolerated, with anemia grade 0−3 in a third of all patients.
The response and survival data were analyzed as a function of previous lines of chemotherapy. The PSA response rate in patients at first-line therapy was 50%; at second or subsequent line was 15%. Progression free survival for first and second line and later was 43 weeks (95% CI 26.9–59.7) and 19 weeks (95% CI 12–26.3) respectively.
Conclusions: In this study with a poor prognosis population, metronomic oral cyclophosphamide plus prednisone have demonstrated efficacy with an excellent tolerance. Oral cyclophosphamide is an interesting alternative to consider in patients non candidates for intravenous chemotherapy.

A randomized open-label study comparing the docetaxel plus prednisone regimen versus mitoxantrone plus prednisone regimen for metastatic hormone refractory prostate cancer in Chinese population

D. Ye[1], Y.H. Sun[2], Q. Wei[3], X. Yao[4], Z.Q. Ye[5], Y.R. Huang[6], W. Zhang[7], Y. Yang[8], Y. Tian[9], Y.Q. Na[10]. *[1]Shanghai Cancer Center Fudan University, Shanghai, China; [2]Changhai Hospital The Second Military Medical University, Urology, Shanghai, China; [3]West China Hospital West China School of Medicine Sichuan University, Urology, Chengdu, China; [4]Chinese PLA General Hospital Medical School of Chinese PLA, Urology, Beijing, China; [5]Tongji Hospital Tongji Medical College Huazhong University of Science & Technology, Urology, Wuhan, China; [6]Renji Hospital Shanghai Jiaotong University School of Medicine, Urology, Shanghai, China; [7]Jiangsu Province Hospital Nanjing Medical University, Urology, Nanjing, China; [8]Beijing Cancer Hospital Peking University, Urology, Beijing, China; [9]Beijing Friendship Hospital Capital Medical University, Urology, Beijing, China; [10]Shougang Hospital Peking University, Urology, Beijing, China*

Background: Most patients with metastatic prostate cancer will eventually progress to a hormone refractory state. Docetaxel-based chemotherapy was the standard treatment for symptomatic metastatic hormone refractory prostate cancer (mHRPC). However, the efficacy and safety in Chinese patients are not well established.
Material and Methods: Patients with symptomatic mHRPC, and KPS⩾70 were randomized (1:1) to the regimens of docetaxel (75 mg per square meter od body surface area) every three week plus 5 mg prednisone twice daily (Arm A) or mitoxantrone (12 mg per square meter) every three week plus 5 mg prednisone twice daily (Arm B). Patients were planned to receive 10 cycles of treatment in both groups. The primary endpoint was overall survival. Secondary endpoints were pain-control progression-free survival (PFS), prostate-specific antigen (PSA) response, quality of life and safety.
Results: 228 patients have been randomized, in which 111 patients in Arm A and 109 patients in Arm B were available for analysis. The median cycles of chemotherapy were 8 cycles (range 1−10) in Arm A and 4 cycles (range 1−10) in Arm B. The median overall survival was 21.9 months in Arm A versus 13.7 months in Arm B. The 12-month overall survival rates were 78.6% in Arm A and 51.9% in Arm B. As compared with the patients in Arm B, patients in Arm A had a hazard ratio for death of 0.62 (95% CI, 0.45–0.85; P = 0.003 by the log-rank test) and 38% of reduced risk of death. 61.1% of patients in Arm A had reduction in pain with median pain control time of 3.7 months, compared with 23.1% (p = 0.0011) of reduction of pain with a median pain control time of 2.2 months. The median pain-control PFS was 12.7 months in Arm A versus 5.6 months in Arm B (p = 0.0002). PSA response rates were observed in 35.1% of patients in Arm A versus 19.4% of patients in Arm B (p = 0.02). The grade 3 or 4 adverse events were observed in 74.8% of patients in Arm A versus 67.0% of patients in Arm B. 20% of patients in Arm A and 15.8% of patients in Arm B had improvements in quality of life (p = 0.54).
Conclusions: These data suggests that the 3-week docetaxel plus prednisone regimen was effective in improving overall survival and pain controlling with acceptable toxicities in Chinese patients with mHRPC.
No conflict of interest.

2928 POSTER

HER2 tissue expression in NeuACT, a Phase 2, randomised, open-label trial of DN24-02 in patients (pts) with surgically resected HER2+ urothelial cancer (UC) at high risk for recurrence

M.F. Press[1], P.H. O'Donnell[2], E.R. Plimack[3], J. Hoffman-Censits[4], D.I. Quinn[1], P. Sharma[5], T. DeVries[6], M. Chen[6], M. Locker[6], D.F. Bajorin[7]. *[1]University of Southern California Norris Comprehensive Cancer Center, Los Angeles CA, USA; [2]The University of Chicago, Chicago IL, USA; [3]Fox Chase Cancer Center, Philadelphia PA, USA; [4]Jefferson Medical College and Kimmel Cancer Center, Philadelphia PA, USA; [5]University of Texas MD Anderson Cancer Center, Houston TX, USA; [6]Dendreon Corporation, Seattle WA, USA; [7]Memorial Sloan-Kettering Cancer Center, New York NY, USA*

Background: HER2 gene amplification and overexpression (immunohistochemistry [IHC] score 3+) in pts with high-risk UC may be a negative prognostic factor. Publications report a wide variability of HER2 expression in UC, with ⩾2+ HER2 expression by IHC reported in <10% to >50% of cases. DN24-02 is an investigational autologous cellular immunotherapy targeting HER2, based on the same manufacturing platform used for sipuleucel-T. NeuACT (N10−1; NCT01353222) aims to evaluate whether DN24-02 prolongs survival when given as adjuvant therapy following surgical resection in pts with high-risk HER2-expressing UC (Bajorin, et al. ASCO 2012). Here we report an updated analysis of HER2 expression on primary tumour and positive lymph node samples.
Methods: Eligibility criteria include surgical resection of a primary UC, with either ⩾pT2 or pN+ staging, and HER2 expression ⩾1+ by IHC. Surgical specimens are screened for HER2 expression by central pathology laboratory review, and scored with the Dako HercepTest system.
Results: As of March 2013, tumour specimens from 154 pts have been screened. Of these pts, 118 (77%; 95% CI: 69−83%) had a HER2 expression score ⩾1+ in the primary tumour, with 52 (34%) having a ⩾2+ score and 13 (8%) having a 3+ score. Fifty-five pts also had HER2 expression levels evaluated in lymph node samples; 50 of these (91%; 95% CI: 80−97%) had a HER2 expression score ⩾1+ in the lymph nodes, with 30 (55%) having a ⩾2+ score and 10 (18%) having a 3+ score. Gender, primary tumour site, tumour grade and prior neoadjuvant chemotherapy were not significantly correlated with HER2 expression in either the primary tumour or lymph node (p⩾0.10); however, nodal stage was correlated with lymph node HER2 expression (p = 0.014). Preliminary analyses suggest no discernible relationship between the magnitude of immune response and HER2 expression levels.
Conclusions: This interim analysis of NeuACT reports high frequencies (⩾77%) of HER2 expression ⩾1+ in primary tumour and lymph node samples of UC pts. While HER2 expression levels in the lymph nodes correlated with nodal stage, no other baseline variables appear to affect HER2 expression rates; no apparent relationship was observed between immune response and HER2 level. Although interim, these data are consistent with prior studies noting a higher incidence of HER2 expression in UC lymph node tumours compared with primary tumours and suggest that HER2 protein expression is common in high-risk UC.

2929 POSTER

Pre-clinical evidence for cross-resistance between taxanes and abiraterone in castration-resistant prostate cancer (mCRPC)

R.J. Van Soest[1], E.S. De Morrée[1], W. Teubel[1], J.M. Moll[1], H. Burger[2], E.A.C. Wiemer[2], R.H.J. Mathijssen[2], W.M. Van Weerden[1], R. De Wit[2]. [1]*Erasmus University Medical Center, Urology, Rotterdam, Netherlands;* [2]*Erasmus University Medical Center, Medical Oncology, Rotterdam, Netherlands*

Background: A recent study suggested impaired efficacy of docetaxel when given after progression on abiraterone in patients with mCRPC. Our recent pre-clinical data demonstrated that docetaxel, cabazitaxel, and abiraterone all act on AR nuclear transport, which is a crucial step in AR signaling, and provide a mechanistical explanation for potential clinical cross-resistance. In the present study, we aimed to identify cross-resistance between taxanes (docetaxel and cabazitaxel), and abiraterone in an abiraterone-resistant cell line model.
Material and Methods: The abiraterone resistant prostate cancer cell line PC346Abi101 was derived by continuous culturing PC346C cells in the presence of abiraterone (1 μM). We used an MTT-assay to determine the effects of docetaxel, cabazitaxel, mitoxantrone, and abiraterone on cell proliferation. Briefly, cells were seeded in 96-well dishes at a density of 5,000 cells per well in DCC medium. After overnight attachment, PC346Abi101 and PC346C cells were treated for 10 days with docetaxel (0.1–100 nM), cabazitaxel (0.1–100 nM), mitoxantrone (0.1−10 μM), abiraterone (0.1−20 μM), or vehicle control.
Results: We observed that docetaxel and cabazitaxel efficacy was impaired in PC346Abi101 cells, as compared to the parental PC346C cells, suggesting cross-resistance between docetaxel and abiraterone, as well as cabazitaxel and abiraterone. We used mitoxantrone as a control cytotoxic agent and showed that this non-tubulin targeted drug was similarly effective in PC346Abi101 and parental PC346C cells, validating that the observed cross-resistance was specific for the tubulin-targeting agents docetaxel and cabazitaxel. Resistance to abiraterone was confirmed by severely impaired efficacy of abiraterone in PC346Abi101 cells, compared to PC346C cells.
Conclusions: Our *in vitro* data show substantial evidence for cross-resistance between docetaxel and abiraterone, as well as cabazitaxel and abiraterone. This observed cross-resistance with abiraterone seems to be specific for the tubulin-targeting agents docetaxel and cabazitaxel, and is likely to be caused by the effects on AR transport of these compounds. Clinical investigations are warranted to define the most appropriate treatment sequence for these agents in patients with CRPC.
Conflict of interest: *Advisory board: Sanofi, Janssen, Millenium. Corporate-sponsored research: Sanofi*

2930 POSTER

Clinical benefit on abiraterone acetate (AA) in patients (pts) with PTEN loss castration-resistant prostate cancer (CRPC)

A. Omlin[1], C. Pezaro[1], A. Reid[1], D. Nava Rodrigues[1], R. Riisnaes[1], S. Miranda[1], N. Tunariu[1], D. Lorente[1], G. Attard[1], J. De Bono[1]. [1]*The Royal Marsden RM and the Institute of Cancer Research ICR, Prostate Cancer Targeted Therapies Group, Surrey, United Kingdom*

Background: The CYP17A1 inhibitor AA is an effective but costly treatment for CRPC, which is a molecularly heterogeneous disease. It has been postulated that upregulated AKT pathway signalling through PTEN loss results in resistance to AA. We therefore aimed to evaluate the impact of PTEN loss on the anti-tumour activity of AA in CRPC in an attempt to deliver more precise treatment for this disease.
Methods: We first acquired patient-matched hormone sensitive (HS) and castration resistant (CR) tumour samples to determine whether PTEN status changes with castration resistance. Four uM tissue sections were cut and immunostained for PTEN (Cell Signaling Technology), with internal controls for all slides. PTEN was scored on a minimum of 100 cancer cells per slide to calculate an H-score as previously reported (Mod Pathol. (2012)25;902−10). H-score >30 was considered positive. Biochemical response to AA was defined as ⩾50% decline in PSA from baseline, confirmed at least 3 weeks later. Treatment duration and survival were estimated using the Kaplan Meier method.
Results: Patient-matched HS and CR tissue samples were available for 49 pts. Of these, the HS tissue showed staining consistent with PTEN loss in 25/49 pts (51%). In the CR samples PTEN loss was identified in 28/49 (57%). Heterogeneity was evident between HS and CR samples, with changed classification from PTEN normal to PTEN loss in 3 pts (6%) and conversely from PTEN loss to PTEN normal in another 3 pts (6%). We therefore proceeded to classify PTEN status by loss in either HS or CR tissue. AA activity and survival data in 99 pts stratified by PTEN status are presented in the table.

Conclusions: PTEN status does not significantly change with development of castration resistance. AA retains significant activity in patients with PTEN loss, both in chemotherapy naive and docetaxel pre-treated patients in our population. Further biomarker studies, including markers that associate specifically with activation of the Pi3K/AKT pathway are urgently required.

	AA		p
	PTEN normal	PTEN loss

2931 POSTER

Circulating tumor cells (CTCs) in high-risk localized prostate cancer: Correlation with clinicopathologic characteristics and characterization of relevant surface markers

S. Pal[1], M. He[2], M. Kawachi[3], T. Wilson[3], M. Kortylewski[4], C. Lau[3]. [1]*City of Hope/Beckman Research Institute, Medical Oncology & Experimental Therapeutics, Duarte CA, USA;* [2]*City of Hope/Beckman Research Institute, Molecular Pharmacology, Duarte CA, USA;* [3]*City of Hope/Beckman Research Institute, Surgery, Duarte CA, USA;* [4]*City of Hope/Beckman Research Institute, Cancer Immunotherapeutics & Tumor Immunology, Duarte CA, USA*

Background: The prognostic value of CTC enumeration in metastatic castration-resistant prostate cancer (mCRPC) is well established. However, previous attempts to characterize CTCs in localized prostate cancer have proven challenging (Davis *et al* J Urol 2008). Using the CellSearch system, we employed a modified sample processing method and enriched our cohort for patients with high-risk localized disease to improve CTC yield.
Methods: Patients with high-risk, localized prostate cancer (defined by ⩾1 of the following criteria: ⩾cT3a disease, Gleason score 8−10, or PSA >20 ng/mL) who had chosen prostatectomy for definitive management were prospectively identified. After obtaining consent, 4 sequential 30 mL blood draws were performed. The first 2 blood draws were conducted 2 weeks prior and immediately prior to surgery, while the second 2 blood draws were conducted at 4 weeks and 12 weeks following surgery. The white blood cell (WBC) fraction from each 30 mL blood draw was pooled and Ficoll purified. A total volume of 7.5 mL was transferred to a CellSave tube and CTCs were enumerated using the CellSearch system. Expression of E-cadherin, a marker of epithelial-to-mesenchymal transition (EMT), and CD133, a stem cell marker, were characterized using open channels on the CellSearch platform.
Results: A total of 35 patients were enrolled from Nov 2011 to March 2013. The median age was 65 (range, 48−74), and the following proportions of patients demonstrated the respective high-risk criteria: (1) PSA >20: 29%, (2) Gleason 8−10: 86%, and (3) ⩾cT3a: 91%. Using the modified methodology, CTCs were detectable in 49% of patients prior to surgery, with a mean count of 2.5 cells. Amongst age, high-risk features and other clinicopathologic characteristics, only seminal vesicle involvement was found to be correlated the presence of CTCs prior to surgery. In total, 76% of individually characterized CTCs expressed CD133, and 84% expressed E-cadherin.
Conclusions: Using a simple modification of the standard CellSearch methodology, CTCs are readily detectable in a large proportion of patients with high-risk localized prostate cancer. The presence of CTCs prior to surgery correlates with seminal vesicle involvement. The majority of CTCs detected in this study were CD133 and E-cadherin expressing, suggesting that CTCs have 'stem-like' properties and may carry an intermediate epithelial–mesenchymal phenotype, respectively.

Efficacy and safety of abiraterone acetate (AA) in elderly (⩾75 years) chemo-naive patients (pts) with metastatic castration-resistant prostate cancer (mCRPC)

M.R. Smith[1], D. Rathkopf[2], P. Mulders[3], J. Carles[4], H. Van Poppel[5], J. Li[6], T. Kheoh[7], T. Griffin[8], A. Molina[9], C. Ryan[10]. Background: AA, a specific inhibitor of CYP17, blocks androgen biosynthesis. In pts with mCRPC pre- and post-chemotherapy, AA + prednisone (P) therapy provides significant overall survival (OS) benefit and manageable safety profile. Many pts with mCRPC are diagnosed after the age of 70 y. We present the efficacy and safety results of AA+P vs P only in elderly (⩾75 y) and younger (<75 y) pt subgroups at the prespecified interim analysis (IA3; 55% total OS events) for study COU-AA-302.
Material and Methods: 1088 pts were stratified by Eastern Cooperative Oncology Group performance status (0 vs 1) and randomized 1:1 to AA 1000 mg + P 5 mg po BID vs P only. Co-primary end points were radiographic progression-free survival (rPFS) and OS. Median time to event variables with 95% CI were estimated using the Kaplan–Meier method for elderly (n = 350) and younger (n = 738) pts.
Results: At IA3, median follow-up was 27.1 months. Elderly and younger pts were well balanced in each treatment arm by baseline disease characteristics. Elderly pts treated with AA+P had significant improvements in OS and rPFS vs P only, similar to the younger pts (Table). All secondary end points also favored the AA+P arm for both age subgroups. Overall, elderly pts in both arms (57%) had more grade 3/4 adverse events (AEs) than younger pts (42%). The incidence of AEs of special interest was also more common in the elderly pts, but the safety profile of AA + P was similar among elderly and younger pts (Table).
Conclusions: These subset analyses demonstrate that the efficacy and safety of AA+P are similar for younger and elderly pts. These observations support use of AA + P in elderly men with metastatic CRPC who have not received chemotherapy.

Phosphoproteomic profiling reveals focal adhesion kinase as a mediator of docetaxel resistance in castrate-resistant prostate cancer

R. Daly[1], B.Y. Lee[2], F. Hochgrafe[2], H.M. Lin[2], L. Castillo[2], J. Wu[2], M. Raftery[3], M. Shreeve[4], L.G. Horvath[5]. [1]*Monash University, Biochemistry & Molecular Biology, Melbourne Victoria, Australia;* [2]*Garvan Institute of Medical Research, Cancer Research Program, Sydney, Australia;* [3]*University of New South Wales, Bioanalytical Mass Spectrometry Facility, Sydney, Australia;* [4]*Pfizer, Science Center Drive, San Diego, USA;* [5]*Royal Prince Alfred Hospital, Sydney Cancer Centre, Sydney, Australia*

Background: Docetaxel remains the standard-of-care for men diagnosed with metastatic castrate resistant prostate cancer (CRPC), but only ~50% of patients benefit from treatment and all develop Docetaxel-resistant disease. This study aimed to characterize global perturbations in tyrosine kinase signaling associated with Docetaxel-resistance and thereby develop a potential therapeutic strategy to overcome chemoresistance.
Methods: We compared tyrosine phosphorylation events in Docetaxel-sensitive and -resistant DU145 and PC3 prostate cancer cell lines using quantitative mass-spectrometry-based phosphoproteomics. Bioinformatic approaches were used to identify perturbations in protein-protein interaction networks and signaling pathways characteristic of Docetaxel-resistant cells. Effects of the focal adhesion kinase (FAK) inhibitors PF562271 and PF4554878 on Docetaxel sensitivity were characterized, using cell viability, clonogenicity, apoptosis and autophagy as end-points. The role of apoptosis and autophagy in cell death induced by Docetaxel/PF562271 co-treatment was interrogated by pharmacological (Z-VAD-FMK, 3-methyladenine) and genetic (Atg5 knockdown) approaches. The antitumor efficacy of Docetaxel (10 mg/kg) +/− PF4554878 (50 mg/kg) was determined in Balb/c nude mice bearing PC3 xenografts.
Results: Docetaxel-resistant cell lines exhibited perturbations in pathways regulating focal adhesions and the actin cytoskeleton and increased FAK phosphorylation on Y397 and Y576, compared to parental controls. While treatment with Docetaxel or either of the FAK tyrosine kinase inhibitors (TKIs) reduced FAK phosphorylation in the resistant cells, co-treatment with Docetaxel and a FAK TKI was required to reduce FAK phosphorylation to that of drug-sensitive cells. Treatment with a FAK TKI alone did not affect cell viability of the resistant cells, but co-treatment with Docetaxel and a FAK TKI overcame chemoresistance. The enhanced efficacy of co-treatment was not due to increased apoptosis, but rather enhanced autophagic cell death. In tumor-bearing mice, co-administration of Docetaxel and PF4554878 resulted in a greater reduction of tumor growth than either monotherapy, and was also associated with increased autophagy.
Conclusions: Enhanced activation of FAK mediates Docetaxel resistance in CRPC. Our study has identified a clinical niche for FAK TKIs, where co-administration with Docetaxel may be used in CRPC to overcome chemoresistance.

2934 POSTER

Cause of death in men with localized prostate cancer: Which clinico-demographic risk factors are important?

M. Van Hemelrijck[1], Y. Folkvaljon[2], H. Garmo[3], L. Holmberg[3], J. Adolfsson[4], O. Akre[5], P. Stattin[6]. [1]*King's College London, Cancer Epidemiology, London, United Kingdom;* [2]*Regional Cancer Centre, Uppsala/Orebro, Uppsala, Sweden;* [3]*King's College London, Cancer Epidemiology Group, London, United Kingdom;* [4]*Karolinska Institute, CLINTEC Department, Stockholm, Sweden;* [5]*Karolinska Institute, Clinical Epidemiology Unit, Stockholm, Sweden;* [6]*Umea University, Surgical and Perioperative Sciences, Umea, Sweden*

Background: Most men with prostate cancer (PCa) do not die of PCa. We investigated cause of death among men with localized PCa and among PCa-free men, while taking into account clinico-demographic factors.
Material and Methods: PCa data Base Sweden (PCBaSe 2.0) is based on the National PCa Register (NPCR) of Sweden and also contains age- and county matched PCa-free men. We selected all men diagnosed with localized low or intermediate risk PCa between 1997 and 2009 (n = 39,115) and their 78,230 matched PCa-free men. Competing risk regression was used to predict 10-year cause-specific survival. All models were adjusted for age, education level, civil status, and Charlson comorbidity index (CCI), and were performed by PCa risk categories.

Results: Civil status and education level did not have a large effect on PCa-specific death. Table 1 shows 10-year overall mortality by age, CCI, and PCa risk group for married men with an intermediate education level. The risk of dying was smaller for those with low risk PCa than for those without PCa. The proportion of PCa-specific death was smaller for those with CCI=2+ than for those with CCI=0, indicating a self-selection of healthy men to PSA testing and diagnosis of low-risk PCa. As expected, high age and comorbidity were related with increased risk of death. The proportion of PCa-specific death was comparable among age groups (e.g. 32, 35, and 33% of men in respective age groups with intermediate risk disease and CCI=0 die <10 years).

Table 1. Predicted 10-year mortality and proportion of cause-specific death by age, CCI, and PCa risk group for married men with intermediate education level.

	CCI = 0			CCI = 2+		
Age	50	60	70	50	60	70
No PCa						
Overall Risk (%)	3.8	8.9	20.0	8.0	18.8	41.7
PCa	4	5	6	2	2	2
Other cancers	58	40	27	54	38	25
CVD	18	24	28	22	29	33
COPD	4	3	3	5	5	5
Other	17	27	37	16	26	35
Low Risk PCa						
Overall Risk (%)	2.9	7.5	18.2	6.5	16.1	37.7
PCa	14	17	18	5	6	7
Other cancers	58	41	29	66	49	34
CVD	11	17	23	13	21	28
COPD	0	1	2	1	2	3
Other	17	23	28	16	22	27
Intermediate Risk PCa						
Overall Risk (%)	5.0	11.2	24.5	9.0	19.1	40.6
PCa	32	35	33	14	16	16
Other cancers	50	35	23	66	48	32
CVD	8	13	19	10	18	25
COPD	1	1	1	2	3	3
Other	8	15	24	8	16	25

Conclusions: High comorbidity is associated with low PCa-specific death due to competing causes of death and there is a healthy selection phenomenon among men with low risk PCa. Interestingly, the proportion of men with localized low or intermediate risk PCa dying of their disease was very similar, irrespective of age.
No conflict of interest.

Metformin to abrogate androgen deprivation therapy-induced insulin resistance and metabolic syndrome

A. Zhang[1], P. Fox[1], B. Balakrishnar[1], A. Menzies[1], B. Gao[1], S. Turner[2], J. Holmes-Walker[3], M. Wong[1], H. Gurney[1]. *[1]Crown Princess Mary Cancer Centre, Medical Oncology, Westmead NSW, Australia; [2]Crown Princess Mary Cancer Centre, Radiation Oncology, Westmead NSW, Australia; [3]Westmead Hospital, Endocrinology, Westmead NSW, Australia*

Background: Androgen-deprivation therapy (ADT) in prostate cancer (PC) decreases insulin sensitivity and increases the risk of the metabolic syndrome (MS). This study assessed the effects of metformin in abrogating ADT-induced insulin resistance.
Methods: In a prospective 12-month study, men beginning ADT and with no history of diabetes mellitus (DM) received metformin for 6 months, followed by no metformin for a further 6 months. Subjects acted as their own controls as all received intervention. The primary outcome measures were the effect of metformin on the Homeostasis Model Assessment of Insulin Resistance ($HOMA_{IR}$) and the Whole Body Insulin Sensitivity Index (WB-ISI), as measure of insulin action in the fasting and stimulated states, respectively. The incidence of MS and related laboratory and anthropometric measures were also assessed.
Results: Twenty-seven patients received ADT and metformin. Median age was 69 years. While all had normal fasting glucose at baseline, 11 (40.7%) had evidence of DM on oral glucose tolerance testing (OGTT). Eleven (40.7%) patients also had MS at baseline. Despite ADT, $HOMA_{IR}$ remained stable during metformin therapy [1.7 (SEM$\pm$0.35) at baseline; 1.9 (SEM$\pm$0.32) at 6 months; P = 0.18]; but increased once metformin was ceased [3.6 (SEM$\pm$2.2) at 12 months; P = 0.07]. There was a significant fall in WB-ISI irrespective of metformin [7.4 (SEM$\pm$1.0) at baseline; 6.0 (SEM$\pm$0.79) at 6 months; 5.2 (SEM$\pm$1.6) at 12 months; P<0.01]. The number of patients with MS remained unchanged during metformin therapy, but 2 further patients developed MS at 12 months. Short-term metformin had no effect on blood pressure or other anthropometric measures, including waist circumference and body mass index, but did improve HDL cholesterol.
Conclusions: Metformin may offset MS in men on ADT. Metformin had a greater impact on fasting metabolic parameters (as measured by $HOMA_{IR}$) compared to its effect after a glucose load (as measured by WB-ISI). Importantly, this study found that a large proportion of PC patients had unsuspected MS and DM, suggesting a role for OGTT in all patients starting ADT.

2936 POSTER

Quality of cancer care in the Netherlands: Variation in treatment of prostate cancer

K. Aben[1], I. Van Oort[2], S. Siesling[1], C. Van de Velde[3], L. Incrocci[4], T. De Reijke[5]. *[1]Comprehensive Cancer Centre The Netherlands, Department of Registry & Research, Utrecht, Netherlands; [2]Radboud University Medical Centre, Department of Urology, Nijmegen, Netherlands; [3]Leiden University Medical Centre, Department of Surgery, Leiden, Netherlands; [4]Erasmus Medical Centre, Department of Radiation Oncology, Rotterdam, Netherlands; [5]Academic Medical Centre, Department of Urology, Amsterdam, Netherlands*

Background: Prostate cancer is the most common cancer among males in the Netherlands (>10,000 patients each year). One in every 9 Dutch males will be diagnosed with prostate cancer sometime during life. Due to aging this number will increase to more than 17,000 in 2020. Earlier studies showed that large variation in cancer care exists. Information on quality of prostate cancer care is rare; therefore the Dutch Cancer Society in collaboration with the Netherlands Cancer Registry (NCR), held by the Comprehensive Cancer Centre the Netherlands, has started a study to evaluate four types of cancer including prostate cancer.
Material and Methods: All patients diagnosed with prostate cancer between 2007–2011 were selected from the NCR and included in the study. Patient- and tumour characteristics as well as information on initial treatment were available.
Results: In the period 2007–2011 51,790 patients were diagnosed with prostate cancer and 9986 (%) underwent a radical prostatectomy (RP) as primary treatment. Large variation is observed concerning the number of RPs performed by hospital. The proportion of hospitals in the Netherlands performing 20 or more RPs as initial treatment has increased from 28% in 2005 to slightly over 40% in 2011. This proportion will increase in the near future as the Dutch Association for Urology has indicated in 2012 that each hospital should perform at least 20 RPs each year. The majority of patients with localized prostate cancer is treated with RP or radiotherapy (RT). However, only 6 to 10% of all patients of 70 years or older underwent a RP. Approximately 10% of patients with a pT3 tumour or patients with post-operative positive margins received adjuvant RT as recommended by the Dutch guideline. Stratified analyses showed large differences between the different subgroups; 19% of pT3 tumours with positive margins were treated with RT versus 6% of the pT3 tumours resected radically. Concerning hormonal therapy in combination with RT in high-risk prostate cancer patients large differences were observed by geographic region; overall 64% of these patients received hormonal therapy with a range of 49% to 79%.
Conclusions: The number of performed RPs varied largely over time. This variation will probably decrease in the near future, as a minimum of 20 RPs has been set. Despite the recommendations in the guideline concerning adjuvant RT and combination of RT and hormonal therapy, a large proportion of men does not receive this treatment.
This study was commissioned by the working party 'Quality of cancer care' of the Signalling Committee Cancer of the Dutch Cancer Society.
No conflict of interest.

2937 POSTER

Use of a risk calculator in a prostate unit to reduce overdiagnosis of prostate cancer

A. Van den Ende[1], J.B.W. Rietbergen[2], M.F. Wildhagen[3], C.H. Bangma[3]. *[1]Sint Franciscus Gasthuis/Erasmus MC, Prostaatcentrum Zuidwest Nederland, Rotterdam, Netherlands; [2]Sint Franciscus Gasthuis, Prostaatcentrum Zuidwest Nederland, Rotterdam, Netherlands; [3]Erasmus MC, Prostaatcentrum Zuidwest Nederland, Rotterdam, Netherlands*

Background: Most prostate cancer (PCa) is detected because of opportunistic screening. It is important to reduce unnecessary biopsies and diagnosing of indolent PCa. PSA as indicator for a biopsy has low specificity, so a web based risk calculator (RC) based on parameters

obtained from a large randomized study of screening for prostate cancer (ERSPC) has been developed. The aim of the current study is to investigate whether use and compliance to RC is safe and effective in reducing the number of unnecessary biopsies.
Materials and Methods: A retrospective descriptive study was performed at the Prostaatcentrum Zuid-West Nederland (PCZ). Men referred for potential PCa screening were analyzed. Excluded were men with a previous diagnosis of PCa, or without PSA measurement and physical examination. For all men risk calculation was performed based on PSA, prostate volume, rectal examination and previous biopsy result. When the chance calculated with RC on a positive biopsy was >20%, or when >12.5% combined with a relevant chance of finding significant prostate cancer (Gleason $\geqslant$7 and clinical stage >T2b), a positive biopsy advice was given. Effects were compared to a historical PSA biopsy cutoff value of 4 ng/ml.
Results: 408 men over a 26 months period were included. A positive RC advice (n = 274) led to 220 biopsies and diagnosis of 143 (detection rate = 65%) cancers. 96 of 143 cancers (67%) were significant. Despite a negative biopsy RC advice (n = 134), 33 biopsies were performed, finding 4 (detection rate = 12%) cancers, 1 was significant, while 29 patients had a benign outcome. When also taking indolent PCa into account, the number of potentially unnecessary biopsies increased up to 32 (97%). This compared to 77 negative biopsies (35%) when having a positive RC advice. Follow-up of patients having an initial negative RC advice (n = 48), showed detection of 4 cancers (12%), one significant tumor (2.1%), while in men who had a positive RC advice and a negative biopsy at first (n = 37), 3 significant PCa (8.1%) were detected.
Due to RC, 11 men were biopsied with a PSA<4, while 138 men were NOT biopsied though having a PSA of >4.
Conclusion: Overall compliance to RC advise was 78.8%. A reduction of biopsies of 33% was obtained compared to traditional PSA cut-off, while missing only 2 relevant cancers.
No conflict of interest.

2938 POSTER

Prevalence of non-metastatic castration-resistant prostate cancer (CRPC) at high risk of bone metastases in 19 countries in 2013

A. Liede[1], J. Arellano[1], G. Hechmati[2], B. Bennett[3], S. Wong[3]. *[1]Amgen Inc, Thousand Oaks, USA; [2]Amgen (Europe) GmbH, Zug, Switzerland; [3]Plan A, Mountain View, USA*

Background: CRPC is a growing public health concern that has not been adequately quantified. In the absence of metastases (M0), CRPC represents a transitional disease state defined by increases in serum prostate-specific antigen (PSA) despite androgen-deprivation therapy (ADT). PSA kinetics can identify men who are likely to progress to develop metastases, and who may benefit most from interventions to halt or delay disease progression. We developed a patient-flow model to estimate prevalence of M0 CRPC at high risk of developing bone metastases in selected populations with high incidence rates of PC.
Methods: The model estimates 5-year limited-duration prevalence of PC and M0 PC using incidence and survival data from cancer registries from 19 countries (EU5 [France, Germany, Italy, Spain, UK], Europe [11], Australia, Canada, and US). Research conducted with urologists and oncologists in these countries provide details of M0 PC treated with ADT. The model assumes that M0 PC patients must receive continuous ADT ($\geqslant$6 months GnRH therapy or bilateral orchiectomy) as a prerequisite for CRPC development. PSA relapse rates from literature sources were used to quantify M0 CRPC. Electronic medical record studies in the US, Denmark, and Sweden provide estimates of patients who have PSA doubling time (DT) $\leqslant$6 months, a definition commonly used to define high risk disease.

Table: Five-year prevalence in 2013.

	PC	M0-PC, % of PC	M0 CRPC	High risk CRPC, % of PC
Australia	81583	85	3249	2
Austria, Switzerland	55387	86	2617	3
Belgium, Netherlands	79749	85	4581	3
Canada	116842	92	5284	2
Czech, Hungary, Poland	90758	80	9198	5
Denmark, Finland, Norway, Sweden	93296	79	7010	4
EU5	992453	85	65120	4
US	979102	92	43341	2

Results: Under the base case scenario, holding incidence and survival relatively constant, prevalence of PC is driven by size and aging in the populations, and most cases represent M0 disease (Table). In 2013, we estimate that a total of 43341 men in the US, 65120 in EU5, 23406 across Europe-11, and 8533 in Canada and Australia are estimated to have M0 CRPC. Approximately 50−60% of M0 CRPC cases will have PSA DT $\leqslant$6 months, which suggests that 2−5% of all PC may be considered high risk M0 CRPC.
Conclusion: A dynamic patient-flow model was developed using latest cancer registry data, as well as physician research in 19 countries, to consider how patients progress through courses of treatment and disease states after diagnosis of PC to estimate the prevalence of M0 CRPC and high risk M0 CRPC. We estimate that high risk M0 CRPC constitutes a relatively small proportion of all patients living with PC.

2939 POSTER

Prognostic value of initial PSA, PSA Nadir and time to Nadir PSA for biochemical failure in patients with intermediate-risk prostate cancer treated with radiation therapy without androgen deprivation

N. Patel[1], L. Souhami[2], J.J. Mansure[3], S. Faria[2], M. Duclos[2], G. Shenouda[2], M. David[2], F.L. Cury[2]. *[1]UCLH NHS Foundation Trust, Department of Clinical Oncology, London, United Kingdom; [2]McGill University Health Centre, Department of Radiation Oncology, Montreal, Canada; [3]McGill University Health Centre, Department of Urologic Oncology, Montreal, Canada*

Background: To assess the relationship between pre-treatment PSA (iPSA), PSA Nadir value (nPSA) and time to PSA Nadir (TnPSA) to biochemical failure (BF) in intermediate-risk prostate cancer patients treated with radical radiotherapy (EBRT).
Methods and Materials: Patients with intermediate-risk prostate cancer who did not receive androgen deprivation therapy were eligible for analysis. Patients were treated with four different EBRT regimes; 50 Gy in 20 fractions EBRT and a 10 Gy single-fraction high-dose rate brachytherapy boost, 66 Gy in 22 fractions EBRT, 72 Gy in 36 fractions EBRT or 76 Gy in 38 fractions EBRT. All patients had a minimum of 2-year follow-up. BF was defined as PSA nadir+2ng/ml.
Results: A total of 267 patients treated between May 2001 and November 2010 were included in this study. With a median follow-up time of 65 months, the median time to nadir was 41 months with a median nadir value of 0.27ng/ml. A total of 34 patients had developed biochemical failure (13%) at a median time to failure of 29 months. On univariate and multivariate analyses, the iPSA, nPSA and TnPSA were all found to be associated with BF ($p < 0.001$). A cut-off value for the iPSA was found to be 11.6ng/ml. A nPSA value of >0.3ng/ml and TnPSA of $\leqslant$24 months were found to be associated with worse biochemical failure free survival (bNED) rates. When all three poor prognostic indicators were pooled together a significant association was found. Patients who had an iPSA $\geqslant$11.6 ng/ml, nPSA >0.3ng/ml and TnPSA $\leqslant$24 months had a bNED rate at 5-years of 0% ($p < 0.001$).
Conclusions: nPSA, TnPSA and lower iPSA are all independently associated with better bNED rates. When pooled together, a significant relationship with BF was found whereby all patients with an iPSA $\geqslant$11.6ng/ml, TnPSA $\leqslant$24 months and nPSA >0.3ng/ml developed BF. This association has not been reported previously and warrants further investigation.
No conflict of interest.

2940 POSTER

Characterization of pathway to non-metastatic (M0) castration-resistant prostate cancer (CRPC) and high risk of bone metastases according to treating physicians in 19 countries

K. Hope[1], A. Graham[1], J. Arellano[2], A. Liede[2], V. Shahinian[3]. *[1]Adelphi Research, Cheshire, United Kingdom; [2]Amgen Inc, Thousand Oaks, USA; [3]University of Michigan, Ann Arbor, USA*

Background: Androgen-deprivation therapy (ADT) represents standard of care for prostate cancer (PC) patients (pts) with signs of recurrence after primary therapy (tx). Nearly all ADT-treated M0 pts relapse to develop CRPC, with a median time to relapse of 18−24 months (mos) (Felici 2012). This study surveyed physicians who treat M0 PC pts in 19 countries to estimate ADT use and CRPC, and explore definitions of high risk of developing bone metastases (BM).
Methods: A 45-minute online survey was completed by urology and oncology practitioners from 19 countries with high or increasing prevalence of M0 PC. Eligibility ensured respondents were responsible for tx decisions in the care of M0 PC, and had $\geqslant$10 pts on ADT. Sampling of oncology (vs. urology) specialists reflected M0 PC tx pattern in the country. Sampling ensured regional distribution and practice type. Country-level weights were applied during analysis to account for differences in prevalence of M0 PC.
Results: In total, 441 physicians completed the survey representing 98689 PC pts under their care, of which 76386 (77%) had M0 PC.

Table (abstract 2940): ADT use, CRPC, and high risk according to treating physicians

	Physicians surveyed	Any ADT, % of M0 PC	ADT ⩾6 mo, % of M0 PC	CRPC by 2 yrs, %	High risk, % of CRPC	Expect to develop BM, % of CRPC

Urologists	387	38	28	75	57	63
Oncologists	54	62	47	81	57	56

Respondents were primarily urologists (88%) (Table). Of M0 PC, 38% received ADT: 37% (28104) gonadotropin-releasing hormone (GnRH) tx and <2% (1251) bilateral orchiectomy. ADT use was highest in Eastern Europe. Across regions, 74% (20729) of GnRH pts received ⩾6 mos, 48% (13594) continuously; of these, 75% have or will develop CRPC. Among CRPC pts, 57% were currently considered high risk, and 63% expected to develop BM in the future. Gleason score (>8), prostate-specific antigen (PSA) level (⩾20 ng/mL) and PSA doubling time (⩽6 mos) were most commonly used to determine high risk of BM.

Conclusion: This study characterised clinical states and pathway to M0 CRPC and high risk of BM as described by treating physicians. The results confirm that most pts who are treated continuously with ADT develop CRPC within 2 years, and approximately 50−60% will be considered at high risk for BM.

In-vivo isolation of circulating tumor cells in prostate cancer patients by a medical device

G. Theil[1], M.R. Hoda[1], A. Schumann[1], K. Fischer[2], K. Haubold[3], C. Boehm[1], T. Krahn[4], N.G. Morgenthaler[3], K. Lücke[3], P. Fonara[1].
[1]Martin-Luther-University Halle-Wittenberg, Urology and Kidney Transplantation Center, Halle, Germany; [2]Martin-Luther-University Halle-Wittenberg, Urology and Kidney Transplant Center, Halle, Germany; [3]GILUPI GmbH, Clinical Trials, Potsdam, Germany; [4]Bayer Pharma AG, Global Biomarker Research, Berlin, Germany

Background: CTCs are discussed as a prognostic and stratification biomarker, and may help to assess the treatment efficacy. The aim was to demonstrate proof of concept of in vivo CTC isolation in Prostate cancer patients (PCa).

Material and Methods: A medical device (CellCollector) was inserted in a cubital vein for 30 minutes. The interaction of target CTCs with the CellCollector was mediated by antibodies to the epithelial cell adhesion molecule (EpCAM). To confirm binding of CTCs to the wire, immunohistochemical staining against Cytokeratin and CD45 was performed. There were 226 applications of the device in 16 metastasized PCa (PCa-m) with up to 8 wire applications per patient, 24 localasized PCa (PCa-l) with up to 3 wire applications per patient as well as 19 men with benign prostate hypertrophy (BPH) and 21 women as control group with only one wire application.

CTC counts from 22 PCa patients with 58 applications were directly compared to the CellSearch technology.

Results: We obtained *in vivo* isolation of CTCs in 73 of 98 applications to PCa patients (74.5%). The sensitivity for metastasized PCa was (86.2%) and for local PCa (57.5%), respectively. Follow up data of one patient with PCa-m: 2009 diagnosed PCa with multiple metastases. 2 years later PSA of 11.2ng/ml and 25 CTCs. After transurethral resection and removal of a brain metastasis, CTCs decreased to 20 cells with no effect on PSA levels. 4 months later we observed 187 CTCs and a PSA level of 76ng/ml, which was correlated with the patient condition.

Median CTC counts in PCa-l (n = 18) were18.2 before radical prostatectomy and decrease to 2.8 and 1.4during 6 and 12 months follow up. A direct comparison of the CellCollector and CellSearch® resulted in detection rates of 65% (13/20) and 20% (4/20), respectively.

Conclusion: We demonstrate the use of CTCs besides PSA during therapy adjustment in PCa patients In summary the CTC detection rate of the CellCollector in PCa-m and PCa-l in comparison to the CellSearch® method increased by 26% and 45%.

2942 POSTER

Baseline bone mineral density in men with prostate cancer commencing with androgen deprivation therapy (ADT): Characteristics of quantitative ultrasound (QUS) of the heel as triage test compared to dual energy x-ray absorptiometry (DXA)

C. Van Casteren-Messidoro[1], A.M. Huisman[1], E. Birnie[2], C.H. Bangma[3], M. Van Gelder[3], F.E. Van de Geijn[1], P. Hamberg[3]. *[1]Sint Franciscus Gasthuis, Rheumatology, Rotterdam, Netherlands; [2]Sint Franciscus Gasthuis, Statistics, Rotterdam, Netherlands; [3]Sint Franciscus Gasthuis, Prostate Cancer Center, Rotterdam, Netherlands*

Background: Androgen deprivation therapy (ADT), part of treatment for prostate cancer, puts patients at an increased risk for developing osteoporosis. Assessment of bone mineral density (BMD) is considered standard of care in patients commencing ADT, most commonly by dual energy x-ray absorptiometry (DXA). Alternative ways of estimating BMD like quantitative ultrasound (QUS) measurement of the heel are explored as DXA is expensive, non-portable and uses ionising radiation. This study explored the value of QUS as compared to DXA in patients commencing ADT.

Methods: In a consecutive retrospective cohort study of 60 patients with prostate cancer initiating ADT, BMD was measured with DXA and QUS.

Results: No significant correlations were found between the separate DXA T-scores and worst DXA T-score, and the QUS T-scores. Mean difference between the worst DXA T-score and QUS T-score was −0.7 (SD 1.49).

If QUS would have been used as screening tool, with a threshold of T ⩽ −0.5 to perform a DXA, then relevant osteopenia/osteoporosis (worst DXA T-score ⩽−2.0) would have been missed in 1/18 (5.6%, 95% CI: 0.1%-27.3%) patients. The negative predictive value (NPV) is 0.95 (95% CI: 75.1%-99.9%). At a threshold of QUS of T < = 0.7 the NPV would be 0.89 (95% CI: 70.8%-97.7%). Using QUS as screening test prior to DXA and a QUS threshold T-score ⩽−0.5 would avoid 21 (35%, 95% CI: 43%-48%) DXA-scans at the cost of missing 1 (5.6%) case.

Conclusion: QUS testing cannot replace DXA scans fully since correlations between QUS and DXA T-scores in prostate cancer patients starting with ADT are absent. However, QUS can be incorporated in the diagnostic strategy as triage test prior to DXA to reduce the need for DXA scans.

No conflict of interest.

2943 POSTER

Dose intensity of abiraterone acetate and administration of post-abiraterone chemotherapy for metastatic castration-resistant prostate cancer (mCRPC) − a real world analysis

G. Sonpavde[1], K. Tangirala[2], J. Mehta[3], J. Sung[2], L. Nicacio[4], R. Dhawan[2]. *[1]UAB Comprehensive Cancer Center, Division of Hematology Oncology, Birmingham, USA; [2]Sanofi, Evidence Based Medicine, Bridgewater, USA; [3]Sanofi, Evidence and Value Development, Cambridge, USA; [4]Sanofi, Medical Affairs Oncology, Bridgewater, USA*

Background: New treatment options for metastatic CRPC have emerged over the last 3 years for post-docetaxel (D) therapy including cabazitaxel (C), abiraterone acetate (AA) and enzalutamide. AA is also approved for use in chemo naive patients. Oral therapy poses challenges such as adherence. Our study aimed to study dose intensity and persistence with AA in pre-D as well as post-D men using real world data and to evaluate the frequency of administration of chemotherapy post-AA.

Methods: mCRPC patients were identified from 1Jan2010 through 30June2012 using a large US national claims based database. The number of days of drug supply was calculated from quantity and dosage information associated with each prescription record. All patients initiated AA in 2011 and those with a gap of 2 months or more after last AA dose were considered discontinued. Study subjects were censored at the time of loss to follow-up or treatment discontinuation, whichever occurred first. MPR (Medication possession ratio) was defined as total AA days divided by days from initiation of AA to censoring. Persistence was defined as average length of continuous therapy duration for AA initiators. The cumulative persistence rate was estimated using Kaplan Meier analysis. Results were stratified by pre and post D group. Post AA regimen usage was determined in patients who discontinued AA by Dec 2011.
Results: Median age was 72 years. Median number of monthly AA refills was 4. MPR was similar in post-D (0.69) and pre-D (0.67) group. In pre-D setting, 421 patients initiated AA of which 137 (32.5%) discontinued AA within 3 months and 244 (58%) discontinued within 6 months. In post-D setting, 313 patients initiated AA of which 94 (30%) discontinued within 3 months and 118 (60.1%) discontinued within 6 months. In the evaluable pre-D group (N = 74), use of D and/or C post-AA occurred in 31.1% of patients. In the evaluable post-D group (N = 34), 44% of patients received D and/or C post-AA.
Conclusion: The observed persistence and dose intensity of AA for mCRPC patients in a real world setting suggest that better patient selection is warranted to address disease and patient heterogeneity and examination of factors responsible for suboptimal adherence may be important. The rate of post-AA chemotherapy with D and/or C appears low. Given the limitations of observational study design, further prospective research into patient profiles who discontinue AA, optimal sequencing of agents and the discovery of predictive biomarkers is required.

Clinical study of autologous dendritic cell therapy targeting mucin 1 for treatment of ovarian cancer patients in first remission

J. Goh[1], C. CAN-003 Study Team[2], S.E. Gargosky[3], H. Gray[4].
[1]Greenslopes Private Hospital, Brisbane Queensland, Australia; [2]USA and Australian, Clinical trial sites, USA, Australia; [3]Prima BioMed, Clinical Development, Sydney, Australia; [4]University of Washington Medical Center, Division of Gynecologic Oncology, Washington, USA

Background: Cvac is an autologous cellular therapy targeted to elicit a T cell response to tumors that over-express mucin 1 such as epithelial ovarian cancer (EOC). CAN-003 is a phase 2b study evaluating the effect of Cvac on progression free and overall survival, as well as safety and immune responses, in patients in remission from EOC.
Design: Patients were eligible if they had stage III or IV EOC and obtained a complete response to standard first or second line platinum/ taxane based chemotherapy. The first 7 patients received Cvac to allow evaluation of manufacturing in the US and for safety evaluation. Patients were then randomized either to Cvac therapy or standard of care (SOC). Patients in the active group were treated with up to 10 doses of Cvac, 4 weekly for 7 doses, and 8 weekly for three additional doses. The trial is closed to enrolment and will be completed in 2013.
Results: 63 patients were enrolled into the trial; 36 Cvac and 27 SOC of which 42 were in first remission and 21 were in second remission. Patients were mostly Caucasian; 1 was African American and 2 were Asian.
10 SAEs were reported in total. 7 SAEs in Cvac patients and 3 SAEs were reported in SOC; none were unexpected and only one (abdominal pain) was classified as possibly-related to Cvac.
Interim analysis has shown positive trends in PFS; as of 17 August 2012, the median PFS for days on study as 365 days for Cvac, 421 day for non-randomized Cvac, and 321 days for OSC. Updated PFS data will be presented at the meeting. As expected, assessment of anti-mucin-1 responses have indicated no humoral response, however, interim immune results show a T cell response that was mucin 1-specific after 3 Cvac doses. T-cell responses throughout the course of Cvac treatment will be presented at the meeting.
Conclusion: Study data show that immunotherapy with Cvac is well tolerated. Immunological outcomes are consistent with the mechanism of action and the interim trends are encouraging for PFS.
No conflict of interest.

Vintafolide therapy shows greater efficacy in patients with folate receptor positive tumors selected by 99mTc-etarfolatide

R.W. Naumann[1], R.A. Burger[2], E.A. Sausville[3], E. Kutarska[4], S.A. Ghamande[5], S.E. DePasquale[6], E. Nowara[7], J.T. Symanowski[8], C. Lovejoy[9], R.L. Coleman[10]. *[1]Levine Cancer Institute, Division of Gynecologic Oncology, Charlotte North Carolina, USA; [2]Fox Chase Cancer Center, Division of Gynecologic Oncology, Philadelphia, USA; [3]Greenebaum Cancer Center, Division of Oncology, Baltimore, USA; [4]Centrum Onkologii Ziemi Lubelskiej, Division of Oncology, Lubland, Poland; [5]Georgia Health Sciences University, Division of Oncology, Augusta, USA; [6]Chattanooga's Program in Women's Oncology, Division of Oncology, Chattanooga, USA; [7]Instytut im. Marii Sklodowskiej-Curie, Division of Oncology, Gliwice, Poland; [8]Levine Cancer Institute, Carolinas Medical Center, Charlotte, USA; [9]Endocyte Inc., Clinical Oncology, West Lafayette, USA; [10]MD Anderson Cancer Center, Gynecologic Oncology, Houston, USA*

Background: Folate drug conjugates can target tumor cells overexpressing membrane bound folate receptor (FR) present on most ovarian cancers (OC) but not other tissues. ^{99m}Tc-etarfolatide (ETAR) allows for real-time tumor imaging of FR expression. This companion agent was investigated in the randomized phase 2 PRECEDENT trial* which demonstrated that the desacetylvinblastine folate conjugate vintafolide (VINTA) combined with pegylated liposomal doxorubicin (PLD) improved PFS over standard therapy in platinum-resistant OC (PROC) patients (pts) (NCT00722592). We now analyse the efficacy of VINTA+PLD in pt subgroups from this trial.
Methods: Women with PROC, ECOG PS of 0−2, and $\leqslant$2 prior systemic cytotoxic regimens were randomized 2:1 to VINTA+PLD or PLD alone. Before randomization, pts were scanned with ETAR to determine FR status. The primary endpoint was progression free survival (PFS) in the ITT population of pts with measureable disease (mITT). The internal consistency of the VINTA+PLD benefit over PLD was evaluated in subgroups defined by baseline pt and disease characteristics (ie, CA-125 levels, PS, etc).
Results: Demographic characteristics at screening were generally balanced between arms. Over 80% of pts scanned with ETAR were FR positive (FR+). Outcomes favored VINTA+PLD over PLD for all subgroups defined by typical baseline factors; hazard ratios for those subpopulation groups were generally close to that of the mITT population (HR = 0.626, 0.409–0.959 95% CI, $P = 0.031$), ranging from 0.524 to 0.794. The most notable benefit was seen in the subgroup of pts identified as FR(100%) (all identified lesions FR+) by ETAR scan. These pts had greater benefit from VINTA+PLD (HR = 0.381, 0.172–0.845 95% CI, $P = 0.013$) vs pts with $\geqslant$1 or 0 FR+ lesions (HR = 0.547, 0.304–0.983 95% CI, $P = 0.041$ and 1.806, 0.369–8.833 95% CI, $P = 0.468$, respectively). Of note, FR+ tumors not treated with VINTA progressed more rapidly than FR negative tumors (~1.7 months vs 5.4 months), supporting FR expression as an adverse prognostic factor. All AEs were grade 4 or lower and most were grade 1−2. Fatigue, anemia, stomatitis, nausea were commonly reported. AEs were generally similar between groups.
Conclusions: VINTA+PLD is the first combination to show improved PFS over standard therapy in PROC. The subgroup analysis indicates selection for pts likely to benefit from therapy with VINTA can be achieved using a companion diagnostic agent such as ETAR. A randomized phase 3 trial is ongoing.

Olaparib plus chemotherapy, followed by maintenance monotherapy, in women with platinum-sensitive recurrent serous ovarian cancer (PSR SOC): BRCA1/2 mutation (BRCAm) and interim overall survival analyses

A.M. Oza[1], D. Cibula[2], A. Oaknin Benzaquen[3], C.J. Poole[4], R.H.J. Mathijssen[5], G.S. Sonke[6], H. Mackay[1], E.S. Lowe[7], J. Read[8], M. Friedlander[9]. *[1]Princess Margaret Hospital, Toronto, Canada; [2]General University Hospital, Prague, Czech Republic; [3]Vall d'Hebron University Hospital, Barcelona, Spain; [4]University Hospitals Coventry and Warwickshire NHS Trust, Coventry, United Kingdom; [5]Erasmus University Medical Center, Rotterdam, Netherlands; [6]Antoni van Leeuwenhoek Hospital–Netherlands Cancer Institute, Amsterdam, Netherlands; [7]AstraZeneca, Wilmington DE, USA; [8]AstraZeneca, Macclesfield, United Kingdom; [9]Prince of Wales Hospital, Randwick, Australia*

Background: We have shown that addition of the oral PARP inhibitor olaparib (200 mg BID capsules on days 1−10 per 21-day treatment cycle)

to carboplatin AUC4 plus paclitaxel, followed by olaparib 400 mg BID as maintenance monotherapy (OC4P), led to a statistically significant improvement in progression-free survival (PFS) vs carboplatin AUC6 plus paclitaxel alone, followed by no maintenance therapy (C6P), in patients (pts) with PSR SOC (Oza *et al* ASCO 2012). Here, we report results of an interim overall survival (OS) analysis and a prespecified exploratory analysis of efficacy by BRCAm status from this open-label, randomized Phase II trial (NCT01081951; sponsor, AstraZeneca).

Materials and Methods: Germline BRCAm status was known for 35/162 pts at study entry. Tumour BRCAm status was determined for 91 pts by retrospective testing of archival samples. Efficacy outcomes for BRCAm analyses: PFS by central review (RECIST 1.1); PFS2 (time to start of second subsequent therapy after first progression, or death). OS was a secondary endpoint.

Results: Of 162 pts randomized (81 per arm), 156 were treated (OC4P, n = 81; C6P, n = 75) and 121 began the maintenance/no further therapy phase (OC4P, n = 66; C6P, n = 55). BRCAm status was known for 107/162 pts, of whom 41 (38%) had a BRCAm; 7 more had BRCAm of unknown significance. A greater PFS benefit with OC4P vs C6P was seen in pts with BRCAm (HR = 0.21; 95% CI 0.08–0.55; $P = 0.0015$) vs pts with no BRCAm/BRCAm of unknown significance (HR = 0.77; 95% CI 0.41–1.44). In the overall population, there was no statistically significant difference between arms in interim OS (38% maturity: HR = 1.37; 95% CI 0.82–2.27; $P = 0.2238$; medians not reached); this analysis was potentially affected by an imbalance in early censoring (OC4P, n = 2; C6P, n = 15) after 16 pts withdrew consent (1 pt lost to follow up). In pts with BRCAm, but not the overall population, a retrospective assessment of PFS2 showed an improvement with OC4P vs C6P (HR = 0.35; 95% CI 0.13–0.88; $P = 0.0258$). OS analyses have yet to be performed by BRCAm status (insufficient events in pts with a BRCAm).

Conclusions: Olaparib plus carboplatin AUC4 and paclitaxel, followed by maintenance monotherapy, led to the greatest clinical benefit in pts with BRCAm. An interim OS analysis in all pts showed no benefit in the OC4P arm, but the PFS2 improvement in pts with BRCAm suggests the benefit is maintained beyond first progression in this subgroup. Olaparib maintenance therapy will be evaluated in two Phase III trials in ovarian cancer pts with BRCAm.

Quality of life in patients with advanced epithelial ovarian, fallopian tube, or primary peritoneal cancer (AEOC) receiving either pazopanib monotherapy or placebo after first-line chemotherapy: AGO-OVAR16 results

M. Friedlander[1], S. Knoll[2], W. Meier[3], A. Lesoin[4], J.W. Kim[5], A. Poveda[6], M. Buck[7], G. Scambia[8], M. Shimada[9], A. Du Bois[10]. [1]*The Prince of Wales Cancer Center, Medical Oncology, Randwick New South Wales, Australia;* [2]*GlaxoSmithKline, GHO Oncology, Collegeville, USA;* [3]*Evangelisches Krankenhaus, Department of Gynecology & Obstetrics, Duesseldorf, Germany;* [4]*Centre Oscar Lambret, Oncology, Lille, France;* [5]*Seoul National University, Department of Obstetrics and Gynecology, Seoul, Korea;* [6]*Fundación Instituto Valenciano de Oncología, Department of Medical Oncology, Valencia, Spain;* [7]*Sir Charles Gairdner Hospital, Medical Oncology, Nedlands, Australia;* [8]*Universita Cattolica del Sacro Cuore Policlinico Gemelli, Medical Oncology, Rome, Italy;* [9]*Tottori University Hospital, Medical Oncology, Tottori, Japan;* [10]*Kliniken Essen Mitte, Department of Gynecology & Gynecologic Oncology, Essen, Germany*

Background: Results of the double-blind, randomized, placebo-controlled phase 3 trial AGO-OVAR16 (VEG110655) indicate that pazopanib monotherapy prolongs progression-free survival (PFS) in women without disease progression after first-line chemotherapy for AEOC (HR = 0.766, P=.0021; median PFS 17.9 months [M] vs placebo 12.3 M). The impact of treatment and correlation of disease progression on health-related quality of life (HRQL) was also assessed.

Materials and Methods: HRQL was measured with EQ-5D, EORTC QLQ-C30 (QLQ30), and the ovarian cancer module (OV28) at baseline (BL) and day 1 of week (W) 13 and M 7, 10, 13, 16, 25, and 31. For patients who discontinued treatment early, regardless of reason, HRQL was also measured at end-of-treatment and first post-treatment visits. For patients on treatment, mean changes from BL were compared between treatment groups via mixed-model repeated measures analysis of covariance. After disease progression (RECIST), data of the first available assessment were pooled and described by summary statistics.

Results: 894 patients had BL HRQL scores. Patient compliance with HRQL assessment was high, ranging from 97% at BL to 76% at M25 for all scales except OV28 'sexual functionality' and 'other chemotherapy side effects' that were excluded from the analysis. The QLQ30 Global Health Status (GHS) remained constant on placebo up to M25 but declined on pazopanib. Between-arm differences on the GHS were statistically significant but were less than or at the low end of the range of published minimally important difference (MID 5−10 points, Table). Treatment differences favoring placebo on the EQ-5D were statistically significant and below the MID (0.08 points). Similar results were obtained for the OV-28 scales, except for abdominal/GI symptoms, which substantially favored placebo.

Table: Treatment difference (pazopanib minus placebo scores) in GHS change from BL

Time point	W13	M7	M10	M13	M16	M25
Δ score	−4.4	−5.6	−6.3	−2.4	−0.4	−5.5
P	<0.001	<0.001	<0.001	0.185	0.847	0.024

After disease progression, GHS and EQ-5D changes from BL were worse than scores observed for patients with no disease progression, as were 12 of 14 QLQ30 subscales and all functional scales of the OV28.

Conclusions: Pazopanib monotherapy maintenance treatment in AEOC is associated with a small, statistically significant decline in HRQL during treatment. However, the treatment, which delays progression by 5.6 M, may also delay the further declines in HRQL that are associated with disease progression.

Adjuvant radio(chemo)therapy in lymph-node positive vulvar cancer − The AGO CaRE-1 study

C. Petersen[1], L. Woelber[2], J. Jueckstock[3], P. Neuser[4], F. Hilpert[5], N. De Gregorio[6], A. Hasenburg[7], J. Sehouli[8], A. Habermann[9], S. Mahner[2]. [1]*Universitätsklinikum Hamburg-Eppendorf, Radiation Oncology, Hamburg, Germany;* [2]*Universitätsklinikum Hamburg-Eppendorf, Gynecology, Hamburg, Germany;* [3]*Klinikum der Universität München LMU, Gynecology, Muenchen, Germany;* [4]*Koordinierungszentrum für Klinische Studien, KKS, Marburg, Germany;* [5]*Universitätsklinikum Schleswig-Holstein Campus Kiel, Gynecology, Kiel, Germany;* [6]*Universitätsklinikum Ulm, Gynecology, Ulm, Germany;* [7]*Universitätsklinikum Freiburg, Gynecology, Freiburg, Germany;* [8]*Charité Campus Virchow Klinikum, Gynecology, Berlin, Germany;* [9]*Universitätsklinikum Magdeburg, Gynecology, Magdeburg, Germany*

Background: While the majority of patients with vulvar cancer can be cured by surgery alone, women with lymph-node metastases often show unfavorable outcome. It is not clear whether postoperative (chemo)radiotherapy improves outcome in all patients with lymph-node positive vulvar carcinoma compared to surgery alone.

Material and Methods: Patients with primary squamous-cell vulvar cancer treated at 29 gynecologic cancer centers in Germany 1998–2008 were included in a centralized database and analyzed retrospectively to examine clinical outcome and relapse patterns.

Results: A total of 1,618 patients were documented with a median follow-up of 38.8 months. UICC-stage distribution was 580 (35.9%) T1b, 818 (50.6%) T2, 160 (9.9%) T3 and 31 (1.9%) T4; in 29 (1.8%) cases the tumor stage was unknown. 495 patients (30.6%) had lymph-node metastases (N+). Median progression-free survival (PFS) of these patients was 15.9 months and overall survival (OS) 46.9 months, compared to 99.1 and 208.8 months for node-negative patients. 172 (34.8%) patients had 1, 102 (20.6%) patients 2, 62 (12.5%) patients 3 and 87 (17.6%) patients >3 positive lymph-nodes (for 72 (14.6%) patients the number was unknown). 254 (51.3%) N+ patients underwent adjuvant radio/chemotherapy (212 [83.5%] received radiotherapy alone, 36 [14.2%] radiochemotherapy and 6 [2.4%] chemotherapy only). Median PFS and OS in these patients were significantly longer compared to N+ patients without adjuvant treatment [PFS: 18.5 vs. 12.0 months, p = 0.0003, HR 0.63 (95% CI: 0.50–0.81); OS: 111.6 vs. 37.1 months, p = 0.029, HR 0.71 (95% CI: 0.52–0.97)]. This effect could be observed in all node-positive subgroups and remained consistent in multivariate analysis of all N+ patients adjusted for age, ECOG, UICC-stage, grade, invasion depth and number of positive nodes (PFS: HR 0.57, 95% CI: 0.43–0.74; OS: HR = 0.61, 95% CI: 0.43–0.86).

Conclusions: This large multicenter study in vulvar cancer shows that prognosis of node-positive patients was improved with adjuvant radiotherapy but still remains poor compared to the outcome of node-negative

patients. In other squamous cell carcinomas, adjuvant chemoradiation is superior to radiotherapy alone; this approach might therefore be the best to further improve outcome in vulvar cancer. In addition, definitions of standardized radiation treatment protocols according to field arrangements need to be determined.

Vaginal brachytherapy versus external beam pelvic radiotherapy for high-intermediate risk endometrial cancer: Long term results of the randomized PORTEC-2 trial

R.A. Nout[1], H. Putter[2], I.M. Jürgenliemk-Schulz[3], J.J. Jobsen[4], L.C.H.W. Lutgens[5], E.M. Van der Steen-Banasik[6], J.W.M. Mens[7], A. Slot[8], V.T.H.B. Smit[9], C.L. Creutzberg[1]. *[1]Leiden University Medical Centre, Clinical Oncology, Leiden, Netherlands; [2]Leiden University Medical Centre, Biostatistics, Leiden, Netherlands; [3]University Medical Centre Utrecht, Radiation Oncology, Utrecht, Netherlands; [4]Medisch Spectrum Twente, Radiotherapy, Enschede, Netherlands; [5]MAAStricht Radiation Oncology Clinic, Radiation Oncology, Maastricht, Netherlands; [6]Radiotherapy Institute Arnhem, Radiotherapy, Arnhem, Netherlands; [7]Daniel den Hoed Cancer Center, Radiation Oncology, Rotterdam, Netherlands; [8]Radiotherapy Institute Friesland, Radiotherapy, Leeuwarden, Netherlands; [9]Leiden University Medical Centre, Pathology, Leiden, Netherlands*

Background: For endometrial cancer (EC) patients with features of high-intermediate risk (HIR), the vagina is the most frequent site of recurrence after surgery alone. Pelvic external beam radiotherapy (EBRT) reduces the risk of vaginal and pelvic recurrence, but without survival benefit. PORTEC-2 was the first randomized trial comparing the efficacy of vaginal brachytherapy (VBT) and EBRT. At a median follow-up of 45 months the results indicated that VBT is highly effective in ensuring vaginal control with fewer side effects and better health-related quality of life than EBRT. The current analysis was done to evaluate long-term results.
Methods: The PORTEC-2 trial was a multicenter randomised trial. After surgery, patients were allocated (1:1) to pelvic EBRT or VBT. Eligible patients had a HIR EC: age >60 and (FIGO 1988) stage 1C grade 1−2 or stage 1B grade 3; any age and stage 2A. Primary endpoint was vaginal recurrence (VR), which was expected to be 2% at 3 yrs in the EBRT group. The trial was powered (85%) to detect a clinical relevant absolute difference of 6% in VR (2% vs. 8% at 3 years). Analysis was done by intention-to-treat, using the competing risk method for VR, pelvic (PR) and locoregional recurrence (LRR, defined as vaginal and/or pelvic recurrence) and distant metastasis (DM), and Kaplan Meier for overall (OS) and disease free survival (DFS).
Results: 427 patients were randomized between 2002–2006 (214 to EBRT and 213 to VBT). At a median follow-up of 85 months, 5-year total actuarial rates of VR were 2.4% in the VBT arm versus 1.4% after EBRT ($p = 0.52$); PR 5.2% vs 0.9% ($p = 0.007$); LRR 6.6% vs 2.4% ($p = 0.025$) and DM 9.3% vs 6.6% ($p = 0.37$). Five-year rates of vaginal and pelvic recurrence as first failure were 1.4% and 1.9% in the VBT group, and 0.9% and 0.5% in the EBRT group ($p = 0.41$ and $p = 0.24$). There were no significant differences in 5-year OS (83.9% vs. 83.8% $p = 0.79$) and DFS (81.1% vs. 81.9% $p = 0.57$).
Conclusions: Long-term analysis of the PORTEC-2 trial confirms that VBT is effective in preventing vaginal recurrence. Despite the significantly increased total pelvic recurrence rate in the VBT arm, most were combined with DM and rates of pelvic recurrence as first failure, distant metastases, OS and DFS were similar. As patient reported quality of life after VBT was shown to be better than after EBRT, VBT remains the treatment of choice for patients with high-intermediate risk endometrial carcinoma.

Age-related heterogeneity of ovarian epithelial carcinomas in a nationwide population (USA)

P. Grimley[1], K. Apostle[1], D.E. Henson[2], W.F. Anderson[3]. *[1]F. Edward Hebert School of Medicine, Pathology, Bethesda Maryland, USA; [2]George Washington University Cancer Institute, Canceer Control and Epidemiology, Washington District of Columbia, USA; [3]National Cancer Institute, Cancer Epidemiology and Genetics, Bethesda Maryland, USA*

Background: Ovarian epithelial carcinomas (OEC) pose significant health care problems in elderly women. While efforts have been increasing to detect genetic biomarkers and OEC therapeutic targets, potentially relevant correlations of chronological 'age-at-diagnosis' (AAD) with descriptive characteristics and clinical behaviors of these usually lethal cancers have not been fully explored in the general population.
Methods: Records accrued in the National Cancer Institute's Surveillance Epidemiology and End Results Database (SEER 18 registries, time period 2000 through 2009), yielded 51,253 cases of primary invasive OEC (~28% of the USA total). This number enabled robust linkage of three AAD subsets (<45, 45−64, >64 years) to classical descriptors: (i) stage (I−IV) standardized by the International Federation for Gynecologic Oncology (FIGO), and (ii) morphology (serous and others) and grades (1−4) recommended by the International Classification of Disease for Oncology (ICD-O-3). Age-specific IR (ASIR) estimated from AAD curves for each descriptor, and fitted for period and birth-cohort effects, tested the reported distinctions for P >.001. Stages or grades of AAD subsets then were compared using age-adjusted incidence rates (IR) and IR ratios (IRR) at P <.001. Comparisons of actuarial or Kaplan–Meier vital statistics were ovarian cancer specific.
Results: The median age of microscopically confirmed OEC (96% of total cases) was 62 years (IR=14.5): 10% of cases appeared before 45 (IR =3.0), 45% from 45−64 (IR=22), and 45% after 64 (IR= 41). FIGO stages and ICD-O-3 morphologies were documented together in 83% of confirmed cases. Grades were enumerated in 62%. Extra-pelvic OEC in FIGO stage III accounted for 42% of staged cases, but IRR of FIGO stages III−IV/I−II (extra-pelvic/intrapelvic), increased exponentially in the ascending order of AAD: 0.92, 1.8, 3.7. The IRR of high/low grades (3−4/1−2) also ascended in AAD order: 0.86, 2.0, 2.9. Serous morphology was always predominant in the high grade extra-pelvic OEC: 47%, 61%, 61%. Parsing of ovarian-specific deaths, registered within 24 months after initial OEC diagnosis, disclosed exponential AAD-dependent increases in the death IR (=0.3,= 3.7, =13), as well as in the originally ascribed IRR (III−IV/I−II): 6.9, 8.3, 11. Median months of survival per AAD subset respectively diminished: 38, 30, 14.
Conclusions: Known genetic heterogeneities in OEC have engendered the prevalent models of OEC bimodal oncogenesis and morphologic diversity. Present findings align age-at-diagnosis to stage of presentation, morphologic expression and survival duration. These signs of age-effect modifications on OEC natural history imply a chronologically determined interplay of epigenetic or host factors. AAD thus warrants integration as a critical variable in translational investigations of OEC molecular genetics or therapeutic trials.

3007 POSTER

The roles of chitinase 3 like 1 in cervical cancer in vitro

N. Ngernyuang[1], R. Francescone[2], P. Jearanaikoon[3], J. Daduang[3], W. Yan[4], R. Shao[5], T. Limpaiboon[3]. *[1]CMDL Khon Kaen University, Associated Medical Sciences, Khonkaen, Thailand; [2]University of Massachusetts Amherst, Molecular and Cellular Biology, MA, USA; [3]CMDL Khon Kean University, Associated Medical Sciences, Khonkaen, Thailand; [4]Pioneer Valley Life Sciences Institute, MA, USA; [5]Department of Molecular and Cellular Biology, University of Massachusetts Amherst, MA, USA*

Background: Chitinase 3 like 1 (CHI3L1) is a 40 kDa mammalian glycoprotein which is related in amino acid sequence to the chitinase protein family but has no enzymatic property. Several studies have reported that CHI3L1 could be used as a serum marker in patients with several solid tumours including cervical cancer (CxCa) in which high serum CHI3L1 is associated with poor prognosis and short survival time. Although functions of CHI3L1 in mediating cell proliferation, anti-apoptosis, migration, and angiogenesis have been reported in several human cancers, not all functions activated by CHI3L1 are covered in one cancer but the action is rather dependent on the cancer type. The previous study on microarray showed an increasing level of CHI3L1 in precancerous and CxCa compared with normal suggesting its role in tumour progression. Thus, this study aimed to find the virtual function of CHI3L1 which contributes to the progression of CxCa in terms of cell proliferation, migration, anti-apoptosis, and angiogenesis.
Methods: The recombinant CHI3L1 protein was produced and used for HeLa and CaSki cell treatment. The treated and untreated cells were examined for cell proliferation by MTS assay, cell survival by Live-Dead cell assay, cell migration by wound healing and transwell chemotaxis assays, and angiogenesis by Matrigel tube formation assay.
Results: The results showed that CHI3L1 could activate angiogenesis by promoting endothelial cell migration and tubular formation. Likewise, CHI3L1 could induce both of CaSki and HeLa to form vascular-like structures. In contrast, CHI3L1 could not protect apoptosis of both CxCa cell lines from gamma irradiation while cell proliferation and migration directed by CHI3L1 were dependent on type of cell line.

Conclusions: CHI3L1 protein is a potent factor in which it can induce angiogenesis through its regulation of endothelial cells. The predominant function of CHI3L1 as an angiogenic factor is worth to further investigate for its receptor which may benefit the CxCa patients in term of targeted therapy leading to the improved quality of life and longer overall disease-free survival.

3008 POSTER

Qualitative and quantitative mtDNA alterations in HPV16-positive cervical neoplasia

C. Rusanu[1], A. Botezatu[1], I. Huica[1], I. Iancu[1], A. Plesa[1], G. Anton[1]. [1]*"Stefan S. Nicolau" Institute of Virology, Molecular Biology, Bucharest, Romania*

Background: Human papillomaviruses (HPV) are known to be the etiological agents of cervical cancer which represents the second most common malignancy in women worldwide. Recently, mitochondrial DNA (mtDNA) mutations have been found in many types of cancer. Here we analysed mutations in the D-loop region of mtDNA and the relationship between mtDNA copy number, HPV16 viral load and MnSOD (manganese superoxide dismutase) mRNA expression level in HPV16-positive samples.
Material and Methods: DNAs were isolated from cervical specimens (using High Pure PCR Template, Roche Diagnostics) from 60 women with different cytology. RNAs were isolated (Trizol reagent, Invitrogen) in order to determine MnSOD mRNA expression levels. DNA PCR amplification and sequencing were used for mtDNA mutations. Real-time PCR (Applied Biosystems) was used to determine mtDNA copy number and HPV16 DNA viral load using in house designed primers.
Results: In patients with normal cytology and ASCUS (Atypical Squamous Cells of Undetermined Significance), HPV16 was absent. 72.2% (13/18) LGSIL (Low-Grade Intraepithelial Lesion) and 93.3% (14/15) HGSIL (High-Grade Intraepithelial Lesion) patients presented infection with HPV16 in single or co-infection (with HPV18, 31 and 33). We detected a significantly greater incidence of mtDNA mutations in D-loop region in LGSIL and HGSIL patients ($P<0.05$). HPV16-positive individuals were more likely to carry mtDNA mutations than HPV-negative controls ($P<0.003$). Furthermore, mtDNA copy number increased during lesion development when compared to control samples. We also observed MnSOD mRNA upregulation during cervical lesion development, from normal epithelium to HGSIL. Moreover, HPV16 viral load was significantly higher in HGSIL patients than in ASCUS/LGSIL and was strongly associated with the increased MnSOD mRNA level ($p < 0.005$).
Conclusions: These findings suggest that mtDNA alterations might be cofactors involved in HPV-induced cervical dysplasia. MtDNA mutations and copy number increase could play a role in cervical precursor lesions and cancer but their role in the mechanism of carcinogenesis remains to be solved.

3009 POSTER

Ubiquitin-proteasome system is activated by oxidative stress and contributes to docosahexaenoic acid-induced degradation of oncogenic HPV E6/E7 viral proteins

K. Jing[1], S. Shin[1], S. Jeong[1], S. Kim[1], J.I. Park[2], G.R. Kweon[2], S.K. Park[2], W.H. Yoon[2], B.D. Hwang[2], K. Lim[3]. [1]*Chungnam National University Medical School, Biochemistry and Infection Signalling Network Research Center, Daejeon, Korea;* [2]*Chungnam National University Medical School, Biochemistry, Daejeon, Korea;* [3]*Chungnam National University Medical School, Biochemistry and Cancer Research Institute and Infection Signalling Network Research Center, Daejeon, Korea*

Background and Aims: Oncogenic human papillomavirus (HPV) E6/E7 proteins are essential for the onset and maintenance of HPV-associated malignancies. The aim of the present study was to investigate whether and how the omega-3 fatty acid, docosahexaenoic acid (DHA) influences E6/E7 viral proteins and the fate of oncogenic HPV-infected cells.
Material and Methods: Oncogenic HPV-infected cell lines and the cell lines transiently or stably expressing different ubiquitin-proteasome system (UPS) reporters that reflect UPS activity were exposed to DHA, and the relationship between E6/E7 oncoproteins, mitochondrial reactive oxygen species (ROS) and cell death were monitored using various in vitro approaches.
Results: DHA diminished E6/E7 protein levels in a time-dependent manner and led to functional restoration of known E6/E7 binding targets, p53 and retinoblastoma tumour suppressors, and apoptosis in oncogenic HPV-infected cancer cells. Additionally, DHA exposure increased the ubiquitination and proteasomal degradation of E6/E7 oncoproteins as well as three different UPS reporter substrates, and UPS inhibition abrogated these effects of DHA, suggesting that E6/E7 viral proteins undergo cellular UPS-mediated degradation in response to DHA via augmented global UPS activity. Further study showed that DHA-induced mitochondrial ROS overproduction was responsible for the increases in UPS activity and degradation of E6/E7 oncoproteins. Meanwhile, exogenous oxidative stress and pharmacological induction of mitochondrial ROS had similar effects as DHA, and inhibition of ROS abolished the increased intracellular UPS activity, destabilization of E6/E7 viral proteins, and apoptosis.
Conclusions: We propose that by promoting mitochondrial ROS production, DHA enhances the global UPS activity and simultaneously accelerates UPS-dependent destruction of oncogenic HPV E6/E7 viral proteins, thereby inducing apoptosis in HPV-infected cancer cells. These findings unravel a novel function of DHA in UPS regulation, and provide evidence for use DHA as a mechanistically unique anticancer agent to treat HPV-associated tumours.

Interleukin-17 produced by tumour microenvironment promotes self-renewal of CD133+ cancer stem-like cells in ovarian cancer

B. Zhu[1], T. Xiang[1]. [1]*Institute of Cancer, Xinqiao Hospital Third Military Medical University, Chongqing, China*

Background: Inflammatory cytokines have been proposed to be the components of niche for cancer stem cells (CSCs), and could affect the characteristics of CSCs, such as self-renewal and metastasis. IL-17 mainly produced by Th17 and macrophages is a new pro-inflammatory cytokine, and has been proved one of markers for the poor prognosis in ovarian cancer. However, the effects of IL-17 on the characteristics of CSCs remain to be explored. Our present study is aimed to explore the effects and the mechanisms of IL-17 on self-renewal of CSCs in ovarian cancer.
Material and Methods: Ovarian CSCs (OCSCs) were obtained from A2780 cell line by serum-free culture selection and from primary tumour tissues of ovarian cancer by CD133-labeled magnetic activated cell sorting (MACS). IL17 receptor (IL-17R) expression on OCSCs was verified by real-time PCR, flow cytometric and immunofluorescence analysis in A2780-derived OCSCs and primary OCSCs respectively. The sources and location of IL-17-positive cells were defined by immunohistochemistry and immunofluorescence. Sphere formation assay was used to determine the ability of self-renewal of CSCs before and after treatment of recombinant IL-17. Western blot and immunofluorescence were used to determine the activity of NF-κB and P38 MAPK signalling mediated by IL-17. Downstream genes of NF-κB and P38 MAPK signalling were analysed by gene expression profiling and verified by real-time PCR.
Results: IL-17-positive cells (CD4-positive cells or CD68-positive macrophages) located in the niche of OCSCs in ovarian cancer. Also, Real-time PCR, flow cytometric and immunofluorescence analysis showed IL-17R expression on OCSCs both from A2780 cell line and primary ovarian cancer tissues. More importantly, the growth and sphere formation capacities of OCSCs were significantly enhanced by recombinant IL-17 in a dose-dependent manner, or when OCSCs were transfected with IL-17. Subcutaneous transplantations of IL-17-OCSCs into nude mice showed greater tumorogenic capacity than vector-OCSCs. To elucidate the underlying mechanisms of IL-17 on self-renewal of OCSCs, we explored NF-κB and P38 MAPK activation in OCSCs by IL-17 treatment and found IL-17 really did activate NF-κB and P38 MAPK, which also proved by the inhibition of IL-17 role on self-renewal of OCSCs by specific inhibitor to NF-κB and P38 MAPK. To gain further insights into which target genes involved in IL-17-induced OCSCs self-renewal, we did gene profiling in OCSCs changed by IL-17 and found that 14 downstream genes (GATA6, ZIC3, IRX4, STAT3, HOXD9, FOXO3, PAX6, TP53, ETV5, SP1, NFATC1, BCL2 SOX2, TCL1A) might mediate IL-17-enhanced self-renewal of OCSCs.
Conclusions: Our present results indicate that IL-17 signalling contributes to ovarian cancer malignancy through the promotion of OCSCs self-renewal, and that targeting IL-17 may offer benefit for the patients with ovarian cancer.
No conflict of interest.

3011 POSTER

Effect of hypoxia, glucose deprivation and glycogen phosphorylase inhibition on ovarian clear cell cancer cell line proliferation

I. Gounaris[1], J. Xian[1], J.D. Brenton[1]. [1]*University of Cambridge, CRUK Cambridge Institute, Cambridge, United Kingdom*

Background: The hypothesis that ovarian clear cell cancer (OCCC) cell lines are resistant to hypoxia and glucose deprivation, possibly because of their high glycogen content was tested.

Methods: 10 ovarian cancer cell lines (PEO1m, ES-2, OV2008, SKOV3, TR175, TOV21G, JHOC-5, JHOC-7, JHOC-9 and OVISE) were cultured under 4 conditions: normal (21% Oxygen, standard DMEM media), hypoxia (1% Oxygen), glucose deprivation (glucose-free DMEM) and combined hypoxia and glucose deprivation and proliferation was assessed using the Sulphorhodamine B (SRB) assay after 7 days in culture. Glycogen content was assayed in 6 cell lines (PEO1m, TOV21G, SKOV3, JHOC-5, JHOC-9 and OVISE) and the effect of siRNA knock-down of glycogen phosphorylase (PYGL) on proliferation was measured with SRB assays.
Results: Glucose deprivation decreased proliferation by 43% in the 5 validated OCCC cell lines (TOV21G, JHOC-5, JHOC-7, JHOC-9 and OVISE) and by 57% in the 5 non-OCCC cell lines ($p = 0.42$). Hypoxia decreased proliferation by 32% in the OCCC compared with 28% in the non-OCCC cell lines ($p = 0.79$). Combined hypoxia and glucose deprivation decreased proliferation by 64% in the OCCC and by 82% in the non-OCCC cell lines ($p = 0.34$). The non-significant differences in response to glucose deprivation, with or without hypoxia, were driven entirely by JHOC-7 which did not show any decrease in proliferation under those conditions. Similarly, there was no difference in proliferation when the comparison was between the 5 OCCC cell lines and the 2 high-grade serous cell lines (PEO1m and TR175). Glycogen content was 5−6-fold higher in SKOV3, JHOC-5 and OVISE ('glycogen-rich') compared with PEO1m, TOV21G and JHOC-9 ('glycogen poor'). Proliferation was reduced to a similar extent under the 4 culture conditions in the glycogen-rich and glycogen-poor cell lines ($p = 0.72–0.79$). When cultured under normal conditions, siRNA PYGL knockdown reduced proliferation by 78% in PEO1m, 65% in TOV21G, 44% in SKOV3, 34% in JHOC-9 and 42% in OVISE cells ($p = 0.0001–0.006$).
Conclusions: Contrary to prior reports, OCCC cell lines are not more resistant to hypoxia or glucose deprivation than other ovarian cancer cell lines. High glycogen content does not predict resistance to glucose deprivation. Access to glycogen stores is important for proliferation in these cell lines even when there is plentiful glucose in the media. Targeting glycogen could be a novel therapeutic strategy in OCCC.
No conflict of interest.

3012 POSTER

Development of a prognostically relevant "angiogenic signature" in ascites from patients with advanced ovarian cancer

S.P. Trachana[1], N.G. Gavalas[1], E. Pilalis[2], A. Papatheodorou[3], A. Chatziioannou[2], O. Papadodima[2], E. Terpos[1], M.A. Dimopoulos[1], A. Bamias[1]. *[1]University of Athens, Clinical Therapeutics, Athens, Greece; [2]Institute of Biology Medicinal Chemistry & Biotechnology, Metabolic Engineering and Bioinformatics Program, Athens, Greece; [3]251 Hellenic Air Force & VA General Hospital, Department of Endocrinology and Diabetes, Athens, Greece*

Background: The main purpose of the proposed project is to use the expression of angiogenic factors in of ascites from patients with ovarian cancer, in order to establish an 'angiogenic profile' which can be used to predict response to chemotherapy as well as anti-angiogenic therapy.
Materials and Methods: Twenty samples of supernatant from ascites (10 from platinum sensitive and 10 from platinum resistant patients) were analyzed using a Protein Arrays method. Proteome Profiler Array Kit® has been used to detect 55 angiogenic factors in every sample. The results were analysed using a densitometry program, and the factors exhibiting statistically significant difference were detected. ELISA was used to confirm the results.
Results: Protein Arrays highlighted 16 factors with statistically significant difference between patients resistant to platinum chemotherapy compared to the chemosensitive ones. Nine factors with statistically significant difference relevant to Chemoresistant patients (Angiogenin, Amphiregulin, Endothelin-1, HB-EGF, IGFBP − 1, IGFBP −3, Platelet Factor 4 (PF4), TIMP- 4 and VEGF), and 7 factors with statistically significant difference relevant to Chemosensitive patients (Angiopoietin-1, FGF basic, GM-CSF, IL-1β, MIP- 1α, PDGF-AB/PDGF-BB, and Thrombospondin-2). Nine factors were examined using ELISA in the same samples (Angiogenin, Angiopoietin-1, TIMP- 4, IL-1β, Endothelin-1, IGFBP −3, MIP- 1α, Angiopoietin-2 and VEGF). Seven factors out of nine were in agreement with the Arrays results (Angiopoietin-1, TIMP- 4, IL-1β, Endothelin-1, MIP- 1α, Angiopoietin-2 and VEGF). Finally, using suitable bioinformatics software 8 additional random samples were characterized as sensitive/resistant with over 75% success and 98% accuracy, in predicting resistance/sensitivity.
Conclusion: There is a strong indication that our Arrays method is able to demonstrate an 'angiogenic signature' for predicting response to chemotherapy.
No conflict of interest.

3013 POSTER

Ovarian cancer stem cells (OCSCs): Therapy for advanced chemo-resistant ovarian cancer

I. Mondal[1], S. Mukhopadhyay[2], P. Sengupta[3], U.K. Ray[4], A. Mukhopadhyay[5]. *[1]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Clinical Research, Kolkata, India; [2]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Molecular Biology, Kolkata, India; [3]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Cell Biology, Kolkata, India; [4]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Pathology, Kolkata, India; [5]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Haematological Oncology, Kolkata, India*

Background: Invasive and mesenchymal property of Ovarian Cancer Stem Cells (OCSCs) with CD44+/CD133+ has made them promising target for targeted treatment. Chemotherapy treatment uses medicine to weaken and destroy cancer cells in body, including cells at original cancer site and any cancer cells that may have spread to another part of body. Chemotherapeutic drugs for advanced chemo-resistant ovarian cancer are yet to be well defined. Combination of drugs is also not fully known. Our objective is to define chemotherapeutic drugs and its action in OCSC which is the major reason for chemo-resistance in case of advanced chemo-resistant ovarian cancer patients.
Methods: A total of forty biopsy proven advanced chemo-resistant ovarian cancer patients in the age group of 22−36 years were selected randomly and tested for CD44/CD133 via flowcytometry. Isolated OCSCs were cultured for ex vivo drug sensitivity towards Platinum, Anthracyclin, Docetaxel, Rapamycin, Sunitinib, Sorafenib and Gefitinib. Correlation was drawn between cell differentiations, % of stem cells and drug response. Accordingly chemotherapy was designed for a particular patient.
Results: We detected OCSCs in 90% of cases. Among positive samples ex vivo drug sensitivity was seen in 8(20%) to Rapamycin, 2(5%) to Sunitinib, 2(5%) to Sorafenib, 2(5%) to Gefitinib, 6(15%) to Platinum, 2(5%) to Anthracyclin, 2(5%) to Docetaxel and rest showed no sensitivity to any drug.
Conclusions: Thus primary aim to target OCSCs at onset of tumors in ovarian cancer patients to control metastasis and relapse of disease was somewhat obtained. Most interestingly, we found that the chemotherapeutic drugs which were less prescribed for ovarian cancer showed greater sensitivity in comparison to the widely used ones. We like to do Animal model study followed by Phase I, II and III Human Clinical Trial to establish our hypothesis for better management of chemo-resistant ovarian cancer.

3014 POSTER

MicroRNA-145, a p70 S6 kinase-activated microRNA, regulates N-cadherin expression and epithelial–mesenchymal transition

S. Lam[1], A. Wong[1]. *[1]University of Hong Kong, School of Biological Sciences, Hong Kong, Hong Kong*

Background: Ovarian cancer is highly metastatic with a poor prognosis (5-year survival <25%), and understanding the underlying mechanisms is of obvious importance. Epithelial–mesenchymal transition (EMT) has been identified as of potential importance in ovarian cancer metastasis. N-cadherin is critically involved in the EMT. Yet, very little is known about the factors regulating N-cadherin expression. Recently, we demonstrated that p70 S6 kinase ($p70^{S6K}$), a downstream effector of phosphatidylinositol 3-kinase/Akt, which is frequently activated in ovarian carcinoma, plays a key role as intracellular signaling mediator for the effects of multiple growth factors in the tumor microenvironment. However, the molecular details of how $p70^{S6K}$controls the malignant properties are still poor understood.
Material and Methods: Expression of Twist, SOX9, and N-cadherin expression was measured by reverse transcription-PCR. The functional effects of $p70^{S6K}$ were examined further using overexpression and knockdown approaches. The putative microRNA (miRNA) was investigated by in silico prediction. A luciferase reporter assay was conducted to confirm miRNA-target interaction.
Results: Here we show that $p70^{S6K}$is a pivotal regulator of N-cadherin, which was mediated through activation of the transcription factors Twist and Sox9. Interestingly, we found that upregulation of Twist and Sox9 was due to increased mRNA stabilities. Using multiple in silico algorithms, we showed that miR-145 may play a critical role in regulating Twist and Sox9. We demonstrated direct targeting of miR-145 to the 3'-untranslated regions of Twist and Sox9. Notably, overexpression of miR-145 significantly suppressed, whereas inhibition of miR-145 enhanced N-cadherin expression and EMT, suggesting that inappropriate expression of miR-145 contributes to the metastatic phenotype. On exploring how $p70^{S6K}$ might regulate miR-145, we found that $p70^{S6K}$ could regulate miRNA biogenesis.

Conclusions: These results illustrate a novel regulatory role of p70^{S6K}-dependent miR-145-Twist/Sox9 signaling axis in the regulation of N-cadherin and EMT properties in ovarian cancer and could have important clinical implications.
No conflict of interest.

3015 POSTER

p70 S6 kinase promotes a critical step in ovarian cancer metastasis by modulating tumor-mesothelial cell adhesion through a P-cadherin-beta1-integrin crosstalk

K.M. Ip[1], S. Yung[2], T.M. Chan[2], G.S.W. Tsao[3], A.S.T. Wong[1]. [1]*University of Hong Kong, School of Biological Sciences, Hong Kong, Hong Kong;* [2]*University of Hong Kong, Department of Medicine, Hong Kong, Hong Kong;* [3]*University of Hong Kong, Department of Anatomy, Hong Kong, Hong Kong*

Background: Ovarian cancer is the leading cause of death of all gynecologic tumors. These deaths are largely due to the fact that most patients are diagnosed at an advanced stage. Unlike most solid tumors, ovarian cancer rarely disseminates through the vasculature but metastasizes by the implantation of tumor spheroids onto the peritoneum, and successful adhesion is the first rate-limiting step in the metastasis formation of ovarian cancer cells. This unique metastatic mechanism poses distinct therapeutic challenges, in which current treatments are not effective. Unraveling the molecular mechanisms underlying this process may lead to new therapeutic targets.
Material and Methods: We employed overexpression and knockdown approaches to investigate the molecular mechanisms of ovarian cancer spheroids which most closely mimic the *in vivo* ovarian carcinoma adhesion to human primary mesothelial cells *in vitro* and different extracellular matrix components, and utilized an intraperitoneal ovarian cancer model to test metastasis *in vivo*.
Results: Here we report a novel function of p70^{S6K} in the peritoneal adhesion of ovarian cancer cells, which is the first rate-limiting step in ovarian cancer metastasis. Ectopic expression of active p70^{S6K} significantly enhanced, whereas depletion of p70^{S6K} expression or inhibition of its activity resulted in diminished ovarian cancer spheroid adhesion to the mesothelium and specific extracellular matrix proteins. These effects were accompanied by an increase in the expression of P-cadherin and beta1 integrin. Furthermore, we provided evidence for the existence of a crosstalk between P-cadherin and beta1 integrin. In particular, we demonstrated that an upregulation of beta1 integrin occurred as a consequence of P-cadherin expression. In an attempt to establish the regulatory mechanism whereby P-cadherin exerted its transacting functions, we found that the upregulation of beta1 integrin mainly due to posttranslational events. Using an experimental metastatic mouse model, we showed that loss of p70^{S6K} significantly attenuated the metastatic spread of ovarian cancer cells to the peritoneum. Targeting the P-cadherin/beta1-integrin interplay also abolished the metastatic dissemination of ovarian cancer cells in mice.
Conclusions: These data strongly support a new function of p70^{S6K} in ovarian cancer metastasis, and provide evidence that a novel interplay between P-cadherin and beta1-integrin is essential for this process.
No conflict of interest.

3016 POSTER

Mechanism of action of the acyclic nucleotide phosphonate, cidofovir, in treatment of human papillomavirus associated neoplasia

A. Flynn[1], A. Tristram[1], T. Onions[1], N. Powell[1]. [1]*Institute of Cancer and Genetics Cardiff School of Medicine Cardiff University, Obstetrics and Gynaecology, Cardiff, United Kingdom*

Background: The acyclic nucleotide phosphonate (ANP) Cidofovir is approved for treatment of cytomegalovirus (CMV) associated retinitis. Cidofovir is also used off label for treatment of human papillomavirus (HPV) associated neoplastic lesions, especially vulval intraepithelial neoplasia (VIN). With CMV, cidofovir targets the viral polymerase, but HPV uses host cell DNA polymerase to replicate, hence in this setting the mechanism of action of the compound is unclear. This study examines the mechanism of action of cidofovir in a HPV transformed cell model designed to represent VIN.
Methods: A HPV naturally transformed short term cell line derived from a VIN biopsy and HPV negative primary human epidermal keratinocytes (HEKs) were dosed with their predetermined IC50 concentrations of cidofovir. At 12 and 36 hours post treatment cells were lysed, RNA was extracted and used to examine gene expression in apoptotic pathways by qPCR array analysis. At 12, 36 and 72 hours post treatment protein was extracted to examine cleaved caspase 3 activity via an in cell fluorescence assay. Finally, 96 hours post treatment cells were fixed, stained with Propidium Iodide (PI) and examined for cell cycle status via FACS analysis.
Results: The apoptosis qPCR array showed specific responses in the HPV positive cell line, with BCL2A1 gene upregulation and genes such as BCL2L10, BIRC3, HRK and P53 down regulated at both time points. The cleaved caspase 3 activity kit showed no significant evidence of apoptosis in the HPV transformed cell line. However, flow cytometry showed a G2-M block in the cell cycle and increases in cell size in HPV transformed cells treated with Cidofovir.
Conclusions: These data give insight in to the mechanism of action of Cidofovir in HPV associated lesions. At a transcriptional level several apoptotic genes were flagged as differentially expressed in comparison to the untreated control and HPV negative cells. At the protein level, however, cleaved caspase 3 activity did not appear to be altered, indicating the absence of apoptosis. This, combined with the FACS analysis suggests that Cidofovir produces an anti-proliferative effect in HPV positive cells by causing cell cycle arrest. Further work is needed to examine how this effect is occurring and its relevance in the clinical setting.

3017 POSTER

Loss of HOXD10 expression induced by upregulation of miR-10b accelerates migration and invasion activities of ovarian cancer cells

I. Nakayama[1], M. Shibazaki[2], A. Yashima-Abo[3], M. Kagabu[1], F. Miura[1], T. Masuda[3], C. Maesawa[2], T. Sugiyama[1]. [1]*Iwate Medical Unversity, Obstetrics and gynecology, Iwate, Japan;* [2]*Iwate Medical Unversity, Tumor Biology, Iwate, Japan;* [3]*Iwate Medical Unversity, Pathology, Iwate, Japan*

Background: Small and large noncoding RNAs (ncRNA) contribute to the acquisition of aggressive tumor behaviors in diverse human malignancies. Two types of ncRNAs, microRNA-10b (miR-10b) and homeobox (HOX) transcript antisense RNA (HOTAIR), can suppress translation of the HOXD10 gene, an mRNA encoding a transcriptional repressor that inhibits the expression of cell migration/invasion-associated genes in human malignancies. We investigated the relationship of the miR-10b/HOTAIR/HOXD10 axis to migration/invasion activity in epithelial ovarian cancers.
Materials and Methods: We used 8 ovarian cancer cell lines and 68 primary ovarian cancers. Expression of miR-10b and HOTAIR was evaluated by real-time PCR, and HOXD10, matrix metallopeptidase 14 (MMP14) and ras homolog family member C (RHOC) proteins were investigated using Western blotting and/or immunohistochemistry. Cell migration and invasion activities of ovarian cancer cell lines were investigated using transwell migration and Matrigel invasion assays after treatment for knockdown and/or overexpression of miR-10b and HOTAIR.
Results: Overexpression of miR-10b induced a decrease of HOXD10 protein, and upregulated the migration/invasion activity of ovarian cancer cell lines ($P<0.05$). In these cells, a significant increase of MMP14 and RHOC was observed. No significant upregulation of HOXD10 was observed in cells treated with HOTAIR-siRNA. Positive signals for HOXD10 and MMP14 were observed in 47 (69%) and 25 (37%) of 68 patients with ovarian cancer. An inverse correlation between HOXD10 and MMP14 immunoreactivities was observed ($P<0.05$), and miR-10b expression was also inversely correlated with HOXD10 expression ($P<0.05$).
Conclusions: The present results suggest that downregulation of HOXD10 expression by miR-10b overexpression in epithelial ovarian cancer cells might induce an increase of pro-metastatic gene products, such as MMP14 and RHOC, thus contributing to acquisition of metastatic phenotypes.
No conflict of interest.

3018 POSTER

Pelvic lymphatic drainage pathways in relation to the autonomic nerves: implications for radical hysterectomy

A. Kraima[1], M. Derks[2], J.C. Van Munsteren[3], J. Van der Velden[2], G.G. Kenter[2], M.C. DeRuiter[4]. [1]*Leiden University Medical Center, Leiden, Netherlands;* [2]*Academical Medical Center, Gynecology and Obstetrics, Amsterdam, Netherlands;* [3]*Leiden University Medical Center, Anatomy and Embryology, Leiden, Netherlands;* [4]*Leiden University Medical Center, Anatomy and Embryology, Amsterdam, Netherlands*

Background: Radical hysterectomy with pelvic lymphadenectomy (RHL) is the treatment of choice for early-stage cervical cancer. Nowadays, emphasis lies on radical removal of the tumor and surrounding parametrium as well as preservation of the autonomic nerves. The Wertheim-Okabayashi (WO) and the Swift are regularly performed procedures. The WO is characterized by the excision of the deep layers of the vesico-uterine ligaments (VLs), whereas the Swift operation is more radical in removing the sacro-uterine ligaments (SLs). Cervical cancer mainly spreads via local growth and lymphatics. While the autonomic network has been studied extensively, the pelvic lymphatic system is remarkably far less understood. The aim of this study is to reveal the lymphatic pathways of the cervix, related to those of the bladder, rectum and autonomic nerves. We determined whether the possible surgical extensions in parametrectomy during RHL are oncologically and functionally necessary.

Material and Methods: A series of 9 female fetal pelves with an embryonic stage 8, 10, 12, 14, 15, 16, 17, 19 and 20 weeks were studied. Paraffin embedded blocks were sliced in transverse sections of 8 or 10 μm. Analysis was performed by conventional histological staining and immunohistochemical staining with S100, a pan-neuron marker and LYVE-1, a lymphatic endothelial marker. A 3D reconstruction was developed to show the relation between the lymphatics and nerves.
Results: The fetal lymphatic drainage pathways from the pelvic viscera are separated. There are no ventro-dorsal connections between the cervix, bladder and/ or rectum. Three major pathways can be detected: the supra-ureteral and infra-ureteral pathways, running in the cardinal ligaments (CLs) respectively superior and inferior to the ureter, and the dorsal pathways running in the SLs towards the rectal pillars. The VLs contain nerve fibers towards the bladder and external genitalia and lymph vessels draining the bladder. The lymphatics from the bladder and cervix are separated by a continuous thin fascia sheath.
Conclusion: During RHL wide excision of the CLs and radical resection of the SLs is necessary to warrant accurate removal of the cervix-draining lymph vessels. Nerve fibers in the VLs innervating the bladder might be preserved in early-stage cervical cancer. However, this is based on the analysis of fetal specimens and has to be investigated in the adult by microscopic analysis.
No conflict of interest.

3019 POSTER

Thrombocytosis as a poor prognostic factor in ovarian cancer

T. Jørgensen[1], S.T. Teiblum[2], M. Paludan[3], L.O. Poulsen[4], A.Y.S. Jørgensen[5], K.H. Bruun[6], J. Herrstedt[7]. *[1]Odense University Hospital, Oncology, Odense, Denmark; [2]Herlev Hospital, Oncology, Copenhagen, Denmark; [3]Aarhus University Hospital, Oncology, Aarhus, Denmark; [4]Aalborg University Hospital, Oncology, Aalborg, Denmark; [5]Næstved Hospital, Oncology, Næstved, Denmark; [6]Copenhagen University Hospital, Oncology, Copenhagen, Denmark; [7]Odense University Hospital & University of Southern Denmark, Oncology, Odense, Denmark*

Background: Thrombocytosis (TC) is often observed in epithelial ovarian cancer (EOC). A recent study suggested increased production of cytokines in tumour and host tissue which could lead to paraneoplastic TC and hypothesizes that targeting these cytokines might have therapeutic potential. We describe characteristics of EOC patients with and without TC and analyse the significance of thrombocytosis on survival.

Materials and Methods: Women registered in the Danish Gynecologic Cancer Database in 2005–2006 with EOC FIGO stage IC-IV were included. Missing data were collected by review of medical records. Patients were followed until death or January 1, 2012. TC was defined as platelet count $>450\times10^9$/l and was registered prior to 1st course of 1st line chemotherapy (CT). The association of TC with progression-free (PFS) and overall (OS) survival was investigated by multivariate analysis adjusted for histology, stage, residual tumour, performance status, primary vs. secondary surgery, CT regimen, and CA-125.
Results: Overall, 703 patients were included of whom 289 (41%) had TC. Characteristics of patients are shown in Table 1. Median OS was 2.3 years (IQR 1.1–5.1) in TC patients vs. 4.3 years (IQR 1.8–5.8) in patients without TC (log rank: $p < 0.0001$). For PFS, corresponding numbers were 1.0 years (IQR 0.6–2.0) vs. 1.6 years (IQR 0.9–4.5) ($p < 0.0001$). TC was independently associated with shorter OS, HR 1.32 (95% CI 1.05–1.66), but not with PFS, HR 1.14 (0.94–1.38).
Conclusion: TC is associated with reduced OS. The effect of targeted therapy aimed at reducing TC in EOC patients should be studied in a prospective setting.
No conflict of interest.

3020 POSTER

Pharmacokinetics of concomitant cisplatin and paclitaxel administration by hyperthermic intraperitoneal chemotherapy (HIPEC) to patients with peritoneal carcinomatosis

L. Ansaloni[1], L.M. Busci[2], F. Coccolini[1], G. Grosso[2], M. Lotti[1], L. Morosi[3], E. Poiasina[1], M. Zucchetti[3], M. D'Incalci[3], L. Frigerio[2]. *[1]Papa Giovanni XXIII Hospital, Surgery, Bergamo, Italy; [2]Papa Giovanni XXIII Hospital, Gynaecology, Bergamo, Italy; [3]Mario Negri Institute for Pharmacological Research, Oncology, Milano, Italy*

Background: Intraperitoneal chemotherapy has been advised as a treatment option for epithelial ovarian cancer (EOC) with peritoneal carcinomatosis. Although its treatment length is considerably shorter, intraoperative hyperthermic intraperitoneal perfusion chemotherapy (HIPEC) has a number of benefits over simple intraperitoneal chemotherapy administration. While the pharmacokinetics of cisplatin (CDDP) and paclitaxel (PTX) administered separately during HIPEC have already been studied before, their concentrations in concomitant administration during HIPEC has not previously been measured. The primary aim was to examine the pharmacokinetics of both drugs during HIPEC in patients affected by peritoneal carcinomatosis from advanced epithelial ovarian cancer.
Materials and Methods: Ten women, nine with advanced EOC, underwent cytoreductive surgery (CRS) and HIPEC with CDDP 100 mg/m^2 and PTX 175 mg/m^2) for 90 minutes. Blood, perfusate and tissue samples were harvested during HIPEC for pharmacokinetic study in ten patients. Intra and postoperative morbidity was noted.
Results: No death was noted perioperatively and during the first 30 postoperative days. Severe surgery-related complications (i.e. grade 3–4 CTCAE) were seen in three patients: one patient had intestinal perforation (grade 4) that required reoperation, one had colo-vaginal fistula (grade 3) that required surgical intervention and one had neurogenic urinary bladder obstruction that involved increased levels of plasmatic creatinine (grade 3). Severe chemotherapy related toxicity (i.e. grade 3–4 CTCAE) was observed in seven patients: two with grade 4 and five with grade 3. Renal toxicity was observed in one patient, grade 3. Haematological toxicity was observed in five patients: anaemia (except the first two postoperative days) grade 3 (three patients), thrombocytopenia (one patient grade 3, one grade 4) and leukopenia (two patients grade 3, one grade 4 all treated with administration of G-CSF). The mean maximum concentration of perfusate CDDP and PTX were 26.09 $\pm$8.5 μg/ml and 73.1$\pm$13.5 μg/ml respectively. The mean maximum concentration of plasma CDDP and PTX were 1.92 $\pm$0.4 μg/ml and 0.062$\pm$0.006 μg/ml respectively. Finally, the mean concentration of CDDP and PTX in peritoneal tissue after 90 minutes of HIPEC were 28.70 $\pm$10.8 μg/g and 34.43 $\pm$16.16 μg/g respectively.
Conclusions: HIPEC with concomitant CDDP and PTX delivery following CRS is feasible, fairly safe, and associated with a highly favourable pharmacokinetic profile, despite its short treatment duration. Larger studies with a more homogenous patient cohort and adequate follow-up should be performed to demonstrate its efficacy.
No conflict of interest.

3021 POSTER

Cytoreductive surgery and hyperthermic intraperitoneal chemotherapy with cisplatin and paclitaxel in advanced ovarian cancer with peritoneal carcinomatosis: Results of a multicenter prospective observational study

L. Ansaloni[1], F. Catena[2], F. Coccolini[1], P. De Iaco[3], G. Ercolani[4], G. Grosso[5], M. Lotti[1], D. Rossetti[5], A.D. Pinna[4], L. Frigerio[5]. *[1]Papa Giovanni XXIII Hospital, Surgery, Bergamo, Italy; [2]Maggiore Hospital, Surgery, Parma, Italy; [3]St. Orsola-Malpighi Hospital, Gynaecology, Bologna, Italy; [4]St. Orsola-Malpighi Hospital, Surgery, Bologna, Italy; [5]Papa Giovanni XXIII Hospital, Gynaecology, Bergamo, Italy*

Background: Cytoreductive surgery (CRS) associated to hyperthermic intraperitoneal chemotherapy (HIPEC) have been recently reported with favourable oncological outcomes as treatment of advanced epithelial ovarian cancer (EOC) with peritoneal carcinomatosis (PC). The aim of this study was to demonstrate the feasibility of CRS and HIPEC with cisplatin (CDDP) and paclitaxel (PTX) for the treatment of advanced EOC.
Materials and Methods: This is a multicentre prospective observational study including patients affected by primary or recurrent EOC with PC treated with CRS and HIPEC with CDDP (100 mg/m^2) and PTX (175 mg/m^2). Patients were included between April 2007 and December 2012 at St. Orsola-Malpighi Hospital (Bologna, Italy) and Papa Giovanni XXIII Hospital, (Bergamo, Italy). Peritoneal cancer Index (PCI), Completeness of Cytoreduction (CC) score and perioperative morbidity were noted. The survival results during follow-up were recorded.
Results: 48 patients were included. The mean age was 54.6 years (s.d. ±9.6 range 33−72). 27 patients (56%) had primary EOC and 21 (44%) had recurrent disease. Mean PCI was 10.5 (s.d. ±6.6; range, 0−28). According to the intraoperative tumour extent, the tumour volume was classified as low (PCI <15) or high (PCI ⩾15) in 33 (69%) and 15 (31%) patients respectively. CC0 was achieved in 39 (81.3%) and CC1 in 9 (18.8%) patients. The mean ICU stay was 5.7 days (s.d. ±6.07 range 1−34) and the mean hospital stay was 24.3 days (s.d. ±10.10 range 1−77). No intraoperative death was observed. Reoperation was required in 6 patients (12.5%). Three patients (6.2%) died within 30 days from the procedure. Severe complications (grade 3−4 CTCAE 3.0) were seen in 17 patients (35.4%). During the follow-up period recurrence occurred in 29 patients (60.4%) with a mean recurrence time of 8.9 months (s.d. ±6.3; range 2.2−25.5). The median disease-free survival was 6.3 months and the median overall survival was 11.3 months.
Conclusions: CRS and HIPEC with CDDP and PTX for advanced EOC with PC is feasible with acceptable morbidity and mortality. Additional follow-up and further studies are needed to determine the effects of HIPEC on long term survival.
No conflict of interest.

3022 POSTER

Individualized prediction of overall survival following postoperative radiotherapy in patients with early-stage cervical cancer: A Korean Radiation Oncology Group study (KROG 13−03)

E. Jwa[1], Y.S. Kim[1], H.J. Lee[1], H.J. Kim[2], J.Y. Kim[3], J.H. Kim[4]. *[1]Asan Medical Center, Radiation Oncology, Seoul, South Korea; [2]Seoul National University Hospital, Radiation Oncology, Seoul, South Korea; [3]National Cancer Center, Center for Uterine Cancer, Goyang, South Korea; [4]Dongsan Medical Center, Radiation Oncology, Daegu, South Korea*

Background: A nomogram is a predictive statistical model that generates the continuous probability of a clinical event such as death or recurrence. The aim of the study was to construct a nomogram to predict 5-year overall survival following postoperative radiotherapy for stage IB−IIA cervical cancer.
Material and Methods: The clinical data from 1,702 patients with early-stage cervical cancer, treated at ten participating hospitals from 1990 to 2011,were reviewed to develop a prediction nomogram based on the Cox proportional hazards model. Demographic, clinical and pathologic variables were included and analyzed to formulate the nomogram. The discrimination and calibration power of the model was measured using a concordance index (c-index) and calibration curve.
Results: The median follow-up period for surviving patients was 75.6 months and the 5-year overall survival probability was 87.1%. The final model was constructed using the following variables: age, number of positive pelvic lymph nodes, parametrial invasion, and lymphovascular invasion. The nomogram predicted the 5-year overall survival with a c-index of 0.69, which was superior to the predictive power of the International Federation of Gynecology and Obstetrics (FIGO) staging system (c-index of 0.54).
Conclusions: A survival-predicting nomogram that offers an accurate level of prediction and discrimination was developed based on a large multi-center study. The model may be more useful than the FIGO staging system for counseling individual patients regarding prognosis.
No conflict of interest.

Table 1. Multivariate Cox proportional hazards model for overall survival

Variable	Hazard ratio	95% CI	*P*
Age	1.01	1.00–1.03	.048
Number of pelvic lymph nodes	1.22	1.13–1.33	<0.001
Lymphovascular invasion			
No	1.00		
Yes	1.34	0.96–1.86	0.083
Parametrial invasion			
No	1.00		
Yes	1.99	1.45–2.73	<0.001

3023 POSTER

Neo-adjuvant low dose fractionated radiotherapy and chemotherapy in locally advanced carcinoma cervix: Phase II clinical study

S. Das[1], J. Subhashini[1], R. Isiah[1], J. Retna[1]. *[1]Christian Medical College Hospital, Radiation Oncology, Vellore, India*

Background: Carcinoma of the uterine cervix is a major public health problem in developing countries in south-east Asia. Majority of the cases are locally advanced (>FIGO stage IIB) with bulky tumors and response to standard chemoradiation is suboptimal due to tumor size and hypoxia. Radiobiologically, chemo-potentiating effect of low dose radiation therapy (LDRT) in the range of 40–100 cGy enhances cell killing by cellular arrest in G2 phase (induced radio-resistance) thus augmenting the effect of cell cycle specific chemotherapy. The aim of this phase II study was to evaluate the safety and efficacy of a neoadjuvant regimen combining two cycles of paclitaxel and carboplatin with LDRT prior to definitive chemoradiation in advanced cervical cancer.
Material and Methods: Patients with squamous cell carcinoma cervix (FIGO stage IIB–IIIB) were included in the study. Patients received two cycles of paclitaxel (175 mg/m^2), carboplatin, (area under the curve of 5), and four 80-cGy fractions of radiotherapy (two each on Days 1 and 2). This sequence was repeated on Days 22 and 23. Clinical and radiological response (MRI) to the neoadjuvant treatment was determined after 3 weeks. All patients underwent subsequent concurrent chemoradiation (50 Gy of external beam radiotherapy with concurrent Cisplatin followed by brachytherapy). The sample size was determined by Simon's two stage design for phase II studies (α= 0.05, power = 0.8) with H_0 ("bad" response probability, 50% according to literature) and H_1 ("good" response probability, 80%).
Results: Total 24 patients (80% IIIB and 20% IIB) were recruited in the study. Mean gross tumor volume (GTV), based on T2 high resolution MRI, before and after neoadjuvant treatment were 92.05 cc and 24.8 cc respectively ($p < 0.0001$, paired t test). Neoadjuvant treatment resulted in significant reduction (>50%) in GTV volume in 75% cases. Clinical complete response was found in 90% patients at 6 weeks. The incidence of grade 3 and 4 neutropenia was 33% and 8% respectively during the entire period of treatment. There was no other grade 3 or 4 acute non-hematological toxicity.
Conclusions: Neo-adjuvant LDRT and chemotherapy prior to definitive chemoradiation is a novel and feasible approach in cervical cancer with a favorable toxicity profile. This treatment paradigm resulted in significant reduction in the GTV, superior response rate and therefore is a good alternative option for bulky, hypoxic cervical tumors.
No conflict of interest.

3024 POSTER

Assessing the quality of life in patients with endometrial cancer treated with adjuvant radiotherapy

H. Karabuga[1], F. Yildiz[1], M. Gultekin[1], G. Tulunay[2], K. Yuce[3], A. Ayhan[4], M. Gurkaynak[1]. *[1]Hacettepe University Faculty of Medicine, Department of Radiation Oncology, Ankara, Turkey; [2]Etlik Research and Teaching Hospital, Department of Gynecological Oncology, Ankara, Turkey; [3]Hacettepe University Faculty of Medicine, Department of Gynecological Oncology, Ankara, Turkey; [4]Baskent University Faculty of Medicine, Department of Gynecological Oncology, Ankara, Turkey*

Purpose: The current study evaluates long-term quality of life and sexual function of patients with endometrial cancer who received adjuvant radiotherapy (RT).
Materials and Methods: Hundred and forty-four patients with the diagnosis of endometrial carcinoma, who received adjuvant radiotherapy in our

department between 2000 and 2009, were included in this study. The median age of the patients was 64 years (range, 48−88 years). Quality of life was evaluated by using EORTC QLQ-C30 questionnaire and the CX-24 module. Surgery was total abdominal hysterectomy and bilateral salphingo-oophorectomy (TAH + BSO) in 136 (94%) cases, an additional pelvic + paraaortic lymph node dissection was performed in 120 (83.3%) patients and only pelvic lymph node dissection in 17 (12%) patients. Adjuvant radiotherapy was vaginal brachytherapy (BRT) in 76 (53%) patients, external beam radiation therapy (EBRT) in 52 (36%) patients, and EBRT + vaginal BRT in 16 (11%) patients.
Results: Compared to patients who received vaginal BRT alone, symptom score ($p = 0.01$), lymphedema ($p = 0.03$), pain ($p = 0.02$), and diarrhea ($p = 0.009$) scores were higher and physical functioning ($p = 0.01$), role functioning ($p = 0.03$) and sexual enjoyment ($p = 0.01$) were significantly lower in patients undergoing EBRT. Vaginal BRT when added to EBRT did not worsen the symptom scales and sexual functions. Physical functioning was worse in patients who received systemic chemotherapy ($p = 0.01$). In patients younger than 65 years, body image ($p = 0.02$), sexual activity ($p < 0.001$) and sexual concern ($p < 0.001$) were significantly higher, while fatigue ($p = 0.005$) was significantly higher in patients older than 65 years. Obese patients experienced higher rates of lymphedema ($p = 0.02$), cognitive functioning ($p = 0.03$) and role functioning ($p = 0.02$) scores were significantly higher in patients with normal body weight. With increasing stage of the disease, lymphedema ($p = 0.008$), peripheral neuropathy ($p = 0.02$), fatigue ($p = 0.02$), pain ($p = 0.04$), and diarrhea ($p = 0.009$) were increased. Deterioration in body image ($p = 0.02$), and emotional functioning ($p = 0.004$) were observed when follow-up interval became longer.
Conclusion: EBRT negatively affects quality of life and sexual functions in endometrial cancer patients. Vaginal BRT provides higher quality of life. Body mass index when in normal limits improve the quality of life.
No conflict of interest.

3025 POSTER

The impact of an automatically generated survivorship care plan on patient reported outcomes (ROGY care): Results of a pragmatic cluster randomized controlled trial among endometrial cancer patients

L.V. Van de Poll-Franse[1], K.A.H. Nicolaije[1], N.P.M. Ezendam[1], M.C. Vos[2], D. Boll[3], J.M.A. Pijnenborg[3], J.A. Roukema[4], R.F.P.M. Kruitwagen[5].
[1]Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands; [2]Elisabeth Hospital, Gynaecology, Tilburg, Netherlands; [3]Tweesteden Hospital, Gynaecology, Tilburg, Netherlands; [4]Elisabeth Hospital, Surgery, Tilburg, Netherlands; [5]Maastricht University Medical Center, Gynaecology, Tilburg, Netherlands

Background: More patient tailored information for cancer survivors is needed. Evidence on effects of implementing Survivorship Care Plans (SCPs), recommended by the IOM, is limited. Aim of this pragmatic cluster randomized trial is to assess the impact of SCPs in routine clinical practice. Primary endpoint is patient satisfaction with information. Secondary endpoints are QoL and health care use.
Material and Methods: We built an SCP-application in the web-based Registrationsystem Oncological GYnecology (ROGY), used in our area since 2006. By clicking the SCP-icon in ROGY, a personalized SCP is automatically generated. Twelve hospitals were randomized to usual care or SCP care. In usual care, gynecologists did not have access to the SCP-icon. In SCP care, SCPs are personally discussed and handed to patients. All newly diagnosed endometrial cancer patients (age $\geqslant$18) were asked to complete a questionnaire after surgery, 6, 12 and 24 months after diagnosis. The questionnaire included the EORTC INFO25 and asked whether patients actually received an SCP. We expected 150 endometrial cancer patients: 75 per arm. We hypothesized that patients receiving SCP care are more satisfied with the information.
Results: 201 patients (74%) returned a questionnaire after surgery: 109 SCP arm, 92 usual care arm. Of the patients in the SCP arm, 69% reported receiving an SCP. Analyses according to randomization arm showed that patients in both arms reported similar scores on all scales of the INFO25, including satisfaction with care (87% vs. 82%, SCP vs usual care, $p = 0.20$). Analyses according to actual care received showed that patients who received SCP care reported significantly higher scores (4−18 points) on all scales of the INFO25, including satisfaction with care (91% vs. 78%, SCP vs usual care, $p = 0.046$) compared to those who did not receive SCP care.
Conclusions: Even in a situation where SCPs are automatically generated, still one third does not receive an SCP. But, those who receive SCP care report better information provision and satisfaction. Follow-up measures will show whether this ultimately results in better QoL and decreased health care use.
No conflict of interest.

3026 POSTER

Compliance to multimodality cancer therapy in gynaecologic malignancies

M. Sharma[1], A. Sharma[2], R. Madan[2], B.K. Mohanti[2], G.K. Rath[2]. *[1]Saket City Hospital, Gynecology, Delhi, India; [2]All India Institute of Medical Sciences New Delhi, Radiation Oncology, Delhi, India*

Background: To evaluate treatment compliance and referral delays to multimodality cancer directed therapy in Gynaecologic malignancies at a tertiary care centre in a developing nation.
Material and Methods: A total of 124 patients of gynaecologic cancer were evaluated in our study. All patients were initially seen in multi-disciplinary clinic at our institute. The patients were assessed as per age, site, stage of disease, intent & modality of treatment. Compliance was studied with regard to patients that were able or unable to complete the stipulated cancer directed therapy. Referral delay from surgery to radiotherapy, delay in treatment from surgery to starting of radiotherapy and radiation waiting period were calculated for all patients. Overall treatment time was calculated for all compliant patients.
Results: Median age for presentation was 54 (35−81) years. The most common site was carcinoma cervix (73%), majority (61%) of the patients presented in stage III disease. Eighty eight per cent of the patients were treated with radical intent. Majority (84%) of the patients were subjected to multimodality cancer directed therapy. Median delay in radiotherapy referral after surgery was 35 (−20 to56) days, median radiation waiting period was 43 (9–132) days, median delay from surgery to start of radiation therapy was 74 (62–134) days. Seventy one per cent of the patients were compliant to therapy, for compliant patients median overall treatment time was 128 (21–224) days.
Conclusions: More than two third of the patients were patients compliant to multimodality cancer directed therapy. For compliant patients substantial delays were noted from the start to completion of cancer therapy. All these referral time gaps add to the increased overall treatment time, i.e. 18.2 weeks (128 days) in this study. It has been proven that overall treatment time influence the local control as well as survival. Even after careful evaluation of patients, more than one fourth of the patients could not comply to the stipulated treatment plan. Our study will help for preparing the benchmark for cancer practice in developing nations for gynaecologic malignancies.
No conflict of interest.

3027 POSTER

Use of immunotherapy in complex treatment of patients with dysplasia and preinvasive carcinoma of the cervix

E. Bakhidze[1]. *[1]N.N. Petrov Research Institute of Oncology, Gynaecological Oncology, Saint Petersburg, Russian Federation*

Background: Standard treatment for dysplasia and preinvasive cervical carcinoma does not always lead to the elimination of the virus, and therefore desire to develop a comprehensive treatment that combines systemic and local effects is justified. The purpose of the study was to evaluate effectiveness of immunomodulatory antiviral drug Oxodihydroacridinilacetat sodium in complex treatment of dysplasia and preinvasive carcinoma of the cervix.
Material and Methods: Study included 20 patients with cervical preinvasive carcinoma and carcinoma in situ underwent cone biopsy in 2012 divided into two groups. First group included 10 patients underwent cone biopsy with application of immunomodulatory antiviral drug Oxodihydroacridinilacetat sodium, second group was control and included 10 patients underwent cone biopsy alone. All patients were performed HPV test before and after treatment. Patients treated with antiviral drug were performed examination of immune status before and after treatment. Patients' monitoring was done with the use of cytology and HPV test.
Results: Mean age in both groups was similar (37.1 vs. 35.2 years). HPV test showed that the predominant one was 16 genotype of HPV, which was found in 7 of 10 patients in group 1, and in 8 of 10 patients in group 2. In three patients it was combined with 18 genotype and in in one case it was combined with 58 genotype. Persistence of HPV-infection after treatment during first two month of monitoring was found in 1 of 10 patients in group 1 and in 3 of 10 patients in group 2. A second course of antiviral drug in patient with persistent HPV in group 1 led to the elimination of the virus. In group 2, in two of three patients with persistent HPV disease there was found a relapse within a few months after treatment. Examination of immune status before and after application of antiviral drug found that the drug has a strong immunomodulatory effects resulting in an increase in the absolute content of CD3+CD19− T-cells by increasing the absolute number of cytotoxic CD3 + CD8 + T-lymphocytes. At that there was marked an expressed local reaction in the remote cone in the form of clusters of lymphocytes. Observed effect of the drug is associated with significant immunostimulatory effect, concluded in strenghtening of effector function of

T-cell immune response. This in turn contributes to the migration of immune cells to the site of inflammation caused by infection and strengthening the capacity of cytotoxic cells to recognize and lyse the abnormal cells.
Conclusions: Monitoring of patients with cervical preinvasive carcinoma and carcinoma in situ after treatment should include HPV test. The observed effect of the drug Oxodihydroacridinilacetat sodium on the immune status and morphology of neoplasms suggests a opportunity to stabilizate neoplastic transformation that takes place under the influence of persistent HPV infection with the immunotherapy.
No conflict of interest.

3028 POSTER

Long-term survival analysis of cervical cancer patients treated with chemoradiation in an outpatient setting

H. Nunes[1], F. Vaz[1], F. Santos[2], S. Bento[3], N. Asensio[4], A. Francisca[5], M. Roldão[2]. *[1]Instituto Português de Oncologia de Lisboa Francisco Gentil, Oncologia Médica, Lisboa, Portugal; [2]Instituto Português de Oncologia de Lisboa Francisco Gentil, Radioterapia, Lisboa, Portugal; [3]Hospital Distrital de Santarém, Oncologia Médica, Santarém, Portugal; [4]Azienda Ospedaliera S.Maria Nuova, Instituto di Ricovero e Cura a Carattere Scientifico in Oncologia, Reggio Emília, Italy; [5]Instituto Português de Oncologia de Lisboa Francisco Gentil, Ginecologia, Lisboa, Portugal*

Background: Chemoradiation (CHRT) with Cisplatin is the standard treatment of locally advanced cervical cancer (LACC) since 1999. In November 2000, the Multidisciplinary Gynecological Oncology Group of our Centre implemented this treatment modality in an outpatient setting. The first 200 consecutive patients (pts) treated in our Institute were then followed prospectively. The main purpose was to analyse the overall survival (OS) and disease free survival (DFS) of our pts and to check if our findings are comparable with clinical trial data. Patterns of treatment failure were also analysed.
Material and Methods: Clinical files were reviewed for staging, toxicities until discharge from our centre and DFS. For OS, if vital status not on clinical records, we either contacted by phone the pts or a first degree relative or checked pts vital status through a National Patient Registry (NPR). Treatment (outpatient setting): cisplatin 40 mg/m^2 (6 weekly cycles), external beam radiation (ERT) 40−50 Gy (in 4−5 weeks) and brachytherapy (BRT) 20−25 Gy (point A, 2 fractions), during 8 weeks (medium). From the initial cohort, 2 patients were excluded, one due to histopathologic diagnosis of small cell carcinoma and the other due to previous hysterectomy. Survival analysis concerns the efficacy reviewed until March/2013.
Results: 198 patients: median age of 50 years (26−79), histopathologic distribution: 178 (89%) squamous cell carcinomas; 12 (6%) adeno-squamous carcinomas; 8 (5%) adenocarcinomas. More than 50% of our patients were staged ⩾ IIB. In march/2013: median follow-up time (intention to treat) of 76.9 months (1.4–145.5), with an overall survival of 67% at 8 years (global mortality rate of 29.8%). Forty nine (49) (24.7%) patients were lost to regular follow-up, but definitive survival data was obtained for 173 pts (26 pts lost to follow up had their vital status included in NPR). Causes of death: from the 149 patients reviewed, 25 had deaths related to cervical cancer, 4 due to causes not related to the disease and 29 died by unknown causes. Treatment failure was observed in 59 (29.8%) patients: 7 by disease progression during CHRT (2 regional only; 3 regional and distant; 2 distant only), 18 by persistence of the disease after CHRT, and 34 by relapse (16 distant and 18 regional). Two (2) pts had distant late relapses with pathology confirmation.
Conclusions: The OS of our cohort is comparable with published clinical trial data. This finding, observed outside of a clinical trial, in an outpatient setting of consecutive pts is remarkable since staging in our cohort had higher proportions of pts IIB and higher. This observation reflects the activity of CHRT in LACC. Risk for treatment failure was greater in the first 36 months, but unexpected late relapses (over 60 months) were observed.
No conflict of interest.

Results of a phase I dose escalation trial of hyperthermic intraperitoneal cisplatin after neoadjuvant chemotherapy and complete cytoreductive surgery and followed by maintenance bevacizumab in initially unresectable ovarian cancer

S. Gouy[1], G. Ferron[2], O. Glehen[3], M.C. Le Deley[4], F. Marchal[5], C. Pomel[6], F. Quenet[7], J.M. Bereder[8], L. Kockler[9], P. Morice[10]. *[1]Institut Gustave Roussy, Villejuif, France; [2]Centre Claudius Regaud, Surgery, Toulouse, France; [3]Hospices Civils Lyon Sud, Surgery, Lyon, France; [4]Institut Gustave Roussy, Biostatistics, Villejuif, France; [5]Centre Alexis Vautrin, Surgery, Nancy, France; [6]Centre Jean Perrin, Surgery, Clermont-Ferrand, France; [7]Centre Val d'Aurelle, Surgery, Montpellier, France; [8]CHU, Surgery, Nice, France; [9]Roche Company, Oncology, Boulogne Billancourt, France; [10]Institut Gustave Roussy, Surgery, Villejuif, France*

Background: Hyperthermic intraperitoneal chemotherapy (HIPEC) may improve the outcome for patients (pts) with initially inoperable ovarian cancer who are offered complete cytoreductive surgery (CCRS) after a response to neoadjuvant chemotherapy. The aim of this study was to identify the recommended dose of cisplatin for HIPEC at CCRS after neoadjuvant carboplatin and paclitaxel (CP).
Methods: Pts were treated with 6 cycles of CP followed by CCRS and HIPEC using cisplatin heated for one hour at 42ºC+/−1ºC. Four dose levels of cisplatin were tested: 50, 60, 70 and 80 mg/m^2. Dose limiting toxicities (DLTs) were defined as a grade ⩾ IIIb surgical adverse event according to the Dindo classification, during the 1st post-operative month. Dose escalation used a Continual Reassessment Method using a one-parameter logistic model in a Bayesian framework, with a target percentage of DLT set at 20%. After surgery, maintenance bevacizumab (15 mg/kg) was offered for 22 cycles, every 3 weeks.
Results: From 08/11 to 10/12, 30 patients were recruited in 7 comprehensive cancer centers. Median age was 58 (range 22−66). Median Peritoneal Cancer Index (PCI) at CCRS was 11 (range 1−35). Median hospital stay was 18.5 days (range 10−69 days). No DLT occurred at the first 3 dose levels (N = 4, 4 and 5 pts respectively). At dose level 4 (80 mg/m^2, N = 17), four DLTs occurred: 2 renal failures, 1 peritonitis and 1 hemorrhage. The estimated DLT probability at dose 80 mg/m^2 was 17%, 95% confidence interval, 6−35%. Eight weeks after surgery, creatinine clearance was reduced to <30 ml/min in 3 (10%) pts, and between 30 and 60 ml/min in 6 (20%) pts (table below). Twenty pts received at least 1 course of maintenance bevacizumab and 10 did not (4 due to previous DLT, 2 due to progression and 4 for miscellaneous reasons). Only one pt stopped maintenance therapy due to adverse events (lymphocyst).

Level	Nb pts	Creatinine clearance 8 weeks after the surgery Cockroft formula, ml/min			DLT
		<30	30−59	⩾60	
1: 50 mg/m^2	4	0	2	2	0
2: 60 mg/m^2	4	0	1	3	0
3: 70 mg/m^2	5	0	1	4	0
4: 80 mg/m^2	17	3	2	12	4
Total	30	3	6	21	4

Conclusions: Based on DLT observations, cisplatin 80 mg/m^2 could be recommended by the model. However we recommend a dose of 70 mg/m^2 considering prolonged impairment of the renal function observed at the level 4. Renal toxicity appears as the limiting morbidity of cisplatin-based HIPEC. Longitudinal analysis of creatinine level is on-going. Careful initial selection of patients is required to avoid long-term renal morbidity.
Conflict of interest: *Other substantive relationships: This trial has been supported by Roche but the company had no involvement in the design or interpretation of the trial.*

3030 POSTER

Adjuvant chemotherapy in the management of cervical cancers − a prospective randomized study

K. Chatterjee[1], S.K. Mondal[2], P. Sarkar[3]. *[1]I.P.G.M.E.R & S.S.K.M Hospitals, Radiotherapy, Kolkata, India; [2]R.G.Kar Medical College & Hospitals, Radiotherapy, Kolkata, India; [3]Medical College & Hospitals Kolkata, Radiotherapy, Kolkata, India*

Background: Concurrent Chemoradiation (CTRT) is the standard of care for locally advanced cervical cancers in India. Translation of the benefits

of this strategy in our patient population is sub-optimal, as compared to that of the west. Evidence of the success of chemotherapy in recurrent setting and its theoretical possibilities to tackle micro metastases, made us envisage this study to look at the role of Adjuvant chemotherapy (Adjuvant CT) in addition to Chemoradiation.
Materials and Methods: Between June 2008 and July 2009, 80 patients with squamous cell CA of Cervix, stage IB to IIIB, age <60 years, ECOG 1&2, Hb >10 gm%, normal renal and liver functions, were treated with the standard CTRT (pelvic EBRT 50 Gy/25 fractions & concurrent Cisplatin 40 mg/m^2 weekly) followed by Brachytherapy. They were then randomized to either receive no further treatment or Adjuvant CT with Cisplatin 50 mg/m^2 i.v day 1 & 5FU 600 mg/m^2 i.v day 1, given every 4 weekly for 2 cycles. These patients were then followed up & analyzed to compare the local & distant failures, toxicity profiles, DFS & OS.
Results: Out of 40 patients in each arm, 36 patients of the CTRT arm & 37 of Adjuvant CT arm were analyzable. The median periods of follow up were 34.4 Months and 35.8 months respectively. CR was seen in 69.44% with CTRT versus 72.97% with Adjuvant CT [P = 0.8149]. Number of patients having failures at the end of follow up were 13 (36.11%) in CTRT arm [6 with local failure comprising residual (3) and recurrence (3), 4 with distant failures, and 3 having both] as compared to 10 patients (27.02%) in Adjuvant CT arm [8 local failures, comprising residual (3) and recurrence (5), 2 with distant failures, and 2 having both] [P = 0.4567]. DFS & OS were 63.88% vs.67.56% [P = 0.8079], and 80.55% vs. 83.78% [P = 0.7676] in the CTRT arm & Adjuvant CT arm respectively (none significant). Toxicity profiles had no significant difference in both arms except, Adjuvant CT arm had higher acute grade I [P = 0.3975] & II anemia [P = 0.6741] & higher grade II leucopenia [P = 0.7997]. Higher number of patients (25 vs. 20) [P = 0.3410] with late toxicities (equivalent grades) were seen in the Adjuvant CT arm, which also had an earlier time of onset (5.83 vs.6.53 months).
Conclusions: In a select group of patients with good performance status, normal hemoglobin levels, and renal & liver functions Adjuvant CT following standard CTRT was well tolerated, and shows a trend towards a better disease free and overall survival.
No conflict of interest.

Prior chemotherapy improves the immune response to a synthetic long peptide cancer vaccine against HPV16: A phase I toxicity-immunogenicity study in cervical cancer patients

C. Melief[1], M.J.P. Welters[2], H. Van Meir[3], T.C. Van der Sluis[4], M.I.E. Van Poelgeest[3], G.G. Kenter[5], K. Burggraaf[6], S.H. Van der Burg[7]. [1]*AZ Leiden, Department of Immunohematology & Blood Bank, Leiden, Netherlands;* [2]*AZ Leiden, Department of Clinical Oncology, Leiden, Netherlands;* [3]*AZ Leiden, Department of Gynaecology, Leiden, Netherlands;* [4]*AZ Leiden, Department of Immunohematology and Blood Transfusion, Leiden, Netherlands;* [5]*Center for Gynaecologic Oncology, Department of Gynaecology, Amsterdam, Netherlands;* [6]*Center for Human Drug Research, Department of Human Drug Research, Leiden, Netherlands*

Background: Therapeutic vaccination of persistent human papilloma virus (HPV) infections and associated diseases including (pre-)cancer requires the induction of robust and consistent T cell responses. This can be obtained by vaccination with a vaccine consisting of 13 synthetic (28−35 amino acid) long peptides (ISA 101®) of the E6 and E7 oncoproteins of HPV16. Such immunogens are more efficiently processed and presented than intact proteins by professional antigen presenting Dendritic Cells (DC). In a preclinical mouse model we have shown marked synergism in eradication of established HPV16 E6/E7+ tumors between platinum-based chemotherapy and HPV16 SLP vaccination.
Material and Methods: In a phase 1 toxicity/immunogenicity clinical study, end stage cervical cancer patients (n==18) were treated with carboplatin and paclitaxel (carbotaxol), after which 12 patients received a single dose of the therapeutic HPV vaccine (300 μg/peptide) in Montanide ISA-51 adjuvant. Six patients served as non-vaccinated controls. Immunophenotyping by 11 parametric flow cytometry was performed on PBMC samples collected prior to, during and after chemotherapy. HPV16-specific and common microbial antigen-specific immune responses were measured in PBMC samples of patients by lymphocyte stimulation test and by cytokine production in the supernatant of these lymphocyte cultures.
Results: Following carbotaxol chemotherapy, the PBMC samples of these patients showed shifts in leukocyte composition associated with improved memory T cell immune responses and increased dendritic cell function. Patients treated with chemotherapy and HPV vaccine (ISA101®), but not non-vaccinated control patients, exhibited robust and sustained HPV16-specific proliferative T responses to a single dose of the vaccine. The observed synergy is in line with data from the preclinical mouse model.
Conclusions: In patients with end-stage HPV16+ cervical cancer, standard chemotherapy with carbotaxol followed by a single dose of HPV-SLP vaccine permits the induction of a robust HPV16-specific T cell response. These findings set the stage for a randomized phase II study of chemo-immunotherapy to compare chemotherapy alone with chemo-immunotherapy in patients with cervical cancer.
Conflict of interest: *Ownership: Cornelis Melief has Stock appreciation rights in ISA pharmaceuticals BV. Corporate-sponsored research: ISA Pharmaceuticals BV has provided the vaccine for this study.*

3032 POSTER

Definitive chemoradiotherapy (CRT) for advanced cervical cancer (CC): Should it be different in elderly?

I.Q.S. Caires[1], R. Caires-Lima[1], R. Barroso-Souza[1], J.A. De Oliveira[1], K.T. Souza[1], M.V. Negrão[1], H. Carvalho[1], E. Abdo Filho[1], P.M. Hoff[1], M.D.P.E. Diz[1]. [1]*Insituto do Cancer do Estado de São Paulo, Clinical Oncology, São Paulo, Brazil*

Background: CC is third women's malignancy in the world and the second in Brazil. Elderly represents around 10% of these patients (pts), however, Brazilian screening CC program is done up to 65 y.o. In this group, disease is usually diagnosed in advanced stages and most of them receive no treatment or less intensive oncological therapies, due to comorbidities and impaired performance status.
Methods: Retrospective analysis of pts ⩾65 y.o. with CC consecutively admitted at a Brazilian university cancer center from Aug/2008 to Feb/2012. We performed a descriptive analysis of baseline performance status (PS), stage disease (FIGO), histology, body mass index (BMI), treatment received, and overall survival, by Kaplan–Meier method.
Results: 900 medical records were analyzed, 75 pts (8%) fulfilled the inclusion criteria. Median age was 73.4 y.o. (± 5.5 y). Squamous cell carcinoma (SCC) was the most common histology (71 pts, 94.7%). 67 (89.3%) had PS 0 or 1 and 52 pts (69.3%) were eutrophic (BMI 18.5−25 kg/m^2). Regarding of staging, 18 pts (24%) were stage I, 35 pts (46.7%) II, 8 pts (10.7%) III, 12 pts (16%) IVa and 2 pts (2.7%) IVb at initial presentation. 24 pts (32%) underwent surgery (hysterectomy, adnexectomy, pelvic and paraaortic lymphadenectomy). Adjuvant treatment with radiotherapy (RT) was done in 13 patients (total dose of external RT in pelvis ranged from 39.6 to 45 Gy, parametrial boost ranged from 14 to 20 Gy and 4 inserts from 7 to 7.5 Gy of brachytherapy); 8 of them did concomitant platinum-based chemotherapy (CT). 30 pts underwent definitive CRT, 17 pts definitive RT, 1 palliative CT and 3 exclusive best supportive care. In CRT group, 18 pts received cisplatin (CDDP 40 mg/m^2/w/6w) and 12 carboplatin (AUC 2/w/6w). During definitive CRT, treatment was discontinuated in 39% of pts who received CDDP and 25% of pts in carboplatin group due to toxicity. CDDP group presented more nefrotoxicity: 5 pts (28%) had renal failure during treatment, with median decrease of 23% in creatinine clearance, versus 1 pt (8.3%) in carboplatin treatment. Besides, CDDP group presented more radiodermatitis and stroke. Myelosuppression and diarrhea were similar in both groups. In median follow up of 26.1 m, mOS was not reached.
Conclusions: Despite elderly, more than 60% of pts underwent full CRT and age should not be the only factor to guide therapeutic decisions in CC. Carboplatin was better tolerated than CDDP in CRT group, but prospective trials are necessary to evaluate the best option in this population.
No conflict of interest.

3033 POSTER

Cytoreductive surgery and hyperthermic intraperitoneal chemotherapy for the treatment of advanced epithelial ovarian carcinoma: Upfront therapy, first recurrence or later?

M. Steiner[1], L. Gonzalez Bayon[1], W. Vasquez[1], J. Asencio[1], P. Alvarez de Sierra[1], F. Atahualpa[1], J. Garcia Sabrido[1]. [1]*Hospital General Gregorio Marañon, Cirugia General, Madrid, Spain*

The strategy of cytoreduction and hyperthermic intraoperative intraperitoneal chemotherapy (CRS + HIPEC) has been proposed as a treatment for advanced epithelial ovarian carcinoma (CEO), although there is currently no data to support what is the best time in the natural history of disease to carry out.
Methods: We analyzed a consecutive series of patients with advanced CEO, collected prospectively in a center with a peritoneal malignant disease treatment program. Patients were treated with CRS + HIPEC in different developmental stages of the disease: the onset, in first or second recurrence or more.
Results: Were included in this study 42 patients with advanced CEO treated with CRS + HIPEC: 15 patients at the onset of the disease, 19 patients in first recurrence and 8 patients in second recurrence or more. The degree of cytoreduction achieved was complete (CC0) in 75% of cases and residual <2.5 mm. (CC1) in 25%. Severe morbidity was 26.2% with a hospital mortality of 3 patients (7%). After a median follow up of 24 months,

the median survival of patients treated at the onset of the disease was 77.8 months, the first recurrence group was 62.8 months and the second recurrence or more group was 35.7 months, the disease free survival was 21.1 months, 18 months and 5.7 months respectively. The overall survival curves in the onset of the disease and first recurrence group did not differ significantly, but instead both groups showed statistical significance compared to the second recurrence or more group ($p < 0.03$).
Conclusion: The strategy of CRS + HIPEC in the treatment of advanced CEO achieves promising results in terms of survival and disease free survival. The optimal timing of implementation of this strategy appears to be at the onset of the disease or in the first recurrence. These results warrant further evaluation in a randomized trial.
No conflict of interest.

3034 POSTER

A nomogram predicting the risks of distant metastasis following postoperative radiotherapy for uterine cervical carcinoma: A Korean radiation oncology group study (KROG 12−08)

Y.S. Kim[1], H.J. Kim[2], W. Park[3], J.H. Kim[4], J. Kim[5], M.S. Yoon[6], J.Y. Kim[7], W.S. Yoon[8], J.H. Choi[9], J.Y. Kim[10]. *[1]Asan Medical Center, Radiation Oncology, Seoul, Korea; [2]Seoul National University Hospital, Radiation Oncology, Seoul, Korea; [3]Samsung Medical Center, Radiation Oncology, Seoul, Korea; [4]Dongsan Medical Center, Radiation Oncology, Daegu, Korea; [5]Cheil General Hospital, Radiation Oncology, Seoul, Korea; [6]Chonman National University Hospital, Radiation Oncology, Jeollanam-do, Korea; [7]The Catholic University of Korea, Radiation Oncology, Seoul, Korea; [8]Korea University Asan Hospital, Radiation Oncology, Ansan, Korea; [9]Chung-Ang University Hospital, Radiation Oncology, Seoul, Korea; [10]National Cancer Center, Radiation Oncology, Goyang, Korea*

Background: To develop a nomogram predicting the risks of distant metastasis following postoperative adjuvant radiation therapy for early stage cervical cancer.
Material and Methods: We retrospectively reviewed the medical records of 1,069 patients from ten participating institutions. These patients were divided into two cohorts: a training set (n = 748) for construction of the prediction model, and a validation set (n = 321) for external validation. The demographic, clinical, and pathological variables were included in the univariate Cox proportional hazards analysis. Clinically established and statistically significant prognostic variables were utilized to develop a nomogram. A concordance index and Hosmer-Lemeshow test were performed to validate its discrimination and calibration ability.
Results: The model was constructed using four variables: histologic type, pelvic lymph node involvement, depth of stromal invasion, and parametrial invasion. This model demonstrated good calibration and discrimination, with an internally validated concordance index of 0.71 (Hosmer-Lemeshow test, P >0.99) and an externally validated c-index of 0.65 (Hosmer-Lemeshow test, $P = 0.56$). Compared to FIGO staging, which showed a broad range in terms of distant metastasis, the developed nomogram can accurately predict individualized risks based on individual risk factors.
Conclusion: The devised model offers a significantly accurate level of prediction and discrimination. In clinical practice, it could be useful for counselling patients and selecting the patient group who could benefit from more intensive/further chemotherapy.
No conflict of interest.

3035 POSTER

Community based practices for endometrial cancer referred for adjuvant treatment to a tertiary care hospital in northern India − 10 years audit

P.K. Gupta[1], S. Singh[1], P. Lal[1], N. Rastogi[1], S. Kumar[1]. *[1]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Radiotherapy, Lucknow, India*

Purpose and Objectives: An increasing trend in incidence rates of endometrial cancer (EC) has been reported by cancer registries in India because of changes in lifestyle. The present retrospective study was done to assess the demography and management practices within the community doctors referred for adjuvant treatment to a tertiary care hospital in a northern part of India.
Material and Methods: Between Jan 2000- Dec 2011, 2314 gynaecological cancer patients were registered in the Department of Radiotherapy. Medical records were retrieved for referral patterns, demography, staging work up and surgical practices within the community; adjuvant treatment received and follow-up policies. Disease free survival (DFS) and overall survival (OS) was calculated from time of registration and computed by Kaplan–Meier method. Death due to any cause or loss to follow-up was considered as an event for survival analysis i.e. assuming the worst case scenario.
Results: Seventy one patients had been referred following surgery for an EC. The mean age (range) at presentation was 55.2 (38−80 years). Postmenopausal vaginal bleeding was the most common presenting symptom with mean (range) duration of 12.9 (1−48 months). About half (45%) were referred from community based gynaecologists, a third from other medical centres in the state and 6% by surgical oncologists. Ultrasonography 32(45%) was the preferred prestaging imaging modality with a rising trend for pre-operative MRI (20%) in later years. FIGO stage I−IV was 42%, 16%, 20% and 2% respectively. However 20% of patients could not be staged because of inadequate documentation. Type 1 endometroid carcinoma was (70%) and total abdominal hysterectomy with bilateral salpingo-oophrectomy (90%) was the commonest surgery. Pelvic lymph-node dissection (PLND) was done in one fourth of patients and only 6% had extended lymph-node dissection. The average number of bilateral PLND done was 10%; however only 3% harbored positive nodes.
The EC risk category was 9 (13%)-low risk, 17 (24%)-intermediate risk, 19 (27%)-high risk group and 26 (36%) could not be assigned due to insufficient surgico-pathological details. Adjuvant radiotherapy (in 90%) with or without vaginal brachytherapy was administered while 5 (7%) with stage III and IV also received adjuvant taxane based chemotherapy. Patients were kept on clinical follow up and imaging was done as and when required. Recurrences were documented in 10 patients (all in high risk group) and presented at multiple sites. The median DFS and OS was 14.3 and 17.5 months respectively with 30% alive and disease free and nearly half of the patients were lost to follow-up without disease at time of analysis, all being regarded as 'events'.
Conclusions: In a resource constrained setting, assuring uniformity of treatment and determining patterns of failure in an infrequent disease such as EC is a challenging task given various avenues of service providers and poor compliance to follow-up.
No conflict of interest.

3036 POSTER

The role of adjuvant therapy in uterine sarcomas after definitive surgery

T. Yu[1], H.J. Kim[1], H.G. Wu[1], S.W. Ha[1]. *[1]Seoul National University, Radiation Oncology, Seoul, Korea*

Purpose: To analyze prognostic factors for survivals and evaluate the impact of postoperative radiotherapy (PORT) on pelvic failure in uterine sarcoma treated with radical surgery.
Patients and Methods: Between 1990 and 2010, 75 patients received radical surgery with (n = 24) or without (n = 54) radiotherapy. Carcinosarcoma (CS) and non-carcinosarcoma (non-CS) patients were 24 and 54, respectively. Prognostic factors such as age, histologic type, stage, menopause, initial hemoglobin, mitotic count, size were defined as prognostic factors for survival. The median follow-up period was 84 months (range, 15–236 months).
Results: 5-year overall (OS) and pelvic failure-free survival (PFFS) of total patients were 71% and 83%, respectively. Loco-regional failure was 25%(n = 6) and distant failure was 17% (n = 4) in carcinosarcoma, whereas loco-regional failure was 6%(n = 3) and distant failure was 24%(n = 13) in non-carcinosarcoma. Histologic type ($p = 0.047$) and stage ($p = 0.006$) were significant predictors of OS in multivariate analysis. However none of the factors analysed were significant predictors of PFFS. PORT significantly reduced pelvic failure in carcinosarcoma (90.9% vs. 46.3%, $p = 0.032$), but not in non-carcinosacorma (88.9% vs. 90.2%, $p = 0.935$).
Conclusion: This study suggests that PORT reduced pelvic failure in carcinosarcoma patients, but not in non-carcinosarcoma uterine sarcoma patients. As failure patterns were mostly distant metastases in non-carcinosarcoma, further attempt with more effective systemic therapy is considered.
No conflict of interest.

3037 POSTER

Impact of "ketofol" sedation on dosimetric parameters in patients undergoing high-dose rate intracavitary radiotherapy

M. Watanabe Nemoto[1], T. Uno[1], N. Taguchi[2], G. Togasaki[1], A. Kanazawa[1], M. Kurokawa[1], M. Saito[1], R. Harada[1], K. Isobe[1]. *[1]Graduate School of Medicine Chiba University, Department of Diagnostic Radiology and Radiation Oncology, Chiba, Japan; [2]Graduate School of Medicine Chiba University, Department of Anaesthesiology, Chiba, Japan*

Background: To relief pain and distress of women undergoing high-dose rate intracavitary radiotherapy (HDR-ICRT), a new intravenous anaesthetic protocol combined propofol and ketamine was developed in collaboration with anaesthesiologist. This new sedation protocol was proved to be safe and provide satisfactory sedation level during HDR-ICRT in our previous study. There is an impression that the application and packing are easy

to carry out. The primary aim is to investigate retrospectively an impact of this sedation on dosimetric parameters in patients with cervical cancers undergoing HDR-ICRT.
Material and Methods: All patients with cervical cancer consecutively treated with 3-channel brachytherapy between December 2008 and May 2012, who received following sedation protocol were evaluated. We administered propofol by using an patient-controlled analgesia (PCA) pump as an initial loading of 10 mg, followed by a maintenance infusion at 2 mg/kg/min, a demand bolus of 20 mg with a limit of four times per an hour, and lockout of 5 min and ketamine in the dose of 1 mg/kg diluted in normal saline 100 ml. As a control, 33 patients, 92 procedures, who received ICRT-HDR before introduction of this protocol were evaluated. We compared the ICRU rectal dose, ICRU bladder dose and the laterality of point A dose between before and after the introduction of this intravenous anaesthesia.
Results: ICRU rectal dose were 80.7±24.4% vs. 66.8±25.4% ($p < 0.00001$) for control vs. sedation group, respectively. There was no significant difference in ICRT bladder dose and the laterality of point A dose 77.4±30.2% vs. 72.6±25.4% and 1.01±0.03 vs. 1.00±0.06 for control vs. sedation group, respectively.
Conclusions: This new sedation protocol reduced ICRU rectal dose during HDR-ICRT.
No conflict of interest.

3038 POSTER

Treatment results of image-guided high-dose-rate interstitial brachytherapy for recurrent uterine cancer

K. Yoshida[1], H. Yamazaki[2], T. Takenaka[3], T. Kotsuma[4], K. Masui[2], Y. Yoshioka[5], Y. Uesugi[1], T. Shinbo[1], E. Tanaka[4], Y. Narumi[1]. *[1]Osaka Medical College, Radiology, Takatsuki, Japan; [2]Kyoto Prefectural University of Medicine, Radiology, Kyoto, Japan; [3]National Hospital Organization Osaka National Hospital, Radiology, Osaka, Japan; [4]National Hospital Organization Osaka National Hospital, Radiation Oncology, Osaka, Japan; [5]Osaka University Graduate School of Medicine, Radiation Oncology, Osaka, Japan*

Background: In order to evaluate the effectiveness of image-guided high-dose-rate interstitial brachytherapy (HDR-ISBT) for recurrent uterine cancer, we analyzed our clinical experience.
Methods and Materials: Between May 2003 and October 2010, 43 patients were treated by HDR-ISBT with or without external beam radiotherapy. The minimum follow-up time for survivor was 24 months (median follow-up: 41 months, range: 24–109 months). Previous treatment before ISBT was radical hysterectomy (Group A) for 27 patients, radical hysterectomy with postoperative radiotherapy (Group B) for 7 patients and radical radiotherapy (Group C) for 9 patients. We implanted the treatment applicator by transrectal ultrasonography. We used template guidance and no-ambulatory implant technique for first 5 patients and free-hand and ambulatory implant technique for latest 38 patients. We also started MRI-assisted CT-based planning for latest 38 patients. Fourteen patients were treated with a combination of HDR-ISBT (median 30 Gy/ 5 fractions; range: 27−36 Gy) and external beam radiotherapy, and the other 29 with HDR-ISBT alone (median 54 Gy/ 9 fractions; range: 42−54 Gy).
Results: The two-year local control and overall survival rates were 81% and 79%, respectively. The 2-year local control rate was 89%, 86% and 56% for Group A, Group B and Group C. Grade 3−4 late complication occurred in 9 patients (21%) with 11 events (3 genitourinary, 7 gastrointestinal and 1 vaginal complications).
Conclusions: Our image-guided HDR-ISBT for recurrent uterine cancer showed promising preliminary results. However, worse local control rate was observed for the tumor recurred after radical radiotherapy.
No conflict of interest.

3039 POSTER

Primary vaginal cancer − the Edinburgh Cancer Centre experience

A. Sundaramurthy[1], A.L. Stillie[1]. *[1]Edinburgh Cancer Centre, Clinical Oncology, Edinburgh, United Kingdom*

Background: Primary vaginal cancer is a rare cancer. The European age standardized incidence rate is 0.6 per 100,000 female populations. We report on patients treated at single institution from January 2000 to Dec 2011 with radical radiotherapy. Our primary objective is to evaluate clinical outcome measured as relapse free survival (RFS) and overall survival (OS) at 2 years. Secondary objective is to assess radiotherapy related chronic morbidity.
Materials and Methods: From January 2000 to December 2011, 34 patients were treated for primary vaginal cancer. Case notes of 33 patients were reviewed retrospectively [1 note untraceable]. 11 patients were excluded [vaginal melanoma − 2, vaginal cancer palliative treatment − 3, VAIN 3−3, upfront chemotherapy − 1, surgical resection only − 1]. The remaining 23 patients were included in the final analysis.
Results: Median follow-up was 34 months [range 4–129 months]. Median age at diagnosis was 65 years [range 43−86].

FIGO Stage	Number of Patients
I	9 (39.1%)
II	4 (17.4%)
III	7 (30.4%)
IV	3 (13.1%)

87% received external beam radiotherapy [EBRT] either alone or in combination with chemotherapy and/or brachytherapy [BT] (n = 20). EBRT dose to pelvis was 45 Gy or 50 Gy (Mean EBRT dose 46.2 Gy). 13% received BT alone following local resection (n = 3). RFS at 2 years was 69.9% and 2 year OS was 74%. Cancer specific 2 year OS was 82.6%. There were 10 cases of relapse. Local relapse was the most common cause of treatment failure (n = 7/10). Of the 7 local relapse, 1 patient relapsed at 18 months which was treated with local excision and she is alive at 129 months. 33.3% of patients with Stage I disease relapsed (n = 3/9) and 50% of patients with > Stage I relapsed (n = 7/14). The estimated relative risk of relapse in > Stage I was 1.501 [95% CI 0.52–4.34]. 60.9% were non-smokers (n = 14), 30.4% were smokers (n = 7), and 8.7% smoking status unknown (n = 2). The estimated relative risk of relapse in smokers was 1.298 [95% CI 0.496–3.052]. Vaginal stenosis was the most common toxicity (n = 10) followed by radiation proctitis (n = 5). Toxicities were predominantly grade 1−2. There was 1 case of grade 4 recto-vaginal fistula.
Conclusion: Local relapse was the commonest cause of treatment failure. Relapse was common in patients with > Stage I disease. Smokers appeared to have a higher risk of relapse. The toxicities were generally low and well tolerated apart from one instance of grade 4 recto-vaginal fistula. Our 2 year RFS and OS was similar to that quoted in literature.
No conflict of interest.

3040 POSTER

Clinical efficiency of brachytherapy with different dose rate for carcinoma of the uterine cervix

V. Turkevich[1]. *[1]N.N. Petrov Research Institute of Oncology, Nuclear Medicine and Radiation Oncology, Saint Petersburg, Russian Federation*

Purpose: Brachytherapy is an integral component of the definitive treatment carcinoma of the uterine cervix. In our Institute we are developing a guideline for clinical practice of low-dose-rate (LDR), middle-dose-rate (MDR) and high-dose rate (HDR) brachytherapy for locally advanced cervical cancer.
Material and Methods: In the present investigation were studied the data about 645 patients with carcinoma of the uterine cervix, who obtained the radiotherapy in Petrov Research Institute of Oncology Ministry of Health, Saint Petersburg. For treating all patient was used the combine (EBRT + Brachytherapy) radiotherapy. Brachytherapy with LDR (0.5 Gy/h) was underwent 221 patients. Adapted three modes for fractionating the summary target dose (STD): the first mode − 20 Gy, once a week, STD=80 Gy (BEDe=86, BEDl=148); the second mode − 20 Gy, once a week, STD=100 Gy (BEDe=107, BEDl=186); the third mode − 20 Gy, once a week, STD=120 Gy (BEDe=129, BEDl=223). Also three modes for fractionating STD were studied with MDR brachytherapy (227 patients) and HDR brachytherapy (197 women): the first mode − 7 Gy, once a week, STD=28 Gy (BEDe=48, BEDl=106); the second mode − 7 Gy, once a week, STD=35 Gy (BEDe=60, BEDl=133); the third mode − 7 Gy, once a week, STD=42 Gy (BEDe=71, BEDl=160).
Results: In all stages five-year overall and local control survival composed 55±2%, ten-year − 46±3%. The overall five-year survival of patients with stage I b − 80±4%, II b − 63±3%, III b − 35±3%, local control survival in the cases stage I b − 80±6%, II b − 64±5%, III b − 35±4%, the differences between the stages are statistically reliable ($p < 0.05$). The total number of acute toxicity among patients treated with MDR brachytherapy substantially ($p < 0.05$) was 10% less in comparison with LDR and HDR, due to the reliable ($p < 0.05$) decrease of a quantity early urinary bladder toxicity (to 6% in comparison with HDR), and rectum toxicity (to 8% − with LDR). The total number of late toxicity among patients treated with HDR brachytherapy substantially ($p < 0.05$) was 5% more in comparison with MDR and 8% more in comparison with LDR, due to a reliable ($p < 0.05$) increase in the quantity of early urinary bladder toxicity (to 5% in comparison with LDR).
Conclusion: Substantial changes in the length of life of patients depending on the brachytherapy with different dose rate we did not found. Quantity early and late toxicity depend from different dose rate brachytherapy for combine radiotherapy carcinoma of the uterine cervix.
No conflict of interest.

3041 POSTER

Outcome of the cervix uteri cancer patients treated with or without concurrent chemotherapy and radiotherapy incorporating high dose rate brachytherapy: An experience from Saudi Arabia

M. El Sayed[1], Y. Bahadur[2], E. Fawzy[1], A. Hassouna[1], A. Nasr[3], K. Sait[4], B. Ben Sadiq[5], R. Dada[6], N. Anfinan[4]. *[1]King Faisal Specialist Hospital & Research Center, Oncology Department, Radiation Oncology Section, Jeddah, Saudi Arabia; [2]King Abdulaziz University Hospital, Radiology Department, Jeddah, Saudi Arabia; [3]King Abdulaziz Oncology Center, Radiation Oncology Department, Jeddah, Saudi Arabia; [4]King Abdulaziz University, Faculty of Medicine, Jeddah, Saudi Arabia; [5]King Faisal Specialist Hospital & Research Center, Research Center, Jeddah, Saudi Arabia; [6]King Faisal Specialist Hospital & Research Center, Oncology Department, Medical Oncology Section, Jeddah, Saudi Arabia*

Background: Concurrent Chemo-Radiotherapy (CRT) plus Brachytherapy (BT) have become the standard treatment modalities for cervix uteri cancer stage IB2-IVA.
Aim of the study: This is a retrospective study evaluating the demographic data, survival outcome, pattern of failure and prognostic factors of cervix uteri cancer patient treated with concurrent chemo-radiotherapy incorporating high dose rate brachytherapy at single instituation in Saudi Arabia.
Materials and Methods: A review of 60 cervix uteri cancer patients with stages IB- IVA; treated with radiotherapy with and without concurrent cisplatin plus high dose rate (HDR) brachytherapy; between January 2004 and December 2010. The overall survival (OS) and disease free survival (DFS) were analyzed using Kaplan–Meier methods. Univariate and multivariate analysis were used to detect the significant prognostic factors.
Results: Most of patients (50 patients; 83 %) had Squamous cell carcinoma. Stage IIB was the most common presentation (41 patients; 68 %). All patients completed the planned external beam radiotherapy (EBRT) and the brachytherapy (BT) treatment course. Forty Seven patients (78%) received Cisplatin concurrent with EBRT. The median follow up period was 24 Months (range, 6 −77 Months). The 2 and 4 years overall survival was 82%, and 79 % respectively, prolongation of the overall treatment time more than 56 days and the pretreatment hemoglobin (Hb) level ($\leqslant$10 g/dL) negatively predict the overall survival in the univariate and multivariate analysis ($p = 0.039$ and $p = 0.008$ respectively). The 2 and 4 years DFS were 80% and 69% respectively, with vaginal extension was the only significant factor determining the relapse ($p = 0.048$). The 2 and 4 years loco-regional and distant metastasis free survival were 78 % & 70 % and 82% &79 % respectively. Vaginal extension was the only negative predictor factor for the loco regional control ($p = 0.045$), while the grade was the only factor for the distant metastases free survival ($p = 0.037$). Grade 3 or 4 late rectal reaction was reported in 2 patients (3 %), severe vaginal adhesion in one patient (1.5%), while no patients developed grade 3 or 4 urinary reaction.
Conclusion: Concurrent chemo-radiotherapy is an effective treatment modality for cervix uteri cancer patients. The overall treatment time and pretreatment Hb level were the most important predictor factors for survival, while vaginal extension and grade of the tumor were negative predictor factors for loco-regional and distant metastases free survival respectively.
No conflict of interest.

3042 POSTER

Dosimetry study on use of image guidance for radical vaginal vault brachytherapy

M. Zahra[1], L. Thear[2], L. Bleakley[2], W. Keough[2]. *[1]Edinburgh Cancer Centre, Edinburgh, United Kingdom; [2]Edinburgh Cancer Centre, Oncology, Edinburgh, United Kingdom*

Background: The aim of this study is to model the doses to the organs at risk (OARs) using CT planning for radical treatment using vaginal vault brachtherapy (VBT).
Material and Methods: Patients had a planning CT scan with the vaginal cylinder in situ. The cylinder diameter was based on clinical examination of the patient using commercially available solid cylinders. The OARs were outlined. The total EQD2 doses to the OARs were modeled using an α/β ratio = 3 Gy, an EBRT component of 45 Gy in 25 fractions and 21 Gy in3 fractions of HDR VBT using a line source and prescribed at 0.5 cm depth from cylinder surface to the cranial 4 cm of the vagina. The 0.1cc, 1cc and 2cc doses for the bladder, rectum, sigmoid and small bowel were calculated and correlations with cylinder diameter, vaginal length and the angle of cylinder relative to the couch top were assessed using the Pearson's correlation coefficient with 2-tailed significance testing.
Results: 95 consecutive patients were scanned, median vaginal length = 11 cm (7−16 cm); median angle of cylinder relative to couch top was −2.9º (4.8º − −20.8º). The cylinder diameter only showed a correlation with d0.1cc bladder ($r = -0.205$; $p = 0.046$). The sigmoid d0.1cc, d1.0cc and d2.0cc correlated with vaginal length $r = 0.251$ ($p = 0.015$), 0.28 ($p = 0.006$) and −0.349 ($p = 0.001$) respectively. The small bowel d0.1cc, d1.0cc and d2.0cc correlated with vaginal length $r = -0.263$ ($p = 0.01$), −0.264 ($p = 0.01$) and −0.252 ($p = 0.01$) and with angle relative to couch top $r = 0.202$ ($p = 0.01$), 0.219 ($p = 0.035$) and 0.222 (0.032).

	Bladder	Rectum	Sigmoid	Small bowel
D 0.1cc (Gy), Median (range)	7.4 (5.2−11.2)	7.6 (4.5−9.9)	5.7 (1.5−9.2)	5.1 (0.3−9.6)
D 1.0cc (Gy), Median (range)	6.6 (4.6−9.1)	6.5 (4.0−8.3)	4.7 (1.3−7.1)	4.1 (0.3−7.9)
D 2.0cc (Gy), Median (range)	6.2 (4.3−8.7)	5.9 (3.6−9.0)	4.1 (1.2−6.6)	3.7 (0.3−7.4)
EQD2 D 2.0cc (Gy) (EBRT + VBT), Median (range)	77.9 (43.3−103.8)	74.4 (57.3−108.6)	60.1 (43.3−81.5)	56.4 (43.3−89.3)
No. exceeding target tolerance dose	(target $\leqslant$90 Gy) 4 (4.2%)	(target $\leqslant$70 Gy) 67 (70.5%)	(target $\leqslant$70 Gy) 16 (16.8%)	(target $\leqslant$70 Gy) 22 (23.3%)

Conclusion: When combining radical EBRT and VBT ($\geqslant$21 Gy in 3 fractions) image guidance can reduce the significant risk of exceeding the OAR's target tolerance doses. These cases cannot be predicted based on cylinder diameter. Potentially high doses can be delivered to the OARs especially the rectum which could result in significant late toxicity.
No conflict of interest.

3043 POSTER

Quantification of air gaps using CT in vaginal vault brachytherapy

M. Zahra[1], L. Bleakley[2], L. Thear[2], W. Keough[2]. *[1]Edinburgh Cancer Centre, Edinburgh, United Kingdom; [2]Edinburgh Cancer Centre, Oncology, Edinburgh, United Kingdom*

Background: Vaginal vault brachytherapy is an effective adjuvant treatment but the presence of air gaps could impact efficacy especially due to the steep dose fall off.
Material and Methods: Patients receiving adjuvant vaginal vault brachytherapy get a planning CT scan with vaginal cylinder in situ prior to the first brachytherapy fraction. The vaginal cylinder diameter is chosen based on the clinical examination and confirmed using a perspex dummy vaginal cylinder developed in our institution which also accurately measures vaginal length. Patients are treated using solid vaginal vault cylinders with a fixed range of diameters (2.0, 2.6, 3.0 and 3.5 cm) available commercially. The CT scans were analysed using Brachyvision® to identify the presence of air gaps and measure the volume, position relative to the vaginal vault and the angle of cylinder relative to the couch top. Correlations were assessed using the Pearson correlation coefficient with 2-tailed significance testing.
Results: 101 consecutive patients were scanned, 66 patients had an air gap identified along the length of the vaginal cylinder but only in 30 cases (29.7%) were these within the cranial 4 cm constituting the treatment volume. The median volume of the gaps within the treatment length was 0.315 cm^3 (0.01–4.84 cm^3) and made up a median of 1.27% of the treatment volume (0.03–20.64%). No correlation was identified between the air gap volume and the vaginal length or the angle of cylinder relative to the couch top. There was a negative correlation between the air gap volume and the cylinder diameter (Pearson coefficient = −0.426; $p = 0.019$).
Conclusion: The practice to choose the vaginal cylinder diameter based on the clinical assessment and inserting the largest diameter cylinder that can be accommodated in the vagina helps to keep air gaps within the treatment volume to a minimum and the dosimetric impact is deemed to be not significant.
No conflict of interest.

3044 POSTER

Uncertainties of organs at risk delineation in MRI guided adaptive cervix cancer brachytherapy: A multi-institutional study

P. Petric[1], T.P. Hellebust[2], K. Tanderup[3], M.R. Poolakundan[1], S.R. Divakar[1], N. Al Hammadi[1], C. Kirisits[4], D. Berger[4], J.C.A. Dimopoulos[5], R. Pötter[4]. [1]*National Center for Cancer Care & Research, Department of Radiotherapy, Doha, Qatar;* [2]*Oslo University Hospital The Radium Hospital, Department of Medical Physics, Oslo, Norway;* [3]*Aarhus University Hospital, Department of Oncology, Aarhus, Denmark;* [4]*Medical University of Vienna, Department of Radiotherapy and Radiobiology, Vienna, Austria;* [5]*Metropolitan Hospital, Department of Radiotherapy, Athens, Greece*

Background: Contouring uncertainties can undermine the overall gain of high-precision radiotherapy techniques. We aimed to quantify uncertainties of organs at risk contouring in cervix cancer MR image-guided adaptive brachytherapy (IGABT).
Materials and Methods: 10 radiation oncologists from 10 centres participating in EMBRACE study (intErnational study on MRI-guided BRachytherapy in locally advanced CErvical cancer; www.embracestudy.dk) contoured bladder (B), rectum (R) and sigmoid colon (S) in 6 patients treated with IGABT. Contours were compared with expert consensus (EC) delineations qualitatively and by calculating conformity index (CI), absolute inter-delineation distances (IDD), and deviations of B top, urethro-vesical junction and RS junction position.
Results: Uncertainties were most prominent at transition of S to posterior pelvic location and RS junction. In 2 (3.3%) B and 2 (3.3%) R contours, bowel and muscles were included, respectively. For S, inclusion of Douglas pouch, bowel, parametria and HR CTV was found in 1 (2%), 3 (5%), 6 (10%) and 1 (2%) delineation. CI for B, R and S was 0.80 (SD 0.07), 0.70 (SD 0.10) and 0.49 (SD 0.16). B top, urethro-vesical junction and RS junction were at 1 (SD 4), 2 (SD 5) and 9 (SD 14) mm from the EC delineation. Higher absolute IDDs were obtained for S (13±4 mm) when compared to B (3±0.5 mm) and R (3±0.5 mm) ($p < 0.001$). Dosimetric consequences of these uncertainties were reported recently [Hellebust, Radiother Oncol 2013].
Conclusions: Variation was more prominent for sigmoid colon when compared to bladder and rectum. Respecting delineation guidelines is needed to minimize uncertainties and their dosimetric impact.
No conflict of interest.

3045 POSTER

A study to evaluate the association between dose volume parameters and vaginal toxicity in patients of cervical cancer undergoing image based brachytherapy in a protocol setting

B. Rai[1], B. Dhanireddy[1], F.D. Patel[1], O.A. Singh[1], V. Simha[1], S.C. Sharma[1]. [1]*Post Graduate Institute of Medical Education and Research, Radiotherapy and Oncology, Chandigarh, India*

Background: Although dose volume parameters have been recommended for the bladder, rectum and sigmoid, the parameters for vagina have not been recommended primarily because of high uncertainties that exist in dose reporting. Data from a single institution have reported no correlation with the vaginal side effects. The aim of the study was evaluate the association between the dose volume parameters and vaginal toxicity in patients with cervical cancer treated with image guided brachytherapy at our institute.
Material and Methods: Thirty-five patients treated with image guided brachytherapy for cervical cancer were included in the study. All patients received external pelvic radiotherapy and dose of 46 Gy over four and a half weeks was delivered along with concurrent weekly cisplatin followed by high dose rate brachytherapy 7 Gy in four fractions. The contouring was done on MRI and DVH parameters were reported in accordance with the GEC-ESTRO guidelines. The vaginal wall was contoured on MRI as well as the CT done in subsequent brachytherapy fractions. The D1cc, D2cc, D5cc and D 10cc were calculated. This was correlated to the vaginal toxicity (assessed by CTCAE version 3) at one year of completion of treatment.
Results: The mean vaginal volume was 27.9±5.9cc.The mean 1cc, 2cc,5cc and 10cc physical doses to the vagina for each brachytherapy fraction were 14.16± 1.2 Gy, 10.84±1.67 Gy, 6.71± 0.98 Gy and 4.21±0.64 Gy respectively. The mean 1cc,2cc, 5cc and 10cc iso-effective doses for vagina were 164.15±24.46 Gy, 123.89±11.05 Gy, 83.65±4.21 Gy and 65.26±2.23 Gy respectively. Vaginal shortness was observed in 22/35 patients (62.8%); Grade −1 in 12/35 patients (34.2%), grade-2 in 9/35 (25.7%) and grade- 3 in only one patient (2.8%). Grade-1 vaginal dryness was observed in 9/35 patients (25.7%), none of the patients had grade2−3 vaginal dryness. Ten patients (28.5%) had contact bleeding. No association could be demonstrated between the dose volume parameters and vaginal toxicity in the present study.
Conclusions: The lack of association between dose volume parameters of vagina with vaginal morbidity may be due to uncertainties involved in the delineation of vaginal wall and dosimetry. A longer follow up could result in more patients with vaginal morbidity. Future research in a larger patient cohort is required to study the clinical effect of dosimetric parameters on the vaginal morbidity.
No conflict of interest.

3046 POSTER

Adjuvant treatment of vulvar cancer with IMRT

A. Mota[1], R. Leite[1], A. Pimenta[1], F. Ribeiro[1], M. Sousa[1], M. Fortunato[1], F. Santos[1], M. Roldão[1]. [1]*Instituto Português de Oncologia de Lisboa Francisco Gentil, Radioterapia, Lisboa, Portugal*

Background: There are very few studies regarding IMRT (Intensity Modulated Radiation Therapy) and the treatment of vulvar cancer. Therefore, we will present our experience on IMRT treatment in adjuvant vulvar cancers, at our Department.
Material and Methods: Retrospective analysis of vulvar cancer treated with surgery and adjuvant IMRT between January 2009 and February 2012. All pacients were treated with IMRT (sliding window), in a Clinac 2100CD (linear accelarator), with photon energy 6MV. For dosimetry, the inversed planning system was used. It was evaluated the PTV (Planning Target Volume) coverage, the dose's homogeneity distribution and the dose tolerance of the organs at risk (rectum (D40), bladder (D40), bowel (D35) and bone marrow (V20)).
The acute toxicity (gastrointestinal, genitourinary, hematologic and skin) was evaluated according to the RTOG (Radiation Therapy Organization Group) criteria.
Results: Thirty women, with a median of age of 75 years old, were treated with adjuvant IMRT. All patients completed treatment in its entirety. The mean dose delivered was 62.32 Gy (50−66 Gy). The mean volume that received less than 95% of the dose on the PTV was 2.12% and only one patient received more than 107% on PTV prescribed dose. The average dose received by the organs at risk were: bladder (31.51 Gy), rectum (33.04 Gy), bowel (23.85 Gy) and bone marrow (22.27 Gy).
The average D40 in rectum was 28.4 Gy, D40 in bladder was 26.09 Gy, D35 in bowel was 26.4 Gy and bone marrow V20 was 48.59 Gy. Nine patients developed grade 3 skin toxicity but this did not lead to treatment interruption. No patients had grade 3 gastrointestinal, genitourinary and hematologic toxicity. Out of the thirty patients, 14 (50%) died, and 14 (50%) were alive at the time of the present analysis. Nine (30%) had loco-regional relapse, and 1 (3.3%) had distant metastasis.
Conclusion: IMRT seems to be a promising treatment in vulvar cancer. IMRT planning has a proper PTV coverage with considerable sparing of organs at risk and is well tolerated by patients. We also achieve with IMRT a low loco-regional relapse, as mentioned in the literature.
No conflict of interest.

3047 POSTER

Nomogram for prediction of outcome for patients with endometrium cancer: a pooled analysis of PORTEC-1 and PORTEC-2 trials

C.L. Creutzberg[1], R.G.P.M. Van Stiphout[2], R.A. Nout[1], L.C.H.W. Lutgens[2], I.M. Jürgenliemk-Schulz[3], J.J. Jobsen[4], V.T.H. Smit[5], P. Lambin[2]. [1]*Leiden University Medical Center, Department of Clinical Oncology, Leiden, Netherlands;* [2]*University Medical Centre Maastricht, Department of Radiation Oncology (MAASTRO), Maastricht, Netherlands;* [3]*University Medical Centre Utrecht, Department of Radiation Oncology, Utrecht, Netherlands;* [4]*Medisch Spectrum Twente, Department of Radiation Oncology, Enschede, Netherlands;* [5]*Leiden University Medical Center, Department of Pathology, Leiden, Netherlands*

Background: Postoperative radiotherapy for endometrial cancer improves locoregional control without a survival benefit. To allow treatment decision support for individual patients and generation of new evidences and hypotheses, accurate statistical models to predict locoregional relapse (LR), distant relapse (DR), overall survival (OS) and disease-free survival (DFS) are required.
Methods: Clinical trial data from the PORTEC-1 (N = 714) and PORTEC-2 (N = 427) trials and of the registration group with grade 3 and deep invasion (N = 99) were pooled for this analysis (total N = 1240). Data from pathology review were used if available; otherwise original pathology was used. The common clinical trial variables which were clinically relevant and eligible according to data constraints were: age, stage at randomization, given treatment (external beam radiotherapy (EBRT), vaginal brachytherapy (VBT) or no adjuvant treatment), FIGO histological grade, depth of invasion, width of the uninvolved myometrium, minimal distance of tumor to serosal surface, involvement in cornuae and vascular invasion. The multivariate analyses were based on the cox proportional hazards regression model.

Variables were ranked according to their predictive power by using a bootstrap scheme (N = 1000). Performance of the models was expressed by the c-index, which has similar properties as the area under the ROC curve (0.5, random prediction and 1, perfect prediction). Validation performance was tested with a 10-fold cross-validation scheme to avoid overfitting.
Results: The accuracy of the developed models was good with training accuracies between 0.68 and 0.79. The validation performances were consistent for all outcomes, between 0.67 and 0.76. Ranking of the variables to their predictive power showed that age, tumor grade and vascular invasion were highly predictive for all outcomes, and given treatment for locoregional relapse. Nomograms were developed for locoregional relapse, distant relapse, disease-free and overall survival and will be presented.
Conclusion: The provided models are internally validated and are able to accurately predict long-term outcome for endometrium cancer patients after surgery and optionally no extra treatment, EBRT or VBT. These models should allow decision support in daily clinical practice, i.e. patient counseling and shared decision making, selection of patients who may benefit most from adjuvant treatments, and generation of new hypotheses.
No conflict of interest.

3048 POSTER

CyberKnife® fractionated stereotactic radiotherapy for loco-regionally recurrent uterine cervical carcinoma

M. Coskun[1], A. Dizman[1], Y. Güney[1]. [1]*Ankara Oncology Hospital, Radiation Oncology, Ankara, Turkey*

Background: Currently there is no standard treatment option for recurrent uterine cervical carcinoma. Surgery, in high selected cases, and of radiation and chemotherapy, or the combination of different modalities can be chosen according to the patient specific characteristics. There is not high-level evidence for the usage of Stereotactic Fractionated Radiotherapy (FSRT). We aim to challenge the role of CyberKnife® FSRT for loco-regionally recurrent uterine cervical carcinoma, especially for those who are not convenient for intra-cavitary brachytherapy because of the localisation of the tumour.
Material and Methods: We retrospectively evaluate the cases that underwent CyberKnife® FSRT for loco-regionally recurrent uterine cervical carcinoma.
Results: Six patients with a median age of 54 (range, 48−67) underwent CyberKnife® FSRT between July 2010 and July 2012. Primary tumour FIGO stage was I−II in all cases. Median time for the recurrence after primary treatment was 30 months (range,16–282). Primary therapy at the time of initial diagnosis was surgery (n = 3) and chemo-radiotherapy (n = 3). Histology of tumours was adenocarcinoma (n = 3), squamous-cell carcinoma (n = 2) and clear cell carcinoma (n = 1). Pelvic radiotherapy (RT) (45 Gy) was applied for the patients who had not receive RT as primary treatment at the time of initial diagnosis (n = 3). All patients underwent CyberKnife® FSRT with fiducial tracking. No complication was observed after fiducial placement. CyberKnife® treatments had given with a median number of 75 nodes (range, 59−86) and 236 beams (range, 115–365). Prescription dose and PTV characteristics of each patient are summarised in Table 1. Median value for the PTV dose maximum and minimum was 112% and 94% of the prescribed dose, respectively. Bladder and rectum maximum doses were kept below 38 Gy in all cases with a median value of 26.7 Gy (8.3–33.2) and 25.7 Gy (21.3–33.8) respectively. No acute toxicity was observed in any of the patients but one who had severe sub-ileus after treatment and died in 3 months. One patient died 1 month after treatment because of comorbidities. Partial tumour regression (n = 2) and progression (n = 2) was detected at 5 month follow-up. One patient with partial tumour regression died at 9th month because of distant disease progression. Two patients with local tumour progression died at 5th and 11th months. Median survival of the patients was 6 months (range, 1−11).

Table 1. Prescription dose and PTV characteristics.

Patient ID	D*pres*. (Gy)	Pres. Isodose (%)	n*F*	PTV *V (cc)*	PTV CI	PTV nCI	PTV HI	PTV coverage(%)
1	25	93	5	89.8	1.1	1.2	1.0	95
2	30	85	6	110.7	1.4	1.4	1.1	99
3	25	92	5	37.9	1.6	1.7	1.0	99
4	25	84	5	126.4	2.0	2.0	1.1	99
5	20	86	5	20.0	1.8	1.8	1.1	99
6	20	85	5	89.8	1.5	1.5	1.1	100

D*pres*, prescription dose; n*F*, number of fractions; V, volume; CI, conformity index; nCI, new conformity index; HI, homogeneity index.

Conclusions: Our series with a limited number of the cases does not show an effective tumour control or survival improvement with FSRT for loco-regionally recurrent uterine cervical carcinoma.
No conflict of interest.

3049 POSTER

Effect of varying bladder volumes with and without a bladder catheter on dosimetry in high dose rate vaginal vault brachytherapy for endometrial cancer

W.S. Owadally[1], V. Fenwick[1], N. Burton[1], I. Hagan[2], A. Cook[1], R. Counsell[1]. [1]*Cheltenham General Hospital, Radiotherapy, Cheltenham, United Kingdom;* [2]*Cheltenham General Hospital, Radiology, Cheltenham, United Kingdom*

Background: Vaginal vault brachytherapy (VBT) is used in the adjuvant treatment of endometrial cancer. It is used alone or after external beam radiotherapy (EBRT). Severe late bowel and bladder toxicity have been reported in 5% of patients, particularly when VBT is added to EBRT. Bladder volumes may affect the dose to organs at risk (OAR). This study looks at the impact of bladder fullness on OAR dosimetry in the presence or absence of a bladder catheter.
Material and Methods: 3D CT plans were reviewed for 28 patients randomly selected from a group of 115 patients treated with high dose rate VBT at our centre. All patients were treated with a single source vaginal cylinder applicator. 5 patients had empty bladders following catheter insertion and received VBT alone. The remaining 23 patients were not catheterised, but were asked to empty their bladder before applicator insertion. 11 patients received VBT alone (22 Gy/4f) and 12 in combination with EBRT (8 Gy/2f). Dose was prescribed to 5 mm from the applicator surface. The rectum, bladder, sigmoid and small bowel were contoured by a radiation oncologist and checked by an expert radiologist. D2cc per gray was measured for each OAR taking into account the different fraction size. Independent samples t tests and Pearson correlation were analysed.
Results: The median bladder volume was 57 cm^3 (44−67) and 67 cm^3 (38–308) with and without a catheter respectively. The bladder volume was significantly smaller when a catheter was used (p = 0.01), although 40% of patients without a catheter had a small bladder (<57 cm^3). Table 1 summarises Pearson correlation between bladder volumes and D2cc per gray for each OAR. There was a significant negative correlation between bladder volume and dose to small bowel (r= −0.45, p = 0.02).

	Bladder	Rectum	Sigmoid	Small bowel
Pearson correlation, r	0.31 p = 0.11	0.22 p = 0.25	−0.27 p = 0.16	−0.45 p = 0.02

Total EQD2 doses were calculated for the 12 patients who received combination EBRT and VBT. Rectum, sigmoid and small bowel received an additional median EQD2 dose of 7.3 Gy (5.3−9.9), 2.4 Gy (1.1−5.2) and 4.7 Gy (0−8.2) respectively.
Conclusions: Routine practice in many centres is to minimise bladder volumes, by using a catheter or emptying bladder before treatment. Our data shows no advantage in having a smaller bladder with respect to dosimetry to bladder, rectum and sigmoid. We confirm previous findings that some bladder filling reduces small bowel dose. This is particularly important in those patients also having EBRT. Further work is being done using a fluid intake protocol in order to achieve bladder filling without the complications of a catheter.
No conflict of interest.

Dose escalation with intensity modulated radiotherapy in the treatment of locally advanced cervical cancer

H. Caglar[1], A. Saran Ikizler[2], B. Atalar[1], N. Sozer[2], O. Er[3], H. Doruk[4], E. Ozyar[1]. [1]*Acibadem University Acibadem Maslak Hospital, Radiation Oncology, Istanbul, Turkey;* [2]*Acibadem University Acibadem Bursa Hospital, Radiation Oncology, Istanbul, Turkey;* [3]*Acibadem University Acibadem Maslak Hospital, Medical Oncology, Istanbul, Turkey;* [4]*Acibadem University Acibadem Bursa Hospital, Medical Oncology, Istanbul, Turkey*

Background: The standard treatment of locally advanced cervical cancer is concurrent chemoradiation. Radiotherapy with newer treatment technologies such as intensity modulated radiotherapy (IMRT) seems to be effective with minimized toxicity.
Material and Methods: Patients who were diagnosed with locally advanced cervical cancer between 7/2009−8/2012 and treated with IMRT

+ concurrent weekly cisplatin with a minimum follow up of 6 months were included in this retrospective analysis. All patients had a CT based treatment planning with proper immobilization prior to treatment. PET-CT and MRI fusion was performed with the planning CT images. The GTV is defined as all known gross disease determined from radiographic studies, clinical information, physical examination and biopsy results and GTVln was determined to be metastatic lymph nodes seen in the PET-CT. CTV1 consisted GTV + cervix and uterus, CTV 2 consisted of parametria and superior third of the vagina, CTV3 included the common, external and internal iliac and presacral lymph nodes. Around CTV1, a 15 mm; around CTV2 a 10 mm; around and CTV3 a 7 mm uniform expansion was used for PTV1, PTV2 and PTV3. For PTVln 7 mm uniform expansion was used around GTVln. A total of 45 Gy in 25 fractions was given to PTV1+PTV2+PTV3 and 62.5 Gy to PTVln using simultaneous integrated boost (SIB) technique. Image guidance was performed daily with electronic portal kV and weekly with cone beam CT. All patients were evaluated for 3D conformal inracavitary brachytherapy. Treatment response was evaluated with physical examination and PET-CT 3 months after the conclusion of the treament.
Results: A total of 49 patients were included. Median age was 55 and 80% were stage IIB. Forty seven percent of the patients had pelvic and 10% had paraaortic metastases according to the PET-CT. All of the patients who had lymph node metastases received escalated dose with SIB except 3 patients who had dissection. The majority of the patients concluded planned chemotherapy and intracavitary brachytherapy. Forty seven patients had a PET-CT for response evaluation and there were 76% complete and 11% partial metabolic response. Progressive disease was seen in 6 patients (13%) and only 1 of them was within the irradiated area. With a median follow up of 19 months (6−41 months) estimated 2 year local, regional and distant control rates were 93%, 80% and 78%. Among the 22 patients who were treated with SIB, 2 of them received in field recurrence. Two year overall survival rate was 89%. None of the patients experienced $\geqslant$ grade 3 toxicity.
Conclusion: Concurrent chemoradiation with IMRT and dose escalation can be performed efficaciously in locally advanced cervical cancer.
No conflict of interest.

3051 POSTER

Rectum and bladder dose calculation from external beam radiotherapy (EBRT) and high dose rate brachytherapy (HDR-BT) in cervix uteri cancer patients: From 2D dose calculations to 3D dose optimization to clinical results − A single institution experience

M. El Sayed[1]. [1]*King Faisal Specialist Hospital and Research Center, Oncology Department.Radiation Oncology Section, Jeddah, Saudi Arabia*

Background: Estimation of the rectum and bladder dose in cervix uteri cancer patients treated with radiotherapy including (HDR-BT) is a crucial step in the treatment planning evaluation and its sequences results.
Material and Methods: Include 2 series: (1) Ten applications of HDR-BT, in which comparison between orthogonal and computed tomography (CT) based planning was done. In orthogonal planning: Dose to point A, rectum and bladder were defined according to ICRU 38 recommendations, while in CT-based planning: DVH was done for rectum and bladder. (2) Include 60 patients with stage II−IVA treated with chemo-radiotherapy (45 Gy/25F of EBRT, weekly Cisplatin) plus HDR-BT (6−7 Gy X3−4 Fractions). Point A, rectal and bladder point dose were determined according to ICRU 38 and used initially for orthogonal film calculation. GEC-ESTRO recommendations were used later for CT planning and 3D optimization. Mean (M), maximum (Max) dose and dose volume histogram (DVH) were generated form the EBRT and BT and correlated with the reported toxicities.
Results: (1) The M dose at ICRU rectum point is 3.4 Gy$\pm$1.2 and 21% of the rectum volume from CT was encompassed by 3.4 Gy isodose line,. while M dose to the ICRU bladder point is 2.9 Gy $\pm$1.2 and 17% of the bladder volume derived from CT was encompassed by 2.9 Gy isodose line. The Max dose to rectum and bladder derived from the CT was 1.7 and 2.8 times higher than the dose to ICRU reference points ($p = 0.053$ and $p = 0.005$).
(2) The Max dose reported to the rectum from EBRT and BT was ranged between 49.1–65.2 Gy, with M value of 56.2 Gy$\pm$4. The average of the maximal dose to the rectum from EBRT was 45.8 Gy$\pm$ 1.8 (41.2–51.6 Gy) and from BT was 10.4 Gy $\pm$3.9 (2.5–20.7 Gy). The Max dose to the bladder from EBRT and BT was ranged between 45.4–68.1 Gy with M value of 57.7 Gy $\pm$4. The average of the Max bladder dose from EBRT was 45.2 Gy $\pm$2.2 (40−51 Gy) and BT 12 Gy$\pm$3.7 (5.8–20.9 Gy). Converting these physical dose to biologically effective dose using linear quadratic model, the iso effective total dose (EBRT+BT) EQD2; was 67.4 Gy as a Max dose to the rectum and 73.1 Gy as a Max dose to the bladder. The majority of patients (80−85%) reported grade 1 or 2 acute reactions of the rectum or bladder, however all patients completed their planned course of treatment. Grade 1&2 late rectal and bladder reactions were reported in 4 patients (7%) and 3 patients (5%) respectively.Grade3&4 late rectal reactions were occurred in 2 patients, one patient developed grade 3 proctitis, and the other one developed recto-vaginal fistula (grade 4). None of the patients developed grade 3or4 bladder reactions.
Conclusion: Using our dose and regimen of EBRT and BT with current treatment planning protocol, yield acceptable reported toxicity for the rectum and bladder.3D planning optimization is an emerging methods and should be applied for EBRT and BT whenever possible.
No conflict of interest.

3052 POSTER

Interfraction dose variance in relationship to vaginal cylinder insertion geometry and organ at risk filling for HDR brachytherapy

S. Patel[1], K.J. Mehta[1], H.G. Kuo[1], Y. Chen[1], W.F. Mourad[1], R. Kabarriti[1], M. Bernstein[1], N. Ohri[1], R. Yaparpalvi[1], S. Kalnicki[1]. [1]*Montefiore Medical Center − The Albert Einstein College of Medicine, Radiation Oncology, Bronx, USA*

Background: In HDR vaginal cylinder brachytherapy, an individualized treatment plan is generated on an initial planning CT and then used for subsequent fractions regardless of changes in interfraction anatomy and cylinder insertion angle. In this study, we analyzed the variance in bladder and rectal doses by comparing the planned dose (PD) to the delivered dose (DD) per fraction in relationship to the cylinder insertion angle, bladder and rectal volume, and cylinder treatment length.
Materials and Methods: We analyzed vaginal cylinder applications from 27 consecutive patients treated postoperatively with external pelvic irradiation and vaginal brachytherapy (VBT) in 2012. VBT consisted of three treatments of 5 Gy prescribed to a 5 mm depth. For each patient, a planning CT simulation scan was performed with a cylinder in place and was used in the generation of a treatment plan. A repeat scan was performed prior to each of the three treatments. The bladder and rectum were outlined on all CT-image sets and reviewed by two physicians. The initial plan parameters were applied to the treatment scans and DVHs were generated for the bladder and rectum. From these DVHs, the dose to 2cc of the bladder and rectum were recorded. From each treatment scan, the x angle (in relationship to the midplane) and y angle (in relationship to the table) of cylinder insertion were determined and recorded. Bladder and rectal volumes were also recorded.
Results: The mean doses and cylinder insertion angles are shown. The DD to the bladder was greater than the PD ($p = 0.01$ by paired t-test), whereas the DD to the rectum was comparable to the PD. On average during planning scans, the proximal portion of the cylinder was inserted and angled to the left (+x) and posteriorly (+y), and this was similar during treatment scans. Multiple regression analysis revealed the y insertion angle ($p = 0.018$) and the cylinder treatment length ($p = 0.014$) to be significant predictors of rectal D2cc. There were no significant predictors for bladder dose.

Table: Mean dose ratios and insertion angles

	Bladder		**Rectum**	
	PD (Gy)	DD	PD (Gy)	DD
D2cc	4.40$\pm$0.57	4.61$\pm$0.67	4.75$\pm$0.42	4.66$\pm$0.48
	X Angle		**Y Angle**	
	Plan (^{o})	Actual	Plan (^{o})	Actual
	2.9$\pm$3.7	2.7$\pm$4.4	11.1$\pm$4.6	10.7$\pm$5.3

Conclusions: Interfractional changes in patient anatomy and positioning in combination with differences in cylinder insertion geometry resulted in varying bladder dose but not rectal dose. While a neutral insertion angle has traditionally been used for vaginal brachytherapy, our data suggests that angling the vaginal cylinder anteriorly may reduce rectal dose without significantly increasing bladder dose.
No conflict of interest.

3053 POSTER

Five years follow up study of treating locally advanced cancer of the cervix with hyperfractionated radiotherapy and HDR brachytherapy compared to conventional radiotherapy and HDR brachytherapy

N. Raj[1], A. Nithya[1], S. Shanmugakumar[1], P. Balasubramoniam[1], R. Arun[1]. [1]*Madras Medical College, Department of Radiation Oncology, Chennai Tamilnadu, India*

Background: To compare the clinical outcome at 5 years of treating locally advanced ca cevix with hyperfractionated RT and HDR brachytherapy to conventional RT and HDR brachytherapy.

Materials and Methods: Patients were divided into two arms. Arm A-received hyperfractionated RT, 1.2 Gy bd,6 hours apart,upto 57.6 Gy,along with weekly cisplatin 40 mg/m^2 followed by two sitting of HDR Brachy OF 8 Gy each. Arm B-received 2 Gy per day upto 50 Gy along with weekly cisplatin followed by two sittings of brachy 8 Gy each.
Results: Results were comparable in both arms. Rectal toxicities were lower (18%vs39%) as was bladder complications (26%vs54%) compared to conventional RT. Sexual function was better in hyperfractionated arm (61%vs42%). A subset analysis showed a benefit with hyperfractionated regime in stage IIIB (OS 60%vs50% and PFS 50% vs 40%), lower hemoglobin, younger age compared to the conventional arm.
Conclusions: Hyperfractionated regimen was found to be better than conventional regime in terms of lower toxicities and better quality of life compared to conventional regimen. The advantages seen in the subset populations has to be evaluated with larger randomised control studies. The results of our study was limited by the small sample size.
No conflict of interest.

Conservative surgery in granulosa cell tumors: Retrospective series of 22 patients

H. Gauthier[1], C. Joly[1], P. Pautier[1], A. Leary[1], C. Uzan[1], A. Rey[1], Y. Tazi[1], P. Duvillard[1], P. Morice[1], C. Lhommé[1]. [1]*Institut Gustave Roussy, Gynecology, Villejuif, France*

The aim of the study was to evaluate fertility and the risk of relapse after conservative surgery for granulosa cell tumor (GCT).
Method: Retrospective study of patients (pts) referred to the Institut Gustave Roussy with a GCT between 1989 and 2011 who underwent conservative surgery (uterus and contralateral ovary in situ).
Results: 22 pts were identified, median age was 28 years (17−41 years). Symptoms at diagnosis included abdominal pain, pelvic mass, vaginal bleeding and amenorrhea. The majority presented with stage I GCT (IA, N = 9; IC (spontaneous or intraoperative rupture), N = 11). There was one stage IIC and one IIIC. Seven (7/22) pts received adjuvant chemotherapy with bleomycin, etoposide, cisplatin (BEP).
Among pts with adult type GCT (N = 16): None of the 9 pts who had complete surgical staging for stage IA has relapsed. Among 6 pts with stage IC, one received adjuvant BEP and has not relapsed, the other 5 did not receive adjuvant BEP and relapsed. 1 patient with stage IIC has recurred despite three cycles of BEP.
Among pts with juvenile type GCT (N = 6): Four of the 5 stage IC pts received adjuvant BEP, 2 relapsed. One stage IC pt did not receive BEP and had a lethal recurrence. The stage IIIC pt received adjuvant BEP and relapsed.
Sites of relapses: ovarian and peritoneal (N = 5) or peritoneal alone (N = 5). Median relapse-free survival at 10 years was 43% (95% CI: 23%-66%), and overall survival 87% (95% CI: 63%-96%). The only bad prognostic factor on univariate analysis was BMI>24. Stage> IA, tumor rupture, age $\geqslant$28 years, lack of adjuvant chemotherapy and juvenile type were not significantly predictive of poor outcome.
21 pts underwent surgery with preservation of the ovary and uterus. Among 11 pts under the age of 36 years, 7 pts had a pregnancy. 2 pts relapsed 6 and 11 years after pregnancy.
Conclusion: Conservative surgery may be possible after complete surgical staging for adult type stage IA GCT. All stage IC must receive adjuvant BEP. The benefit/risk balance of conservative surgery in stage IC GCT must be carefully considered and discussed with the pt. Conservative treatment is not appropriate for $\geqslant$stage II GCT. The role of secondary surgery after pregnancy remains debated.
No conflict of interest.

3055 POSTER

Primary repair of rectovaginal fistulas complicating pelvic surgery by gracilis myocutaneous flap

O. Nassar[1]. [1]*National Cancer Institute, Surgical Oncology, Cairo, Egypt*

Background: Complex rectovaginal fistulas repair are extremely challenging. Various surgical options have been suggested; nevertheless, none had been universally accepted as the procedure of choice. This study discussed a novel surgical technique using gracilis myocutaneous flap interposition.
Patient and Methods: Ten patients had fistulas as a complication post treatment of pelvic malignant tumors and one patient had fistula after resection of rectal endometriosis. Primary treatment was pelvic resection; nevertheless, 6 cases had adjuvant chemo-irradiation, 2 cases had post operative irradiation and 2 patients had adjuvant chemotherapy. Fistulas mean diameter was 2$\pm$0.24 cm (1−3) and 8 patients (72.7%) had their fistulas in the middle vaginal third.
All cases had synchronous diverting stomas and wide debridement of fistulas. According to vaginal defect diameter 5 patients were repaired by single gracilis myocutaneous flaps, 2 cases by simple gracilis muscle and 4 cases by double gracilis myocutaneous flaps.
Results: Patients had a mean follow-up time of 34.8$\pm$5.03 months (12−67) and all patients had definitive healing of their fistulas (100%). Median time to stoma closure was 2 months (1−5). Four women (36.4%) had at least one early postoperative complications including temporary leak (n = 3), vaginal sepsis (n = 1), partial skin paddle necrosis (n = 1) and donor limb deep venous thrombosis (n = 1). Late morbidities were seen in 3 cases (27.3%) including vaginal stricture, anorectal anastomotic stricture and anastomotic tumor recurrence.
Conclusion: Successful repair requires adequate debridement of necrotic devascularized tissues, tissue transposition to the rectovaginal septum and reconstruction of vaginal wall. Gracilis myocutaneous flaps are ideal for this issue.
No conflict of interest.

3056 POSTER

The effectiveness of embolization and chemoembolization in cervix cancer with bleeding complication

O. Ahmedov[1], N. Yuldasheva[1], K. Saidova[1], G. Nekova[1]. [1]*National Cancer Center of Uzbekistan, Gynecology, Tashkent, Uzbekistan*

Background: Cervix cancer (CC) is very dangerous disease for women's life and health. The problem of increasing the effect of radial treatment CC patients is very important. The local-spread CC is often complicated by acute bleeding and pain. To control these symptoms we often use surgical ligation of internal iliac artery (IIA). This operation is traumatic and developing of collaterals after it leads to bleeding again.
Material and Methods: One of the modern methods of CC treatment is the selective embolization and chemoembolization of anterior branch of internal iliac artery were performed on 78 patients with CC stage T_{2b} N_{0-1} M_0, $T_{3a,b}$ N_{0-1} M_0. 23 of them had severe form of the disease (profuse bleeding, pronounced pains). Bilateral embolization of anterior branch of internal iliac artery were performed urgently in severe cases. After supporting and medical treatment bilateral embolization with doxorubicin 40 mg/m^2 was performed on 55 patients. After performance antibacterial immuno-potentiative and infusion supporting treatment were used.
Results: Bleeding, decreasing of pains were observed after it.In a short time the regress of tumor (20−50%) was observed and it made possible to do radial therapy. This method of treatment of CC patients is being used in our centre successfully.
Conclusions: The obtained data expressing in full resorption parametrical infiltration, reduction and vanishing be pain, risk of bleeding, that allows here to conduct a course of radial therapy less traumatically, in conditions of a continued regression of a swelling.
No conflict of interest.

3057 POSTER

Cisplatin/taxane or carboplatin/taxane-based chemotherapy in advanced cervical cancer

F. Petrelli[1], D. Lorusso[2], A. Coinu[1], M. Cabiddu[1], M. Ghilardi[1], K. Borgonovo[1], M. Cremonesi[1], F. Raspagliesi[2], S. Barni[1]. [1]*Azienda Ospedaliera Treviglio, Oncology, Treviglio, Italy;* [2]*Fondazione IRCCS National Cancer Institute, Gynaecologic Oncology, Milano, Italy*

Background: Cisplatin (CDDP) + paclitaxel represent the standard first line chemotherapy for advanced cervical carcinoma (CC). Carboplatin (CBDCA)/paclitaxel doublet retains activity, is less toxic and currently compared with CDDP/paclitaxel. This study summarizes the current literature on the efficacy of CDDP/taxane vs. CBDCA/taxane in the treatment of advanced CC.
Material and Methods: PubMed, EMBASE, Web of Science and The Cochrane Library were systematically searched to identify relevant publications. Studies that were conducted in advanced CC patients treated with CCDP/taxane and CBDCA/taxane and reporting objective response rate (RR), progression-free survival (PFS), time-to-progression (TTP) and overall survival (OS) were included. Data on RRs were pooled by using Comprehensive Meta-Analysis software with a random-effects model. Data on PFS/TTP and OS were summarised descriptively.
Results: Eighteen (3 phase III, 7 single-arm and 1 randomized phase II, 6 retrospective and 1 prospective series) studies containing 1,204 advanced CC patients treated with CDDP/taxane or CBDCA/taxane-based chemotherapy were included. Eight studies included CBDCA/taxane arms, 9 CDDP/taxane arms and 1 directly compared CDDP/paclitaxel with CBDCA/paclitaxel. Only 1 out of 18 used a docetaxel-combination, the remaining included a paclitaxel-based combination. The reported weighted median PFS/TTP, median OS and pooled objective RRs were 6.9 months,

12.87 months and 49.3% for CDDP-combinations and 5 months, 10 months and 49.3% for CBDCA-combinations. The difference in PFS/TTP but not in OS was significant in favour of CCDP/paclitaxel chemotherapy (T-test). Response rate were similar with CDDP- and CBDCA-combinations in CDDP-pre-treated patients (43.9 vs 40%). On the contrary in CDDP naive patient RRs were 68.3% and 59.1% for CBDCA-based vs. CDDP-based chemotherapy respectively (p=ns).
Conclusions: CBDCA + paclitaxel represents a valid alternative option for the treatment of advanced CC, with similar RR (about 50%) and OS compared to CDDP + paclitaxel.
No conflict of interest.

3058 POSTER

A single-institution experience of bevacizumab-based therapy in heavily pretreated epithelial ovarian and other Mullerian tract carcinomas

C.M. Kurbacher[1], S. Herz[1], G. Wessling[1], J. Lepique[1], J.A. Kurbacher[1]. *[1]Medical Centre Bonn-Friedensplatz, Gynecologic Oncology, Bonn, Germany*

Background: Recently, bevacizumab (Bev) is considered an active blocker of tumour angiogenesis in epithelial ovarian (EOC) and other Mullerian tract cancers (MTC) such as fallopian tube (FTC), type II endometrial (EC-II), and peritoneal papillary-serous carcinomas (PPSC). Although found to be as active as any salvage chemotherapy (CTx) in platinum-resistant MTCs, the current approval of Bev covers only platinum-sensitive primary and recurrent tumours. We hereby summarise our long-term experience with Bev based systemic therapy (Tx) in patients (pts) with heavily pretreated recurrent MTCs.
Methods: Since 2006, a total of 78 intensively pretreated MTC pts (EOC, n = 69; FTC, n = 2; EC-II, n = 3; PPSC, n = 4) who did not qualify for recruitment into a controlled clinical trial were included in this study with 45 pts (57.7%) being platinum-resistant. Pts had received a median of 4 (range 1−10) prior CTx. In all pts, Bev based Tx was given including Bev monotherapy (group A, n = 19), Bev + metronomic CTx (group B, n = 38), and Bev + conventionally dosed CTx (Group C, n = 21). In all pts, Bev was administered at either 10 mg/kg BW q2w or 15 mg/kg BW q3w. Adverse effects were classified according to the CTCAE Vs 4.03 scale. TTP was calculated from the start of Bev until progression, OS was calculated from the start of Bev until death of any case or loss to follow-up.
Results: The most common adverse effects associated with Bev based Tx were hypertension, proteinuria, headache, inflammation/infection, epistaxis, and subileus. Hypertension which often required adequate treatment was limiting in only case as also were renal toxicity and infection. In the entire population, median TTP was 29.9 wks and median OS was 55.1 wks with no significant difference between platinum-resistant and -sensitive pts. In regard to both TTP and OS, there was a non-significant trend favouring group A (36.0/63.0 wks) and B (29.9/67.7 wks) vs group C (20.3/36.0 wks).
Conclusion: Bev based Tx was active and generally well tolerated in this hard-to-treat population of pts with recurrent MTC. Both TTP and OS were equal or even superior to any conventional CTx used in this setting. Clinical platinum-resistance did not predict a worse clinical outcome. Although this is not a randomised trial, Bev may be preferably given either as single agent or combined with metronomic CTx in pts with heavily pretreated MTCs.
No conflict of interest.

CA-125 as a response marker for vintafolide+pegylated liposomal doxorubicin (PLD) vs PLD alone in platinum-resistant ovarian cancer: The PRECEDENT trial

R. Naumann[1], M. Bidzinski[2], C. Lovejoy[3], K.M. Anderson[4], R.A. Rangwala[5], E. Kutarska[6]. *[1]Levine Cancer Institute, Division of Gynecologic Oncology, Charlotte North Carolina, USA; [2]Holycross Cancer Center, Department of Gynecological Oncology, Kielce, Poland; [3]Endocyte Inc., Department of Regulatory Affairs, West Lafayette Indiana, USA; [4]Merck, Department of Biostatistics, White House Station New Jersey, USA; [5]Merck, Department of Clinical Research, White House Station New Jersey, USA; [6]Centrum Onkologii Ziemi Lubelskiej, Department of Gynecology/Oncology III, Lublin, Poland*

Background: Vintafolide (EC145), an investigational folic acid/desacetylvinblastine conjugate, binds with high affinity to the folate receptor expressed on most epithelial ovarian cancers. In the randomized, open-label PRECEDENT trial, subjects with platinum-resistant ovarian cancer received vintafolide+PLD or PLD alone. Statistical significance of the primary objective (progression-free survival based on investigator assessment using RECIST v1.0 and prespecified clinical events) was achieved in the ITT population: median 21.7 weeks − vintafolide+PLD (n = 100) vs 11.7 weeks − PLD alone (n = 49) (HR 0.63; 95% CI 0.41–0.96; *P*=.031). An efficacy assessment based on CA-125 response is reported here and compared with overall response rate (ORR; complete response [CR]+partial response [PR]) based on RECIST criteria.
Methods: Women $\geqslant$18 years old with ECOG status 0−2 and exposure to $\leqslant$2 prior systemic cytotoxic regimens were randomized 2:1 to vintafolide (2.5 mg IV tiw, weeks 1 and 3, q 28 days)+PLD (50 mg/m^2 IV day 1, q 28 days) or PLD alone (same dose/schedule). Best overall CA-125 response was assessed in a subset of the ITT population with a baseline CA-125 $\geqslant$2$\times$ ULN and $\geqslant$1 follow-up CA-125 evaluation. CA-125 CR was defined as a return to normal CA-125 levels ($\leqslant$35 U/mL); PR was defined as a CA-125 decrease to $\leqslant$50% of baseline that was still above the ULN.
Results: 60 (vintafolide+PLD) and 26 (PLD alone) subjects were evaluable for CA-125 response. A higher confirmed CA-125 ORR was seen for vintafolide+PLD (21.7%) vs PLD alone (11.5%), as was a higher unconfirmed CA-125 ORR (38.3% vs 19.2%, respectively). CA-125 CR (confirmed and unconfirmed) occurred in 8.3% and 15.0% of vintafolide+PLD subjects, respectively, with no CA-125 CR in the PLD alone arm. In the same population, RECIST confirmed ORR was 21.7% for vintafolide+PLD vs 15.4% for PLD alone, and RECIST unconfirmed ORRs were 36.7% and 19.2%, respectively. One confirmed and 1 unconfirmed RECIST CR were noted in the vintafolide+PLD arm, with no RECIST CR in the PLD alone arm.
Conclusions: CA-125 level changes correlated with RECIST changes in subjects with platinum-resistant ovarian cancer and elevated CA-125 treated with vintafolide and PLD. CA-125 may overestimate CR compared with RECIST in the same population.

Combination therapy with Bevacizumab and GEMOX for patients with platinum-resistant recurrent ovarian cancers: A phase II study

M. Takano[1], Y. Ikeda[2], K. Oda[3], H. Kouta[4], K. Kudoh[5], T. Kita[6], N. Sasaki[1], T. Goto[1], K. Furuya[1], Y. Kikuchi[4]. *[1]National Defense Medical College, Department of Obstetrics and Gynecology, Tokorozawa, Japan; [2]Saitama Medical College International Medical Center, Department of Gynecologic Oncology, Hidaka, Japan; [3]Tokyo University, Department of Obstetrics and Gynecology, Hongo, Japan; [4]Ohki Memorial Kikuchi Cancer Center for Women, Department of Gynecology, Tokorozawa, Japan; [5]Nishisaitama-Chuo National Hospital, Department of Obstetrics and Gynecology, Tokorozawa, Japan; [6]Nara Prefectural Nara Hospital, Department of Obstetrics and Gynecology, Nara, Japan*

Objective: Combination therapy using gemcitabine with oxaliplatin (GEMOX) showed moderate activity in recurrent ovarian cancers (ROC), however, severe toxicities have been frequently observed. On the other hand, bevacizumab enhances chemotherapeutic efficacy in various cancers. Here we conducted a phase II study to evaluate the effect of weekly low-dose administration of GEMOX in combination with bevacizumab (B-GEMOX) for patients with platinum-resistant ROC.
Methods: Simon's two-stage design was used, and a total number of 25 cases were enrolled in the study. This design yielded a type I error rate of 0.05 and power of 0.8 when the true response rate was 40%. B-GEMOX therapy consisted of 2 mg/kg of bevacizumab, 300 mg/m^2 of gemcitabine, and 30 mg/m^2 of oxaliplatin, three weeks on and one week off, q4weeks. The treatment was continued until development of severe toxicities or progressive disease. Tumor responses were assessed using the Response Evaluation Criteria In Solid Tumors (RECIST) and Gynecologic Cancer Intergroup (GCIG) criteria.
Results: Median number of the B-GEMOX therapy was five cycles. Response was observed in seven cases (41%) by RECIST, and in 2 cases (29%) by GCIG criteria, resulting in overall response rate of 36%. Clinical benefit including stable disease was obtained in 84% of the patients. Median progression-free survival was 4.5 months (range: 2−18+ months). Toxicities were mild and mainly consisted of hematologic, gastrointestinal, and neuropathy, however, there were no non-hematologic toxicities more than grade 1.
Conclusion: Weekly administration of B-GEMOX was active for patients with ROC, and showed mild toxicities. These results warrant further prospective studies for patients with ROC.
No conflict of interest.

3061 POSTER

Adverse event profile by folate receptor status for vintafolide+pegylated liposomal doxorubicin (PLD) vs PLD alone in platinum-resistant ovarian cancer

T. Herzog[1], E. Kutarska[2], M. Bidzinski[3], J. Symanowski[4], B. Nguyen[5], R.A. Rangwala[6], R.W. Naumann[7]. [1]*Columbia University Medical Center, Division of Gynecologic Oncology Department of Obstetrics and Gynecology, New York, USA;* [2]*Centrum Onkologii Ziemi Lubelskiej, Department of Gynecology Oncology III, Lublin, Poland;* [3]*Holycross Cancer Center, Department of Gynecological Oncology, Kielce, Poland;* [4]*Levine Cancer Institute, Department of Cancer Biostatistics, Charlotte, USA;* [5]*Endocyte Inc., Department of Clinical Affairs, West Lafayette, USA;* [6]*Merck, Clinical Research Department, White House Station, USA;* [7]*Levine Cancer Institute, Division of Gynecologic Oncology, Charlotte, USA*

Background: Vintafolide (EC145, MK8109), a folic acid/desacetylvinblastine conjugate, binds with high affinity to folate receptors (FRs) expressed in cancers. This exploratory analysis evaluated the incidence of adverse events (AEs) by FR status in the PRECEDENT trial, a randomized open-label study of subjects with platinum-resistant ovarian cancer receiving vintafolide+PLD or PLD alone.
Methods: Women ⩾18 years old with ECOG status 0−2 and exposure to ⩽2 prior systemic cytotoxic regimens were randomized 2:1 to vintafolide (2.5 mg IV tiw, weeks 1 and 3, q28 days)+PLD (50 mg/m^2 IV day 1, q28 days) or PLD alone (same dose+schedule). Patients at centers with ^{99m}Tc nuclear imaging capability underwent SPECT imaging with etarfolatide to identify patients with functionally active FRs. AEs in the safety population (received at least 1 dose of study drug) were evaluated by FR status (FR [100%, all target lesions positive]; FR [0%, all lesions negative]).
Results: 37 patients were FR (100%) (22, vintafolide+PLD; 15, PLD alone), and 19 were FR (0%) (13, vintafolide+PLD; 6, PLD alone). The number of patients reporting at least 1 drug-related AE was generally similar regardless of FR status or treatment arm. One subject in the FR (100%) group and 4 subjects in FR (0%) who received vintafolide+PLD discontinued either vintafolide or PLD during the study due to drug-related AEs.
For the FR (100%) vs FR (0%) groups, the most common drug-related AEs (⩾30% of patients in either group) in the vintafolide+PLD arm were fatigue (54.5% vs 46.2%), constipation (50.0% vs 46.2%), hand–foot syndrome (HFS) (40.9% vs 30.8%), anemia (40.9% vs 30.8%), nausea (36.4% vs 53.8%), stomatitis (36.4% vs 61.5%), rash (36.4% vs 15.4%), peripheral sensory neuropathy (31.8% vs 0%), neutropenia (27.3% vs 30.8%), vomiting (22.7% vs 38.5%), and asthenia (13.6% vs 38.5%).
For the FR (100%) vs FR (0%) groups, the most common drug-related AEs (⩾30% of patients in any group) in the PLD alone arm were HFS (53.3% vs 50.0%), nausea (33.3% vs 33.3%), stomatitis (33.3% vs 50.0%), fatigue (33.3% vs 33.3%), anemia (20.0% vs 50.0%), neutropenia (27.3% vs 50.0%), and leukopenia (13.6% vs 33.3%).
Conclusion: This exploratory analysis suggests that the AE profile appears numerically similar based upon FR status for the vintafolide+PLD and PLD alone groups; however, the small sample size precludes a statistical analysis. Future analyses in larger patient populations are needed to confirm these findings.

3062 POSTER

Efficacy and safety of generic pegylated liposomal doxorubicin (PLD) in relapsed ovarian cancer

I. Ghosh[1], A. Dwary[1], D. Dabkara[1], J. Bhaumik[1]. [1]*Tata Medical Center, Kolkata, India*

Background: Currently the innovator product of PLD is not being marketed. Due to drug shortage, even USFDA has permitted the usage of generic formulation. The purpose of this analysis was to evaluate the efficacy and safety of the same formulation in Indian patients.
Methods: We analyzed the case records of the patients of relapsed ovarian or primary peritoneal cancer who started treatment with PLD at our center between May 2011 and October 2012. Starting dose of PLD was 30 mg/m^2 q4 weekly for combination and 40 mg/m^2 q4 weekly for single-agent. Response assessment was done by combined RECIST and CA 125 criteria.
Results: 20 such patients were identified; median age 56 (range 45−71) years. Histology was serous-14, clear cell-2, poorly differentiated-1, transitional-1 and adenosquamous-1. 70% patients received PLD as 2nd line, 20% as 3rd line and 10% beyond 3rd line. 100% patients were platinum and taxane pretreated; 30% received >1 course of platinum and 20% received >1 course of taxane previously. In addition, three patients received gemcitabine and one etoposide. Median interval from last chemotherapy was 8 months; <6 months − 40%, >6−12 months − 40% and >12 months − 20%. ECOG performance status was 0 in 5%, 1 in 85%, 2 in 10%.
Measurable disease on imaging was present in 80% and CA 125 was >ULN in 80%. Three patients underwent surgery for this relapse prior to starting chemotherapy. 40% patient received single agent PLD and 60% received combination with carboplatin. Median Number of cycles received was 6 (range 1−6); 65% received 4−6. Among 18 patients evaluable for response, best overall response obtained was CR in 1 (5.5%), PR in 9 (50%), SD in 1 (5.5%) and PD in 7 (39%). At a median follow-up of 9 months (range, 4−23), 5 (25%) are alive and progression free. Median PFS was 6 months (8 months in platinum sensitive and 3 months in resistant) and median OS not reached; 80% were alive at last follow-up. Nine patients received further chemotherapy after progression. There were 15 Grade 3−4 toxicity events in 8 patients − anemia in 7, neutropenia in 3, thrombocytopenia in 3, mucositis 2. Two patients had to discontinue therapy because of toxicities.
Conclusion: Generic formulation of PLD was effective as therapy for relapsed ovarian cancer, especially in platinum-sensitive. There were more grade 3−4 myelosuppressive events than expected which may be explained by the multiple lines of prior therapy received.
No conflict of interest.

3063 POSTER

Effects of temozolomide combined with bevacizumab in patients with recurrent or refractory uterine leiomyosarcoma (LMS): A preliminary case series

N. Sasaki[1], M. Takano[1], Y. Ikeda[2], K. Oda[3], H. Kouta[4], K. Kudoh[5], T. Kita[6], T. Goto[1], K. Furuya[1], Y. Kikuchi[4]. [1]*National Defense Medical College, Department of Obstetrics and Gynecology, Tokorozawa, Japan;* [2]*Saitama Medical University International Medical Center, Department of Gynecologic Oncology, Hidaka, Japan;* [3]*Tokyo University, Department of Obstetrics and Gynecology, Hongo, Japan;* [4]*Ohki Memorial Kikuchi Cancer Center for Women, Department of Gynecology, Tokorozawa, Japan;* [5]*Nishisaitama-Chuo National Hospital, Department of Obstetrics and Gynecology, Tokorozawa, Japan;* [6]*Nara Prefectural Nara Hospital, Department of Obstetrics and Gynecology, Nara, Japan*

Background: Treatment modality of patients with recurrent or refractory uterine LMS is mainly systemic therapy, such as anthracycline-based combination, and gemcitabine plus docetaxel, however, the effects are limited, and too toxic. We conducted a preliminary study to evaluate the effects of combination with temozolomide and bevacizumab in patients with recurrent or refractory uterine (LMS).
Material and Methods: From 2009 to 2012, nine patients with recurrent or refractory uterine LMS were treated with weekly bevacizumab (2 mg/kg; days 1, 8, and 15, q4weeks) and temozolomide (80 mg/body, daily) until disease progression or development of unmanageable toxicity. Response and adverse effects were evaluated using the response evaluation criteria in solid tumors (RECIST), and common terminology criteria for adverse events (CTCAE) version 3.0.
Results: One (11%) of 9 patients had complete response (CR) and another case (11%) had partial response (PR) in RECIST evaluation. Four patients (44%) obtained stable disease (SD) more than three months. The response rate (RR; CR+PR) and clinical benefit rate (CBR; CR+PR+SD) were 22% and 67%, respectively. The median progression-free survival was 9.8 months (range: 3−32 months). There were no treatment-related deaths or grade 4 toxicities, and no patient needed dose-reduction due to toxicities.
Conclusions: Chemotherapy with temozolomide and weekly bevacizumab was active and safe in patients with recurrent or refractory uterine (LMS). The present case series suggested that this combination could be a candidate for the treatment not only recurrent LMS, but also first-line therapy for uterine LMS.
No conflict of interest.

3064 POSTER

Response to tamoxifen (T) and letrozole (L) in patients with relapsed high-grade ovarian carcinoma − the Royal Marsden experience

A. George[1], N. Tunariu[2], C. Della Pepa[3], C. Migali[3], M. Gore[3], S.B. Kaye[3], S.B. Banerjee[3]. *[1]Royal Marsden Hospital, Department of Medicine and Department of Genetics, London, United Kingdom; [2]Royal Marsden Hospital, Department of Radiology, London, United Kingdom; [3]Royal Marsden Hospital, Department of Medicine, London, United Kingdom*

Background: Hormone treatment is commonly used in ovarian cancer, but the choice of treatment and its role in high grade (HG) ovarian cancer is unclear. It has been suggested that there is a higher response rate to L than T, and that response is associated with platinum sensitivity and ER receptor status. Our aim was therefore to assess the efficacy of T and L in HG ovarian cancer and to explore the factors influencing clinical outcome.
Method: Patients who started T or L for relapsed, confirmed HG ovarian, peritoneal or fallopian tube cancer between 1/6/07 and 1/6/12 were analysed retrospectively. The primary endpoint was response rate (RR, RECIST). Secondary endpoints included clinical benefit rate (CBR), CA-125 response and duration of response. The platinum sensitivity and ER status of the patient were assessed as predictors of response to treatment.
Results: 97 patients were identified (43T, 54L); median age 63 years (20−92); median lines of chemotherapy 3 (1−8); 91% HG serous, 5% endometroid, 4% clear cell/other; 59% platinum resistant, 41% platinum sensitive. ER was positive in 45%, and unknown in 55%. There were no complete responses. 14 patients (6T, 8L) had a partial response, with RR (RECIST) of 14% (T) and 15% (L). A further 22 patients in each group had stable disease for >3 months, giving overall CBR of 65% (T) and 57% (L). All responses were in serous or endometroid cancers. There was no significant difference in RR ($p = 0.99$) or CBR ($p = 0.14$) between T and L. 22 patients (23%) had a CA-125 response (10 T − 23% and 12 L − 22%). There were no differences in response rates between patients with unknown ER status, and known ER positivity ($p = 0.12$); nor by platinum sensitivity ($p = 0.42$). Patients responding to L had longer durations of response than those responding to T (26 vs 11.5 months, $p = 0.03$), but there was no difference in mean duration of disease stability between the treatments (9.6 vs 7.2 months respectively, $p = 0.11$). Hormone treatment was well tolerated, with only 3 patients stopping treatment due to intolerance (all L). 5 patients were diagnosed with either PE or DVT during treatment (3T, 2L, $p = 0.49$).
Conclusion: Within the limits of a retrospective audit, we observed that patients treated with L had a significantly longer duration of response than those treated with T, but the duration of disease stability was equivalent. Endocrine treatment with either T or L is a valid option for patients with ER positive HG ovarian cancer, with equivalent RR and CBR.
No conflict of interest.

3065 POSTER

Lurbinectedin (PM01183) activity in platinum-resistant/refractory ovarian cancer patients: Updated results of an ongoing two stage Phase II study

A. Poveda[1], D. Berton-Rigaud[2], I. Ray-Coquard[3], J. Alexandre[4], M. Provansal[5], C. Fernandez[6], E.M. Guerra[7], A. Casado[8], A. Gonzalez Martin[9], J.M. Del Campo[10]. *[1]Instituto Valenciano de Oncología, Valencia, Spain; [2]Centre René Gaducheau, Nantes, France; [3]Centre Léon Bérard, Lyon, France; [4]GH Cochin-Hôtel Dieu, Paris, France; [5]Institut Paoli Calmettes, Marseille, France; [6]PharmaMar, Madrid, Spain; [7]Hospital Ramon y Cajal, Madrid, Spain; [8]Hospital Clínico Universitario San Carlos, Madrid, Spain; [9]M.D.Anderson Cancer Center, Madrid, Spain; [10]Hospital Universitario Vall d'Hebrón, Barcelona, Spain*

Background: PM01183 is a new anticancer agent that acts through DNA minor groove-binding in a wide range of cancer cell lines and orthotopic models, including several platinum resistant (pt-res).
Methods: Pt-res or platinum refractory (pt-ref) ovarian cancer patients (pts) with less than 3 prior chemotherapy (CT)-containing lines, adequate major organ function and performance status (PS) 0−2 are included. The primary endpoint of the study is overall response rate (ORR) (by RECIST v1.1 and/or Rustin criteria). It was designed to reject if true response rate is 8% or less *vs* the alternative of 25% or higher. During the first stage, 22 pts were treated with i.v. PM01183, 7 mg flat dose, q3wk. The second stage is randomizing 60 pts (ratio 1:1) to receive PM01183 (P) or topotecan (T) (standard or weekly regimen according to Investigator's choice). Cross-over to the P arm is allowed for pts who progress to T. The study was not properly powered to detect clinical significant differences across arms.
Results: As of April 2013, 56 pts from both stages (P/T: 41/15) have been included in the analysis. Median age: 59 years; median ECOG: 1; serous histology: 71% pts; pt-res: 59% pts; pt-ref: 41% pts; PFI <3 months: 46% pts; visceral disease: 34% pts; ascites: 23% pts; median advanced lines: 1; prior bevacizumab: 18% pts.
Efficacy results in evaluable pts (both stages) are summarized in the table.

	PM01183 (n = 38)		Topotecan
	1st stage (n = 22)	2nd stage (n = 16)	(n = 15)
OR, n (%)			
CR	0 (0)	1 (6)	0 (0)
PR	§6 (27)	2 (13)	0 (0)
SD	12 (55)	5 (31)	7 (47)
PD	4 (18)	7 (44)	8 (53)
Treatment failure	0 (0)	1 (6)	0 (0)
ORR (%) (95% CI)†	24 (11−40)		0
DCR (%)	68		47
PFS (months)*	3.5		1.4
− Pt-res (n = 16/7/8)**	4.5	5.7	1.4
− Pt-ref (n = 5/8/7)***	3.5	1.3	2.7

§ 2 PRs by Rustin criteria; † $p = 0.0474$; * $p = 0.0769$; ** $p = 0.0287$; *** $p = 0.2501$.

The preliminary PM01183 safety profile confirms prior phase I results, with myelosuppression (neutropenia [Gr 4 65%, FN 15%], thrombocytopenia [Gr 3−4 32.5%]), nausea/vomiting (Gr 3 15/7.5%) and fatigue (Gr 3 37.5%) being the most common drug-related AEs.
Conclusions: PM01183 is an active drug in pt-res/pt-ref ovarian cancer and the study has met its primary endpoint. Toxicity is predictable and manageable. Further studies are warranted. Updated results will be presented.
Conflict of interest: *Advisory board: PharmaMar*

3066 POSTER

Model prediction of mean PFS and OS Time from a phase II trial comparing vintafolide (V) plus pegylated liposomal doxorubicin (PLD), versus PLD alone, in platinum-resistant ovarian cancer (PROC) patients with 100% folate receptor (FR) positive target lesions

T. Herzog[1], K. Anderson[2], J. Wang[3], R. Xu[3]. *[1]Columbia University Medical Center, Division of Gynecologic Oncology Department of Obstetrics and Gynecology, New-York NY, USA; [2]Merck & Co. Inc., Late Stage Statistics, North Wales PA, USA; [3]Merck & Co. Inc., Health Economic Statistics, North Wales PA, USA*

Background: A recent randomized phase II trial (PRECEDENT) has shown that vintafolide plus PLD (V+PLD) resulted in a statistically significant improvement in progression-free survival (PFS) compared with PLD for PROC. Importantly, the observed efficacy was greatest in patients with 100% FR positive tumors, identified by ^{99m}Tc etarfolatide. The median PFS were 24.0 vs. 6.6 weeks for FR(100%) patients treated with V+PLD vs. PLD (HR 0.381; $p = 0.018$). Notably, FR(100%) patients represent a subpopulation in PROC with a worse prognosis when treated with PLD. In addition to median PFS, mean times on PFS, post-progression (post-PD), and overall survival (OS) are meaningful. The objective of this study is to predict mean PFS, post-PD survival and OS for FR(100%) patients treated with V+PLD vs. PLD.
Material and Methods: Parametric Weibull survival models are estimated for FR(100%) subpopulation (n = 37; V+PLD:22, PLD:15) using the PRECEDENT trial data, adjusted for the following pre-specified baseline factors: age (⩾65 vs. <65 years), platinum failure (primary vs. secondary), CA-125 level (⩾200 vs. <200 U/mL), geography (North America vs. Europe), log of the sum of the target lesions longest diameters, log of months since last platinum treatment, and ECOG (1 or 2 vs. 0). The models provide survival probabilities for each patient given the baseline covariates for a given treatment. The mean of each individual's survival probabilities at any time point across all times yields the population survival curve for the treatment. Area under the curve is the mean survival time over a time period. Variance of the mean is estimated using bootstrapping.
Results: The model predictions based on patients' assigned treatment in the trial are very close to the actual mean times calculated from the Kaplan–Meier curves. The models further predict the mean times for a given treatment across all trial patients over 2 years as presented in the table.

Mean time (months)	PFS	(95% CI)	post-PD	(95% CI)	OS	(95% CI)
PLD	2.6	(1.4, 5.7)	6.7	(2.5, 12.4)	9.3	(5.3, 15.4)
V+PLD	6.8	(3.9, 10.9)	7.6	(2.8, 11.5)	14.3	(11.0, 17.6)
Diff	4.1	(−0.8, 8.3)	0.9	(−7.4, 7.4)	5.0	(−2.9, 10.1)

Conclusions: The results suggest there may be a benefit in mean PFS and OS associated with V+PLD. The results will be further evaluated following the ongoing phase III trial (PROCEED). These results may be used for future evaluation of the benefit and cost of V+PLD vs. PLD for decision makers.

3067 POSTER

Nuclear translocation of FTS (Fused Toes Homolog) is related with EGFR phosphorylation and radiation resistance of uterine cervix cancer

W. Park[1], A. Anandharaj[1], S. Cinghu[1], J. Yu[2]. [1]*Chungbuk National University, Dept of Radiation Oncology, Cheongju, Korea;* [2]*Konkuk University, Dept of Environmental and Tropical Medicine, Chungju, Korea*

Background: Radiation therapy (RT) is the major treatment modality for uterine cervix cancer. However, about one third of the patients especially with locally advanced disease (FIGO IIIB-IVA) suffer from recurrence. Defining the molecular events that contribute to radiation resistance is of critical importance to improve the treatment results. Fused Toes Homolog (FTS) is a member of a group of proteins termed as E2 variants and this group of proteins lacks an active cysteine residue that is required for ubiquitin transfer. Here we evaluated the role of nuclear translocation of FTS in radiation resistance of cervix cancer.
Material and Methods: The expression of FTS in the cervix cancer tissues with patients received curative RT was studied from formalin-fixed paraffin-embedded specimens by immunohistochemistry. The point mutation constructs of FTS were made by using site directed mutagenesis and the change of translocation of FTS and its downstream signaling were studied by transfecting normal FTS and its mutants into the normal and cervix cancer cell lines.
Results: Immunostaining of cervix cancer tissues revealed that FTS was located in the nucleus in the patients with recurrence after RT. In vitro study also revealed that this protein was translocated into nucleus from cytoplasm upon irradiation. Among the six mutants of possible phosphorylated sites of FTS only the threonine into alanine (T190A) mutant failed to translocate into nucleus. The cells transfected with this mutant FTS (T190A) showed decreased phosphorylatation of EGFR, p38 and JNK.
Conclusions: Nuclear translocation of FTS confers radiation resistance on uterine cervix cancer. Threonine residue of FTS at position 190 is essential for its nuclear translocation, which is related with EGFR phosphorylation and its downstream effects.
No conflict of interest.

3068 POSTER

Analysis of the immune status of patients with vulvar cancer

G. Neroda[1], E. Zlatnik[1], E. Nerodo[1], G. Zakora[1]. [1]*Rostov Oncological Research Institute, Gynecology, Rostov-Don, Russian Federation*

Background: Immune system analysis in patients with vulva cancer.
Material and Methods: The study was conducted in 127 patients with cancer of the vulva at the age of 31−80 years with stage I−IV, the control of 30 healthy women of identical age. Evaluated the T and B − cell parts of the immune system condition NK cells, macrophages studied indicators of transformation of monocytes and the level of the CIC (circulating immune complexes).
Results: In patients with stage I functional activity in absolute terms, the T-cells were reduced and the mitogen PHA − 0.38±0.08 h109/l. The total number of T cells 0.53±0.07 h109/l significantly reduced in half. Transformation of monocytes into macrophages is depressed − PMTM is 0.48±0.05 h109/l. A high level of circulating immune complexes (CIC) − 36.8±4.1 compared to 25.0±3.3 in healthy stage II to PHA proliferative activity was significantly reduced, RBTL to PHA is 34.0±2.6%, and the data in absolute terms to PHA-0.28±0.05 h109/L was significantly reduced compared with those of healthy women. In patients with stage III-th marked a marked imbalance of the immune system, there was a significant increase in CIC compared with the initial stages, and even more so with women's health indicators. The number of T and B cells was reduced by 30% and 20%, respectively. Contents of monocytes remains at I-th stage, but their functional activity (PMTM) was significantly reduced. With the IV-th stage of cancer of the vulva percentage of T cells at the level of patients with the II-nd and III-th stage, the number of functionally active T cells was significantly reduced from 48.0±4.3% to 27.5±2.4%, the number of LPS-stimulated B cells had the tendency to decrease, and reduced by 20% compared with patients in I-th stage. CIC levels in the blood of patients with Stage IV-2-fold higher than in healthy women, and significantly higher than in patients with I-st and II-nd stage of cancer of the vulva.
Conclusion: The study showed the presence of both quantitative and qualitative immune deficiency in patients with cancer of the vulva, the degree of which is characteristic for each stage of the disease, which requires a special correction.
No conflict of interest.

3069 POSTER

Factors of local cellular immunity in patients with ovarian cancer

E. Zlatnik[1], G. Neroda[1], A. Mordan[1], E. Mkrtchyan[1]. [1]*Rostov Oncological Research Institute, Gynecology, Rostov-Don, Russian Federation*

Background: The aim of this work was to study the factors of local immunity in patients with primary ovarian cancer (OC).
Materials and Methods: Investigated the blood and ascitic fluid (AF) 18 patients with generalized OC before treatment. At the time of treatment for patients with medical disease duration ranged from 3 to 18 months., On average, 7±2.2 months. Using flow cytometry BD FACS Canto II in blood and AF were determined percentage of lymphocytes of different subpopulations (CD3 + CD4 +, CD3 + CD8 +, CD19 +, CD16 + CD56 +); in fractions CD3 + CD4 + and CD3 + CD8 + lymphocytes estimated the number of naive T cells (CD45RA + CD62L +) and memory T cells (CD45RA-CD45RO +).
Results: The study showed that the total number of lymphocytes in the AF was significantly higher than in the blood (43.7±11.6 vs 11.7±2.8%; $P < 0.05$). The total number of T-, B-and NK-cells and CD3+CD4+CD8− and CD3+CD4−CD8+ in blood and AF patients had no significant differences, although the blood CD3 + CD4 + cells predominate over the CD3 + CD8 + (immunoregulatory index greater than 1.0), and the AF ratio CD4 +/ CD8 + less than 1.0. A significant difference was found in the studied biological fluids between the levels of naive T cells and memory T cells. Found that the latter are present in high amounts in the AF, and the levels of naive T-cells in it are much lower than in the blood. Thus, the content of T cells with the phenotype of memory cells of CD3+CD4+ lymphocytes in the blood is 68.3±4.7%, and in AJ 89.4±2.5%; maintenance of naive T-cells are respectively 7.1±0.7 and 2.4±0.8% (in both cases, $P < 0.05$). T-lymphocyte memory and naive T cells in a subset of CD3 + CD8 + differences are similar: in blood T cells were found in the number of memory 45.6±7.1, in AJ 73.1±2.7%, and the T-naive in the amount of 21.7±3.4 and 7.2±0.87%, respectively (both $P < 0.05$).
Conclusion: Our data suggest that T-cell memory as a subset of CTL, and of CD3 + CD4 +, have the ability to accumulate in the hearth of tumor growth, and naive T cells predominate in peripheral blood. Establishing specificity of memory cells is not yet possible, we consider it as our future objectives. According to the duration of the disease, they may be associated with tumor process.

Viral DNA in patients with cancer of the vulva

G. Nerodo[1], T. Zykov[1], E. Nerodo[1], A. Antonets[1], K. Dvadnenko[1]. [1]*Rostov Oncological Research Institute, Gynecology, Rostov-Don, Russian Federation*

Background: The analysis of HPV DNA and the herpes group of viruses in patients with cancer of the vulva.
Materials and Methods: In 131 patients with cancer of the vulva at the age of 26−82 years I to stage IV disease were determined HPV (Human Papillomavirus) high cancer risk: 16, 18, 31, 33, 35, 45, 51, 52, 56, 58, and 59 types of herpes virus group (HSV type 1.2, cytomegalovirus, Epstein-Barr virus and herpesvirus type 6). Determination of DNA was performed retrospectively by deparafinirovaniya sections and DNA isolation fenolhloroformnym and by adsorption on silica particles. Determination of HPV PCR was performed using quick sets AmpliSens HPV screen and WRC WRC AmpliSens HPV genotype ('InterLabService' Russia).
Results: Of the total group (131 patients) data confirm that the DNA of a virus were detected in 45 (34.35%), including different types of HPV DNA detected in 33 (25.19%), cytomegalovirus − in 2 (1, 5%), Epstein-Barr virus − in 12 (9.16%) and herpes type 6 in 4 (3.05%). In the analysis by age found that in young (26−50 years old) of different types of viruses were identified in 23 of 32 (71.87%), while in the older group, 22 of 99 (22.2%). HPV DNA was detected in 18 of 32 young patients (56.25%), and in the elderly in 15 of 39 (15.5%). Epstein-Barr virus was detected in 5 (15.6%) of the young, and 7 (7.07%) in elderly patients, the herpes virus type 6 detected in 6.25% and 2% of young elderly, cytomegalovirus was isolated only in the elderly 2%. In patients with cancer of the vulva young adults with HPV detected in 62% of HPV type 16, 20.8% − 18 type, 39 and 45 and 56 4% − 8%, 33% noted a combination of 16 and 18 (27, 7%) and

16 and 39 (5.2%). Among the elderly to the presence of HPV type 16 was more common (77.7%), 31 (16.6%) and 52 (5.5%), the combination was observed in 20% (16 and 31) type.
Conclusion: Thus, infection with all types of viruses with cancer of the vulva is for young 71.87%, and 22% for older, more often among patients with a virus found HPV DNA − the young to 56.2%, and 15% in the elderly. Our data confirm the importance of infection, especially HPV in the pathogenesis of cancer of the vulva.

3071 POSTER

Prognostic value and importance of CIP2A as a therapeutic target: Rethinking the use of conventional chemotherapy drugs for the treatment of ovarian cancer

A. Cvrljevic[1], I. Pukonen[1], J. Westermarck[2]. [1]*Turku Centre for Biotechnology, University of Turku and Åbo Akademi University, Turku, Finland;* [2]*Turku Centre for Biotechnology, University of Turku and Åbo Akademi University/Department of Pathology (University of Turku), Turku, Finland*

Background: Epithelial ovarian cancers represent the leading cause of death in women with gynaecologic cancers. The development of acquired resistance to current first-line Taxane and Platinum-based chemotherapy agents is common and a strong motivator for the development of therapeutic approaches that combines targeted drugs and cytotoxics in a more effective manner. The cancerous inhibitor of protein phosphatase 2A (CIP2A) is a novel oncogene overexpressed in many solid human cancers. Recently, CIP2A was found to correlate with reduced survival and parameters associated with high grade disease in many human cancers, including ovarian cancer. Here, we demonstrate that chemo-resistant ovarian cancer cells are sensitized to conventional chemotherapeutic drugs following inhibition of CIP2A.
Methods: A library of conventional chemotherapeutic agents targeting different parts of the human kinome, were screened to identify synthetic lethality with CIP2A depletion in a panel of ovarian cancer cell lines (Hey, Skov-3, Ovcar-8, Ovcar-3 & Caov-3). Gene silencing was done by small interference RNA (siRNA). CIP2A depleted cell lines were developed via lentiviral transduction of cells with shCIP2A. Cell viability and signal transduction analysis was assessed by CTG assay and Western blot. The *in vivo* assessment of CIP2A depletion and treatment with these chemotherapy drugs in xenograft mouse models is in progress. Potential side-effect profiles were determined by examining the consequences of combined CIP2A inhibition and chemotherapy treatment *in vivo* using the CIP2A deficient mouse model.
Results: First-line adjuvant chemotherapy agents, Cisplatin and Paclitaxel, had little effect on the inhibition of cell viability of chemo-resistant ovarian cancer cell lines, consistent with previous reports. The depletion of CIP2A however, significantly sensitized these cell lines to a number of chemotherapeutic agents including Cisplatin and Paclitaxel. We have also identified new therapeutic strategies for the treatment of CIP2A null ovarian cancer cells.
Conclusion: CIP2A is a novel oncogene, previously shown to be a marker of poor outcome in ovarian cancer patients, including the subset of patients currently receiving first-line adjuvant chemotherapy treatment. Our results demonstrate a new therapeutic strategy for the treatment of CIP2A depleted ovarian cancer cells and highlight the potential value of patient stratification based on tumor expression of CIP2A.
No conflict of interest.

3072 POSTER

Molecular analysis of endometrial endometrioid adenocarcinomas based on estrogen receptor, progesterone receptor, and HER2 expression: A proposal for novel classification of endometrioid adenocarcinomas

H. Tomabechi[1], T. Sugai[2], Y. Suga[1], T. Nagasawa[1], N. Uesugi[2], K. Ishida[2], S. Takeuchi[1], T. Sugiyama[1]. [1]*Iwate Medical University, Obstetrics and Gynecology, Iwate, Japan;* [2]*Iwate Medical University, Division of Molecular Diagnostic Pathology Department of Pathology, Iwate, Japan*

Background: Endometrial cancer comprises about 4% of cancers in women worldwide, with a higher incidence in developed countries. The American Cancer Society estimated that endometrial cancer was the fourth most common cancer diagnosed and the eighth leading cause of cancer deaths in women in 2010. And there are two main clinicpathological variants of endometrial carcinoma. type 1 tumor are low grade and estrogen-related endometrial endometrioid adenocarcinomas (EEA). On the other hand, type 2 tumors are non-ECC unrelated to estrogen stimulation. Non-EEA are usually serous and clear cell carcinomas. In recent yaer, status of estrogen receptor (ER), progesterone receptor (PgR), and human epidermal growth factor receptor 2 (HER2) is key to clinical management in breast cancer. Molecular subtype of breast cancer based on ER, PgR and HER2 plays crucial roles in the treatment. However, in endometrioid adenocarcinoma (EA) which is the same estrogen-dependent tumor, neither such examination nor classification have been considered. In this study, our aim was to examine clinicopathological and molecular pathological findings of EAs according to their ER, PgR, and HER2 expression status in order to propose a comprehensive classification system for EAs.
Material and Methods: 83 EAs cases were analyzed for genetic alteration and immunohistochemistry, usingtumor cell isolated by both conventional technique and the crypt isolation method. Using immunohistochemistry, subtype definitions were as follows: Type A (ER+ and/or PgR+, HER2−), Type B (ER+ and/or PgR+, HER2+), Type C (ER−, PgR−, HER2+), Type D (ER−, PgR−, HER2−). And we examined MSI, methylations, LOH and mutation of *K-RAS*, *BRAF* and *PIK3CA* according to each subtypes.
Results: In immunohistochemistry, subtype were defined as follows: Type A (ER and/or PgR+, HER2−), Type B (ER and/or PgR+, HER2+), Type C (ER/PgR−, HER2+), Type D (ER/PgR−, HER2−). Altough loss of *PTEN* expression was commonly found in all subtypes, the frequency (frq) of *PTEN* expression of Type C was lower than that of others. *K-RAS* mutation was found more frq in Type C, and *PIK3CA* mutation was more common in Type A and B. The frq of LOH-high status in Type C and D was significantly higher than in Type A and B.
Conclusion: The classification of subtypes based on ER, PgR and HER2 in EAs were characterized by each different molecular abnormality and may be helpful to molecular targeted therapy like breast cancer.

3073 POSTER

In situ estrogen metabolism in subgroups of obese women with differing potential risk for developing endometrial cancer

A. Villavicencio[1], V. Lopez[1], E. Medina[1], C. Barahona[1], P. Peñaloza[2], F. Gaete[2], C. Albornoz[3], F. Castro[3], M. Celis[3], G. Owen[4]. [1]*INTA University of Chile, Human Nutrition Unit, Santiago, Chile;* [2]*School of Medicine University of Chile, Pathology Department, Santiago, Chile;* [3]*School of Medicine University of Chile, Obstetrics and Gynecology Department, Santiago, Chile;* [4]*Pontificia Universidad Católica de Chile, Faculty of Biological Sciences, Santiago, Chile*

Background: Enhanced endometrial proliferation correlates obesity to type-I (estrogen dependent) endometrial cancer (EC). Hypothezing that not all obese women develop EC and this is due to differing endometrial proliferation through impaired endometrial estrogenic metabolism, our laboratory previously identified cycling obese women *without EC* with differing endometrial proliferation levels: Obese High Proliferating (O_{HP}) and Obese Low Proliferating (O_{LP}).
Objective: To assess endometrial expression of estrogen metabolic enzymes, 17β-hydroxysteroid dehydrogenase (17β-HSD) type 1 and 2, aromatase, steroid sulfatase (STS) and estrogen sulfotransferase (EST), and the endometrial levels of 17β-estradiol (E2), estrone (E1) and estrone sulfate (E1-S) in the aforementioned subgroups of obese women.
Materials and Methods: The endometrial tissue samples were obtained from from cycling women in the proliferative phase (without type-I EC) with body mass index (BMI) = 18–24.9 kg/m^2 (normal-weight, N, n = 27), BMI $\geqslant$30 kg/m^2 (obese, O_{HP}, n = 28; O_{LP}, n = 15) and obese women with type-I EC (n = 25). Endometrial expression of estrogen metabolic enzymes was measured by immunohistochemistry. Endometrial E2, E1, E1-S levels were determined by radioimmunoassay. Institutional and Health Service Review Boards approved this study before its execution. Informed written consent was obtained before surgery for all patients.
Results: O_{HP} demonstrated increased endometrial expression of 17β-HSD1/17β-HSD2 (30%, $P<0.05$) and aromatase (60.4%, $P<0.05$), and higher endometrial E2 level (26%, $P<0.05$) compared with O_{LP} group. The O_{HP} did not differ from O_{LP} group in endometrial expression of STS and EST or in E1 and E1-S levels. The O_{LP} and normal-weight groups had similar 17β-HSD1/17β-HSD2 ratio, aromatase expression and endometrial E2 levels. Interestingly, obese women with type-I EC possessed similar aromatase and 17β-HSD1/17β-HSD2 expression as O_{HP}.
Conclusions: These data suggest that the 17β-HSD and aromatase pathways may produce higher local concentrations of E2 in the O_{HP} group, and thus explain the higher endometrial proliferation observed in this group. Our data may help identify obese women more susceptible to develop type-I EC, allowing early intervention and a potential reduction in mortality. (FONDECYT 1110232).

3074 POSTER

Integrin alpha(v) beta(3) expression in premalignant and malignant lesions of the uterine cervix

L.A. Guerra[1], M.I. Edelweiss[2], D.D. Rosa[3], D.A. Silveira[4], A.M. Marcolan[5]. *[1]Hospital Sao Vicente de Paulo and Universidade de Passo Fundo, Medical Oncology, Passo Fundo − RS, Brazil; [2]Hospital de Clinicas of Porto Alegre, Department of Pathology, Porto Alegre − RS, Brazil; [3]Hospital Femina Grupo Hospitalar Conceição, Research Unit, Porto Alegre − RS, Brazil; [4]Hospital Sao Vicente de Paulo and Universidade de Passo Fundo, Department of Pathology, Passo Fundo − RS, Brazil; [5]Instituto de Patologia de Passo Fundo and Universidade de Passo Fundo, Department of Pathology, Passo Fundo − RS, Brazil*

Cervix cancer has a high prevalence in Brazil, representing 10% of all malignant diseases in women. For the year of 2013 there is an estimative of 17,540 new cases of cervix cancer in Brazil. A high rate of women with locally advanced disease will recur after primary treatment with chemoradiation, and there are only few therapeutic options available for the recurrent setting. Therefore, there is a need to study new therapeutic targets as well as new prognostic factors for cervix cancer. Preclinical studies showed that the expression of several integrins are associated with neoplastic cellular invasion, angiogenesis and carcinogenesis.

Objectives: To evaluate the expression of alpha(v) beta(3) integrin in premalignant and malignat lesions of the uterine cervix and to associate its expression with the outcome of patients with cervix cancer.

Methods: A retrospective cohort study was performed in the Pathology Unit of Hospital Sao Vicente and in the Pathology Institute of Passo Fundo, Southern Brazil. Archives of patients with premalignat or malignant lesions of the cervix diagnosed from 2001 to 2008 were reviewed and their paraffin-embedded blocks were selected. Immunohistochemistry (IHC) was performed with the specific alpha(v) beta(3) (a_Vb_3) mouse monoclonal antibody BV3 (Abcam, Inc. Cambridge, MA) with a dilution of 1:400. Two gynecologic pathologists independently analyzed the results.

Results: It was possible to obtain clinical and pathological data from 146 patients. The interobserver kappa concordance for the IHC results was 0.808 ($p < 0.05$). The a_Vb_3 integrin was expressed in only 22 cases (15.06%). From these positive cases, 45.5% had the diagnosis of premalignant lesion and 54.5% of cervix cancer. There were no differences in disease-free survival for patients with cervix cancer with a_Vb_3 expression compared to those without expression.

Conclusions: There was no association of a_Vb_3 integrin expression with the outcome of patients with cervix cancer.

No conflict of interest.

3075 POSTER

ERBB signaling network in endometrial cancer − determination of clinical significance

A. Supernat[1], S. Lapinska-Szumczyk[2], H. Majewska[3], J. Gulczynski[4], S. Sawicki[2], A.J. Zaczek[1]. *[1]Medical University of Gdansk, Department of Medical Biotechnology, Gdansk, Poland; [2]Medical University of Gdansk, Department of Gynaecology Gynaecological Oncology and Gynaecological Endocrinology, Gdansk, Poland; [3]Medical University of Gdansk, Department of Pathomorphology, Gdansk, Poland; [4]Medical University of Gdansk, Department of Pathology and Neuropathology, Gdansk, Poland*

Background: Dysregulation of the ERBB signaling network occurs in many human cancers and is implicated in more aggressive tumor behavior. Data about the family of those four receptor tyrosine kinases in endometrial cancer (EC) are scarce. Results obtained by our team showed *ERBB* gene aberrations to correlate with more aggressive disease characteristics. In order to investigate ERBB family further in the context of EC, we aimed to determine clinical significance of ERBB expression on the protein level.

Material and Methods: The study group included 406 consecutive staged I−IV endometrial cancer patients treated between 2000 and 2010. ErbB1, ErbB2, ErbB3 and ErbB4 protein expression was examined by immunohistochemistry (IHC) on tissue-microarrays (TMA), using the following antibodies: anti-EGFR, clone EGFR113 (Novocastra); anti-HER-2/neu, clone 4B5 (Roche); anti-HER3, clone DAK-H3-IC (Dako); anti-ErbB4, clone HFR1 (Abcam). IHC results were compared with *ERBB1*, *ERBB2*, *ERBB3*, *ERBB4* gene dosages measured by SYBR-Green-based qPCR assay in 107 matching fresh frozen tumor samples.

Results: Out of the studied samples 167 (41%) were classified as ErbB1-positive, 145 (37%) as ErbB2-positive, 143 (35%) as ErbB3-positive and 228 (56%) as ErbB4-positive. Protein expression levels of all the four receptors correlated with each other, with the weakest and strongest correlation for ErbB2 vs. ErbB3 ($p = 0.013$) and ErbB1 vs. ErbB3 ($p<0.00001$), respectively. ErbB2 overexpression correlated with higher stage of the disease ($p = 0.001$) and histology type II ($p = 0.03$) but not with grading. IHC results of ErbB1, ErbB3 and ErbB4 did not reach statistical significance when juxtaposed with the aforementioned characteristics. Higher stage of the disease correlated with gene aberrations of *ERBB2* ($p = 0.004$) and *ERBB3* ($p = 0.00005$) while grading − with *ERBB1* ($p = 0.00005$) and *ERBB3* ($p = 0.03$). Histology type II was associated with amplification of *ERBB1* ($p = 0.00001$) and *ERBB3* ($p = 0.01$). Aberrations of *ERBB4* were not statistically significant. No correlations were found between protein expression levels and gene dosages.

Conclusions: Out of the studied receptors, ErbB2 protein level seems to carry the most useful information. No correlation between protein expression and DNA aberrations has been found. Examined genes, but not necessary their products, play a crucial role in the progression of endometrial carcinoma. Therefore, qPCR should be considered the method of choice in ERBB status determination.

No conflict of interest.

3076 POSTER

[18F]Fluorodeoxyglucose PET and Volumetric CT analysis are early biomarkers of survival in platinum-sensitive relapsed ovarian cancer − a multicentre trial

A.G. Rockall[1], N.E. Avril[2], R. Lam[3], P.D. Mozley[4], R. Iannone[5], M. Lockley[6], C. Parkinson[7], I.A. McNeish[8], J.D. Brenton[9]. *[1]Barts Health NHS Trust, Department of Radiology, London, United Kingdom; [2]Barts Health NHS Trust, Department of Nuclear Medicine, London, United Kingdom; [3]Merck and Company, Biostatistics and Research Decision Sciences, Whitehouse Station NJ, USA; [4]Merck and Company, Imaging in Exploratory and Translational Sciences, Whitehouse Station NJ, USA; [5]Merck and Company, Section of Clinical Oncology, Whitehouse Station NJ, USA; [6]Barts Health NHS Trust, Department of Medical Oncology, London, United Kingdom; [7]Cambridge University Hospitals Foundation Trust, Department of Oncology, Cambridge, United Kingdom; [8]Barts Cancer Institute, Centre for Experimental Cancer Medicine, London, United Kingdom; [9]Cancer Research UK Cambridge Institute, Functional Genomics of Ovarian Cancer Laboratory, Cambridge, United Kingdom*

Background: The activity of novel agents in relapsed ovarian cancer (OC) is assessed by reduction in tumour size, and increased progression-free (PFS) and overall survival (OS). However, early tumour response (measured by RECIST) correlates poorly with both PFS and OS. To inform future trial design, we evaluated FDG-PET and volumetric CT as early biomarkers of response and predictors of PFS and OS in relapsed OC.

Patients and Methods: This 2-centre trial (MK-0000-143, NCT00959582, sponsor Merck & Co) enrolled women aged >35 with platinum-sensitive (defined as >6 month progression-free interval since prior platinum-based treatment) relapsed OC, scheduled to receive standard-of-care platinum-based chemotherapy. FDG-PET and volumetric CT were performed at baseline, end-of-cycles (EoC) 1, 2 and 6 of chemotherapy. A volumetric CT was performed at week 40. Evaluable patients required $\geqslant$1 lesion with both SUV $\geqslant$2.5 (baseline FDG-PET) and longest diameter $\geqslant$1.5 cm (baseline volumetric CT). Blinded, independent reporting of all images was performed by site investigators and an external imaging CRO. Primary endpoints were 1) concordance of metabolic non-response, defined as <20% decrease in FDG uptake (SUVmean, SUVmax) compared to previous scan, during first 2 cycles of chemotherapy and 2) 40 week PFS rate in EoC1 metabolic responders and non-responders. Secondary endpoints included association between changes in tumour volume and both FDG-PET changes and OS, and the test-retest reproducibility of FDG-PET in relapsed OC.

Results: 43 patients, median age 62, were enrolled. 37 had post-baseline scans and 21 had baseline reproducibility scans. 36/37 have progressed (median PFS 268 days, 40 week PFS rate 0.31) and 21/37 have died (median OS 472 days, 40 and 52 week OS rates 0.94 and 0.66 respectively). The concordance in metabolic non-response rate between EoC1 and EoC2 was 100% (6/6) and 86% (6/7) for SUVmean and SUVmax respectively. There was no significant association between 40-week PFS rate and decreases in SUV parameters at EoC1 and EoC2. By contrast, statistically significant associations between OS and decreases in SUV, tumour diameter and tumour volume at both EoC1 and EoC2 were detected.

Conclusions: In women with relapsed OC receiving platinum chemotherapy, changes in both FDG-PET and volumetric CT after 1 and 2 cycles of treatment are significantly associated with greater OS. These imaging methods may have utility as biomarkers in future trials.

Conflict of interest: *Other substantive relationships: R. Lam and R. Iannone are employees of Merck and Company. P.D. Mozley was an employee of Merck and Company*

3077 POSTER

Tumour-associated inflammatory cytokines are reduced following primary platinum-based chemotherapy in plasma of high-grade serous ovarian cancer patients

S. Boehm[1], D. Ennis[2], T. Dowe[3], M. Canosa[1], I. McNeish[2], M. Lockley[3], F. Balkwill[1]. *[1]Barts Cancer Institute, Centre for Cancer and Inflammation, London, United Kingdom; [2]Beatson Institute for Cancer Research, Wolfson Wohl Cancer Research Centre, Glasgow, United Kingdom; [3]Barts Cancer Institute, Centre for Molecular Oncology, London, United Kingdom*

Background: Complete remissions in response to platinum-based first line chemotherapy in patients with advanced stage high-grade serous ovarian cancer (HGSC) are rare. Relapses are frequent even after optimal debulking surgery and chemoresistance ultimately occurs in the majority of FIGO stage IIIC and IV patients. Cancer related inflammation in the microenvironment of peritoneal metastases is tumour-promoting and contributes to chemoresistance. Interleukin 6 (IL-6), tumor necrosis factor α (TNFα) and Interleukin 8 (IL-8) are major components of an autocrine cytokine network in ovarian cancer with paracrine actions on angiogenesis and infiltration of myeloid cells. It is currently unknown how standard chemotherapy influences the production of these cytokines in patients.
Material and Methods: Plasma samples were collected from HGSC patients with ethical permission and informed consent. Inflammatory cytokines (IL-6, TNFα and IL-8) were measured in patients prior to any treatment (chemotherapy or debulking surgery, n = 12) and in patients who had received 3−4 cycles of platinum-based neoadjuvant chemotherapy (n = 21). Inclusive in these were eight patients where matched pre- and postchemotherapy samples were available. Meso Scale Discovery (MSD®) electrochemiluminescence assays were performed to measure the cytokine levels.
Results: Pre-treatment levels of IL-6 and TNFα were significantly elevated compared to controls ($p < 0.05$). After 3−4 cycles of chemotherapy plasma levels of IL-6, TNFα and IL-8 were significantly lower compared to pre-treatment samples ($p < 0.001$, $p < 0.01$ and $p < 0.05$ respectively). Also in the matched pre- and post-chemotherapy samples the mean of the cytokines decreased significantly ($p < 0.01$, $p < 0.05$ and $p < 0.05$ respectively).
Conclusions: Key cytokines of cancer related inflammation are elevated prior to treatment in the plasma of HGSC patients and come down after neoadjuvant chemotherapy closer to values of controls. Correlation to tissue immune cell subsets is warranted to see whether there might be a window of opportunity for immunotherapies to support anti-tumour immune responses.
No conflict of interest.

3078 POSTER

Clinical phase I/IIa study with TERT and survivin double loaded dendritic cell vaccine for patients with advanced ovarian cancer: Focus on safety and immunological proof of concept results

M. Imhof[1,2], M. Lipovac[2], J. Barta[2], I. Gomez[1], B. Haiderer[3], A. Hrdina[3], E. Krupa[3], K. Pieta[1], S. Tamregger[3]. *[1]Life Research Technologies, Research & Clinical Research, Vienna, Austria; [2]General Public Teaching Hospital, Gynecology and Obstetrics, Korneuburg, Austria; [3]Cell Pro Danube, GMP Production, Krems, Austria*

Background: Ovarian cancer is still characterized by a high unmet medical need with high recurrence and mortality rates after initial good responsiveness to surgery and chemotherapy. Dendritic cells (DC) can be processed to be used as cancer treatment vaccines. Patients at early stages or after successful first line therapy, who carry minimal residual disease (that nevertheless leads to recurrence with high probability) as it is the case for ovarian cancer, seem ideal candidates for the proof of concept of DC treatments.
Material and Methods: Data are presented from the clinical phase I/IIa trial with Eudract no 200800383726, short LRT-I-L01-Ovar, and sponsor Life Research Technologies. For vaccine preparation monocytes were collected via apheresis, matured into DCs and pulsed with two universal tumor associated antigens (uTAA) in our GMP facility. DCs were loaded with TERT and survivin via two different pathways (mRNA and peptide) to elicit $CD8^+$ and $CD4^+$T cells directly. Endpoints of the study were tolerability and safety, immunological and clinical responses. Vaccine specific T cell responses were evaluated by cytokine bead array and intracellular staining assays.
Results: 15 patients with advanced ovarian cancer were enrolled 8 weeks after first-line standard treatment with last patient out Dec 2012. Each patient was vaccinated intradermally on a weekly or fortnightly basis with a maximum of 8 doses of $13*10^6$ double loaded DCs. The majority of treatment related side effects were grade 1 fever and erythema. Overall the therapy was well tolerated. Immune response data is available for 14/15 patients, 1 was withdrawn after the first administration. Highly significant immune responses specific to the vaccine will be presented in detail. The positive response frequency of more than 90% is remarkably high for this kind of treatment and is proven for both uTAAs in CD8+ as well as CD4+ T cells. A clear positive trend in progression free survival is demonstrated compared to matched historical control.
Conclusions: Therapy with our unique double loaded DC vaccine was feasible, safe and well-tolerated by patients. The novel DC-based vaccine was immune stimulatory with high significance and elicited both, long-term and short-term anti-tumor immune responses. Overall these results establish a promising platform for immune therapy for ovarian cancer and all solid tumors in general with the final goal to delay or even prevent recurrent and metastatic disease.
No conflict of interest.

3079 POSTER

Anti-tumour efficacy of the PI3K inhibitor GDC0941, the dual PI3K/mTOR inhibitor GDC0980 and the MEK inhibitor GDC0973 as single agents and in combination in endometrial carcinomas

O. Aslan[1], A.M. Farrelly[1], B. Stordal[2], B.T. Hennessy[1]. *[1]Royal College of Surgeons, Medical Oncology, Dublin, Ireland; [2]Trinity College Dublin, Histopathology, Dublin, Ireland*

Background: The phosphoinositide-3 kinase (PI3K) pathway is commonly activated in cancer, including endometrial cancer (EC) due to mutations at multiple nodes, for example *PIK3CA,* or loss of expression of PTEN. Additionally, we and others have shown that, in EC, mutations in the RAS/RAF/MEK/MAPK pathway and the PI3K pathway frequently co-exist. Here, we examined the hypothesis that interaction between PI3K and RAS/RAF/MEK/MAPK pathway mutations is important in determining responsiveness of EC to therapies targeted to these pathways.
Methods: We used a large panel of genetically defined EC cell lines (n = 16, with diverse genetic backgrounds) to identify the anti-tumour effects (using IC_{50} values derived from viability assays) of a PI3K inhibitor GDC0941, a MEK inhibitor GDC0973 and a dual PI3K/mTOR inhibitor GDC0980 as single agents and in combination. We subdivided 16 endometrial cancer cell lines into 4 groups according to the mutational status of *PIK3CA*, *PTEN*, and *KRAS*: group 1 (n = 2), cell lines with *PIK3CA* mutations only; group 2 (n = 9), cell lines with *PTEN* mutations (+/−*PIK3CA* mutations) and wild type for *KRAS*; group 3 (n = 3) all cell lines with *KRAS* mutations; group 4 (n = 2), cell lines wild type for *PIK3CA*, *PTEN* and *KRAS*.
Results: We observed that the cell lines in groups 1 ($p = 0.02$) and 2 ($p = 0.04$) but not group 4 ($p = 0.77$) are significantly more sensitive to GDC0941 than cell lines in group 3. Group 2 cell lines with *PTEN* mutations without *KRAS* mutations and group 4 cell lines are significantly more resistant to the MEK inhibitor GDC0973 than cell lines in either group 1 ($p = 0.0007$, 0.008, respectively) or group 3 ($p < 0.0001$, =0.002, respectively) (surprisingly, IC_{50} values for GDC0973 were not significantly different between cell lines in groups 1 and 3, p=0.1). Both the combination of the PI3K inhibitor GDC0941 with the MEK inhibitor GDC0973 (CI from 0.03 to 0.19) and the combination of the dual PI3K/mTOR inhibitor GDC0980 with the MEK inhibitor GDC0973 (CI from 0.13 to 0.30) demonstrated significant synergy in cell lines in groups 1 and 2. While both combinations also showed strong synergism in group 3 cell lines also possessing *PIK3CA* or *PTEN* mutations, group 3 cell lines with *KRAS* mutations only demonstrated strong antagonism (CI>10).
Conclusions: Our data suggest that the mutational status of *PIK3CA*, *PTEN* and *KRAS* can be used as biomarkers to select patients for PI3K and RAS/RAF-targeted therapies. Further, the combinations of the PI3K inhibitors GDC0941 and GDC0980 with the MEK inhibitor GDC0973 are promising approaches for the treatment of patients with *PIK3CA*, *PTEN* and KRAS-mutated EC. Surprisingly, *PIK3CA*-mutated group 1 EC cell lines were as sensitive to the single agent MEK inhibitor GDC0973 as group 3 cell lines with *KRAS* mutations.
No conflict of interest.

CYP2D6*4 Polymorphism: A prognostic value in advanced ovarian cancer?

D. Pereira[1], M.H. Abreu[1], M. Gomes[2], M. Luís[1], J. Assis[2], A. Nogueira[2], R. Medeiros[2]. *[1]Oncology Portuguese Institute, Medical Oncology, Oporto, Portugal; [2]Oncology Portuguese Institute, Molecular Oncology Group, Oporto, Portugal*

Background: The survival of patients with ovarian cancer (OC) stands at 45 % at 5 years despite advances in surgery and chemotherapy. Pegylated liposomal doxorubicin (PLD), is a nucleolar non-selective class I anthracycline that inhibits both DNA and nucleolar RNA synthesis. This agent is a DNA-intercalating agent that inhibits topoisomerase-II, is widely

applied in advanced stages of the disease, in particular group of patients platinum-resistant.
Cytochrome P450 2D6 (CYP2D6) is an important enzyme involved in the metabolism of innumerous therapeutic drugs and its activity is mainly determined by the presence of genetic polymorphisms, as *CYP2D6*4* polymorphism (rs3892097). Individuals carrying two non-functional alleles of the *CYP2D6*4* polymorphism lack CYP2D6 activity whereas the presence of two functional alleles give rise to a normal enzymatic activity. The aim of this study was to evaluate the influence of *CYP2D6*4* polymorphism as prognostic factor in patients with OC.
Material and Methods: DNA was extracted from peripheral blood of 188 patients diagnosed with advanced OC (FIGO stage III and IV) submitted to chemotherapy. The characterization of *CYP2D6*4* genotypes was genotyped by Taqman® Allelic Discrimination methodology. Overall survival (OS) was the endpoint of this analysis and survival data were analyzed according to CYP2D6*4 polymorphisms' genotypes.
Results: The frequencies obtained for the CC, CT and TT genotypes were 71.28%, 23.40% and 5.32% respectively. The *CYP2D6*4* polymorphism genotypes were grouped as CC genotype and T carrier genotypes. Our results demonstrate that women with advanced OC (stage III and IV) and carriers of the T allele present a decreased overall survival (34 vs 64 months; $p = 0.005$; log-rank test).
Conclusion: CYP2D6 shows great importance in a metabolic level and is greatly studied in the field of translational research. Our results exhibit an association between *CYP2D6*4* and overall survival in patients with advanced stages. LPD plays a central role in the treatment of OC patients platinum-resistant. The interindividual variation in LPD metabolism may have implications on the toxicity and potentially efficacy of the drug, making it critical to understand the pharmacogenetics and pharmacokinetics of the drug. These results could help in the prediction and monitorization of patients, with advanced OC, platinum-resistant and to define the role of this genetic variant in the pharmacogenomic profile of OC.
No conflict of interest.

3081 POSTER

Silver-enhanced in situ hybridization (SISH) for detection of CCNE1/URI amplification in ovarian cancer

A. Noske[1], L.A. Henricksen[2], B. LaFleur[2], S. Singh[3], A. Tubbs[2], A.K. Zimmermann[1], M. Storz[1], H. Moch[1]. *[1]University Hospital Zurich, Pathology, Zurich, Switzerland; [2]Ventana Medical Systems, Medical Innovation, Tucson, USA; [3]Ventana Medical Systems, Pathology, Tucson, USA*

Background: CCNE1, coding cyclin E, is a potential target for ovarian cancer treatment. CCNE1 and URI are part of the frequent genomic amplification site on 19q12 in ovarian cancer, but URI may have more functionality in ovarian tumorigenesis than CCNE1. Purpose of the study was the establishment of a silver-enhanced in situ hybridization (SISH) technique for automated detection of CCNE1/URI. The CCNE1/URI status was further compared with clinico-pathological factors and patient outcome.
Material and Methods: Development and validation of a dual SISH assay for detection of CCNE1/URI copy numbers and Chromosome 19 as a surrogate on ovarian cancer samples using VENTANA BenchMark XT Platform and conventional bright field microscopy. The concordance of the novel probe for SISH was compared with URI amplification status previously assessed by fluorescence ISH (FISH) as well as Cyclin E immunohistochemistry. Dual SISH and Cyclin E immunohistochemistry was applied to a cohort of 136 epithelial ovarian carcinomas.
Results: SISH technique was established for detection of CCNE1/URI amplification and shows a high concordance with known URI amplification by FISH ($p < 0.001$). CCNE1/URI amplification correlates with high Cyclin E expression levels in ovarian cancer ($p < 0.001$). CCNE1/URI amplification was observed in 18% of the ovarian carcinomas and was associated with higher tumor grade and advanced FIGO stage. There was also a trend for a slightly worse survival for the amplified cases.
Conclusion: Our results show that SISH with the novel CCNE1/URI probe is feasible to reliably detect CCNE1/URI amplification. This assay may serve to monitor CCNE1/URI amplification status in patients with ovarian cancer, which may benefit from CCNE1 (Cyclin E) targeted therapies.
Conflict of interest: *Other substantive relationships: The Institute of Pathology (University Hospital Zurich) received research funds from Ventana Medical Systems, Inc.*

3082 POSTER

First evidence and experience of patient-derived xenograft models for endometrial cancer

L. Coenegrachts[1], S. Schrauwen[1], E. Hermans[1], D. Garcia Dios[1], G. Verbist[1], D. Lambrechts[2], F. Amant[3]. *[1]KU Leuven, Department of Oncology − Gynaecologic Oncology, Leuven, Belgium; [2]VIB − KU Leuven, Department of Oncology − Laboratory for Translational Genetics, Leuven, Belgium; [3]KU Leuven − UZ Leuven, Department of Oncology − Gynaecologic Oncology, Leuven, Belgium*

Background: Endometrial cancer is the most frequent malignancy of the female genital tract. Treatment modalities are limited for primary advanced and recurrent disease. Development of new treatment strategies is therefore warranted but may be hampered by the lack of representative pre-clinical *in vivo* models. Patient-derived tumor xenograft (PDTX) models appear to have better retention of the morphological and molecular markers of the source tumors, despite serial passages across several generations of mice. In our study, we here present preliminary data on the establishment and characterization of these PDTX models for endometrial cancer.
Materials and Methods: We established PDTXs of different histological subtypes of endometrial cancer. After written informed consent of the patient and within 1 h after surgery, tumor samples were implanted s.c. in NOD-SCID mice (F1 generation). When ~1000 mm^3, tumors were retransplanted in NOD-SCID and/or nude mice. Validation and comparison with the original patient's tumor was performed by histological and genetic analyses.
Results: For engraftment, a current success rate of ~50% is reached, which is comparable to other tumor types. In particular, 18 PDTX models, of different histological subtypes (endometrioid, serous, carcinosarcoma, undifferentiated carcinoma), were initiated, of which 7 were successful (i.e. tumor growth in at least F1-F2). Five PDTX models were categorized as 'failed' since no tumor growth was observed 8 months after implantation. Six other PDTX models were only recently initiated. Tumor growth rate in F1 xenografts was generally slower than in the subsequent generations (F2, F3, . . .). A protocol for re-implantation of cryopreserved xenografts was successfully optimized. Histological analyses showed that general tumor morphology (by H&E staining), proliferation capacity (Ki-67), hormone receptor status (ER, PR) and PTEN status remained similar in F1-F2-F3 xenografts as compared to the original patient tumor. Hotspot mutation profiling showed that mutations present in the original tumor were also observed in the xenograft tumors and no additional mutations in the xenografts were identified. Finally, we successfully evaluated the *in vivo* responsiveness to standard chemotherapy and a PI3K − mTOR inhibitor, BEZ-235, in one of the established models.
Conclusion: We here show first evidence for the establishment of PDTX models for endometrial cancer that can be used for future preclinical drug evaluation.
No conflict of interest.

3083 POSTER

Identifying predictive biomarkers of carboplatin resistance in ovarian cancer

Z. Pénzváltó[1], A. Lánczky[1], B. Gyorffy[1]. *[1]Semmelweis University, 1st Department of Pediatrics, Budapest, Hungary*

Background: Ovarian cancer is the most lethal gynecological cancer. Besides surgery, paclitaxel and carboplatin chemotherapy represent the primary treatment option. Platinum resistant cancer recurs in approximately 25% of patients within six months. There is no clinically applicable predictive biomarker of platinum resistance. Our aim was to identify such biomarkers.
Materials and Methods: We have set up a databank of ovarian microarray datasets containing treatment and response information of the patients. For this, we searched GEO and TCGA to identify datasets suitable for the analysis of the effect of the expression change of each gene on therapy response. We performed receiver operating characteristic (ROC) analysis in R for all genes and then ranked them based on the area under the curve (AUC) values. We identified the most promising candidates and compared these to the available literature. Then, eight genes were selected for in vitro functional validation including JRK, CNOT8, RTF1, CCT3, NFAT2CIP, MAP2K1, FUBP1 and CSDE1. We performed gene silencing with simultaneous 48 h carboplatin administration in four epithelial ovarian cancer cell lines (SKOV-3, CAOV-3, ES-2, and OVCAR-3), to evaluate the effect of the genes in carboplatin resistance with MTT viability assay.
Results: We identified 1267 patients in 8 datasets meeting our criteria in GEO and TCGA. The average progression free survival is 24.8 months with 731 progressions. 1152 patients received a platinum-based chemotherapy and 631 received taxol (614 patients received both taxol and platinum). The ROC values of the selected genes were JRK (0.625), CNOT8 (0.610),

RTF1 (0.620), CCT3 (0.620), NFAT2CIP (0.612), MAP2K1 (0.611), FUBP1 (0.608) and CSDE1 (0.605). The expression change of JRK ($p = 0.0002$), MAP2K1 ($p = 0.0117$) and CNOT8 ($p = 0.0036$) were significantly correlated with progression free survival. JRK was not expressed in the cell lines. The silencing of RTF1, FUBP1 MAP2K1, CSDE1 and CNOT8 caused significant sensitization in each cell line. Greatest sensitizing effect (compared to negative control siRNA treated cells) and p values are: RTF1:19.7% p= 5E-07, FUBP1: 31.7% p=3E-03, MAP2K1: 16.9% p=1E-03, CSDE1: 23.3% p=4E-04, CNOT8: 16.7% p=9E-07).
Conclusion: We identified potential biomarkers of carboplatin response on a large patient cohort and in vitro validated the effect. Expression of RTF1, FUBP1 MAP2K1, CSDE1 and CNOT8 correlated to platinum resistance in ovarian cancer.
No conflict of interest.

3084 POSTER

Clinical outcome of BRCA1-associated epithelial ovarian cancer: Significance of the 4153delA and 5382insC mutations

G. Plakhins[1], A. Irmejs[1], G. Purkalne[1], G. Trofimovics[1], E. Miklasevics[1], J. Gardovskis[1]. [1]*Riga Stradins University, Oncology Institute, Riga, Latvia*

Background: The impact of the mutations in the *BRCA1* gene on the clinical outcome of epithelial ovarian cancer has been extensively investigated, and despite some conflicting results, most recently published studies have reported higher survival rates for *BRCA1*-associated ovarian cancer patients. Due to the genotype-phenotype correlation effect, carriers of *BRCA1* mutations in different regions of the *BRCA1* gene have different risks for developing breast and ovarian cancer. Moreover, breast cancer patients who are carriers of the 4153delA mutation have a poorer clinical outcome than carriers of the 5382insC mutation. However, the correlation of individual *BRCA1* mutations with the survival rates of epithelial ovarian cancer patients has not yet been fully investigated.
Methods: Ovarian cancer patients carrying the three most prevalent *BRCA1* mutations in Latvia (300T/G, 4153delA and 5382insC) were screened at the Institute of Oncology of Riga Stradins University as part of a nationwide case-control study. Patients who were diagnosed with primary ovarian cancer from 2005–2011 and who underwent mutational analysis before or within 6 months following surgery were included in the study.
Results: Out of 196 patients, 91 had BRCA1 mutations: 4153delA(n = 45), 5382insC (n = 46). The mean estimated survival time was 41.6 months among carriers (36.4 and 46.4 months among 4153delA and 5382insC mutation carriers, respectively), and 36.1 months among non-carriers. The overall survival of the 5382insC mutation carriers was significantly better than both 4153delA mutation carriers($\chi^2 = 4.09$, DF=1, $P = 0.043$)and non-carriers ($\chi^2 = 7.14$,DF=1, $P = 0.008$). The difference in overall survival between the 4153delA mutation carriers and non-carriers was not statistically significant. A multivariable analysis revealed that the 5382insC mutation remains an independent predictive factor of improved survival for epithelial ovarian cancer patients.
Conclusions: Specific mutations within the *BRCA1* gene can have different impacts on the clinical outcome of epithelial ovarian cancer. Further clinical studies are needed to determine the significance of various ovarian cancer treatment options for carriers of individual *BRCA1* mutations located in different parts of the *BRCA1* gene.
No conflict of interest.

3085 POSTER

A redistribution of resistance and sensitivity to platinum according to the observation period after the treatment of epithelial ovarian cancer

Y. Yokoyama[1], M. Futagami[1], H. Mizunuma[1], T. Shoji[2], T. Sugiyama[2], N. Sato[3], N. Yaegashi[4], H. Kurachi[5], H. Nishiyama[6], T. Tase[7]. [1]*Hirosaki University School of Medicine, Obstetrics and Gynecology, Hirosaki, Japan;* [2]*Iwate Medical University School of Medicine, Obstetrics and Gynecology, Morioka, Japan;* [3]*Akita University School of Medicine, Obstetrics and Gynecology, Akita, Japan;* [4]*Tohoku University School of Medicine, Obstetrics and Gynecology, Sendai, Japan;* [5]*Yamagata University School of Medicine, Obstetrics and Gynecology, Yamagata, Japan;* [6]*School of Medicine Fukushima Medical University, Obstetrics and Gynecology, Fukushima, Japan;* [7]*Miyagi Cancer Center, Gynecology, Natori, Japan*

Background: In epithelial ovarian cancer (EOC), platinum-resistant/sensitive relapse is divided into 2 categories: platinum-resistant/sensitive EOC relapse less than 6 months after the completion of the initial treatment and that at 6 months or later following the completion of the initial treatment. This study evaluated the justification for setting the boundary of the treatment-free interval (TFI) at 6 months.
Materials and Methods: Of 405 patients with stage III/IV disease, 107 with relapsed or recurrent disease after attaining a clinical complete response with first-line regimen were assessed retrospectively. The degree of platinum sensitivity was calculated by comparing progression-free survival (PFS) values.
Results: The median TFI in in relapsed patients was 11.5 months. In serous/endometrioid groups treated with platinum after relapse, there were significant differences in PFS between patients who relapsed <6 months and those who relapsed between 6−12 months, and between those who relapsed between 6−12 months and those who relapsed between 12−18 months, and between those who relapsed between 12−18 months and those who relapsed $\geqslant$18 months. There were no significant differences in PFS between patients who relapsed <6 months and those who relapsed between 6−12 months, while there were significant differences in PFS between those who relapsed between 6−12 months and those who relapsed $\geqslant$12 months in clear cell/mucinous adenocarcinoma groups treated with platinum after relapse. PFS of patients who relapsed $\geqslant$12 months in clear cell/mucinous adenocarcinoma groups was significantly shorter compared with that of those who relapsed $\geqslant$12 months in serous/endometrioid adenocarcinoma groups, and similar to that of those who relapsed between 6−12 months in serous/endometrioid adenocarcinoma groups.
Conclusions: It might be rational to classify patients who relapsed <12 months as platinum resistant and patients who relapsed $\geqslant$12 months as platinum sensitive in clear cell/mucinous adenocarcinomas.
No conflict of interest.

3086 POSTER

Living between anxiety and hope: the experiences of women with vulvar intraepithelial neoplasia during their course of illness − a qualitative study

D. Gafner[1], M. Eicher[2], R. Spirig[3], B. Senn[4]. [1]*Inselspital University Hospital Bern, Department of Obstetrics and Gynecology, Bern, Switzerland;* [2]*University of Applied Sciences Western Switzerland, School of Health Fribourg, Fribourg, Switzerland;* [3]*University Hospital Zürich, Department of Clinical Nursing Science, Zürich, Switzerland;* [4]*University of Applied Sciences FHS St. Gallen, Institute for Applied Nursing Sciences IPW, St. Gallen, Switzerland*

Background: The vulvar intraepithelial neoplasia (VIN) is a uncommon chronic skin condition which can progress to an invasive carcinoma of the vulva. The most frequent issues affecting women's health were described as occurring symptoms, negative influences on sexuality, changes in the body image and uncertainty concerning the illness progression. Despite this, there is little known about the lived experiences during the course of the illness. Thus, the aim of this study was to describe the lived experiences of women with VIN during the course of illness.
Methods: This study is a secondary data analysis of a foregoing qualitative study. We analyzed eight narrative interviews with women with VIN by using thematic analysis in combination with critical hermeneutics.
Results: A sense of 'hope and fear' was essential for women with VIN during their course of illness. This constitutive pattern reflects the fear of recurrence as well as the trust in healing. The eight narratives showed that women's lived experiences during the course of illness occurred in five phases: 1) 'there is something unknown', 2) 'one knows, what IT is', 3) 'IT is treated and should heal', 4) 'IT has effects on daily life' and 5) 'meanwhile it works'. Furthermore, women's lived experiences were particularly influenced by a feeling of 'embarrassment' and by 'dealing with professionals'.
Conclusion: Current care seems to lack adequate support for women with VIN in order to manage these five occurring phases. Based on our study and the international literature we suggest, that new models of counseling and providing information (such as the WOMAN-PRO II *program*) for women with VIN need to be developed and evaluated.
No conflict of interest.

3087 POSTER

Experimental development of a new antitumor drug for the use in high-dose chemoperfusion treatment

O. Belyaeva[1], V.G. Bespalov[1], A.N. Stukov[1], K.Y.U. Senchik[1], G.S. Kireeva[1], V.A. Aristova[1]. [1]*N.Petrov Research Institute of Oncology, Chemoprevention of Cancer and Oncopharmacology, St.-Petersburg, Russian Federation*

Background: Nowadays in the Russia morbidity of ovarian cancer is 2.5% of the overall malignancies morbidity and 4.6% of gynecologic tumors. Intraperitoneal chemoperfusion (IPEC) is currently considered as a promising high-technology method of treatment of peritoneal carcinomatosis and tumor ascites. The purpose of the study is development of new antineoplastic drug from group of alkylating agents (ethylenimines)

named dioxadet for the use in high-dose IPEC treatment. It is earlier established that dioxadet is more safety that platinum drugs.
Materials and Methods: Ovarian cancer cells were transplanted intraperitoneally in 90 Wistar female rats. We used dioxadet in doses 1.5 mg/kg for single intraperitoneally injection and 30 mg/kg for normothermal IPEC. In the comparing group we applied cisplatin in doses 4 mg/kg for single intraperitoneally injection and 40 mg/kg for normothermal IPEC. Both drugs were administered 48 hours after the intraperitoneal tumor transplantation. In rats of control group saline solution was administered intraperitoneally (0.5 ml) and in the normothermal IPEC (200 ml). The antitumor effects of the drugs were estimated by median survival time (MST) and increasing life span of rats.
Results and Discussion: In the control group MST was 9.0 days. Single intraperitoneal injection of dioxadet increased MST by 128% (MST=20.5, $p = 0.001$) as well as cisplatin increased MST by 117% (MST=19.5, $p = 0.008$) compared with the control group. In normothermal IPEC dioxadet and cisplatin had the most significant cytostatic effects. Increase of MST after normothermal IPEC with dioxadet was 244% (MST = 31.0, $p = 0.001$) and with cisplatin was 317% (MST = 37.5, $p \leqslant 0.001$) compared with control group. In comparison with normothermal IPEC group without drug (MST = 16.0) increase of MST with dioxadet and cisplatin were 94% ($p = 0.006$) and 134% ($p = 0.002$), respectively.
Conclusion: IPEC enhances cytostatic effects of the drugs; antineoplastic effect of dioxadet is comparable to the effect of cisplatin in normothermal chemoperfusion, while dioxadet has less local and systemic side effects than platinum drugs.
No conflict of interest.

3088 POSTER

Pre-treatment thrombocytosis and prognosis of stage III and IV ovarian cancer

A. Digklia[1], I.A. Voutsadakis[1]. [1]*University Hospital Lausanne (CHUV), Medical Oncology, Lausanne, Switzerland*

Background: Thrombocytosis has been found to be an adverse prognostic factor in many types of cancer such as breast, GI and GU. In epithelial ovarian cancer patients across all stages and histologic types pre-treatment thrombocytosis was an independent prognostic factor for overall survival. We investigated if pre-treatment platelet counts provide prognostic information in patients with advanced (stage III and IV) serous ovarian cancer which is the most common clinical presentation and type of ovarian cancer.
Methods: Platelet number on diagnosis of stage III and IV serous ovarian adenocarcinoma was evaluated in 91 patients treated in our hospital and for whom there were complete follow-up data on survival. Survival of patients with normal platelet counts (150–350 $x10^9$/L) was compared with that of patients with thrombocytosis (>350 $x10^9$/L) by x^2 and LogRank tests. Patients with other histologic types of ovarian cancer or earlier stages of disease were excluded.
Results: The median age of the patients was 66 years-old. From the 91 patients, 52 (57.1%) had normal platelet counts (median: 273 $x10^9$/L, range: 153–350) at diagnosis of their disease and 39 patients (42.9%) had thrombocytosis (median: 463 $x10^9$/L, range: 354–631). The median age of the patients with normal counts was 65 years-old (range 27 to 87) and of those with thrombocytosis was 70 years-old (range 41 to 90). In the group of patients with normal platelet counts, 24 of the 52 patients had died with a median survival of 43 months (range: 3–100) and 28 patients were alive at last follow-up with a median follow-up of 32.5 months (range: 1–140). In the group of patients with thrombocytosis, 24 of the 39 patients had died with a median survival of 23 months (range: 4−79) and 15 patients were alive at last follow-up with a median follow-up of 20 months (range: 4−69). Among the 48 patients (24 patients in each group) who had died, the 3 year survival of patients with normal platelet counts was 54.2% and of patients with thrombocytosis was 33.3%. In the entire group of 91 patients there was a statistically significant difference of the overall survival between the two groups (LogRank test $p = 0.02$).
Conclusion: In this retrospective analysis of stage III and IV ovarian cancer patients, thrombocytosis at the time of diagnosis has prognostic value regarding overall survival. Platelets are carriers of VEGF-A, TGF-β and many other active bio-molecules in their granules and their number in circulation may have implications for the amount of these factors in seeding sites, besides the mechanistic support that they provide to circulating tumor cells.
No conflict of interest.

3089 POSTER

Impact of Ki67 expression in prognostic factors and clinical outcome of endometrial carcinoma

S.R. Bella[1], J.R. Llugdar[1], M.F. Diaz Vazquez[2], A. Lingua[1], I. Magri[1], A. Guidi[3], M. Ramirez[3], L. Armando[3], G. Ferraris[2]. [1]*Clinica Reina Fabiola, Medical Oncology, Córdoba, Argentina;* [2]*Instituto Privado de Radioterapia Cuyo, Radiotherapy, Mendoza, Argentina;* [3]*Clinica Reina Fabiola, Pathology, Córdoba, Argentina*

Background: Most decisions regarding the indication of adjuvant radiotherapy in endometrial carcinoma are based on adverse histopathological factors. In the last years there is also an increased interest in relation to the indication of adjuvant chemotherapy in early high risk endometrial carcinoma (GOG 0249 and PORTEC 3 studies are ongoing). Therefore, given the growing importance of adjuvant therapies, there is a need to count on others prognostic markers. Ki67 index is a proliferating cell nuclear marker that could be correlated with adverse factors previously known as well as with clinical outcome in patients with endometrial carcinoma.
Material and Methods: We included patients with endometrial carcinoma of endometrioid type confirmed by histology, stage IA to stage IIIC2 diagnosed between 2006 and 2012. The degree of expression of Ki67 index was evaluated by immunohistochemistry technique. We included the following measuring ranges: 0−10%, 11−49% and $\geqslant$50%. The objectives were to analyze the association between Ki67 expression with histological grade, myometrial invasion, lymphovascular invasion, cervical invasion, patient age and relapse-free survival, using the Pearson's chi-squared test and Fisher's exact test. The analysis of relapse-free survival was performed by log rank test (Mantel-Cox).
Results: 58 patients were included. A significant correlation between Ki67 and histological grade ($p = 0.001$), lymphovascular invasion ($p = 0.029$) and myometrial invasion ($P = 0.025$) was found. We did not found an association between Ki67 and age ($p = 0.303$) and Ki67 and cervical invasion ($p = 0.282$). Median follow-up was 27 months. We found an association between Ki67 and risk of relapse ($p = 0.007$). The analysis of relapse-free survival by log rank test among patients with Ki67 <50% and those with Ki67 $\geqslant$50%, showed a statistically significant difference ($p = 0.003$). Odds Ratio for relapse if Ki67 $\geqslant$50% was 11.04.
Conclusions: An association between Ki67 expression and other adverse histological factors was found. We also found a correlation between high level of Ki67 expression (>50%) and risk of relapse.
No conflict of interest.

3090 POSTER

A phase I study of multiple peptides cocktail vaccine for advanced/recurrent ovarian/cervical cancer

S. Takeuchi[1], T. Shoji[1], M. Kagabu[1], F. Miura[1], T. Honda[1], H. Omi[1], A. Takada[1], H. Onoue[1], Y. Nitta[1]. [1]*Iwate Medical University School of Medicine, Obstetrics and Gynecology, Monioka, Japan*

Background: Despite of improvement in chemotherapy including the molecular targeting agents, advanced or recurrent ovarian cancer (A/ROC) and cervical cancer (A/RCxC) are still incurable. Some tumor associated proteins and tumor related vascular endothelial growth factor receptor 1,2 (VEGFR1, VEGFR2) were found to be candidates as new targets, and their epitope peptides which are restricted human leukocyte antigens (HLA) of A2402 and A0201 have been shown to have the ability to induce specific cytotoxic T lymphocyte (CTL) responses. We conducted a phase I study of these peptides cocktail vaccine (PCV) in patients with A/ROC and A/RCxC in order to evaluate toxicity and immunological response.
Patients and Methods: Cohorts were divided in four groups; such as HLA-A2402 positive A/ROC(A24-Ov), and A/RCxC(A24-Cx), which would cover nearly 60% in patients of Japanese female, and HLA-A0201 positive patients (A02-Ov and A02-Cx) which would cover the rest 20%. Theoretically, 80% of A/ROC and A/RCxC would be covered by theses PCV treatment. The setting of this phase I study was one arm trial according to duplicate Fibonacci method without dose modification. Eligible patients were heavily treated chemo-resistent patients with PS0−2 and normal organ functions. PCV for A24-Ov comprises FOXM1 (Forkhead Box M1), MELK(maternal embryonic leucine zipper kinase, HJURP(Holliday junction recognition protein, VEGFR1 and VEGFR2. As for A02- Ov, PCV comprises hypoxia-inducible protein 2 (HIG2), VEGFR1and VEGFR2. A24-Cx PVC comprises FOXM1, MELK, and HJURP. A02-Cx comprises HIG2 and up-regulated lung cancer 10 (URLC10). Cocktails were made at a dose of 1 mg of each peptide with GMP grade-adjuvant, MONTANIDE ISA51. Vaccination schedule included weekly subcutaneous administration for first 12 weeks, then bi-weekly administration for next 16 weeks, then further vaccination was done monthly for 8 times and 3−6 months as a maintenance step according to patient's need. Pre- and post-vaccination blood samples were obtained from the patients for toxicity assessment and immunological evaluation by ELISpot Assay.

Results: 23 patients were enrolled as for these four cohorts. Only A02-Cx cohort did not reached for 6 patients. A24-Ov, A02-OV, and A24-Cx were completed but A02-Cx has not completed yet and this cohort is going to be terminated. PCV were generally well tolerated with no major adverse events, and most of the patients developed specific CTL responses. Only Grade 1 dermatologic reactions (redness, itching, swelling, induration, pain, scaling) as non-hematologic adverse event by the agents was detected and the trials moved on phase 2 study for more 24 patients in each groups.
Conclusions: PCV for these cohorts of disease were safe and feasible and further patient accrual for phase 2 study is now on going.

Impact of relative dose intensity (RDI) on the outcome of patients with metastatic solid tumors: A systematic review

L. Havrilesky[1], M. Reiner[2], P.K. Morrow[3], H. Watson[3], E. Abella[3], J. Crawford[4]. *[1]Duke University Medical Center, Gynecology Oncology, Durham NC, USA; [2]Amgen Inc., Global Biostatistical Science, Thousand Oaks CA, USA; [3]Amgen Inc., Hematology/Oncology, Thousand Oaks CA, USA; [4]Duke University Medical Center, Medical Oncology, Durham NC, USA*

Background: High RDI has been associated with improved outcomes in various cancers in the curative setting, yet the impact of RDI in advanced/metastatic cancer remains unclear. We performed a systematic literature review to evaluate the impact of RDI on outcomes in patients with metastatic lung, breast, or ovarian cancer receiving chemotherapy (CT).
Material and Methods: PubMed was searched for peer-reviewed English articles published from January 1, 2000 to December 31, 2012 using search terms including RDI, metastatic, breast, lung, ovarian, and cancer. Articles on radiotherapy, stem cell transplantation, and targeted therapy were excluded. Heterogeneity in methods and type of RDI analysis precluded meta-analysis.
Results: 78 studies were identified (lung=33, breast=34, ovarian=11). Overall most trials were phase 2 (lung=19, breast=18, ovarian=1) and involved first-line CT (lung=25, breast=14, ovarian=5). 26 studies (lung=11, breast=11, ovarian=4) estimated RDI. 7 studies analyzed overall survival (OS) as a function of RDI (Table).
Conclusions: The number of clinical trials reporting RDI is insufficient to determine the impact of maintaining planned DI on outcome in metastatic solid tumors.

3092 POSTER

Itgbl1 over expression stimulates ovarian cancer cell migration rate

A. Maciola[1], A.J. Cortez[2,3], M. Olbryt[1], T. Kujawa[1], K. Lisowska[1]. *[1]Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Center for Translational Research and Molecular Biology of Cancer, Gliwice, Poland; [2]Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Center for Translational Research and Molecular Biology of Cancer, Poland; [3]Polish-Japanese Institute of Information Technology Koszykowa Warsaw, Gliwice, Poland*

Introduction: Previously, we performed a microarray analysis of 100 ovarian cancer samples. We found that among serous tumors, two molecular subtypes can be distinguished on the basis of their distinct gene expression profile. Further analysis indicated that these molecular subtypes are correlated with different survival of the patients. One of the genes that were differentially expressed between two subtypes of ovarian cancer was Integrin, beta-like 1 gene (ITGBL1). It codes for a poorly characterized adhesion protein that contains 10 tandem EGF-like repeats similar to those found in the cysteine-rich structure of integrin subunits. ITGBL1 is supposed to be evolutionarily and functionally cognate with integrin β. On this basis this is speculated that this protein may influence adhesion and motility, thus affecting the ability of cancer cell to spread and metastasize. Our aim was to study whether and how ITGBL1 can influence the biology of ovarian cancer cells.
Methods: Microarray analysis of 99 ovarian cancer samples was performed using Affymetrix HGU 133 Plus arrays. ITGBL1 expression in 5 ovarian cancer cell lines (OAW42, SKOV3, OVCAR-3, OVP-10 and ES2) was assayed using semi-quantitative RT-PCR. ITGBL1 coding sequence was amplified from cDNA and cloned in pCRII-TOPO vector than transferred into pLNCX2. Retroviral system was used to obtain cell lines with ITGBL1 overexpression. Wild type and ITGBL1-expressing isogonics cell lines were then used in scratch assay to evaluate the difference in cell proliferation rate and motility.
Results: We checked 5 ovarian cancer cell lines for the expression of ITGBL1 mRNA. Only in the ES2 line ITGBL1 expression was detectable, while 4 other cell lines were negative. Thus we did an attempt to modify these 4 cell lines to obtain overexpression of ITGBL1. We successfully obtained 3 cell lines with overexpression of ITGBL1: SKOV3, OAW42 and OVCAR-3. Than SKOV3/ITGBL1(+) and OAW42/ITGBL(+) cell lines were assayed for cell proliferation and migration rate. The results were analyzed in comparison to the non-modified SKOV3 and OAW42 cell lines. We found that in the scratch assay the scratch area was faster covered with the cells overexpressing ITGBL1 than in the isogenic cell lines that do not express ITGBL1.
Conclusion: It seems that ITGBL1 protein may enhance ovarian cancer cell proliferation and motility. This suggests that ITGBL1 may play an important role in ovarian cancer progression; however this must be further confirmed.

Modern approaches to the diagnosis and monitoring of pre-cancer conditions and early forms of cervical cancer

E. Bakhidze[1]. [1]*N.N. Petrov Research Institute of Oncology, Gynaecological Oncology, Saint Petersburg, Russian Federation*

Background: The incidence of invasive cervical cancer tends to increase in women of reproductive age that makes it necessary to revise the traditional approaches to the diagnosis and monitoring of pre-cancer and early forms of cervical cancer. The purpose of the study was to assess expediency of application HPV test, along with cytology in diagnosis and monitoring of cervical CIN II−III and carcinoma in situ.
Material and Methods: Study was conducted in two directions: 1) correlation of cytologic findings before cone biopsy and histological findings after it were analyzed and compare with data of HPV test; 2) predictive value of HPV-test in estimated risk of residual process or recurrence of severe dysplasia (CIN III) and carcinoma in situ was investigated. 69 patients with cervical severe dysplasia and carcinoma in situ underwent cone biopsy from 2009 to 2011 were enrolled. Cytological study of ecto- and endocervix and HPV test were done before cone biopsy. After operation histological examination of the cone with estimation of resection margin was performed, and then patients were observed with the use of cytology and HPV test.
Results: Mean age was 31.4 years. HPV genotype 16 was found in 33 patients (63.7%), 18 − in 7 patients (14.3%), 31 − in 7 patients (14.3%). The other oncogenic HPV genotypes were detected in isolated cases. Histological examination revealed carcinoma in situ in 40 from 69 patients (57.9%), severe dysplasia (CIN III) − in 8 (11.6%), moderate dysplasia (CIN II) − in 12 (17.4%), and hyperplasia of reserve cells − in 10 (14.5%) patients. Comparison of cytologic and histologic examinations data revealed overdiagnosis CIN or carcinoma in situ in 10 of 69 patients (14.5%), while one patient was overdiagnosis carcinoma in situ. In all 10 cases (100%) with histological diagnosis of hyperplasia of reserve cells HPV test was negative. In two patients with negative cytological data with long-term persistence of HPV type 16 there was detected carcinoma in situ in one case, and CIN II in another. 11 (16%) patients after cone had positive HPV test with negative cytology test in 4. Positive resection margin was revealed in a remote cone in 7 patients. All of them underwent re-conization, with histologically confirmed relapse in 3 cases. At the further monitoring positive HPV test was observed in three patients with negative cytology test.
Conclusions: The combination of cytological and HPV testing methods shows a higher accuracy in the diagnosis of CIN II−III and carcinoma in situ of the cervix comparing to one cytology and in monitoring of patients after cone biopsy.
No conflict of interest.

3094 POSTER

The phase II study of docetaxel and carboplatin combination chemotherapy for advanced/recurrent patients with non-squamous uterine cervical cancer

T. Shoji[1], M. Shimada[2], S. Nagao[3], K. Fujiwara[4], T. Otsuki[5], T.T. Takano[5], A. Murakami[6], T. Sugiyama[1], J. Kigawa[2]. [1]*Iwate Medical University School of Medicine, Obstetrics and Gynecology, Morioka, Japan;* [2]*Tottori University School of Medicine, Obstetrics and Gynecology, Yonago, Japan;* [3]*Hyogo Cancer Center, Gynecologic Oncology, Akashi, Japan;* [4]*Saitama Medical University International Medical Center, Gynecologic Oncology, Hidaka, Japan;* [5]*Tohoku University School of Medicine, Obstetrics and Gynecology, Sendai, Japan;* [6]*Yamaguchi University Graduate School of Medicine, Obstetrics and Gynecology, Ube, Japan*

Background: Non-squamous cell carcinoma (non-SCC) of the uterine cervix has gradually increased, comprising more than 20% of all uterine cervical cancer. Uterine cervical cancer with non-SCC has a resistance to radiotherapy, suggesting to be associated with worse prognosis compared with SCC. Few prospective studies focusing on this rare disease could conclude the optimal chemotherapeutic regimen, since non-SCC cervical cancer is rare. We conducted this phase II study to evaluate the efficacy and safety of docetaxel (DTX) and carboplatin (CBDCA) combination chemotherapy (DC) for advanced/ recurrent cervical cancer with non-SCC.
Material and Methods: Forty six patients enrolled in this study. The patients were administered DTX at a dose of 60 mg/m^2, followed by CBDCA at a dose based on an AUC of 6. Patients underwent DC chemotherapy until disease progression. The response was evaluated in 41 patients based on RECIST criteria 1.0 and toxicity grade was determined in 46 patients by NCI-CTC version 3.0.
Results: Median age and cycles of DC chemotherapy were 55 years old (range: 25−77), and 5 (range: 1−12). The response rate (RR) and disease control rate (DCR) were 56% and 83%, with 5 patients achieving complete response, 18 partial response, 11 stable disease, 7 progressive disease. The most frequent grade 3 and grade 4 hematological toxicity was neutropenia, with 36 patients (78%) having grade 4 neutropenia and 4 patients (9%) having grade 3 neutropenia. Grade 3 febrile neutropenia was observed in 6 patients. Nineteen patients (41%) had more than grade 3 anemia, and 18 patients (39%) showed more than grade 3 thrombocytopenia. The non-hematological toxicities were mainly grade 1 or 2 in severity. With regard to grade 3 non-hematological toxicities, 8 patients had infection, 7 nausea or anorexia, 2 diarrhea, and 1 vomiting, fatigue or allergic reaction to DTX. Only one patient had grade 4 allergic reaction to DTX.
Conclusions: DC chemotherapy had good RR and DCR to advanced/ recurrent uterine cervical cancer with non-SCC, suggesting to prolong overall survival. DC chemotherapy might be also tolerated, although DC chemotherapy showed high incidence of hematologic toxicities, especially neutropenia.

A prospective study of ERCC1 protein expression and gene polymorphisms in locally advanced cervical squamous cell carcinoma patients treated with cisplatin-based concurrent chemoradiotherapy

A. Álvarez[1], A. Zwenger[2], G. Marechal[2], S. Acevedo[2], S. Audero[2], N. Krause[2], A. Cuevas[2], A. Yanzi[2], X. García[2], M. Pallotta[2]. [1]*Asociación Argentina de Oncología Clínica, Buenos Aires, Argentina;* [2]*Asociación Argentina de Oncología Clínica, Research, Buenos Aires, Argentina*

Background: Excision repair cross-complementation group 1 (ERCC1) expression and some polymorphisms of the gene could predict treatment efficacy in patients with different types of tumors receiving platinum-based treatments. The purpose of this study is to correlate ERCC1 gene polymorphism and protein expression by immunohistochemistry (ICH) with recurrence free survival (RFS) and overall survival (OS) in locally advanced cervical squamous cell carcinoma patients who have undergone cisplatin-based concurrent chemoradiotherapy (CRT).
Methods: Sixty-six patients with locally advanced cervical squamous cell carcinoma treated with radical CRT from a cooperative group were evaluated. This group studied the polymorphism that causes a single nucleotide change C to T at codon 118 -becoming AAC on AAT- resulting in a decreased ERCC1 gene expression carrying a loss of DNA repair activity, using quantitative real-time PCR in blood samples. ERCC1 protein expression was determined in pre-treatment tumor tissues by IHC. The association of ERCC1 status with clinicopathological characteristics (age, hemoglobin, grade, FIGO stage) and treatment outcome were analyzed.
Results: Thirty-three patients (50%) were homozygous for AAC codon (C/C genotype), 17 (26%) were homozygous for AAT codon (T/T genotype), and 16 (24%) were heterozygous (C/T genotype). Thirty-eight percent of patients were ERCC1 negative or low expression by IHC, whereas 62% were positive. There was a significant association of C/C genotype and positive ERCC1 by IHC (p 0.003). No significant correlation between ERCC1 expression, codon 118 polymorphism and clinicopathological characteristics was observed. No difference was observed between C/C or non C/C genotypes in terms of RFS or OS. Positive ERCC1 expression by IHC was related to worse RFS (p 0.04).
Conclusions: C/C genotype was associated to high expression of the protein but without impact on RFS or OS. ERCC1 expression by IHC has been shown to be a biomarker for RFS in cervical squamous cell carcinoma patients treated with CRT.
No conflict of interest.

3096 POSTER

Elevated platelet count as a marker of aggressive disease in patients with ovarian cancer

S. Gupta[1], S. Pathak[2], A. Mangla[2], C. Nolasco[2], T. Lad[1]. [1]*John H Stroger Jr Hospital of Cook County, Hematology-Oncology, Chicago IL, USA;* [2]*John H Stroger Jr Hospital of Cook County, Medicine, Chicago IL, USA*

Background: Ovarian cancer is the leading cause of death from gynecological cancers in the United States. Over 70% of patients present with advanced disease. Cho et al showed that the proliferation of ovarian cancer cells increased significantly upon coincubation with platelets (Blood 2012;120:4869). The same investigators, alongside the laboratory analysis, also reviewed epithelial ovarian cancer patients from four cancer centers and found that increased platelet count was associated with a worse overall survival. However the study had 92% patients with advanced stage III/IV disease with 97% high grade tumors suggesting a more sicker and hence, skewed patient population (NEJM 2012;366:610). We undertook this study to see the effect of thrombocytosis on our ovarian cancer patient population in a public hospital setting.

Methods: All patients with a diagnosis of ovarian cancer from January 2006 to December 2011 were identified from the tumor registry of our hospital. All charts were retrospectively screened for histologic identification of the epithelial origin of the tumor, platelet count at diagnosis (before any surgical procedure), age at diagnosis, tumor grade, FIGO stage and survival at one year. Patients with non-epithelial histology, iron deficiency, other inflammatory disorders, known platelet disorder and ones with incomplete records were excluded. Statistical analysis was done using the relative risk calculator and student t-test.
Results: A total of 188 patients were screened of which 136 met the inclusion criteria. The ethnic mix was 32% african-americans, 23% hispanics, 33% caucasians and 12% asians. Stage III/IV disease was seen in 71% of all patients. Fifty-eight patients had elevated platelet counts at diagnosis (Group A) and 78 had normal platelet counts (Group B). The average age was 53 years for both groups. High grade 3 tumors were seen in 44 of 50 patients (88%) in group A compared to 37 of 60 patients (62%) in group B ($p < 0.001$) with low grade 1 tumors seen in only 3 (6%) group A and 12 (20%) group B patients. Stage III/IV disease was seen in 53 (91%) patients in group A compared to 44 (56%) in group B ($p < 0.001$). Only 3 (5%) patients had stage I cancer in group A compared to 27 (35%) in group B. At one year only 75% patients were alive in group A compared to 96% in group B ($p = 0.003$, CI 0.67–0.92).
Conclusion: Our data from a non-referral public hospital confirms that an elevated platelet count at diagnosis in patients with ovarian cancer is associated with a higher grade and higher stage of the cancer and a significantly worse one-year survival.
No conflict of interest.

Treatment with the trifunctional antibody catumaxomab followed by systemic chemotherapy: Results of a subgroup analysis from a phase III study in patients with relapsed ovarian cancer and malignant ascites

R. Chekerov[1], P. Wimberger[2], I. Vergote[3], A. Schneeweiss[4], G. Scambia[5], N. Colombo[6], J.P. Guastalla[7], F. Lordick[8], E. Schulze[9], J. Sehouli[1].
[1]Charité University Hospital, Department of Gynecology, Berlin, Germany; [2]Technical University Dresden, University Cancer Center Dresden, Dresden, Germany; [3]University Hospitals Leuven, Obstetrics and Gynecology, Leuven, Belgium; [4]University Hospital Heidelberg, National Center for Tumor Diseases, Heidelberg, Germany; [5]Catholic University of the Sacred Heart, Gynecology and Obstetrics, Rome, Italy; [6]European Institute of Oncology, Medical Gynecologic Oncology, Milan, Italy; [7]Centre Léon Bérard, Internal Medicine, Lyon, France; [8]University Cancer Center Leipzig, Leipzig, Germany; [9]Fresenius Biotech GmbH, Munich, Germany

Background: Malignant ascites (MA) can compromise quality of life in patients with relapsed ovarian cancer (OC). The trifunctional antibody catumaxomab has been approved for intraperitoneal (ip) treatment of patients with MA due to EpCAM-positive carcinomas where standard therapy is not available or no longer feasible. The safety and efficacy of catumaxomab in MA patients was confirmed in a 2nd phase III trial (CASIMAS, NCT00822809) comparing a 3-h ip infusion with and without prednisolone premedication (Sehouli, ESMO 2012). In order to investigate the value of catumaxomab in the entire treatment algorithm of ovarian cancer, a subgroup analysis was performed on OC patients with regard to subsequent chemotherapy after treatment with catumaxomab (post-catumaxomab CTX).
Materials and Methods: OC patients in both treatment arms were pooled. The efficacy parameters time to next puncture (TTPu), puncture-free survival (PuFS) and overall survival (OS) were evaluated in relation to post-catumaxomab CTX.
Results: 42/109 (39%) patients with MA due to OC received post-catumaxomab CTX, which included a platinum-containing regimen in 19 patients (17%). 21/109 (19%) received >1 post-catumaxomab CTX regimens. Patients with any post-catumaxomab CTX compared with those without CTX had significantly prolonged OS (median 273 vs 81 d, HR 0.24, $p < 0.0001$) and PuFS (median 138 vs 43 d, HR 0.46, $p = 0.0002$). The difference in TTPu was not significant (223 vs 110 d, HR 0.68, $p = 0.1788$). Patients with >1 post-catumaxomab CTX compared with 1 post-catumaxomab CTX had significantly prolonged OS (480 vs 167 d, HR 0.20, $p < 0.0001$). The difference between the groups with >1 and 1 post-catumaxomab CTX in PuFS (153 vs 123 d, HR 0.64, $p = 0.1804$) and TTPu (153 vs 169 d, HR 1.52, $p = 0.3600$) was not significant. Patients who received platinum-containing post-catumaxomab CTX had significantly prolonged OS compared with those who received post-catumaxomab CTX without platinum (462 vs 169 d, HR 0.32, $p = 0.0026$). The difference between the groups with and without platinum in PuFS (153 vs 123 d, HR 0.76, $p = 0.4448$) and TTPu (153 vs 229 d, HR 1.68, $p = 0.2373$) was not significant.
Conclusions: The data indicate that patients with MA due to OC who are able to receive CTX after catumaxomab treatment have significantly prolonged OS compared with patients who could not receive CTX. Further trials have been initiated to identify the best patient population to receive catumaxomab followed by subsequent CTX.

3098 POSTER

UK guidance on diagnosis of ovarian cancer: Its impact on services in an acute general hospital

A. Ford[1], O. Marshall[2], S. Crawford[2]. *[1]Airedale General Hospital, Gynaecology, Keighley, United Kingdom; [2]Airedale General Hospital, Medical Oncology, Keighley, United Kingdom*

Introduction: The UK National Institute for Health and Clinical Excellence (NICE) recommended in April 2011 that women with symptoms suggesting epithelial ovarian cancer (EOC) should have measurement of CA125 with ultrasound (U/S) examination of the pelvis for those with values 35 IU/ml or greater. Airedale General Hospital (AGH) provides diagnostic services for gynaecological cancer for about 200,000 people. We have monitored the demand for services and analysed the outcome of patients found to have elevated CA125 values in the year following publication.
Methods: The records of the biochemistry laboratory were scrutinised to identify CA125 measurements requested from primary care. The radiological and clinical pathology records of patients with values exceeding the defined cut-off were futher scrutinised to identify tests done and their outcomes.
Results: There were 486 requests to AGH laboratory for CA125 from primary care November 2010 − April 2011 compared with 1,314 in May–October 2011, an increase of 170%. 117 (8.9%, 95% CI 7.4–10.4%) post-April results were 35 IU/ml or more. Among requests from primary care practices known routinely to refer patients to AGH clinical services we identified 84 patients with elevated CA125 in the first six month period (May-October 2011). Among these, no follow-up test could be identified from hospital imaging records in 7 (8.3%, 2.4–14.2%)) patients. EOC was diagnosed in 7 (8.3%, 3.4–16.4%) cases, CA125 range 144–6645 IU/ML. Other cancers were diagnosed in 5. Nonmalignant pathology was found in 17 and 37 had U/S examinations, 11 of whom had repeat imaging, without an abnormality being identified. Five patients had chronically elevated stable CA125. In the second period (November 2011 to April 2012) there were 34 elevated measurements. One (2.9%, 0.1–15.3%) was not followed up, EOC was diagnosed in 5 (14.7%, 5.0–31.0%) CA125 range 268–2344.7 IU/ml. Other cancer was diagnosed in 5 cases, nonmalignant pathology was found in 16 and 5 had U/S with no abnormality detected. Two cases with chronically elevated CA125 were detected. In the first period 13 EOCs and 9 in the second period were diagnosed by other routes.
Conclusion: Primary care doctors have responded to NICE guidance with increased CA125 measurements. Most elevated values have been followed up. The impact of this on EOC diagnosis is not yet apparent; those that were diagnosed by this route had markedly elevated CA125 values. There were fewer elevated CA125 measurements in the second six months but the number of diagnoses of all types did not change; possibly primary care doctors are getting used to the system. The most common cause of raised CA125 is benign gynaecological pathology. Unexplained elevated CA125 levels will be a clinical dilemma in coming years.
No conflict of interest.

3099 POSTER

Cancer in pregnancy: To treat or not?

E. Walsh[1], G. O'Kane[1], K.A. Cadoo[1], D.M. Graham[1], G. Korpanty[1], D.G. Power[1], D.N. Carney[1]. *[1]Mater Misericordiae University Hospital, Medical Oncology, Dublin, Ireland*

Background: Cancer in pregnancy accounts for ~1 in 1000 pregnancies. Studies show that cytotoxic agents are safe from the second trimester. Long-term follow up has not shown increased malformations or malignancies in children exposed to chemotherapy in utero. There is no evidence of worse outcomes among women diagnosed in pregnancy.
Material and Methods: We retrospectively identified women diagnosed with cancer in pregnancy over a 25-year period. Medical records were reviewed for demographics, diagnosis, gestation, timing of treatment and outcomes. We assessed if all cancers need to be treated in pregnancy or if treatment could be safely deferred to allow normal delivery.
Results: Twenty-five women were diagnosed with cancer in pregnancy and referred to medical oncology.
Of twenty-five women, sixteen (64%) received chemotherapy during pregnancy. These included thirteen cases of breast cancer, one Ewing's

sarcoma, one ovarian cancer and one small cell of cervix. All sixteen women received Doxorubicin/Cyclophosphamide. There were fifteen live births and no abnormalities seen in children who received chemotherapy in utero. At a median follow-up of six years eleven mothers (69%) are disease free and four (25%) have recurrent disease. Of nine mothers who did not receive chemotherapy in pregnancy, seven received chemotherapy immediately post-partum. Six (86%) were diagnosed in early pregnancy (median gestation 13 weeks). There were three cases of Hodgkin's lymphoma, two breast cancers and one ovarian cancer. At a median follow-up of 12 years, all mothers remain disease free. There were no abnormalities seen in these children.

Conclusions: We did not identify any adverse outcomes in mothers or infants exposed to chemotherapy during pregnancy. We identified a cohort of patients that do not need immediate treatment during pregnancy. In selected cases, it is safe and appropriate to delay chemotherapy until delivery of the baby. There were no adverse outcomes to mothers due to delayed treatment and no adverse outcomes to babies not exposed to chemotherapy in utero. A multi-disciplinary team is essential to individualize treatment planning.

No conflict of interest.

Table: Characteristics of 25 patients

Median age (range)	33 (20−42)
Gestation at Dx (range)	14 (6−36)
Tumour type	
Breast	15
Hodgkin's	3
Ovarian	3
Soft Tissue Sarcoma	2
Small Cell Cervix	1

3100 POSTER

The impact of survival on ovarian cancer and non ovarian cancer-specific health care charges during ovarian cancer treatment

B.K. Bellows[1], A. Dahal[1], D. Stenehjem[1], D. Brixner[1]. *[1]University of Utah, Pharmacotherapy Outcomes Research Center, Salt Lake City UT, USA*

Background: Treatment charges typically increase during the last year of life in women with ovarian cancer, but it remains unknown if charges differ between patients who die while receiving treatment compared to those who survive. The objective of this study was to assess the mean charge per patient in those diagnosed with ovarian cancer by survival status.

Materials and Methods: Women $\geqslant$18 years with a diagnosis of ovarian cancer, identified by ICD-9 code (initial diagnosis defined as index date), treated at the Huntsman Cancer institute (HCI) from 2002–2010 were identified using the University of Utah Enterprise Data Warehouse. The HCI Tumor Registry was used to determine stage at diagnosis. Cause and date of death were captured from the Utah Population Database. Ovarian cancer-related (OCR) and non-OCR charges were identified using ICD-9 codes and were assessed from index date until death or the end of the study period. Patients who died were matched to survivors based upon the Kaplan–Meier probability of survival at the time of death or end of the study period. A generalized linear model (GLM) with gamma distribution and log link function was then used to examine charges by survival status, while adjusting for baseline characteristics including stage, demographics, year of diagnosis, cancer treatments, and comorbidities.

Results: A total of 228 matched patients were included in the analysis. When compared to survivors, patients who died were significantly older (mean age: 63 vs. 54, $p < 0.001$) and fewer were white (68% vs. 86%, $p < 0.001$). Additionally, more deceased patients were diagnosed with stage IV disease (40% vs. 19%, $p < 0.005$) and fewer with stage I (8% vs. 18%, $p = 0.03$) than survivors. Mean unadjusted OCR charges ($55,885 vs. $56,832; $p = 0.89$) and non-OCR charges ($84,131 vs. $74,624; $p = 0.49$) were not significantly different between deceased patients and survivors. However, results from the GLM indicated deceased patients had significant increases in mean OCR charges ($18,072; $p = 0.03$) and non-OCR charges ($43,945; $p < 0.001$). Being older and being diagnosed at worse stage were the primary factors driving up the mean OCR charges.

Conclusions: When adjusting for confounders, women with ovarian cancer who died had significantly higher OCR and non-OCR charges. Though cancer stage, comorbidities, and other potential confounders were included in the analysis, patients who died may have had more aggressive disease leading to increased heathcare utilization.

Mean platelet volume could be a prognostic biomarker for monitoring ovarian cancer

G. Demirag[1], Y. Kemal[1], K. Ekiz[2], B. Yilmaz[1], F. Teker[1], I. Yucel[1]. *[1]19 Mayis University Hospital, Medical Oncology, Samsun, Turkey; [2]19 Mayis University Hospital, Internal Medicine, Samsun, Turkey*

Background: Epithelial ovarian cancer (EOC) accounts for 3.6% of all cancers among women all over the world, and is leading cause of death from gynecologic cancer. After initial treatment with debulking surgery and taxane and platinum based chemotheraphy, most patients will relapse; outcomes of patients are still unsatisfactory with a 5-year survival of only %20−40 Recently new studies showed that inflammatory markers and blood cells may have relation with epithelial ovarian cancer. It has been shown that mean platelet volume (MPV) is a sign of inflammation in hepatocellular carcinoma and pancreatic adenocarcinoma; also elevated platelets, neutrophils and lymphocytes or neutrophil to lymphocyte ratio (NLR) and platelet to lymphocyte ratio (PLR) were reported in EOC.

The aim of this study is to determine whether MPV would be a useful inflammatory marker for predicting prognosis and tumor burden in EOC patients.; also to examine the importance of preoperative PLR and NLR in our study subjects.

Material and Methods: We retrospectively investigated 113 EOC patients who underwent surgery at 19 Mayis University Hospital between 2005 and 2012. Patients with hypertension, hematological and renal disease, heart failure, chronic infection, hepatic disorder and other cancer were excluded from the study. Complete blood count data were collected before and after surgery from recorded computerized database.

Results: Preoperative MPV levels were significantly higher compared to postoperative values(mean 8.27 ± 0.10 vs 7.61 ± 0.09 $p = 0.000$). But we did not find statistically significant relationship between MPVlevels and TNM stages, grade, OS, PFS and CA125 levels. On the other hand smilar to MPVand CA125, NLR values also significantly decreased after the surgery (mean 3.49 ± 0.18 vs 2.49 ± 0.11 $p = 0.000$). The decrease in PLR values were statistically nonsignificant ($p = 0.06$).

Conclusions: Our data suggests that MPV could be a promising and easily available biomarker for the diagnosis and monitoring of EOC patients at low-cost compared with other modalities.

3102 POSTER

Malignant transformation of ovarian mature cystic teratoma

F. Elomrani[1], I. Ouziane[1], R. Khmamouch[1], Y. Bensouda[1], S. Boutayeb[1], H. Mrabti[1], H. Errihani[1]. *[1]National Institute of Oncology, Medical Oncology, Rabat, Morocco*

Background: Mature cystic teratoma MCT is not a rare occurrence, accounting for about 20% of ovarian tumors, but malignant transformation of MCT is infrequent, the risk of transformation is estimated to be between 0.17−2%.

Material and Methods: The objective of this study is to determine clinicopathologic factors affecting survival in this rare tumor. From January 2000 to December 2009, 03 patients with malignant transformation arising in ovarian MCT were treated at department of pediatric surgery, and national institute of oncology in Rabat. Symptoms, signs, stage, mode of therapy, and results of follow-up were reviewed retrospectively.

Results: There were 03 cases of the malignant transformation of ovarian MCT out of 34 cases of MCT. Their ages were 47, 35 and 60 years. Histologically, 2 cases were squamous cell carcinoma and one adenocarcinoma. Abdominal pain and palpable abdominal mass were the most frequent complaint. As for the stage of disease, 2 cases were in stage IA, and the other was in stage IIIC. All the patients had surgery, and adjuvant chemotherapy. 2 patients in stage IA survived until the period of follow-up median of 74 months. Patient in stage IIIC died 4 months from the surgery.

Conclusions: We reported in our experience supports the use of radical surgery and adjuvant chemotherapy, but the prognosis of MCT is highly dependent on age, stage, and optimal treatment.

No conflict of interest.

Very accelerated radiotherapy or chemoradiotherapy for N3 head and neck squamous cell carcinoma: Pooled analysis of two GORTEC randomized trials

Y. Tao[1], A. Aupérin[2], P. Graff[3], M. Lapeyre[4], V. Grégoire[5], P. Maingon[6], G. Calais[7], B. Gery[8], C. Sire[9], J. Bourhis[10]. *[1]Institut Gustave Roussy, Radiotherapy, Villejuif, France; [2]Institut Gustave Roussy, Statistics, Villejuif, France; [3]Centre Alexis Vautrin, Radiotherapy, Nancy, France; [4]Centre Jean Perrin, Radiotherapy, Clermont-Ferrand, France; [5]Université Catholique de Louvain, Radiotherapy, Bruxelles, Belgium; [6]Centre F. Leclerc, Radiotherapy, Dijon, France; [7]CHU Bretonneau, Radiotherapy, Tours, France; [8]Centre F Baclesse, Radiotherapy, Caen, France; [9]Centre Hospitalier de Lorient, Radiotherapy, Lorient, France; [10]Centre Hospitalier Universitaire Vaudois, Radiotherapy, Lausanne, Switzerland*

Background: The optimal management of inoperable N3 head and neck squamous cell carcinoma (HNSCC) remains controversial. The outcome of patients treated with very accelerated radiotherapy (VART) or different schedules of concomitant chemoradiotherapy (CRT) within two phase III trials was analyzed.
Materials and Methods: Data of 179 patients with N3 HNSCC from two randomized trials (GORTEC 96−01 and GORTEC 99−02) were pooled. Patients received either VART: 64.8 Gy in 3.5 weeks (1.8−2 Gy BID) or one of the 3 following CRT regimens: 1) Conventional CRT: 70 Gy in 7 weeks + 3 cycles of 4 days of carboplatin−5FU; 2) Moderately accelerated CRT: 70 Gy in 6 weeks + 2 cycles of 5 days of carboplatin−5FU; 3) Strongly accelerated CRT: 64 Gy in 5 weeks + cisplatin (days 2, 16, 30) and 5FU (days 1−5, 29−33) followed by 2 cycles of adjuvant cisplatin−5FU. Analyses were performed using Cox models stratified for trial.
Results: Median follow-up was 13.3 and 5.2 years for GORTEC 96−01 and GORTEC 99−02, respectively. Overall survival (OS) at five years was 13.8%. No significant difference was observed between CRT versus VART in terms of OS (hazard ratio (HR): 0.93, 95% confidence interval: 0.67–1.29, $p = 0.68$), locoregional progression (HR: 0.70, 0.44–1.11, $p = 0.13$), or distant progression (HR: 0.86, 0.53–1.39, $p = 0.53$). OS was worse for patients with T3−4 tumors versus early T stage (11.0% versus 25.7%, HR: 1.66, 1.11–2.50, $p = 0.015$) and those with initial performance status WHO $\geqslant 1$ versus 0 (10.1% versus 16.9%, HR: 1.49, 1.06–2.10, $p = 0.023$). The oropharyngeal primary site was associated with higher risk of distant metastasis (77.4% versus 28.7%, HR: 3.24, 1.83–5.74, $p < 0.0001$).
Conclusions: The outcome of N3 HNSCC remains poor despite recent efforts for treatment intensification and without difference between CRT and VART. Early T stage patients with good performance status could benefit from further investigation. Different treatment strategies are probably needed for oropharyngeal cancer compared with others sites.
No conflict of interest.

Association of XPF and HPV among squamous cell head and neck cancer tumors: Biomarker analysis of ECOG 3303

R. Mehra[1], J.W. Lee[2], A.M. Egloff[3], D.H. Yang[4], J.R. Grandis[3], B.A. Burtness[5], C.J. Langer[6], A.A. Forastiere[7]. *[1]Fox Chase Cancer Center, Medical Oncology Developmental Therapeutics, Philadelphia PA, USA; [2]Dana-Farber Cancer Institute, Biostatistics, Boston, USA; [3]University of Pittsburgh, Head and Neck Cancer Program, Pittsburgh, USA; [4]Fox Chase Cancer Center, Biosample Repository, Philadelphia, USA; [5]Fox Chase Cancer Center, Medical Oncology Developmental Therapeutics, Philadelphia, USA; [6]University of Pennsylvania, Hematology/Oncology, Philadelphia, USA; [7]Johns Hopkins, Medical Oncology, Baltimore, USA*

Background: In locally advanced head and neck cancer (LA-SCCHN) HPV+ tumors have a better prognosis than HPV−. An understanding of treatment resistance is required, especially for HPV− LA-SCCHN. XPF and ERCC1, components of nucleotide excision repair, are potential biomarkers of cisplatin (C)/radiation (RT) resistance. E3303 is a phase II trial to study the safety and efficacy of RT, C and cetuximab (C225) for LA-SCCHN.
Materials and Methods: Archival pre-treatment tissues were obtained and HPV16 DNA was detected by in situ hybridization (Dako GenPoint). For immunofluorescent IHC analysis, sections were incubated with XPF ab (1:100, ab 17798, Abcam), ERCC1 ab (1:5000 HPA0297731, Sigma) and a wide-spectrum rabbit cytokeratin ab (Dako Z0622) to create tumor mask. Prolong Gold mounting medium (P36931; Molecular Probes) containing 4,6-Diamidino-2-phenylindole (DAPI) defined nuclear staining. Staining intensity was measured using HistoRx PM-2000 image analysis, with AQUA algorithms. Data were analyzed based on the median cut point for nuclear staining of XPF, and quartiles for ERCC1. Time-to-event distributions were estimated by the Kaplan–Meier method and compared using the log-rank test. Cox's proportional hazards models were used to estimate hazard ratios (HR) and test for significance for overall survival (OS) and progression free survival (PFS). All p-values were two-sided with type I error rate at 0.05.
Results: Analysis of XPF, ERCC1 and HPV was conducted in 31, 32 and 29 of 69 patients. Median XPF AQUA score was 159.9 (58–660); ERCC1 was 930.5 (101.7–3557). Incidence of XPF/HPV: HPV+/XPF high (H) = 2, HPV+/XPF low (L) = 7, HPV−/XPF H = 14, HPV−/XPF L = 3. Thus, HPV+ tumors were more likely to be XPF L ($p = 0.01$); a 2-way interaction between HPV and XPF in PFS was noted ($p = 0.0597$), but not with HPV and ERCC1. XPF was not a predictor for PFS after controlling for sex, race, ECOG performance status, weight loss (<5% vs. $\geqslant$5%), primary site (oropharynx vs. non-oropharynx), smoking, and HPV (HR (L vs. H)=2.71, 95% CI=(0.39, 18.96), $p = 0.31$). For HPV− median PFS was 15.7 months (m) (XPF H) vs. 7.7 m (XPF L). For HPV+, the 25th percentile PFS was 15.3 m (XPF L)(95% CI=(11.4, NR) and 11.1 m (XPF H) (95% CI=(11.1, NR).
Conclusions: Among LA-SCCHN treated with C/C225/RT, HPV+ disease is more likely to be XPF L; this subgroup has an improved PFS. Future research should further study DNA repair mechanisms and treatment resistance in HPV− SCCHN.
No conflict of interest.

A cancer specific enteral nutrition formula improves nutritional status and functional performance in patients with head and neck cancer undergoing chemoradiotherapy

R. Fietkau[1], V. Lewitzki[2], T. Kuhnt[2], T. Hölscher[3], B. Berger[4], T. Wiegel[5], C. Rödel[6], M. Niewald[7], R.M. Hermann[8], D. Lubgan[1]. *[1]University Hospital Erlangen, Department of Radiation Oncology, Erlangen, Germany; [2]University Hospital Rostock, Department of Radiotherapy, Rostock, Germany; [3]University Hospital Carl Gustav Carus, Department of Radiotherapy and Radiooncology, Dresden, Germany; [4]University Hospital Tübingen, Department of Radiooncology, Tübingen, Germany; [5]University Hospital Ulm, Department of Radiotherapy and Radiooncology, Ulm, Germany; [6]University Hospital Goethe University Frankfurt, Department of Radiotherapy and Oncology, Frankfurt/Main, Germany; [7]Saarland University Medical Center, Department of Radiotherapy and Radiooncology, Homburg/Saar, Germany; [8]Medical Department Georg-August University Göttingen and Centre for Radiotherapy and Radiooncology Westerstede, Department of Radiotherapy and Radiooncology Göttingen and Centre for Radiotherapy and Radiooncology Westerstede, Göttingen Westerstede, Germany*

Background: The aim of this study was to investigate the influence of cancer-specific enteral nutrition (EN) high in fat, protein, eicosapentaenoic- (EPA) and docosahexaenoic acid (DHA) from fish oil on body composition, nutritional and functional status in head and neck (H&N) cancer patients undergoing chemoradiotherapy (CRT).
Material and Methods: Subgroup analysis restricted to patients with H&N cancer (n = 102), derived from a larger prospective, randomized, controlled, double-blind, multicenter study (NCT01025167) of oesophageal- (n = 9) and H&N cancer (n = 102) recruited from ten radiooncological centers in Germany. Patients either received standard EN (control group, n = 51) or metabolically adapted, cancer-specific EN (Supportan®) high in fat, protein, EPA + DHA, low in carbohydrates (experimental group, n = 51) via percutaneous endoscopic gastrostomy (PEG) for $\leqslant$14 weeks. Primary endpoint was the change in body cell mass (BCM) directly following CRT (week 7) and after follow-up (week 14) as compared to the baseline value. Secondary endpoints included additional parameters of body composition, anthropometric parameters, nutritional status (Kondrup Score, Subjective Global Assessment (SGA)) and functional status, inflammation (TNF-α, IL-6) and quality of life.
Results: Patients receiving experimental nutrition lost only -0.75 ± 0.64 kg BCM, compared to -2.82 ± 0.73 kg BCM in the control group ($p = 0.0407$) after follow-up. For objectively measured parameters of nutritional status, such as body weight, BMI, fat-free mass, and skinfold thickness, a tendency towards smaller decreases during the study period was observed in the experimental vs. control group. In the experimental group the Kondrup score of impaired nutritional status (-0.47 ± 0.15 vs. 0.02 ± 0.16; $p = 0.0320$) and overall SGA-rating ($p = 0.0145$) improved significantly at follow-up.
A significant difference ($p = 0.0227$) between the trial groups was observed in the Karnofsky index due to higher improvement rates in the experimental group after CRT. The significantly attenuated increase in IL-6 after CRT in the experimental group compared to the control group (5.29 ± 3.74 vs. 17.33 ± 4.08 pg/mL; $p = 0.0338$) suggests an anti-inflammatory effect of Supportan®.
Conclusions: Cancer-specific enteral nutrition high in fat, protein, EPA and DHA may be advantageous in patients with H&N cancer by reducing losses

in BCM and counteracting the deterioration of parameters of nutritional and functional status during and following CRT.
No conflict of interest.

Progressive, metastatic medullary thyroid cancer: Baseline symptoms and disease characteristics among patients enrolled in the EXAM trial

P. Schöffski[1], E. Cohen[2], F. Bentzien[3], S. Sherman[4]. *[1]University Hospitals Leuven, Experimental Oncology Department of Oncology, Leuven, Belgium; [2]University of Chicago, Chicago, USA; [3]Exelixis Inc, South San Francisco, USA; [4]University of Texas, MD Anderson Cancer Center, Houston, USA*

Background: The symptomatology and disease burden in patients with progressive, metastatic medullary thyroid cancer (MTC) are not well characterized. Patients in the EXAM trial (NCT00704730) placebo arm had short median progression-free survival (4.0 months). Therefore, we analyzed the baseline characteristics of all patients enrolled in the EXAM trial to define the study population and characterize the disease burden and symptomatology in patients with progressive MTC as a reference for future clinical research.
Material and Methods: In the EXAM trial, 330 patients with MTC and radiographic evidence of disease progression ($\leqslant$14 months between reference and screening scans) by mRECIST were randomized to cabozantinib or placebo. Patient baseline symptoms (CTCAE v3.0) and disease characteristics were collected and analyzed descriptively.
Results: At baseline, 312 (94.6%) patients had measurable disease (independent radiology review); most (87.0%) had metastatic disease at $\geqslant$2 sites/organs, including lymph nodes (79.1%), liver (66.4%), lungs (54.5%), and bone (50.9%). Median age was 55 years (20−86), mean bodyweight was 73.4 kg ($\pm$18.5), 67.0% were male, 89.4% were white, and 92.4% were thyroidectomized. The median interval between the initial diagnosis of MTC and randomization was 3.9 years (0.07–48.4), and the median interval between diagnosis of metastatic disease and randomization was 2.0 years (0.04–33.7). Overall, 39% of patients had prior systemic anticancer therapy and 20.6% had prior tyrosine kinase inhibitor therapy (10.3% vandetanib). The most frequent patient-reported baseline symptoms were mainly grades 1 or 2 and included pain 46.1% (54% grade 1, 38% grade 2, 5% grade 3, <1% grade 4), diarrhea 39.7% (63% grade 1, 28% grade 2, 5% grade 3), fatigue 25.8% (79% grade 1, 17% grade 2), dysphonia 23% (73% grade 1, 5% grade 2, 1% grade 3), dyspnea 16.1% (70% grade 1, 17% grade 2, 2% grade 3), cough 12.1% (78% grade 1, 15% grade 2), dysphagia 9.1% (80% grade 1, 10% grade 2, 3% grade 3), anorexia 7% (78% grade 1, 9% grade 2, 9% grade 3), weight loss 5.5% (50% grade 1, 33% grade 2, 6% grade 3), and flushing 4.2% (86% grade 1, 14% grade 2).
Conclusions: MTC is often considered an indolent disease. However, our baseline data indicate that patients with radiographic evidence of progressive MTC have a substantial disease burden and high incidence of disease-related symptoms.

Association between tumor BRAF and RAS mutation status and clinical outcomes in patients with radioactive iodine (RAI)-refractory differentiated thyroid cancer (DTC) randomized to sorafenib or placebo: sub-analysis of the phase III DECISION trial

M.S. Brose[1], C. Nutting[2], Y.K. Shong[3], S.I. Sherman[4], J.W.A. Smit[5], J. Chung[6], I. Molnar[6], M. Jeffers[7], C. Pena[8], M. Schlumberger[9]. *[1]Abramson Cancer Center of the University of Pennsylvania, Department of Medicine Division of Hematology/Oncology, Philadelphia PA, USA; [2]Royal Marsden Hospital and The Institute of Cancer Research, Clinical Oncology, London, United Kingdom; [3]Asan Medical Center and University of Ulsan College of Medicine, Department of Internal Medicine, Seoul, Korea; [4]MD Anderson Cancer Center, Department of Endocrine Neoplasia & Hormonal Disorders, Houston TX, USA; [5]Radboud University Nijmegen Medical Center, Department of Medicine Division of Endocrinology, Nijmegen, Netherlands; [6]Bayer HealthCare Pharmaceuticals, Global Clinical Development, Montville NJ, USA; [7]Bayer HealthCare Pharmaceuticals, Clinical Sciences, Montville NJ, USA; [8]Bayer HealthCare Pharmaceuticals, Clinical Biomarkers, Montville NJ, USA; [9]Institut Gustave-Roussy, Nuclear Medicine and Endocrine Oncology, Villejuif, France*

Background: We recently reported that treatment of RAI-refractory DTC patients with sorafenib reduced the risk of progression or death by 42% compared to placebo in the randomized, phase III trial DECISION. A number of genetic abnormalities have been implicated in the etiology of DTCs. We examined BRAF and RAS mutations as possible prognostic biomarkers and as predictors of sorafenib efficacy in RAI-refractory DTC patients.
Methods: In DECISION, patients with locally advanced/metastatic RAI-refractory DTC progressing in the preceding 14 months were randomized 1:1 to sorafenib 400 mg bid po or placebo. Placebo patients were allowed to receive sorafenib upon progression. Archived tumor samples were analyzed for 238 mutations in 19 common oncogenes (Sequenom OncoCarta 1.0).
Results: Tumor mutation data was available from 256 patients (61.4% of the study population); 126 in sorafenib arm and 130 in the placebo arm. Demographics of the genetic subgroup were similar to the overall study population. BRAF and RAS mutations were detected in 30.1% and 19.5% of patients, respectively, and were well balanced across arms. Other point mutations occurred in less than 5% of patients, with 47.3% of patients having no detectable mutations. Placebo patients with mutant (m) RAS tumors had worse PFS outcomes vs wild-type (wt) RAS (HR = 1.78, p = 0.03), whereas placebo patients with mBRAF tumors had better PFS outcomes vs wtBRAF (HR = 0.53, p = 0.01); no significant difference in OS was observed with either mutation. Both wtBRAF (n = 92) and mutant (n = 34) patients treated with sorafenib had improved PFS vs placebo (n = 87 and 43, respectively) (wtBRAF: HR = 0.54, p < 0.001; mBRAF: HR = 0.47, p = 0.02; interaction p-value=0.68). Similarly, sorafenib-treated patients benefited independently of RAS mutation status in terms of PFS prolongation (wtRAS: sorafenib n = 102, placebo n = 104, HR = 0.60, p = 0.004; mRAS: sorafenib n = 24, placebo n = 26, HR = 0.45, p = 0.037; interaction p-value=0.39). Although the number of events were small, mBRAF patients treated with sorafenib appeared to have a better OS compared to placebo (HR = 0.32, p = 0.03). No difference in OS was seen with regards to RAS mutation status.
Conclusion: These exploratory analyses suggest that mutant RAS and mutant BRAF were negative and positive prognostic factors, respectively, for PFS in RAI-refractory DTC patients and that patients benefited from sorafenib treatment in terms of PFS prolongation independent of BRAF and RAS mutation status.

Head and Neck Cancer

3156 POSTER

Biomarkers of radioresistance in head and neck squamous cell carcinoma and their relation to cancer stem cell

I. Kurth[1], C. Peitzsch[2], L. Hein[2], V. Lukiyanchuk[2], M. Baumann[3], A. Dubrovska[2]. *[1]Oncoray, Dresden, Germany; [2]Oncoray, Biomarker for Individualized Therapy, Dresden, Germany; [3]Oncoray, Department of Radiotherapy, Dresden, Germany*

The development and growth of a tumor have been attributed to the existence of cancer stem cells (CSCs), or tumor progenitor cells, which have been discovered for many types of cancer including head and neck squamous cell carcinoma (HNSCC). Radiotherapy plays a key role in the management of head and neck squamous-cell carcinomas (HNSCC). The evidence continues to accumulate that current anti-cancer therapy fail to achieve long-lasting cancer cures because they do not eliminate CSCs, which are protected by multiple intrinsic and extrinsic mechanisms. The number of CSCs and their radiosensitivity vary between tumors, which affects their radiocurability. Therefore, the objective of this study is the investigation of novel HNSCC CSC-related biomarkers to benefit individualized radiotherapy.
In a first step we created radioresistant cancer cell lines, which have been exposed to minimum 40 Gy given in small clinically relevant fractions of 2 or 4 Gy. Their radioresistance was verified in radiobiological 3D in vitro assays in comparison to the non-irradiated parental cell lines. Comparative analysis of stem cell marker expression and assessment of in vivo tumor growth were performed in order to elucidate putative CSC-related biomarkers, which expression correlates with cell radioresistance. Next, we used the aldehyde dehydrogenase (ALDH) activity as an already

known cancer- and stem cell feature to ascertain its role in the development of radioresistance. For this purpose, we investigated and characterized the ALDH positive and ALDH negative populations within the above mentioned radioresistant and non-irradiated cancer cells.
Our study suggests a highly dynamic regulation of the stem cell marker expression after irradiation stress. Irradiation of cancer cells increased the tumor progenitor populations that can be defined by classical stem cell markers including ALDH activity, CXCR4, CD133, ABCG2, and led to activation of PI3K/AKT and epithelial–mesenchymal transition (EMT) signaling pathways, which were increased with increasing number of radiation fractions. Analysis of radiation-induced DNA double-strand breaks using immune fluorescent staining of γH2AX revealed an initial quick DNA damage response to irradiation in ALDH positive cell population as compared to negative or total population. Moreover, our in vivo studies suggest that high ALDH activity defines tumorigenic and radioresistant cell subsets only within the parental non-irradiated cell lines.
Our studies revealed ALDH activity is indicative of HNSCC progenitor cells with increased radioresistance. Our finding suggests that radioresistant properties of cancer progenitor population may be dynamic in nature and can be differently employed throughout the course of radiotherapy. Thus, different therapeutic strategies and different predictive biomarkers may be required at the different stage of tumor treatment.
No conflict of interest.

3157 POSTER

Association of MSH2 IVS1+9G>C and EXO1 K589E polymorphisms with inherited risk of head and neck squamous cells carcinoma

G.A.S. Nogueira[1], T.R.P. Lima[1], E.F.D. Costa[1], L. Lopes-Aguiar[1], C.M.B. Oliveira[1], G.J. Lourenço[1], C.S.P. Lima[1]. *[1]University of Campinas, Faculty of Medical Sciences, Campinas São Paulo, Brazil*

Background: The MSH2 and EXO1 are fundamental proteins involved in mismatch repair (MMR) system that contribute to DNA stability. The proteins are encoded by the polymorphic *MSH2* and *EXO1* genes. The C and A variant alleles of the *MSH2* IVS1+9G>C and *EXO1* K598E polymorphisms promote lower DNA repair than the respective G and G wild alleles, and seems to be involved on the onset of cancer. Since the roles of the above-mentioned polymorphisms in the risk of head and neck squamous cells carcinoma (HNSCC) are unclear, we aimed to analyze this issue in the present study.
Materials and Methods: Genomic DNA of 212 HNSCC patients and 212 controls was analyzed by the polymerase chain reaction and enzymatic digestion. The differences between groups were analyzed by the logistic regression model. Power analysis (PA) was used to verify the effect of sample size on the results obtained in the study.
Results: Patient's and control's samples were in Hardy–Weinberg equilibrium for *MSH2* (χ2= 0.81, P = 0.37; χ2= 2.11, P= 0.15) and *EXO1* (χ2= 0.02, P = 0.88; χ2= 1.89, P = 0.17) loci. The frequency of *MSH2*GC+CC combined genotype was higher in patients than in controls (83.5% *versus* 66.0%, P = 0.012, PA= 92%). Carriers of the C variant allele were at 2.10-fold (95% CI: 1.18–3.74) increased risk for HNSCC development than those with the wild genotype. An excess of the *EXO1*AA genotype was seen in patients when compared to controls (15.5% *versus* 9.0%, P= 0.028, PA= 88%). Individuals with the homozygous variant genotype were at 2.47-fold (95% CI: 1.10–5.53) increased risk for HNSCC than those with the remaining genotypes. Moreover, the frequency of *MSH2*GC+CC + *EXO1*GA+AA combined genotype was higher in patients than in controls (50.9% *versus* 35.4%, P = 0.037; PA>99.0%). Carriers of the variant alleles of the above-mentioned genes, when combined, were at 2.78-fold (95% CI: 1.06–7.26) increased risk for HNSCC than those with the respective wild genotypes. Similar frequencies of the distinct genotypes of the *MSH2* IVS1+9G>C and *EXO1* K598E polymorphisms were seen in patients stratified by clinical aspects and tumor biological features.
Conclusion: Our results suggest, for the first time, that *MSH2* and *EXO1* polymorphisms alone or combined, are important inherited risk factor for HNSCC. We believe that healthy carriers of variant alleles of both genes deserve additional recommendations for disease prevention and early diagnosis.
No conflict of interest.

Mesenchymal phenotype is associated with increased cell migration and cisplatin resistance in head and neck squamous cell carcinoma cell lines

M. Téllez-Gabriel[1], L.C. Navas[1], X. León[2], A. López-Pousa[3], M. Quer[4], A. Barnadas[5], R. Mangues[1], M.A. Pavon[1]. *[1]Institut d' Investigacions Biomèdiques Sant Pau (IIB-Sant Pau)/Centro de Investigación Biomédica en red de Bioingenieria Biomateriales y Biomedicina (CIBER-BBN), Grupo de Oncogénesis i Antitumorales (GOA), Barcelona, Spain; [2]Institut d' Investigacions Biomèdiques Sant Pau (IIB-Sant Pau)/Centro de Investigación Biomédica en red de Bioingenieria Biomateriales y Biomedicina (CIBER-BBN), Department of Otorhinolaringology, Barcelona, Spain; [3]Institut d' Investigacions Biomèdiques Sant Pau (IIB-Sant Pau)/Centro de Investigación Biomédica en red de Bioingenieria Biomateriales y Biomedicina (CIBER-BBN), Department of Medical Oncology, Barcelona, Spain; [4]Institut d' Investigacions Biomèdiques Sant Pau (IIB-Sant Pau), Department of Otorhinolaringology, Barcelona, Spain; [5]Institut d' Investigacions Biomèdiques Sant Pau (IIB-Sant Pau), Department of Medical Oncology, Barcelona, Spain*

Background: We previously identified three head and neck squamous cell carcinoma (HNSCC) subtypes which were significantly associated with patient clinical outcome. The poor prognosis subtype presented mesenchymal features indicative of having undergone epithelial–mesenchymal transition (EMT). The purpose of this study is to study the relationship between the mesenchymal phenotype and response to cisplatin or cell migration in HNSCC cell lines.
Methods: We determined E-cadherin, N-cadherin and Vimentin protein expression in six HNSCC cells lines. We determined cisplatin sensitivity by XTT assays. For the migration assays, cells were deprived of FBS (12 h.), incubated in 24-well transwell plates (48 h.) and stained with crystal violet. We analyzed the gene expression profile of the cell lines using the HG-U133Plus2.0 array. Gene expression analysis was performed using Bioconductor. Probe sets with a FDR value lower than 0.05 were identified as differentially expressed.
Results: We identified two different morphologies and patterns of growth in HNSCC cell lines. UM-SCC-74B and SCC9 showed a fibroblast-like morphology and scattered growth, while UM-SCC-22A, UM-SCC-22B, SCC25 and Fadu grew forming cell colonies and depicted epithelial features. Western Blot and immunocytochemistry analysis showed a high Vimentin and N-Cadherin expression in UM-SCC-74B and SCC9. In addition, these two cell lines did not express E-Cadherin. This expression pattern was consistent with EMT. In contrast, UM-SCC22A and UM-SCC22B cell lines maintained E-Cadherin expression. Fadu and SCC25 expressed both epithelial and mesenchymal markers. We identified 93 genes differentially expressed by comparing the expression profiles between cells with mesenchymal and those with epithelial phenotype. Genes differentially expressed were associated with EMT (VIM, ZEB2, FGFR2 and FGFBP1), cell polarization (DAAM1), the secretory pathway (Rab38 and SRGN1) and differentiation (SPRR1A, SPRR3, SPRR1B, KRT6, S100A8 and S100A9). The cell lines with mesenchymal phenotype showed higher migration capacity than those with epithelial phenotype. SCC9 showed the highest resistance to 48 h of treatment with cisplatin.
Conclusion: Mesenchymal phenotype was associated with increased cell migration and cisplatin resistance in HNSCC cell lines. This could explain the poor rates of response and high recurrence rates, observed in patients having tumors that display mesenchymal features, after cisplatin-based chemotherapy.
No conflict of interest.

3159 POSTER

Role of IKBB, a NFKB inhibitor, as putative tumour suppressor candidate in nasopharyngeal carcinoma

Y.P. Phoon[1], A.K.L. Cheung[1], M.L. Lung[1]. *[1]University of Hong Kong, Clinical Oncology, Pokfulam, Hong Kong*

Background: Nasopharyngeal carcinoma (NPC), endemic in southern China and Southeast Asia, was ranked 4th as the most common new malignancy in Hong Kong. Inactivation of tumour suppressor genes (TSGs) through the loss of chromosomal regions is frequently reported in NPC, including chromosome 14. NFkB inhibitor, IkBB, a major isoform of inhibitor of kB, is a putative TSG candidate identified by our previous chromosome 14 microarray analyses. To date, the role of IkBB as a TSG is still largely unknown. In this study, we aimed to study the role of IKBB as a putative TSG candidate in NPC.
Material and Methods: Gene expression of IKBB in NPC tumour and matched normal tissue samples was determined by qPCR. Using a tetracycline-inducible system, IkBB-expressing clones were obtained for further phenotype and functional studies. Wound healing and HUVEC tube

formation assays were performed to study the inhibitory effect of IKBB on cell migration and angiogenesis fin NPC cell lines, respectively.
Results: The gene expression level of IkBB is down-regulated in approximately 40% of the NPC patient samples (n = 36), as observed by qPCR analysis. After 24 hours, stable IkBB-expressing clones (−DOX) show <50% of wound closure in average. Similarly, HUVEC tube formation is disrupted by IkBB, as compared to the vector-alone control (+DOX).
Conclusions: Down-regulation of IkBB in the majority of NPC patients indicates that IkBB may play an essential role as a TSG in NPC. Interestingly, our preliminary results on both wound healing and HUVEC tube formation assays demonstrate that IkBB exerts its tumour suppressive functions through inhibition of cell migration, proliferation, and angiogenesis. However, further investigation is warranted for further elucidation of the molecular and biological mechanisms of candidate TSG IkBB in cancer, specifically in NPC.

3160 POSTER

The FASL −844C/T polymorphism is associated with inherited increased risk for head and neck squamous cell cancer

T. Penna Lima[1], G.A.S. Nogueira[1], L. Lopes-Aguiar[1], E.F.D. Costa[1], C.M.B. Oliveira[1], G.J. Lourenço[1], C.S.P. Lima[1]. [1]*State University of Campinas Faculty of Medical Sciences, Faculty of Medical Sciences, Campinas SP, Brazil*

Background: Fas ligand (*FASL*) is a member of the Tumor Necrosis Factor (TNF) super family and acts in cell apoptosis. The extracellular region of *FASL* binds to CD95 (*Fas*) and typically induces apoptosis in activated cells expressing *Fas*. The *FASL* −844C/T polymorphism, in the promoter region of the gene, impairs apoptotic signal transduction and is associated with the onset of tumors. We aimed in this study to analyze the role of the *FASL* −844C/T polymorphism in the head and neck squamous cell cancer (HNSCC) risk.
Material and Methods: Genomic DNA from peripheral blood of 268 consecutive HNSCC patients (aged 27−92 years; 248 males, 20 female, 227 Caucasians, 41 non-Caucasians) and 268 healthy subjects, matched to patients by gender and race, were genotyped using the polymerase chain reaction and enzymatic digestion. The differences between groups were analyzed by the logistic regression model. Power analysis (PA) was used to verify the effect of sample size on the results obtained in the study.
Results: Patients' and controls' samples were in Hardy–Weinberg equilibrium for *FASL* −844C/T ($\chi^2 = 0.031$, $P = 0.860$; $\chi^2 = 3.14$, $P = 0.076$) locus. The frequencies of the *FASL* CT and *FASL* TT genotypes were higher in patients than in controls (48.9% *versus* 44.0%, P = 0.008, PA = 99%, 31.0% *versus* 22.4%, $P = 0.002$, PA = 99%; respectively). Carriers of these genotypes were at a 2.22-fold (95% CI: 1.23–4.04) and 2.74-fold (95% CI: 1.45–5.20) increased risks for HNSCC development than those with the remaining genotypes. The frequency of *FASL* CT+TT combined genotype was also higher in patients than in controls (79.8% *versus* 66.4%, $P = 0.001$, PA = 99%). Carriers of the T variant allele were at a 2.45-fold (95% CI: 1.44–4.18) increased risk for HNSCC than those with the wild genotype. No differences in frequencies of the distinct genotypes were seen in patients stratified by clinical aspects and biological features of the tumor.
Conclusions: Our data suggest, that *FASL* −844C/T polymorphism alter consistently the risk for HNSCC. We believe that healthy carriers of the variant allele of the above-mentioned gene should receive additional recommendation to avoid smoking and alcohol consumption and to adhere to periodic follow-up for HNSCC prevention and early diagnosis.
No conflict of interest.

3161 POSTER

Inherited risk for head and neck squamous cell carcinoma and tumor suppressor gene MCC c.*5077A>G polymorphism

L. Lopes Aguiar[1], E.F.D. Costa[1], G.A.S. Nogueira[1], T.R.P. Lima[1], G.J. Lourenço[1], C.S.P. Lima[1]. [1]*University of Campinas, Faculty of Medical Sciences, Campinas São Paulo, Brazil*

Background: The mutated in colorectal cancer (*MCC*), a tumor suppressor gene, regulates negatively cell cycle progression. The *MCC* c.*5077A>G (rs7033) polymorphism may be related with the onset of tumors, but the role of the distinct alleles in gene expression is still unknown, as well as its role in head and neck (HN) squamous cell carcinoma (SCC). We aimed in this study to investigate whether this polymorphism would be an inherited risk factor for HNSCC.
Material and Methods: Genomic DNA of 150 HNSCC patients (27−85 years; 134 males, 16 females; 133 caucasians, 17 non-caucasians; 109 pharynx, 27 larynx, 14 oral cavity) and 150 controls matched to patients by age, gender and race were analyzed by TaqMan® genotyping assays. Significant differences between groups were evaluated by logistic regression model. Power of analysis (PA) was used to verify the effect of sample size on the results obtained in the study.
Results: HNSCC patient's and control's samples were in Hardy–Weinberg (HW) equilibrium for *MCC* c.*5077A>G locus ($\chi^2 = 3.8$, $P = 0.05$; $\chi^2 = 1.7$, $P = 0.19$). The frequencies of isolated *MCC* AA and combined AA+AG genotypes were higher in patients than in controls (59% *vs* 45%, $P = 0.02$, PA=79%; 98% *vs* 93%, $P = 0.04$, PA=73%; respectively). Carriers of the isolated and combined genotypes had a 1.9-fold (95% CI:1.13–3.25) and a 5.8-fold (95% CI:1.09–31.21) increased risks for HNSCC than others, respectively. The *MCC* AA genotype was also more common in male patients than in female patients (62% *vs* 31%, $P = 0.02$, PA=66%). The frequency of the genotype in male patients was also higher than that found in controls (62% *vs* 45%, $P = 0.001$, PA=98%). Male individuals with *MCC* AA genotype had a 2.6-fold (95% CI:1.45–4.76) increased risk for HNSCC than others. Additionally, the frequency of *MCC* AA genotype was similar in patients with pharynx SCC (PSCC) than in those with other types of HNSCC (61% *vs* 51%, $P = 0.16$, PA=21%). The samples of PSCC patients were in HW disequilibrium for *MCC* c.*5077A>G loci ($\chi^2 = 6.2$, $P = 0.01$). The frequency of the isolated *MCC* AA genotype was also higher in PSCC patients than in controls (61% *vs* 45%, $P = 0.009$, PA=87%). Carriers of the AA genotype had a 2.2-fold (95% CI:1.21–3.88) increased risk for PSCC than others.
Conclusions: Our results suggest, for the first time, that *MCC* polymorphism is an important inherited risk factor for HNSCC. We believe that healthy individuals with *MCC* AA genotype should receive additional care for HNSCC prevention and early diagnosis.
No conflict of interest.

Recurrent genomic alteration and high risk HPV with impact on prognosis in oropharyngeal cancer

D. Sun[1], Y.H. Joo[1], J.O. Park[1], K.J. Cho[1]. [1]*The Catholic University of Korea, Dept of Otolaryngology-HNS, Seoul, Korea*

Objectives: The whole picture of chromosomal alterations in oropharyngeal cancer and their prognostic implications have not been well studied. We aimed to identify chromosomal changes and high risk HPV infection associated with prognosis in oropharyngeal cancers.
Methods: For this purpose, we analyzed copy number alterations in the discovery set of 32 oropharyngeal cancers using oligoarraycomparative genomic hybridization and validated the recurrently altered regions (RARs). High risk HPV in situ hybridization was performed to detect HPV infection.
Results: The positive rate of high risk HPV in situ hybridization was 28.1% (9/32). A total of 10 RARs were defined in the discovery set. Among them, gains on 16p11.2 and 17q12 showed significant associations with high risk HPV infection ($P = 0.019$ and $P = 0.019$, respectively). There was statistical significant association between gains on 16p11.2 and 17q12 with high risk HPV positivity and the disease-specific survival in patients with oropharyngeal cancer (p = 0.001).
Conclusion: Our findings will help to elucidate molecular mechanisms underlying tumorigenesis of oropharyngeal cancer with high risk HPV infection and to develop clinical tool for predicting prognosis of oropharyngeal cancer.
No conflict of interest.

3163 POSTER

Expression of Bmi-1 and ZEB1 in tongue squamous cell carcinoma and epithelial dysplasia

K. Kurihara[1], T. Tachikawa[2], Y. Tanaka[3], A. Katakura[1], A. Katakura[4]. [1]*Tokyo Dental College, Department of Oral Medicine Oral and Maxillofacial Surgery, Chiba, Japan;* [2]*Showa University, Innovative Research of Oral Cancer, Tokyo, Japan;* [3]*Tokyo Dental College Ichikawa General Hospital, Division of Surgical Pathology Clinical Laboratory, Chiba, Japan;* [4]*Tokyo Dental College, Oral Cancer Center, Chiba, Japan*

Background: The Epithelial–mesenchymal transition (EMT), the crucial event for the invasion and progression of epithelial carcinogenesis, induces stem-like properties epithelial cells. However, the relationship between EMT in the carcinogenesis process of squamous cell carcinoma is not reported in most. Expression of Bmi-1 which is the stem cell line marker and ZEB1 which is the EMT inducer were studied on the role in the carcinogenesis process of tongue squamous cell carcinoma using immunohistochemistry.
Material and Methods: Sixty five tongue tissue specimens (33 carcinoma and 32 dysplasia) formed the materials of this study. We compared the expressions of Bmi-1, ZEB1, vimentin, E-cadherin with clinicopathologic parameters.
Result: By the immunohistologic examination, Bmi-1 was highly expressed in tumor cells at the invasive front compared with normal stratified squamous epithelia, demonstrated a significant correlation Between Bmi-1 expression and INF (Kruskal-Wallis H-test, p = 0.024).

Elevated levels of Bmi-1 were accompanied by downreguration of E-cadherin and the expression of vimentin at the invasive front, demonstrated a significant negative correlation between Bmi-1 and E-cadherin expressions (x^2-test, $p = 0.016$). Elevated levels of ZEB1 were found in tumor cells at the invasive front of advanced tongue carcinoma compared with normal stratified squamous epithelia, demonstrated no significant correlation Between ZEB1 and Bmi-1 expression.
Conclusions: As a result of this study, Bmi-1, ZEB1 and E-cadherin fulfilled the role which was important for EMT and invasion in tongue squamous cell carcinoma, and it was indicated to be concerned to various carcinogenesis process.
No conflict of interest.

3164 POSTER

The role of tumor markers and clinico-laboratories result in prognosis of relapse oral squamous cell carcinoma

S.I. Kutukova[1], G.M. Manikhas[1], A.I. Yaremenko[2], S.S. Bozhor[2].
[1]Saint-Petersburg City Oncological Dispensary, Chemotherapy, Saint-Petersburg, Russian Federation; [2]Saint-Petersburg State Medical University, Maxillo-facial Surgery, Saint-Petersburg, Russian Federation

Background: The most common malignancy of the oral cavity is squamous cell carcinoma (SCC). The prognosis of treatment is limited by recurrent disease or lymph node metastasis. Secondary to, chemotherapy, surgery and radiotherapy, anatomical structures are often severely changed and make early diagnosis of renewed tumour growth by clinical and radiological examination difficult. The aim of this study was to estimate prognostic importance of value of serum tumour markers (CEA, SCC-Ag), performances of peripheral blood (WBC, ACN, PLT) characteristics, histological type of the tumour, tumour size in relation to the appearance of lymph node metastases and relapse in oral SCC.
Material and Methods: In the prospective study 133 cases of oral SCC were analysed. They were diagnosed from 2009 to 2011 in City clinical oncology centre, Saint-Petersburg, Russia. All patients were treated by standard protocol: the first phase was 1−3 cycles neoadjuvant chemotherapy (PF regime ± Cetuximab®). In the second phase all patients were conducted the radical surgical treatment. The third phase contained a post-surgery radiotherapy. All patients were examined by standard programs: vital signs, height, weight, BSA, ECOG status, physical examination, ECG, ultrasound examination and standard and special clinical pathology. The standard laboratories tests were WBC, ACN and PLT; the special tests were CEA and SCC-Ag which were detected with enzyme-linked immunosorbent assay (ELISA) and time-resolved fluoroimmunoassay (TRFIA). CEA and SCC-Ag were detected the first time before neoadjuvant chemotherapy, the second time before surgical treatment, the third time before radiology and in the end of radiology treatment. The level of WBC, ACN and PLT were taken from routine schedule. The data about localisation, histological type were taken from patient's medical files. All cases were followed up for 23±2.7 months. The follow-up period started from confirmed diagnosis to progressive disease.
Results: The earliest and latest recurrence occurred, respectively 5 and 26 month after radical treatment. The average recurrence time (PFS) was 16.4 months after radical complex treatment. The recurrence rate of oral cavity SCC, age, TNM staging, tumour's histological type and localisation, laboratory tests were taken into account for statistical analysis. There was statistically significant difference in level of serum tumour markers, level of WBC, ACN and PLT among the patients with and without disease relapse.
Conclusion: From the results, combination of high level of CEA and serum SCC-Ag, increasing counts of WBC, ACN and PLT, poorly differential histological type and localisation in the tongue and mouth floor was associated with poor prognosis. This complex of activities will apply practically as prognostic factors for the appearance of the disease relapse during and after complete treatment. Thereby, comprehensive analysis of complex common and special factors is recommended to predict early recurrence of oral SCC.
No conflict of interest.

3165 POSTER

The epidemiological factors in prognosis of recurrent HNSCC

S.I. Kutukova[1], G.M. Manikhas[1], A.I. Yaremenko[2], T.S. Ermakova[3].
[1]Saint-Petersburg City Oncological Dispensary, Chemotherapy, Saint-Petersburg, Russian Federation; [2]Pavlov State Medical University, Maxillo-facial Surgery, Saint-Petersburg, Russian Federation; [3]Saint-Petersburg City Clinical Oncology Dispensary, Maxillo-facial Surgery, Saint-Petersburg, Russian Federation

Background: The role of viral infection in relapse of HNSCC now is very discussed by many authors. Knowledge of epidemiology factors would give us the chance of real prognosis of the running of HNSCC and choosing correct scheme of complex treatment for each patient.
Material and Methods: In the prospective study 86 cases (group A) of oral SCC were analysed. They were diagnosed from 2010 to 2012 in City clinical oncology centre, Saint-Petersburg, Russia. All patients were treated by standard protocol for complex treatment: the first phase was 1−3 cycles neoadjuvant chemotherapy (PF regime). During the second phase all patients were conducted the radical surgical treatment. The third phase contained a post-surgery radiotherapy. All tumour tissues were studied for detection of expression of HPV6, 11, HPV 16 and HPV 18, EBV, CMV and HSV I and II before the treatment using real-time PCR (qPCR) analysis. Treatment response, progression free survival and their correlation with expressions of genes were obtained for all patients. The control group (group B) contained 35 healthy volunteers.
Statistical differences were considered significant if 'p' was <0.05.
Results: EBV was identified in 59.28% tumour samples (group A) and in 20% intact mucosa in group B. Frequency of occurrence HPV 6, 11, HPV 16 and HPV 18 was 6.8% in group A with HNSCC and in 40% cases in control group. CMV was identified in 3% cases in group with HNSCC and wasn't registerd in control group B. HSV I and II was registered in 2% patients in group A and 1% healthy volunteers.
Conclusion: Our preliminary results suggest, evaluation of EBV. HPV 6, 11, HPV 16 and HPV 18, CMV, HSV I and II before the planning of complex treatment of patients with HNSCC are appropriate for definition of disease prognosis and give possibility to provide individual treatment scheme for each patient. This complex of activities will apply practically as prognostic factors for the appearance of the disease relapse during and after complete treatment. Thereby, comprehensive analysis of complex common and special factors is recommended to predict early recurrence of oral SCC.
No conflict of interest.

3166 POSTER

10 year follow-up of high-dose intra-arterial cisplatin and concomitant radiation (RADPLAT) for advanced head and neck cancer

J. Heukelom[1], M. Lopez[2], I.B. Tan[3], J.P. De Boer[4], R.T. Gregor[5], D.H.F. Rietveld[6], O.B. Weijers[7], R.G.J. Wiggenraad[8], A.J.M. Balm[3], C.R. Rasch[9]. *[1]Netherlands Cancer Institute, Radiotherapy, Amsterdam, Netherlands; [2]Netherlands Cancer Institute, Statistics, Amsterdam, Netherlands; [3]Netherlands Cancer Institute, Head and Neck Surgery, Amsterdam, Netherlands; [4]Netherlands Cancer Institute, Medical Oncology, Amsterdam, Netherlands; [5]Waikato Hospital, Head and Neck Surgery, Hamilton, New Zealand; [6]VU University Medical Center Amsterdam, Radiotherapy, Amsterdam, Netherlands; [7]Radiotherapeutisch Instituut Friesland, Radiotherapy, Leeuwarden, Netherlands; [8]Medisch Centrum Haaglanden, Radiotherapy, The Hague, Netherlands; [9]Academic Medical Centre, Radiotherapy, Amsterdam, Netherlands*

Background: The RADPLAT randomized phase III trial compared intra-arterial (IA) to intravenous (IV) cisplatin-based chemoradiation for advanced stage IV head and neck cancer. In the IA regimen higher doses of cisplatin reached the tumor while the addition of IV sodium thiosulfate neutralized systemic exposure of cisplatin, thus minimizing the risk for toxicity. With 10 years of follow up data now available for the last patients, long term differences in late toxicity, locoregional control, overall and disease free survival can be assessed.
Material and Methods: This trial included 237 patients with inoperable squamous cell carcinoma of the oropharynx, oral cavity or hypopharynx, stage IV (T3-T4, any N, M0); WHO 0−1 and adequate laboratory parameters. Patients were randomly assigned to either radiotherapy (RT) + IA cisplatin or RT + IV cisplatin. The RT regimen consisted of a dose to the primary tumor and all nodal areas of 46 Gy in 23 fractions (fx), 5 fx/week, followed by a boost of 24 Gy in 12 fx to all involved areas including the primary tumor (total dose 70 Gy). A 3D conformal technique was used for all patients. Chemotherapy comprised cisplatin 150 mg/m^2 IA on days 1, 8, 15 and 22, followed by sodium thiosulfate 12 g/m^2 IV or cisplatin 100 mg/m^2 IV on treatment days 1, 22 and 43.
Results: Median follow-up was 90 months. Among 237 patients, 57 recurred locally, 35 regionally and 80 loco-regionally. There were 32 new primary tumors, 65 distant metastases (all as first events) and 154 deaths. No significant difference was found between treatment arms in locoregional control, survival or late toxicity. 95% of the recurrences occurred within 3 years. In multivariable analyses, increasing age and T-stage were linked with poorer severe-toxicity free survival ($p = 0.007$ and $p = 0.053$, respectively). The risk of developing any severe toxicity was 45% ($p = 0.037$), 67% ($p = 0.010$) and 73% ($p = 0.028$) lower in the 2nd, 3rd and 4th year after treatment, respectively, compared to the 1st year. Toxicities developing more than 3 years after treatment were found to have median

durations between 1 and 3 years, while those developing earlier ended after less than a year.
Conclusions: After 10 years of follow-up of the RADPLAT trial, we conclude that IA cisplatin is not superior to IV cisplatin. Therefore, IV cisplatin treatment remains the standard of care. The combination of the highest risk of severe late toxicity in the 1st year post treatment and the timing of (loco)regional recurrences indicates 3 years of follow up to be sufficient.
No conflict of interest.

3167 POSTER

Efficacy and toxicity of docetaxel/cisplatin/5-fluorouracil (TPF) induction chemotherapy followed by two schedules cisplatin-containing concomitant chemoradiotherapy (CRT) in patients with locally advanced head and neck cancer (LAHNC): The CONDOR study

C.M.L. Driessen[1], J.P. De Boer[2], H. Gelderblom[3], C.R.N. Rasch[4], M.A. De Jong[5], B.M. Verbist[6], M.E.T. Tesselaar[2], W.T.A. Van der Graaf[1], J.H.A.M. Kaanders[7], C.M.L. Van Herpen[1]. *[1]Radboud University Nijmegen Medical Centre, Department of Medical Oncology, Nijmegen, Netherlands; [2]Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Department of Medical Oncology, Amsterdam, Netherlands; [3]Leiden University Medical Centre, Department of Medical Oncology, Leiden, Netherlands; [4]Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Department of Radiation Oncology, Amsterdam, Netherlands; [5]Leiden University Medical Centre, Department of Radiation Oncology, Leiden, Netherlands; [6]Radboud University Nijmegen Medical Centre, Department of Radiology, Nijmegen, Netherlands; [7]Radboud University Nijmegen Medical Centre, Department of Radiation Oncology, Nijmegen, Netherlands*

Background: TPF induction chemotherapy (ICT) has been associated with survival benefit compared to cisplatin/5-fluorouracil. However, hardly any data are available on TPF ICT followed by standard cisplatin-containing concomitant CRT. The aim of this multicentre phase II study was to evaluate the feasibility (>90% of the planned RT) of TPF followed by cisplatin-containing CRT schedules.
Material and Methods: Pts with LAHNC, PS 0−1 were included. They were treated with 4 TPF courses (T 75 mg/m^2, P 75 mg/m^2 and F 750 mg/m^2 day 1−5) and thereafter randomized between P 100 mg/m^2 on days 1, 22, 43 combined with conventional RT (arm A) or P 40 mg/m^2 weekly combined with accelerated RT (arm B). Based on power analysis for feasibility 70 pts were needed. Interim analysis for safety was planned.
Results: Between Dec 2008 and Dec 2011 65 pts were included; 2 were ineligible and 1 withdrew consent. 81.5% of pts was male, median age was 56 yrs and PS was 0 in 79%, primary site: oral cavity (23%), oropharynx (57%), hypopharynx (12%), larynx (8%). Six (10%) of the 62 pts were not randomized after TPF, due to death (1), toxicity (3) or PD (2). 27 pts were randomized to arm A and 29 to arm B. 96.4% of the pts received the total planned irradiation dose. However, only 22% of pts in arm A and 41% pts in arm B, received the total planned cisplatin courses during CRT due to toxicity. Grade 3−4 toxicity during CRT consisted of: dehydration (26% vs 14%), dysphagia (26% vs 24%), mucositis (22% vs 57%) and rise in serum creatinin (19% vs 3%) in arm A vs arm B. After the second interim analysis the low rate of pts tolerating cisplatin during CRT was reason to terminate further inclusion of pts in the study.
Response after TPF was CR in 4 pts (6.5%), PR in 34 pts (54.8%), SD in 19 pts (29.2%), PD in 2 pts (3.2%). The RR twelve weeks after end of CRT is shown in the Table. After a median follow up of 23 months (0−49) 2 years OS and DFS survival was equal in both arms (Table).
Conclusions: Cisplatin-containing concomitant CRT after induction TPF is not feasible with the used schedules. Although after induction TPF only 32% of the pts completed the planned concomitant treatment, OS and DFS compared favorable relative to other schedules employing concomitant CRT or TPF containing regimens in LAHNC.
No conflict of interest.

	Total pts (62)	Arm A (27)	Arm B (29)	
RR after TPF	61.3% (CR: 6.5%; PR 54.8%)			
RR 12 weeks after CRT		81.5% (CR: 62%; PR 23%)	72.4% (CR: 55%; PR 17%)	ns
OS (2 yrs)	70%	77%	76%	ns
DFS (2 yrs)	63%	69%	68%	ns

3168 POSTER

Phase I trial of nab-paclitaxel (A), cisplatin (P) and 5-fluorouracil (F) induction chemotherapy (IC) followed by concurrent chemoradiotherapy (CCRT) in patients (pts) with locoregionally advanced squamous cell carcinoma of head and neck (LA-SCCHN): final results

H.H. Loong[1], A. Hope[2], E. Winquist[3], A. Hammond[4], J. Waldron[2], I. Diaz-Padilla[1], E.X. Chen[1], J. Kim[2], A.R. Razak[1], L.L. Siu[1]. *[1]Princess Margaret Cancer Centre, Department of Medical Oncology & Haematology, Toronto − Ontario, Canada; [2]Princess Margaret Cancer Centre, Department of Radiation Oncology, Toronto − Ontario, Canada; [3]London Health Sciences Centre, Department of Medicine & Oncology & Otolaryngology, London − Ontario, Canada; [4]London Health Sciences Centre, Department of Radiation Oncology, London − Ontario, Canada*

Background: Sequential therapy (IC followed by CCRT) has been evaluated in the treatment of LA-SCCHN, with triplet IC (docetaxel, P and F) shown to be superior to PF doublet. The final results of a study evaluating 130nm albumin-bound paclitaxel (A) in SCCHN are presented here.
Methods: A phase I trial to determine maximum tolerated dose, recommended phase II dose (RP2D), and assess the safety and preliminary efficacy of APF as IC for 3 cycles followed by concurrent carboplatin (Cb) (AUC 1.5 weekly) with radiation therapy (RT) (70 Gy/35), was conducted using a 3+3 design in previously untreated LA-SCCHN pts. Dose-limiting toxicities (DLT) included: standard hematologic and non-hematologic toxicities, treatment delays, inability to complete $\geqslant$95% of RT and skin/mucosal toxicity related to RT were assessed from day 1 of IC to 8 weeks after completion of CCRT.
Results: 17 pts were enrolled at 3 dose levels: M:F = 14:3; median age = 54 yrs (range 44−65 yrs); ECOG 0:1 = 5:12; oropharynx p16 positive/negative/unknown = 11/2/4; T1/2/3/4 = 2/4/5/6; N2a/2b/2c/3 = 1/3/7/6. 15 pts were DLT evaluable (1 withdrew consent, 1 PD after cycle 1 of IC). Dose level 1 was considered toxic despite 1/3 DLT since both pts without DLT missed d8 of cycles 2 and 3; dose level −1A was evaluated as intermediate between dose levels 1 and −1. Common Gr 3/4 adverse events (no. of pts) were: lymphopenia (12), stomatitis (10), neutropenia (7), dysphagia (4) and hyponatraemia (4). Best response to IC include: partial response 10 pts (63%) stable disease 5 pts (31%), progressive disease 1 pt (6%). At median follow-up of 12.3 months, 2 deaths were observed: 1 due to disease relapse and 1 due to intercurrent illness. Median progression-free survival has not been reached, 2-year PFS rate = 73% (95% CI, 38−91%).
Conclusion: The RP2D of APF was: A 100 mg/m^2 IV d1+d8, P 75 mg/mg^2 IV d1 and F 1000 mg/m^2/d CIV x 96 hrs d1−4, Q3W, for 3 cycles prior to CCRT.
Study APF-001; clinicaltrials.gov identifier NCT00731380; Sponsored by University Health Network, Toronto, Canada.
No conflict of interest.

Dose level	Induction regimen	No. of DLT/ No. of evaluable pts	DLT descriptions
1	A 75 mg/m^2 d1+d8, P 100 mg/m^2 d1, F 1000 mg/m^2/d $\times$ 96 hrs, Q3W $\times$ 3 cycles	1/3	Febrile neutropenia; inability to receive 95% of RT; received <6/7 doses of Cb due to Gr3 stomatitis
−1	A 75 mg/m^2 d1+d8, P 75 mg/m^2 d1, F 1000 mg/m^2/d $\times$ 96 hrs, Q3W $\times$ 3 cycles	1/6	Received <6/7 doses of Cb due to Gr3 stomatitis and prolonged neutropenia
−1A	A 100 mg/m^2 d1+d8, P 75 mg/m^2 d1, F 1000 mg/m^2/d $\times$ 96 hrs, Q3W $\times$ 3 cycles	1/6	Gr3 stomatitis during IC

3169 POSTER

A phase II study of nimotuzumab and CDDP concurrent with radiation in locally advanced squamous cell carcinoma of the head and neck (SCCHN) [NCT00702481]

M.K. Ang[1], E. Tharavichitkul[2], Q.S. Ng[1], D.S.W. Tan[1], C. Lim[3], J. Srikawin[2], L.Y. Wang[3], E.H. Tan[1], W.T. Lim[1]. *[1]National Cancer Centre Singapore, Department of Medical Oncology, Singapore, Singapore; [2]Chiang Mai University, Division of Therapeutic Radiology and Oncology, Chiang Mai, Thailand; [3]National Cancer Centre Singapore, Division of Clinical Trials and Epidemiology, Singapore, Singapore*

Background: Nimotuzumab is a humanized monoclonal antibody (MAb) to EGFR. Concurrent cisplatin with radical radiotherapy (RT) is standard treatment for locally advanced SCCHN where it is unresectable or for

organ-preservation. We explored the combination of nimotuzumab with concurrent CDDP and RT in these patients (pts).
Materials and Methods: Patients with locally advanced stage III/IV SCCHN were eligible for study if: age >18, ECOG 0−1, SCC, normal organ function. CDDP 100 mg/m^2 on days 1, 22, and 43 was given with RT (70 Gy over 35 fractions). Nimotuzumab was given as a flat dose of 200 mg weekly on weeks 1 to 8 of treatment. Pts were followed up for RECIST response, progression free survival and toxicity. Using Simon's minimax 2-stage design with a type I error of 5%, power of 80%, target response rate of 70% and no further interest rate of 50%, a total of 37 patients were required. The combination would be considered for further study if 24 or more responses of 37 were reported. Analysis was by intention-to-treat (ITT).
Results: Thirty seven patients were recruited. The median age was 57 (29−68). Most were Chinese (76%) and all ECOG 0−1. The ratio of oropharynx/non-oropharynx was 19 (51%):18 (49%). Majority of pts had stage IVA disease. Per protocol treatment was completed in 76% of pts. Twenty-nine pts were evaluable for response, 3 pts withdrew from study, 1 early death from undiagnosed Fanconi's anemia, 4 pts did not have post-treatment scans (2 unconfirmed PR). By ITT, the response rate was CR: 43%/PR: 30% (ORR = 73%), PD: 5%. Pts with oropharynx Ca had significantly higher 1-year PFS rate than non-oropharynx (90% vs 42%, P = 0.019). Major G3/4 toxicities were limited to mucositis, dysphagia, and hyponatremia. One G5 toxicity from febrile pancytopenia occurred in 1 pt with undiagnosed Fanconi's. Acneiform rash typical of EGFR MAb was limited to G1/2 severity. Thirteen patients with non-oropharynx cancer were referred with organ-preservation intent. Of these, 11 completed treatment and the ORR was 77% (CR/PR). Seven pts relapsed. Three pts who had locoregional relapse underwent successful salvage surgery.
Conclusions: This combination is tolerable and acneiform rash was distinctly minimal. Pts with oropharynx Ca had significantly better 1-yr PFS than non-oropharynx Ca. This combination is being evaluated in a phase 3 randomized controlled study as adjuvant therapy following surgery for resectable disease (NCT00957086).

3170 POSTER

Comprehensive genotyping of the receptor tyrosine kinase pathway using semi-conductor sequencing in HPV+ and HPV− oropharyngeal cancers (OPC)

C. Van Herpen[1], B. Tops[2], C. Driessen[1], A. Van Raaij[2], R. Willems[2], P. Slootweg[2], M. Ligtenberg[3]. *[1]UMC St. Radboud, Medical Oncology, Nijmegen, Netherlands; [2]UMC St. Radboud, Laboratory of Tumorgenetics Department of Pathology, Nijmegen, Netherlands; [3]UMC St. Radboud, Laboratory of Tumorgenetics Department of Pathology and Department of Human Genetics, Nijmegen, Netherlands*

Background: Recently, HPV was recognized as an important etiological and prognostic factor in OPC. At this moment treatment of locally advanced OPC consists of concomitant CRT or cetuximab-RT in elderly or non-fit patients. In OPC no predictive marker for response to EGFR inhibition is known. Therefore genotyping is of utmost importance, but is often hampered by the small amount of tumour material available. The aim of this study is to assess the feasibility of testing actionable mutations in multiple genes of the receptor tyrosine kinase (RTK) pathway in small amounts of formalin fixed paraffin embed (FFPE) material and to determine the frequency of these mutations in HPV+ and HPV− OPC.
Materials and Methods: We included the archival material of 50 OPC, 25 HPV+ and 25 HPV-, all treated with concomitant CRT between 2003 and 2010. We assessed mutations in the RTK-pathway using an in-house developed gene-panel that targets 90 genetic regions in 22 genes using the AmpliSeq technology (Life Technologies). The single multiplex PCR requires only 10 ng input DNA. 8 samples were pooled and sequenced on an Ion 316 chip using the Ion PGM 200 sequencing kit protocol. Data were analysed using SeqNext software package 4.0.1 (JSI). All variants were confirmed by Sanger sequencing.
Results: So far 12 HPV- and 9 HPV+ samples OPC have been successfully analysed. As expected we identified a *TP53* mutation in almost all HPV− samples (11/12), while no *TP53* mutations were detected in the HPV+ samples. We only identified 1 mutation in the RTK-pathway, i.e. in *FGFR3* in an HPV+ patient, and 1 incidental mutation in *FBXW7* in an HPV− patient. We are currently expanding the series and re-analysing the data for gene deletions and/or amplifications.
Conclusion: We developed an assay to identify mutations in the RTK pathway with high sensitivity by semiconductor-based sequencing. As only small amounts of FFPE material are sufficient for reliable analysis, this test opens new possibilities to investigate small biopsies of primary tumours and metastases even when only archived clinical material is available. This is of special importance for head and neck cancer pts, of which we do have a limited amount of archival material, especially in those patients, which are not surgically treated. In the near future we will test HPV+ en HPV− OPC patients to investigate if we can detect mutations that can predict responsiveness to EGFR inhibition.
No conflict of interest.

3171 POSTER

Radiotherapy, gemcitabine, and cetuximab (RAGE) in patients (pts) with locoregionally advanced squamous cell carcinoma of the head and neck (LA-SCCHN): A feasibility study

P. Specenier[1], D. Van den Weyngaert[2], C. Van Laer[3], O.M. Vanderveken[3], D. Van Gestel[2], C. Verschueren[4], M. Peeters[1], J.B. Vermorken[1]. *[1]Antwerp University Hospital, Oncology, Antwerp, Belgium; [2]Antwerp University Hospital, Radiotherapy, Antwerp, Belgium; [3]Antwerp University Hospital, Otorhinolaryngology Head and Neck Surgery, Antwerp, Belgium; [4]Antwerp University Hospital, Moca, Antwerp, Belgium*

Background: Concurrent chemoradiation (CCRT) is the standard treatment for inoperable LA-SCCHN. Gemcitabine and cetuximab are potent, synergistic radiosensitizers. The aim was to study the feasibility of the gemcitabine, cetuximab, and radiotherapy (RT) combination in SCCHN.
Material and Methods: Eligible were patients with SCCHN who qualified for definitive CCRT. Cetuximab 400 mg/m^2 was started 1 week before (RT). Gemcitabine 10 mg/m^2 and cetuximab 250 mg/m^2 were administered weekly for the duration of RT (32 fractions, 5 fractions/week, up to 69.12 Gy, simultaneous integrated boost technique). Induction chemotherapy prior to RAGE was allowed. During RAGE, toxicity was scored weekly according to NCI-CTC version 4.
Results: 17 patients (15 male) were treated between April 2010 and June 2012. Median age: 60 (range: 47−72). Tumor sites: hypopharynx: 7; oropharynx: 5; supraglottis: 2; maxillary sinus, tongue, unknown: each 1. Stage: T2N1: 2; T2N2b: 2; T3N2b: 4; T1N2b, T1N3, T3N0, T3N2c, T3N3, T4N1, T4N2b, T4N2c, recurrence after prior surgery and RT: each 1. In 13 patients, RAGE was preceded by induction chemotherapy: 6 x weekly carboplatin (AUC 2)/paclitaxel (70 mg/m^2): 2; TPF: 10 (4 cycles: 9; 2 cycles + weekly carboplatin/paclitaxel: 1 [stop TPF for renal toxicity]); 4 x docetaxel, 5-FU, carboplatin: 1. Median duration of RT: 44 days (range: 42−50). Duration of RT was $\leqslant$47 days in 16 patients, 50 days in 1. 17/17 received planned RT dose. Gemcitabine and cetuximab dose intensity was >98%. Toxicity during RAGE is shown in table (maximum grade; number of patients).

Grade	1	2	3	4
Radiodermatitis	1	5	9	2
Mucositis		1	16	
Weigth loss	3	2	9	

9 patients needed temporary tube feeding or parenteral nutrition, 9 needed hospitalization(s) (16 episodes, median duration: 13 days). 15 needed opioids. 1 patient (T3N2b hypopharynx) required a partial colectomy followed by prolonged tracheal intubation for a bowel perforation (diverticulitis) 9 days after the end of RAGE (which was preceded by 4 x TPF). He required a laryngectomy for laryngopharyngeal dysfunction 12 months after RAGE (no tumor in specimen). 1 patient (T3N3 at diagnosis) was rendered tumor-free by salvage lymphadenectomy. 2 patients had persistent unresectable local disease at the end of RAGE. Lung metastases developed in 2 (1 with persistent local disease), a local recurrence in 1. Median follow-up for surviving patients is 21 months (range: 8−35). 12 patients are alive without evidence of SCCHN disease, all feeding-tube independent. No toxicity-related deaths.
Conclusions: With adequate support, the concomitant administration of cetuximab, gemcitabine and RT in SCCHN patients is feasible, both with and without induction chemotherapy, without treatment interruptions, with patients receiving >98 % of planned cetuximab and gemcitabine dose, and 100 % of planned RT dose.
Conflict of interest: *Advisory board: Jan B Vermorken participated in advisory boards of Merck-Serono, Amgen, Genentech, and Boehringer-Ingelheim. Corporate-sponsored research: The project was funded by an unrestricted grant from Merck Serono*

3172 POSTER

A phase II randomized study to compare short course palliative radiotherapy with short-course concurrent palliative chemotherapy plus radiotherapy in advanced and unresectable head and neck cancer [interim analysis]

A. Kumar[1], A. Sharma[1], B.K. Mohanti[2], A. Thakar[3], S. Thulkar[4], N.K. Shukla[5]. *[1]All India Institute of Medical Sciences, Medical Oncology, Delhi, India; [2]All India Institute of Medical Sciences, Radiation Oncology, Delhi, India; [3]All India Institute of Medical Sciences, Ear Nose and Throat, Delhi, India; [4]All India Institute of Medical Sciences, Radiodiagnosis, Delhi, India; [5]All India Institute of Medical Sciences, Surgical Oncology, Delhi, India*

Background: Head and neck cancer is the commonest cancer in India. Locally advanced and unresectable disease constitute one third of cases. Treatment for this group is not very well defined and has poor results.
Materials and Methods: Patients with locally advanced and unresectable squamous cell carcinoma of oral cavity, oropharynx or hypopharynx were randomized either to arm A [Short course palliative RT alone(4 Gy/#/day on 5 consecutive days, to a total of 20 Gy in the first schedule)] or arm B [short course concurrent palliative CTRT]. RT was identical in both arms. In arm B, cisplatin was given as i.v. bolus at 6 mg/m^2/day along with RT. Patients in both the arms were taken for further radical treatment [FRT] only if they had atleast a PR both clinically and radiologically. Patients eligible for FRT were given RT at 2 Gy/#/day with a total radiobiological equivalent dose of 70 Gy, in both the arms. In arm B, concurrent Cisplatin was given at a dose of 40 mg/m^2/week along with RT. Response and toxicity assessment was done at 4 weeks; and proportion of patients eligible for FRT, OS and PFS was compared between the treatment arms.
Results: Enrollment started in March 2012 and is ongoing. Of 100 planned patients, 53 patients who have completed 6 months of follow-up are included in this interim analysis. Median age for the whole cohort was 55 years [range, 27−74 years]; 44 patients were male. 26 patients were randomized to arm A and 27 to arm B. At 4 weeks, 8 patients [32%] in arm A and 16 (59%) in arm B had either CR or PR and 17 (68%) in arm A and 11 (41%) in arm B had SD or PD ($p = 0.045$). 7 patients (27%) in arm A and 16 (59%) in arm B were taken for FRT ($p = 0.027$), At 1 month, significant symptom relief was noted for pain ($p = 0.029$) and trismus ($p = 0.049$) in arm B. At 1 week, grade 3/4 toxicities were not significantly different between both arms and no grade 3/4 toxicity was noted at 1 month. At a median follow-up of 8.5 months, median OS was 5.4 months for arm A and 6.9 months for arm B and estimated OS at 6 months was 44.5% and 55.6% respectively ($p = 0.292$). Median PFS was 2.6 months (95% CI, 2.2−3.1) for arm A and 8.8 months (95% CI, 3.0–14.6) for arm B and estimated PFS at 6 months was 28.1% and 60.9% respectively ($p = 0.012$).
Conclusion: Compared to palliative RT alone, concurrent low dose CTRT improves PFS for advanced and incurable HNSCC with tolerable toxicity profile.
Clinical trial registry number: CTRI/2012/06/002717
No conflict of interest.

3173 POSTER

Toxicity and efficacy of concomitant chemoradiotherapy with weekly cisplatin for locally advanced head and neck carcinoma

C.M.L. Driessen[1], G.O.R.J. Janssens[2], W.T.A. Van der Graaf[1], R.P. Takes[3], M.A. Merkx[4], C.C.M. Van Opstal[1], J.H.A.M. Kaanders[2], C.M.L. Van Herpen[1]. *[1]Radboud University Nijmegen Medical Centre, Department of Medical Oncology, Nijmegen, Netherlands; [2]Radboud University Nijmegen Medical Centre, Department of Radiation Oncology, Nijmegen, Netherlands; [3]Radboud University Nijmegen Medical Centre, Department of Otorhinolaryngology, Nijmegen, Netherlands; [4]Radboud University Nijmegen Medical Centre, Department of Oral and Maxillofacial Surgery, Nijmegen, Netherlands*

Background: This retrospective study reports on the acute toxicity, relapse pattern and survival of (patients) pts treated with weekly cisplatin concomitant with accelerated radiotherapy (AR) as primary treatment for locally advanced head and neck carcinoma (LAHNC).
Material and Methods: Between 2003 and 2010, 106 pts with LAHNC of the oral cavity (n = 12), oropharynx (OPC) (n = 53), hypopharynx (n = 34) and larynx (n = 7), median age 57 yrs, male 76.4%, stage III 17.9% and stage IV 82.1% were enrolled in this protocol in our institute. Treatment consisted of cisplatin 40 mg/m^2 weekly concomitant with AR with concomitant boost up to a dose of 68 Gy over 5.5 weeks. IMRT was used in 30 pts. Acute toxicity was recorded based on the CTC v3.0. HPV analysis was performed using p16 immunohistochemistry and PCR.
Results: AR was given as planned without interruptions in 97.2% of pts; 60.4% received all 6 cycles and 89.6% received at least 5 cycles of cisplatin. Overall dermatitis was seen less in pts treated with IMRT ($p = <0.05$); dermatitis grade 3 was present in 53.6% of pts treated without IMRT and 26.7% with IMRT (ns). Grade 3 mucositis was observed in 86.8% of the pts treated without IMRT vs 76.7% treated with IMRT (ns). The majority of pts (78.7%) were temporary feeding-tube dependent, median 9.0 weeks during and directly after treatment, the prevalence of tube feeding at 12 months was 3.7%. Only 1 pt developed a grade 1 nephrotoxicity. Gastro-intestinal toxicity of cisplatin was mild. There was 1 toxic death due to sepsis. The median follow-up was 34 months (range 2−92 months). The 3-year loco-regional control (LRC), DFS and OS were 70%, 51% and 61% and 5 yrs LRC, DFS and OS were 64%, 38% and 48%, respectively. In 50 of the 53 pts with OPC HPV status could be determined; PCR and p16 were positive in 11 pts. OS after 3 and 5 yrs was 81% and 67% in HPV + pts and 72% and 55% in HPV − pts (ns).
Conclusion: Weekly cisplatin 40 mg/m^2 concomitant with AR with concomitant boost is feasible and associated with a high level of compliance. LRC and survival rates in this series of predominantly HPV− LAHNC pts, are at the upper percentile of what is reported in literature using cisplatin 100 mg/m^2 (day 1−22−43) concomitant with conventional RT. We suggest that LAHNC pts with renal impairment are treated preferably with weekly cisplatin 40 mg/m^2, as renal toxicity with this schedule is infrequent.
No conflict of interest.

3174 POSTER

Nimotuzumab with induction chemotherapy and chemoradiation in patients with advanced head and neck cancer: A pilot study

S. Sundaram[1], B. Venkatnarayanan[2], N. Sridharan[1]. *[1]V.S.Hospitals, Medical Oncology, Chennai, India; [2]V.S.Hospitals, Radiation Oncology, Chennai, India*

Background: Head and neck squamous cell carcinoma (HNSCC), is a common malignancy in the Indian population. In locally advanced disease, chemoradiation is the standard of care. Although induction chemotherapy has been much studied, no clear benefit has been identified apart from laryngeal preservation. A few randomised trials have demonstrated improved response rate, disease free survival, and overall survival with induction chemotherapy. Nimotuzumab is a humanized monoclonal antibody targeting EGFR receptors and has been demonstrated to be safe and effective when combined with chemotherapy and/or chemoradiotherapy. We evaluated safety and efficacy of administrating Nimotuzumab with chemotherapy to target EGFR over expression in patients with HNSCC in usual health care setting.
Material and Methods: The present study was an open label single arm study, with a retrospective analysis of results. Patients of age 18 years and above with histologically confirmed advanced HNSCC were included in the study. Informed consent was obtained from all the patients. The patients were treated with three cycles of induction chemotherapy consisting of modified TPF regimen along with Nimotuzumab (200 mg IV) on day 1, followed by radiotherapy for a dose of 66 Gy along with concurrent weekly Cisplatin (30 mg/m^2) and Nimotuzumab (200 mg) throughout the course of radiation. Patients were evaluated based on RECIST criteria, four weeks after completion of radiotherapy.
Results: Sixteen patients were included this study. Mean age of the patients was 54±11 yrs. Most common subsite of cancer was oral cavity in 69% (n = 11), followed by pharynx in 19% (n = 3). Four patients had metastasis at the time of presentation. Six patients (37.5%) had a complete response, six patients (37.5%) had progressive disease and four patients (25%) were lost to follow up. The combination chemotherapy with Nimotuzumab was well tolerated. Addition of Nimotuzumab to TPF regimen was not associated with added toxicity.
Conclusions: Addition of Nimotuzumab to induction chemotherapy and chemoradiation may be a promising alternative to concurrent chemoradiotherapy in HNSCC due to the known overexpression of EGFR receptors. The results of this study need further evaluation in a larger study setting.
No conflict of interest.

3175 POSTER

Predicitve factors of cisplatin completion/discontinuation in concurrent chemoradiotherapy to locally advanced head and neck cancer patients

K. Nakano[1], Y. Sato[1], T. Toshiyasu[2], Y. Sato[3], K. Kawabata[4], S. Takahashi[1]. *[1]The Cancer Institute Hospital of JFCR, Medical Oncology, Tokyo, Japan; [2]The Cancer Institute Hospital of JFCR, Radiation Oncology, Tokyo, Japan; [3]The Cancer Institute, Pathology, Tokyo, Japan; [4]The Cancer Institute Hospital of JFCR, Head and Neck Surgery, Tokyo, Japan*

Background: Concurrent chemoradiotherapy (CCRT) with cisplatin (CDDP) is a standard therapy for locally advanced head and neck cancer

patients, but some patients have intolerance to high dose density of CDDP. Predictive factors for CDDP completion/discontinuation need to be investigated for making appropriate treatment decisions.
Material and Methods: We retrospectively analyzed non-metastatic head and neck cancer patients treated with CCRT with CDDP (80 mg/m^2 per 3 weeks) from November 2005 to April 2012 in our institute. Radiation therapy was performed as three-dimensional radiotherapy or intensity-modified radiotherapy (IMRT).
Results: A total of 164 patients received CCRT, of which 89 (54 %) were Stage 4. Primary sites were as follows; oral cavity 7, oropharynx 52, hypopharynx 53, larynx 14, nasopharynx 30, paranasal sinus/nasal cavity 3, and unknown primary 5. IMRT was performed to 54 (33 %) patients. Median follow-up time was 19 months (range 1−69 months); 1-year overall survival (OS) and progression free survival (PFS) were 90 % and 78%. Non-Stage 4 and high creatinine clearance (>70 ml/min) were associated with longer OS in Cox proportional hazard model (p = 0.004, hazard ratio 5.923; p = 0.001. hazard ratio 4.167, respectively). As for CDDP treatment cycles, 75 (46 %) patients completed 3 cycles of CDDP, 69 (42 %) patients received 2 cycles, and 20 (12 %) patients received only 1 cycle because of adverse events. The main reasons for CDDP discontinuation were infection (24 patients) and renal dysfunction (18 patients). In logistic regression analysis, male sex, younger age (<61 years) and high body mass index (BMI) (>25) were associated with 3 cycles completion of CDDP statistically significantly (p = 0.002, odds ratio 6.622; p = 0.006, odds ratio 2.602; p = 0.035, odds ratio 2.655, respectively).
Conclusions: In CCRT to head and neck cancer patients, infection and renal dysfunction were the main reasons for CDDP discontinuation. Sex, age and BMI could be predictive factors of CDDP continuation.
No conflict of interest.

3176 POSTER

Quality of life of elderly patients receiving weekly carboplatin and paclitaxel chemotherapy plus cetuximab first line for metastatic squamous cell carcinoma of the head and neck

A. Lugini[1], R. Rossi[2], R. Pace[1], A. Rauco[1], M. Santarelli[3], V. Capparella[1]. *[1]San Camillo dé Lellis, Medical Oncology Unit, Rieti, Italy; [2]Santa Maria Goretti, Medical Oncolgy Unit, Latina, Italy; [3]San Camillo dé Lellis, Radiotherapy Unit, Rieti, Italy*

Background: A phase III trial demostrated that Cetuximab is the first agent to improve survival when added tho platinum-based chemotherapy for metastatic squamous cell carcinoma of the head and neck. The safety and tolerability of a combination of weekly Paclitaxel and Carboplatin and the epidermal growth factor receptor (EGFR) monoclonal antibody Cetuximab for the first line treatment for metastatic squamous cell carcinoma of the head and neck in elderly population were investigated.
Patients and Methods: Patients >70 years of age with histologically confirmed metastatic squamous cell carcinoma were enrolled. Other eligibility criteria included: measurable disease (using RECIST), Karnofsky performance status (KPS) >60% and adequate hematologic, hepatic and renal functions. Patients receiving Paclitaxel (80 mg/mq), Carboplatin AUC 2 and Cetuximab (400/250 mg/mq) weekly. Treatment was continued for a maximum of six cycles of chemotherapy. After six cycles, patients in the who had at least stable disease received cetuximab monotherapy until disease progression or unacceptable toxicity. The European Organisation for Research and Treatment of Cancer QoL Questionnaire-Core 30 (QLQ-C30) and QLQ-Head and Neck 35 (QLQ-H&N35) module were used to assess QoL.
Results: From September 2010 to September 2012 were evaluated 40 patients with metastatic squamous cell carcinoma of the head and neck. Patients were scheduled to complete the questionnaires at screening or baseline, on day 1 of every cycle. The analysis of the responses to the questionnaires from patients shows that the pattern of chemotherapy used provides excellent control of symptoms related to the disease. Common grade 3/4 adverse events were acne-like rash (18%), asthenia (20%) and neutropenia (10%).
Conclusion: This analysis shows an important clinical benefit of chemotherapy regimen proposed in the population included in the study. Relevant results in terms of overall survival, PFS, in response rates and disease control.
No conflict of interest.

Weekly cisplatin concurrently with radiotherapy in head and neck squamous cell carcinoma: A retrospective analysis of a tertiary institute

Y.Y. Elamin[1], H. Ebrahem[1], A. Flynn[1], E. O'Regan[2], S. Brennan[3], N. Osman[1]. *[1]St James Hospital, Medical Oncology, Dublin, Ireland; [2]St James Hospital, Histopathology, Dublin, Ireland; [3]St James Hospital, Radiation Oncology, Dublin, Ireland*

Background: The widely used regimen in locally advanced head and neck squamous cell carcinoma (HNSCC) of combined radiation and 100 mg/m^2 of cisplatin every three weeks on day 1, 22, and 43 causes severe toxic effects. To limit toxic effects alternative schedules are being used, including once weekly cisplatin dose of 40 mg/m^2. Here, we report the cumulative dose, compliance and the acute toxicities of weekly cisplatin given concurrently with radiation in HNSCC patients in a single tertiary institute.
Methods: Retrospective review of data of HNSCC patients treated with concurrent weekly cisplatin and radiotherapy between January 2012 and January 2013 in St James's Hospital, Dublin. Toxicities were defined according to the common terminology criteria for adverse events (CTCAE) Version 4.0.
Results: 52 patients with squamous cell carcinoma of the oropharynx (73%), larynx (19%), or hypopharynx (8%) were treated with concurrent standard radiotherapy and weekly 40 mg/m^2 of cisplatin for 6 consecutive weeks in the study period. 19 (36.5%) patients had stage IV disease and 33 (63.5%) had stage III. Treatment was given as radical chemoradiation or adjuvant chemoradiation in 35(67%) and 17 (33%) patients respectively. Cumulative dose of 200 mg/m^2 or more was reached in 37 (71%) patients. 22 (42.3%) patients completed 6 cycles of cisplatin. Commonest adverse effects were mucositis, neutropenia, and renal toxicity in a decreasing order of frequency. Grade 3 and 4 mucositis occurred in 22 (43.3%) and 12 (23%) patients respectively. Grade 3 and 4 neutropenia occurred in 6(11.5%) and 3 (5.7%) respectively. No grade 3 or 4 renal toxicity occurred in the study cohort. Death occurred in one patient due to neutropenic septicemia.
Conclusion: Weekly cisplatin at 40 mg/m^2 combined with radiotherapy is a feasible option in the treatment of locally advanced HNSCC. Adverse effects are generally manageable; however it might affect treatment completion. Due to lack of strong comparative data from large phase III trials with three weekly cisplatin, each center will continue to develop its own experience in selecting the ideal regimen for different patients' populations.
No conflict of interest.

3178 POSTER

Neoadjuvant chemotherapy in 13 patients with locally advanced poorly differentiated thyroid carcinoma − a phase 1/2 study

I. Edhemovic[1], B. Gazic[2], M. Dremelj[3], B. Vidergar-Kralj[4], N. Besic[1]. *[1]Institute of Oncology Ljubljana, Surgical Oncology, Ljubljana, Slovenia; [2]Institute of Oncology Ljubljana, Pathology, Ljubljana, Slovenia; [3]Institute of Oncology Ljubljana, Radiotherapy, Ljubljana, Slovenia; [4]Institute of Oncology Ljubljana, Nuclear Medicine, Ljubljana, Slovenia*

Background: There is a paradigm that chemotherapy is ineffective in thyroid carcinoma. The aim of our study was to find out if neodjuvant chemotherapy before thyroid surgery had effect on the size of primary tumor in patients with poorly differentiated thyroid carcinoma.
Patients and Methods: Altogether 13 patients (8 women, 5 men; median age 61 years) with poorly differentiated thyroid carcinoma were treated with neoadjuvant chemotherapy from 1986–2005 at our institute. Papillary and follicular poorly differentiated carcinoma was diagnosed in 5 and 8 patients, respectively. Tumor diameter was from 4.5−18 cm (median 9 cm). Regional and distant metastases were detected in 6 and 8 patients, respectively. Eight (61%) patients had pT4 tumor. Chemotherapy consisted of Vinblastine, Vinblastine with Adriamycin or Vinblastine with Cysplatin in 11, 1 and 1 cases, respectively.
Results: Altogether, 29 (range 1−5) cycles of chemotherapy were given. Tumor size decreased for more than 50% in 5 patients (=38%). Chemotherapy was effective in follicular and papillary thyroid carcinoma in 37.5% and 40%, respectively. Total thyroidectomy, lobectomy and neck dissection was performed in 10, 3 and 5 cases, respectively. R0 resection was done in 8 cases and R1 resection in 5 cases. Eight patients had postoperative external beam irradiation of the neck and upper mediastinum. Distant metastases were diagnosed in two patients during follow-up of 7–189 (median 118) months. Seven patients died of distant metastases, one of other causes, while five patients are alive. The 5-year and 10-year cause-specific survivals of the patients were 77% and 46%, respectively.
Conclusions: Neoadjuvant chemotherapy may decrease tumor size for more than half in 38% of patients with poorly differentiated thyroid carcinoma.
No conflict of interest.

3179 POSTER

25-year experience with primary major salivary gland carcinoma at a single institution in Japan

Y. Imamura[1], N. Kiyota[1], N. Otsuki[2], C. Hirai[3], Y. Funakoshi[1], T. Mukohara[1], D. Yamashita[2], T. Ito[3], K. Nibu[2], H. Minami[1]. *[1]Kobe University Graduate School of Medicine, Department of Medicine Division of Medical Oncology/Hematology, Kobe, Japan; [2]Kobe University Graduate School of Medicine, Department of Otolaryngology-Head and Neck Surgery, Kobe, Japan; [3]Kobe University Graduate School of Medicine, Department of Diagnostic Pathology, Kobe, Japan*

Background: Salivary gland cancers (SGC) are rare neoplasms which account for less than 5% of all cancers of the head and neck. The major histological subtypes mucoepidermoid carcinoma (MEC), acinic cell carcinoma (AcCC) and adenoidcystic carcinoma (AdCC) together account for about 60% of cases, but SGC encompass a wide spectrum of histologies with varied biologic behavior. Further, geographic variation in subtype frequency is present.
Patients and Methods: We retrospectively reviewed 150 Japanese patients (pts) with malignant SGC from medical records between 1987 and 2012. Thirteen pts with metastatic salivary tumors and 9 who received initial treatment at other institutions were excluded, leaving 128 pts with primary major SGC for analysis. Clinical and pathological information was corrected from medical records. Histology was re-evaluated using the WHO classification (2005) and re-staging with UICC 7^{th}.
Results: Pts consisted of 81 men and 47 women (median age 62 years, range 5 to 88). Primary tumor sites were the parotid gland (74%) and submandibular gland (25%). 40% of pts had pain and 27% had facial paralysis at initial diagnosis. 56% of pts presented with a stage IV tumor, and 89% received surgery as initial treatment. Neck dissection and postoperative radiation were carried out for 68% and 40%, respectively. Locoregional recurrence was observed in 22%, and distant metastasis in 30%. Incidence of subtypes was MEC (24%), AdCC (19%), carcinoma ex pleomorphic adenoma (EXPA, 15%), adenocarcinoma (ADE, 11%), squamous cell carcinoma (SCC, 11%), salivary duct carcinoma (SDC, 9%) and AcCC (7%). On follow-up (median 42 months), overall 5-year survival rate was 75%, and that of subtypes was 86%, 80%, 60%, 62%, 91%, 67%, and 100%, respectively. Although univariate analysis revealed that high grade SGC, T4 disease, node positivity, Stage III/IV, pain, and facial paralysis had statistically significant poorer survival, multivariate analysis suggested that T4 disease (HR: 7.29, 95% CI: 2.33–22.80, p = 0.001) and node positivity (HR: 4.20, 95% CI: 1.35–13.11, p = 0.013) were dependent prognostic factor for survival.
Conclusion: This is one of the largest clinicopathological reports of major SGC from Japan. The incidence of histological subtypes in our institution differed slightly from those reported previously, in particular a higher rate of SDC and lower rate of AcCC, but prognosis and prognostic factors were closely similar.
No conflict of interest.

Adenoid cystic carcinoma of head and neck: A single institutional analysis of 73 cases treated with multimodality approach

A.K. Gandhi[1], R. Soumyajit[1], A. Biswas[1], S. Bhasker[1], A. Sharma[2], S. Bakhshi[2], A. Thakkar[3], B.K. Mohanti[1]. *[1]All India Institute of Medical Sciences, Department of Radiation Oncology, New Delhi, India; [2]All India Institute of Medical Sciences, Department of Medical Oncology, New Delhi, India; [3]All India Institute of Medical Sciences, Department of Oto-Rhino-Laryngology, New Delhi, India*

Background: Adenoid cystic carcinoma (ACC) accounts for less than 5% of head and neck (H&N) cancers. These are usually locally invasive tumors with propensity for perineural invasion, osseous involvement, local and distant failure.
Materials and Methods: Medical records of 73 patients of ACC of H & N region from 1995–2011 were retrieved from the departmental archives and analyzed for demographic profile, clinical presentation, disease site, stage, treatment modalities and survival outcome. Patients were retrospectively staged as per AJCC (2010) TNM classification. Disease free survival (DFS) was estimated by Kaplan Meier method. SPSS version 12.0 was used for statistical analysis.
Results: Median age at presentation was 35 years (range 12−73 years) and male: female ratio was 34:39. Primary disease site was sino-nasal in 23 (31.5%) patients, lacrimal gland in 14 (19.1%) patients, salivary gland in 25 (34.25%; 15 major & 10 minor salivary glands) patients and others in 11 patients. AJCC T stage was T4, T3, T2 and unknown in 15%, 23%, 55% and 7% of patients, respectively.10 patients had clinical and 8 patients had pathological node positive disease.15 (20.5%) patients had either intracranial or skull base extension. 57 (78%) patients were treated with surgery followed by radiotherapy (60−64 Gray at 2 Gray per fraction) and concurrent chemotherapy (cisplatin 40 mg/m^2 weekly) was used in 8 of these patients. 3 patients underwent surgery alone. 9 patients (lacrimal gland ACC) had surgery followed by adjuvant chemotherapy (3−6 cycles of cisplatin and doxorubicin). 4 patients with advanced disease received palliative radiotherapy (20−30 Gray/ 5−10 fractions/ 1−2 weeks). 17 (24.64%) patients had margin positive disease and all of them received post-operative radiotherapy.
Median follow up duration was 20 months (range 12–211 months). In the evaluable patients (N = 61), 15 (24.5%) patients failed locally, 8 (13.11%) patients had distant metastasis and 2 patients failed at both site. 2 year and 4 year DFS was noted to be 73% and 44% respectively. On univariate analysis (Log rank test), skull base/intracranial extension at presentation (HR 4.16, 95% CI 1.35–12.79; p = 0.0001), lymph node involvement (HR 2.81, 95% CI 0.56–13.99; p = 0.04) and treatment modality (others versus surgery and postoperative radiotherapy, HR 2.41, 95% CI 0.83–6.97; p = 0.01) were significant predictors of DFS. Other factors viz age ($\leqslant$45 years and >45 years; P = 0.64), sex (P = 0.54), T stage (T2&T3 versus T4; P = 0.11) and margin positivity (P = 0.95) did not correlate significantly with DFS.Treatment modality (HR 3.40, 95% CI 1.29–8.91; p = 0.01) and skull base/intracranial extension (HR 5.10, 95% CI 1.89–13.69; p = 0.001) continued to have significant impact on DFS on multivariate analysis(Cox proportional hazard regression method).
Conclusion: Surgery followed by postoperative radiotherapy remains the treatment of choice for ACC of H&N cancers. Lymph node involvement and skull base/intracranial extension confers poor prognosis. The risk of recurrence due to margin positivity seems to be negated by the use of postoperative radiotherapy.
No conflict of interest.

3181 POSTER

Prognostic factors of head and neck sarcomas in a tertiary care centre

P. Ramanathan[1], S.V.S. Deo[1], N.K. Shukla[1]. *[1]All India Institute of Medical Sciences, Surgical Oncology, Delhi, India*

Background: Head and neck sarcomas are rare heterogeneous group of tumors. Due to lack of guidelines, rarity and different biologic behavior, treatment of these tumors is challenging. However few prognostic factors had been made out and described in this study.
Materials and Methods: Retrospective analysis of head and neck cancer database of Department of Surgical Oncology, BRA IRCH, AIIMS (1992–2010) was performed and 45 cases of histologically proven head and neck sarcomas[HNS] were identified. Spectrum of head and neck sarcomas, their treatment patterns and prognostic factors were analyzed.
Results: HNS constituted 4% [45 /1118]of head and neck cancers. Median age was 41 years with slight male predilection [M-28, F-17]. Out of 45 cases 12 were skeletal sarcomas and 33 were of soft tissue origin. Dermatofibrosarcoma [n = 10] was the major sub type of soft tissue sarcoma followed by malignant peripheral nerve sheath tumor[n = 6] and synovial sarcoma[n = 4]. Osteosarcoma[n = 8] and chondrosarcoma[n = 4] were the major histological variants among skeletal sarcomas. Median size was 7 cm [range 1.5 cm to 30 cm]. Thirty eight cases were deep and 7 were superficial in location. All patients underwent radical surgery and R 0 resection could be achieved in 33 patients. Twenty three patients required reconstruction using flaps. In 5 borderline resectable cases, pre-operative chemotherapy and radiotherapy was used. Twenty six received post-operative radiotherapy and 14 received chemotherapy. During follow up 11 [24.44%] recurrences were detected with local recurrence being more common [n = 9, 20%] than distant recurrence[n = 4, 8.8%]. Similar survival seen in soft tissue sarcoma and bone sarcoma. Deep tumors, margin positive resections and large tumors [>5 cm] are found to be poor prognostic factors.
Conclusion: HNS is a rare and heterogenous disease entity comprising a diverse group of histopathological variants involving a complex anatomical head and neck sites. Optimal outcomes can be achieved by using radical surgery in combination with chemotherapy and/ or radiotherapy especially for deep tumors, margin positive resections and large tumors [>5 cm].
No conflict of interest.

3182 POSTER

Second primary malignancies after radioiodine in thyroid cancer patients and the association with radioiodine dosage: A nationwide population-based study

C.J. Teng[1], Y.W. Hu[2], C.J. Liu[3], H.L. Chiang[4], T.J. Chen[5]. *[1]Far Eastern Memorial Hospital, Division of Hematology and Oncology Department of Medicine, New Taipei City, Taiwan; [2]Taipei Veterans General Hospital, Cancer Center, Taipei, Taiwan; [3]Taipei Veterans General Hospital, Division of Hematology and Oncology Department of Medicine, Taipei, Taiwan; [4]Far Eastern Memorial Hospital, Department of Psychiatry, New Taipei City, Taiwan; [5]Taipei Veterans General Hospital, Department of Family Medicine, Taipei, Taiwan*

Background: Radioactive iodine (RAI) is widely used in the diagnosis and treatment for thyroid cancers, and increased risk of second primary malignancies (SPM) in thyroid cancer patients has been reported. However, dose-response correlation between RAI and SPM is lacking, so the potential risk of SPM caused by RAI still cannot be determined. Therefore, we investigated the risk of SPM among thyroid cancer patients and the association between RAI dosage and cancer development using a nationwide population-based dataset.
Material and Methods: We recruited patients with newly diagnosed thyroid cancer aged 20 years or older without antecedent cancer from the Taiwan National Health Insurance database between 1997 and 2006. Standardized incidence ratios (SIRs) of cancers were calculated to compare the cancer incidence of thyroid cancer patients to the general population. The association of RAI dosage and cancer development was estimated using time-dependent analysis.
Results: After a median follow-up of 7.9 years, 617 SPM developed among 13,018 patients of thyroid cancer (79.3% females; n = 10,317), with a follow-up of 102,527 person-years. The median age of all thyroid cancer patients was 44 years, and the percentages of each age-of-diagnosis groups were 37.3% (n = 4,860), 43.6% (n = 5672), 17.4% (n = 2264), and 1.7% (n = 222) at age 20−39, 40−59, 60−79, and ⩾80 years, respectively. The SIR for all cancers was 1.46 [95% confidence interval (CI), 1.35–1.58], and increased with the duration of follow-up: 1.08 (95% CI, 0.69–1.61) at 0.5−1 years, 1.28 (95% CI, 1.12–1.46) at 1−5 years, and 1.47 (95% CI, 1.31–1.65) at ⩾5 years. The increased risks of SPM of lung and hematologic malignancies were significant in all patients [SIRs, 2.1 (95% CI, 1.70–2.58) and 2.83 (95% CI, 2.11–3.72)], in male patients [SIRs, 1.81 (95% CI, 1.20–2.62) and 2.67 (95% CI, 1.42–4.56)], and in female patients [SIRs, 2.26 (95% CI, 1.75–2.88) and 2.89 (95% CI, 2.05–3.97)]. The increased SPM that only observed in male patients included prostate (SIR, 2.47; 95% CI, 1.55–3.74) and bladder (SIR, 2.65; 95% CI, 1.37–4.63). The increased SPM that only observed in female patients included head and neck (SIR, 1.78; 95% CI, 1.07–2.78), colon and rectum (SIR, 1.42; 95% CI, 1.09–1.82), and breast (SIR, 1.46; 95% CI, 1.22–1.74). As a time-dependent covariate with a 2-year latency period, RAI significantly increased risk of hematologic malignancies (age- and sex-adjusted hazard ratio, 1.005; 95% CI, 1.002–1.007, *P*=.001) with a clear dose-response correlation (shown in the table). This effect was not seen in other SPM.
Conclusions: Our study finds an increased SPM risk among thyroid cancer patients receiving RAI, and the significantly increased SPM risks of lung and hematologic malignancies are observed in both genders. RAI increases the risk of hematologic malignancies with a clear dose-response effect.
No conflict of interest.

RAI dosage	Hazard ratio	95% CI	*P* value
100 mCi	2.959	1.047–5.358	0.041
200 mCi	5.455	1.813–16.408	0.003

3183 POSTER

Pre-treatment EBV DNA differentiates different stages of undifferentiated carcinoma of the nasopharynx

V. Lee[1], D.L.W. Kwong[1], K.O. Lam[1], D.K.C. Leung[1], P.P.Y. Ho[1], Y.T. Cheung[1], S.Y. Wong[1], J.W.H. Tsang[1], T.W. Leung[1]. *[1]The University of Hong Kong, Clinical Oncology, Hong Kong, Hong Kong*

Background: Nasopharyngeal carcinoma of undifferentiated type (NPC) is endemic in Southern China including Hong Kong. Previous meta-analysis showed that concurrent chemoradiation conferred a better survival for stage III or above disease than radiotherapy alone. EBV DNA is the most accurate tumour marker for diagnosis and treatment response monitoring of NPC. We investigated if pre-treatment EBV DNA correlates with different stages of NPC in a prospective cohort of Chinese population.
Material and Methods: A total of 228 out of 249 consecutive patients with untreated histologically confirmed NPC had pre-treatment serum EBV DNA taken which was analysed by RT-PCR. The results were compared among different stage stratification according to AJCC 7th edition by independent sample t-tests.
Results: The distribution of stage of NPC in our patients was as follows: I=14 (6.1%); II=24 (10.5%); III=109 (47.8%), IVA/B=63 (27.6%) and IVC=18 (7.9%) patients. Overall sensitivity of EBV DNA was 91.7%. EBV DNA sensitivity for stage I, II, III, IVA/B and IVC were 35.7%, 87.5%, 93.6%, 100% and 100% respectively. Table 1 showed the mean EBV DNA for every stage of NPC. EBV DNA of stage IVC disease was higher than stage IVA/B (p = 0.053), which was higher than stage III (p = 0.026), which was higher than stage II (p = 0.019), which in turn was higher than stage I disease (p = 0.008). There was no difference in EBV DNA between stage IVA (16437 copies/ml) and IVB (62902 copies/ml, p = 0.202). When stratifying NPC into locally advanced vs early-stage disease, Stage III to IVB has higher EBV DNA (20327 copies/ml) than stage I to II (mean 1749 copies/ml, p = 0.012). Within stage III disease, there was no difference in EBV DNA between T3N0 (9417 copies/ml, 8 patients) and non-T3N0 disease (7852 copies/ml, 100 patients, p = 0.839).
Conclusions: Pre-treatment EBV DNA enabled us to differentiate different stages of newly diagnosed NPC. However it may not be sensitive enough for stage I disease.
Acknowledgment: This study was supported by SK Yee Medical Foundation (Project number 210212).
No conflict of interest.

Table 1. Pre-treatment EBV DNA among different stages of NPC

	Stage distribution of NPC patients according to AJCC classification 7th edition (N = 228)				
	I (n = 14)	II (n = 24)	III (n = 109)	IVAB (n = 63)	IVC (n = 18)
EBV DNA (copies/ml, mean)	26	2753	7968	41513	4449256

3184 POSTER

Cochrane review: Effectiveness of psychosocial interventions for patients with head and neck cancer

C. Semple[1], K. Parahoo[2], A. Bessell[3], E. McCaughan[2], G. Humphris[4], M. Mills[5]. *[1]The Ulster Hospital, Cancer Services, Belfast N. Ireland, United Kingdom; [2]University of Ulster, Institute of Nursing and Health Research, N. Ireland, United Kingdom; [3]University of Plymouth, Health Psychology, Plymouth, United Kingdom; [4]University of St. Andrews, School of Medicine, Fife, United Kingdom; [5]Northern Health & Social Care Trust, Cancer Services, Antrim N. Ireland, United Kingdom*

Background: A diagnosis of head and neck cancer, like many other cancers, can lead to significant psychosocial distress. Patients with head and neck cancer can have very specific needs, due to both the location of their disease and the impact of treatment, which can interfere with basic day-to-day activities such as eating, speaking and breathing. There is a lack of clarity on the effectiveness of the interventions developed to address the psychosocial distress experienced by patients living with head and neck cancer. The objective of this systematic review was to assess the effectiveness of psychosocial interventions to improve quality of life and psychosocial well-being for patients with head and neck cancer.
Methods: Electronic searches were conducted in the Cochrane Ear, Nose and Throat Disorders Group Trials Register; the Cochrane Central Register of Controlled Trials (CENTRAL); PubMed; EMBASE; CINAHL; Web of Science; BIOSIS Previews; Cambridge Scientific Abstracts; ICTRP; and additional sources for published and unpublished trials up to 17 December 2012. Two review authors independently selected trials, extracted data and assessed the risk of bias, with mediation from a third author where required.
Results: Seven trials, totalling 542 participants, met the eligibility criteria. Studies varied widely on risk of bias, interventions used, and outcome measures reported. From these studies, there was no evidence to suggest that psychosocial intervention promotes global quality of life for patients with head and neck cancer at end of intervention (MD 1.23, 95% CI −5.82 to 8.27) as measured by the EORTC QLQ-C30. This quality of life tool includes five functional scales, namely cognitive, physical, emotional, social and role. There was no evidence to demonstrate that psychosocial intervention provides an immediate or medium-term improvement on any of these five functional scales. From the data available, there was no significant change in levels of anxiety (SMD −0.09, 95% CI −0.40 to 0.23) or depression following intervention (SMD −0.03, 95% CI −0.29 to 0.19). At present, there is insufficient evidence to refute or support the effectiveness of psychosocial intervention for patients with head and neck cancer.

Conclusion: Evidence for psychosocial interventions is limited by the small number of studies, methodological shortcomings and difficulties with comparability between types of intervention, and a range of outcome measures used. Future good quality research is required in this field and should target those in need of psychosocial intervention, in order to guide service development.
No conflict of interest.

3185 POSTER

Gastrostomy use and weight loss in patients treated for head & neck cancer

V. Law[1], D. Holyoake[2]. [1]*Cambridge University Hospitals NHS Foundation Trust, Nutrition & Dietetics, Cambridge, United Kingdom;* [2]*Cambridge University Hospitals NHS Foundation Trust, Clinical Oncology, Cambridge, United Kingdom*

Background: National guidance recommends gastrostomy placement prior to treatment for head & neck cancer if it is likely to cause problems with eating. We collected data on practice and outcomes in our centre.
Materials and Methods: Clinical data was collected retrospectively on all 66 patients with head and neck cancer that required gastrostomy placement at Cambridge University Hospitals between January 2010 and December 2011.
Results: The age range of patients was 38−76 (median 57), while 47 were male and 19 female. The majority (52/66−79%) received radiotherapy with concomitant chemotherapy for oropharyngeal squamous cell carcinoma (SCC). Percutaneous Endoscopic Gastrostomy (PEG) was placed, using the push method, for all but one patient (who underwent a Radiologically Inserted Gastrostomy procedure). In all but one case gastrostomy was performed prior to commencing radiotherapy.
91% of patients used their gastrostomy for feeding. 74% of patients had their gastrostomy removed less than 6 months after treatment and 91% were removed within 12 months. 44% of patients lost 5−10% of their starting weight during treatment and 33% lost over 10%. 30% of patients were admitted during treatment but only 10% of these admissions were primarily due to problems with nutrition. Possible gastrostomy site infections were recorded in 26% of patients. Staphlococcous aureus (53%) and pseudomonas (6%) were the commonest causal pathogens identified.
Conclusions: The main indication for head & neck cancer patients to require feeding gastrostomy was elective placement prior to concomitant chemoradiation for Oropharyngeal SCC. Despite tube placement most patients lost weight and gastrostomy site infections were not uncommon. Almost a third of patients required a hospital admission during treatment but not usually primarily due to nutrition problems. Average time on PEG feeding was short with the few patients requiring nutrition via their gastrostomy beyond one year after treatment. Ongoing further work will collect comparable data from other centres in our network.
No conflict of interest.

3186 POSTER

Impact of aprepitant on emesis control, dose intensity (DI) and recurrence free survival (RFS) in head and neck cancer patients (HNC) receiving high dose cisplatin chemotherapy

G. Dranitsaris[1], S. Makarenko[2], R. Peixoto[2], W.Y. Cheung[2]. [1]*Consultant Statistician, Outcomes Research, Toronto, Canada;* [2]*British Columbia Cancer Agency, Division of Medical Oncology, Vancouver, Canada*

Background: The standard of care for locally advanced HNC patients consists of three cycles of high dose cisplatin (>75 mg/m^2) administered concurrently with radiation. The intent of treatment is the prolongation of RFS. However, poorly controlled emesis can compromise maximum DI, which could affect disease control. In this observational study, the impact of aprepitant therapy on emesis control, DI and RFS is described.
Methods: A retrospective analysis of 192 HNC patients treated within the British Columbia Cancer Agency was conducted. Within this sample, 141 patients received aprepitant prophylaxis compared to 51 patients who did not. RFS was evaluated using Kaplan–Meier methods and adjusted Cox proportional hazard models. To control for selection bias, a propensity score analysis was incorporated into the Cox regression models.
Results: Patients between groups were comparable with respect to mean age (56.3 vs. 58.1), male gender (82.3% vs. 86.3%), tumour location and number of metastatic sites (median = 1). However, more patients in the aprepitant group had surgically resectable disease (31.2% vs. 15.7%) and had a better performance status (PS 0/1 = 87.9% vs. 76.4%). Less emesis was reported in aprepitant patients (21.3% vs. 28.0%) and they were more likely to complete three full cycles of high dose cisplatin (OR = 2.3, p = 0.03). The propensity score adjusted Cox regression analysis suggested a reduced risk for disease recurrence in patients who received aprepitant (HR = 0.47, [95% CI: 0.17 to 1.28]). However, there was no indication by the magnitude of the 95% CI that a difference existed in overall survival between groups (HR = 1.29, [95% CI: 0.36 to 4.6]).
Conclusion: In this observational study, aprepitant antiemetic therapy contributed to improved emesis control, enhanced DI and was associated with a reduction in disease relapse. These findings warrant further investigation in a larger sample of patients.
No conflict of interest.

Metabolic therapy with iodine-131: Removal of the radioisotope and duration of the radiation protection recommendations

I. Castro Ramirez[1], L.A. Quiñones Rodriguez[1], M.A. Iborra Oquendo[1], A. Seguro Fernandez[1]. [1]*Hospital Puerta Del Mar, UGC Radiofisica y P.R., Cadiz, Spain*

Background: The aim of this paper is to analyze the length of the radiation protection recommendations that are delivered to the patient at the time of radiologic discharge, taking into account the treatment duration, radiopharmaceutical dose, time of admission, the dose rate measured at one meter and family environment among others.
Material and Methods: We have available data for more than 100 patients treated in our hospital, both thyroid cancer or hyperthyroidism during the years 2011 and 2013 and with activities ranging from 100 to 200 mCi.
We consider here the value of the measured dose rate at one meter in two different times: the day of discharge and the tracking day (performed to search for thyroid remnants or metastasis). In this regard, we analyze the removal of radioisotope based on the remnant radiation and, therefore, it is possible to adapt the radiation protection recommendations taking into account the new measurement.
Results: Applying discharge criteria of patients and measures for the radiation protection of the public after treatment with iodine 131 metabolic Radiological Protection Forum in the health, based on the IAEA-63, we get a noticeable difference in the duration of restrictions of 8.3±4.1 for 100 mCi, 10.7±4.1 for 150 mCi and 11.1±4.4 for 200 mCi days if we consider measures to discharge or subsequent tracking.

	Mean difference (days)	Standard deviation (days)
100 mCi	8.3	4.1
150 mCi	10.7	4.1
200 mCi	11.1	4.4
Complete	10.2	4.3

Conclusions: This study demonstrates the usefulness of monitoring patients when they come to the hospital to make the tracking, greatly reducing the time to follow the radiation protection recommendations to avoid unnecessary exposure of other people, the time to return to work, going to shows, traveling by public transport, etc.
In the same way, the duration of the recommendations appear to be almost independent of the administered dose.
It seems clear that the values of the recommendations adopted in Spain from the 'Safety Report Series No. 63' IAEA, can be optimized if updated measurements of the dose rate and therefore the time duration of the radiation protection recommendations considered.
No conflict of interest.

3188 POSTER

A proposed new model of follow-up for patients with head and neck cancer

C. Semple[1], D. Lannon[2], E. Qudairat[3], R. McCormac[1], W. Boydcarson[1], C. Lynas[2], E. McCaughan[4], M. Waldon[4]. [1]*The Ulster Hospital, Cancer Services, Belfast N. Ireland, United Kingdom;* [2]*The Ulster Hospital, Plastic Surgery, Belfast N. Ireland, United Kingdom;* [3]*The Ulster Hospital, Maxillofacial Surgery, Belfast N. Ireland, United Kingdom;* [4]*University of Ulster, Institute of Nursing & Health Research, N. Ireland, United Kingdom*

Background: Over two million people are living with cancer in the United Kingdom, of which 51,000 live in Northern Ireland. The number of cancer survivors is growing by over 3% per year. If this trend continues there will be 4 million cancer survivors by 2030, adding to the ever increasing demands on time and resources within the NHS.
Traditionally, most patients experience the 'one size fits all' medical approach to clinical follow-up with the focus on monitoring for signs and symptoms of recurrence. There is much debate over the efficacy of this practice as patients themselves detect many recurrences between scheduled follow-up visits.
Aim: Implement and evaluate a new model of follow-up clinic, which will incorporate the completion of UWQOLv4 and PCI on touchscreen computer.

Objectives:
- To evaluate the patients' satisfaction with the new follow-up clinic
- To examine the impact of using a HRQOL questionnaire and problem concern checklist at follow-up clinic on QOL and empowerment
- To explore the feasibility of using touch screen assessments in routine follow-up clinics from the clinician's perspective.

Methods: A mixed methodology of both quantitative and qualitative approaches will be used.

A − First post-treatment visit − baseline:
i. Informed consent
ii. Consultation in its current format
iii. After consultation completion of:
  – UWQOLv4 & PCI
  – Exit Interview Checklist
  – Patient Enablement Instrument

B − Second post-treatment visit − intervention:
i. Prior to consultation completion of UWQOL & PCI
ii. Information used to focus consultation
iii. After Consultation completion of
  – Exit Interview Checklist
  – Patient Enablement Checklist
  – Patient satisfaction with new model of follow-up care

Evaluating process of care will include the review of clinical letters to ascertain the type and number of onward referrals and a proforma to collate information on the detection of HNC recurrence.

Clinicians' perspectives One-to-one semi-structured interviews focusing on suitability of using touchscreen computers in the routine follow-up, quality of the information gathered and clinical relevance of information.

No conflict of interest.

3189 POSTER

Locally advanced nasopharyngeal carcinoma in the Algerian West: Outcomes and prognostic factors in a cohort of 180 cases

A. Boukerche[1], R. Madouri[1], S. Boumediene[2], M. Yamouni[3], A.F. Dali-Youcef[1]. *[1]CHUOran/Faculty of Medicine − University of Oran, Radiation Oncology, Oran, Algeria; [2]CHUOran, Radiation Oncology, Oran, Algeria; [3]CHUOran/Faculty of Medicine − University of Oran, Medical Oncology, Oran, Algeria*

Background: The objective of this study was to analyze the clinical and therapeutic aspects, long-term outcome and determine the prognostic factors of locally advanced nasopharyngeal carcinoma (LANPC) in the west of Algeria.

Patients et methods: This is a study including 180 patients who had histopathologically confirmed LANPC treated in our department between 2002 and 2005. Survival rates were estimated using the Kaplan–Meier method. Univariate and multivariate analyses were performed using the Cox proportional hazards regression models.

Results: There were 123 males and 57 females with a mean age of 39.9±1.1 years (Range 12−73). Stage III, IVA and IVB (UICC2002) were 62, 56 and 62 respectively. 87 patients received induction chemotherapy platinum-based (with docetaxel, 5 fluorouracil or epirubicin) followed by radiotherapy (CT/RT) and 93 concomitant chemo-radiotherapy (CCRT). 8-years locoregional control (LRC), disease free survival (DFS) and overall survival (OS) rates were: 82% (±3%), 57.6% (±3.7%) et 77% (±3.6%), respectively. In univariate analysis, age>40 years ($p = 0.03$), T3−4 ($p = 0.04$) showed poor prognosis for LRC; stage IV ($p = 0.03$) for DFS; age >40 years ($p = 0.05$), stage IV ($p = 0.01$) and CT/RT ($p<10^{-3}$) for OS respectively. In a multivariate analysis, independent prognostic factors were: age (>40 years vs ⩽40 years) [$p = 0.07$] and Tumor (T3−4 vs T1−2) [$p = 0.09$] for LRC; Stage (IV vs II/III) for DFS ($p = 0.06$) and OS ($p = 0.07$), Treatment (CT/RT vs CCRT) for OS ($p = 0.001$).

Conclusion: The therapeutic results of our series seem satisfactory, however an optimization of the association of the chemotherapy and the radiotherapy in concomitant is necessary to have a better therapeutic index especially for the patients aged >40 years and stages IV of disease.

No conflict of interest.

3190 POSTER

Nasopharyngeal carcinoma in young patients in the Algerian West: About 92 cases

A. Boukerche[1], R. Madouri[1], M. Yamouni[2], A.F. Dali-Youcef[1]. *[1]CHU Oran Faculty of Medicine University of Oran, Department of Radiation Oncology, Oran, Algeria; [2]CHU Oran Faculty of Medicine University of Oran, Department of Medical Oncology, Oran, Algeria*

Background: The objective of this study was to discuss the clinical feature, long-term outcome and determine the prognostic factors of nasopharyngeal carcinoma (NPC) in young patients (paediatric patients and young adults), in the west of Algeria.

Patients and Methods: Data were collected from 92 patients ⩽40 years diagnosed with NPC and treated at our department between 2002 and 2005. Survival rates were estimated using the Kaplan–Meier method. Univariate and multivariate analyses were performed using the Log rank test and Cox proportional hazards regression models respectively.

Results: There were 57 males (62%) and 35 females (38%). The mean age was 26.4±0.8 years (Range12−40). We have found: 3 T1 (3.3%), 31 T2 (33.7%), 34 T3 (37%), 24 T4 (26.1); 16 N0 (17.4%), 19 N1 (20.7%), 24 N2 (26.1%), 33 N3 (35.9%). Stage II, III and IV (UICC2002) were 7.6%, 37% and 55.4% respectively. It was undifferentiated carcinoma in 94.6% of cases and WHO type1 or 2 in 5.4%. 40 (43.5%) patients received induction chemotherapy platinum-based (with docetaxel, 5 fluorouracil or epirubicin) followed by radiotherapy (CT/RT) and 52 (56.5%) concomitant chemo-radiotherapy (CCRT). After a median follow-up of 72 months (range 10–106), 37 patients (40.2%) developed recurrences (locoregional and/or distant metastasis). 8-years locoregional control (LRC), disease free survival (DFS) and overall survival (OS) rates were: 89% (±3.5%), 58.9% (±5.2%) and 81.9% (±5.1%), respectively. Only treatment (CT/RT, CCRT) have an influence on OS in univariate ($p = 0.02$) and multivariate analysis ($p = 0.07$ − HR: 0.571).

Conclusion: This study shows that the NPC in patient 40 years old or younger, in the Algerian west is diagnosed at advanced stage with acceptable long term outcome. Another therapeutic sequence associated to the concurrent chemoradiotherapy seems necessary to improve our results.

No conflict of interest.

3191 POSTER

Serum alkaline phosphatase predicts survival outcomes in patients with nasopharyngeal carcinoma and bone metastasis

Y. Jin[1], Y.P. Zhang[1], M.Q. Yuan[1]. *[1]Zhejiang Cancer Hospital, Department of Medical Oncology, Hangzhou, China*

Background: Bone metastasis is a frequent event of nasopharyngeal carcinoma (NPC) with a potential for complications such as pain, hypercalcaemia and pathologic fractures. The diagnosis and follow-up of bone metastatic patients usually relies on skeletal X-ray and bone scintigraphy which are time-consuming and costly. This study aims to evaluate whether serum alkaline phosphatase (S-ALP) has a clinical value in predicting clinical response and survival outcome for patients with NPC and metastatic bone disease.

Material and Methods: S-ALP level were measured at baseline and then before every cycle of treatment in 416 NPC patients with bone metastasis admitted to Zhejiang Cancer Hospital between January 2000 and December 2011. Correlations of pre-treatment and post-treatment S-ALP levels to treatment efficacy were analysed using the Chi-Square test. Survivals were analysed using the Kaplan–Meier method and were compared using the log-rank test. Univariate and multivariable analyses were performed using the Cox proportion hazards model.

Results: Patients with elevated values of pre-treatment S-ALP (>110IU/L) had significantly worse progression-free survival ($P<0.001$) and overall survival ($P<0.001$) than those with normal values of pre-treatment S-ALP (⩽110IU/L). Patients with elevated values of post-treatment S-ALP had worse progression-free survival ($P<0.001$) and overall survival ($P<0.001$) compared with those with normal values of post-treatment S-ALP. Patients with normal values of pre-treatment and post-treatment S-ALP showed the the most favourable prognosis. The Cox multivariate analysis identified that only pre-treatment S-ALP level (HR=1.794,P<0.001)and post-treatment S-ALP level (HR=2.657,P<0.001) were independent prognostic factors for overall survival.

Conclusion: S-ALP appears to be a significant independent prognostic index in NPC patients with bone metastatic involvement, which could reflect the short-term treatment response of palliative chemotherapy as well as the long-term survival outcomes.

No conflict of interest.

3192 POSTER

Institutional experience of RADPLAT for advanced maxillary cancer

Y. Asada[1], W. Matsumoto[2], K. Matsuura[3], T. Imai[3], D. Saitoh[3], K. Watanabe[3], R. Sadayasu[3]. *[1]Miyagi Cancer Center, Natori, Japan; [2]Miyagi Cancer Center, Radiology, Natori, Japan; [3]Miyagi Cancer Center, Head and Neck Surgery, Natori, Japan*

Background: Originally devised by Robbins et al. RADPLAT or intra-arterial chemotherapy for head and neck squamous cell carcinomas using cis-diamminedichloroplatinum (CDDP) with concurrent radiotherapy has led to participation of some Japanese facilities in this new treatment. While there have been some reports on feasibility and efficacy of this treatment,

the regimen of RADPLAT is yet to be established. The purpose of the present study was to evaluate our modified RADPLAT in terms of its feasibility and short-term the efficacy.
Methods: Between 2008 and 2012, we treated 20 patients (18 male and 2 female with a median age of 66 years old; range 55−78) with T4 (15 patients with T4a, 5 patients with T4b) squamous cell carcinoma of maxillary antrum. Eight patients (two N1 patients, five N2b patients, and 1 N2c patient) had lymph node metastasis. The treatment consisted of intra-arterial infusion of CDDP(150–200 mg/body, weekly for 7 weeks) combined with simultaneous intravenous administration of sodium thiosulfate (30−40 g/body) and concurrent radiotherapy (70 Gy, 2.0 Gy/fraction, daily for 5 days over 7 weeks).
Results: Apart from one patient, in whom radiotherapy was interrupted for 14 days because of the Great East Japan Earthquake, full-dose irradiation could be performed in 19 patients without interruptions. Seven IA infusions of CDDP was possible as planned, whereas in some cases fewer infusions were conceded sufficient because there was anticipated effect on the tumor. All in all, RADPLAT was feasible in 17 patients (85%). There were three patients who did not attain the planned IA infusions. The reasons for the failure were that lung metastasis was found during the treatment in one patient and the remaining two ejected the treat ment because of the patient's social problem or the fatigue and lassitude related to RADPLAT. Average total dosage of CDDP was 1236 mg. Maximum CDDP dosage per infusion was ranging from 109 mg/m^2 to 148 mg/m^2. Major adverse events (grade 3 or higher) were only mucositis and nausea. No grade 4 toxicity was observed. The rates of grade 3 mucositis were 45%(9 patients). Grade 3 nausea was observed in six patients (30%) The complete response (CR) rate was 85%. At a median follow-up of 1.1 years (range, 0.2 to 4.6 years), the estimated 1-year and 2-year locoregional tumor control rates are 72% and 63%, respectively.
Comclusions: Despite being a single-institution experience, the results of the current study suggest that our intensive treatment regimen of RADPLAT for advanced maxillary cancer is feasible and efficacious.
No conflict of interest.

3193 POSTER

The evaluation proinflamatory cytokine levels in thyroid papillary carcinoma

F. Kosova[1], G. Kismali[2], B. Cetin[3], M. Akinci[4], T. Sel[2], O. Uyar[3].
[1]Celal Bayar University, Biochemistry, Manisa, Turkey; [2]Ankara University, Biochemistry, Ankara, Turkey; [3]Ankara Oncology Hospital, General Surgery, Ankara, Turkey; [4]Diskapi Yildirim Beyazit Hospital, General Surgery, Ankara, Turkey

Background: Cytokines are secreted or membrane-bound proteins that regulate the growth, differentiation and activation of immune cells. The cellular alterations that give rise to cancer provoke changes in local cytokine expression. Cancer-related inflammation recently has been proposed as a major physiological hallmark of malignancy and has important value in diagnosis, treatment, and prognosis. The aim of this study was to investigate pro-inflammatory cytokine levels IL-1β, IL-6, IL-8 and Neopterin levels in thyroid papillary carcinoma (TPC) patients before and after treatment.
Material and Methods: Thirty-nine female TPC patients before treatment and 31 female TPC patient's after treatment sera were recruited for the study. TPC was diagnosed by fine needle aspiration biopsy. TPC patients had a bilateral total thyroidectomy operation and serum IL-1β, IL-6, IL-8 and Neopterin levels were evaluated before and 20 days after the operation with ELISA.
Results: There were no significant differences on Nepterin levels between the before and after treatment ($P > 0.05$). However, IL-1 β and IL-8 levels were detected statistically importantly high after treatment but IL-6 serum levels were significantly decreased in patients after treatment.
Conclusions: Assessment of serum IL-6, IL-8 and IL-1 β levels can be performed in patients with TPC. They can be considered as both diagnostic and prognostic biomarkers.
No conflict of interest.

3194 POSTER

Analysis of the solitary pulmonary nodule on FDG-PET/CT in patients with head and neck cancers

H. Song[1], G. Jang[2], J.H. Kwon[2], H.J. Kim[3], J.H. Kim[2], D.R. Choi[4], J.Y. Jung[5]. *[1]Kangdong Sacred Heart Hospital College of Medicine Hallym University, Seoul, Korea; [2]Kangdong Sacred Heart Hospital College of Medicine Hallym University, Internal Medicine, Seoul, Korea; [3]Hallym Sacred Heart Hospital College of Medicine Hallym University, Internal Medicine, Anyang, Korea; [4]Chuncheon Sacred Heart Hospital College of Medicine Hallym University, Internal Medicine, Chuncheon, Korea; [5]Dongtan Sacred Heart Hospital College of Medicine Hallym University, Internal Medicine, Hwaseong, Korea*

Background: This study was conducted to determine the accuracy of FDG-PET/CT for characterization of solitary pulmonary nodules (SPNs) in the patients with head and neck cancer.
Material and Methods: A total of 457 patients with head and neck cancer except thyroid cancer and lymphoma treated at Kangdong Sacred Heart Hospital from January 2009 to December 2012 and performed FDG-PET/CT as initial staging work up or follow-up exam. were screened. We retrospectively analyzed the 40 patients who had SPNs. Thirty of them had squamous cell carcinoma, 4 adenoid cystic carcinoma (ADCC), and 6 other type of malignancy.
Results: Ten patients were assumed to have solitary metastasis; 5 confirmed by biopsy, 5 aggravated by follow-up exam. Five of them had squamous cell carcinoma, 4 adenoid cystic carcinoma, and 1 adenocarcinoma. One patient had another malignancy in the lung. The median value of the SUVmax for malignancy was 2.95 (0.4−8.2). Ten of them had hypermetabolic SPNs and one non-hypermetabolic lesion (ADCC). Three of metastatic squamous cell cancer were performed resection and have been alive for 9, 25.5, 31 months without recurrent tumor. Among benign SPNs, 4 patients had pulmonary tuberculosis; 2 confirmed by biopsy, 2 by laboratory test. All of them had hypermetabolic SPNs. The median value of the SUVmax was 3.9 (3.4−9.3). Twenty three had other benign inflammatory SPNs, however 14 patients had hypermetabolic SPNs (median SUVmax. 2.8, range 1.6−8.1). There was no significant difference in SUVmax between malignant and benign hypermetabolic SPNs ($p = 0.773$).
Conclusions: FDG-PET/CT was not sensitive and specific, and not the best method to identify the SPN in the patient with malignancy. There was no significant difference in SUVmax between the malignant SPN and benign inflammatory SPN in the FDG-PET/CT. Early tissue diagnosis or careful follow-up exam could help in relevant treatment.
No conflict of interest.

3195 POSTER

Esthesioneuroblastoma: The 15-year experience of a Cancer Institute

D. Costa[1], C. Costa[2], P. Winckler[1], I. Sargento[1], M. Ferreira[1], A. Moreira[1]. *[1]Instituto Portugues de Oncologia Francisco Gentil Lisboa, Medical Oncology, Lisboa, Portugal; [2]Instituto Portugues de Oncologia Francisco Gentil Lisboa, Heamatology, Lisboa, Portugal*

Background: Esthesioneuroblastoma (ENB) is a cancer originating from olfactory neuroepithelium, with an estimated incidence of 4 cases per 10 million individuals. ENB displays wide range of biologic activity from indolent growth to a highly aggressive behaviour capable of fast widespread metastization. Etiology, optimal staging system and treatment modalities vary according to different authors. The prognosis depends on the extension of the disease at diagnosis. We present a series of patients (pts) from a single cancer center.
Material and Methods: 15-year (1998–2012) retrospective cohort analysis was performed on pts with histologically confirmed ENB, followed at the Instituto Português de Oncologia de Lisboa. The Kaplan–Meier analysis was used to estimate and compare survival and progression rates.
Results: 17 pts were evaluated with a median age of 60 years (range 18−83), 9 males and 8 females. The median time between the first symptom and the definitive diagnosis was 6 months. 10 pts were treated with surgery and radiotherapy, 3 with radiotherapy, 2 with surgery, radiotherapy and chemotherapy, 1 with chemotherapy and 1 with surgery alone. The median follow-up and overall survival was 11.6 months (range 1.7 to 160 months) and 79.1 months, respectively. According to the modified Kadish staging system, 7 pts were in the low risk group (A-B) and 10 pts in the high risk group (C-D). Among the high risk pts, median overall survival was 10.5 months (95% confidence interval 6.35–14.64); only one patient from the first group died (median overall survival not reached), $p < 0.052$. All ($n = 8$) except one of the pts died within the first year of follow-up. The median overall progression free survival was 31.3 months and was worse for the high risk group (9.5 months, 95% confidence interval, 3.49–15.64, $p < 0.053$).

Conclusions: ENB is an uncommon malignant tumour. An accurate and rapid histological evaluation allows for an early staging and is the key for planning the combined modality therapy. The presented results could gain more statistical significance with a higher sample size.
No conflict of interest.

3196 POSTER

DAHANCA 9 − a randomized multicenter study to compare accelerated normo-fractionated radiotherapy with accelerated hyperfractionated radiotherapy in patients with primary squamous cell carcinoma of the head and neck

J.F. Evensen[1], H.S. Hansen[2], M. Overgaard[3], J. Johansen[4], L.J. Andersen[5], J. Overgaard[6]. *[1]Oslo University Hospital, 1Norwegian Radium Hospital, Oslo, Norway; [2]Rigshospitalet, Finsen Centre Dept of Oncology, Copenhagen, Denmark; [3]Aarhus University Hospital, Dept of Oncology, Aarhus, Denmark; [4]Odense University Hospital, Dept of Oncology, Odense, Denmark; [5]Aalborg University Hospital, Dept of Oncology, Aalborg, Denmark; [6]Aarhus University Hospital, Dept of Exp Clinical Oncology, Aarhus, Denmark*

Background and Aim: Based on the experience from the DAHANCA 5 trial, which showed the benefit of the hypoxic sensitizer Nimorazole, and the DAHANCA 6&7 trial, which demonstrated superiority of accelerated fractionation, the study was designed to evaluate in an randomized trial if the use of accelerated hyperfractionated radiotherapy (to a higher total dose) was feasible and superior to normo-fractionated accelerated fractionation. Both regimes being supplemented with the hypoxic radiosensitizer Nimorazole.
Patients and methods: Pts with squamous cell carcinoma of the larynx (except glottis St.I), pharynx or oral cavity (HNSCC) eligible for primary radiotherapy alone were randomized to receive accelerated hyperfractionated radiotherapy with 76 Gy in 56 fx with 10 fx per week or accelerated fractionation with 66−68 Gy in 33−34 fractions given with 6 fx per week.All patients were also treated with the hypoxic radiosensitizer Nimorazole. Patients were recruited from Danish Oncological Centers and from the Norwegian Radium Hospital in Oslo.
Results: The trial was planned for a total of 1,000 patients. It was, however, introduced at a time were radiotherapy resources was limited in Scandinavia, and thus, a hyperfractionated regime demanding more treatments was difficult to implement. Consequently was the trial stopped prematurely. In total, 77 patients patients were randomized between 2000–2004. The median follow-up time was 73 months (range 1–151). All patients were eligible for analysis (41 pts treated with hyperfractionation (hyperfx) and 36 pts with acceleration only (control). The patients were evenly distributed according to the stratification parameters (gender, T and N stage, tumor site).
The compliance to the treatment was good and only 2 pts did not complete treatment due to early death (one in each arm).
Overall, the results showed no significant difference in 5-year actuarial loco-regional control (71% vs. 69% (p = 0.74, HR: 0.86 [0.34–2.17])) for the hyperfx vs. control arm, respectively. This was also seen for the endpoint of disease-specific survival (83% vs. 71% for hyperfx vs. control, respectively, p = 0.20, HR: 0.52 [0.19–1.44]). Overall survival was indistinguishable HR: 1.05 [0.54–2.04]). Despite the difference in total dose, we did not observe significant differences in neither acute, nor late radiation related morbidity.
Conclusion: Hyperfractionated accelerated raditotherapy to HNSCC was a feasible treatment and suggested at better outcome than conventional accecerated radiotherapy. However, the study was closed prematurely due to lack of sufficient radiotherapy resources.
Supported by grants from the Danish Cancer Society.
No conflict of interest.

3197 POSTER

Volumetric stratification of cT4 stage head neck cancer

G. Studer[1], C. Glanzmann[1]. *[1]University Hospital Zürich, Radiation Oncology, Zürich, Switzerland*

Background: Advanced stage head neck cancer (HNC) is known for generally unfavorable outcome with only ~40−50% 3-year overall survival (OAS). Clinical T4 stage includes a wide range of tumor burden. The lack of further subgrouping of cT4 stage makes inter-center comparison of outcome results in irradiated cT4 cohorts difficult. In addition, in- or exclusion of very advanced cT4 anyNM0 into curatively aimed treatment regimens remains quite subjective.
Aim of this analysis was to further stratify cT4 stage HNC disease using volumetric staging. Included in the presented analysis were all cT4 stage HNC patients referred to our center for definitive radiation.
Material and Methods: Between 01/2002 and 05/2012, 202 cT4 stage HNC patients have curatively been irradiated. Radiation was performed using modulated radiation techniques +/− concomitant systemic therapy. All patients have retrospectively been stratified using a prospectively evaluated volumetric staging system which bases on 3 cut offs (15/70/130cc, see also former publications 2007//08/11/12) to stratify the total gross tumor volumes (tGTV: primary and nodal tumor volume), allowing a subdivision of cT4 into 4 prognostic subgroups (V1: 1−15cc (n = 17), V2: 16−70cc (n = 108), V3: 71–130cc (n = 61), V4: >130cc (n = 16)). OAS, disease free survival (DFS), loco-regional control (LRC) and distant metastasis free survival (DMFS) rates were calculated (Kaplan Meier curves).
Results: The mean follow up was 31 months (1–113). 3-year OAS, DFS, LRC and DMFS rates of the entire cohort were 73%, 54%, 61%, and 81%, respectively. Volumetric staging revealed its potential to prognostically statistically significantly divide the cT4 cohort into 4 volume subgroups (V1/V2/V3/V4), see the table.
Conclusion: Volumetric staging allowed a highly statistically significant stratification of cT4 HNC stages into prognostic subgroups, which offers the chance of better inter-center comparability of irradiated advanced stage HNC cohorts.
No conflict of interest.

cT4 (N = 202)	n (%)	3-year survival rate (%)			
		LRC	DMFS	DFS	OAS
V1 (1−15cc)	17 (7%)	92	93	83	90
V2 (16−70cc)	108 (64%)	70	85	52	72
V3 (71–130cc)	61 (21%)	61	68	42	60
V4 (>130cc)	16 (8%)	32	47	12	18
p-value	–	<0.0001	<0.0001	<0.0001	<0.0001

3198 POSTER

Changes in brain white matter diffusion tensor imaging indices following radiotherapy for head & neck cancer

L.C. Welsh[1], C. Powell[2], M. Schmidt[2], M. Borri[2], D.M. Koh[3], A. Riddell[3], S.A. Bhide[1], C.M. Nutting[2], M.O. Leach[4], K.L. Newbold[2]. *[1]The Institute of Cancer Research and The Royal Marsden Hospital NHS Foundation Trust, Head & Neck Unit, London, United Kingdom; [2]The Royal Marsden Hospital NHS Foundation Trust, Head & Neck Unit, London, United Kingdom; [3]The Royal Marsden Hospital NHS Foundation Trust, Department of Radiology, London, United Kingdom; [4]The Institute of Cancer Research, Division of Radiotherapy & Imaging, London, United Kingdom*

Background: Radical radiotherapy (RT) for head and neck cancer (HNC) by intensity modulated techniques typically results in radiation doses to adjacent brain tissues which may cause acute and chronic neurotoxicity. This study uses diffusion tensor imaging (DTI) to examine regional variation in brain white matter changes following RT for HNC.
Materials and Methods: Permission for the study was obtained from institutional review boards. Adult patients undergoing curative RT (with or without concomitant chemotherapy) for HNC, including primary radical and post-operative RT, were eligible. All patients gave written informed consent. Patients underwent DTI before, during (week 5) and after (2 and 6 months) RT. Changes in three DTI parameters over time were analysed: fractional anisotropy (FA), axial diffusivity (AD), and radial diffusivity (RD). Voxelwise statistical data analysis was carried out using tract-based spatial statistics as implemented in the FSL software suite.
Results: DTI data from 17 patients have been processed: 10 men, and 7 women, of median age 55 (range 27 to 68) years. Primary cancer sites were: 9 nasopharyngeal, 3 nasal cavity, 3 unknown primary, 2 para-nasal sinus. All patients experienced RT-related fatigue, to maximum grade 2 severity, but no other neurological symptoms. Changes in DTI parameters occurred in brain areas receiving the highest RT doses but did not correlate with RT dose, and the data provide evidence that brain white matter structures vary in their response to RT. Changes in DTI parameters were greatest at 2 months post-RT and included decreased FA in the left cingulum bundle.
Conclusions: Radical RT for HNC causes detectable brain white matter changes in specific regions as measured by DTI. Changes in DTI parameters following RT for HNC may reflect RT-induced disruption to specific brain white matter structures, including the cingulum. Such disruption may partly explain the acute fatigue noted in patients receiving RT for HNC, and may also relate to longer term neurocognitive side-effects. It may be possible to lessen such side effects by specifically limiting RT dose to brain regions identified as showing greatest changes in DTI parameters.
No conflict of interest.

N09C6 (Alliance) − a phase III, randomized double-blind study of doxepin rinse versus placebo in the treatment of acute oral mucositis pain: secondary analysis of the continuation phase

R. Miller[1], J. Leenstra[2], R. Qin[3], J. Martenson[1], K. Dornfeld[4], J. Bearden[5], D. Puri[6], P. Stella[7], R. Foote[1], C. Loprinzi[8]. [1]*Mayo Clinic Cancer Center, Radiation Oncology, Rochester Minnesota, USA;* [2]*Saint Vincent Hospital, Radiation Oncology, Green Bay Wisconsin, USA;* [3]*Mayo Clinic Cancer Center, Biostatistics, Rochester Minnesota, USA;* [4]*Essentia Health Duluth Clinic CCOP, Radiation Oncology, Duluth Minnesota, USA;* [5]*Spartanburg Regional Medical Center, Radiation Oncology, Spartanburg South Carolina, USA;* [6]*Mercy Cancer Center, Radiation Oncology, Des Moines Iowa, USA;* [7]*St. Joseph Mercy Health System, Radiation Oncology, Ann Arbor Michigan, USA;* [8]*Mayo Clinic Cancer Center, Medical Oncology, Rochester Minnesota, USA*

Background: Patients undergoing radiotherapy (RT) for head and neck (H&N) cancers often develop painful oral mucositis (OM), which may cause patient distress and lead to treatment interruptions.
Materials and Methods: N09C6 (Alliance), a Multi-Institutional Phase III randomized controlled trial with a cross-over phase and optional continuation phase compared a single dose of doxepin rinse (25 mg in 5 ml water) versus placebo rinse in patients with breakthrough OM pain rated $\geqslant$4 out of 10 (on a linear analog 0 to 10 scale) during H&N RT, with and without chemotherapy. Analysis of the primary endpoint demonstrated a modest benefit in the reduction of the AUC of patient reported OM pain over fours hour for doxepin (−9.1) over placebo (−4.7), p = 0.0003. Average pain reduction was 2.0 for Doxepin and 1.0 for placebo. This was confirmed in the single dose cross-over phase, AUC reduction for doxepin (−7.9) vs. placebo (−5.6), p = 0.009. (ASTRO Plenary 2012) Following completion of the cross-over, the study agents were unblinded and the patients were given the option of continuing doxepin rinse on as needed basis for pain, up to every four hours, during the remainder of RT until their OM pain resolved. A weekly questionnaire was administered to assess pain during the continuation phase.
Results: 155 patients were enrolled in the study between 12/17/2010 and 5/17/2012. 129 patients were evaluable for continuation of doxepin after the cross-over phase of the study. 81 patients (64%), p = 0.002, chose to receive doxepin in the continuation phase. 69 of 81 patients (86%) reported doxepin was helpful in alleviation of pain in the continuation phase. 14 of 81 (17%) patients discontinued doxepin before completion of RT − 2 because of pain improvement, 3 because of lack of pain relief, 8 because of side effects (drowsiness, stinging, or taste), and 7 because of other reasons.
Conclusions: The majority of patients completing the blinded portion of the study expressed a preference to continue the active study agent, with most patients reporting improvement in pain with use of doxepin. A minority of patients discontinued the drug due to side effects. Doxepin rinse provides superior pain relief in comparison to placebo rinse and should be considered as a breakthrough medication in addition to conventional analgesics.
No conflict of interest.

3200 POSTER

Effect of short course palliative radiotherapy (RT) for head and neck cancer: A prospective single institution quality of life (QoL) trial

K. Jensen[1], H.H. Schmidt[1], A.B. Jensen[1], C. Grau[1]. [1]*Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark*

Background: Almost every second patient with head and neck cancer treated with curative intent recur, additionally a substantial group of patients can not be treated with curative intend due to age or co-morbidity. A treatment option for these patients is palliative radiotherapy. There exist only limited knowledge about optimal dosage and outcome.
Material and Methods: 30 patients with a median age of 67, with cancer of the, oral cavity (7), pharynx (13), larynx (6) and other sites (2) were included in a prospective study of QoL during and after palliative RT using 20 Gy in 4 fx. Patients filled in the EORTC QLQ-C30 and H&N35 quality of life questionnaire at inclusion, after 1 and 2 weeks, at 1, 2, 3, 5, 7, 9 and 11 months after treatment. Questions regarding odour, bleeding and perceived benefit of the radiotherapy was added using the usual scale. Nineteen patients were previously treated with RT and 9 have had surgery with curative intent. After treatment per protocol nine patients proceeded to systemic therapy after progression and 8 had further palliative radiotherapy in their remaining life span.
Results: Side effects (HN pain and HN swallowing) peaked at 2 weeks after RT and were resolved at 1 month. At 2 weeks there was a significant increase in pain compared with baseline score. Previously irradiated patients' had more symptoms, including pain in general except pain at 2 weeks after RT i.e. no indication of increased acute toxicity. Median survival was 6.1 months (range 0.5−26.4 months). At the time points after RT 14, 15, 46, 47, 22, 27, 22, 36 and 0 percent of the patients' stated that they have had 'some' or 'a lot' of benefit of the therapy. This perceived improvement was not reflected by a significant improvement of symptom scores in the quality of life questionnaire compared with baseline. Nevertheless, 8 patients had an improved HN pain score and 10 patients had an improved HN swallowing score at 2 months (n = 21) compared with baseline. This was related to perceived benefit of the RT, however not significant.
Conclusion: Short course radiotherapy had very limited side effects among the patients. Contrary to the overall positive evaluation from the patients a statistically significant improvements of specific symptoms could not be proven in this cohort with often rapid disease progression. There were no indication of difference in treatment response between patients previously irradiated with curative intent and never irradiated patients.
No conflict of interest.

3201 POSTER

Prospective longitudinal assessment of salivary function using quantitative pertechnate scintigraphy and estimation of dose-volume response relationship after parotid-sparing radiotherapy in head-neck cancers

T. Gupta[1], C. Hotwani[2], S. Kannan[3], Z. Master[1], V. Rangarajan[4], V. Murthy[1], S. Ghosh-Laskar[2], A. Budrukkar[2], J.P. Agarwal[2]. [1]*ACTREC TATA Memorial Centre, Department of Radiation Oncology, Navi Mumbai, India;* [2]*Tata Memorial Centre, Department of Radiation Oncology, Mumbai, India;* [3]*ACTREC TATA Memorial Centre, ECTU-CRS, Navi Mumbai, India;* [4]*Tata Memorial Centre, Department of Nuclear Medicine & Molecular Imaging, Mumbai, India*

Background: Conformal radiotherapy can reduce acute and late xerostomia with potential positive impact on quality of life in head and neck squamous cell carcinoma (HNSCC). Limitations of salivary flow-rate estimation have encouraged the use of dynamic salivary gland scintigraphy for quantification of post-radiation deterioration of salivary function. The aim of this study was to assess functional changes in parotid glands using quantitative pertechnate scintigraphy and estimate their dose-volume response relationship in patients treated with definitive three-dimensional conformal radiotherapy (3D-CRT) or intensity-modulated radiation therapy (IMRT).
Methods: Quantitative salivary gland scintigraphy was performed at baseline prior to definitive (chemo)radiotherapy, 3-months after completion of therapy, and yearly thereafter using 15 mCi of 99mTc-pertechnetate. Salivary excretion fraction (SEF) was quantified by determination of the maximal excretion activity per gland as a fraction of the maximal uptake. SEF ratio (SEF at time point't'/baseline SEF x 100%) <45% was used for defining severe xerostomia based on previously published data. Dose-volume response curves were calculated using standardized methodology and modeled for normal tissue complication probability (NTCP) to calculate parotid tolerance doses (TD).
Results: Forty-one patients with non-metastatic HNSCC with a median age of 54 years (range 33−65 years) treated definitively on a prospective trial of 3D-CRT or IMRT constituted the study cohort. The mean (interquartile range) parotid doses were 50 Gy (36.2–59.7 Gy) and 35.4 Gy (28.0–53.5 Gy) for the ipsilateral and contralateral glands respectively. There was good correlation of SEF at all post-treatment time-points with mean parotid doses. Using SEF ratio <45% as the endpoint, TD50 (defined as 50% probability of complications) of the parotid gland was 32.8 Gy and 40.5 Gy at 3-months and 1-year respectively. The corresponding values increased to 55.9 Gy and 64.3 Gy at 2-year and 3-years respectively suggesting significant recovery of salivary function over time.
Conclusions: There is consistent and significant decline in salivary function even after parotid-sparing conformal radiotherapy. However, there is significant recovery of salivary function over time. Quantitative pertechnate scintigraphy is a simple, reproducible, and minimally invasive test of major salivary gland function that has the potential to replace direct salivary flow-rate measurements.
No conflict of interest.

3202 POSTER

Intensity-modulated radiation therapy for head and neck cancer: Systematic review and metanalysis

G. Marta[1], V. Silva[2], H.A. Carvalho[1], F.F. De Arruda[1], S.A. Hanna[1], R. Gadia[1], J.L.F. Da Silva[1], S.F.M. Correa[1], C.E.C.V. Abreu[1], R. Riera[2]. [1]*Hospital Sírio-Libanês, Radiation Oncology, São Paulo, Brazil;* [2]*Universidade Federal De São Paulo–Escola Paulista De Medicina, Brazilian Cochrane Center and Discipline of Emergency Medicine and Evidence-based Medicine, São Paulo, Brazil*

Background: The potential overall benefit of Intensity-modulated radiation therapy (IMRT) over two-dimensional (2D-RT) or three-dimensional

conformal radiation therapy (3D-CRT) for head and neck cancers has not yet been clarified, except for reduction of side effects, especially xerostomia. This systematic review and metanalysis was undertaken to assess whether IMRT can improve clinical outcomes when compared to 2D-RT or 3D-CRT including xerostomia, local control, and overall survival.
Material and Methods: Only prospective phase III randomized trials were eligible and had to compare IMRT with 2D-RT or 3D-CRT in previously untreated patients, with non-metastatic head and neck cancers. Patients underwent radiotherapy either primarily or combined with surgery or chemotherapy. Medline, CENTRAL, EMBASE, and LILACS databases were searched with no language, publication year or publication status restrictions. Two authors independently selected and assessed the studies regarding eligibility criteria and risk of bias.
Results: Five studies fulfilled the eligibility criteria. A total of 871 patients were randomly assigned for 2D-RT or 3D-CRT (437), versus IMRT (434). Most patients presented with nasopharyngeal cancers (82%), and stages III/IV (62.1%). Three studies were classified as unclear risk and two as high risk of bias. A significant overall benefit in favor of IMRT was found ($p<0.0001$) for all studies (hazard ratio [HR], 0.76; 95% CI: 0.66–0.87) regarding xerostomia scores grade 2−4. At a mean follow-up of 4.23 years, the overall number needed to treat analysis of the prevention of 'xerostomia grade 2−4' was 19.3 (95% CI:13.5–36.2). There were non-significant increases in local control (HR 1.07; 95% CI:0.93–1.23; p=0.35) and overall survival (HR 1.12; 95% CI:0.97–1.29; p=0.11) in favor of IMRT.
Conclusions: Based on moderate to high risk of bias studies, IMRT significantly reduces the incidence of grade 2−4 xerostomia. No differences were observed in local control and overall survival in patients with head and neck cancers.
No conflict of interest.

3203 POSTER

Change of practice: Does an outpatient tube clinic affect patient weight and duration of tube feeding?

M. Hansen[1], H. Primdahl[1]. [1]*Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark*

Background: In our radiotherapy department 63% of patients with head and neck cancer (HNC) treated with chemoradiation receive a feeding tube during their treatment. Previously, the patients were admitted to hospital for training in tube use and care. After discharge, nurses assisted with adjustment of the nutrition plan. All HNC patients were seen by doctor two weeks after treatment, but there was no systematic follow-up on nutrition. In November 2010, we started an outpatient-based tube clinic with the purpose to train and support patients with a feeding tube, adjust nutrition plans and start up normal feeding after treatment.
The purpose of the study was to investigate if the outpatient clinic could be a substitute for hospitalisation and if systematic follow-up affects patient weight loss and duration of tube feeding.
Material and Methods: A retrospective descriptive study of HNC patients receiving a tube because of curative chemoradiation, min 60 Gy.
The first group (38 patients) consisted of all patients completing treatment from December 2006 to August 2009 before establishment of the clinic. These data originated from an earlier study.
The other group (24 patients) consisted of all patients completing treatment after establishment of the clinic between November 2010 and November 2011. Some of these patients did not start up at the clinic, because other needs required hospitalisation, but was followed by the clinic at discharge. Only 5 patients had no contact at all. They were all included to obtain comparable groups.
The two groups were comparable in terms of baseline data.
Weight loss was calculated at three time points: During treatment, the first two months after treatment and from application of the tube until two months after treatment. Duration of tube feeding was measured from termination of treatment to discontinuation of tube feeding.
Results: This study showed no significant difference. Both groups had the same proportion of patients who lost weight and weight loss was similar at all tree time points. There was no significant difference in duration of tube feeding, neither for nasal nor gastric tube.
Conclusions: Although the patient number is small, the study suggests that there was no significant difference between the groups before and after establishing the tube clinic.
Thus, start-up training on an outpatient basis and a systematic follow-up after treatment can replace admission; Duration of tube feeding time was not reduced.
No conflict of interest.

3204 POSTER

A randomised study comparing prophylactic gastrostomy to feeding tube as needed in head and neck carcinomas

A. Fortin[1], M. Demers[2], J. Desjardins[2], J. Archambault[2]. [1]*CHUQ (Hôtel-Dieu de Québec), Québec, Canada;* [2]*CHUQ (Hôtel-Dieu de Québec), Radiation-Oncology, Québec, Canada*

Background: Weight loss is a major problem during chemoradiotherapy and the best way to prevent it remains controversial. The main objective of the study was to compare weight loss percentage between prophylactic percutaneous gastrostomy (PG) and feeding tube as needed (FT) during chemoradiotherapy. Secondary objectives were to evaluate difference in quality of life (QOL), number of hospitalisation and, treatment interruption between for both groups.
Material and Method: This randomised study was stratified according to site (larynx/hypopharynx vs other sites). The study was design to include 96 patients. It aims to detect a clinically significant weight loss with a power of 20% but, the study was interrupted after the demission of our interventional radiologist. The study was performed at the Hotel-Dieu de Québec between October 2008 and July 2012. All patients were treated with radical IMRT and cisplatin based chemotherapy. Exclusion criteria were: need for initial hospitalisation, aspiration, malnutrition or initial surgery.
Results: A total of 37 patients were randomised (18 in the GP group and 19 in the FT group). At the end of treatment, 3/18 (16%) and 9/19 (47%) of patients lost more than 10% of their initial body mass in the GP and FT group, respectively, $p = 0.04$. Mean percentage of weight lost was 5.4 kg and 8.7 kg in the GP and FT group, respectively, $p = 0.04$. At the end of treatment, mean pre-albumin was 275 vs 233 mg/l in the GP and FT group, respectively, $p = 0.13$. The need for enteral nutrition treatment was 17/18 (94%) for GP and 9/19 (47%) for FT, $p = 0.001$. At 6 months, only one patient still needed enteral nutrition in the FT group. There was 2/18 and 2/19 treatment interruption in the GP and FT group, respectively. Only 3 patients need treatment re-simulation. There were 7/18 (38%) and 6/19 (31%) unexpected hospitalisation in the GP and FT group, respectively, $p = 0.65$. For the global QOL assessment (EQ-5D, How good is your health today), the mean decline in QOL was 27% in the FT and 17% in the GP group, $p = 0.2$. In the EORTC HN35 questionnaire, only q48 (bothered by appearance) was significant, $p = 0.02$. Minors complications were seen in 12/18 (66%) patients in the GP group and in one patient in the FT group. One patient had peritonitis (GP group).
Conclusions: Compare to FT, PG was useful to prevent weight loss of more than 10% of the initial body mass during chemoradiation in this selected group of head and neck carcinomas patients. This has to be weighed against the invasive nature of the PG procedure.
No conflict of interest.

3205 POSTER

Speckle tracking to measure arterial strain as a marker of radiation-induced atherosclerosis

D.M. Gujral[1], B.N. Shah[2], N.S. Chahal[2], S. Bhattacharyya[2], U. Schick[1], R. Senior[2], K.J. Harrington[1], C.M. Nutting[1]. [1]*Royal Marsden Hospital, Head and Neck Unit, London, United Kingdom;* [2]*Royal Brompton Hospital, Department of Echocardiography, London, United Kingdom*

Background: The late effects of radiotherapy in patients with head and neck cancer include increased risk of carotid artery stenosis and subsequent stroke. Reduced carotid arterial stiffness is thought to be a precursor of atherosclerosis and occur prior to arterial thickening. Carotid artery strain (a surrogate for arterial stiffness) can be measured using a novel ultrasound technique. We sought to investigate the effect of radiotherapy on arterial stiffness in patients with head and neck cancer.
Methods: Patients with head and neck cancer treated with unilateral hemi-neck radiotherapy to a dose of at least 50 Gy at least 2 years previously were included. Bilateral carotid artery ultrasound scans were obtained using a 10MHz transducer. Carotid arterial strain using speckle tracking was measured in 6 segments at three different arterial levels (proximal, mid and distal) (total of 18 segments) in the irradiated common carotid artery. Global circumferential strain for each level was calculated from the mean segmental value. Total global circumferential strain for the entire artery was calculated from the mean of proximal, mid and distal global circumferential strains. The contralateral unirradiated carotid artery served as a control.
Results: 15 patients (total 540 segments, 36 per patient) with a median age of 61 yrs (interquartile range (IQR) 52−67 yrs) were studied. Median global circumferential strain was reduced in the irradiated carotid artery (2.4% (IQR 1.7−3.1)) compared to the unirradiated carotid artery (3.1% (IQR 2.1−3.9)), $p = 0.05$. There was no difference in median global circumferential strain between proximal (−2.6% (IQR 1.7−4.2)), mid (2.5% (IQR 1.6−3.3)) and distal (2.1% (IQR 1.7−2.9)) segments of the irradiated artery, $p = 0.43$. There was no difference in global circumferential strain

between proximal (3.7% (IQR 2.3−4.4)), mid (3.0% (IQR 2.1−3.7)) and distal (3.0% (IQR 1.8−3.9)) segments of the unirradiated artery, p = 0.29.
Conclusion: Carotid arterial stiffness, measured by speckle tracking, is reduced in irradiated compared to unirradiated carotid arteries. Corroboration of these findings in a larger cohort may allow detection of early radiation-induced damage to the carotid arteries.
No conflict of interest.

3206 POSTER

Common carotid artery stenosis as measured by computed tomography following radiotherapy for early glottic carcinoma

R. Harada[1], K. Isobe[1], A. Kanazawa[1], G. Togasaki[1], M. Saito[1], M. Nemoto Watanabe[1], T. Uno[1]. *[1]Chiba University Hospital, Radiology, Chiba, Japan*

Background: Carotid artery stenosis is a late toxic effect followingradiotherapy (RT) for head and neck malignancies. Patients with T1-T2 glotticcarcinoma are usually treated with small radiation field, which yields highrate of cure. We conducted a retrospective study to evaluate the incidence ofcarotid artery stenosis in these patients.
Materials and Methods: Contrast-enhanced computed tomography(CECT) of head and neck performed from Jan 2009 to Jan 2013 for patients withT1-T2 glottic carcinoma after radiotherapy were retrospectively reviewed. CTswith interval less than 4 years after treatment were excluded. Rate of stenosiswithin distal half of common carotid artery (CCA) were measured inreconstructed images, then classified into four groups: grade 0 (no stenosis),grade 1 (stenosis <15%), grade 2 (15−50%), grade 3 (<50%). For comparison,pre-treatment CECT of patients with T1-T2 glottic carcinoma diagnosed duringthe same period were also reviewed. The rate of CCA stenosis in each group wascompared by Fisher's exact test. Association of each clinical parameters withCCA stenosis was analyzed through multiple logistic regression.
Results: Overall, 52 CECTs were reviewed, including18 patients in RT group and 34 patients in the control group. Thus, a total of104 coronary arteries (right and left) were evaluated for analysis. Theinterval between treatment and CT in the RT group ranged from 4 to 9 years. Theincidence of CCA stenosis grade 2−3 in the RT group and the control group were33% and 6%, respectively (p < 0.01). In multivariate analysis, only previousRT significantly correlated with grade 2−3 CCA stenosis (p < 0.001, odds ratio14.9 {95% confidence interval 2.6–86.5}).
Conclusion: Patients with T1-T2 glottic carcinoma whohad been treated by RT had higher incidence of CCA stenosis than those who hadnever received RT.
No conflict of interest.

3207 POSTER

Comparison of two stereotactic body radiotherapy protocols for recurrent head and neck cancers

G. Ozyigit[1], T. Sanli[1], G. Yazici[1], M. Gurkaynak[1], M. Cengiz[1]. *[1]Hacettepe University Faculty of Medicine, Department of Radiation Oncology, Ankara, Turkey*

Background: This study aimed to compare the local control rate, overall survival rate, and toxicity rate associated with two stereotactic body radiotherapy (SBRT) protocols for re-irradiation in patients with locally recurrent head and neck cancer.
Materials and Methods: The study included 75 patients with inoperable recurrent head and neck cancer that were treated with SBRT. Group I included 43 patients that were treated sequentially and group II included 32 patients that were treated every other day. Median age of all the patients was 53 years (range: 15−87 years). There wasn't any significant difference in demographic or clinical characteristics between the 2 groups. The most common site of re-irradiation was the nasopharynx (n = 34 patients), followed by the oral cavity and larynx. Multiplan (Accuray Inc., Sunnyvale, CA) software was used for inverse planning. The treatments were delivered via a CyberKnife® (Accuray Inc., Sunnyvale, CA). The circumference of the carotid artery entrapped by the tumour was calculated in each patient; median carotid artery wall entrapment by the tumour in all patients was 180º, versus 270º in the patients that had bleeding were considered.
Results: Median overall survival in group I and group II was 11 months and 23 months, respectively (P = 0.006). Ultimate local control was achieved in 77.4% of the patients. The local control rate in group I was 67.5%, versus 90.6% in group II (P = 0.029). Progression-free survival was 9 months in group I, and 18 months in group II (P = 0.004). Dysphagia was observed in 10 patients (23%) in group I, versus only 3 patients (6.3%) in group II (P = 0.047). The overall survival and local control rates were higher, and the number of patients with grade 3 or higher side effects was lower in group II. The median radiation dose received by the carotid artery in patients with carotid blow-out syndrome (CBOS) was 36.5 Gy (range: 34–42.8 Gy), versus 34.7 Gy (range: 0−44 Gy) in the patients that didn't have CBOS (P = 0.15). CBOS was not observed in patients with lesions entrapping <180º of the carotid artery.
Conclusions: CBOS did not occur in any of the patients with a maximum carotid artery radiation dose <34 Gy. Every other day SBRT protocol for re-irradiation of recurrent head and neck cancer is promising.
No conflict of interest.

3208 POSTER

Dosimetric evaluation of nasopharyngeal carcinomas irradiated with different IMRT techniques

S. Ozdemir[1], Y. Coban[1], M. Akin[1], P. Ambarcioglu[2], O. Onay[1], S. Karacam[1], E. Kocak Uzel[3], O. Uzel[1]. *[1]Cerrahpasa Medical Faculty, Radiation Oncology, Istanbul Findikzade, Turkey; [2]Cerrahpasa Medical Faculty, Biostatistics, Istanbul Findikzade, Turkey; [3]Sisli Etfal Teaching and Research Hospital, Radiation Oncology, Istanbul, Turkey*

Background: To compare intensity modulated arc radiotherapy (IMAT), dynamic IMRT and step and shoot IMRT on nasopharyngeal carcinomas (NPC).
Material and Methods: IMRT plans of 48 NPC patients treated between May 2010 and December 2012, were evaluated. Median age was 43.5 (14−79) and 73% of the patients were male. The majority of patients showed advanced clinical stages (stage III/IV:72.9%) with undifferentiated histology (70.8%). PET-CT or MRI images were fusioned with planning CT for all patients. Target volumes and critical organs were delineated 2.5 mm sliced planning CT according to RTOG atlas. Forty patients were planned using the Eclipse (ver. 8.6) treatment planning system (22 IMAT, 18 dynamic IMRT) and treated with Varian Rapid-Arc linear accelerator. Eight cases were planned using the planning system of Prowess Panther V5.01. The plan was delivered on an Elekta Synergy Linac equipped with an 80-leaf 1 cm multileaf collimator with step-and-shoot intensity-modulated radiation therapy. IMRT was administered using sequential (9 patients) or simultaneous integrated boost (39 patients) approach. A median of 70 Gy (63−70 Gy) was given to primary tumour and involved lymph nodes and 50 Gy for electively irradiated neck nodes with sequential boost tecnique. The doses of the planning target volumes of primary tumor and involved lymph nodes, high risk, and uninvolved regional nodal areas were 70 Gy, 60 Gy, and 54 Gy respectively and delivered simultaneously over 33 fractions. Maximum doses to spinal cord and brain stem were limited to 45 Gy and 54 Gy respectively. Mean parotid dose was aimed to be less than to 26 Gy. Conformity index (CI), homogenity index (HI), monitor unit (MU) and normal tissue doses were calculated for each plan. CI, HI and MU were compared between the three IMRT modalities.
Result: Dmean, D98, D2, CI and HI were 102.2±2.04%, 97±2.27%, 105.1±2.23%, 1.18±0.23 and 1.08±0.02 for all patients, respectively. Maximum doses to brain stem and spinal cord were 54.2±2.2 and 44.7±1.9 respectively. The maximum MU was found in dynamic IMRT technique (1657.2±674.8 versus 548.1± 249.8 and 451.3± 41.2) CI; 1.10±0.12 for dynamic IMRT, 1.19± 0.251 for IMAT and 1.35±0.26 for step and shoot IMRT technique.
Conclusion: The improvement in tumour target coverage and significant sparing of adjacent critical structures allow the feasibility of IMRT for NPC. MU values were similar with IMAT and step and shoot IMRT techniques while two-thirds less monitor units than dynamic IMRT. IMAT and dynamic IMRT techniques gave superior results in terms of CI compared with step and shoot IMRT. This difference is thought to be due to the technical differences of linear accelerator devices like fiber size, variable fiber, dose rate and gantry.
No conflict of interest.

3209 POSTER

Role of adjuvant postoperative external beam radiotherapy for well differentiated thyroid cancer

J. Kwon[1], H.G. Wu[1], Y.K. Youn[2], K.E. Lee[2], K.H. Kim[3], D.J. Park[4]. *[1]Seoul National University College of Medicine, Department of Radiation Oncology, Seoul, South Korea; [2]Seoul National University College of Medicine, Department of Surgery, Seoul, South Korea; [3]Seoul National University College of Medicine, Department of Otolaryngology, Seoul, South Korea; [4]Seoul National University College of Medicine, Department of Internal Medicine, Seoul, South Korea*

Background: To analyze the outcome of adjuvant postoperative external beam radiotherapy (EBRT) in well differentiated thyroid cancer (WDTC).
Material and Methods: We identified of 84 WDTC patients treated with EBRT for WDTC in Seoul National University Hospital from February, 1981 to December, 2010. Among them, we analyzed 40 patients who received EBRT after initial radical surgery. Twenty-five females and 15 males were included. Median age was 49 years (range, 16−72 years). There were 35 papillary thyroid carcinomas and 5 follicular thyroid carcinomas. Most

patients showed pathologic T3 or T4 stage (55%/25%). Eleven patients (27.5%) had gross residual tumors. Five (12.5%) patients were involved by tumor cells at margin. Median EBRT dose and fraction size was 62.6 Gy and 1.8−2.0 Gy, respectively.
Results: Median follow-up was 66 months (range, 22–377). Five-year overall survival (OS) and locoregional recurrence free survival (LRFS) was 97.5% and 86.1%, respectively. Locoregional failures occurred in 5 and all failure sites were neck node area. In univariate analysis, OS was significantly influenced by invasion of trachea ($p = 0.028$) or esophagus ($p = 0.005$). LRFS rates was significantly decreased by male ($p = 0.016$), gross residuum after resection ($p = 0.006$), close or positive tumor at surgical margin involvement ($p = 0.0015$), and tracheal invasion ($p = 0.046$). There was no significant prognostic factor in multivariate analysis. No patient experienced RTOG grade 3 or more toxicity.
Conclusions: Our locoregional control rate of 87.5% is comparable to historical controls with surgery alone, even though mainly with advanced stage. EBRT is effective and safe treatment option in patients with WDTC.
No conflict of interest.

3210 POSTER

Clinical effect by improvement of facilities in the radiotherapy of locally advanced head and neck squamous cell cancer patients

N. Fukumitsu[1], Y. Hayashi[2], T. Okumura[1], K. Takahashi[3]. *[1]University of Tsukuba, Proton Medical Research Center, Tsukuba, Japan; [2]Ibaraki Prefectural Central Hospital, Radiation Oncology, Kasama, Japan; [3]Ibaraki Prefectural Central Hospital, Otorhinolaryngology, Kasama, Japan*

Background: Improvement of facilities is expected to reflect the improvement of treatment outcome. Technical and methodological aspect which surrounds radiotherapy has rapidly progressed in these decades. We investigated how improvement of facilities had an impact on the treatment outcome in the radiotherapy of locally advanced head and neck squamous cell cancer (HNSCC) patients.
Material and Methods: Eligibility is locally advanced HNSCC patients whose curative radiotherapy was conducted between 2002 and 2012. (n = 92, male: 81, female: 11, 43−92 (68) years old). Clinical stage was III: 29, IVA: 50 and IVB: 13, The site of origin was oropharynx: 31, hypopharynx: 31, larynx: 16, nasal-paranasal sinus: 7, oral: 6 and nasopharynx: 1. Total irradiation dose was 65−86 (70.2) Gy and concurrent chemotherapy was performed in 67 patients. Patients were divided into 3 groups according to the presence or absence of PET operation before radiotherapy and type of treatment machine as group A: before introduction of PET, linear accelerator with the energy of 4 and 10 MV (2002–2006): n = 32, group B: presence of PET operation before radiotherapy, linear accelerator with the energy of 4 and 10 MV (2006–2009): n = 27 and group C presence of PET operation before radiotherapy, linear accelerator with the energy of 6 and 10MV equipped with on-board imaging function (2009–2012): n = 30. No large variety of age, disease type, clinical stage or total irradiation dose was observed among the groups. Cause specific survival (CSS) and progression free survival (PFS) were compared among the groups.
Results: CSS at 3 years was much improved in group B and C than A such as 54.2% in group A, 80.1% in group B and 81.0% in group C (p = 0.023). PFS at 3 years was 44.8% in group A, 53.8% in group B and 63.4% in group C. Although no significant change was observed in PFS, number of the patients who showed recurrence within 6 months after treatment tended to be smaller in group B and C than group A such as 8 in group A, 4 in group B and 4 in group C.
Conclusions: Improvement of facilities favorably reflected the improvement of treatment outcome in the radiotherapy of HNSCC patients. Especially, presence of PET operation before radiotherapy was suggested to reduce early recurrence after treatment, consequently contributed to improve treatment outcome in the radiotherapy of HNSCC patients.
No conflict of interest.

3211 POSTER

Role of fluconazole in the prevention of radiation induced mucositis in head and neck cancer patients

S. Mukesh[1], S. Nirmala[2], B.S. Ramesh[3], K. Praveen[4]. *[1]Mysore Medical College and Research Institute, Radiation Oncology, Mysore, India; [2]BGS Global Hospitals, Radiation Oncology, Bangalore, India; [3]HCG Cancer Hospitals, Radiation Oncology, Bangalore, India; [4]M.S.Ramiaha Medical College, Microbiology, Bangalore, India*

Background: To evaluate the effect of fluconazole on prevention of oral candidiasis and also to determine whether fluconazole prophylaxis will reduce the severity of oral mucositis induced by radiotherapy.
Materials and Methods: The study was conducted on 48 patients with histopathologically proven Head and Neck cancer.Each patient underwent thorough dental prophylaxis before start of radiation. Patients were randomly divided into two groups A and B.Group A represents treatment arm and group B control arm. Oral swabs were collected from both groups. Maximum of three swabs were collected, one before the start of radiotherapy, second one three weeks after start of radiotherapy and last one after completion of radiotherapy. Oral swab were cultured on Sabouradad's dextrose agar for candidial growth. Patients in both groups received radiotherapy with or without chemotherapy which was decided by the radiation oncologist depending on the site and stage of tumor. Patients in group A received oral fluconazole 50 mg/day after food from the first day of radiotherapy till the completion of radiotherapy treatment. Patients in Group 'B' did not receive fluconazole as prophylactic therapy. Patients in both groups were examined weekly for oral mucositis and were graded according to CTC version 2.0.
Results: Oral swab taken from patients before start of radiotherapy for candidial growth showed that it was present in 22% of all patients. During the course of radiation treatment, oral candidal culture was positive in 44% of control patients and 37.5% of treatment patients. When the grade of mucositis was assessed in both the arms, it was found that there was statistically significant reduction in the severity of mucositis in the treatment arm (p = 0.021). In the control arm, there was no grade 0 mucositis noted, grade 1 was seen in 20%, grade 2 in 64%,grade 3 in 16% and no grade 4 mucositis. In the treatment arm there was grade 0 mucositis in 25%, grade 1 in 25%,grade 2 in 29.2%, grade 3 in 20.8% and no grade 4 mucositis. Patients in whom candidal culture was negative had less severe mucositis as compared to patients with positive candidal culture(p = 0.029).
Conclusion: Prophylactic use of oral fluconazole is effective in reducing the severity of oral mucositis. Presence of oral candidasis increases the severity of mucositis and the incidence of oral candidasis can be reduced by flucanzaole, there by reducing the severity of oral mucositis.
No conflict of interest.

Is FDG-PET-CT a valuable tool in prediction of persistent disease in head and neck cancer

E. Kocak Uzel[1], O. Ekmekcioglu[2], O. Elicin[3], M. Halac[2], O.E. Uzel[3]. *[1]Cerrahpasa Medicine Faculty, Istanbul, Turkey; [2]Cerrahpasa Medicine Faculty, Nucleer Medicine, Istanbul, Turkey; [3]Cerrahpasa Medicine Faculty, Radiation Oncology, Istanbul, Turkey*

Objectives: To evaluate accuracy of FDG-PET CT in prediction of persistent disease in head and neck cancer and to determine prognostic value of metabolic tumor response.
Methods: Between 2009 and 2011 46 patients with squamous cell carcinoma of Head and Neck who had pre treatment PET- CT were treated with definitive Radiotherapy with or without chemotherapy. There were 29 Nasopharyngeal, 11 Hypopharyngeal, 3 Oropharyngeal, 3 Laryngeal cancer patients median age of patients was 50.5 years (range 16−84) there were 32 males and 14 females. All patients were evaluated with PET-CT median 3.5 months (2.4−9.4) after completion of radiotherapy.

Table 1. Patterns of outcome in patients with control FDG PET CT non-complete responders.

Patients	PET-CT result	Location site	Recurrence	Recurrence site	Follow up (months)
Patient 1	suspicious	Nasopharyngeal	absent	–	20.1
Patient 2	suspicious	hypopharyngeal	present	Local	19.3
Patient 3	suspicious	hypopharyngeal	absent	–	25.6
Patient 4	suspicious	oropharyngeal	Present	Regional	14.8
Patient 5	suspicious	laryngeal	present	Local	36.3
Patient 6	positive	Nasopharyngeal	Absent	–	13.5
Patient 7	Positive	Nasopharyngeal	Present	Locoregional	9.5
Patient 8	Positive	Nasopharyngeal	Absent	–	19.1
Patient 9	Positive	Nasopharyngeal	Absent	–	24.2
Patient 10	Positive	hypopharyngeal	Present	Local	13.1
Patient 11	Positive	hypopharyngeal	Absent	–	18
Patient 12	Positive	hypopharyngeal	Present	Local	14
Patient 13	Positive	hypopharyngeal	Present	Locoregional	11.3
Patient 14	Positive	hypopharyngeal	Present	Local	8.9
Patient 15	Positive	hypopharyngeal	Present	Local	15.4
Patient 16	Positive	oropharyngeal	Present	Locoregional	15
Patient 17	positive	hypopharyngeal	Present	regional	31.9

Results: After median 20 months of follow up complete metabolic response was observed in %63 of all patients. Suspicious residual up take was present in 10.86% and residual metabolic up take in 26% of patients. The overall sensitivity, specificity, positive predictive value and negative predictive value of FDG-PET-CT for detection of residual disease was 64% and 96%, 91% and 82% respectively. Two year LRC was 95 % in complete responders while it was 34% in non complete responders (Table 1).

Conclusion: FDG PET CT is a valuable tool for assessment of treatment response especially in high risk patients for local recurrence, is also good indicator for prognosis. Definitely more precise criteria is required for assessment of response, there is no clear cut up take value indicating residual disease, on the other hand repair process of normal tissue may consume glucose which appear as increased up take in control FDG PET CT.
No conflict of interest.

3213 POSTER

Long-term treatment outcomes of patients with mucoepidermoid carcinoma of the parotid gland treated with surgery plus postoperative radiotherapy

G. Park[1], S.W. Lee[1], K.J. Cho[2], S.Y. Kim[3], S.Y. Nam[3], S.H. Choi[3], J.L. Roh[3], J.H. Kim[1], E.K. Choi[1], S.D. Ahn[1]. *[1]Asan Medical Center, Radiation Oncology, Seoul, South Korea; [2]Asan Medical Center, Pathology, Seoul, South Korea; [3]Asan Medical Center, Otolaryngology, Seoul, South Korea*

Background: To investigate the long-term treatment outcomes and to evaluate the prognostic factors in patients with mucoepidermoid carcinoma (MEC) of parotid gland treated with surgery and postoperative radiotherapy.
Material and Methods: We retrospectively reviewed the clinical data of 31 patients with MEC of parotid gland who were treated with surgery followed by radiotherapy between 1991 and 2010. Radiotherapy was delivered with a median total dose of 60 Gy (range, 50−67 Gy). Elective nodal irradiation (ENI) was applied to T3−4 or node-positive tumors. The histopathologic features of all cases were prospectively reviewed by one head and neck pathologist. The median follow-up period was 102 months (range, 9–232 months).
Results: Overall outcomes at 5 and 10 years were overall survival (OS), 83%; locoregional recurrence-free survival (LRFS), 93% and 89%; distant recurrence-free survival (DRFS), 90%; disease-free survival (DFS), 87% and 83%, respectively. On univariate analysis, N stage (N0−1 vs. N2, $p < 0.01$), overall stage (I−II vs. III−IV, $p = 0.04$), and histologic grade (low vs. intermediate vs. high, $p < 0.01$) were statistically significant predictors of OS. A poorer survival was observed in patients with high grade tumors or more than N2 disease than in patients without any factor (5-year OS, 86% vs. 29%, $p < 0.01$; 5-year DRFS, 100% vs. 57%, $p < 0.01$).
Conclusions: Our results demonstrated that surgery plus postoperative radiotherapy resulted in excellent locoregional control. However, high grade tumors or node-positive disease more than N2 showed a poor distant control and overall survival. More aggressive treatment including adjuvant chemotherapy or targeted therapy should be investigated for patients with such high risk factors.
No conflict of interest.

3214 POSTER

Superselective intra-arterial chemoradiotheapy for locally advanced maxillary sinus carcinoma

H. Hojo[1], H. Kunogi[1], M. Nakashiro[1], T. Hirai[2], A.I. Saito[3], K. Yamada[2], S. Ishikura[1], J. Yokoyama[4], K. Sasai[1]. *[1]Juntendo University, Radiology, Tokyo, Japan; [2]Juntendo University Nerima Hospital, Radiology, Tokyo, Japan; [3]Juntendo University Urayasu Hospital, Radiology, Chiba, Japan; [4]Juntendo University, Head and Neck Surgery, Tokyo, Japan*

Background: For stage III or IVA maxillary sinus carcinoma (MSC), standard treatment is craniofacial surgery with postoperative radiation therapy. However, surgical approaches are often complicated accompanied with risk of serious functional deformity and lack of satisfactory surgical clearance. For stage IVB MSC, standard treatment is not established. Definitive radiation therapy (RT) including 3D-conformal radiation therapy (3DCRT) with super-selective intra-arterial chemoradiothearpy (SIACRT) is indicated in selected patients unfit for surgery. Here we retrospectively evaluated the treatment outcome of SIACRT in patients with locally advanced MSC.
Materials and Methods: We identified consecutive 34 patients with locally advanced MSC underwent SIACRT at our institution between January 2009 and March 2013. The treatment protocol consisted of 3DCRT (60 Gy/30 fractions) with super-selective arterial infusions of weekly docetaxel (10−36 mg) and cisplatin (100–350 mg) for 4−6 cycles.
Results: Patient characteristics were: median age, 68 years (range 43−86); male 29 (85%), female 5 (15%); squamous cell carcinoma 31 (91%), small cell carcinoma 1 (3%), others 2 (6%); stage III 4 (12%), stage IVA 20 (59%), stage IVB 10 (29%). With median follow-up period of 12 months, the 1-year overall survival, progression free survival, and local control rate were 68%, 45%, and 80%, respectively. Seven (21%) patients died of MSC. As to first site of progression, 7 (21%) local progression and four (12%) regional progression, all of which were successfully salvaged by surgery, and 5 (15%) distant metastases were seen. Grade 2 keratoconjunctivitis occurred in 11 (32%) patients. Grade 3 or 4 mucositis and dermatitis occurred in 18 (53%) and 5 (15%) patients, respectively. Grade 4 optic neuritis occurred in 3 (9%).
Conclusions: SIACRT showed good local control, but longer follow up is needed to confirm the efficacy and toxicity of SIACRT.
No conflict of interest.

3215 POSTER

Postoperative image-guided intensity modulated radiation therapy in sinonasal cancer: Dosimetry, clinical outcome and quality of life − an updated series

A. Biswas[1], S. Mallick[1], M.A. Laviraj[1], B.K. Mohanti[1], G.K. Rath[1]. *[1]All India Institute of Medical Sciences, Radiotherapy & Oncology, Delhi, India*

Background: This study is aimed to assess the dosimetry, clinical outcome and quality of life in patients of locally advanced sinonasal cancer undergoing surgery followed by adjuvant image-guided intensity modulated radiation therapy (IGIMRT).
Materials and Methods: We enrolled 10 patients (pts) of sinonasal cancer (stage II−IV, age $\leqslant$70 years, KPS $\geqslant$70, R0/R1 resection) for IGIMRT in a project. Clinical target volume (CTV) comprised high risk (HR) CTV: surgical bed and low risk (LR) CTV: retropharyngeal, level IB and II lymphnodal site (only in T3/T4 squamous carcinoma). An isotropic 3 mm expansion was given around CTV to generate planning target volume (PTV). Prescribed dose was 60−64 Gy/30#/6 weeks to HRPTV (as per margin status) and 50 Gy/30#/5 weeks to LRPTV (simultaneous integrated boost). IMRT was planned by 7−9 coplanar equally spaced beams (step & shoot multileaf collimator with DMPO) with 6 MV photons (Pinnacle TPS v8.0m). Treatment verification was performed with kilo-voltage cone beam CT(KVCBCT, Elekta Synergy S) on first 3 days of treatment & subsequently twice a week. Positional correction was done when translational error was >3 mm. Quality of life was assessed pre-RT, immediate post-RT & 3 month post-RT using EORTC QLQ-C30 version3 & QLQ-H&N35module.
Results: The median age was 45 years with male: female ratio of 1:1. Primary site was maxilla-5 pts, nasal cavity-4 pts, and eithmoid-1 pt (stage T4:T3:T2 = 8:1:1 and N0M0 in all). Histology was adenoid cystic, squamous, & adenocarcinoma in 6, 3 &1 pt respectively. Median D95 PTV was 97.39% of prescribed dose. Median conformity & homogeneity (D2/D98) indices were respectively 1.14 & 1.16. Median value of dose maximum to organs at risk (OAR) were- brainstem: 51.93 Gy, spinal cord: 35.37 Gy, optic chiasma: 52.79 Gy, optic nerve: 53.95 Gy (left) & 51.6 Gy (right), eye: 49.99 Gy(left) & 49.3 Gy(right), temporal lobe: 61.6 Gy (left) & 62.23 Gy (right). Median value of mean dose to OAR were- parotid: 20.67 Gy(left) & 21.48 Gy (right) & oral cavity: 23.9 Gy. Median number of KVCBCT done per patient was 11. Median translational error (cm) in x, y & z axis was 0.11, 0.16 & 0.14 respectively. Acute radiation morbidity (RTOG criterion) included dermatitis: Gr1 (60%) & Gr2 (30%), mucositis: Gr2 (60%), Gr3 (10%) & Gr4 (20%), salivary gland toxicity: Gr1 (80%) & Gr2 (10%), conjunctivitis: Gr1 (50%) & Gr2 (10%), pharyngitis: Gr1 (50%), Gr2 (30%) and Gr3 10%). After a median follow-up of 2.23 years, local recurrence and death were observed in 40% and 10% of the patients respectively (1 year actuarial rate of overall and recurrence-free survival − 90% & 80%). Median overall and recurrence free survival were not reached. Median global health status (QoL) declined from 75(pre-RT) to 62.5(immediate post-RT) but recovered back to baseline value 3 months post RT. Symptom scores pertaining to pain, sense organ dysfunction, mouth opening worsened immediately post RT but gradually came back to baseline level (median-0) 3 months after RT.
Conclusion: Adjuvant IGIMRT in locally advanced sinonasal cancer permits precise delivery of radiation to the target with sparing of the adjacent OAR with excellent toxicity profile, quality of life & clinical outcome.
No conflict of interest.

3216 POSTER

Long-term outcomes of tongue hemiatrophy and patient satisfaction following low-dose-rate interstitial brachytherapy for mobile tongue cancer: An almost 20-year follow-up study

H. Akiyama[1], K. Yoshida[2], H. Yamazaki[3], T. Kotsuma[4], K. Masui[3], Y. Yoshioka[5], K. Ogawa[5], T. Teshima[6], E. Tanaka[4], K. Shimizutani[1]. *[1]Osaka Dental University, Department of Oral Radiology, Osaka-city, Japan; [2]Osaka Medical College, Department of Radiology, Takatsuki-City, Japan; [3]Kyoto Prefectural University of Medicine, Department of Radiology, Kyoto-City, Japan; [4]National Hospital Organization Osaka National Hospital, Department of Radiation Oncology, Osaka-city, Japan; [5]Osaka University Graduate School of Medicine, Department of Radiation Oncology, Suita-City, Japan; [6]Osaka Medical Center for Cancer and Cardiovascular Diseases, Department of Radiation Oncology, Osaka-city, Japan*

Background: Tongue hemiatrophy is a relatively common disorder that typically progresses over a long period following low-dose-rate interstitial brachytherapy (LDR ISBT) for mobile tongue cancer. However, there are few reports regarding long-term follow-up of the grade of tongue hemiatrophy. In this study, we evaluated tongue hemiatrophy and patient satisfaction during a follow-up period of almost over 20 years.
Material and Methods: We selected 9 patients (5 males and 4 females) with mobile tongue cancer that were treated with LDR ISBT at Osaka University Hospital and followed-up for almost over 20 years. The median age at the time of LDR ISBT was 43 years (range: 21−57 years). The mean duration of follow-up was 297 months (range: 238–373 months). Using the UICC classification system, 4 patients were classified as T1, 3 as T2, 1 as T3N0M0, and 1 as T4N1M0. Prior to treatment, we obtained verbal and written informed consent from all patients. For primary lesions, LDR ISBT was performed using Ir-192 hairpins with or without a single pin. Four patients were treated with LDR ISBT alone with a total dose of 70–84.6 Gy (median: 74.12 Gy) and 5 were treated with 50−70 Gy of LDR ISBT (median: 61.2 Gy) combined with 20–54.6 Gy (median: 30 Gy) of external beam radiation (EBR). Using the grading system proposed by Yoshioka et al. (G0−G3), we evaluated the tongue hemiatrophy and analyzed association between the grade of hemiatrophy and receipt of EBR. We also investigated the relationship between the grade and patient characteristics (duration of follow-up, target volume, age at the time of LDR ISBT, tumor thickness) using Spearman's rank correlation coefficient. All patients were queried regarding their satisfaction with the extent of return of oral function to pretreatment levels using a visual analog scale.
Results: Concerning the grade of tongue hemiatrophy, 2 patients were classified as G0, 3 as G1, 1 as G2, and 3 as G3. All G0 patients were treated with LDR ISBT alone. Patient satisfaction rate was 50−90% (mean: 85%). There were no statistically significant correlations between the grade of tongue atrophy and patient characteristics.
Conclusions: LDR ISBT with or without EBR for mobile tongue cancer showed a high degree of patient satisfaction after a long-term follow-up for almost over 20 years, although tongue hemiatrophy occurred.
No conflict of interest.

3217 POSTER

Efficacy of reirradiation in head and neck cancer

L. Diaz Gomez[1], E. Gonzalez Calvo[1], L. Gutierrez Bayard[1], I. Villanego Beltran[1], E. Munive Alvarez[1], V. Diaz Diaz[1], L. De Ingunza Baron[1], M.C. Salas Buzon[1]. *[1]Hospital Puerta del Mar, Unidad de Gestion Clinica Atención Integral al Cancer, Cadiz, Spain*

Background: Despite advances in treating head and neck cancer, 15−50% of patients will relapse. Survivors also face the risk of second primary tumors, their incidence is estimated at 8−22% and third place in the head and neck. In this retrospective research we assessed toxicities secondary to initial radiotherapy and reirradiation and analyzed the PFS (Progression-free survival) from the primary tumor and local recurrence or second primary on the previously irradiated field. The response to reirradiation was assessed.
Material and Methods: We evaluated 31 patients diagnosed with squamous cell carcinoma of head and neck who underwent reirradiation in our service from 1999–2011. Patients were classified into 2 groups according to local recurrence, 7 of these second primary tumors in the treated area and 24 local recurrences.
Results: We analyzed acute and late toxicities after initial treatment and reirradiation. In addition to the PFS between primary tumor recurrence or second primary tumor in the treated field. We realise that acute toxicities (RTOG) more frequent after initial treatment were mucositis G2 (28.8%), dermatitis G1 (22%) and G2 xerostomia (22.2%). Late toxicities were mainly G1 xerostomia (54.5%) and odynophagia G1 (13.6%). The most prevalent acute toxicities after reirradiation were: mucositis G1−2 (25.7%), dermatitis G1 (22.8%), xerostomia G1 (14.2%), dysphagia G1−2 (11.4%). Late toxicities secondary to reirradiation were xerostomia G2(35%), fibrosis G1−2 (20%) and dysgeusia G1 (15%). PFS to local recurrence mean was 37.3 months and to second primary tumors was 81.6 months. Currently, we have 17 patients in complete remission, 5 in partial response and 9 in progression.
Conclusion: Recurrence in head and neck on previously treated areas present a therapeutic challenge and therapeutic options are limited. Reirradiation with or without chemotherapy is an acceptable alternative when it's not suitable salvage surgery. However this treatment regimen is associated with considerable acute and late toxicity therefore must be assessed in highly selected cases.
No conflict of interest.

3218 POSTER

High dose re-irradiation using 3D-CRT and IMRT for recurrent and second primary head and neck cancers

M. Patel[1], S. Agarwal[1], S. Goswami[1], G. Sahu[1], A. Jadhav[1], S. Narayan[1], B. Goswami[1]. *[1]Jaslok Hospital & Research Centre, Radiation Oncology, Mumbai, India*

Background: Head & neck cancer is one of the most common cancers in India. Management of recurrent & second primary head and neck cancers in previously irradiated cases pose a significant therapeutic challenge. The role of external re-irradiation was rarely investigated and practiced mainly due to the fear of severe toxicity from cumulative high radiation doses exceeding the normal tissue tolerance. However, in the last decades re-irradiation has begun to gain conceptual acceptance as experimental and clinical studies have demonstrated that high dose re-irradiation can be administered successfully in a significant proportion of patients without unacceptable toxicities.
Material and Methods: Twenty four consecutive recurrent or second primary head and neck cancer patients treated with 3D-CRT (n = 2) or IMRT (n = 22) techniques with MV-CBCT image guidance from May 2009 to February 2013. All patients are biopsy proven squamous cell carcinomas with no evidence of distant metastasis investigated using a PET-CT or CT scan. Surgery prior to radiotherapy and concurrent chemotherapy with radiotherapy has been received by selected patients. Radiotherapy target volume delineation included the GTV with strict margin (5−7 mm) to create CTV and elective nodal irradiation was avoided.
Results: All patients have completed prescribed treatment with acceptable acute radiation toxicities managed conservatively. Fourteen patients are alive without disease; one of them underwent salvage surgery for relapse outside radiation field. Three patients are alive with disease; one of them remains locally controlled. Seven patients died of progressive cancer; again one of them was locally controlled. Overall sixteen patients achieved local control of the disease indicating efficacy of re-irradiation in controlling local recurrence.
Conclusion: Re-irradiation in recurrent and second primary head and neck cancers is feasible using newer radiotherapy techniques. In our study we have observed good patient compliance, encouraging local control of disease. However, with strict CTV delineation we have observed recurrences in the adjacent area suggesting use of larger CTV margin as and when necessary. Head and neck cancer is a heterogeneous disease and each patient needs proper evaluation and planning depending upon the clinical parameters.
No conflict of interest.

3219 POSTER

Surgical management of primary tracheal tumours − a herculean task

B. Venkitaraman[1], A. Kumar[2], B. Asaf[2], R. Parshad[2], P. Shivanna[1]. *[1]Institute Rotary Cancer Hospital, Department of Surgical Oncology, New Delhi, India; [2]All India Institute of Medical Sciences, Department of Surgical Disciplines, New Delhi, India*

Background: Surgical management of primary tracheal tumors is a complex task. Surgical expertise in this field is also very limited. The peculiar surgical anatomy of the trachea and lack of an ideal tracheal substitute,issues with anesthesia all make the surgical management more complicated. We, herein, share our experience in the surgical management of primary tracheal tumors.
Materials and Methods: Retrospective analysis of the patient's records was done to identify patients with primary tracheal tumors who underwent surgery, during the last 6 years at our tertiary care institute.
Results: A total of 11 cases of primary tracheal tumours having undergone surgical management were identified. On histo-pathological analysis there were 6 adenoid cystic carcinoma, 2 schwannoma, 1 carcinoid tumour, 1 squamous cell carcinoma, 1 mucoepidermoid carcinoma. On evaluation with contrast enhanced computerized tomography, 10/11

cases had disease confined to trachea. All cases with localized disease underwent definitive surgical management in the form of primary resection and anastomosis (9), carinal pneumonectomy with tracheobronchial anastomosis (1). One patient had presented in emergency with stridor, underwent emergency tracheostomy and debulking. On further evaluation, this patient was found to have locally advanced disease and so was referred to palliative treatment. The length of trachea resected ranged from 2.8−6 cms. Laryngeal release- (suprahyoid and in some cases subhyoid release) and hilar release were done to achieve adequate tracheal mobilisation for primary tension free anastomosis. All patients had margin free resection. Patients with adenoid cystic carcinoma were also given adjuvant radiotherapy. At follow up (range 8−45 months), all patients having received definitive surgical management are doing well with no symptoms/disease recurrence on imaging and bronchoscopy. There were no perioperative mortality.
Conclusion: Primary resection and anastomosis for tracheal tumours is a complex procedure. With experience and adequate planning, this can be achieved without significant mortality or morbidity.
No conflict of interest.

3220 POSTER

Drugs affecting bone remodeling and postoperative hypercalcemia in patients with primary hyperparathyroidism

B. Peric[1], G. Pilko[1], Z. Dragonja[1], M. Hocevar[1]. [1]*Insititute of Oncology Ljubljana, Department of Surgical Oncology, Ljubljana, Slovenia*

Background: Primary hyperparathyroidism (PHPT) is a benign disease which, if left untreated, carries a near two-fold increase in development of several cancers and doubles the risk of cardiovascular diseases. Single adenoma is the source of an excess parathyroid hormone (PTH) in up to 90% of pts. Cure can be achieved with parathyroidectomy in up to 98% of cases which is reflected by normocalcemia on the first postoperative day. However, some patients (pts) remain hypercalcemic after the procedure. The usual cause is failure to recognize multigland disease but drugs affecting bone remodeling (bisphosphonates, calcitonin-salmon) may have the influence on early postoperative calcium levels as well.
Materials and Methods: Since January 2003 until December 2012, 577 pts with PHPT were operated at the Institute of Oncology Ljubljana. Pts with hypercalcemia on the first postoperative day were divided according to the PTH levels in two groups; normal/low PTH level or increased PTH level. The influence of preoperative application of drugs affecting bone remodeling on serum calcium level on the first postoperative day was compared between the groups with normal/low PTH level and increased PTH levels with Fisher's exact test.
Results: Out of 577 pts operated for PHPT, 495 (85.7%) were normocalcemic on the first postoperative day and 31 (5.4%) pts were hypocalcemic. Out of the remaining 51 pts (8.8%) with hypercalcemia, 16 pts had normal/low PTH level and 35 pts had increased level of PTH. Fifteen pts received drugs affecting bone remodeling preoperatively (8/16 with normal/low PTH, 7/35 with increased PTH). The influence of drugs on serum calcium level was compared between the groups with normal/low PTH level and increased PTH level. The difference was statistically significant with $p = 0.047$. Spontaneous resolution of the hypercalcemia in one week was observed in all pts with normal/low PTH level who received drugs affecting bone remodeling (8/16).
Conclusion: Drugs affecting bone remodeling may affect early postoperative serum calcium levels in pts with PHPT causing spontaneously resolving hypercalcemia with no need for repeat imaging and reoperation.
No conflict of interest.

3221 POSTER

Significance of depth of invasion in squamous cell carcinoma of buccal mucosa

S. Arora[1], D. Sarin[1], P. Acharjee[1], D. Gautam[2]. [1]*Medanta The Medicity Hospital, Head and Neck Oncology Surgery, Gurgaon Haryana, India;* [2]*Medanta The Medicity Hospital, Pathology, Gurgaon Haryana, India*

Background: (1) To study if the depth of invasion of primary site has an impact on neck node metastasis in squamous cell carcinoma (SCCA) of the buccal mucosa.
(2) A comparison of the impact of depth of invasion in buccal mucosa carcinoma versus tongue carcinoma on nodal metastasis.
Material and Methods: It is a retrospective study conducted in the Departments of Head and Neck oncology surgery and Department of Pathology at Medanta, The Medicity, Gurgaon, India.
66 consecutive patients of primary buccal mucosa and tongue squamous cell carcinoma who underwent surgery from January 2011 to December 2012 were included in the study. There were 39 buccal mucosa and 27 tongue carcinoma patients.
Patients were divided into two categories:
1. Tumors with depth of invasion of 4 mm or less
2. Tumors with depth of invasion of more than 4 mm

Results: Depth of invasion was a statistically significant criteria in predicting neck nodal metastasis (p value <0.01) in patients with buccal carcinoma.
When compared with tongue SCCA, the depth of invasion of the primary tumor in buccal mucosa SCCA correlated better with predicting presence or absence of neck metastasis.
Conclusion: Depth of invasion is significant criteria for predicting neck node metastasis in buccal mucosa cancer. There is only limited literature available on this aspect and needs further evaluation with prospectively collected data. Overall impact on prognosis of depth of invasion has not been studied in our data and would need further evaluation.
No conflict of interest.

3222 POSTER

Clinicopathologic study and outcome analysis of major glossectomy: Experience from a tertiary cancer center

K. Rakesh[1], A. Deshmukh[1], D.A. Chaukar[1], A.K. D'Cruz[1]. [1]*Tata Memorial Centre, Head and Neck Services, Mumbai, India*

Background: Advanced cancers of the tongue is a therapeutic challenge due to associated high morbidity and poor survival. Despite advances in treatment options and improved rehabilitation methods it is still considered a bottleneck. Major glossectomy is considered a radical form of treatment with significant associated morbidity and more or less considered an palliative procedure because of poor survival in this group of patients.
Methods: With this background we retrospectively evaluated 194 patients operated at a tertiary cancer center during a period of 2007−11. The patients were evaluated for clinico-pathological details and various predictive factors associated with it.
Results: Of 194 patients who underwent major glossectomy mean age at presentation was 49 years with M:F ratio of 2.88:1. Total/Near total glossectomy was performed in 58.7%, anterior 2/3rd glossectomy in 20.1% and tongue composite resections in around 21.1%. Pull through approach was mainly used for access to the tumor (73.1%) with peroral access used only in 5 % of patients. Pedicled flaps were the mainstay of reconstruction with Pectoralis major flap ruling the roost in around 64% patients. All patients except 3 had histology in form of squamous cell carcinoma with moderately differentiated squamous cell carcinoma in around 54.6% patients.
Conclusion: Major glossectomy in present era of advanced chemoradiation protocols is still an valid option despite being associated with high morbidity and poor survival rates.
No conflict of interest.

3223 POSTER

Reconstruction of extensive composite oromandibular defects with FFOCF role of pre operative mapping of septocutaneous perforators

P. Yadav[1], V. Shankdhar[1]. [1]*Tata Memorial Hospital, Surgery, Mumbai, India*

Introduction: Oromandibular cancers are very common in India. Resection results in varying defects and are classified according to tissue loss. Even extensive defects can be reconstructed with single FFOCF. From 2005 to 2012, 850 oromandibular reconstructions with single FFOCF were done at Tata Memorial Hospital Mumbai, India. The outer paddle loss was observed mainly in extensive defects when skin paddle was de-epithelised and rotated out for skin cover. Study was done to identify and resolve the problem.

Table (abstract 3223).

Year	Fibula flaps	Single paddle	Skin excision	Primary closure	Faciocervical flap	De-Epithelise		Divided paddle	Regional Flap	2nd Free Flap	Super charge
							*				
2005	85	47	38	−	−	38	6	0	5	−	−
2006	81	54	27	−	−	27	4	0	4	−	−
2007	66	35	31	−	−	31	3	0	3	−	−
2008	77	43	34	−	−	34	5	0	3		
2009	109	68	41			41	4	0	3		
2010	119	58	61	1	4	51	8	03	1	0	1
2011	140	70	70	9	4	27	4	26	1	3	0
2012	143	57	86	3	2	27	5	39	1	14	0

*Partial necrosis.

Material and Method: See the table.
Septocutaneous perforator vessels for fibular skin paddle were studied extensively. Number of perforators, location of perforators in relation to bone segments to be used were analysed and a protocol is developed and followed since 2010.
Technique: Pre op Doppler mapping is done to locate number and location of perforators. Perforators are marked from distal to proximal on the leg. Osteotomy is planned from distal to proximal end. Location of perforators to bone segment to be used play significant role during osteotomy planning.
Results: Since this protocol is followed there is no loss in divided skin paddle used for outer cover.
Conclusion: Pre op perforator mapping is important and helpful in planning reconstruction of composite or extensive oromandibular defects where external skin cover is required.
Tentative plan for second flap is made at the time of perforator mapping depending on number and location of perforators and the defect size.
Ideally located perforators are, one on bony segment for mucosal lining and other one just beyond required bone segment. Based on second perforator skin is divided and rotated out.
No conflict of interest.

3224 POSTER

Suboccipital lymphadenectomy for patients with occipital squamous cell carcinoma of the scalp: Results in 14 patients

F. Fouad Saleep[1], I. Fayek[1], I. Farahat[2]. *[1]National Cancer Institute − Cairo University, Surgical Oncology, Cairo, Egypt; [2]National Cancer Institute − Cairo University, Pathology Department, Cairo, Egypt*

Aim: To highlight the role and benefit of suboccipital lymph node dissection as an integral step in the surgical management of occipital scalp squamous cell carcinoma.
Methods: Between 2007 to 2011 fourteen patients with pathologically proven squamous cell carcinoma at the occipital region of the scalp underwent suboccipital and retro auricular lymph node dissection in continuity with the contents of the upper part of the posterior triangle of the neck.
Results: All patients underwent elective suboccipital lymphadenectomy; the number of dissected lymph nodes ranged from 3−9 LNs (mean 5.8 LNs). No serious complications were observed apart from mild wound infections in 2 patients. In 6 out of 14 patients lymph nodes were metastatic (42.8%). 4 patients lost follow-up. All the remaining 10 patients were followed up between 12−26 months. One patient developed local recurrence after 8 months and another one developed nodal recurrence at the spinal accessory group of lymph nodes after 14 months; both patients had +ve LN metastases at the suboccipital nodes at the initial dissection.
Conclusion: Suboccipital lymphadenectomy is a safe procedure with low morbidity and should be done in all patients with scalp squamous cell carcinoma at the occipital region of the scalp which could add to the locoregional control of the disease and serves as a prognostic indicator for future locoregional recurrences.
No conflict of interest.

3225 POSTER

Lymphatic drainage and regional metastases in papillary thyroid carcinoma of pyramidal lobe − a single institution experience

N. Santrac[1], N. Besic[2], L. Petrovic[1], M. Buta[1], I. Djurisic[1], M. Oruci[1], G. Pupic[3], Y. Ito[4], R. Dzodic[1]. *[1]Institute for Oncology & Radiology, Surgery, Belgrade, Serbia; [2]Institute for Oncology Ljubljana, Surgery, Ljubljana, Slovenia; [3]Institute for Oncology & Radiology, Pathology, Belgrade, Serbia; [4]Kuma Hospital, Surgery, Kobe, Japan*

Background: The pyramidal lobe (PL) represents the remnant of the distal part of thyroglossal tract. PL varies in position, size and shape. Papillary thyroid carcinoma (PTC) is the most common histological type of thyroid malignancy. It may be multicentric in up to 80% of cases and it frequently involves both lobes. The aim of our retrospective study was to find out the incidence of primary single focus PTC in PL and routes of lymphatic drainage and lymphonodal metastases from PL.
Material and Methods: A chart review of all patients who had thyroid surgery in our tertiary center by a single surgeon from year 2003 to 2012 was presented. Altogether 753 patients were treated surgically for PTC. The patients who had PTC located only in PL or in PL-isthmus junction were included in this study. Cases with primary PTC in lateral and pyramidal lobe (multifocal) were excluded from our study. In all cases, methylene blue dye was injected in isthmus of thyroid gland (periturmoraly) during surgical procedure in order to perform sentinel lymph node (SLN) biopsy in lateral neck compartments. In all cases of PTC a total thyroidectomy was done together with central neck dissection. Additionally, SLN biopsy was performed in both lateral compartments. Lateral neck dissection was not performed because frozen section analysis in all SLNs from lateral compartment was benign, which was confirmed also on standard histopathology.
Results: Only 3 of 753 patients (0.4%) had primary PTC in PL and that was the only PTC focus. All of them were females, aged 22, 36 and 41. Blue lymph nodes were present in 5, 14 and 5 nodes per patient. Primary tumor diameter in pathological report was 12, 15 and 20 mm. In all three patients blue SLNs were present bilaterally in central compartment and in lateral neck compartments. Altogether 9, 22 and 31 lymph nodes per patient were examined by a pathologist. The only metastatic lymph node was present in a midline prelaryngeal node (Delphian). One patient was postoperatively treated with 131-I, while all patients had suppression of TSH with L-thyroxin. Patients were followed for 5 to 108 months and there were no recurrences.
Conclusion: Incidence of primary PTC in PL was 0.4%. The only site of metastasis in our patients with primary T1 stage of PTC was a midline prelaryngeal node (Delphian). All other lymph nodes from central compartment, as well as SLNs from lateral compartments, were benign.
No conflict of interest.

3226 POSTER

Minimally invasive parathyroidectomy seems suitable for day surgery in patients with primary hyperparathyroidism

Z. Faiz[1], P.C. Baas[1], W. Kelder[1]. *[1]Martini Ziekenhuis Groningen, Surgery, Groningen, Netherlands*

Background: Minimally invasive parathyroidectomy (MIP) is performed in several high-volume foreign centers in day care. However, that is not the standard in the Netherlands. Our retrospective study was designed to evaluate if our population and surgical technique are suitable to perform minimally invasive parathyroidectomy in day care.
Methods: Eighty-two patients with primary hyperparathyroidism were included in the period December 2005 to October 2012. Patients with previous neck surgery including parathyroid surgery were excluded. Patients with secondary and tertiary hyperparathyroidism were also excluded. Sestamibi scan and ultrasound were performed for preoperative localisation. In addition, we measured the perioperative PTH (5, 10, 15 min) and performed intraoperative frozen section analysis of the adenoma. We have also searched for predictive factors for hypocalcemia. Group analysis was performed using non-parametric tests. Univariate analysis was performed with the Log-Rank or Chi2 test. Multivariate analysis was performed with Cox regression analysis.
Results: A solitary adenoma was found in 77 patients (93.9%). MIP was performed in 69 patients (84.1%) and bilateral in 13 patients due to insufficient preoperative localisation. Based on the frozen section results we have performed bilateral exploration in 2 patients (2.4%). The operation time was 80 minutes (including PTH measurement and frozen section analysis). Temporary hoarseness was noticed in 3 (3.6%) patients.

Postoperative asymptomatic hypocalcemia was diagnosed in 5 patients. Sestamibi scan was more sensitive than the ultrasound (58.5% vs. 24.7%). The weight of the resected adenoma was significantly correlated with the baseline value of PTH ($p < 0.001$). After univariate analysis operation time was the only significant predictive factor for the development of hypocalcemia ($p < 0.05$).
Conclusion: The weight of the adenoma is associated with the baseline PTH. For the localisation of the adenoma has ultrasound limited contribution. Given the limited effect on the course of the operation, the time consuming frozen section analysis should only be performed in selected cases. Operation time is the only risk factor for hypocalcemia after parathyroidectomy. Overall, minimally invasive parathyroidectomy seems a suitable method for day surgery in patients with primary hyperparathyroidism.
No conflict of interest.

3227 POSTER

Surgical resection post neoadjuvant chemotherapy in technically unresectable locally advanced oral cancers rendered resectable by neoadjuvant chemotherapy

V. Sharma[1], V. Patil[1], V. Noronha[1], A. Joshi[1], S. Juvekar[2], D. Chaukar[3], P. Chaturvedi[3], P. Pai[3], A. DCruz[3], K. Prabhash[1]. [1]*Tata Memorial Centre, Medical Oncology, Mumbai, India;* [2]*Tata Memorial Centre, Radiodiagnosis, Mumbai, India;* [3]*Tata Memorial Centre, Surgical Oncology, Mumbai, India*

Background: Locally advanced oral cancers (T4) with extensive disease and skin infiltration are commonly considered as unresectable, as in such tumors the need of resection of vital organs is high or probability of achieving a negative margin is low. Can giving neoadjuvant chemotherapy (NACT) render these large tumors resectable with negative tumor margins is an open question.
Materials and Methods: We retrospectively analysed our data of locally advanced oral cancers that were technically unresectable upfront and were rendered resectable after NACT. The hypothesis of this analysis was to test whether NACT enabled us achieve a R0 resection in more than 90% of these patients, who were considered resectable at the end of 2 cycles of NACT. The figure of 90% was chosen as in T4 oral cancers that are upfront resectable, margin positive rates of upto 15−20% are described in literature. Predetermined (our previously published) landmarks of extensive skin involvement upto zygoma in buccal cancers, extensive soft tissue extension leading to involvement upto either the level of the hyoid bone in primary of tongue cancers or floor of mouth cancers, extensive involvement of base of tongue and vallecula from a primary in tongue and involvement of the infratemporal fossa in any oral cavity primary was used for definition of technically unresectable. The criteria used for deciding resectabiliy post neoadjuvant chemotherapy was disappearance of the disease or decrement in the disease leading to clearance of disease from these anatomical landmarks on radiology. Two hundred and thirty six patients out of 528 technically unresectable locally advanced oral cancers underwent surgery. The margin status & resection status were noted.
Results: Five hundred and twenty eight patients were given chemotherapy with the intention of making them resectable.The chemotherapy delivered was TPF in 35 (6.6%) and two drug combination of taxane & platinum in rest. Out of these, 245 patients (46.4%) were considered resectable in the multidisciplinary clinic and 236 (44.7%) underwent resection. The median time to surgery after last dose of chemotherapy was 4 weeks. R0 resection was achieved in all patients (100%). The incidence of close margin (<5 mm) was 2.96% (7 patients). There was no postoperative mortality noted in these patients.
Conclusion: Surgical resection post NACT in technically unresectable oral cancers is possible in nearly half of such advanced patients. In the patients undergoing surgical resection at our centre, all patients could be resected with a negative margin.
No conflict of interest.

3228 POSTER

Outcome of patients treated with palliative weekly paclitaxel plus cetuximab in recurrent head and neck cancer after failure of platinum-based therapy

A.E. Sosa[1], J.J. Grau[1], L.R. Feliz[1], M.V. Pereira[1], D.W. Alcaraz[1], C. Muñoz-García[2], M. Caballero[3]. [1]*Hospital Clinic de Barcelona, Medical Oncology, Barcelona, Spain;* [2]*Laboratory of Molecular Biology, University of Barcelona, Barcelona, Spain;* [3]*Hospital Clinic de Barcelona, Otorhinolaryngology, Barcelona, Spain*

Background: Few therapeutic options are available for recurrent/metastatic head and neck cancer when progression occurs after initial chemotherapy with platinum-based regimens. We analyzed retrospectively the efficacy of weekly paclitaxel plus cetuximab as second line of palliative chemotherapy.
Material and Methods: Patients with squamous carcinoma of head and neck with documented progression after initial treatment were enrolled. Tumor response was evaluated through the RECIST 1.1 criteria. The retrospective analysis focused on overall survival (OS) and progression-free survival (PFS).
Results: Between 2008 and 2011, 33 consecutive patients were treated. An overall response rate (ORR) of 55% was observed, with median response duration of 5.0 months. The median PFS was 4.0 months and the median OS time was 10.0 months. Chronic anemia was the most common adverse event and it ocurred in 12 patients.
Conclusions: A weekly schedule of paclitaxel plus cetuximab is a promising regimen for patients with advanced head and neck cancer after failure of platinum-based therapy. Good tolerance allows treating more fragile patients.
No conflict of interest.

3229 POSTER

A phase II study of combination chemotherapy with S-1 and nedaplatin as neoadjuvant manner for oral squamous cell carcinoma patients

M. Nakazawa[1], A. Niki[1], F. Ogawa[2], Y. Matsumoto[1], S. Iwai[1], I. Kato[1], T. Sumi[1], T. Ohnishi[2], K. Amino[3]. [1]*Osaka University Dental Hospital, Oral & Maxillofacial Surgery, Suita, Japan;* [2]*Ikeda Municipal Hospital, Oral & Maxillofacial Surgery, Ikeda, Japan;* [3]*Nishinomiya Municipal Central Hospital, Oral & Maxillofacial Surgery, Nishinomiya, Japan*

Background: In oral cancer therapy, functional preservation is very important matter. Effective preoperative (neoadjuvant) chemotherapy is required. We investigated the feasibility of combination chemotherapy with S-1 (an oral fluoropyrimidine) and Nedaplatin (CDGP) as a neoadjuvant regimen for oral squamous cell carcinoma patients.
Materials and Methods: Twenty-three fresh cases with stage II−IV oral squamous cell carcinoma were enrolled in this study from April 2010 to March 2012. Patients were administered S-1 80 mg/m^2/day (day 1−14) and CDGP 80 mg/m^2/day (day 8) and followed by definitive surgery. Clinical response was examined by clinical findings and/or CT and histopathological effects were evaluated with surgical specimens.
Results: The rate of clinical response including complete response(CR) and partial response(PR) was 43.6%: CR 21.8%, PR 21.8%, NC 56.4%. The rate of histological response was same. The response rate by T category was 53.3% for T2, 33.3% for T3 and 20% for T4 tumor. Main toxicities were myelosuppression and gastrointestinal disturbances; leukocytopenia 39.1%(Grade II:6, III:2), neutropenia 34.8%(Grade II:5, III:2, IV:1), thrombocytopenia 47.8%(Grade I:2, II:4, III:5), hypohemoglobinemia 47.8%(Grade I:10, II:1), anorexia 21.7%(Grade I:5), nausea 47.8%(Grade I:9, II:2). The toxicities more than grade III were leukocytopenia (8.3%), neutropenia (13%), thrombocytopenia (21.7%), diarrhea(4.3%) and oral mucositis(4.3%). The most part of toxicities disappeared within 4 weeks after chemotherapy. No serious adverse effects were observed in all patients.
Conclusions: Combination chemothetapy with S-1 and CDGP represents an effective antitumor activity and mild to moderate toxicities. It is suggested that this regimen is suitable for neoadjuvant chemotherapy.
No conflict of interest.

3230 POSTER

Angiotensin-converting enzyme (ACE) inhibitors could prevent aspiration pneumonia in head and neck cancer patients treated with concurrent chemoradiotherapy (CCRT)

Y. Sato[1], K. Nakano[1], Y. Sato[2], T. Toshiyasu[3], K. Kawabata[4], S. Takahashi[1]. [1]*Cancer Institute Hospital of Japanese Foundation of Cancer Research, Medical Oncology, Tokyo, Japan;* [2]*Cancer Institute Hospital of Japanese Foundation of Cancer Research, Pathology, Tokyo, Japan;* [3]*Cancer Institute Hospital of Japanese Foundation of Cancer Research, Radiology, Tokyo, Japan;* [4]*Cancer Institute Hospital of Japanese Foundation of Cancer Research, Head and Neck Surgery, Tokyo, Japan*

Background: Concurrent chemoradiotherapy (CCRT) is a standard treatment for locally advanced head and neck cancer patients, but some patients complicate aspiration pneumonia, which might interrupt their therapy. For preventing aspiration pneumonia, angiotension-converting enzyme (ACE) inhibitors have been known to be effective in high risk patients such as post -stroke. We retrospectively evaluated the effectiveness of ACE inhibitors on the risk reduction of aspiration pneumonia in head and neck cancer patients treated with CCRT.
Methods: We retrospectively analyzed non-metastatic head and neck cancer patients treated with CCRT from November 2005 to December 2012 in our hospital. Chemotherapy consisted of cisplatin (CDDP) (80 mg/m^2 per

3 weeks), but carboplatin (AUC 1.5 weekly) or docetaxel (10 mg/m^2 weekly) was administered in case patients were consider to be intolerable to CDDP. Radiation therapy was performed as three-dimensional radiotherapy (3D-RT) or intensity-modified radiotherapy (IMRT).
Results: A total of 224 patients (192 male, 32 female; median age 59.6 years) received CCRT, of which 128 (57.1%) were Stage4. Median follow-up time was 19.3 months (range 0.99–71.4 months). Patients were divided into three groups based on their antihypertensive medication; 17 patients (7.6%) received ACE inhibitors,56 patients (25.0%) received antihypertensive drugs other than ACE inhibitors, and 151 patients (67.4%) received no antihypertensive drugs. Twenty-nine (12.9%) patients were complicated by aspiration pneumonia, but no patient with ACE inhibitors had aspiration pneumonia. On the other hand, 17.8% (10 patients) of patients with other antihypertensive drugs, and 12.5% (19 patients) of patients without antihypertensive drugs were complicated by aspiration pneumonia. Statistical analysis could not be performed because of lack of aspiration pneumonia events in patients with ACE inhibitors.
Conclusion: In head and neck cancer patients treated with CCRT, ACE inhibitors could be effective for preventing aspiration pneumonia.
No conflict of interest.

3231 POSTER

Development of hyponatremia on neoadjuvant chemotherapy in locally advanced head & neck cancers

B. Poladia[1], V. Patil[1], V. Noronha[1], A. Joshi[1], V. Sharma[1], S. Punatar[1], A. Sahu[1], G. Goyal[1], S. Dhumal[1], K. Prabhash[1]. *[1]Tata Memorial Hospital, Medical Oncology, Mumbai, India*

Background: Hyponatremia is a potential life threatening complication. The incidence of this toxicity is minimal to absent in recently reported studies of neoadjuvant chemotherapy (NACT) in head & neck cancers.
Material and Methods: This is a retrospective analysis of 528 patients of locally advanced oral cancers who received NACT at our centre. The aim of this study was to report the incidence of hyponatremia & to study the factors leading to its development. The database maintained in our department, electronic medical record system & case charts of these patients were reviewed to note the incidence of hyponatremia. The hyponatremia was graded in accordance to CTCAE version 4.02. In addition factors like age, sex, body mass index, drug regimen, types of drugs, co morbidities & concurrent medications which can lead to hyponatremia were noted. SPSS version 16 was used for analysis.
Results: The median age of this cohort was 45 years (22−78 years). It was a male predominant population (83.72%). Co morbidities in the form diabetes mellitus was present in 118 patients (22.3%), hypertension in 100 patients (18.9%) & ischemic heart disease in 70 patients (13.3%). The concurrent use of thiazide diuretics was present in 60 patients (11.36%) & sulfonylurea hypoglycaemic in 82 patients (15.15%). Baseline hyponatremia prior to start of chemotherapy was present in 43 patients (8.14%) & median baseline sodium levels in these 43 patients were 132 meq/L(129–134 meq/L). The chemotherapy delivered was TPF in 35 (6.6%) and combination of taxane with platinum in rest all. Taxane used in the 2 drug combination was Docetaxel in 249 patients (47.3%) & Paclitaxel in 244 patients (46.3%). The platinum administered in 2 drug combination was cisplatin in 419 patients (79.6%). The incidence of any grade hyponatremia was 34.5% in the first cycle of chemotherapy & 19.1% in the second cycle of chemotherapy. The nadir value of hyponatremia was seen mainly on day 8 (5−14 days) in both first & second cycle The cumulative incidence of hyponatremia was 44.5%. The cumulative incidence of grade 3−4 hyponatremia was 35%. Among the variables tested on univariate analysis use of a 3 drug regimen of TPF ($p = 0.0001$) & in 2 drug regimen use of docetaxel ($p = 0.0034$) was significantly associated with hyponatremia. Use of Cisplatin containing regimen was not associated with hyponatremia.
Conclusion: Around one-third of our patients develop grade 3−4 hyponatremia post neoadjuvant chemotherapy. Regular monitoring & vigilance about development of this complication is recommended.
No conflict of interest.

3232 POSTER

Neoadjuvant chemotherapy (CT) with docetaxel, cisplatin and 5-fluorouracil (TPF) before concomitant chemoradiation for locoregionally advanced (LA) squamous cell carcinomas of the head and neck (SCCHN): single-center experience and results of an intensive nurse-led support program (INLSP)

J. Mouta[1], A. Mayer[1], D. Costa[1], E. Gouveia[1], I. Miguel[1], P. Winckler[1], I. Sargento[1], M. Ferreira[1], A.L. Rita Moreira[1]. *[1]Instituto Potuguês de Oncologia de Lisboa, Medical Oncology, Lisboa, Portugal*

Background: SCCHN is the sixth most common cancer worldwide, 2/3 of the patients (pts) presenting in advanced stages (III and IV). Since 2007, in some centres, the standard of care for LA SCCHN is neoadjuvant CT with TPF, followed by concomitant chemoradiation. This approach has led to improved progression-free and overall survival. In 2012 we started at our institution an INLSP for these pts. We present our toxicity and survival results.
Material and Methods: Patients were treated with Docetaxel 75 mg/m^2 (day 1), Cisplatin 75 mg/m^2 (day 1) and 5-Fluorouracil 750 mg/m^2/day (days 1−5) for three cycles, followed by concomitant chemoradiation.
The clinical records of all pts were retrospectively reviewed. We retrieved demographical, epidemiological and clinical information. We evaluated efficacy using clinical criteria. Toxicity was evaluated using Common Terminology Criteria for Adverse Events 4.0. Statistical analysis was performed using STATA (R) and Microsoft Excel 14.2.3 (R). Survival was estimated using Kaplan–Meier method.
Results: Between July 2008 and February 2013 117 pts were treated at our institution (87% male). Mean age at diagnosis was 53 years-old. 92% of the pts had ECOG PS 0 or 1. The most common primary tumor locations were Oropharynx (47%), oral cavity (23%) and hypopharynx (22.2%). The majority had stage IVA (47%) or IVB (51.3%) disease. Tobacco (95.7%) and Alcohol use (92.3%) were the most common comorbidities. 29.92% of the pts were enrolled on our INLSP. Pts received a mean number of 2.73 cycles of TPF. Overall Clinical Response rate with TPF was 87.2%, with a Complete Clinical Response Rate of 14.5%. The most common adverse events were anemia (50.4%) and diarrhea (28.2%). 26.5% of the pts experienced grade 3−4 toxicity (mainly neutropenia and diarrhea). Six pts died as a result of the treatment (5.1%). With a median follow-up of 7.17 months, median PFS is 14.97 months. With a median follow-up of 14.48 months, 1- and 3-year OS are 82% and 38%, respectively, with a median OS of 20.5 months. Pts enrolled in the INLSP experienced less toxicity and fewer grade 3−4 events, but diferences were not statistically significant.
Conclusions: Neoadjuvant CT with TPF followed by concomitant chemoradiation is an effective treatment for pts with LA SCCHN. Toxicity is important. These pts should be treated at high-volume, experienced institutions. Our INLSP is improving toxicity and treatment-associated death rates, but differences are still nonsignificant.
No conflict of interest.

3233 POSTER

Bone marrow toxicity from large cumulative activity of radioiodine therapy in advanced differentiated thyroid cancer patients

D.H.Y. Shen[1], C.H. Hou[2], L.F. Lin[2], C.H. Ku[3], C.Y. Cheng[1]. *[1]Tri-Service General Hospital National Defense Medical Center, Nuclear Medicine, Taipei City, Taiwan; [2]Tri-Service General Hospital National Defense Medical Center, Nuclear Medicine, Taipei City, Taiwan; [3]National Defense Medical Center, Public Health, Taipei City, Taiwan*

Radioiodine therapy (RAIT) is usually repetitively given to patients with advanced differentiated thyroid cancers (DTC) provided the tumors remain iodine-avid. However, bone marrow depression with permanent leukopenia might happen with large cumulative dose used. We intend to investigate the possible factors influencing its occurrence.
Material and Methods: We retrospectively reviewed 728 consecutive DTC patients receiving RAIT during 2006 Feb to 2012 Aug at our institute (the most important academic tertiary referral center for RAIT in Taiwan). All the patients were treated based on empirically selected dosage regimen (100–200 mCi for each time) and had WBC tested on a pre-RAIT routine and/or at least 6 months apart from prior RAIT. Totally 43 patients with cumulative RAIT dose to $\geqslant$500 mCi were studied. 8 cases with initially low leukocyte count (WBC) or experiences of external beam radiotherapy were excluded and 35 patients were used to analyze their WBC decrease in related to various factors, including age, gender, histopathology, metastases, and cumulative dose.
Result: Eight out of 35 cases revealed WBC <4000/uL after repetitive RAIT. The counts varied from 2080 to 3900/uL and none of the patients experienced severe infection. The change of WBC (i.e. percentage difference between post RAIT and original ones) ranged from +34% to −70% (Average: +0.5% $\pm$ 41.3%). The reduction in WBC was significantly related to the presence of bony metastases and non-papillary cancer type, while age at RAIT, gender, cumulated dose did not affect the WBC change. After the adjustment for age and gender, we found that metastases and histopathology were strong predictors to indicate decreased WBC after large cumulative dose.
Conclusion: The permanent bone marrow toxicity is regarded as a serious RAIT-related side effect but its occurrence seems not high. From our data, bone metastasis is a reliable predictor for DTC patients more sensitive to large cumulative RAIT dose. However, whether the reduced WBC is due to bony metastases *per se* or via more absorbed dose from RAIT requires further clarification.
No conflict of interest.

Induction chemotherapy followed by either chemoradiotherapy or bioradiotherapy in locoregionally advanced head and neck cancer

Y. Seol[1], C.Y.J. Choi Yong Jin[1]. [1]*Pusan National University Hospital, Internal Medicine, Busan, South Korea*

Background: To compare the efficacy and safety of induction chemotherapy (ICT) followed by chemoradiotherapy (CRT) or bioradiotherapy (BRT) in locoregionally advanced head and neck cancer.
Methods: Previously untreated patients with stage III to IV larynx/hypopharynx squamous cell carcinoma received three cycles of ICT−docetaxel and cisplatin 75 mg/m^2 each on day 1. Poor responders (<50% response) underwent salvage surgery. Responders (>50% response) were randomly assigned to conventional radiotherapy (RT;70 Gy) with concurrent cisplatin 40 mg/m^2 per week of RT (arm A) or concurrent cetuximab 400 mg/m^2 loading dose and 250 mg/m^2 per week during RT (arm B). Primary end point was Larynx Preservation (LP). Secondary end points were larynx function preservation(LFP) and overall survival (OS) at 24 months.
Results: Of the 77 enrolled patients, 52 patients enrolled in Arm A, 25 patients enrolled in Arm B. Toxicity of both CRT and BRT was substantial following ICT. However, treatment compliance was higher in the BRT arm. In an intent-to-treat analysis, there was no significant difference in LP at 3 months between arms A and B (92% and 93%, respectively), LFP (87% and 82%, respectively), and OS at 24 months (75% and 72.2%, respectively). There were fewer local treatment failures in arm A than in arm B; salvage surgery was feasible in arm B only.
Conclusions: Induction DP chemotherapy followed by Chemoradiotherapy or Bioradiotherapy is feasible treatment strategy for patients with locoregionally advanced head and neck cancer. However,There is no evidence that one treatment was superior to the other or could improve the outcome reported with ICT followed by RT alone.
No conflict of interest.

3235 POSTER

Cetuximab plus platinum-based chemotherapy in head and neck cancer: A retrospective study in a single European Institution

R.A. De Mello[1], M. Pantarotto Alves[1], S. Gerós[2], F. Moreira[3], C. Vieira[1], I. Azevedo[1], J. Dinis[1]. [1]*CROP − Instituto Portugues Oncologia, Medical Oncology/Head and Neck Unit, Porto, Portugal;* [2]*Centro Hospitalar de Vila Nova de Gaia/Espinho, Service of Otorhinolaryngology and Cervical Facial Surgery, Vila Nova de Gaia, Portugal;* [3]*CROP − Instituto Portugues Oncologia, Head and Neck Unit, Porto, Portugal*

Background: Cetuximab in association with platinum plus 5-fluorouracil was previous demonstrated to be effective in metastatic squamous tumor of head and neck. We investigated in a retrospective cohort the efficacy and outcome of this protocol as first line treatment for patients with recurrent or metastatic disease, with the primary end point of overall-survival (OS); and secondary end-point, progression-free-survival (PFS) and toxicities profile.
Material and Methods: We enrolled 121 out of 280 eligible patients (between January 2010 and December 2012) with untreated recurrent or metastatic squamous-cell carcinoma of the head and neck to receive cisplatin (at a dose of 100 mg per square meter of body-surface area on day 1) or carboplatin (at an area under the curve of 5 mg per milliliter per minute, as a 1-hour intravenous infusion on day 1) plus fluorouracil (at a dose of 1000 mg per square meter per day for 4 days) every 3 weeks for a maximum of 6 cycles plus cetuximab (at a dose of 400 mg per square meter initially, as a 2-hour intravenous infusion, then 250 mg per square meter, as a 1-hour intravenous infusion per week) for a maximum of 6 cycles. Patients with stable disease who received chemotherapy plus cetuximab continued to receive cetuximab until disease progression or unacceptable toxic effects, whichever occurred first.
Results: The median age was 53.5 (37−78) years old. Male gender was predominant: 86.3%. Primary tumor site was: oropharynx (21%), hypopharynx (20.3%), larynx (25.3%), oral cavity (30.4), others (2.5%). Extent of disease was only localrecurrent (51.3%) and metastatic with or without locoregional recurrence (48.7%). The addition of cetuximab to platinum plus 5-fluorouracil in recurrent or metastatic setting provided an OS of 11 (Confidential Interval, CI, 95%, 9.065–12.935) months and PFS of 9 (95% CI, 6.425–11.575) months. The most common grade 3 or 4 adverse events in the chemotherapy-alone and cetuximab groups were febrile neutropenia (6.3%), skin rash (5.1%), mucosistis (5.1%) and anemia (3.8%). Of total patients receiving cetuximab, 6.3% had grade 3 skin reactions and 7.7% had grade 3 or 4 infusion-related reactions. There were no cetuximab-related deaths.
Conclusions: Our group suggests that cetuximab plus platinum–fluorouracil chemotherapy is indeed a very good option for systemic treatment in advanced head and neck squamous tumors notwithstanding well-tolerated toxicity profile and management.
No conflict of interest.

3236 POSTER

Indications for neoadjuvant chemotherapy (NACT) in head & neck cancers − do we differ from the West?

V. Patil[1], V. Noronha[1], A. Joshi[1], S. Punatar[1], G. Goyal[1], S. Juvekar[2], P. Chaturvedi[3], D. Chaukar[3], A. DCruz[3], K. Prabhash[1]. [1]*TMH, Medical Oncology, Mumbai, India;* [2]*TMH, Radiodiagnosis, Mumbai, India;* [3]*TMH, Surgical Oncology, Mumbai, India*

Background: Use of any treatment modality in cancer depends not only on the effectiveness of the modality but also on other factors like local expertise, tolerance of the modality, cost & prevalence of the disease. Oropharyngeal & laryngeal cancer are the major subsites in which majority of NACT literature in head & neck cancers is available. However oral cancers form a major subsite in Eastern Asia.
Method: This is an analysis of a prospectively maintained data on NACT in head & neck cancers from 2008–2012. All these patients were referred for NACT for various indications from a multidisciplinary clinic. Descriptive analysis of indications for NACT in this data base is presented.
Results: 862 patients received NACT within the stipulated time period. The sites were oral cavity 721 patients (83.6%), maxilla 41 patients (4.8%), larynx 33 patients (3.8%), laryngo-pharynx 8 patients (0.9%) & Hypopharynx 59 patients (8.2%). Out of oral cancers, the major indication for NACT was to make the cancer resectable in 703 patients (97.5%of oral cancers) while preservation of mandible was an indication in 19 patients (2.5% of oral cancers). The indication in carcinoma of maxilla was to make the disease resectable in 29 patients (70.7% of maxillary cancers) & in 12 patients it was given as an attempt to preserve the eyeball (29.3% of maxillary cancers). The indication for NACT in laryngeal cancers was organ preservation in 14 patients (42.4% of laryngeal cancer) & to achieve resectability in 19 patients (57.6%of laryngeal cancer). The group with laryngo-pharynx is a cohort of 8 patients in whom NACT was given to prevent tracheostomy, these patients had presented with early stridor (CTCAE grade 3). The reason for NACT in hypopharyngeal cancers was for organ preservation in 24 patients (40.7% of hypopharyngeal cancer) & for acheivement of resectability in 35 patients (59.3% of hypopharyngeal cancer).
Conclusion: The major indication for NACT is to make disease resectable at our centre while cases for organ preservation are few.
No conflict of interest.

3237 POSTER

Is gemcitabine & nimotuzumab (Nim-Gem) an option post cetuximab based chemotherapy failure in head & neck cancers?

V. Patil[1], V. Noronha[1], A. Joshi[1], G. Goyal[1], B. Poladia[1], S. Juvekar[2], K. Prabhash[2]. [1]*TMH, Medical Oncology, Mumbai, India;* [2]*TMH, Radiodiagnosis, Mumbai, India*

Background: There is no standard recommended treatment post Cetuximab failure in squamous cell carcinoma of head & neck region. In our institute some patients received Nim-Gem on compassionate basis.
Material and Methods: This is a retrospective analysis of patients who received Gemcitabine & Nimotuzumab post progression on Cetuximab based therapy in squamous cell carcinoma of head & neck cancer. This data was obtained from a prospectively maintained database of patients treated with Cetuximab in our department. The above mentioned regimen was administered weekly. The dose of Nimotuzumab was 200 mg weekly (fixed dose) & Gemcitabine 1000 mg/m^2 given on D1 & D8 of a 21 day cycle. This regimen was delivered till progression or unacceptable toxicity. The response was measured clinically at each week & radiologically at 2 months interval. The toxicity was charted in accordance with CTCAE version 4.02. SPSS version 16 was for used analysis. Progression free survival & overall survival were estimated by Kaplan Meier survival analysis.
Results: Ten patients received Nim-Gem regimen. The median age was 51.5 years (43−66 years). The site distribution was oral cancers in 7 patients, pharyngeal cancers in two & laryngeal cancers in one. All patients except one patient were treated initially with radical intent. In these 9 patients all had received platinum based chemotherapy either as concurrent Cisplatin during radiation or as neoadjuvant chemotherapy. Post failure all nine patients & one patient per prima received weekly Paclitaxel & Cetuximab chemotherapy. On progression all 10 patients received Nim-Gem. It was third line chemotherapy in 9 patients & second line in one patient. The best response achieved at 2 months was stable disease in 3 patients & progression in 6 patients. One patient didn't undergo response evaluation at 2 months. The median PFS was 56 days (14−97 days). The median OS was 112 days (29–228 days). The grade 2 or above toxicity

noted were mucositis grade 2 in 5 patients, grade 2 vomiting in 3 patients, myalgia grade 2 in 3 patients, myalgia grade 3 in 1 patient. There was no discontinuation because of toxicity.
Conclusion: Nim-Gem regimen appears to be a promising regimen in patients post cetuximab failure. We plan to evaluate it further in a phase 2 study.
No conflict of interest.

3238 POSTER

Induction chemotherapy of docetaxel and cisplatin combination with or without doxorubicin in locally advanced nasopharyngeal carcinoma

A. Kornietskaya[1], L. Bolotina[1]. [1]*Moscow Research Institute of Oncology P.A. Hertzen, Chemotherapy, Moscow, Russian Federation*

Introduction: Compare the tumor control, progression-free and overall survival of patients with nasopharyngeal carcinoma (NPC) underwent two alternative regimen of induction chemotherapy (CT).
Materials and Methods: Previously untreated patients with locally advanced NPC. From 2004 to 2010, 50 pat. were included in group A, age 20−71 years (mediana 42 years), 33 men and 17 women. Nasopharyngeal carcinoma was diagnosed in 29 pat., squamous cell carcinoma G2−3 in 21. Initial staging at diagnosis: T2−3N2M0 in 4 pat., T4N0−2M0−36 and T2−4N3M0−10 pat., respectively. Treatment regimen: docetaxel 75 mg/m^2 − 1 day, cisplatin 75 mg/m^2 − 1 day, doxorubicin 45 mg/m^2 − 1 day. In August 2011 began the set in group B. Now in this group 15 people were included − 5 women and 10 men, from 19 to 73 years (mediana 48.8 years). Squamous-cell carcinoma G2−3 was diagnosed in 8 pat., undifferentiated nasopharyngeal in 7. Tumor characteristics: T3N1−2M0 and T1−3N3M0 on 3 pat., T4N0−2M0−6 and T4N3M0−3 pat. Treatment regimen: docetaxel 75 mg/m^2 − 1 day, cisplatin 75 mg/m^2 − 1 day. Cycles were repeated every 21 days in both groups. Efficiency was estimated after 3 courses of CT. If the tumor regress was 50% and more, treatment continued to 6−8 courses from the subsequent radiotherapy (RT) and if positive lymph nodes were found out in the neck, they were subjected to lymphadenectomy.
Results: Overall response rate in group A (WHO) was 88% − 44 pat. (CR − 48% − 24 pat., including T4N2M0 and PR in 40% − 20 pat.). Stabilization of disease is noted in 3 (6%) and the progression of disease in 3 (6%) pat. The median time to progression of disease was 32 months and the median of overall survival 37.5 months. In group B OR after end of induction chemotherapy was 87% − 13 people (CR in 3 cases − 20%, PR in 10 patients − 66%). Disease progression was in 2 pat. Supervision periods in second group made from 3 to 18 months.
Conclusion: Induction CT on a basis docetaxel and cisplatin combination is a highly active regimen in locally advanced NPC and allows to carry out further RT at this category of patients that significantly improves results of treatment. But question of choice the optimum treatment modes still open.
No conflict of interest.

3239 POSTER

Clinical outcomes of induction chemotherapy in locally advanced head and neck cancer

I. Kim[1], H.S. Won[2], E.K. Jeon[3], S.H. Hong[3], J.H. Kang[3], Y.S. Lee[4], Y.S. Kim[5], D.I. Sun[6], M.S. Kim[6]. [1]*Seoul St. Mary's Hospital, Internal Medicine, Seoul, Korea;* [2]*Uijeongbu St. Mary's Hospital, Internal Medicine Medical Oncology, Uijeongbu, Korea;* [3]*Seoul St. Mary's Hospital, Internal Medicine Medical Oncology, Seoul, Korea;* [4]*Seoul St. Mary's Hospital, Pathology, Seoul, Korea;* [5]*Seoul St. Mary's Hospital, Radiation Oncology, Seoul, Korea;* [6]*Seoul St. Mary's Hospital, Otorhinolaryngology, Seoul, Korea*

Background: The aim of this study was to evaluate the efficacy and survival analysis of induction chemotherapy in locally advanced head and neck cancer.
Material and Methods: Fifty patients who received induction chemotherapy for squamous cell carcinoma of the head and neck in Seoul St. Mary's Hospital between January 2000 and December 2012 were evaluated. Clinical records and pathology reports were reviewed retrospectively.
Results: Twenty patients received docetaxel plus cisplatin (DP); 12 patients received 5-fluorouracil plus cisplatin (FP); 18 patients received docetaxel, cisplatin, and 5-fluorouracil (TPF). There was no significant difference in clinical characteristics between the three groups except for smoking and performance status. The overall response rate (ORR) for DP, FP, and TPF was 80.0%, 83.3%, and 88.9%, respectively (p = 0.755). Two patients for DP and a patient for FP experienced disease progression after induction chemotherapy. Among 25 patients who underwent surgery, pathologic complete response (pCR) was observed in 3 (33.3%) for DP, 1 (25.0%) for FP, and 6 (50.0%) for TPF, respectively (p = 0.044). Complete metabolic response measured at post-chemotherapy F-18 fluorodeoxyglucose positron emission tomography/ computed tomography was observed in 1 (9.1%) for DP, 1 (25.0%) for FP, and 9 (69.2%) for TPF, respectively (p = 0.009). Patients with human papillomavirus (HPV)-positive cancer showed higher pCR rates than patients with HPV-negative cancer, regardless of the type of chemotherapy (p = 0.012). Disease relapse or progression occurred in 16 (32.0%) patients. The relapse/progression rate did not differ between the three regimens (p = 0.197). There were no significant differences in hematologic and non-hematologic toxicities between the three regimens. The relative dose intensities of DP, FP and TPF were approximately 85%, with no significant difference. In univariate analysis using Kaplan–Meier method, the prognostic factor significantly affecting progression-free survival (PFS) was a pCR (p = 0.027).
Conclusions: The TPF induction chemotherapy had a better ORR and higher pCR rate in locally advanced head and neck cancer, but did not improve survival outcomes. The achievement of pCR was a good prognostic factor for PFS.
No conflict of interest.

3240 POSTER

Concurrent chemoradiation with low dose weekly cisplatin in stage IV head and neck squamous cell carcinoma

M. Kang[1], H. Song[1], J. Kang[1], S. Woo[2], J. Park[2], J. Kim[2], B. Jeong[3], K. Kang[3], G. Chai[3]. [1]*Gyeongsang National University Hospital, Internal Medicine, Jinju, South Korea;* [2]*Gyeongsang Naiotnal University Hospital, Otorhinolaryngology, Jinju, South Korea;* [3]*Gyeongsang National University Hospital, Radiation Oncology, Jinju, South Korea*

Background: Concurrent chemoradation(CCRT) with 3-weekly cisplatin in loco-regionally advanced head and neck squamous cell carcinoma(HNSCC) is standard treatment. But 3-weekly cisplatin is often associated with several adverse events because of high dose cisplatin. In this retrospective analysis, we conducted to determine the efficacy and tolerability of CCRT with low dose weekly cisplatin in stage IV HNSCC patients.
Material and Methods: Review of medical records of patients who diagnosed stage IV HNSCC and received definitive CCRT were analyzed. All patients treated with weekly cisplatin 10−30 mg/m^2 until radiotherapy completed.
Results: Total 35 patients were reviewed, all were stage IV and 15 patients had an oropharyngeal primary. Median follow up was 10.7 months (range 1.7–90.5 months). Median radiation dose were 7040 cGy, and median dose of actually received cisplatin were 157 mg/m^2. Two(5.7%) patients were reduced dose of radiation, and 16(45.7%) patients received modified dose or schedule of chemotherapy. Twenty-five(71.4%) patients achieved complete response(CR), 8(22.9%) had partial response(PR), but 6(24%) recurred after CR.
Grade 3−4 adverse events were stomatitis(82.9%), dermatitis(22.9%), infection(11.4%), dysphagia(8.6%), and neutropenia (5.7%). One patient died due to pneumonia during CCRT. Long term grade 3 adverse events after treatment were only 2 cases of xerostomia.
Median overall survival was 42.7 months, 3 year survival rate was 51.2%. Disease free survival was not reached to median, and 3 year disease free survival rate was 72.8%. Overall survival was improved in patients who achieved CR than others (59.7 vs. 13.4 months, $p = 0.008$).
Conclusions: In this retrospective study, low dose weekly cisplatin showed acceptable response compare to 3-weekly cisplatin, and seemed to reduce severe adverse events, especially long term toxicities. CCRT with low dose, weekly cisplatin will be effective and tolerable even in patients with stage IV head and neck cancer.
No conflict of interest.

3241 POSTER

Next generation sequencing: A powerful tool providing new insights into the genomic landscape of oral verrucous carcinomas

M. Samman[1], H. Wood[1], A. High[1], P. Rabbitts[1]. [1]*Leeds Institute of Molecular Medicine, Pre-cancer Genomics, Leeds, United Kingdom*

Background: Oral verrucous carcinoma (OVC) is a low grade, non-metastasising, slow growing variant of oral squamous cell carcinoma (OSCC), with an estimated incidence range between 2%-10% of all OSCC cases. In general, OVC histopathological diagnosis is ambiguous and difficult. Distinguishing OVC from classical OSCC is a common problem for pathologists due to the poorly defined diagnostic criteria and sampling difficulties. Early OVC usually presents as a pre-malignant lesion such as proliferative verrucous leukoplakia (PVL) or oral verrucous hyperplasia (OVH). OVH lesions may transform into either an OVC or an OSCC. The genomic alterations underlying OVH, and OVC lesions is still not clear and requires further investigations. The rarity of these lesions also makes

them difficult to investigate, so most previous studies have been made on small numbers of cases. The aim of this study is to use next generation sequencing (NGS) copy number analysis to identify oral verrucous lesions (including OVC, and OVH cases) genomic characteristic features, and to investigate the differences in the genomic damage pattern between OVC and OSCC lesions.
Methods: We identified a total of 62 oral verrucous cases: 49 OVCs, and 13 OVHs in this study. FFPE blocks were retrieved for all samples and DNA was extracted from the macro-dissected tumour tissues. DNA libraries were prepared and assessed for quality and concentration followed by sequencing at coverage between 2.5% and 13%. Copy number (CN) gain and loss pattern along the whole genome was compared between OVH, and OVC karyograms, besides OSCC karyograms from another study conducted by our group.
Results: Genomic copy number karyograms were produced for all samples, and visual inspection of the 62 patient genomic copy number karyograms demonstrated regions of gain and loss along the whole genome in OVC cases. In general, OVC karyograms showed different types of copy number patterns, in terms of both the complexity of the damage and the proportion of the genomes involved. This pattern ranged from whole chromosome gain to amplified or lost chromosome arms and regions. On the other hand, gain and loss features were minimally found in OVH cases. The analysis of CN aberrations across the entire OVCs data set revealed lower chromosomal instability features in OVC samples when compared to OSCC samples.
Conclusion: This study shows that NGS analysis can be used for a more specific assessment and evaluation of OVCs heterogeneity based on the analysis of the whole genome CN karyograms. The results of our study show a lower degree of tumor heterogeneity and chromosomal instability in OVCs when compared to OSCCs. Such a result confirms the well-known definition of OVC and that they appear as a low grade, slow growing variant of OSCC.
No conflict of interest.

3242 POSTER

Systemic inflammation is an independent predictive marker of clinical outcomes in mucosal squamous cell carcinoma of the head and neck

K.A. Charles[1], S.J. Clarke[2], M. Stevens[3], M. Back[3], T. Eade[3]. *[1]University of Sydney, Pharmacology, Sydney NSW, Australia; [2]Royal North Shore Hospital − Medical Oncology, University of Sydney − Northern Clinical School (Medicine), Sydney NSW, Australia; [3]Royal North Shore Hospital − Radiation Oncology, University of Sydney − Northern Clinical School (Medicine), Sydney NSW, Australia*

Background: Inflammation is a key driver of the tumour progression and response to treatment. Elevations in markers of systemic inflammation are prognostic in many different cancer types. This study aimed to investigate whether a marker of systemic inflammation, the neutrophil-to-lymphocyte ratio (NLR), was predictive of clinical outcomes in patients with mucosal oropharyngeal cancers.
Material and Methods: We performed a retrospective analysis of the association of NLR and clinical outcomes (recurrence and overall survival) in patients with mucosal oropharyngeal cancer. The NLR was determined prior to start of radiotherapy (RT) from routine full blood counts using the absolute neutrophil count/absolute lymphocyte count (cut-off >5). NLR and clinicopathological features were correlated with clinical outcomes using Chi squared and log-rank tests and Cox-regression analysis.
Results: A total of 152 patients with AJCC Stage I−IV mucosal oropharyngeal cancer were included in analysis. All patients had RT as part of the treatment regimen (11% RT alone, 24% surgery + RT, 56% chemotherapy + RT and 9% surgery + CRT). Elevated NLR >5 was observed in 21% patients and was only associated with higher tumour stage ($p < 0.001$). Current/previous smoking, and not NLR, was associated with older age, tumour site (oropharynx) and poorer ECOG performance status. Smoking status was the only independent predictor of locoregional recurrence ($p < 0.001$). While, elevated NLR and tumour site were predictive of metastatic recurrence ($p < 0.03$). On multivariate analysis, elevated NLR, poor performance status and smoking status were independent predictors of overall survival (Cox Regression model $p = 0.001$, hazard ratios = 4.4 [95% CI: 2.0−9.3], 2.9 [95% CI: 1.8−4.8], 2.9 [95% CI: 1.6−5.3], respectively).
Conclusions: The results of this study show that the presence of tumour-related systemic inflammation, as measured by NLR, is a better predictor of metastatic recurrence and overall survival than tumour grade/stage/site. NLR is a routinely available, cheap biomarker that can aid in the prognostication of patients with oropharygeal cancer. Understanding whether tumour biology, such as p16 status, impacts NLR is unclear and is currently being investigated.
No conflict of interest.

3243 POSTER

p16 expression in HNSCC: Identification of the cut-off and prognostic value in oropharynx tumours (OT) vs non OT

M. Merlano[1], D. Vivenza[1], M. Monteverde[1], N. Denaro[1], M. Fortunato[2], A. Comino[2], C. Lo Nigro[1]. *[1]Ospedale San Croce e Carle, Medical Oncology, Cuneo, Italy; [2]Ospedale San Croce e Carle, Pathology, Cuneo, Italy*

Background: We analysed tumour samples from patients with locally advanced HNSCC, to establish a predictive cut-off of p16 expression and to compare its role in OT vs non OT.
Materials and Methods: We analysed 206 samples from patients treated with CRT from 1997 to 2011. Pts characteristics were: M/F 175/31; median age 59.6 (range 20–85.6); primary site OT/non OT 66/140. Smoking information is available in 186 pts. Among them, 93% were heavy smokers (>10 pack/year).
P16 was calculated by IHC.
Positivity (pos) was defined as $\geqslant$1% pos cells. On the basis of the clinical literature, we considered two cut-off in pos cells (10% and 70%). Therefore, we initially compared four groups: negative (0 pos cells), low pos (1−9%), median pos (10−69%), and high pos (70–100%). Based on early results, we later considered only one cut off (50% pos cells) and 3 groups: negative, low pos (1−50%) and high pos (51–100%).
Results: P16 pos was 68% in OT and 50% in non OT ($p < 0.007$). Taken together, the pos status confers a survival (OS) advantage (36.8 months vs 19.5 months, $p = 0.06$). Considering the 3 pos levels (low, median and high), only high pos tumours show a better OS in the OT group (median 22.5, 15 and 97.9 months respectively, $p = 0.098$) while no difference emerges in the non OT. If we include also the p16 negative tumours, the latter behaves as the low pos and the median pos group in OT, and as all the three pos groups in non OT.
The cumulative analysis showed that the pos values place around two focus points at a median value of 2% (lower focus, the median value of all the pos values between 0 and 50%, range 1−45) and 96% (higher focus, the median value of all pos values between 51 and 100%, range 55−99). On these findings, we than divided p16 pos tumours in two groups < or >50% pos.
OT showed a larger number of cases in the >50% group (31%) compared to non OT (17%) ($p = 0.08$).
P16 high pos (>50%) confers a survival advantage in patients with OT, while in the non OT the same pos values correlate with a non significant negative prognostic effect (tab 1).
Conclusions:
1. The cut-off of p16 expression of clinical relevance can be considered 50% of positive cells.
2. Effect of high p16 pos expression is evident only in OT while it disappears in non OT. A possible negative prognostic impact in non OT should be investigated.
3. Smoking cannot be considered a confounding factor in the present series since most of our patients were heavy smokers (>10 pack/year). For the same reason, the prognostic role of p16 expression may result attenuated.

No conflict of interest.

Table 1.

	Med OS (months)		P value
	<50% pos cells	>50% pos cells	
OT	15.8	97.9	0.16
Non OT	38.3	15.3	0.46
P value	0.31	0.27	

3244 POSTER

Targeting Rac1 as a novel treatment for chemo-radioresistant head and neck squamous cell carcinomas (HNSCC)

S. Skvortsov[1], J. Dudás[2], P. Eichberger[1], C. Pritz[2], V.H. Schartinger[2], H. Maier[3], J. Hall[4], H. Riechelmann[2], P. Lukas[1], I. Skvortsova[1]. *[1]Innsbruck Medical University, Dept. of Therapeutic Radiology and Oncology, Innsbruck, Austria; [2]Innsbruck Medical University, Dept. of Otorhinolaryngology, Innsbruck, Austria; [3]Innsbruck Medical University, Section of General Pathology Dept. of Pathology, Innsbruck, Austria; [4]European Organization for Research and Treatment of Cancer (EORTC), Translational Research Unit, Brussels, Belgium*

Purpose: In order to improve therapy for HNSCC patients, novel methods to predict and combat local and/or distant tumor relapses are urgently needed. This study has been dedicated to identify proteins involved in HNSCC cell insensitivity to chemo-radiotherapy resulting in recurrence development.

Material and Methods: Radiation resistant IRR cells were derived from parental HNSCC cells after repeated exposure to ionizing radiation at a total dose of 100 Gy. All cells were investigated for their sensitivity to ionizing radiation and cisplatin. Protein profiling in parental and IRR cells was carried out using two-dimensional differential gel electrophoresis (2D-DIGE) followed by MALDI-TOF/TOF mass spectrometry. Cell viability, cell migration assays, G-LISA and Western blot analysis were used to confirm results obtained using the proteome approach. Additionally, tumor tissues obtained from 60 HNSCC patients showing different therapy response were evaluated for intratumoral Rac1 expression.
Results: Forty-five proteins that were similarly modulated in IRR cells compared to parental HNSCC cells were selected to analyze their common targets. It was found that these either up- or down-regulated proteins are closely related to the enhancement of cell migration which is regulated by Rac1 protein. Radiation and cisplatin resistances of IRR cells were accompanied by increased expression, activity and trend towards nuclear translocation of Rac1 protein. Chemical inhibition of Rac1 expression and activity resulted in significant improvement of HNSCC sensitivity to ionizing radiation and cisplatin and inhibition of migratory activities of IRR cells. Pre-clinical results were confirmed in clinical samples. While Rac1 was poorly presented in normal mucosa, tumor tissues revealed increased Rac1 expression. The most pronounced Rac1 presence was observed in HNSCC patients with poor early or late responses to chemo-radiotherapy. Tissues taken at recurrence were characterized not only by enhanced Rac1 expression, but also increased nuclear Rac1 content.
Conclusion: Increased expression, activity and subcellular localization of Rac1 could help to predict early response rates and higher risk of tumor recurrences in HNSCC patients and warrants further validation in larger independent studies. Inhibition of Rac1 activity can be useful in overcoming treatment resistance and could be proposed for HNSCC patients with primary or secondary chemo-radioresistance.
No conflict of interest.

3245 POSTER

2D, 3D and in vivo models of head and neck cancer identify novel correlates of resistance to epidermal growth factor receptor tyrosine kinase inhibitors

C. Box[1], L.C.J. Baker[2], M. Beloueche-Babari[2], S.J. Rogers[1], G.M. Box[1], K.J. Harrington[3], M.O. Leach[2], S.P. Robinson[2], S.A. Eccles[1]. *[1]The Institute of Cancer Research, Division of Cancer Therapeutics, Sutton, United Kingdom; [2]The Institute of Cancer Research, Division of Radiotherapy and Imaging, Sutton, United Kingdom; [3]The Royal Marsden Hospital NHS Trust, Head and Neck Unit, London, United Kingdom*

Background: Clinical responses to single agent epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) have been disappointing, especially in head and neck cancers (HNSCCs), most of which overexpress EGFR. Reported predictive response markers do not reliably translate between different cancer types. There is a need to identify patients likely to fail therapy and to understand the underlying molecular mechanisms. We aimed to discover markers of EGFR TKI resistance in HNSCC, focussing on parameters translatable to the clinic via minimally invasive techniques and with potential mechanistic relevance.
Materials and Methods: Chronic exposure of human HNSCC cells (CAL 27 and PE/CA-PJ34) to gefitinib *in vitro* yielded sublines resistant to EGFR TKIs, including erlotinib and afatinib. Biological behaviour was analysed in standard 2D monolayers and 3D tumour spheroids. Culture supernatants and patient sera were analysed using immunoassays for potential secreted biomarkers. Xenografts were investigated using intrinsic susceptibility magnetic resonance imaging (IS-MRI) and immunohistochemistry. Metabolic profiles were obtained using ^{1}H and ^{31}P magnetic resonance spectroscopy (MRS).
Results: EGFR TKI-resistant and -sensitive HNSCC cell lines grew at similar rates in 2D cultures. *In vivo,* however, resistant cells generated rapidly-growing, invasive tumours, a phenotype that was replicated in 3D tumour spheroid cultures. MRS revealed that acquired drug resistance was associated with changes in glycolytic, bioenergetic and choline phospholipid metabolism, both *in vitro* and *in vivo*. Resistant xenograft tumours also exhibited an attenuated haemodynamic response, decreased vessel perfusion and increased hypoxia as determined by IS-MRI and *ex vivo* microscopy. Molecular analyses of resistant cells identified overexpressed hypoxia-regulated proteins with functions linked to tumour angiogenesis and invasion. Subsequently, we were able to define a 'resistance-associated protein signature' detectable in the sera of a small cohort of HNSCC patients and associated with reduced survival.
Conclusions: We developed and characterised models of EGFR TKI-resistance using a wide range of biological and physical techniques. This led to the identification of 1) a metabolite profile, 2) a serum protein signature and 3) magnetic resonance imaging parameters, linked to a more aggressive phenotype, which warrant further investigation as potential markers of EGFR TKI-resistance.

Reduced methylation and increased protein expression of CSPG4 negatively influences survival of HNSCC patients

C. Herold-Mende[1], R. Warta[2], J. Chaisaingmongkol[3], O. Popanda[3], E. Herpel[4], C. Mogler[4], C. Plass[3], P. Plinkert[2], P. Schmezer[3], G. Dyckhoff[2]. *[1]University of Heidelberg, Experimental Neurosurgery, Heidelberg, Germany; [2]University of Heidelberg, Department of Otorhinolaryngology Head and Neck Surgery, Heidelberg, Germany; [3]German Cancer Research Center, Division of Epigenomics and Cancer Risk Factors, Heidelberg, Germany; [4]University of Heidelberg, NCT Tissue Bank Institute of Pathology, Heidelberg, Germany*

Background: Several family members of the proteoglycans have shown their importance in many cancer types as well as in head and neck squamous cell carcinoma (HNSCC). In this study we analyzed in-depth the role of chondroitin sulfate proteoglycan 4 (CSPG4) (also known as NG2/ MCSP/ HW-MAA) in HNSCC tumor progression.
Material and Methods: Tissues of HNSCC and non-tumorous mucosa were analyzed for CSPG4 expression by immunohistochemistry (IHC) and quantitative-real-time PCR (qPCR) as well as for CSPG4 promoter methylation by MassARRAY. Functional validation was performed by 5-AZA treatment in HNSCC cell lines exhibiting CSPG4 promoter methylation. Results were compared with survival estimates by log-rank test.
Results: Examination of protein expression in HNSCC patients (n = 72) compared to normal controls (n = 14) by IHC staining revealed an over-expression in a subgroup of HNSCC tumors. Furthermore, survival analysis using a log-rank test showed a significant correlation of high CSPG4 protein levels and shortened HNSCC patient survival, whereas patients with low or no expression had better survival times. In addition, the CSPG4 over-expression was confirmed by qPCR on mRNA levels (n = 42) as well as in three public available microarray data sets. As a potential cause for differential CSPG4 expression in HNSCC the DNA methylation in a CpG-island in the promoter region was analyzed by MassARRAY. No difference of the mean methylation in HNSCC (n = 100) and normal controls (n = 25) was observed. Nevertheless, in HNSCC tissue samples mean methylation correlated significantly with CSPG4 mRNA and protein expression. The functional relation of CSPG4 DNA methylation and expression were confirmed by demethylating treatment of two highly methylated HNSCC cell lines and subsequent mRNA and protein re-xpression. In addition, survival analysis of HNSCC patients grouped in high and low methylation revealed like shown before for protein levels an inverse correlation of methylation and patient survival.
Conclusions: We identified DNA methylation as a regulatory factor of CSPG4 protein and mRNA expression. Furthermore CSPG4 protein levels and DNA methylation might be useful as prognostic markers for HNSCC patient survival.
No conflict of interest.

Evaluation of hTERC (3q26) gain by fluorescence in situ hybridization (FISH) to predict the behavior of oral epithelial precursor lesions

S. Gabba[1], E. Giannini[1], L. Borghi[1], G. Fellegara[1], C. Marcialis[1], M. Grugni[1], M.P. Foschini[2], E. Repetti[1], T. Dorji[1], V. Grazioli[1]. *[1]Centro Diagnostico Italiano, Molecular Biology, Milan, Italy; [2]Bellaria Hospital, Anatomic Pathology, Bologna, Italy*

Background: Oral Squamous Cell Carcinoma (OSCC) is the most common tumor of the oral cavity with 500.000 new cases/year worldwide. Infection of oral mucosa by oncogenic HPV is strongly associated with OSCC among subjects with the established risk factor of tobacco and alcohol abuse. The development of OSCC is a multistep process where genetic and epigenetic events accumulate leading to cell cycle deregulation and chromosomal abnormalities. Based on the evidence that genomic integration of oncogenic HPV and gain of human telomerase RNA gene (hTERC), which is located on chromosome 3q26, appear to be an important genetic events in the progression of cervical intraepithelial neoplasia to invasive cancer, we evaluated the gain of hTERC in oral epithelial precursor lesion and if this genetic alteration could predict the progression to OSSC.
Material and Methods: Preliminary retrospective analysis was performed on 9 out of 40 oral samples with long-term follow up (ranging from 5 to 10 years) with histological diagnosis of: squamous cell hyperplasia (2 cases), mild dysplasia (2 cases) and moderate dysplasia (5 cases). Formalin fixed paraffin embedded (FFPE) tissue from each case was cut into 3 μm sections and were assayed by dual-color interphase FISH for

LSI 3q26 (gold), to investigate the gain of hTERC, and for CEP 7 (aqua) as a control probe. The slides were analyzed with the aid of automated fluorescence microscope Ikoniskope® for counting the gold and aqua signals. Scoring was performed only in the single non overlapping nuclei with clear intact nuclear membranes and signals of both probes present. The cell is considered abnormal if more than two hTERC signals were observed.
Results: 4 out of 9 cases (2 cases of hyperkeratosis and two of moderate dysplasia) showed tissue foci with an increase in the number of 3q26 signals. Interestingly, looking to the follow-up, these tissues belong to patients that developed an OSSC. The 5 cases without hTERC gain never progress to OSSC.
Conclusions: Our preliminary results seem very promising since only those cases with the gain of hTERC developed OSCC. Since we've analyzed only a limited number of cases i.e 9/40, the result should be taken very cautiously. If the result in the rest of the case reflect the clinical outcome, the evaluation of hTERC gain by FISH could precisely predict the behavior of oral epithelial precursor lesion and help the clinician in the early diagnosis of OSSC to address further clinical treatment.
No conflict of interest.

3248 POSTER

Relationship of p16INK4A cellular localization and overall survival in head and neck cancer (HNC)

S.H. Ang[1], B. Haaland[1], S.G. Hwang[2], P.H. Tan[2], E.H. Tan[3], W.T. Lim[3], M.K. Ang[3]. *[1]Duke-NUS Graduate Medical School Singapore, Duke-NUS Graduate Medical School, Singapore, Singapore; [2]Singapore General Hospital, Pathology, Singapore, Singapore; [3]National Cancer Centre Singapore, Medical Oncology, Singapore, Singapore*

Background: Overexpression of nuclear and/or cytoplasmic p16 is regarded as a surrogate of Human papillomavirus (HPV)-positive oropharyngeal carcinoma (OPC) and associated with good outcomes. Conversely, loss of nuclear p16 expression has been associated with poor outcome in many cancers. While $p16^{INK4A}$ protein acts as a cell cycle inhibitor in the nucleus, cytoplasmic p16 expression has also been reported, particularly in association with poor outcomes, suggesting differing roles of cytoplasmic and nuclear p16. We evaluated the relationship of nuclear and cytoplasmic p16 expression with overall survival (OS) in OPC and hypopharyngeal squamous cell carcinoma (HPC).
Patients and Methods: p16 immunohistochemical analysis was performed in 176 (101 OPC, 75 HPC) patients (pts) who were treated with curative intent. p16 nuclear and cytoplasmic expression status was dichotomized according to the mean product of staining intensity and percentage of tumor cells. Clinicopathological characteristics were assessed using a Cox regression model and overall survival (OS) evaluated by Kaplan–Meier method.
Results: Among 176 pts, median age was 63 years and comprised 79.8% males, of which 72% had a positive smoking history and 91.6% had locally advanced HNC. 41 pts (23.2%; 34 with OPC) had high nuclear and high cytoplasmic p16 staining (HN). 6 pts (3.4%, 3 OPC) had low nuclear and high cytoplasmic staining (HC) and 128 (72.7%, 64 OPC) had low nuclear and cytoplasm (LC) staining. Compared to pts with HN, pts with low nuclear p16 (HC and LC) had poor overall survival outcome regardless of cytoplasmic p16 status (HC: Hazard ratio (HR) 3.78, $p = 0.003$, LC: HR 3.71, $p < 0.001$; median OS not reached (HN) vs 24.9 months (HC) vs 24.6 months (LC)). On multi-variable analysis, higher Charlson co-morbidity index (HR 1.31, $p = 0.001$), low nuclear and low cytoplasmic p16 (LC: HR 2.79, $p = 0.047$) and positive smoking status (HR2.47, $p = 0.011$) were associated with poor overall survival, independent of tumor site and HPV status.
Conclusion: High nuclear p16 expression is associated with superior OS, independent of tumor site and HPV. Conversely, high cytoplasmic p16 expression, in presence of loss of nuclear p16, had poor survival. Thus, in HNC, nuclear and cytoplasmic localization of p16 may reflect differential p16 function and affect outcomes differently.
No conflict of interest.

Low incidence of PI3KCA, BRAF, and KRAS mutations in refractory squamous cell carcinoma of the head and neck (SCCHN) treated with temsirolimus in the phase II TEMHEAD study

V. Grünwald[1], T. Gauler[2], U. Keilholz[3], A. Boehm[4], O. Guntinas-Lichius[5], B. Hennemann[6], H.J. Schmoll[7], P. Ivanyi[8], M. Abbas[9], U. Lehmann[9]. *[1]Medical University Hannover, Hematology Hemostaseology Oncology and Stemcelltransplantation, Hannover, Germany; [2]Medical University Essen, West German Tumor Center, Essen, Germany; [3]Medical University Charite, Hematology and Oncology, Berlin, Germany; [4]Medical University Leipzig, Clinic of Ear Nose and Throat, Leipzig, Germany; [5]Medical University Jena, Clinic of Ear Nose and Throat, Jena, Germany; [6]Ev. Bethesda-Johanniter Clinic, Medical Clinic of hematology and Oncology, Duisburg, Germany; [7]University Clinic Halle, Medical Clinic of hematology and Oncology, Halle, Germany; [8]University Clinic Hannover, Hematology Hemostaseology Oncology and Stem Cell Transplantation, Hannover, Germany; [9]University Clinic Hannover, Pathology, Hannover, Germany*

Background: Temsirolimus has been shown to exert clinical activity in previously treated SCCHN in a phase II study. We now evaluated KRAS, BRAF, PI3KCA as predictive molecular markers for temsirolimus activity.
Material and Methods: Patients with progressive SCCHN and failure of platinum-based and cetuximab therapy were eligible for the trial. Tumor assessment was assessed according to RECIST 1.0 and the primary endpoint was the progression free survival rate (PFR) at 12 weeks >20%. PFS, PFR, and OS estimates were calculated by Kaplan–Meier-Curves. 25 mg temsirolimus was given i.v. weekly until progression or toxicity prevail. KRAS, BRAF, and PIK3CA mutations were assessed in formalin-fixed, paraffin-embedded archived tumor tissue by DNA sequence. Tumors have been collected prior to study entry from previous procedures.
DNA was extracted from manually microdissected tumor sections. An H&E stained serial section served as guidance. Tumor cell content of selected areas was in all cases well above 70%. K-RAS Codon 12 and 13 and B-RAF Codon 600 were analyzed by pyrosequencing. PIK3CA exon 9 and 20 were analyzed by Sanger sequencing.
Results: 42 patients entered the trial of whom 40 were eligible. 25 patients had accessible archived tumor tissue for sequencing. KRAS and BRAF have been analysed in 25 patients each, and 23 patients for PI3KCA. None of the patients showed mutations of KRAS or BRAF. H1048Y and G1050S PIK3CA missense mutations have been found in 1 patient each and were associated with a PFS of 46d and 27d, respectively. OS were 26d, and 55d (censored), respectively. The unselected patient population achieved a PFS and OS of 56 d (95% CI 36–113d), and 152d (95% CI 76–256d), respectively.
Conclusions: The incidence of activating mutations were lower than anticipated. No mutations were found for BRAF and KRAS. PIK3CA missense mutations were detected in 2 out of 25 patients only (8%), which was not associated with an improved PFS. However, the small sample size limits mutational sequencing and supports a larger study set in order to assess the predictive nature of PI3KCA mutations for temsirolimus treatment in SCCHN.

Prognostic impact of the enhancer of zeste homolog 2 overexpression in node-positive laryngeal cancer

J. Lim[1], I.S. Park[2], C.S. Kim[1]. *[1]Inha University School of Medicine, Internal Medicine, Incheon, South Korea; [2]Inha University School of Medicine, Pathology, Incheon, South Korea*

Background: Epithelial mesenchymal transition (EMT) has an important role in invasion and metastasis of tumor cells. Elevated Enhancer of Zeste Homologue 2 (EZH2) is a polycomb group family protein and its overexpression is involved in many human malignancies through epigenetically silencing related genes. EZH2 overexpression is also commonly associated with poor prognosis in a variety of tumor types. However, the exact role of EZH2 and its clinical significance in laryngeal cancer are not yet known. The purpose of this study is to evaluate the roles of EZH2 and other EMT associated proteins on progression and metastasis in locally advanced node-positive laryngeal cancer.
Materials and Methods: We analyzed the significance of these EMT associated protein expression in curatively resected (R0) laryngeal cancer patient as a prognostic marker. Total twenty nine consecutive patients were included in our study. We used protein immunohistochemistry to evaluate EZH2, vimentin, E-cadherin and ki-67 expression on tissue microarray in duplicate. Also we retrospectively reviewed all medical records and tried to analyze the relationship between the expression of EMT markers and

prognosis. The relationship between these protein expressions and survival was plotted on a Kaplan–Meier curve.
Results: EZH2 was expressed in 11 patients (37.9%). Recurrence rate was significantly higher in patients with positive EZH2 expression than that of patients with no expression (Recurrence rate 72.7% vs 33.3%, p = 0.039). Patients with a positive EZH2 expression showed a tendency of shorter their disease progression free survival (median PFS; 11.8 months) than did the patients without expression (median PFS; 23.9 months). However there was no statistical significance (p = 0.0892). The presence of EZH2 expression was not associated with patients' age, pattern of recurrence, T-stage, smoking status, alcohol consumption and histology.
Conclusions: Our immunohistochemical stainings confirm that EZH2 overexpression showed a close correlation in recurrence rate and relapse free survival. Our findings suggest an important role of EZH2 in progression of laryngeal cancer.
No conflict of interest.

Bevacizumab, irinotecan and radiotherapy versus standard temozolomide and radiotherapy in newly diagnosed, MGMT-non-methylated glioblastoma patients: Updated results from the randomized multicenter GLARIUS trial

U. Herrlinger[1], N. Schäfer[1], J.P. Steinbach[2], A. Weyerbrock[3], P. Hau[4], R. Goldbrunner[5], R. Kohnen[6], H. Urbach[7], W. Stummer[8], M. Glas[9].
[1]University of Bonn, Division of Clinical Neurooncology Department of Neurology, Bonn, Germany; [2]University of Frankfurt, Senckenberg Institute of Neurooncology, Frankfurt, Germany; [3]University of Freiburg, Department of Neurosurgery, Freiburg, Germany; [4]University of Regensburg, Department of Neurology and Wilhelm Sander NeuroOncology Unit, Regensburg, Germany; [5]University of Cologne, Department of Neurosurgery, Cologne, Germany; [6]RPS Research, Clinical Research Europe, Nuremberg, Germany; [7]University of Bonn, Department of Radiology Division of Neuroradiology, Bonn, Germany; [8]University of Munster, Department of Neurosurgery, Munster, Germany; [9]University of Bonn, Division of Clinical Neurooncology Department of Neurology and Stem Cell Pathologies Group, Bonn, Germany

Background: Alkylating chemotherapy with temozolomide (TMZ) is only marginally effective in patients with MGMT-non-methylated glioblastoma (GBM). Thus, more effective therapies are urgently needed in this large subgroup of GBM. Based on encouraging results of phase II trials with the antiangiogenic agent bevacizumab (BEV) +/− irinotecan (IRI) in recurrent GBM, the GLARIUS trial investigated the efficacy of BEV/IRI therapy as compared to standard TMZ in the first-line therapy of MGMT-non-methylated GBM.
Material and Methods: In the randomized, multicenter, open-label GLARIUS trial (NCT00967330, sponsored by Roche Pharma), adult patients with newly diagnosed, histologically confirmed and MGMT-non-methylated GBM received local radiotherapy (RT, 30 x 2 Gy) and were randomized (2:1) for experimental therapy with BEV (10 mg/kg q2w) during RT followed by maintenance BEV (10 mg/kg q2w) + IRI (125 mg/m^2 q2w (without enzyme-inducing antiepileptic drugs (EIAEDs)) or 340 mg/m^2 (with EIAEDs)) or standard therapy with daily TMZ (75 mg/m^2) during RT followed by 6 courses of TMZ (150–200 mg/m^2/day for 5 days q4w). The primary endpoint was progression-free survival rate after 6 months (PFS-6). Determination of PFS-6 als included a central neuroradiological review of MRI scans.
Results: The intent-to-treat population included 170 patients with a median age of 56 years (range 25−78 years). 67.1% of patients were male. 48.8% had a complete resection rate, and 78.8% of patients had a KPS of 90% or higher. 116 patients received BEV/IRI, 54 patients had TMZ. The frequencies of adverse events in both arms of the trial were within the expected range. The PFS-6 rate was significantly higher in the BEV/IRI arm (71.1%, 95% CI 58.1–80.8%) than in the TMZ arm (26.2%, 95% CI 13.1–41.4%, p < 0.0001 logrank test). Updated PFS and overall survival data will be also presented.
Conclusion: The increase in the primary endpoint PFS-6 upon BEV/IRI chemotherapy is significant and clinically meaningful. This suggests that BEV/IRI is more effective than standard TMZ therapy in newly diagnosed MGMT-non-methylated GBM patients.

Do we know the optimal bevacizumab (BV) dose in recurrent malignant glioma? Final results of a prospective multicenter GEINO protocol using BV 5 mg/kg/2w

M. Gil-Gil[1], J. Canellas[1], J. Fuster[2], H. Bennis[3], S. Del Barco[4], C. Mesia[1], O. Etxanitz[5], M. Benavides[6], J. Perez-Martin[1], C. Balana[5].
[1]Institut Catala d'Oncologia, Oncologia Medica, L'Hospitalet.Barcelona, Spain; [2]Hospital Son Espases, Oncologia Medica, Palma de Mallorca, Spain; [3]Hospital La Fe, Oncologia Medica, Valencia, Spain; [4]Institut Catala d'Oncologia, Oncologia Medica, Girona, Spain; [5]Institut Catala d'Oncologia, Oncologia Medica, Badalona.Barcelona, Spain; [6]Hospital Carlos Haya, Oncologia Medica, Málaga, Spain

Background: Bevacizumab (BV) received FDA approval as a single-agent therapy for patients with progressive glioblastoma (GBM) based on the results of 2 phase II trials using 10 mg/kg/2w. Although Stark-Vance's initial experience showed a high response rate (RR) using 5 mg/kg and a metha-analysis not showed differences between 5 and 10 mg/kg.
Aim: To evaluate efficacy of BV 5 mg/kg in a prospective series of patients with recurrent malignant glioma (MG) and to compare with a GEINO previous cohort treated with BV 10 mg/kg plus irinotecan (CPT11) with the same inclusion criteria.
Methods: Data from 6 Spanish hospitals was prospectively collected following a clinical protocol. Inclusion criteria were age ⩾18; histology of MG; progression after radiation (RT) and temozolomide; IK ⩾60 and informed consent. Treatment schedule: BV 5 mg/kg/2w. BV was scaled to 10 mg/kg and CPT11 125 mg/m^2/2w was added if progression. RR was determined by MRI using RANO criteria every 8−12 w. Kaplan Meier and Cox model were performed to calculate PFS and OS.
Results: 71 patients were included between Feb2011-Jan2013. Histology: GBM 55 and grade 3 MG 16. Median age: 52 (18−75). Median IK: 70 (50–100). BV was used after first relapse in 42 and after second relapse in 29 patients. Time between end of RT and beginning BV was over 3 months in 93% of patients, median time 8.2 months (1.9–113.5). 51 patients received dexamethasone (DX) at inclusion: median 5.5 mg/day (1−18).
Toxicity: At 5 mg/kg dose the incidence of BV selected adverse events (AE) and G3 AE was consistent with the reported in the 2 pivotal trials. Grade 3−4 were asthenia 9 pts; thromboembolic events 6; diarrhea 4; neutropenia 4; cognitive deterioration 4 and hemorrhage 3 (2 died).
Efficacy: Mean follow-up: 6.1 months (0.5–18.67). BV at 5 mg/kg leads to an IK and neurological improve in 28.2% and reduced/withdraw of DX in 40.8%.
After progression to BV 5 mg 43.6% (24/55) patients received BV10 mg/kg plus CPT11.
Only 1 of 14 evaluable patients showed MRI response.
Conclusion: BV 5 mg/kg in recurrent MG offers similar OS than BV 10 mg/kg although seems to be lower inferior in RR and PFS.
Conflict of interest: *Advisory board: Roche: M. Gil-Gil and C. Balana*

Efficacy and safety of bevacizumab (Bv) plus standard combination temozolomide (T) and radiotherapy (RT) in newly diagnosed glioblastoma: final results from AVAglio

O. Chinot[1], T. Cloughesy[2], R. Henriksson[3], F. Saran[4], W. Mason[5], R. Nishikawa[6], M. Hilton[7], L. Abrey[7], W. Wick[8]. *[1]Aix-Marseille University AP-HM, Marseille, France; [2]University of California, Los Angeles, USA; [3]Regional Cancer Center Stockholm and Umeå University, Umeå, Sweden; [4]The Royal Marsden NHS Foundation Trust, Surrey, United Kingdom; [5]Princess Margaret Hospital, Toronto, Canada; [6]Saitama Medical University, Saitama, Japan; [7]F. Hoffmann-La Roche Ltd, Basel, Switzerland; [8]Heidelberg University Medical Center, Heidelberg, Germany*

Background: Glioblastoma has a high disease burden and poor prognosis, despite the widespread use of combination therapy with RT and T. AVAglio is the first randomised, double-blind, placebo (P)-controlled phase III study to evaluate the efficacy and safety of the addition of bevacizumab (Bv) to standard T/RT for newly diagnosed glioblastoma.
Methods: In AVAglio, patients (pts) ⩾18 yrs with newly diagnosed glioblastoma were randomised to receive P or Bv (10 mg/kg, q2w) with

6 wks of T (75 mg/m^2/d) + RT (2 Gy, 5d/wk) followed by 28 treatment-free days, then 6 cycles of T (150–200 mg/m^2/d, 5d q4w) with P or Bv (10 mg/kg, q2w), and then single-agent P or Bv (15 mg/kg, q3w) until disease progression (PD)/unacceptable toxicity. Co-primary endpoints were investigator-assessed progression-free survival (PFS) and overall survival (OS). Secondary endpoints included HRQoL (EORTC QLQ-C30 and BN20) and safety, and exploratory endpoints included Karnofsky performance score (KPS) and corticosteroid (CS) use.

Results: Baseline characteristics were well balanced. The study met the co-primary endpoint for PFS (HR 0.64, 95% CI 0.55–0.74, $p < 0.0001$; median 10.6 vs 6.2 mo) and this result was supported by measurements of clinical benefit, including delayed deterioration in HRQoL with Bv compared with P ($p < 0.0001$, predefined analysis in 5 preselected domains) and reduced reliance on CS; among pts on CS ($\geqslant$2 mg) at baseline, CS discontinuation ($\geqslant$5 consecutive days) was more frequent with Bv than P (66% vs 47%), and in those off CS at baseline (<2 mg), time to CS initiation was significantly longer with Bv than P (HR 0.71, 95% CI 0.57–0.88; median 12.3 vs 3.7 mo). Functional independence (KPS $\geqslant$70%) was maintained during PFS in both arms (median Bv vs P: 9 vs 6 mo). Interim OS did not cross the threshold for significance with Bv+T/RT (HR 0.89, 95% CI 0.75–1.07, $p = 0.2135$) and one-year OS rates were 72% and 66% with Bv+T/RT and P+T/RT, respectively ($p = 0.052$). Safety was consistent with known bevacizumab side effects. Final OS data, 2-year OS rates, OS subgroup analyses and updated safety will be presented.

Conclusions: Addition of Bv to T/RT achieved clinically meaningful benefits, including a statistically significant and clinically meaningful PFS improvement associated with stable/improved HRQoL and KPS, and reduced CS requirement. Interim OS did not cross the threshold for significance; final OS will be presented.

Standard chemoradiotherapy ± cilengitide in newly diagnosed glioblastoma (GBM): Updated results and subgroup analyses of the international randomized phase III CENTRIC trial (EORTC trial #26071-22072/Canadian Brain Tumor Consortium)

R. Stupp[1], M.E. Hegi[1], T. Gorlia[2], J.R. Perry[3], S. Erridge[4], D.A. Reardon[5], A. Markivskyy[6], W. Wick[7], Y.K. Hong[8], M. Weller[9]. *[1]Centre Hospitalier Universitaire Vaudois, Département de Neurosciences Cliniques, Lausanne, Switzerland; [2]EORTC, Data Centre, Brussels, Belgium; [3]Sunnybrook Health Sciences Centre, Division of Neurology, Toronto, Canada; [4]University of Edinburgh, Edinburgh Cancer Centre, Edinburgh, United Kingdom; [5]Dana-Farber Cancer Institute, Center for Neuro-Oncology, Boston, USA; [6]Merck KGaA, Global Clinical Development Unit − Oncology, Darmstadt, Germany; [7]Universitätsklinik Heidelberg, Neurologische Klinik und Nationales Tumorzentrum, Heidelberg, Germany; [8]Catholic University of Korea, Seoul St Mary's Hospital, Seoul, South Korea; [9]University Hospital Zurich, Department of Neurology, Zurich, Switzerland*

Background: Cilengitide is a selective $\alpha v\beta 3$ and $\alpha v\beta 5$ integrin inhibitor interfering with cell attachment and migration. In preclinical models, synergy with other treatments including chemotherapy and irradiation was shown. Randomized dose finding phase II studies in both recurrent and newly diagnosed glioblastoma indicated a dose-related trend towards prolonged survival with a high dose of cilengitide (2000 mg twice weekly i.v.) compared to a lower dose (500 mg tiw).

Materials and Methods: This randomized phase III study investigated the addition of cilengitide (2000 mg tiw) to standard chemoradiotherapy (RT 30x2 Gy with concomitant and adjuvant temozolomide, TMZ/RT->TMZ for up to 6 cycles). A methylated *MGMT* gene promoter was required aiming at exploiting the synergy with alkylating agent chemotherapy. Cilengitide was to be continued for 18 months or until progression. The primary endpoint was overall survival; secondary objectives comprised progression-free survival (PFS) per independent read, Quality of Life, and safety.

Results: After screening over 3000 patients for *MGMT* gene promoter methylation, a total of 545 were randomized. 34% of patients tested for *MGMT* status were methylated. Baseline characteristics were well balanced. Median age was 58 years, and 23% $\geqslant$ over age 65 years. ECOG performance status was 0 in 56% and 1 in 44% of patients; prior tumor resection was reported as complete in 49% of patients, partial in 48%, and 3% had a biopsy only. Median OS was 26.3 months in both groups (Hazard Ratio [HR] = 1.02 [95% CI: 0.81–1.29], $p = 0.86$) while median PFS per independent read was 10.6 months in cilengitide treated patients and 7.9 months in the control group (HR = 0.92 [95% CI: 0.75–1.12], $p = 0.41$). The Quality of Life analysis did not reveal significant differences. Cilengitide treatment was generally well tolerated and its known safety profile was confirmed. 56% of patients received subsequent second-line therapy after disease progression including repeat surgery 10%, re-irradiation 12%, cytotoxic chemotherapy 40%, and bevacizumab 19% of all patients.

Conclusions: Cilengitide failed to improve survival in patients with newly diagnosed GBM despite promising preclinical and early clinical results; the absence of benefit is observed in all predefined clinical subgroups. Feasibility of upfront molecular testing and *MGMT* determination was demonstrated.

Trial was sponsored by Merck KGaA.

Progression-free survival as a surrogate endpoint for hazard ratio and median overall survival in glioblastoma: A literature-based meta-analysis from 91 trials

K. Han[1], M. Ren[1], W. Wick[2], J. Jin[1], L. Abrey[3], A. Das[1], D. Reardon[4]. *[1]Genentech, Clinical Pharmacology, South San Francisco, USA; [2]University Medical Center, Department of Neurooncology, Heidelberg, Germany; [3]F. Hoffmann-La Roche Ltd, Oncology Development, Basel, Switzerland; [4]Dana Farber Cancer Institute Harvard Medical School, Center for Neuro-Oncology, Boston, USA*

Background: Glioblastoma, a highly malignant tumour, has a poor prognosis despite the introduction of combination temozolomide (TMZ)/radiotherapy. The gold standard for new anti-cancer therapy evaluation is a randomised, phase III trial with an overall survival (OS) endpoint, but use of OS is limited by long trial times and confounding post-protocol events. Proposed surrogates for OS include objective response rate (ORR) and progression-free survival (PFS), but responses are rare in glioblastoma and little is known about the PFS-OS relationship. This study aimed to determine correlations between ORR and PFS with OS in glioblastoma, in order to evaluate their potential as surrogates for OS.

Materials and Methods: Published glioblastoma trials reporting OS and ORR and/or PFS were identified; those reporting sufficient detail were included in the analyses. The correlations between: hazard ratio (HR) in PFS and OS, median PFS and OS, and between OS and ORR were evaluated using Pearson's R^2 coefficient. An ANCOVA was conducted to test for any differences in the PFS/OS correlations due to treatment and histology. The predictive power of 6-month PFS was evaluated by correlation with 1-year and median OS.

Results: Of 306 published glioblastoma trials, 91 were included in the analysis. No relevant correlation was observed between ORR and OS (R^2=0.22). HRs of PFS and OS were strongly correlated (R^2=0.92 95% CI, 0.71–0.99). Linear regression determined that a 10% risk reduction for PFS would yield a 8.1%±0.8% risk reduction for OS. The R^2 between median PFS and OS was 0.70 (95% CI, 0.59–0.79), with a higher value observed in trials using RANO (R^2=0.96, n = 8) compared with Macdonald criteria (R^2=0.70, n = 83). There were no significant differences in the correlations between TMZ- and bevacizumab-containing regimens (p = 0.10), between trials using RANO and Macdonald criteria (p = 0.49), or between trials conducted at different time periods (from 1991 to present). However, the slope of the regression line between median PFS and OS was significantly higher in newly diagnosed compared with recurrent disease (0.58 vs 0.35, p = 0.04). R^2 values for 6-month PFS and 1-year OS with median OS were 0.60 (95% CI, 0.37–0.77) and 0.64 (95% CI, 0.42–0.77), respectively.
Conclusions: In glioblastoma trials, PFS and OS are strongly correlated, indicating that PFS may be an appropriate surrogate for OS. Compared with OS, PFS offers earlier assessment of efficacy and higher statistical power.

A phase II, randomized, open-label, multi-center study of weekly APG101 + reirradiation versus reirradiation in the treatment of patients with recurrent glioblastoma

W. Wick[1], J. Debus[2], M. Bendszus[3], G. Kobyakov[4], T. Martens[5], O. Heese[5], J. Pichler[6], S.E. Combs[2], C. Kunz[7], H. Fricke[7]. [1]*University of Heidelberg, Abteilung Neuroonkologie Neurologische Klinik und Nationales Tumorzentrum, Heidelberg, Germany;* [2]*University of Heidelberg, Abteilung Radioonkologie, Heidelberg, Germany;* [3]*University of Heidelberg, Abteilung Neuroradiologie, Heidelberg, Germany;* [4]*Burdenko Institute for Neurosurgery, Research Institute, Moscow, Russian Federation;* [5]*University of Hamburg, Neurochirurgie, Hamburg, Germany;* [6]*Landeskrankenhaus Linz, Neurologie, Linz, Austria;* [7]*Apogenix GmbH, Apogenix, Heidelberg, Germany*

Background: Preclinical data indicate antiinvasive activity of APG101, an intravenous CD95 ligand-binding fusion protein, as well as synergistic activity together with radiotherapy (RT) in glioblastoma. Doses up to 20 mg/kg body weight were considered safe in a phase I trial in healthy volunteers. After application of 400 mg in two glioma patients steady state for AGP101 seemed to be reached.
Materials and Methods: Patients with recurrent glioblastoma after prior standard radiochemotherapy with temozolomide (± 1 second-line chemotherapy) were considered for re-irradiation provided a tumor diameter 1−4 cm and time since the end RT ⩾8 months. Patients were randomized 1:2 between RT (36 Gy; 5 times 2 Gy per week) or RT plus APG101 at 400 mg weekly flat dose to be continued until progression. RT plans were centrally evaluated. Primary endpoint was 6-months progression free survival (PFS-6). MRIs were performed every 6-weeks and centrally read.
Results: Between 12/09 and 09/11, a total of 84 pts in 25 centers were randomized. Median age was 57 years, median KPS 90%. Patients were stratified according to a maximal tumor diameter of ⩽2.5 cm and >2.5 cm. No SUSARs had to be reported. One patient achieved PFS-6 in the RT arm (4%) and twelve patients in the APG101 arm (21%). Median overall survival (OS) was 11.5 months in the RT and 11.8 months in the APG101 arm with 7% patients alive at 24 months in the RT and 22% in the APG101 arm. Subgroup analysis for CD95L expression by immunohistochemistry on the FFPE tissue of the initial diagnosis revealed an OS in the CD95L expressing patients of 8.2 months in the RT group and 11.5 months in the APG101 group and in patients with CD95L-negative tumors median OS was 15 months in the RT- and 13.5 months in the APG101-treated patients.
Conclusions: APG101_CD_002 is the first trial evaluating CD95-mediated pathway inhibition as a therapeutic strategy. This trial is also the first prospective trial on reirradiation in glioblastoma. The experimental arm met the primary endpoint; the activity of reirradiation alone was unexpectedly low. Subgroup analysis suggest CD95L as a negative prognostic biomarker, which may help to delineate patients with glioblastoma deriving benefit from APG101, that are patients with CD95L-expressing tumors. The approach to block the CD95 system is breaking a paradigm and CD95L would be one of the first predictive markers in neurooncology.

Background: We previously demonstrated that it is possible to objectively interrogate human glioblastoma (GB) by using 5-aminolevulinic acid (5-ALA), an endogenous intermediate of the porphyrin biosynthesis pathway. Tumour tissue resection is performed on a fluorescence-guided basis allowing direct visualization of tumour tissue. This approach gave us the possibility to identify and characterize tumour compartments in GB.
Material and Methods: The tissue was collected in GB debulking operations in accordance with local ethical guidelines. Sixty-five patients were administered with 5-ALA 5 hours before surgery as oral dose of 20 mg/kg. Primary culture, culture propagation and immunofluorescence were performed according to the Cambridge protocol. Intracerebral transplantation of $3X10^5$ cells into the right striatum of Nod/Scid mice was carried out according to the Home Office guidelines. Gene expression profiling was determined using standard array Illumina platform (HumanWG6_V3). Quality of RNA was evaluated by running tests. SNP analysis was performed using the Affymetrix SNP6 arrays. Molecular clock analysis was performed using the Roche 454 Junior system and Neighbor Joining was used to reconstruct phylogeny for each patient. Drug-response analysis was carried out using different concentration of Temozolomide (Sigma) and the in vitro BrdU cell proliferation assay.
Results: Our results demonstrate that:
1. cells residing in the tumour margin are not self-renewing *in vitro* but are tumorigenic *in vivo*,
2. fluorescence material is present in the sub-ependymal zone (SEZ) of 65% of our GB (n = 65 patients),
3. SNP analysis of SEZ tissues reveals distinct genetic aberrations,
4. molecular clock analysis shows that the SEZ contains precursor cells of the corresponding tumour mass,
5. drug-resistant tumour cells persist in the SEZ.

Conclusions: Fluorescence-guided tumour sampling allows identification of a new compartment in human GB, i.e. the SEZ. Tumour precursors residing in this compartment are resistant to conventional chemotherapies.

Clinical research of simultaneous integrated boost intensity-modulated radiotherapy combined with temozolomide in treatment of postoperative residual glioblastoma

S. Qian[1], L.I. Jian-Bin[1]. [1]*Shandong Cancer Hospital, Radiation Oncology, Jinan Shandong, China*

Objective: To research clinical efficacy of simultaneous integrated boost intensity-modulated radiotherapy (SIB-IMRT) combined with temozolomide in treatment of patients with postoperative residual glioblastoma.
Methods: Fifty six patients with postoperative residual glioblastoma of brain received SIB-IMRT.The postoperative residual lesion was defined as gross tumor volume(GTV). The margin of GTV expanded 5 mm was defined as CTV. The margin of CTV expanded 5 mm was defined as PTV. The postoperative resectional cavity was defined as CTV1. The margins of CTV1 were enlarged 15 mm and 30 mm defined as PTV1 and PTV2 respectively. The prescribe doses of PTV, PTV1 and PTV2 were 2.5 Gy/f,2.3 Gy/f and 2.0 Gy/f respectively. All patients received

irradiation 5 weeks with 5 times per week. All patients were given temozolomide 75 mg/m^2 oral daily during radiotherapy. Four weeks after radiotherapy,there were 30 patients (defined as group 2) received 6 cycles of temozolomide,each cycle lasted 5 days with 28 days interval between two cycles. The other 26 patients (defined as group 1) did not continue to take temozolomide.
Result: In the 56 patients,CR was 7 cases (12.5%), PR was 38 cases (67.8%),SD was 8 cases (14.3%), PD was 3 cases (5.4%). The responed rate was 45 cases (80.3%). The median survival time in all patients, group 1 and group 2 was 30 months,23 months and 36 months respectively. The mean survival time was 29.82±9.11 months in all patients.The overall survival rates of one-, two- and three-year were 96.4%,73.2%, and 33.9% respectively. The mean survival time and survival curve in group 1 were significantly lower than that in group 2($P<0.05$). There were no severe radiochemotherapy-related toxicities.
Conclusion: Concurrent SIB-IMRT with temozolomide and followed by 6 cycles of temozolomide chemotherapy for postoperative residual glioblastoma have a better clinical outcome, good tolerance and no severe radiochemotherapy-related toxicities.
No conflict of interest.

Local delivery of the soluble form of the tumor suppressor and stem cell regulator LRIG1 potently inhibits in vivo growth of glioblastomas with either wildtype or mutant EGFR expression

S.P. Niclou[1], M. Johansson[1], K. Tiemann[1], A. Oudin[1], H. Hedman[2]. [1]*Centre de Recherche Public de la Santé (CRP-Santé), Norlux Neuro-Oncology, Luxembourg, Luxembourg;* [2]*Umeå University, Department of Radiation Sciences, Umeå, Sweden*

Background: Deregulated growth factor signaling is a major driving force in the initiation and progression of glioblastoma. The tumor suppressor and stem cell marker Lrig1 is a negative regulator of the epidermal growth factor receptor (EGFR) family. Here we addressed the therapeutic potential of the soluble form of Lrig1 (sLrig1) in glioblastoma treatment and the mechanism of sLrig1-induced growth inhibition.
Methods: Using encapsulated cells, recombinant sLrig1 was locally delivered in orthotopic glioblastoma xenografts generated from freshly isolated patient tumors. Tumor growth and mouse survival was evaluated. The efficacy of sLrig1 and the affected downstream signalling was studied *in vitro* and *in vivo* in glioma cells displaying variable expression of wildtype and/or constitutively active mutant EGFR (EGFRvIII).
Results: Continuous interstitial delivery of sLrig1 in genetically diverse patient-derived glioma xenografts led to strong tumor growth inhibition. Glioma cell proliferation *in vitro* and tumor growth *in vivo* were potently inhibited by sLrig1 irrespective of EGFR expression levels. Importantly tumor growth was also suppressed in EGFRvIII driven gliomas. sLrig1 induced cell cycle arrest without changing total receptor level or phosphorylation. Affected downstream effectors included MAP kinase but not AKT signaling. Importantly local delivery of sLrig1 into established tumors led to a dramatic survival advantage in treated mice.
Conclusions: This is the first report demonstrating that sLrig1 is a potent inhibitor of glioblastoma growth in clinically relevant experimental glioma models, and that this effect is largely independent of EGFR status. The potent anti-tumor effect of sLrig1, in combination with cell encapsulation technology for *in situ* delivery holds promise for future treatment of glioblastoma.

3308 POSTER

Sensitivity of glioblastoma cell lines to GDC-0973/RG7420

C. Schmitt[1], J. Guehennec[1], C. Levasseur[1], M. Verreault[1], K. Mokhtari[2], M. Sanson[3], K. Hoang-Xuan[3], J.Y. Delattre[3], A. Idbaih[3]. [1]*Hopital de la Salpétrière, Institut Cerveau Moelle epiniere, Paris Cedex 13, France;* [2]*AP-HP Groupe Hospitalier Pitié-Salpêtrière, Service de Neuropathologie, Paris Cedex 13, France;* [3]*AP-HP Groupe Hospitalier Pitié-Salpêtrière, Service de Neurologie 2-Mazarin, Paris Cedex 13, France*

Background: Although therapeutic advances have accomplished, glioblastoma remains a devastating primary brain tumor in adults. Therefore new therapeutic strategies are urgently needed. Molecular targeted therapies have demonstrated their efficacy in multiples cancer subtypes including brain tumors. MAPK pathway is activated in human glioblastoma through various mechanisms including tyrosine kinase receptors, Ras or Raf activation contributing to several hallmarks of cancer cells, including uncontrolled proliferation, invasion, and evasion of apoptosis. In this setting, GDC-0973 compound, a novel small-molecule inhibiting MEK appears promising.
Material and Methods: We have investigated the effects of GDC-0973 on viability/proliferation in four preclinical models of glioblastomas including one cell line growing adherently (U87-MG) and three glioblastoma stem cell lines, established recently from human tumors, growing in serum-free media (4627, 6240, 7060).
Results: Using WST-1 assay and impedancemetry measurement, we have shown that GDC-0973 inhibits viability and proliferation of the four cells lines. Cell lines 6240 and 7060 exhibiting higher level of phospho-MEK determined by western-blot seem more sensitive, with an IC50 twice as low. This suggests that the sensitivity to GDC-0973 seems associated of the level of expression of phospho-MEK, but this correlation is currently being investigated. FACS analysis revealed that apoptosis is one of the mechanisms of glioblastoma cell death induced by GDC-0973.
Conclusion: To our knowledge, our study is the first showing in vitro efficacy of GDC-0973 in glioblastoma models. These encouraging results support the conduction of *in vivo* studies aimed at evaluating GDC-0973 therapeutic activity in orthotopic glioblastoma-bearing mice.
No conflict of interest.

3309 POSTER

Regulation of glioblastoma stem-like cell self-renewal and tumorigenicity

F. Verginelli[1], A. Perin[1], R. Dali[1], K.H. Fung[1], R. Del Maestro[2], S. Rossi[3], U. Di Porzio[4], O. Stechishin[5], S. Weiss[5], S. Stifani[1]. [1]*Montreal Neurological Institute, Neurology and Neurosurgery, Montreal, Canada;* [2]*Montreal Neurological Institute and Hospital, Brain Tumor Research Center, Montreal, Canada;* [3]*Treviso Hospital, Pathology, Treviso, Italy;* [4]*Institute Genetics and Biophysics, Neuroscience, Napoli, Italy;* [5]*Hotchkiss Brain Institute, Department of Cell Biology & Anatomy, Calgary, Canada*

Background: Glioblastoma (GBM) is the most common and malignant primary brain cancer. GBM prognosis remains dismal despite available treatments, mostly because of tumor recurrence. According to the 'glioma stem-like cell' (GSC) hypothesis, GBM tumorigenesis is mediated by a fraction of cancer cells resembling normal neural stem/progenitor cells (NSPCs). In potential agreement with this possibility, it is possible to establish primary cultures of human GBM-derived cells exhibiting the predicted properties of GSCs, namely unlimited self-renewal and multipotency *in vitro* and, most importantly, tumorigenic ability when transplanted intracranially into host mice *in vivo*. We hypothesize that the tumorigenic potential of GSCs may result from the deregulation of the normal balance between self-renewal and differentiation along the glial lineage. In this regard, the transcription factor FOXG1, a member of the forkhead family, is a key regulator of self-renewal, proliferation and differentiation in embryonic and adult NSPCs. In this study, we sought to characterize the expression and function of FOXG1 and its functional transcriptional partners belonging to the Groucho/TLE family (TLE) in high-grade glioma and cultured GSCs.
Material and Methods: FOXG1 and Gro/TLE expression was characterized at mRNA or protein level in human GBM surgical specimens and GSCs. Knock-down and dominant-negative approaches were utilized to interfere with the functions of FOXG1 and Gro/TLE in cultured GSCs in order to characterize their contribution to the self-renewal, proliferation, differentiation and *in vivo* tumorigenic ability of these cells.
Results: We show that human *FOXG1* mRNA level is inversely correlated with GBM patient survival and that FOXG1 is highly expressed in both GBM and cultured GSCs. FOXG1 knockdown in GSCs causes decreased self-renewal and downregulation of NSPC markers, reduced proliferation, upregulation of glial differentiation genes, and decreased tumorigenic potential upon intracranial transplantation. These effects are phenocopied by knockdown or dominant-inhibition of Gro/TLE using the Gro/TLE family member, GRG6.
Conclusions: These results show that FOXG1 is important for GBM progression and suggest that FOXG1 and Gro/TLE act in GSCs to promote a stem-like state and inhibit differentiation.
No conflict of interest.

3310 POSTER

The growth hormone receptor as an alternative oncogenic pathway in glioblastoma

M. Verreault[1], F. Ducray[2], Y. Marie[1], F. Laigle-Donadey[3], A. Rousseau[4], K. Mokhtari[5], K. Hoang-Xuan[3], M. Sanson[3], J.Y. Delattre[3], A. Idbaih[3]. *[1]Hopital de la Salpétrière, Institut du cerveau et de la moelle, Paris Cedex 13, France; [2]Centre de recherche en neuroscience de Lyon, Equipe Neuro-oncologie et neuro-inflammation, Lyon, France; [3]Hopital de la Salpétrière, Service de neurologie, Paris Cedex 13, France; [4]Centre Hospitalo-Universitaire d'Angers, Service de Pathologie Cellulaire et Tissulaire, Angers, France; [5]Hopital de la Salpétrière, Service de Neuropathologie, Paris Cedex 13, France*

Background: Primary glioblastomas (GBM) are the most frequent and the most aggressive primary brain tumors in adults. Despite intensive treatments, the prognosis of GBM patients remains poor with a median overall survival comprised between 12 and 24 months. Improvement of the prognosis of GBM patients is highly dependent on a better understanding of molecular oncogenesis, which can ultimately lead to the development of new personalized targeted treatments.
We have conducted a large molecular screen with the objective of identifying signaling pathways that are activated in GBM that do not exhibit activation of classic oncogenic pathways (i.e. Receptor Tyrosine Kinase and PTEN/PI3K). Interestingly, we identified the Growth Hormone Receptor (GHR) pathway as a promising candidate for alternative oncogenic signaling pathways. This project aims at characterizing the role of GH signaling pathway in GBM oncogenesis.
Material and Methods: GBM cell lines exhibiting activated GHR pathway (type B) and cell lines which do not exhibit activated GHR pathway (type A) were selected from our primary cell line bank. The effects of stimulation with GHR substrate Growth Hormone (GH) were assessed *in vitro* by immunofluorescence staining and western blots analysis. Moreover, levels of Growth Hormone were measured by ELISA in the plasma of GBM patients and *in vitro* in the supernatant of GBM cells.
Results: It was found that stimulation of type B cell lines with the GH induces a translocation of GHR at the cytoplasm and nucleus membranes, and activates JAK2/STAT5 and ERK/Src pathways. These effects were not observed in type A cell lines. Levels of GH in the plasma of GBM patients were found to correlate with GHR expression in the tumor. Significant levels of GH were also detected in the supernatant of GBM cell lines *in vitro* but did not correlate with GHR expression in these cells.
Conclusion: Increased levels of plasmatic GH in type B GBM patients, secretion of GH by type B GBM cells *in vitro* and signaling changes induced by GH in type B GBM cells suggest a significant role of GHR pathway in type B GBM oncogenicity compared to type A GBM. Effects of GHR gain (transduction of *GHR* gene in non-GHR expressing GBM cells and immortalized astrocytes) and loss of function (pharmacological inhibitor Pegvisomant, shRNA and transduction of a *GHR* dominant negative gene in group B cells) are being characterized.
No conflict of interest.

3311 POSTER

Claudin-5 participates in the regulation of tight junction in brain vascular endothelial cells

W. Jia[1], T. Martin[2], P. Couraud[3]. *[1]Beijing Tiantan Hospital affiliated to Capital Medical University, Beijing, China; [2]Cardiff University-Capital Medical University Joint Centre for Biomedical Research Cardiff University School of Medicine Heath Park Cardiff UK, Metastasis and Angiogenesis Research Group Department of Surgery, Cardiff, United Kingdom; [3]Universite Paris Descartes, Institut COCHIN, Paris, France*

Background: A key step in brain metastasis (BM) is the interaction and penetration of the Blood–brain barrier (BBB) by cancer cells. Tight junction (TJ) of brain vascular endothelium, part of the BBB, is critical barrier which the cancer cells have to overcome in order to penetrate and initiate brain metastasis. The transmembrane protein claudin-5 is a key TJ protein in endothelial cells. However, its the molecular mechanisms in regulation BBB in the formation of brain metastases are poorly understood. In the present study, we aimed to investigate the pattern of expression of this molecule in regulation the tight junction of brain vascular endothelial cell and try to identify the role of claudin-5 in the regulation of BBB permeability during the brain metastatic process.
Materials and Methods: The Claudin-5 gene was highly expressed in human brain vascular endothelial cell, hCMEC/D3 cell line and was virtually negative in the non-brain vascular endothelial cells, HECV. Claudin-5 was either knocked down using ribozyme technology in hCMEC/D3 or over-expressed in HECV cells. Lung cancer cell line A549 was added to observe the interaction between the cancer cell and brain vascular endothelial cell. Changes in function were assessed using *in vitro* assays for growth, adhesion, wounding, endothelial cell barrier invasion, and transendothelial electrical resistance (TEER)/electric cell-substrate impedance sensing (ECIS). Results data was analyzed using a Students two sample t-test and by Two-way Anova test when the data was found to be normalized and have equal variances. In all cases 95% confidence intervals were used.
Results: Claudin-5 was successfully knocked down from the hCMEC/D3 cells. The knockdown resulted in a phenotype that had significantly increased cell motility ($p < 0.005$). Knockdown of Claudin-5 gene in hCMEC/D3 cells resulted in significant lower transendothelial electrical resistance (TEER) values were observed. Similarly, reduced levels of Claudin-5 in the hCMEC/D3 cells resulted in a decrease in adhesion to matrix ($p < 0.001$). Endothelial cell barrier invasion assay showed that lung cancer cells were more readily to penetrate the monolayer of hCMEC/D3 cells after knocking down claudin-5 from the endothelial cells. HECV cells were forced to over-express claudin-5. The overexpression markedly increased the barrier function of the cell layer and reduced the permeability.
Conclusions: The present study portrays an interesting role for Claudin-5 in keeping the the barrier functions of the brain vascular endothelial cells and blocking cancer cells from trespassing. Claudin-5 through the integrity of blood–brain barrier, reduces tumor cell penetration, which play an important role in controlling brain metastases.
No conflict of interest.

3312 POSTER

The role of MDGI in glioma progression

M. Hyvönen[1], J. Virtanen[1], M. Mutikainen[2], N. Sugiyama[3], J. Enbäck[1], B. Mari[4], P. Tavi[2], K. Lehti[3], P. Laakkonen[5]. *[1]University of Helsinki, Research Programs Unit Translational Cancer Biology Institute of Biomedicine, Helsinki, Finland; [2]University of Eastern Finland, A.I. Virtanen Institute, Kuopio, Finland; [3]University of Helsinki, Research Programs Unit Genome Scale Biology Institute of Biomedicine, Helsinki, Finland; [4]University of Nice-Sophia-Antipolis, IPMC CNRS, Nice, France; [5]University of Helsinki, Research Programs Unit Translational Cancer Biology Institute of Biomedicine, Helsinki, Finland*

Background: Gliomas, a class of highly malignant brain tumors, are the most common primary brain tumors in adults. Despite of advances in cancer therapies, the prognosis of high-grade glioma patients is poor due to the invasive growth of the tumor cells. Therefore, in order to develop novel therapeutic strategies, it is essential to clarify the molecular mechanisms underlying the behavior of these tumors. Using *in vivo* phage display technology we have identified a peptide, CooP, which, after systemic delivery, specifically homes to malignant brain tumor islets harboring co-opted blood vessels. Mammary-derived growth inhibitor (MDGI) was validated as an interacting partner for our peptide. This protein is involved in fatty acid metabolism but its role in glioma is currently unknown.
Materials and Methods: To facilitate functional studies of MDGI, stable human glioma cell line (U87MG) overexpressing MDGI was used in 2D and 3D cell culture systems as well as in orthotopical murine tumor models. Changes in the gene expression patterns in response to MDGI expression were studied using gene arrays. In addition, MDGI's effect on glioma cell metabolism was studied with a metabolic analyzer.
Results: Our preliminary results show MDGI to be expressed in a grade-dependent manner in clinical human astrocytoma samples. MDGI expression was also detected in several primary human glioma cell lines. Based on our first *in vitro* experiments MDGI overexpression increased cell invasion in matrigel matrix. The overexpressing cells had also a higher tendency to form colonies in soft agar. In addition, our metabolic analyses revealed altered metabolia-associated characteristics, such as reduction in the oxygen uptake, in the cells overexpressing MDGI.
Immunohistological analyses of the glioma xenografts overexpressing MDGI revealed more abundant vasculature *in vivo*. Interestingly, gene expression analysis from the xenografts revealed also several metabolia-associated genes that were potentially upregulated in the MDGI overexpressing xenografts.
Conclusion: Our results using CooP homing peptide suggest MDGI to be a novel biomarker for malignant gliomas. Since increased invasiveness is a well-known characteristic of gliomas, our *in vitro* results demonstrate a functional role for MDGI in glioma progression. Furthermore, since metabolic abnormalities are common among gliomas, both our gene array results and metabolic analyses suggest an interesting role for MDGI in glioma cell bioenergetics.

3313 POSTER

Vascular endothelial growth inhibitor, VEGI, is an independent indicator for suprasellar invasion and sella destruction in human pituitary adenomas

W. Jia[1], A. Sanders[2], W. Jiang[2]. [1]*Beijing Tiantan Hospital affiliated to Capital Medical University, Beijing, China;* [2]*Cardiff University–Capital Medical University Joint Centre for Biomedical Research Cardiff University School of Medicine Heath Park Cardiff, UK, Metastasis and Angiogenesis Research Group Department of Surgery, Cardiff, United Kingdom*

Background: Pituitary ademonas are benign tumours from the pituitary gland and mostly non-cancerous but may have invasive and destructive growth pattern. It is a relative common type of the primary intracranial tumours. An interesting feature of the tumours is that some of the tumours are functional, namely endocrine active from the pituitary tumours cells. There is little understanding of the growth and progression control of pituitary tumours. In the present study, we investigated the expression of vascular endothelial growth inhibitor (VEGI) which is also known as tumour necrosis factor superfamily member 15 or TNFSF15 and is a vascular endothelial growth and apoptosis regulator in clinical pituitary tumours.
Materials and Methods: Pituitary tumours from 101 patients were included in the study. Fresh pituitary tumours were obtained immediately after surgery and processed for histological, immunohistological and molecular based analyses. Histolopathological and clinical information including tumour type and size, tumour sphenoidal invasion and sella destruction and endocrine status were analysed against the gene transcript expression of VEGI and VEGF. VEGI and VEGF family and VEGF receptors were quantitatively determined for their gene transcript expression.
Results: The expression levels of VEGI was significantly lower in pituitary tumours which invaded cranial floor and sphanoid bone, and with suprasellar extension than the non-invasive tumours ($p = 0.0073$). Low levels of VEGI transcripts were associated with the intrapituitary haemorrhage ($p = 0.05$). VEGI levels were also seen to be correlated with tumour stage ($p < 0.0001$), in that high levels of VEGI was associated with low tumour grade. Of all the pituitary tumours, 59 were non-functional. Multivariat analysis has indicated that VEGI is an independent factor for the invasion ($p = 0.05$). It was further demonstrated the relationship between VEGI and pituitary tumour grade and invasion were independent of the expression of VEGF and its receptors. Of the functional tumours, it was found that FSH and gonadotrophic tumours tend to have markedly low levels of VEGI transcript, compared with non-functional tumours ($p = 0.0026$ and $p = 0.003$, respectively). The opposite was seen with thyroid-stimulating hormone secreting tumours.
Conclusions: Vascular endothelial growth inhibitor, VEGI, is a negative regulator of the aggressive nature of pituitary tumours and that the expression level is closely linked to the invasion and destruction of the suprasellar and sella region. It also has implications on the endocrine nature of the tumours. VEGI thus has an important predictive and prognostic value in patients with pituitary adenomas.

Expression level of HOX genes is higher in human medulloblastoma tumorigenic cell line than in non-tumorigenic cell lines

R. Bonfim Silva[1], T.V.C.A. Pimentel[2], E.T. Valera[3], F.S. Ramalho[4], H.R. Machado[5], D.T. Covas[2], G.J. Riggins[6], A.A. Cardoso[7], A.M. Fontes[1]. [1]*Medical School of Ribeirao Preto-USP, Genetics, Ribeirao Preto − SP, Brazil;* [2]*Bloodcenter of Ribeirao Preto-USP, Clinical Oncology Stem Cells and Cell Therapy, Ribeirao Preto − SP, Brazil;* [3]*Medical School of Ribeirao Preto-USP, Pediatrics, Ribeirao Preto − SP, Brazil;* [4]*Medical School of Ribeirao Preto-USP, Pathology, Ribeirao Preto − SP, Brazil;* [5]*Medical School of Ribeirao Preto-USP, Surgery and Anatomy, Ribeirao Preto − SP, Brazil;* [6]*Johns Hopkins University, Oncology and Genetic Medicine, Baltimore-MD, USA;* [7]*Indiana University School of Medicine, Medical and Molecular Genetics, Indianapolis-IN, USA*

HOX genes are a family of homeodomain-containing transcription factors defined as master genes of development, altered in cancer cells and thus having implications for tumorigenesis. Developmental genes have been recognized as one of the keys to understanding the tumor development in some type of cancers. This study aimed to correlate gene expression profile of some HOX genes with the tumorigenic potential of medulloblastoma cell lines (MCL). We used three human MCL, UW473, UW472 and DAOY and two human cerebellum primary cultures (CPC). The MCL and CPC were characterized morphologically by light microscopy and immunophenotypically by flow cytometry. MCL were assessed by tumorigenic potential infusing $3x10^6$ cells subcutaneously in NUDE mice. MCL and CPC were evaluated for gene expression profile of HOXA3, HOXA10, HOXB3, HOXB4 and HOXB6 genes by quantitative real time PCR. MCL are morphologically heterogeneous (polygonal and fibroblastoid morphology) and CPC present fibroblastoid morphology. Immunophenotypically, MCL and CPC were similar for some CD markers and showed a high percentage (70−99%) for CD44, CD73, CD105, CD166 and CD29 and low or absence (0−5.3%) for CD144, CD31, CD34, CD45 and CD133. Some differences were observed for CD140b ($0.28\pm0.11\%$; $6.2\pm8.3\%$; $0.78\pm1.1\%$; 0.44%), CD24 ($52.5\pm1.7\%$; $64.6\pm6.4\%$; $20.5\pm6.4\%$; 1.9%), CD146 ($60.4\pm8.8\%$; $90.6\pm3.8\%$; $34.6\pm12\%$; 98.4%), CD73 ($77.2\pm6.9\%$; $81.4\pm8.98\%$; $52.97\pm12.4\%$; 99.1%), CD271 ($3.3\pm3.7\%$; $26.9\pm16.22\%$; $0.6\pm0.8\%$; 0.26%) and CD90 ($3.7\pm1\%$; $99.3\pm0.8\%$; $88.5\pm3.3\%$; 77%) in UW472, UW473 and DAOY MCL, and CPC respectively. Regarding to tumorigenic potential, among the UW402, UW473 and DAOY MCL, only DAOY cell line gave rise to tumor nodules that presented histology features similar to medulloblastoma. About gene expression, HOXA3 gene was $4{,}028\pm431$, $2{,}959\pm316$ and 14 ± 1.5 times higher expressed in DAOY when compared to CPC, UW402 and UW473 MCL respectively (**$p > 0.0001$**, $p = 0.004$, $p = 0.0066$), HOXA10 gene was $22{,}463\pm27$, $18{,}997\pm22.8$ and $25{,}103\pm30.1$ times (**$p > 0.0001$**, **$p < 0.0001$**, **$p < 0.0001$**), HOXB3 gene was $2{,}867\pm1{,}319$, 42.27 ± 19.4 and 24.73 ± 11.37 times ($p = 0.0074$, both non-significant), HOXB4 gene was $5{,}648\pm567$, 93.25 ± 9.37 and 105.38 ± 10.59 times (**$p > 0.0001$**, $p = 0.0003$, $p = 0.0051$) and HOXB6 gene was $2{,}422\pm580$, $1{,}650\pm394.8$ and 3.35 ± 0.8 times (**$p > 0.0001$**, $p = 0.0275$, non-significant). Taken together, our results demonstrates that MCL are morphologically heterogeneous and CPC present fibroblastoid morphology. MCL and CPC showed an immunophenotype somewhat different for some markers and DAOY cell line was the only one that gave rise to tumor nodules in NUDE mice. Correlating the tumorigenic potential with the expression level of HOX genes, all HOX genes (HOXA3, HOXA10, HOXB3, HOXB4 and HOXB6) were more expressed in DAOY tumorigenic cell line when compared to UW402 and UW473 non-tumorigenic cell lines. In detail, HOXA10 was the most expressed among HOX genes that were analyzed and the only one with a similar low expression in both UW402 and UW473 non-tumorigenic cell lines as well as in CPC. This implicates that HOXA10 gene might be related to tumor development in medulloblastoma.

A novel fluorinated stilbene exerts antitumor activity in glioblastoma cells

H. Nakabayashi[1]. [1]*Oita University of Nursing and Health Sciences, Human Biology, Oita, Japan*

Background: Glioblastoma is the most common and aggressive form of malignant glioma and is very difficult to treat. Controlling glioblastoma cell invasion and angiogenesis is essential to improve the prognosis of glioblastoma patients. It has been reported that anti-inflammatory agents, such as NF-κB inhibitors, have antitmor effects to malignant tumors. A novel fluorinated stilbene, 2-fluoro-4' -methoxystilbene (NF-κB acitivity inhibitor 4; NF-κBAI4), which is known as a potent inhibitor of the NF-κB signalling pathway in vitro. Our study aimed to evaluate the antitumor effects of NF-κBAI4 on two human glioblastoma cell lines (U87MG, T98G) and the molecular mechanisms underlying these effects.
Material and Methods: The anti-invasive effect of NF-κBAI4 was analysed by an in vitro invasion assay. An in vitro angiogenesis assay was also performed. In vitro growth inhibition of glioblastoma cells by NF-κBAI4 was determined by the MTT assay. The effect of NF-κBAI4 on an orthotropic implantation model using athymic mice was also evaluated.
Results: NF-κBAI4 suppressed the proliferation of glioblastoma cells. NF-κBAI4 also suppressed both the invasion of glioblastoma cells and tumor-induced angiogenesis. Molecular-based studies demonstrated that NF-κBAI4 suppressed gene and protein expression of angiogenic factors. An *in vivo* intracerebral human glioblastoma xenograft mouse model demonstrated that NF-κBAI4 suppressed neovascularity and tumor growth.
Conclusions: The results of the present study suggest that NF-κBAI4 may be a new therapeutic agent for glioblastomas.

Health-related quality of life (HRQoL) in AVAglio, a randomized, placebo (P)-controlled phase III study of bevacizumab (B), temozolomide (T) and radiotherapy (RT) in patients (pts) with newly diagnosed glioblastoma (GBM)

A. Bottomley[1], R. Henrikkson[2], M.J.B. Taphoorn[3], T. Cloughesy[4], W. Wick[5], W. Mason[6], F. Saran[7], R. Nishikawa[8], A. Ravelo[9], O.L. Chinot[10]. [1]*European Organisation for Research and Treatment of Cancer (EORTC), Quality of Life Department, Brussels, Belgium;* [2]*Regional Cancer Center Stockholm and Umeå University, Department of Oncology and Radiotherapy, Stockholm/Umeå, Sweden;* [3]*Medical Center Haaglanden The Hague and VU University Medical Center, Department of Neurology, Amsterdam, Netherlands;* [4]*University of California, Department of Neurology, Los Angeles, USA;* [5]*University Medical Center, Department of Neurooncology, Heidelberg, Germany;* [6]*Princess Margaret Hospital University of Toronto, Faculty of Medicine, Toronto, Canada;* [7]*The Royal Marsden NHS Foundation Trust, Neuro-oncology Unit, Surrey, United Kingdom;* [8]*International Medical Center Saitama Medical University, Department of Neuro-Oncology/Neurosurgery, Saitama, Japan;* [9]*Genentech, Clinical Pharmacology, South San Francisco, USA;* [10]*Aix-Marseille University AP-HM CHU Timone, Service de Neuro-Oncologie, Marseille, France*

Background: GBM is associated with poor HRQoL. AVAglio investigated P or B plus RT/T in GBM and results showed longer PFS with B+RT/T. To understand the added value of B, HRQoL was an important secondary endpoint.
Methods: Pts received B or P + standard of care (RT+T) until disease progression (PD)/unacceptable toxicity. HRQoL (EORTC QLQ-C30/BN20) time to definitive deterioration (TDD) was assessed − a 10-point change from baseline (BL) was considered clinically meaningful. Primary HRQoL analysis: five preselected scales. Exploratory analyses: TDD excluding PD as an event, duration of stable/improved HRQoL from BL, TDD for other non-preselected scales (no adjustment for multiple testing).
Results: P+RT/T, n = 463; B+RT/T, n = 458. There was high compliance: 78−91% of evaluable pts (no PD) completed each assessment (all scales) in the first year. BL scores were comparable between arms. B+RT/T achieved a clinically meaningful significant delay in TDD (all preselected scales, table). Post-hoc sensitivity analyses (excl. PD as an event) were supportive for 3 of these and B+RT/T benefit was seen in 8/21 non-preselected scales: cognitive (HR 0.74, p = 0.0018), role (HR 0.82, p = 0.0435) and emotional (HR 0.78, p = 0.0246) functioning; bladder control difficulty (HR 0.71, p = 0.0082); leg weakness (HR 0.81, p = 0.0396); visual disorder (HR 0.80, p = 0.0433); fatigue (HR 0.74, p = 0.0013); hair loss (HR 0.81, p = 0.0337). Treatment arms were not significantly different for appetite loss, headache, nausea/vomiting, constipation, pain, dyspnoea, insomnia, diarrhoea, future uncertainty, seizures, drowsiness, itchy skin, financial difficulty (TDD; p⩾0.05). Median duration of stable/improved HRQoL during PFS was longer with B+RT/T (7−8 mo) versus P+RT/T (4−5 mo) and as a proportion of PFS time it was similar between arms.
Conclusions: B+RT/T-treated pts experienced a longer time to HRQoL TDD compared with P+RT/T.

Background: The impact on the general population of temozolomide concurrent with and adjuvant to radiotherapy (RT/TMZ) was assessed in the context of the Registry of the Project of the Emilia-Romagna Region in Neuro-Oncology (PERNO), the first Italian prospective observational population-based study in the field of neuro-oncology.
Methods: Patients (pts) meeting the following inclusion criteria were evaluated: age ⩾18 years; PS 0−3; histologically confirmed GBM, no previous or concomitant non-glial tumoral disease, residence in the Emilia Romagna region. The data were collected prospectively.
Results: Study accrual, started on January 1 2009, was closed, as planned, on December 31 2010. Two hundred sixty-eight pts (F=111, M=157; median age, 63.5 [range 29−34] years) were studied. mOS was 10.7 months (95% CI: 9.2–12.3). MGMT status, assessed in 186 (89%) of 210 pts who had at least radiotherapy was evaluable in 174 pts (83%), being methylated in 76 (43.7%), and unmethylated in 98 (56.3%) pts. mOS for pts with MGMT methylated status was 18.5 months (95% CI: 14.4–22.6), and 12.4 months for those with MGMT unmethylated status (95% CI: 10.5–14.3, p < 0.0001). 140 pts <70 years were treated with RT/TMZ; mOS in this group was 16.4 months (95% CI: 14.5–18.4). mOS was 20 months in the 59 pts (42%) harboring MGMT methylation (95% CI: 12.8–27.2), and 13.5 months in the 73 pts (52%) without MGMT methylation (95% CI: 10.8–16.2, p < 0.0001). At multivariate analysis, a significant prognostic role was found for performance status (p = 0.001), extent of surgery (p = 0.009), age (p = 0.004), postsurgical treatment (p = 0.03), and MGMT status (methylated vs unmethylated, p = 0.01).
Conclusions: The data from the present large prospective population study are in line with those reported in the EORTC/NCIC randomized trial, confirming that this successful approach has been widely incorporated in daily practice.
No conflict of interest.

3318 POSTER

Factors impacting survival following second surgery in patients with glioblastoma (GBM) in the temozolomide (TMZ) treatment era, incorporating neutrophil/lymphocyte ratio (NLR) and time to first progression

M. McNamara[1], Z. Lwin[2], H. Jiang[3], A. Templeton[4], G. Zadeh[5], M. Bernstein[5], C. Chung[6], B.A. Millar[6], N. Laperriere[6], W.P. Mason[7]. [1]*Princess Margaret Hospital, Toronto Ontario, Canada;* [2]*Mater Adult Hospital, Medical Oncology, Brisbane, Australia;* [3]*Princess Margaret Hospital, Biostatistics, Toronto, Canada;* [4]*Princess Margaret Hospital, Medical Oncology, Toronto, Canada;* [5]*Toronto Western Hospital, Neurosurgery, Toronto, Canada;* [6]*Princess Margaret Hospital, Radiation Oncology, Toronto, Canada;* [7]*Princess Margaret Hospital, Neuro-Oncology, Toronto, Canada*

Background: Patients (pts) with progressive GBM have a poor prognosis. NLR, an inflammatory marker, is prognostic in several cancers. The

prognostic impact of either NLR or time to 1st progression (TTP), in GBM pts undergoing 2nd surgery, has not been assessed.
Material and Methods: We reviewed outcomes and prognostic factors in GBM pts having 2nd surgery in the TMZ treatment era, who were treated at Princess Margaret Cancer Centre, Toronto. Baseline demographics, NLR, treatment received, dexamethasone therapy, TTP, and overall survival (OS) were analyzed. Multivariable analysis (MVA) of OS from 2nd surgery was performed using Weibull model (accelerated failure time model).
Results: 107 (18%) of 584 adult pts who underwent primary surgery for GBM were followed from 01/04−12/11. Median (med) time between primary and 2nd surgery was 11.5 mo (range 1.2–85.8). Indication for 2nd surgery was both clinical and radiological in 74 (69%). Med age at 2nd surgery was 52 yrs (20−76), 76 (71%) were male, with performance status 0−1 in 80 (75%), partial resection in 104 (97%) and unifocality in 104 (97%). 88 pts (82%) had prior radiotherapy with concurrent and adjuvant TMZ. 72 pts (67%) had dexamethasone prior to 2nd surgery. Patients who underwent 2nd surgery had longer OS vs those having primary surgery alone; 20.9 mo vs 9.9 mo (P<0.001) and med OS from date of 2nd surgery was 7.1 mo (range 5.9−8.2). Med OS from 2nd surgery in pts with NLR⩽4 vs NLR>4 was 9.7 mo vs 5.9 mo (Logrank test P<0.05). NLR retained its prognostic significance for survival on MVA (Table) as did no chemotherapy post 2nd surgery (Time Ratio [TR] 0.23, 95% CI 0.16–0.33, P<0.001). In pts undergoing 2nd surgery, when TTP was ⩽12 mo, 12 to24 mo, or >24 mo, med OS from 1st progression was 9.5, 11.2 and 22.2 mo, respectively (P<0.05).
Conclusion: NLR>4 prior to 2nd surgery is a poor prognostic factor in GBM. In addition, later progression is associated with longer survival after 2nd surgery, and may be informative for those who have survived for some time after diagnosis.
No conflict of interest.

Variable	OS from 2nd surgery, TR (95% CI, P-value)	
	UVA	MVA
NLR ⩽4 vs NLR >4	1.86 (1.18–2.93, <0.01)	1.65 (1.15–2.35, <0.01)

3319 POSTER

A large prospective Italian population study (Project of Emilia-Romagna Region in Neuro-Oncology; PERNO) in newly diagnosed GBM patients (pts): Outcome analysis and correlations with MGMT methylation status in the elderly population

E. Franceschi[1], A. Baruzzi[2], A. Tosoni[1], R. Depenni[3], C. Dazzi[4], B. Urbini[5], C. Biasini[6], G. Crisi[7], M. Ermani[8], A.A. Brandes[1]. [1]*Azienda USL, Medical Oncology, Bologna, Italy;* [2]*University of Bologna, IRCCS Institute of Neurological Sciences of Bologna, Bologna, Italy;* [3]*University Hospital, Oncology Haematology and Respiratory Diseases, Modena, Italy;* [4]*General Hospital, Oncology and Hematology, Ravenna, Italy;* [5]*St Anna University Hospital, Clinical Oncology, Ferrara, Italy;* [6]*Azienda Ospedaliera Guglielmo da Saliceto, Oncology and Hematology, Piacenza, Italy;* [7]*University Hospital, Neuroradiology, Parma, Italy;* [8]*Azienda Ospedale-Università, Neurosciences Department Statistic and Informatic Unit, Padova, Italy*

Background: The role of temozolomide concurrent with and adjuvant to radiotherapy (RT/TMZ) in elderly pts with GBM remains unclear. We therefore evaluated the efficacy of this approach in pts >70 years in the context of the Project of Emilia-Romagna Region in Neuro-Oncology (PERNO), the first Italian prospective observational population-based study in neuro-oncology.
Methods: The criteria for selecting pts enrolled in the PERNO study were: age >70 years; PS 0−3; histologically confirmed GBM; postoperative radiotherapy after surgery; residence in the Emilia Romagna region. Data were collected prospectively.
Results: Pts accrual, started on January 1 2009, was closed, as planned, on December 31 2010. In the pts enrolled (n = 53), median overall survival (mOS) was 11.1 months (95% CI: 8.8–13.5); survival rates at 1-, 2- and 3-years were 41.5% (95% CI: 28.2–54.8%), 15.2% (95% CI: 4.8–25.6%) and 6.1% (95% CI: 0–15.9%), respectively. Twenty-eight pts received RT/TMZ, and 25 pts RT alone. mOS was 11.6 months (95% CI: 8.6–14.6) following RT/TMZ and 9.3 months (95% CI: 8.1–10.6) following RT alone. mOS for pts with MGMT methylated status (n = 17) was 13.5 months (95% CI: 7.7–19.2), being 17.2 months (95% CI: 11.5–22.9) in those treated with RT/TMZ (n = 6) and 8.8 months (95% CI: 2–15.6) in those treated with RT alone (n = 11, p = 0.09). Elderly pts with MGMT unmethylated status (n = 25) had a mOS of 8.5 months (95% CI: 6−11, p = 0.014), being 8.5 months (95% CI: 2.3–14.7) in pts treated with RT/TMZ (n = 10), and 8 months (95% CI: 3–12.9) in those treated with RT (n = 15, p = 0.55).
Conclusions: RT/TMZ appears to be more effective in prolonging the mOS of elderly pts in those with MGMT methylation status (17.2 vs 8.5 months), and seem to perform better than TMZ alone, for which mOS was 9.7 months in the Nordic phase III trial. These findings underline the value of the ongoing randomized EORTC 26062–22061/NCIC CE.6 phase III comparing RT/TMZ with short course RT alone.
No conflict of interest.

Background: Early MRI assessment of GBM pts following CRT with temozolomide can be misleading. Functional analysis using parameters such as apparent difusion coeficient (ADC) and relative cerebral blood volume (rCBV) can provide valuable information on cellularity, vascularity, metabolism and tissue micro-structure, and seem to correlate with patients outcomes in previous studies. Our objective is to correlate ADC and rCBV parameters obtained during the first MRI after completion of CRT with survival.
Methods: We retrospectively analyzed the first MRI done within 12 weeks post CRT in all consecutive GBM pts that included MR perfusion and diffusion sequences, at two brazilian institutions in a 3-year period. Maximum, minimum values of ADC and rCBV were calculated by a single observer. Overall survival was estimated by Kaplan–Meier and Cox regression analysis was used to evaluate the association between ADC and rCBV with survival. In addition, we also evaluated a possible association between ADC, as categoric variable and survival applying long-rank test (categorization cutoff of 1.0×10^{-3} mm^2/s).
Results: From February 2009 to July 2012, 41 pts were included. Median time for early MRI after CRT was 12 (2−65) days. Median pts age was 54 years (22−84), 56% were male and 82% had an ECOG ⩽1. Median survival was 24.04 months.Isolated ADC and rCBV values post CRT did not correlate with overall survival: maximum ADC value (OR 1.184 [95% CI 0.224–6.273] p = 0.842), minimum ADC value (OR 0.792 (95% CI 0.138–4.541) p = 0.794) and rCBV (OR 1.001 (95% CI 0.997–1.004) p = 0.707). ADCmin value was below 1.0×10^{-3} mm^2/s in 34 pts. Overall survival was 21.25 and 19.64 months in the low and high ADCmin value groups, respectively (p = 0.820). Thirty patients had a pre CRT MRI. Pre and post CRT rCBV variation was not prognostic for survival (OR 1.000 (95% CI 0.991–1.009) p = 0.941).
Conclusion: In this study, early MRI assessment of ADC and rCBV upon completion of CRT in pts with GBM was not prognostic for survival.
No conflict of interest.

Outcome evaluation in glioblastoma patients older than 65 years: A retrospective single center study

M. Ackerl[1], B. Flechl[1], K. Dieckmann[2], M. Preusser[1], G. Widhalm[3], C. Sax[1], C. Marosi[1]. [1]*Medical University of Vienna, Department of Medicine I Division of Oncology, Vienna, Austria;* [2]*Medical University of Vienna, Department of Radiotherapy and Radiobiology, Vienna, Austria;* [3]*Medical University of Vienna, Department of Neurosurgery, Vienna, Austria*

Introduction: The NCT00820963 trial, the Nordic Glioma Study (NGS) started in 2003 to investigate an experimental radiotherapy scheme with 10x3.4 Gy vs. chemotherapy with Temozolomide (TMZ) 200 mg/m^2, days 1−5 for 6 cycles vs. radiotherapy with 60 Gy in 30 fractions for elderly patients with newly diagnosed glioblastoma (GBM).
Methods: In this retrospective study, we evaluated the outcome of patients with primary GBM, aged ⩾65 years, treated in our institution during the period of recruitment for the NGS study (2003–2009), to which our site contributed 35 patients (NGS group). The primary endpoint was overall survival.
The study population of 70 patients, 32 women and 38 men, aged 65 to 83, median 71 years, was divided into two groups: the NGS group consisted of 35 patients with13 patients in the standard radiation therapy arm with 60 Gy, 12 patients in the hypofractioned radiation therapy arm with 34 Gy and 10 patients in the TMZ arm. The other group of 35 patients consisted in 23 fit patients in the RCT arm who were treated with standard radiochemotherapy (RCT) like younger GBM patients and 12 frail patients who mostly started radiotherapy with 60 Gy but did not receive chemotherapy (nonRCT arm).

Results: 31 of the 70 patients underwent gross total resection (44%), 21 patients had subtotal resection (30%) whereas 18 patients underwent biopsy (26%).
The median overall survival in the three study arms of the NGS group in particular was 6.0 months in the 60 Gy arm, 7.0 months in the hypofractioned 34 Gy arm and 10.0 months in the TMZ arm (p = 0.012). The median overall survival in the RCT group was 21.0 months vs. 3.0 months in the nonRCT arm (p = 0.0001).
Karnofsky scores were evaluated in three months interval. The median time to the loss of functional independence (KI 60%) was >6 months in RCT patients, 6 months in the NGS group and less than three months in the nonRCT arm.
No grade 3 or 4 toxicities were documented in the 60 Gy and 34 Gy arm of the NGS group. In the TMZ arm 2 of 10 patients (20%) suffered from grade 3/4 thrombocytopenia.
In the RCT group grade 3 haematologic toxicity (thrombocytopenia and leucopenia) occurred in 2 of 23 patients (8.7%) and in one patient of the nonRCT arm (8.3%), probably due to dexamethasone.
Conclusion: This retrospective single center experience shows the wide variety of outcomes in elderly patients with GBM and underlines the need for individualized, geriatric assessment based therapy planning, performance and follow up.
No conflict of interest.

3322 POSTER

Pilot study defining patterns of relapse in high grade glioma receiving anti-VEGF treatment either in neoadjuvant setting or after first relapse

S. Comas[1], S. Villà[1], O. Etxaniz[2], S. Domènech[3], C. Hostalot[4], C. Carrato[5], C. Bugès[2], J. Molero[6], C. Balañá[2]. *[1]Catalan Institute of Oncology. Hospital Universitari Germans Trias i Pujol, Radiation Oncology, Badalona; [2]Catalan Institute of Oncology. Hospital Universitari Germans Trias i Pujol, Medical Oncology, Badalona; [3]IDI. Hospital Universitari Germans Trias i Pujol, Radiodiagnosis, Badalona; [4]Hospital Universitari Germans Trias i Pujol, Neurosurgery, Badalona; [5]Hospital Universitari Germans Trias i Pujol, Pathology, Badalona; [6]Catalan Institute of Oncology, Hospital Universitari Germans Trias i Pujol, Physics, Badalona, Catalonia, Spain*

Purpose: To determine at first progression, which kind of pattern of relapse is showed in patients who has received anti-VEGF treatment.
Methods: We analyse twenty-six patients from our centre, twenty of them included in two ongoing prospective trials. All GD-enhanced T1 and FLAIR MRI sequences were reviewed and co-registered with treatment planning done just before radiotherapy. Patterns of relapse after radiotherapy were defined as follows: *A*. all relapses were within the 95% of isodose; *B*. all relapses were between 95% and 50% of isodose; *C*. all relapses were outside 50% of isodose. Two groups of patients were include: those treated with neoadjuvant temozolomide (TMZ) and Bevacizumab (BV) before EORTC schedule and those who received BV at first relapse after concomitant treatment.
Results: Seventeen had progressed after BV and were available for evaluation (9 in neoadjuvant BV group and 8 in BV after first relapse group). GD-enhanced T1 did not show differences in patterns of relapse between both groups, being the pattern *A* the most common (88.8% in neoadjuvant BV group vs 87.5% in BV after first relapse). However, FLAIR sequence showed more *B* and *C* patterns than *A* pattern in both groups. *A, B* and *C* patterns were observed in 33.3% in neoadjuvant BV group for every pattern; and 50%, 25% and 25% after first relapse group, respectively.
Conclusions: These results show that FLAIR sequence is essential in defining the patterns of relapse in patients receiving anti-VEGF treatment. Sample will be updated at presentation. Defining patterns of relapse with new drugs could be definitive for radiotherapy volumes and doses.
No conflict of interest.

3323 POSTER

Brainstem glioma treated with radiation with or without temozolomide

S. Mallick[1], S. Das[1], A.K. Gandhi[1], N.P. Joshi[1], P.K. Julka[1], D.N. Sharma[1], G.K. Rath[1]. *[1]All India Institute of Medical Sciences, Radiation Oncology, New Delhi, India*

Background: Brainstem glioma (BSG) is an aggressive and rare tumour of childhood and adults. Treatment outcomes are dismal and role of concurrent chemoradiotherapy (CTRT) is not established in these patients. We intended to study the clinical characteristics along with outcome of BSG patients treated with CTRT at our institution.
Methods: We retrospectively evaluated 71 patients of all age groups with BSG treated at our department in the period January to December 2011. Demographic and disease characteristics in this patient cohort were recorded, and their progression free survival (PFS) was analysed with respect to age (</>18 years), gender, grade, use of CTRT and adjuvant chemotherapy.
Results: Median age at presentation was 15 years (range 3−66 years), with a male:female ratio of 1.5. 31 patients presented with gait ataxia and 29 presented with cranial nerve palsies. 34 patients were diagnosed radiologically as high grade, 32 as low grade and grade was equivocal in 5 patients. None of the patient underwent surgery. Radiotherapy dose was 56−60 Gray over 5.5 −6 weeks at 1.8−2 gray/fraction. All patients completed their radiotherapy except 7 patients.28 patients received concurrent temozolomide (75 mg/m^2), 17 patients received adjuvant temozolomide (150–200 mg/m^2 D1−5 every 4 weeks for 3−6 cycles) and 9 patient received both concurrent and adjuvant temozolomide. Median follow up duration was 8.2 months (range 1–65.3 months). At last follow up, 21 patients had progressive disease. Median PFS for the entire group was 16.7 months and PFS at 24 months and 36 months was 75% and 65% respectively. On univariate analysis, patients less than 18 years had poorer outcome as compared to older (Median PFS 9.5 vs. 41.32 months; p 0.004) and PFS was significantly poorer in the patients who received concurrent temozolomide than those who did not (Median PFS 9.8 vs. 21.5 months; p 0.05). Gender, grade and adjuvant chemotherapy did not statistically alter treatment outcomes. Age less than 18 years and CTRT with temozolomide continued to be statistically significant on multivariate analysis (p 0.01).
Conclusions: Younger age appears to be a bad prognostic factor for BSG patients. Temozolomide has a questionable role to play in the treatment of these patients.
No conflict of interest.

3324 POSTER

Reirradiation for recurrent glial tumors − experience from a regional cancer centre in North India

S. Mallick[1], A. Biswas[1], N.P. Joshi[1], P.K. Julka[1], G.K. Rath[1]. *[1]All India Institute of Medical Sciences, Radiation Oncology, New Delhi, India*

Background: This study is aimed to assess the safety and efficacy of reirradiation in patients with recurrent glial tumor.
Materials and Methods: We identified 29 patients of recurrent glial tumor receiving reirradiation as a part of salvage treatment by retrospective chart review from 1993–2012. Event free survival (EFS) after recurrence was defined as the duration of time from date of recurrence to the date of death, disease progression or development of radiation necrosis. Survival analysis was done by Kaplan–Meier method.
Results: The median age at presentation was 32 years (range 11−57 years) with male: female ratio of 23:6. The initial site of disease was frontal (37.93%), parietal (10.34%), temporal (6.9%), occipital (3.45%), multilobed (31.03%), brainstem (3.45%) and optic nerve (3.45%). Initial surgical resection was gross total in 44.83% and subtotal in 48.28% patients. Histopathology was confirmative of diffuse astrocytoma (17.24%), gemistocyticastrocytoma (3.45%), ganglioglioma (3.45%), oligodendroglioma (24.14%), oligoastrocytoma (3.45%), anaplastic oligodendroglioma (10.34%), anaplastic oligoastrocytoma (6.9%), anaplstic astrocytoma (6.9%) and glioblastoma (10.34%). Initial radiotherapy dose varied from 56−60 Gy/ 28−30fractions/ 5.5−6 weeks as per the grade of the tumor(low grade-44.83%; high grade-55.17%). 37.93% and 51.72% of the patients received concurrent and adjuvant chemotherapy. The median recurrence free survival was noted to be 4.85 years. At recurrence, 44.83% of the patients underwent surgical resection (gross total-17.24%, subtotal-20.69%, details unavailable-6.9%). Median reirradiation dose was 45 Gy/ 25fractions/ 5 weeks (range 40−55 Gy at 1.8 Gy/ fraction/day). Majority (96.55%) underwent 3D-CRT and only 1 patient underwent SRT (mMLC based). Reirradiation was well tolerated and only 2 patients defaulted during the last week of treatment due to neurological deterioration. Concurrent and adjuvant temozolomide (EORTC-NCIC regimen) were used in 62.07% and 58.62% of the patients respectively. In the evaluable patients (N = 26), after a median follow-up of 10.38 months from the date of recurrence (range 1.77–88.52 months), complete response, stable and progressive disease were noted in 26.92%, 50% and 23.08% respectively. Radiation necrosis was discerned in 2 patients with 1 having debilitating neurological symptoms.The median EFS was noted to be 2.82 years. On univariate analysis, age (<40 vs. >40 years), sex, tumor grade, temporal pattern of recurrence (<2 years vs. >2 years), resurgery, use of concurrent or adjuvant chemotherapy along with reirradiation, had no significant impact on EFS.
Conclusion: Conformalreirradiation is a safe, feasible and useful treatment option in recurrent glial tumor.Radiation free interval (<2 versus >2 years) and cumulative brain dose (<100 Gy versus >100 Gy) should be taken into account before using this option.
No conflict of interest.

3325 POSTER

Treatment patterns and survival in patients with metastatic brain tumors

D. Stenehjem[1], B. Cai[2], K. Kuo[2], M. Martel[3], S. Ray[3], T. McLaughlin[3], D. Brixner[4]. [1]*University of Utah, Huntsman Cancer Institute, Salt Lake City, USA;* [2]*University of Utah, Pharmacotherapy Outcomes Research Center, Salt Lake City, USA;* [3]*AbbVie, Health Economic and Outcomes Research Oncology, North Chicago, USA;* [4]*University of Utah, Program in Personalized Health Care, Salt Lake City, USA*

Background: The rising incidence of metastatic brain tumors (MBT) due to better control of systemic disease represents a growing societal burden. The objective of this study was to characterize treatment patterns and outcomes of patients with MBTs using electronic health records of a major US cancer center in the Intermountain West.
Material and Methods: A cohort of patients diagnosed with MBTs during 1995–2010, was identified by linking the Utah Population Database and the University of Utah Enterprise Data Warehouse with the Huntsman Cancer Institute Tumor Registry. Patients were included if they were $\geqslant$18 years at MBT diagnosis (defined as $\geqslant$2 MBT diagnoses; ICD9-CM code 198.3), a primary cancer diagnosis, and $\geqslant$2 healthcare encounters during the study period. Patient demographics, survival, and treatment patterns (from 2002–2010) were assessed by the four most prevalent primary cancer sites.
Results: A total of 1900 cancer patients also diagnosed with MBT were identified from 1995–2010 (median age 60 years, 55% male). The most prevalent primary cancer sites were lung (30.5%), breast (16.2%), melanoma (15.5%), and kidney (8.3%). The median time from diagnosis of the primary cancer to the diagnosis of MBT was 51, 308, 761, and 1168 days for lung, kidney, melanoma and breast cancer, respectively. A subset of patients (n = 964), whose MBT was diagnosed during 2002–2010, were followed for survival and treatments received after MBT diagnosis. The first treatment used after MBT diagnosis was radiation (41%), followed by chemotherapy (19%), stereotactic radiotherapy (17%), and neurosurgery (12%); 117 (12%) patients received no treatment other than supportive care. Approximately 87% of patients received dexamethasone as a supportive therapy. Median survival after MBT diagnosis ranged from 114 days (lung primary) to 268 days (breast primary), which translates in mortality rates of 144.8 deaths per 100 person-years (lung) and 70.3 deaths per 100 person-years (breast). Compared to the median survival of 129 days for patients diagnosed with MBT during the period 1997–2000, the median survival for patients diagnosed during 2001–2004 and 2005–2008 were 160 days (p = 0.21) and 186 days (p = 0.02) respectively.
Conclusion: Survival of patients after the diagnosis of MBT has improved over time and differs by primary cancer site, but remains poor for most patients and reflects the high unmet need in this patient population.
No conflict of interest.

3327 POSTER

Clinical outcome of patients with primary gliosarcoma treated with concomitant and adjuvant temozolomide: A single institutional analysis of 27 cases

A.K. Gandhi[1], S. Mallick[1], N.P. Joshi[1], D.N. Sharma[1], G.K. Rath[1], C. Sarkar[2], P.K. Julka[1]. [1]*All India Institute of Medical Sciences, Department of Radiation Oncology, New Delhi, India;* [2]*All India Institute of Medical Sciences, Department of Pathology, New Delhi, India*

Background: Primary gliosarcoma (PGS) is an aggressive and rare tumour and survival remain dismal with current treatment modalities. We intended to study the outcome of PGS patients treated with concurrent and adjuvant temozolomide (TMZ).
Materials and Methods: We retrospectively evaluated 27 patients of PGS treated with radiotherapy (RT) and TMZ at our institute during 2007–2012. Demographic and disease characteristics in this patient cohort were recorded. Overall survival (OS) was estimated by the use of Kaplan Meier method and univariate analysis (log rank test) was done to assess the impact of prognostic variables on OS. Multivariate analysis was done by Cox-proportional hazard model and SPSS (version 12.0) was used for all statistical analysis. Toxicities were evaluated using CTCAE version 2.0.
Results: Median age at presentation was 45 years (range 7−75 years) with a male: female ratio of 20:7. Median Karnofsky performance status (KPS) was 90 (range 70−90). Tumour was present in the temporal, parietal and frontal lobe in respectively 31%, 26% and 15% of the cases and involved more than 1 lobe in 28% of cases. 12 (44%) patients each underwent a gross total excision and sub-total excision and 3 (12%) had a decompression and biopsy of the tumour only. All patients received adjuvant RT to a total dose of 60 gray at 2 gray per fraction except 3 patients [one received 8 gray and two patients received 46 gray] median interval between surgery and RT was 38 days (range, 17−83 days). All patients except 1 received concurrent TMZ. All patients except 5 received adjuvant TMZ to a median number of 6 cycles (range 2−6 cycles). 2 patients had grade 2 (one neutropenia and one thrombocytopenia) and 1 patient had grade 3 (both neutropenia and thrombocytopenia) during concurrent RT. During adjuvant chemotherapy 3 patients (13.6%) had grade 3 thrombocytopenia and 2 patients had grade 3 neutropenia (9.5%). Median follow up duration for the entire cohort was 13 months (range, 2−48 months). At the time of last follow up 13 patients had expired, 4 had progressive disease and 10 patients were free of disease. Median OS of the entire cohort was 16.7 months. 1 year and 2 year actuarial OS was 70.8% and 32.6% respectively. On univariate analysis, use of adjuvant chemotherapy with TMZ was associated with a significantly better survival (median survival 21.21 months versus 11.93 months; p = 0.0046) and continued to be an independent prognostic factor for survival on multivariate analysis ((HR 1.82, 95% CI 1.503–25.58); p = 0.012). Other prognostic variables viz age, sex, extent of surgical resection, KPS and tumour site did not impact survival significantly.
Conclusion: The results of our study, largest series of patients with PGS treated with concurrent and adjuvant TMZ shows an impressive survival with acceptable toxicity. We suggest TMZ be included in the 'standard of care' for this tumour.
No conflict of interest.

3328 POSTER

Pineal parenchymal tumor − clinical experience from a regional cancer centre in north India

A. Biswas[1], S. Mallick[1], A.K. Gandhi[1], C. Sarkar[2], P.K. Julka[1], G.K. Rath[1]. [1]*All India Institute of Medical Sciences, Radiotherapy & Oncology, Delhi, India;* [2]*All India Institute of Medical Sciences, Pathology, Delhi, India*

Introduction: Pineal parenchymal tumor constitutes less than 1% of primitive tumors of the CNS and is classified by WHO into pineocytoma (PC)-grade I, pineal parenchymal tumor of intermediate differentiation (PPTID)-grade II/III and pinealoblastoma (PB)-grade IV.
Materials and Methods: We intended to assess the clinical features and treatment outcome in patients of pineal parenchymal tumor attending our hospital from 2003−13. Overall survival (OS) and recurrence free survival (RFS) were analyzed by Kaplan–Meier method.
Results: 23 patients met the study criterion (median age=22 years and male: female=14:9). Presenting complaints included headache (73.91%), visual symptoms (43.48%), vomiting (30.43%) and ataxia (26.09%). Preoperative contrast enhanced MRI and CT scan of brain were performed in 78.26% and 17.3% of patients respectively. Spinal drop metastasis and CSF cytology positivity were noted in 3 and 2 patients respectively. Surgery included gross total resection in 21.74%, near total resection in 13.04%, subtotal resection in 17.39% and tumor biopsy in 43.48% of the patients. 12 (52.17%) patients required the placement of VP shunt. Histopathology was confirmative of PB in 14 (60.87%) patients, PPTID in 6 (26.09%) patients and PC in 3 (13.04%) patients. MIB-1 labeling index varied from 2−80% with median value of 30% and 4.5% in PB and PPTID respectively. 22 (95.65%) patients underwent radiation therapy- craniospinal irradiation (CSI) in 14(60.87%) patients, whole brain radiation in 1 patient, whole ventricular radiation in 1 patient and local radiation in 6 (26.09%) patients. Majority (85.7%) of patients of PB underwent CSI- 36 Gy/ 20 fractions/ 4 weeks to whole brain followed by boost of 20 Gy/10 fractions/ 2 weeks to pineal region and 30−36 Gy/ 20 fractions/ 4 weeks to spinal axis as per risk stratification. Systemic chemotherapy was administered in 12 (52.17%) patients (11-PB and 1-PC) with EP (etoposide and carboplatin) being the most common regimen (30.43%). The median number of cycles administered was 6 (range 3−6). After a median follow-up of 26.87 months, death and recurrence were observed in 2 and 10 patients (local recurrence-34.78% and spinal drop metastases- 26.09%) respectively. Median RFS was noted to be 2.33 years, 14.29 years and 6.76 years in patients of PB, PPTID and PC respectively. The 2 and 3 year actuarial RFS rates in the entire cohort were respectively 71.6% and 57.9%. Salvage treatment was offered in 6 patients. Median overall survival was not reached. On univariate analysis (Log rank test), age (<18 versus >18 years), sex, histology, extent of surgery (biopsy versus resection) and use of chemotherapy had no significant impact on RFS.
Conclusion: Maximal safe resection followed by radiation therapy is the mainstay of treatment in pineal parenchymal tumor. Radiation volume encompasses the craniospinal axis in pinealoblastoma and the tumor bed with margin in pineocytoma. Platinum based combination chemotherapy should be added in adjuvant treatment in pinealoblastoma.
No conflict of interest.

3329 POSTER

Prognostic value of pseudoprogression after stereotactic reirradiation in locally recurrent glioblastoma patients

G. Yazici[1], M. Cengiz[1], G. Ozyigit[1], G. Eren[1], F. Yildiz[1], F. Akyol[1], M. Gurkaynak[1], F. Zorlu[1]. [1]*Hacettepe University Faculty of Medicine, Radiation Oncology, Ankara, Turkey*

Background: We assessed the prognostic impact of pseudoprogression in locally recurrent glioblastoma patients re-irradiated with frameless stereotactic radiotherapy (SRT).
Material and Methods: Between September 2009 and December 2011, 37 patients with recurrent glioblastoma were treated with CyberKnife in our department. All patients had unresectable, recurrent disease and were previously treated with conformal radiotherapy. The gross tumor volume (GTV) was delineated based on the contrast enhancing lesion on T1-weihgted magnetic resonance images (MRI). A 3 mm margin was added to GTV for defining the planning target volume (PTV). The median fraction number was 5 fractions (range, 1 to 5), and the median total delivered dose was 30 Gy (range, 14 to 32 Gy). The median volume of the GTV was 24 cc (range, 2 to 81cc). The interval between the primary radiotherapy and SRT ranged from 5 months to 45 months (median 15 months).
Results: The median follow was 20 months. The first MRI evaluation revealed that five patients had regression, 14 had stable disease, and 8 had progression. Another 7 patients had progression in their first MRI however they had regression in the follow-up and were diagnosed as pseudoprogression. Three patients died of disease in their first month of follow up. The median overall survival was 10.6 months in median (range, 1.1 to 20 months). The median progression free survival was 7.9 months (range, 7.4 to 13.3 months). The median overall survival for patients with pseudoprogression, regression, stable disease, and progression was 20 months, 13.7 months, 10.4 months, and 7 months respectively. Patients with pseudoprogression had a significantly longer overall survival compared to patients with regression, stable or progressive disease ($p = 0.01$).
Conclusion: In this retrospective cohort, SRT seems to be effective in patients with locally recurrent glioblastoma. We also found that patients with pseudoprogression after SRT had longer overall survival.
No conflict of interest.

3330 POSTER

NG2/CSPG4 promotes resistance to therapy in glioblastoma multiforme

R. Heywood[1], C. Watts[1]. [1]*Cambridge Centre for Brain Repair, Cambridge, United Kingdom*

Background: The CSPG4/NG2 proteoglycan has been shown to be a marker of an aggressive proliferative phenotype, and as a potential marker of treatment resistant cells in GBM, and it may play a functional role in this resistance. However, this has not yet been demonstrated in cell lines derived from fresh surgical tissue. We sought to determine whether CSPG4 plays a role in treatment resistance in freshly derived cell lines.
Methods: Glioblastoma cell lines were derived using the Cambridge Protocol, and were exposed to ionising radiation, temozolomide and carmustine, the main therapies used in GBM. The proportion of live cells expressing CSPG4 was assessed by flow cytometry. Cell lines were FACS sorted, and the survival of positive and negative cells assessed by the MTT assay. To investigate a functional role of CSPG4, shRNA knockdown cell lines were generated before exposure to the therapeutic agents.
Results: CSPG4+ cells were enriched after exposure to all therapeutic modalities, and expression of CSPG4 correlated with survival of cell lines after therapy. FACS sorting confirmed that CSPG4+ cells are more resistant than CSPG4- cells, and growth curve analysis demonstrated long-term expansion of CSPG4+, but not CSPG4-, cells over a long period of time. shRNA knockdown demonstrated that cells were less proliferative and more sensitive to therapy.
Conclusion: CSPG4 is a reliable marker of therapy resistant cells in glioblastoma, and appears to play a functional role in this resistance. The exact mechanisms are under investigation, but targeting of CSPG4 may be beneficial in overcoming treatment resistance.
No conflict of interest.

3331 POSTER

Long-term outcome fractionated stereotactic radiotherapy and radiosurgery for treatment of symptomatic cavernous sinus meningioma: a 15-year experience

G. Marta[1], S.F.M. Correa[1], M.J. Teixeira[2]. [1]*Hospital Sírio-Libanês, Radiation Oncology, São Paulo, Brazil;* [2]*University of São Paulo Medical School, Neurosurgery Department, São Paulo, Brazil*

Background: To evaluate the clinical results and radiological local control of symptomatic cavernous sinus meningioma patients treated with fractionated stereotactic radiotherapy (FSRT) or stereotactic radiosurgery (SRS).
Material and Methods: Retrospective cohort study evaluating 89 patients with symptomatic cavernous sinus meningiomas treated with SRS (36%) or FSRS (64%) from January 1994 to March 2007. Neurosurgical partial resection or biopsy was performed in 29.2% of the patients previously to radiotherapy. The single SRS dose was 14 Gy and the FSRT dose, 50.4−54 Gy fractionated in 1.8−2 Gy/dose.
Results: The follow-up period ranged from 36 to 129 months (median 73 months). Improvement in individual symptoms was the same regardless of treatment given, and Clinical improvement occurred in 41.6% of patients and radiological in 48.3%. Approximately 43% of the patients presented radiologically stable disease. The recurrence-free survival was 98.8%, 92.3%, and 92.3%, respectively, in 5, 10, and 15 years. Disease progression occurred in four patients (4.49%). No statistically significant association was observed between the radiotherapeutic method and symptom improvement ($p > 0.05$).
Conclusions: Both FSRT and SRS were equally safe and effective for the management of symptomatic cavernous sinus meningioma patients. There was clinical improvement in 41.6% of the patients and radiological stabilization or lesion regression of the lesion in 92.1%. The 15-year progression-free survival was 92.3%.
No conflict of interest.

3332 POSTER

Initial results of stereotactic linear accelerator based irradiation for pituitary adenoma

A. De Campos[1], N.R.C. Musolino[1], M.B.C. Cunha Neto[1], E.C. Souza[1], S.C. Leal[1], V.A.S. Cescato[1], I.T. Carvalho[1], R.C. Villar[1], W. Nadalin[1], E. Weltman[1]. [1]*University of São Paulo, Radiology, São Paulo, Brazil*

Background: Radiotherapy is an efficient treatment for recurrent pituitary adenomas. Stereotactic linear accelerator based radiosurgery (LINAC) have been used in our Institution since 2008. The purpose of this analysis was to evaluate the initial results in control rate after radiosurgery or fractionated stereotatic radiotherapy in pituitary adenoma.
Material and Method: From september 2008 to July 2011, 36 patients were treated with fractionated stereotatic radiotherapy (FSR) or radiosurgery (RS) for pituitary adenomas. Tumor control was defined as normalization of basal hormonal levels and lack of progression of adenoma assessed by imaging studies. Follow-up included MRI and hormone evaluation.
Results: Twenty patients had nonfunctioning (NF) and sixteen had functional adenomas (acromegaly in ten and Cushing's disease in six cases). The median age was 44 years (range 17−72), with 29 females and 7 males. The median follow-up was 31 months (range 8−53). All patients received radiotherapy postoperatively for residual disease. All acromegaly patients were resistant to octreotide and cabergoline treatment. Mean total dose was 50.4 Gy for fractionated stereotactic radiotherapy ($n = 25$), and 20 Gy for radiosurgery ($n = 11$: 3 with Cushing's disease, 5 with acromegaly and 3 with NF). Twenty patients had stable disease based on MRI, while 15 had a reduction of tumor volume after 12 months. Regarding hormonal control, three of the six Cushing patients achieved normal urinary cortisol and midnight salivary cortisol levels after radiotherapy, one of them treated by RS. Although all patients were resistant to octreotide/cabergoline before radiotherapy, 3 of them obtained normal IGF-1 levels under medical treatment after irradiation and one patients with aggressive and invasive tumor showed normal IGF-1 levels without drug besides hypopituitarism.
Conclusions: Stereotatic radiotherapy is effective and safe in the treatment of pituitary adenomas to improve local control and can improve the hormonal control, with or without medical treatment.
No conflict of interest.

3333 POSTER

The incidence of brain metastases in correlation to dominant hemisphere and different brain lobes

W. Mourad[1], L.X. Hong[1], P. LaSala[2], T. Santiago[1], S. Patel[1], R.A. Shourbaji[1], R. Kabarriti[1], M. Bernstein[1], S. Kalnicki[1], M.K. Garg[1]. [1]*Albert Einstein college of Medicine, Radiation Oncology, New York, USA;* [2]*Albert Einstein college of Medicine, Neurosurgery, New York, USA*

Purpose: Blood flow to the brain varies according to the dominance and functionality of each brain lobe. We hypothesized that this greater blood flow would lead to an increase in seeding of metastases to areas within the dominant lobe when compared to the nondominant lobe.
Methods: This is a single institution retrospective study of 190 patients (pts) who underwent SRS for 382 metastatic brain lesions from January 2007 through December 2012. All pts underwent single fraction LINAC-based SRS via 6 MV photon using either noncoplanar conformal fixed beams (68%) or dynamic conformal arcs (32%) prescribed to 100% of the planning

target volume (PTV) of which 13, 17, and 6% underwent surgery, whole brain radiotherapy (WBRT), or both, respectively. The median prescribed dose and PTV were 21 Gy (range 15−25) and 2cc (0.1−32). The median Dmax (dose to isocenter) and Dmin were 26.5 and 21 Gy, respectively. All patients had an ECOG performance status $\leqslant$2. The cohort consisted of Hispanics (39%), Caucasians (31%), African Americans (29%), and Asians (1%); 50% of the cohort was male. Histologies included lung (52%), breast (20%), renal (14%), and other malignancies (14%).
Results: The median follow-up for the entire cohort was 5.5 months (ms); however, the median follow-up intervals for survivors vs. expired pts were 12.8 ms (4–94.4ms) vs. 5 ms (1−60). The incidence of brain metastases in the different brain lobes were: 43%, 24%, 12%, 11.5%, and 9.5%, for frontal lobe, parietal lobe, cerebellum, temporal lobe, and occipital lobe, respectively. The incidence of brain metastases in the dominant hemisphere was 97% ($p = 0.01$). The LC for the entire cohort was 88%. The actuarial overall survival (OS) was 26%. No patients experienced RTOG grade $\geqslant$3 toxicities. Breast cancer pts had a longer median actuarial OS (9 ms) vs. other histologies (5 ms). Chi-square analysis showed that metastectomy prior to SRS was a statistically significant predictor for better LC ($p < 0.0001$).
Conclusion: Our data reveal increased seeding of brain metastases to the dominant brain hemisphere and brain lobes with higher blood flow.
No conflict of interest.

3334 POSTER

The number of brain metastases should not be used as a decisive factor to select patients for radiosurgery or not

P. Hanssens[1], B. Karlsson[2], V. Ng[2], G. Beute[1], Y. Tseng Tsai[2]. [1]*St. Elisabeth Hospital, Gamma Knife Center Tilburg, Tilburg, Netherlands;* [2]*National University Hospital, Division of Neurosurgery, Singapore, Singapore*

Background: Radiosurgery is an accepted treatment modality for selected patients with 1 to 3 brain metastases (BM). It is also well known that patients with a single brain metastasis have a better prognosis than those with multiple BM. However, the impact of the number of BM among patients with multiple brain lesions is unclear. Is the prognostic significance of the number of lesions sufficient to withhold radiosurgery for patients with more than 3 BM? In order to assess this question we analyzed our experience following Gamma Knife radiosurgery (GK) in patients with multiple BM.
Material and Methods: Of the 1365 consecutive BM patients treated in the Gamma Knife Center Tilburg between June 1, 2002 and June 20, 2011, 806 had multiple lesions. There were no differences between the groups of patients with 2 or 3 as compared to 4 or more BM for gender, ($P = 0.35$), age ($P = 0.062$), primary tumor (NSCLC or not; $P = 0.42$) and primary tumor control ($P = 0.60$). Prior WBRT was more common among patients with 4 or more BM ($P = 0.046$).
Results: The likelihood to develop distant recurrences in the brain was higher among the patients with more than 3 BM, 42 as compared to 33%, ($P = 0.014$). However, this difference did not translate into a significant difference in survival following GK. The median survival was 6.2 months for patients with 4 or more BM as compared to 7.2 months for patients with 2 to 3 BM, a non-significant difference ($P = 0.23$). The management of distant recurrences in the brain did not differ significantly between the two groups, ($P = 0.73$).
Conclusions: The number of BM in the patients treated with GK did not have an impact on the survival. In our opinion, the number of BM cannot be used as a decisive factor to select which patients should be offered GK for their BM and which should not.
No conflict of interest.

3335 POSTER

Outcomes of fractionated stereotactic radiotherapy for skull base meningiomas

D. Nakamura[1], T. Mizowaki[1], K. Ogura[1], M. Hiraoka[1]. [1]*Kyoto University Graduate School of Medicine, Department of Radiation Oncology and Image-Applied Therapy, Kyoto, Japan*

Background: The management of skull base meningioma (SBM) is a challenging proposition because SBM often involves cranial nerves. Preserving cranial nerve functions, fractionated stereotactic radiotherapy (FSRT) is more effective than other treatments; i.e. surgery, radiosurgery and hypofractionated stereotactic radiotherapy. The response criteria in SBM is indefinite for its irregular shape. The purpose of this study is to evaluate the safety and efficacy of FSRT and the morphologic change to FSRT.
Material and Methods: Consecutive 28 patients with SBMs were treated with FSRT using Novalis system between March 2007 and November 2011 at Kyoto University Hospital. 21 patients received FSRT following open surgery. 18 patients had WHO grade I meningiomas, one had WHO grade II, two had unknown grade meningioma. Other 7 patients were clinically diagnosed as meningioma based on radiological findings. 21 and 7 patients were treated by multiple dynamic conformal arc and IMRT technique, respectively. The youngest 11 years old patient was received 47.6 Gy in the 1.7 Gy fraction size, and the prescribed dose of the other 27 patients was ranged from 50.4 to 52.2 Gy in the 1.8 Gy franction size. The longest diameter and the short-axis diameter of tumor were measured to evaluate the morphologic change.
Results: The median follow up time was 38 months. All patients had completed the planned FSRT without severe acute adverse events. The 3 year local control and overall survival rates were both 100%. One patient died due to tumor hemorrhage after 42 months from the beginning of FSRT. The other 27 patients were alive with local control during follow-up periods. No patients developed progression of cranial nerve symptoms. All of the longest diameters coincided with the dural attachment. 95% confidence intervals of reduction ratio of the longest diameter and the short-axis diameter were respectively (0.92–1.00) and (0.79–0.95), and there was a significant difference between them.($p = 0.0045$).
Conclusion: Our results demonstrate that FSRT for SBM bring about good local control with preserving cranial nerve functions in limited patients and follow-up. Difference in reduction ratios of the longest diameter and the short-axis diameter may show that it is insufficient to evaluate response to radiotherapy only by the longest diameter.
No conflict of interest.

3336 POSTER

Can fractionated stereotactic re-irradiation improve the outcome in patients with recurrent glioblastoma? Single institutional experience

P. Ciammella[1], M. Galeandro[1], A. Podgornii[1], N. D'Abbiero[1], A. Botti[1], M. Iori[1], C. Iotti[1]. [1]*Arcispedale Santa Maria Nuova, Radiation Department, Reggio Emilia, Italy*

Background: Glioblastoma (GBM) is the most common malignant primary brain tumour in adults. Tumour control and survival have improved with the use of radiotherapy (RT) plus concomitant and adjuvant TMZ, but the prognosis remains poor. In most cases recurrence occurs within 7−9 months and up to 90% in close proximity to the resection cavity or the target volume of postoperative RT. Currently, many approaches are available for the salvage treatment of patients with recurrent GBM, including resection, re-irrradiation or systemic agents, but no standard of care exists.
Materials and Methods: This is a retrospective analysis of twenty-four patients with recurrent GBM treated with hypofractionated radiation therapy (HFRT) at our department. After primary therapy, the recurrences were defined as 'in-field', 'marginal' or outside the radiation field. Indication for re-irradiation was evaluated by interdisciplinary neurooncology team and based on: patient clinical condition, lesion location and spread of disease. All patients were treated with multiple noncoplanar beams with a total dose of 25 Gy in 5 consecutive fractions, prescribed to the 70% isodose line.
Results: Of 95 consecutive patients with newly diagnosed GBM treated between 2007 and 2012 with conventional adjuvant chemo-radiation therapy at our department, 24 underwent salvage RT at recurrence. At the time of data analysis, 77 out 95 patients had died and the tumour progression was the primary cause of death in 74 patients. Among 18 patients still alive, 11 were in stable disease and 7 in course of systemic salvage therapy. Recurrence occurred 'in-field' in 59 patients (73%), at RT field margin in 8 patients (9%) and 'out-field' in 14 patients (17%). Salvage RT was performed in 15 of 68 patients with regional or marginal progression and in 9 of 13 patients with distant recurrence. The median time interval between primary RT and salvage RT was 8.8 months (range, 6−54 months). Overall, patients undergoing salvage RT showed a longer survival, with a median survival of 27.3 vs 10.4 months ($p = 0.00149$). Median OS from salvage RT was 10 months (range 4−42 months). In salvage RT patients, KPS ($p = 0.03$) and MGMT methylation status ($p = 0.02$) were statistically correlated with OS. No patients demonstrated clinically significant acute morbidity, and all patients were able to complete the prescribed radiation dose without interruption. Neurological deterioration occurred in two patients at 1 and 3 months after re-irradiation and was managed successfully with dexamethasone.
Conclusion: The current literature suggests that HFRT is effective and safe in recurrent glioblastoma after conventional chemo-radiation treatment. Until prospective randomized trials consolidate these results, the decisions for salvage treatment will remain individual and should be based on multidisciplinary analysis of each patient.
No conflict of interest.

3337 POSTER

Hypofractionated chemoradiotherapy with temozolomide as an appropriate treatment option for glioblastoma patients with poor prognostic features

Y. Lim[1], I.H. Kim[1], T.J. Han[2]. [1]*Seoul National University Hospital, Radiation Oncology, Seoul, Korea;* [2]*Kangdong Sacred Heart Hospital, Radiation Oncology, Seoul, Korea*

Background: Since high-risk GBM patients showed median OS of less than 1 year, clinical benefit of the 6-week postoperative treatment for the high-risk patients has been questioned. This study evaluated the feasibility and safety of hypofractionated radiotherapy (RT) with concomitant temozolomide (TMZ) for glioblastoma (GBM) patients with poor prognostic features.
Material and Methods: From Feb 2007 to Dec 2011, 33 patients with pathologically confirmed GBM received hypofractionated concurrent chemoradiotherapy (CRT) with TMZ, with or without adjuvant TMZ. The patients were either $\geqslant$70 years or <70 years with one or more risk factors (pre-RT ECOG score $\geqslant$3, stereotactic biopsy only, or immediate disease progression after surgical procedure). The median radiation dose was 45 Gy (range, 30 to 45 Gy) with a fraction size of 3 Gy.
Results: With the median age of 66.0 years, 18 patients (54.5%) showed poor performance status (ECOG $\geqslant$3) before starting CRT and 16 patients (48.5%) received stereotactic biopsy only. The median overall survival (OS) and progression-free survival (PFS) were 10.6 months and 4.4 months, respectively. Pre- and post-RT poor performance status (ECOG $\geqslant$3) (HR 3.12, 95% CI 1.21–8.07 and HR 4.51, 95% CI 1.44–14.12, respectively) and no early pseudoprogression (PsPD) (HR 5.43, 95% CI 1.58–18.61) were associated with poor OS. In PFS, post-RT performance status (ECOG $\geqslant$3) (HR 2.97, 95% CI 1.15–7.62) and extent of tumor (HR 2.50, 95% CI 1.05–5.96) were statistically significant. While acute neurologic symptoms during the CRT were reported in 5 patients (15.2%), there was no treatment-related aggravation in performance status with acceptable toxicity profiles.
Conclusion: We suggest a reasonable and well-tolerated therapeutic approach of hypofractionated concurrent CRT with TMZ in high-risk GBM patients. Despite the presence of one or more poor prognostic features in the patient cohort, the median OS comparable to previous studies was remarkable. Maintenance of good performance status before and after concurrent CRT will be beneficial for better prognosis.
No conflict of interest.

3338 POSTER

Hypo-fractionated radiation therapy compared to standard treatment regimen for glioblastoma: Local control and toxicity

P. Ciammella[1], M. Galeandro[1], N. D'Abbiero[1], A. Botti[1], E. Cagni[1], M. Iori[1], C. Iotti[1]. [1]*Arcispedale Santa Maria Nuova, Radiation Department, Reggio Emilia, Italy*

Background: The standard treatment today is maximal surgical resection followed by concomitant chemo-radiation therapy followed by adjuvant TMZ, with median overall survival of 14.6 months and 2-year survival rate of 26.5%. Despite the progress in neurosurgery, radiotherapy and oncology, the prognosis still result poor. In order to reduce the long time of standard treatment, in our institute we investigated the effects of hypofractionated radiation therapy (HFRT). For comparison, a group of 95 patients with similar characteristics and treated with Stupp protocol was retrospectively selected.
Materials and Methods: 67 patients affected by glioblastoma (GBM) underwent surgical resection were treated between October 2005 and December 2011 with HFRT followed or not by adjuvant chemotherapy with temozolomide (6−12 cycles). HFRT (5 Gy/fraction/day) was delivered to a total dose of 25 Gy in 5 fractions, dose prescribed at the 70% isodose. All patients received a non-contrast CT scan and MRI for treatment planning. After image fusion, the target volume was defined by the contrast-enhanced tumour edges on axial T1 and FLAIR sequences by consensus agreement of the neurosurgeon, neuroradiologist, and radiation oncologist. Treatment planning was performed to cover the 100% of planning target volume by 25 Gy, with maximum dose of 35.7 Gy. For treatment delivery, all patients received an portal image prior to each treatment fraction. Sex, age, type of surgery, Karnofsky performance status (KPS), Recursive Partitioning Analysis (RPA) classification, time between surgery and initiation of radiotherapy were analysed as potential prognostic factors for survival using the univariate log-rank method.
Results: All patients have completed the treatment protocol. Median age was 64.5 years (range 41–82 yrs) with 31 females (46%) and 36 males (54%). Median KPS at time of treatment was 80. The surgery was gross total in 38 patients and subtotal in 14 patients; 15 patients underwent only biopsy. The patients characteristics of the two groups of patients are similar. With mean follow-up of 14.9 months (range 3−62 months), the median overall survival and median progression- free survival were 12.43 and 6.9 months, respectively. No grade 3−4 acute or late neurotoxicity was observed. Post-treatment median KPS was 90 (range 70–100). The overall tolerance of patients to HFRT was not different from that for conventional radiotherapy. Not statistically significant difference in terms of overall survival between HFRT group and Stupp protocol group was reported (p 0.12).
Conclusions: The HFRT can be used for patients with GBM, resulting in favourable overall survival, low rates of toxicity and satisfying QoL. Future investigations are needed to determine the optimal fractionation for GBM.
No conflict of interest.

3339 POSTER

Efficacy of bevacizumab on radiation necrosis of the brain diagnosed by positron emission tomography with 11C-methionine

K. Miwa[1], S. Yonezawa[1], J. Sinoda[1], H. Yano[2], T. Iwama[2]. [1]*Chubu Medical Center Kizawa Memorial Hospital, Department of Neurosurgery, Gifu, Japan;* [2]*Gifu University Graduate School of Medicine, Department of Neurosurgery, Gifu, Japan*

Background: We reasoned that bevacizumab might be a new effective treatment of cerebral radiation necrosis because its ability to block vascular endothelial growth factor, although accurate diagnosis of radiation necrosis remains controversial. In this study, we examined to differentiate radiation necrosis from recurrent malignant brain tumor by positron emission tomography (PET) with 11C-methionine (MET), and evaluated the efficacy of bevacizumab for the treatment of radiation necrosis.
Material and Methods: 10 patients with malignant brain tumors (6 Glioblastoma, 1 anaplastic oligodendroglioma, 2 metastatic brain tumor, and 1 primary central nervous system lymphoma) were treated with bevacizumab for their symptomatic cerebral radiation necrosis on a 5 mg/kg biweekly, for a maximum total of 6 cycles. Radiation necrosis was diagnosed on the basis of the cut off value of lesion/normal tissue ratios (L/N ratio) on MET-PET. We evaluated the efficacy of bevacizumab treatment by MRI studies, MET-PET and 11C-choline (CHO)-PET, Karnofsky performance status (KPS), adverse events, and clinical courses before and after bevacizumab treatment completion.
Results: Seven patients showed significant clinical improvement in terms of neurologic symptoms expressed by KPS. Post-treatment MRI performed after bevacizumab therapy showed a reduction significantly in all 10 patients in both the MRI post-gadolinium and T2-weighted sequence (median reduction rate was 69.6% and 67.1%, respectively). PET imaging after bevacizumab therapy revealed that the median reduction rate of L/N ratio on CHO-PET was much higher than that of L/N ratio on MET-PET (62.1% and 22.9%, respectively). Bevacizumab-related adverse events of grade 1 or 2 occurred in three patients. During the median follow-up period of 16 months (range, 7−25), radiation necrosis recurred in four patients and the newly tumor lesion appeared in seven patients. All newly tumor lesion was appeared as an intraparenchymal newly enhanced lesion distant from the original tumor site. The 1-year tumor-progression-free survival rates from the completion of bevacizumab treatment were 40.0%. The 1-year survival rates from the completion of bevacizumab treatment were 70.0%.
Conclusions: We concluded that MET-PET could be useful for diagnosing radiation necrosis, and that bevacizumab could alleviate symptomatic radiation necrosis significantly by the restoration of blood–brain barrier and the associated brain edema.
No conflict of interest.

RTOG compared to EORTC volume recommendations in high grade glioma: Acute toxicity and integral dose

C. Faul[1], M.N. ElBeltagi[2]. [1]*St Luke's Hospital, Radiation Oncology, Dublin, Ireland;* [2]*NCI Cairo University/St Luke's Hospital, Radiation Oncology, Dublin, Ireland*

Background: Radiotherapy for high grade glioma could be delivered either in single phase (EORTC guidelines) or two phases (RTOG guidelines). We aim to compare the target integral dose and the acute toxicity of radiotherapy in both techniques.
Material and Methods: Patients with high grade glioma eligible for full course of adjuvant radiotherapy during the year 2011 were enrolled in this study. Volumes were contoured for both techniques, the one phase (Gross tumor volume (GTV) with 3 cm margin 60 Gy) and 2 phases' techniques (Edema with 2 cm margin 46 Gy and GTV with 1 cm margin 14 Gy). Decision regarding treatment technique was individualized based on the volumes of the PTVs and its distance from the critical structures. Patients were seen weekly during treatment. Acute toxicity was documented according to the CTCAE version 4.

Results: 42 patients were included and contoured for both techniques. The target integral dose was statistically significant higher with one phase technique (32.1 Gy/L) compared to two phases technique (27.8 Gy/L) P = 0.004. Treatment was actually delivered in one phase in 23 patients and in 2 phases in 19 patients. Patients with larger tumor received treatment more in 2 phases. There was no statistically significant difference in the target integral dose and the acute toxicity profile between the 2 groups. Patients with higher treatment volume and higher target integer dose (>30 Gy/L) had more acute toxicity regardless of the treatment technique.
Conclusions: One phase technique leads to higher target integral dose. Higher target integral dose (>30 Gy/L) is associated with higher acute toxicity. Treating all patients with single phase technique may lead to unjustified increase in the acute toxicity and treatment technique should be individualized based on the tumor size and location.
No conflict of interest.

3341 POSTER

Impact of glycemia on survival in glioblastoma patients

M. Tieu[1], L.E. Lovblom[2], M. McNamara[3], W. Mason[3], K. Uhbi[1], E. Tai[1], N. Laperriere[1], B. Millar[1], B. Perkins[2], C. Chung[1]. *[1]Princess Margaret Cancer Centre, Radiation Oncology, Toronto Ontario, Canada; [2]Toronto General Hospital/Mt Sinai Hospital, Endocrinology, Toronto Ontario, Canada; [3]Princess Margaret Cancer Centre, Neuro-Oncology, Toronto Ontario, Canada*

Background: Hyperglycemia has been associated with worse survival in glioblastoma (GBM) patients. This study aims to assess whether there is an independent association between glycemia and survival in GBM patients treated with radiotherapy (RT) and temozolomide (TMZ).
Materials and Methods: This was a retrospective chart review of GBM patients treated radically with RT and TMZ chemotherapy between 2004 and 2010. We calculated a time-weighted mean (TWM) glucose based on glucose values from diagnosis to 4 weeks after completion of RT and investigated the association of these values with survival, accounting for confounding factors including time weighted mean dexamethasone dose, age, body mass index (BMI), pre-existing diabetes and performance status.
Results: In total, 277 patients with a mean age of 55 years (18−77 years) with a mean body mass index of $26.7 \pm 4.9\ kg/m^2$ were evaluated. Patient performance status was ECOG 0−1 in 89%. Time-weighted mean daily dexamethasone dose was 6.7 mg (0–32.9 mg). After a median follow up of 15 months (1–104 months), the median survival was 15 months. The median TWM glucose from diagnosis to 4 weeks after completing RT was 6.5 mmol/L. For patients with a mean glucose $\leqslant$6.5 mmol/L and >6.5 mmol/L, the median survival was 20 months and 14 months, respectively. On univariable analysis, the following variables were associated with survival: TWM glucose, TWM dexamethasone dose, age, BMI and ECOG performance status. On multivariable analysis, TWM glucose remained an independent predictor of survival such that patients with mean glucose >6.5 mmol/L had an adjusted hazard ratio of 1.7 ($p < 0.0003$). Other independent predictors included the following: TWM daily dexamethasone dose ($p < 0.0001$), BMI ($p = 0.01$), and age ($p = 0.0005$).
Conclusions: This analysis suggests that glycemia is an independent prognostic factor for survival in patients with GBM treated with RT and TMZ, and proposes a biologically-important glycemic threshold for risk. Specifically, lower glucose levels, even below 6.5 mmol/L, were associated with better survival in our study, warranting prospective study of intensive glycemic intervention for patients with GBM.

3342 POSTER

The incidence and clinical feature of brain metastasis from non-small cell lung cancer, and their associations with EGFR mutation

T. Iuchi[1], M. Shingyoji[2], T. Sakaida[1], M. Itakura[2], H. Kageyama[3], S. Yokoi[3], Y. Hasegawa[1], K. Kawasaki[1], T. Iizasa[2]. *[1]Chiba Cancer Center, Neurological Surgery, Chiba, Japan; [2]Chiba Cancer Center, Thoracic Disease, Chiba, Japan; [3]Chiba Cancer Center, Gene Diagnosis, Chiba, Japan*

Background: Molecular diagnosis had made a great impact on classification of various tumors, including non-small cell lung cancer (NSCLC). Mutation of epidermal growth factor receptor (EGFR) correlates to remarkable response of NSCLC with tyrosine kinase inhibitors (TKIs). We previously reported the favorable control of brain metastases (BMs) with TKIs in EGRF-mutant cases. The aim of this study is to clarify the incidence and clinical feature of BMs and their differences owing to EGFR mutation.
Materials and Methods: We investigated the clinical data of 853 consecutive Asian patients with NSCLC who diagnosed between Apr. 2008 and Jan. 2013 in our institution retrospectively. The EGFR mutation status and brain MRIs were evaluated before initiating treatment in all cases. The incidence of BMs, survival of patients after BMs (OSaBM), and their association with EGFR mutations were investigated. The differences of OSaBM owing to patients' age, Karnofsky performance status (KPS), number and maximum size of BMs were also evaluated.
Results: EGFR mutations were found in 245 cases (28.7%); L858R in 137, Ex19 deletion (Ex19del) in 98, G719X in 5, and L861Q in 5. BMs existed in 121 cases (14.2% of all cases) at diagnosis of lung disease. Additionally, 59 patients (6.9%) developed BMs during their disease course. NSCLC with EGFR mutation more frequently developed BMs (27.8%) in compared with those without mutation (18.4%, $p = 0.002$). The incidence of BMs was higher in cases with Ex19del (34.7%) than those with L858R (22.6%, $p = 0.030$). From a different viewpoint, EGFR mutation was observed in 37.8% of BMs from NSCLC. EGFR mutation correlated not only with better survival after diagnosis of lung disease (not reached vs. 51.9m, $p < 0.0001$) but also with better OSaBM (22.4m vs. 8.0m, $p < 0.0001$). There was no significant difference in OSaBM between L858R and Ex19del. Good KPS ($\geqslant$70%) at BMs was significantly correlated with better OSaBM, regardless of EGFR mutation status ($p = 0.0003$ in mutant and $p = 0.005$ in wild cases). Number of BMs was significant prognostic factor of BMs in EGFR wild cases ($p = 0.039$) but not in mutant ones ($p = 0.134$). Leptomeningeal dissemination was significantly correlated with poor OSaBM in EGFR wild cases (3.0m with dissemination vs. 11.5m without dissemination, $p = 0.0007$), but not in mutant cases (12.3m vs. 25.6m, $p = 0.189$).
Conclusions: Nearly 40% of BMs from NSCLC harbored EGFR mutation and showed favorable outcome regardless of the number of brain lesions.
No conflict of interest.

Association of health-related quality of life and neurocognitive function with progression free survival and progressive disease in patients with glioblastoma: A review of the literature

A. Shields[1], S. Burgess[1], A. Ravelo[2], F. Taylor[1], I. Mazar[1], L. Abrey[3]. *[1]Adelphi Values, Endpoint Development and Outcomes Assessment, Boston, USA; [2]Genentech, Health Economics and Outcomes Research, South San Francisco, USA; [3]Roche, Clinical Development, Basel, Switzerland*

Background: Glioblastoma (GBM) is the most common malignant primary brain tumor. As disease burden is increasingly of interest in GBM trials, investigators now consider sustaining patient function as a critical treatment outcome. However, it remains unclear how the timing and extent of changes in health-related quality of life (HRQoL) and neurocognitive function (NCF) are associated with progressive disease (PD) or progression free survival (PFS).
Material and Methods: Literature searches were conducted for relevant English-language studies in the Embase®, PsycINFO®, and MEDLINE® databases (01/01/2002 through 12/10/2012). Searches included terms for GBM and brain cancer, quality of life, NCF, and disease survival and progression. Reference lists of included studies were also examined. All studies returned from the literature search were screened by abstract, and a sampling of studies were selected based on their perceived relevance.
Results: Eighty-eight studies were identified as potentially relevant, of which 25 were selected for full-text review. Of these, 4 GBM studies reported data regarding the association of PD or PFS with HRQoL, as measured by the EORTC QLQ-C30 and QLQ-BN20, and 4 studies with NCF, as measured by the MMSE or a battery of NCF tests. With regard to HRQoL: One study reported improved HRQoL scores (in global health status and several functioning scales) prior to disease progression; 1 study reported that HRQoL improvements were more common in patients with a partial or complete response than in those with PD; and 2 studies reported that HRQoL declined at the time of disease progression. With regard to NCF: Two studies (in GBM and brain metastases) reported declines in NCF at PD; 1 study in GBM reported that NCF improved prior to progression; and 1 study in high-grade glioma indicated that higher baseline NCF scores predicted better overall survival but not PFS.
Conclusions: The findings of this review in GBM and brain cancer studies provide evidence of an association between changes in HRQoL and NCF and disease progression or PFS.

The prognostic value of cognition in patients with glioblastoma multiforme

B. Flechl[1], M. Ackerl[2], C. Sax[2], R. Crevenna[3], M. Keilani[3], A. Gaiger[2], G. Widhalm[4], K. Dieckmann[5], C. Marosi[2]. [1]*Medical University, Wien, Austria;* [2]*Medical University, Internal Medicine, Wien, Austria;* [3]*Medical University, PM & R, Wien, Austria;* [4]*Medical University, Neurosurgery, Wien, Austria;* [5]*Medical University, Radiooncology, Wien, Austria*

Purpose In patients with glioblastoma multiforme (GBM) progressive disease leads sooner or later to cognitive decline. In this study we evaluated if two cognitive assessments performed early in the treatment course have a prognostic significance for predicting progression free survival (PFS).
Methods: We assessed the cognition of 35 patients with GBM using the program NeuroCogFX with four subscales (working memory, attention, verbal and figural memory, verbal fluency) and summary scale. Baseline evaluation was done at initiation of radiotherapy (11−57 days after diagnosis) and second evaluation three months later (82–117 days after baseline). Results in subscales were categorized in 'declined', 'stable' and 'improved'. Tumor progression was based on MRI scans.
Results: The patients (12 women, 23 men) were in median 54 years old (21−75 years). The majority (63%) showed stable cognitive results, 23% improved and 14% decreased in the summary scale of cognition. The median PFS was 11 months (2.6–27.4 months). An improvement of attention correlated significantly with longer PFS (p = 0.015) whereas the other three cognitive subscales and the summary scale were not associated with PFS (see table 1).
Conclusion: Our data show evidence, that an increase or decrease of attention scales in patients with GBM is associated with the duration of PFS.
No conflict of interest.

Prognostic implications of clinical, radiologic, & pathologic markers in recurrent and non-recurrent meningiomas Grade I. Identification of alterations associated with tumor recurrence risk and disease progression

J. Martinez[1], C. Mateos[2], M.V. Toledo[3], R. Samaniego[4], S. Sacristan[5], S. Ropero[6]. [1]*Instituto Oftalmico/Hospital Universitario Gregorio Marañón, Anatomia Patologica, Madrid, Spain;* [2]*Universidad de Extremadura, Facultad de Veterinaria (Biologia), Caceres, Spain;* [3]*Universidad de Alcala, Facultad de Biologia y Genetica, Alcala de Henares, Spain;* [4]*Hospital Universitario Gregorio Marañon, Microscopia Confocal, Madrid, Spain;* [5]*Hospital Universitario Ramon y Cajal, Investigacion (Neurobiologia), Madrid, Spain;* [6]*Universidad de Alcala, Bioquimica y Biologia Celular, Alcala de Henares, Spain*

Background: Most meningiomas are slow growing tumors, but in spite of complete surgical removal, the recurrence rate at 5 years is 5%, rising to 19% in long-term follow-up. However, there are no markers predictive of this evolution.
We study 140 specimens of meningiomas: 29 non recurrent & 57 recurrent in one, two or three times, related with clinical, radiological and pathologic prognosis factors.
Material and Methods: Age, gender, tumor size, Glasgow index recovery & neuroradiologic images were obtained from medical records. Growth fraction (ki 67 index) & progesterone receptors (PR), were assessed by immunohistochemistry (IHC) staining.
Results: Patients with good recovery according to Glasgow index show a lower recurrence rate (p = 0.036). There is a higher probability of recurrence among bigger tumors (>5 cm) (p = 0.257). A heterogeneous neuroimage occurs in the majority of recurrent cases (p = 0.008). Convexity meningiomas show the lowest rate of recurrence as compared with parasagital and basal ones. High levels of PR expression are associated with good recovery.
Conclusions: In our series, Glasgow index, size >5 cm, and heterogeneous neuroimage, are associated with recurrence risk of meningiomas. High levels of PR expression & convexity location occur more frequently in non-recurrent cases.
No conflict of interest.

3346 POSTER

Leptomeningeal metastases from solid tumors − retrospective review of a single institution

M. Carneiro[1], S. Torres[1], M. Sousa[1], F. Pinto[2], M. Brito[1], S. Bento[3], A. Marques[1], A. Moreira[1]. [1]*Instituto Portugues de Oncologia de Lisboa, Medical Oncology Department, Lisboa, Portugal;* [2]*Instituto Portugues de Oncologia de Lisboa, Regional Oncologic Register, Lisboa, Portugal;* [3]*Hospital Distrital de Santarém, Medical Oncology Department, Santarém, Portugal*

Background: Leptomeningeal metastases (LM) from solid tumors are a rare but devastating complication due to the high incidence of neurological morbidity and mortality. Their incidence appears to be increasing. Neurologic signs and symptoms are the hallmark of LM. Intrathecal chemotherapy (ITC) is the standard of care for LM. However, overall response is low with a median survival of 7−24 weeks, questioning the benefit of this therapy.
Material and Methods: We performed a retrospective review that included all patients (pts) with solid tumors and LM diagnosed by cerebrospinal fluid (CSF) cytology from January 2000 to April 2013. Our main objectives were to characterize the initial signs and symptoms of LM and determine the overall survival (OS) of our pts. Primary brain tumors were not included. OS was estimated using Kaplan–Meier methodology.
Results: Sixty-three cases were reviewed. Median age at LM diagnosis was 56 y (26−81). 75% were females. The primary tumor was breast cancer (56%), lung cancer (20%), melanoma (5%), cervical cancer (5%), gastric cancer (5%), unknow origin (3%), endometrial cancer (2%), prostate cancer (2%), rectal cancer (1%).
Ninety percent had previously diagnosed metastatic disease treated with systemic chemotherapy (CT). Seventy-six percent of pts with LM presented with central nervous system signs and symptoms, 21% with cranial neuropathies and 21% with spinal signs and symptoms (a combination of two sites was seen in 16% of pts). ITC (methotrexate and/or cytosine arabinoside) was administered in 43 pts; 14 pts received radiation therapy to the neuroaxis; 21 pts were treated with systemic CT. The Kaplan–Meier estimates of 1-month, 3-month, 5-month and 12-month OS were 77%, 41%, 25% and 16% respectively (pts treated with ITC); and 45%, 10%, 5% and 0% (pts not treated with ITC). Breast cancer pts had a longer OS than pts with other primaries.
Conclusions: In our series, neurological manifestations prompt the diagnosis of LM, confirming that the diagnosis of LM requires a high index of suspicion. Pts treated with ITC, had a better OS, suggesting that ITC is a valid therapeutic option when feasible. Breast cancer pts, the majority, as expected, appear to have a better prognosis in the setting of LM.

Resveratrol effects on cell viability, morphology and migration in cancer stem cell lines from glioblastoma multiforme

G. Riva[1], V. Butta[1], L. Paoletta[1], C. Cilibrasi[1], A. Bentivegna[1], L. Dalprà[1]. [1]*Medical School University of Milano-Bicocca, Department of Surgery and Interdisciplinary Medicine, Monza, Italy*

Background: Glioblastoma multiforme (GBM) is a grade IV astrocytoma and the most common malignant brain tumor. Current therapies provide a median survival of 12−15 months after diagnosis, due to the high recurrence rate. The failure of current therapies may be due to the presence within tumor of cells characterized by enhanced self-renewal capacity, multilineage differentiation potential and elevated invasive behavior, called glioma stem cells (GSCs). The development of novel GSC-targeted therapies plays a crucial role in order to eradicate this tumor.
Resveratrol (RV) is a polyphenolic phytoalexin, found in fruits and vegetables, possessing a variety of biological activities, including antioxidant, anti-inflammatory and antineoplastic properties. Many studies have highlighted

its antiproliferative and proapoptotic effects on several type of cancers, including GBM. Moreover, RV is able to reverse temozolomide resistance, to induce the acquisition of a long-lasting differentiated phenotype and to reduce tumor invasion in GBM cell lines. RV represents an attractive agent for the treatment of brain cancers because of its minimal toxicity and blood–brain barrier permeability.
Material and Methods: In this study, we analyzed the effects of RV exposure (24−48−72 h) on cell viability, using MTT assay, and cell morphology in four GSC lines isolated from GBM (GBM2, GBM7, G179, GliNS2). Furthermore, we performed the analysis of cell migration through Wound Healing assay after RV administration for 48−72−96 h.
Results: Results showed that response to RV exposure was heterogeneous among GSC lines. Cell viability was significantly reduced only in GBM2 and G179 cell lines (70% of reduction at 72 h treatment), while GBM7 and GliNS2 were resistant. The analysis of morphology did not highlight any relevant modification in cellular shape after RV administration, except for GBM2 line which showed mild changes in morphology after 48 and 72 hours of treatment. With regards to cell migration, RV strongly reduced cellular motility in all cell lines.
Conclusions: GBM treatment with RV could represent a new interesting therapeutical approach in order to defeat the cancer stem compartment, providing a novel GSC-targeted therapy.
No conflict of interest.

3348 POSTER

Application of intraoperative magnetic resonance imaging and functional neuronavigation in microsurgery for gliomas encroaching both sides of cerebra

X. Ma[1], B. Xu[1], H. Lin[1], D. Zhou[1]. [1]*Chinese PLA General Hospital, Neurosurgery, Beijing, China*

Objective: The microsurgery for glioma located on corpus callosum gliomas encroaching both sides of cerebra is one of the most difficult surgeries in brain because of its bigger volume and adjacent to many important structures.
Thereby, the safe total removing and low deficit rate is hard to get with the routine surgical methods. With the using of the intraoperative magnetic resonance imaging (iMRI) and functional neuronavigation, many difficult operations were done and the good results were got. To explore the advantages and the application foreground of in microsurgery for corpus callosum gliomas encroaching both sides of cerebra and to sum up the operation strategy of corpus callosum gliomas, we deducted this study.
Methods: Retrospective analysis of 74 cases (male:female = 46:28) for corpus callosum gliomas encroaching both sides of cerebra from January 2009 through May 2011 were done. The patients were divided into two groups: A (iMRI) including 56 and B (functional neuronavigation uniquely) 18 cases. The clinical symptoms of both groups before and post operation were compared and the the gross total resection,the postoperative neurological deficit, the Karnofsky (KPS), the rate survived for over 1 year were also analyzed perspectively.
Results: The pathology result shows low grade glioma account for 33.8% (25/74) and hige grade glioma was 66.2% (49/74) in this series. The gross total resection rate of group A was 91.1%, the B group was 55.6%. The preoperative KPS was 50−90 (78±6), and the post operation was 50−90 (82.2±13.5). Compare the post operative KPS in the different groups showed that A group got 60−90 (84.2±10.6), and B group was 50−90 (81.4±8.8). The early postoperative neurological deficit was found of 3.6% in group A, and 16.7% in group B. The follow up were 5−40 months, 1 year survive was 93.3% for A group and 84.6% for B group. The long-term postoperative neurological deficit was noticed of 8.9% in A group, and 15.4% in B group.
Conclusion: The use of imaging guided surgery (IGS) with iMRI and functional neuronavigation are both effective methods to improve the total resection and reduce the postoperative neurological deficits for the large acrossing midline glioms. Meanwhile the 1 year survive rate was higher in the iMRI and functional neuronavigation assisted operation group than the functional neuronavigation unique one.
No conflict of interest.

3349 POSTER

Incidence of brain metastases in patients treated with bevacizumab

F. Winkler[1], M. Reck[2], D. Miles[3], P. Mariani[4], B. Lutiger[5], V. Nendel[5], S. Srock[5], P. Perez-Moreno[5], W. Wick[1]. [1]*University of Heidelberg, Neurooncology, Heidelberg, Germany;* [2]*LungenClinic Grosshansdorf, Thoracic Oncology, Hamburg, Germany;* [3]*Mount Vernon Cancer Center, Medical Oncology, Northwood, United Kingdom;* [4]*Ospedale San Raffaele, Medical Oncology, Milano, Italy;* [5]*F. Hoffmann-La Roche AG, Basel, Switzerland*

Background: Metastasis to the brain is a frequent complication in certain tumor entities, including non-squamous non-small cell lung cancer (nsNSCLC), and HER2-positive and triple-negative breast cancer. Antiangiogenic therapy with bevacizumab has been investigated in a number of phase III trials in patients with advanced disease who generally had a large tumor burden and metastatic disease at treatment onset. As there are (mainly preclinical) indications that angiogenesis may be crucial for metastatic outgrowth via an early, mandatory angiogenic switch in the colonized organ and as brain metastases are among the most important prognosis limitating factors, it would be interesting to analyze a potential effect of bevacizumab on the development of brain metastases in randomised controlled trials.
Material and Methods: We performed a retrospective analysis of the incidence of brain metastases as first site of recurrence in the AVAIL (nsNSCLC, n = 1043 patients), AVADO (HER2-negative breast cancer, n = 736), and AVEREL (HER2-positive breast cancer, n = 424) randomized clinical trials. Importantly, pre-existing brain metastases where an exclusion criterion at study enrollment in all of these trials due to safety reasons. This setting may bias for patients with a metastatic pattern not involving the brain, but allowed a determination of the effects of bevacizumab on the development of new metastases during and after therapy.
Results: In the AVAIL trial, 20/347 patients (5.8%) in the placebo group developed brain metastases as first site of relapse, but only 18/696 patients (2.6%) in the bevacizumab group (hazard ratio (HR) 0.36; CI, 0.19–0.68, p = 0.001). The median time to brain progression was prolonged under bevacizumab therapy (237 vs. 137 days). The effect of bevacizumab was even stronger when the first 6 months of therapy where analyzed, which cover the average time of bevacizumab exposure in this study: during that time, 3.5% developed brain metastases as site of first relapse in the placebo group, but only 0.9% in the bevacizumab group (p = 0.002). In breast cancer patients, effects did not reach statistical significance for the single studies, likely due to a low number of brain metastases as site of first relapse: In the AVADO trial, the HR was 0.60 (p = 0.19), and in the AVEREL trial, the HR was 0.73 (p = 0.19).
Conclusions: Bevacizumab might prevent the formation of brain metastases in nsNSCLC, especially during drug exposure.

3350 POSTER

Phase I dose escalating study of 2B3-101, glutathione PEGylated liposomal doxorubicin, in patients with solid tumors and brain metastases or recurrent malignant glioma

B. Milojkovic Kerklaan[1], P. Aftimos[2], S. Altintas[3], A. Jager[4], F. Lonnqvist[5], P. Soetekouw[6], M. Van Linde[7], A. Awada[2], J. Schellens[1], D. Brandsma[8]. [1]*Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Department of Clinical Pharmacology, Amsterdam, Netherlands;* [2]*Jules Bordet Institute Universite Libre de Bruxelles, Medical Oncology Clinic, Brussels, Belgium;* [3]*Antwerp University Hospital, Department of Medical Oncology, Antwerp, Belgium;* [4]*Erasmus MC, Daniel den Hoed Oncology Center, Rotterdam, Netherlands;* [5]*to-BBB technologies B.V., Medical Department, Leiden, Netherlands;* [6]*Maastricht University Medical Center, Department of Medical Oncology, Maastricht, Netherlands;* [7]*VU Medical Center, Department of Medical Oncology, Amsterdam, Netherlands;* [8]*Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Department of Neuro-oncology, Amsterdam, Netherlands*

Background: Without active delivery across the blood–brain barrier, the efficacy of doxorubicin in the treatment of brain tumors or metastases is limited. Therefore, 2B3-101, glutathione PEGylated liposomal doxorubicin, has been developed as a brain-targeted chemotherapy. In preclinical studies, 2B3-101 showed a 5-fold enhanced delivery of doxorubicin to the brain compared to pegylated liposomal doxorubicin (Caelyx®, Doxil®), and improved survival of mice with glioblastoma.
Methods: Patients with either brain metastases from solid tumors or recurrent malignant gliomas have been treated with 2B3-101 by a 90 min IV infusion q21d to assess (1) the safety, tolerability and MTD and (2) the PK and preliminary anti-tumor efficacy of 2B3-101. Antitumor activity was determined by brain MRIs and body CTs, according to RANO or RECIST criteria. Doses were escalated using a modified Fibonacci scheme in cohorts of 3−6 patients each.
Results: So far, 25 patients have received 2B3-101 at doses of 5−60 mg/m^2, without DLTs. 15 patients had brain metastases from solid tumors, and 10 patients had recurrent malignant gliomas WHO grade IV (7) or III (3). 24 patients had received ⩾3 prior therapies.
No cardiac or CNS toxicity was observed. At doses of ⩾40 mg/m^2, the observed adverse events ⩾ grade II (CTCAE v.4.0) were: neutropenia (46%), leucopenia (46%), thrombocytopenia (8%), mucositis (8%), and PPE (31%). Grade I−II infusion reactions were observed in 6/25 patients. All events were transient and manageable with standard treatments. The PK data show non-linear exposure of 2B3-101 without signs of accumulation with repeat dosing. Due to 1 case of thrombocytopenia grade IV at

60 mg/m^2 the cohort was expanded to 6 patients. In the absence of DLTs the study proceeded to 70 mg/m^2.

At doses of $\geqslant$40 mg/m^2, 8 of the 11 patients evaluated to date have demonstrated either stable disease (7 patients) or a partial response (1 melanoma patient) of their pretreated intracranial disease after 2 cycles. 3 out of 4 progressive glioblastoma patients showed stable disease after 2 cycles. In addition, 2B3-101 has been shown to act on extracranial disease in a patient with SCLC (65% reduction after 4 cycles).

Conclusions: 2B3-101 is safe and well tolerated up to 60 mg/m^2 q21d in both brain metastases from solid tumors and recurrent malignant gliomas and demonstrates preliminary antitumor activity in brain metastases.

ClinicalTrials.gov NCT01386580, sponsored by to-BBB technologies BV.

3351 POSTER

Bevacizumab for recurrent glioblastoma, observations on patient outcome in the Belgian Medical Need Program

J. Duerinck[1], P. Clement[2], F. Bouttens[3], C. Andre[4], B. Neyns[5], Y. Staelens[6], F. Van Fraeyenhove[7], J.F. Baurain[8], S. Luce[9], A. Rogiers[10]. *[1]UZ Brussel, Neurosurgery Neuro-oncology, Brussels, Belgium; [2]UZ Gasthuisberg, Medical Oncology, Leuven, Belgium; [3]AZ Sint-Lucas, Radiotherapy, Gent, Belgium; [4]CHU Sart-Tilman, Medical Oncology, Liege, Belgium; [5]UZ Brussel, Medical Oncology, Brussels, Belgium; [6]ZH Oost Limburg, Medical Oncology, Genk, Belgium; [7]ZNA Middelheim, Medical Oncology, Antwerpen, Belgium; [8]UCL Saint-Luc, Medical Oncology, Brussels, Belgium; [9]ULB Erasme, Medical Oncology, Brussels, Belgium; [10]FAGG, Brussels, Belgium*

Background: Bevacizumab (BEV), a monoclonal antibody targeted against the vascular endothelial growth factor has anti-tumor activity in patients (pts) with recurrent glioblastoma (rGBM).

Patients and Methods: Between Nov 2010 and Feb 2013, a total of 309 pts with rGBM were enrolled at 15 centers participating in the Belgian medical need program on BEV for rGBM (median No. of pts per center: 19, range 5−46). BEV was administered at a dose of 10 mg/kg every 2 wks.

Results: Baseline pts characteristics: 61% M, 39% F; median age 54 y (range 16−82); ethnicity: 91% Caucasian, 6% Arabic/North-African; 41% had $\geqslant$1 neurosurgical resection; all pts had failed RT and temozolomide and 71% had failed $\geqslant$1 prior therapy for recurrent disease; baseline WHO-PS 0/1/2/3: respectively 10, 67, 19 and 4%; 66% of pts used corticosteroid at baseline. At the time of analysis (28 Feb 2013), BEV treatment was ongoing in 42 pts. A median of 8 BEV cycles were administered per pt (range 1−53). BEV was stopped in 85% of pts because of PD and in 6.8% because of adverse-events (AE). Overall BEV was well tolerated. Hypertension (12%), proteinuria (8.4%), thrombocytopenia (4.2%) and thrombo-embolic events (3.2%) were the most frequently encountered AE. The best objective tumor response (investigator assessment according to RANO criteria): 9 CR (3%), 70 PR (26%), 112 SD (42%), and 77 PD (29%). Out of the 205 pts using corticosteroids at baseline, 71 (34%) decreased their corticosteroid dosing during BEV and 33 (16%) stopped corticosteroid treatment completel. The WHO-PS improved in 57 pts (18%) and 138 (45%) experienced a stabilization for $\geqslant$6 wks during BEV. Median and 6-mths rates (with 95% CI) for PFS 13.9 wks (13−15) and 29% (24−35), for OS 27 wks (23−31) and 54% (48−60). Baseline WHO-PS (0−1 vs. 2−3) was the only baseline characteristic that correlated with PFS and OS (Log Rank $p < 0.01$; HR of. 58 [95% CI. 43-.78] and. 53 [95% CI. 38-.73] for PFS and OS respectively). Pts with a baseline WHO-PS of 0−1 had a significantly lower chance for immediate tumor progression or decline of their WHO-PS (Fisher's exact test two-tailed P value: 0.01 and 0.03 respectively).

Conclusions: Notwithstanding the poor prognosis baseline characteristics of the population treated in this MNP, BEV was well tolerated and demonstrated anti-tumor activity, a corticoid sparing effect, and a beneficial effect on the WHO-PS in a meaningful subgroup of pts legitimating this MNP in the absence of alternative treatment options.

No conflict of interest.

3352 POSTER

Clinical and genetic factors associated with severe myelotoxicity during radiation therapy (RT) plus temozolomide (TMZ) in glioblastoma (GBM) patients: A prospective observational study

G. Lombardi[1], E. Rumiato[2], P. Farina[1], R. Bertorelle[2], D. Saggioro[2], F. Zustovich[1], A. Della Puppa[3], F. Berti[4], Z. Vittorina[1]. *[1]Veneto Institute of Oncology, Medical Oncology 1, Padua, Italy; [2]Veneto Institute of Oncology, Molecular Immunology and Oncology, Padua, Italy; [3]Neurosurgery Department, Azienda Ospedale − Univerity of Padua, Padua, Italy; [4]Veneto Institute of Oncology, Radiation Therapy Unit, Padua, Italy*

Background: TMZ administered daily with RT for six weeks, followed by adjuvant TMZ for six cycles is the standard therapy for newly diagnosed GBM. A few case reports and small series studies have reported severe myelotoxicity developing during TMZ+RT. We performed a prospective study to analyze the incidence of early severe myelotoxicity and its possible clinical and genetic factors.

Patients and Methods: From November 2010 to July 2012 newly diagnosed GBM patients beginning treatment with RT (2 Gy/die for 30 days) plus continuous daily TMZ (75 mg/m^2/day for 42 days) were enrolled. They met the following criteria: pathologically proven GBM, age $\geqslant$18 years, ECOG PS 0−2, adequate blood cell counts before starting TMZ+RT. Grading of haematological toxicity was based on the NCI CTCAE v. 4.0. Clinical factors from all patients were recorded. Fisher's exact test was performed to compare frequency distribution of clinical factors between GBM patients with and without myelosuppression. Methylation status and polymorphic variants of MGMT gene in peripheral blood mononuclear cells, and polymorphic genetic variants of genes involved in the pharmacokinetics and pharmacodinamics of TMZ were analyzed by DMET Plus GeneChip array. For genetic analyses the patients with toxicity were matched (1:2) for age, ECOG PS, anticonvulsants and proton pump inhibitors with patients without myelotoxicity.

Results: We enrolled 87 consecutive GBM patients, 32 females and 55 males; the average age was 60 years. During TMZ+RT, 4 patients (5%) showed grade 3−4 myelotoxicity with a median duration of 255 days. Predictor factors of severe myelotoxicity were: female sex (4/4 pts with toxicity vs 28/83 pts without toxicity, $p = 0.01$), pre-treatment platelet count $\leqslant$300,000/mm^3 (2/4 vs 7/83, $p = 0.05$); anticonvulsants, proton pump inhibitors, age and pre-treatment WBC were not associated with myelotoxicity. Methylated MGMT promoter in haematopoietic cell system (4/4 vs 0/9, $p = 0.001$) and specific polymorphic variants of the cytochrome P450 oxidoreductase and methionine adenosyltransferase 1A genes ($p = 0.007$) were also associated with myelotoxicity.

Conclusions: We suggest that both clinical and genetic factors might simultaneously be associated with severe myelosuppression developed during TMZ+RT. Patients with these factors should be followed more accurately during the concomitant treatment.

No conflict of interest.

3353 POSTER

Bevacizumab-irinotecan versus procarbazine-lomustine-vincristine in recurrent high-grade astrocytomas − retrospective analysis of one center

C. Fernandes[1], D. Almeida[1], B. Carvalho[2], A. Costa[1], C. Caeiro[1], L. Osório[3], P. Linhares[2], L. Castro[4], M. Damasceno[1]. *[1]Hospital de S. João, Medical Oncology, Porto, Portugal; [2]Hospital de S. João, Neurosurgery, Porto, Portugal; [3]Hospital de S. João, Radiotherapy, Porto, Portugal; [4]Hospital de S. João, Pathology, Porto, Portugal*

Background: High-grade astrocytomas (HGA) are the most common malignant primary central nervous system (CNS) tumors in adults. Standard-of-care therapy includes surgical resection, radiotherapy and temozolomide, but nearly all patients experience disease progression. Second-line options include procarbazine-lomustine-vincristine (PCV) and bevacizumab-irinotecan (BI). The purpose of this study is to compare response rate, survival times and toxicities between these two options.

Material and Methods: Retrospective analysis of HGA patients treated at our center with PCV or BI, after progression with temozolomide, between 2004 and 2012. Response to therapy was evaluated according to the Macdonald Criteria. Overall Survival (OS) and Progression-Free Survival (PFS) were assessed via Kaplan–Meier method and the multivariate analysis was performed using Cox Regression.

Results: Among 61 patients, 41 were treated with BI, and 20 with PCV. The majority were male (67.2%, n = 41), with a median age of 52 years (34−61) and a median follow-up of 17 months. The most common histology was glioblastoma multiforme (90.2%, n = 55) and 63.9% (n = 39) were submitted to complete macroscopic resection. It was possible to assess response in 58 patients (39 BI and 19 PCV). The median number of cycles in BI and PCV was 9.0 and 2.0, respectively. In the BI group 74.4% had some

response to treatment − 35.9% (n = 14) had complete/partial response and 38.5% (n = 15) stable disease. In contrast, only 21.1% (n = 4) in the PCV group showed response. Median PFS with BI was superior to PCV (5 months, 95% CI, 3.8−6.2 vs. 3 months, 95% CI, 1.6−4.4; p = 0.119), with a 9 month PFS of 33.5% and 13.1%, respectively. Median OS was also longer in the BI group (31 months, 95% CI, 19.6–42.4 vs. 16 months, 95% CI, 14.6–17.4; p < 0.001) and these differences retained statistical significance even in multivariate analysis (p = 0.002; HR 3.74; 95% CI, 3.74–1.59). Male gender was associated with worse prognosis in multivariate analysis (p = 0.026; HR 2.63; 95% CI, 1.12–6.18). The PCV group had a worse toxicity profile than the BI group (grade 3−4: 55% vs. 17.1%; p = 0.002; grade 1−2: 90% vs. 65.9%; p = 0.044).
Conclusions: In our series, patients with recurrent HGA treated with BI showed higher response rates, almost twice the OS and lower degree of toxicity in comparison to the PCV group, which agrees with current knowledge. Nevertheless, our results must be interpreted with caution given the small sample size.
No conflict of interest.

Axitinib for the treatment of recurrent glioblastoma − early results from a randomized phase II trial

J. Duerinck[1], S. Du Four[1], A. Van Binst[2], H. Everaert[3], J. D'haens[4], B. Neyns[5]. [1]*UZ Brussel, Neurosurgery Neuro-oncology, Brussels, Belgium;* [2]*UZ Brussel, Radiology, Brussels, Belgium;* [3]*UZ Brussel, Nuclear Medicine, Brussels, Belgium;* [4]*UZ Brussel, Neurosurgery, Brussels, Belgium;* [5]*UZ Brussel, Medical Oncology Neuro-Oncology, Brussels, Belgium*

Introduction: Glioblastoma (GBM) is characterized by profound tumor related neo-angiogenesis and intracranial peri-lesional edema. GBM express high levels of the vascular endothelial growth factor (VEGF) and frequently carry an amplified copy number of the VEGFR2 gene. Axitinib (Inlyta®) is a small molecule tyrosine kinase inhibitor with specificity for the VEGF-receptors, approved for pts who failed 1 prior therapy for advanced renal cell cancer.
Patients and Methods: The AxiG protocol (ClinicalTrials.gov Identifier: NCT01562197) is an ongoing open label, controlled, multi-center, phase II clinical trial in which pts with recurrent GBM are randomized to treatment with axitinib (5 mg BID) or the physicians best choice of alternative therapy.
Results: Between Sep 2011 and Apr 2013, 22 pts were treated (11 pts with axitinib [5M/6F], and 11 pts, with bevacizumab). Baseline characteristics for axitinib treated pts: median age 55 y (range 42−80); all pts failed prior surgery, RT and temozolomide; 3, 5 and 3 pts had a WHO-PS of 0, 1 and 2, respectively; 9/11pts were on corticosteroids. Overall axitinib was well tolerated; treatment related AEs consisted of: hoarseness (9 pts [8x gr1, 1x gr2]), fatigue (6 pts [2x gr1, 3x gr2, 1x gr3], thrombocytopenia (2pt, gr1), arterial hypertension (3pts, gr2), mucositis (3pts, gr2), diarrhea (3pts; 1x gr1, 2x gr2), hypothyroidism (2pt; gr1), and rash (1pt, gr1). Axitinib dosing was interrupted in 4 pts, and subsequently dose reduced in 3; axitinib was escalated to 7 mg BID in 1 pt. The best overall tumor response for axitinib treated patients (RANO criteria): 1 CR, 6 PR, 1 SD and 3 PD (BORR 64%, DCR 72%). A significant decrease of maximal tumoral uptake (SUVmax/BG) on [18F]FET-PET was documented in 4/5 pts at the time of response on MRI. Analysis of MRS, CBV and CBF measurements is ongoing. Corticosteroids could be stopped in 3, and tapered in 5 pts. After a median follow-up of 45 wks (95% CI 5−73), the median PFS and OS for pts treated on the axitinib- vs. control-arm are respectively 15- (95% CI 8−22) vs. 14.2- (95% CI 2−26) and 45- (95% CI 0–106) vs. 17 wks (95% CI 0−54); 6-mths PFS and OS rates are respectively 42 vs. 23% and 59 vs. 50%.
Conclusion: Early results from this ongoing randomized phase II clinical trial indicate that axitinib has single agent anti-tumor activity and can be safely administered to patients with recurrent GBM who failed prior therapy with RT and temozolomide.

Growth kinetics of low-grade glioma before and after treatment with CCNU alone

G. Kaloshi[1], E. Roci[1], B. Cakani[1], R. Zoga[2], R. Doka[3], G. Fejzo[1], A. Rroji[1], M. Petrela[1]. [1]*University Hospital Center "Mother Theresa", Neurosurgery, Tirana, Albania;* [2]*Regional Hospital Center, Neurology, Fier, Albania;* [3]*Regional Hospital Center, Neurology, Lushnje, Albania*

Background: Previous studies have reported that low-grade gliomas (LGG) grow continuously and that temozolomide and PCV have an impact in their growth kinetics. No data exists on the impact of CCNU alone. The aim of this study was to evaluate the effect of first-line CCNU alone chemotherapy.
Material and Methods: The mean tumor diameter (MTD) of LGG was evaluated on serial magnetic resonance images before (n = 28), during, and after (n = 36) treatment with neoadjuvant CCNU.
Results: Before CCNU onset, MTD increased linearly over time (range 2.1 to 4.9 mm/year). During treatment with CCNU alone, 91% of patients experienced a decrease of MTD. After CCNU discontinuation, 28 of 33 patients who responded, an ongoing decrease of MTD was observed. Unresponsive tumors resumed their progressive growth within a year.
Conclusion: Our results confirmed that CCNU alone is an effective treatment for progressive LGG and its pattern of MTD decrease is comparable with previous study using Temozolomide and PCV chemotherapy.
No conflict of interest.

3356 POSTER

A randomized phase II trial of hydroxyurea ± imatinib in the treatment of recurrent or progressive meningiomas

E. Mazza[1], M. Reni[1], G. Lombardi[2], M. Eoli[3], E. Franceschi[4], M. Faedi[5], C. Fugazza[1], P. Maggiora[1], G. Finocchiaro[3], A. Brandes[4]. [1]*San Raffaele Hospital, Medical Oncology, Milano, Italy;* [2]*Istituto Oncologico Veneto − IRCCS, Medical Oncology, Padova, Italy;* [3]*Istituto Neurologico C. Besta, Unit of Molecular Neuro-Oncology, Milano, Italy;* [4]*Bellaria-Maggiore Hospital, Medical Oncology, Bologna, Italy;* [5]*M. Bufalini Hospital, Medical Oncology, Cesena, Italy*

Background: Hydroxyurea (HU) is amongst the most widely used salvage therapies in progressive meningiomas after surgery, radiosurgery, and radiotherapy. Platelet-derived growth factor receptors (PDGF-R) are expressed in virtually all meningiomas. Imatinib sensitizes transformed cells to the cytotoxic effects of chemotherapeutic agents that interfere with DNA metabolism. The combination of HU with Imatinib yielded intriguing results in recurrent malignant glioma. The current trial addressed the activity of this association against meningioma.
Methods: Patients with recurrent or progressive WHO grade I−III meningioma, without therapeutic indication for surgery, radiotherapy or stereotactic radiosurgery, aged 18−75 years, ECOG performance status (PS) 0−2 and not on enzyme-inducing anti-epileptic drugs (EIAED) were randomized to receive HU 500 mg BID ± Imatinib 400 mg QD. Treatment was administered until progression, unacceptable toxicity, or patient's refusal. The primary endpoint was progression-free survival rate at 6 months (PFS-6).
Results: Between September 2009 and June 2011, 15 eligible patients were randomized to receive, HU+Imatinb (N = 7; Arm A) or HU alone (N = 8; Arm B). Afterwards the trial was prematurely closed due to slow enrollment. Patients' characteristics were (A/B): median age 68/68, median PS 1/1, grade 1: 1/1; grade 2: 4/5, grade 3: 1/0, unknown: 1/2, second surgery: 6/6, three or more surgeries: 4/ 1, biopsy: 1/0; radiotherapy: 6/5, radiosurgery: 1/3. All arm A patients progressed within 6 months while 4/8 are currently progression-free in arm B. PFS-6 and median PFS (A/B) was 0%/75% and 4/15.4 months. Two arm A and 4 arm B patients are alive. Median and 2-y OS (A/B) were: 6.5/21.8 months; 14.3%/62.5%. No objective response was observed; 4 arm A and 8 arm B patients had stable disease. Median number of cycles (A/B) was 4 (range 2−7) and 11 (range 4−14). Main G3−4 toxicities were: G3 neutropenia in 1/0, G4 headache in 1/1 and G3 vomiting in 1/0.
Conclusion: This study confirmed that HU is an active and well tolerated agent in recurrent meningioma. Conversely, the addition of imatinib may have a detrimental effect. However due to the small number of patients included in this study, no firm conclusion can be drawn.
No conflict of interest.

3357 POSTER

Concomitant radio-chemotherapy with CCNU after radical removal of newly diagnosed glioblastoma: Preliminary results of a single center retrospective study

G. Kaloshi[1], G. Brace[1], B. Cakani[2], O. Spahiu[3], A. Rroji[1], M. Petrela[1]. [1]*University Hospital Center "Mother Theresa", Neurosurgery, Tirana, Albania;* [2]*Regional Hospital Center, Neurology, Elbasan, Albania;* [3]*University Hospital Center "Mother Theresa", Oncology, Tirana, Albania*

Background: When given concurrently with radiotherapy, Temozolomide has led to improved survival in GBM patients raising the possibility of radiation potentiation of Temozolomide. This study was conducted to determine the relative contribution of concomitant CCNU in patients with newly-diagnosed GBM.
Material and Methods: We identified all patients operated on for a supratentorial GBM and further treated with radiotherapy and CCNU

based chemotherapy either in a concomitant and adjuvant (group 1) or adjuvant only (group 2) setting. The primary endpoints of this study were progression-free survival (PFS), overall survival (OS) and the secondary endpoint was the toxicity.
Results: Forty-two patients (group 1, n = 20; group 2, n = 22) were included in this study. The two arms were well balanced according to their baseline characteristics (including age, KPS). The median follow-up was 15.7 months (95% CI, 12 to inf months). A borderline statistically difference (p = 0.07) was observed according to the PFS between two groups (12 vs 8 months). The median survival OS was 19 months (95% CI 14.1 and 24.7 months) with RT plus CCNU and 11.6 months (95% CI 11.2 and 17.2 months) with adjuvant group, P = 0.09 by the log-rank test. Hematological toxicity was absent during concomitant chemo-radiation and mild (9%) in adjuvant therapy.
Conclusions: Concurrent and adjuvant CCNU is associated with improved survival compared to adjuvant CCNU alone. These results highlight the contribution of CCNU in the radiation effect when given concomitantly.
No conflict of interest.

Stem-like glioblastoma cells can be targeted with a novel radiomimetic agent with dual roles in DNA double strand break induction and homologous recombination inhibition

Y.C. Lim[1], B.W. Stringer[1], K.S. Ensbey[1], Z.C. Bruce[1], P.R. Jamieson[1], T.L. Roberts[2], L. Wiesmüller[3], A.W. Boyd[1], B.W. Day[1]. *[1]Queensland Institute of Medical Research, Brain Cancer Research Unit, Brisbane, Australia; [2]Queensland Institute of Medical Research, Radiation Biology and Oncology, Brisbane, Australia; [3]University of Ulm, Obstetrics and Gynaecology, Ulm, Germany*

Background: Glioblastoma (GBM) is a malignant tumour known to limit the efficacy of ionizing radiation (IR) and alkylating-based drug treatment. In GBM cells, the DNA damage response cascade serves as a key radioresistance mechanism, promoting cell-cycle arrest and DNA repair to restore genomic integrity and ensure cell-survival. Hence patients undergoing DNA damage-based therapies are likely to relapse or even be refractory to further treatment. In this study, we introduce a new radiomimetic agent, which achieves DNA damage induced-apoptosis by eliciting lethal DNA double strand breaks (DSB) and blocking the error-free homologous recombination (HR) repair pathway.
Material and Methods: Primary glioma initiating cell (GIC) cultures were established from GBM patients using a serum-free media supplemented with essential growth factors. Surface markers (CD133, EphA3, etc) and neurosphere assay validated the multipotency of GICs while proliferation and colony formation assay confirmed radioresistant survival after IR treatment.
Results: Among 40 different therapeutic agents investigated, only salinomycin showed potential anti-cancer activity. The agent induces DNA strand breakage that is identical to IR but with a higher DNA damage efficacy in which >80% of the GIC population undergoes apoptosis. Cell-cycle profiling showed salinomycin retards GICs at late-S phase instead of G_2/M as seen with IR treatment. The agent did not affect Brca1 and RPA recruitment to the DNA damage site which is essential for HR initiation. However, immunofluorescence analysis of downstream HR components showed absence of Rad51 foci. Western blotting indicated salinomycin targets HR by degrading Rad51 protein which is required for DNA strand invasion. In agreement with its specificity, salinomycin treatment did not alter non-homologous end joining repair that represents the other major DNA DSB repair pathway. In a murine model, the median survival of mice following receipt of GIC with or without IR treatment prior to intracranial engraftment was 103 days and 102 days respectively. In contrast, pre-treated with salinomycin significantly inhibited tumour growth (mice median survival = 133 days).
Conclusions: Current treatment strategies rely on excessive lethal DNA DSB to achieve apoptosis can be easily overcome by DNA DSB repair. Our data demonstrate not only proof-of-principle that HR is essential for GIC genome integrity and survival, and consequently must be targeted to successfully achieve DNA damage-induced apoptosis, but also identify a new radiomimetic analogue with functions in DNA DSB induction and HR inhibition.

MGMT promoter hypermethylation is present in grade II/III gliomas and GBM in the absence of IDH mutations

H. Haynes[1], C. Crosby[2], H. Williams[1], K. Hopkins[3], M. Williams[2], K.M. Kurian[1]. *[1]Frenchay Hospital, Neuropathology, Bristol, United Kingdom; [2]Southmead Hospital, Genetics, Bristol, United Kingdom; [3]Bristol Oncology Centre, Neurooncology, Bristol, United Kingdom*

Introduction: There is a high rate of IDH1/2 mutations in low grade gliomas and in high grade gliomas deriving from them. IDH mutation is an early event in gliomagenesis and independently confers a better prognosis in Grade III and IV tumours. Mutated IDH is believed to predispose glioma cells to DNA hypermethylation because the abnormal IDH product 2 hydroxyglutarate (2-HG) is known to inhibit histone demethylation. Methylation of the MGMT gene promoter silences its expression and improves outcome in patients treated with temozolomide (TMZ) chemotherapy. We compared the expression of mutated IDH and hypermethylated MGMT in a cohort of glioma patients.
Method: 88 samples from 71 patients were identified: 15 WHO Grade 2 gliomas, 29 Grade 3 gliomas and 27 Grade 4 GBM. 31 samples were excluded due to insufficient sample for DNA extraction. For immunohistochemistry, sections were stained with anti-IDH1R132H antibody. For sequencing, DNA was extracted from fresh, frozen tissue. Sanger sequencing of the R132 region of IDH1 and the R172 region of IDH2 was performed. MGMT methylation status was assessed by methylation specific PCR.
Results: We found a high rate of IDH1 mutations in lower grade lesions (grade II & III) (23/43) (53%) and a low rate in GBMs (2/28) (7%). Both grade II gliomas and anaplastic astrocytomas show a statistically different distribution of IDH1 mutation load compared to GBMs ($p < 0.0001$; $p = 0.0021$ respectively). For grade II/III gliomas, 96% (22/23) of IDH mutations are associated with MGMT hypermethylation and 55% (6/11) of IDH mutation negative samples showed MGMT hypermethylation ($p = 0.008$). In the GBM cohort, both samples with IDH mutations show MGMT hypermethylation 100% (2/2) with 54% (14/26) of IDH mutation negative samples showing hypermethylation ($p = 0.5$). In this cohort, the difference in % methylation in grade II/III, 32/43, [74%] and GBM, 16/28, [57%]), did not achieve significance ($p = 0.2$).
Conclusion: In our cohort the difference in MGMT hypermethylation between gradeII/III glioma and GBM is non-significant. IDH mutations are overrepresented and significantly associated with MGMT hypermethylation in grade II/III gliomas compared with GBM. However there is a proportion of IDH negative cases with MGMT hypermethylation in all grades. This suggests that alternate epigenetic mechanisms apart from 2HG-mediated inhibition of histone demethylation may be acting to silence MGMT expression in these cases.
No conflict of interest.

3360 POSTER

Proliferation and microvascular density predict survival in patients with brain metastases of non-small cell lung cancer

A. Berghoff[1], A. Ilhan-Mutlu[2], A. Wöhrer[1], M. Hackl[3], G. Widhalm[4], J.A. Hainfellner[1], K. Dieckmann[5], C.C. Zielinski[2], P. Birner[6], M. Preusser[2]. *[1]Medical University of Vienna, Institute of Neurology, Vienna, Austria; [2]Medical University of Vienna, Department of Medicine I, Vienna, Austria; [3]Austrian National Cancer Registry, Statistics Austria, Vienna, Austria; [4]Medical University of Vienna, Department of Neurosurgery, Vienna, Austria; [5]Medical University of Vienna, Department of Radiotherapy, Vienna, Austria; [6]Medical University of Vienna, Institute of Pathology, Vienna, Austria*

Background: Non-small cell lung cancer (NSCLC) is the most frequent cause of brain metastases (BM). Survival upon diagnosis of BM is variable and established prognostic scores do not include tissue-based parameters. We studied the prognostic value of proliferation, angiogenesis and hypoxia in NSCLC BM.
Methods: All patients treated with neuro-surgery as first line therapy for newly diagnosed NSCLC BM between 01/1990 and 02/2011, were identified from the Neuro-Biobank, Medical University of Vienna. We determined microvascular density (MVD), Ki67 tumor cell proliferation index and hypoxia-inducible factor 1 alpha (HIF1a) score using immunohistochemistry and standard protocols. Clinical and demographic data were retrieved by chart review. We performed statistical correlations including survival analyses using log-rank test and Cox-regression.
Results: BM specimens of 210 patients were available for analysis (133 male (63.3%), 77 female (36.7%), median age at diagnosis of BM 56 (range 31−78). 38/210 (18.1%) patients had squamous and 172/210 (81.9%) non-squamous histology of the primary tumour. Median overall survival (OS) from first diagnosis of BM was 8.0 months (range 0.0–

158.0). Diagnosis specific graded prognostic assessment (DS-GPA) groups showed statistically significant correlation with survival (class 1: 19 months; class 2: 8 months; class 3: 5 months; class 4: 1 month; $p < 0.001$; log rank test). Patients receiving adjuvant whole brain radiation therapy (WBRT) after surgery had a significantly improved survival (6 vs 11 months; $p = 0.039$; log rank test). Median MVD was 71.5 (range 7–298), median ki67 39.1% (range 3−97%) and median HIF1a index was 60.0 (range 0–250). Neither Ki67, MVD nor HIF1a index of the primary tumour showed correlation with time till first occurrence of BM. At univariate survival analysis, patients with low MVD (8 vs. 11 months; $p = 0.045$; log rank test), high HIF1a index (7 months vs. 13 months; $p = 0.027$; log rank test) and high Ki67 (6 months vs. 11 months; $p = 0.005$; log rank test) had an impaired OS. In multivariate analysis, DS-GPA ($p < 0.001$), Ki67 ($p < 0.001$), MVD ($p = 0.008$) and adjuvant WBRT ($p = 0.049$) remained statistically significant.
Conclusion: Ki67 proliferation index and MVD of BM are independent predictors of survival in NSCLC BM patients and should be included in disease- and BM-specific prognostic scores.
No conflict of interest.

3361 POSTER

The immunohistochemical expression of c-Met is an independent predictor of survival in patients with glioblastoma multiforme

O.F. Olmez[1], E. Cubukcu[1], T. Evrensel[1], M. Kurt[2], N. Avci[1], S. Tolunay[3], A. Bekar[4], A. Deligonul[1], M. Hartavi[1], N. Alkis[1]. *[1]Uludag University Medical Faculty, Medical Oncology, Bursa, Turkey; [2]Uludag University Medical Faculty, Radiation Oncology, Bursa, Turkey; [3]Uludag University Medical Faculty, Neuropathology, Bursa, Turkey; [4]Uludag University Medical Faculty, Neurosurgery, Bursa, Turkey*

Background and Aims: Because the outcome of glioblastoma multiforme (GBM) remains dismal, there is an urgent need for a better molecular characterisation of this malignancy. The aim of this study was to investigate the prognostic impact of the expression of c-Met a receptor tyrosine kinase implicated in expression growth, survival, motility/migration, and invasion in GMB patients managed according to the established diagnostic and therapeutic protocols.
Methods: Between May 2003 and March 2011, a total of 69 patients (33 males and 36 females; mean age: 52.2±12.9 years, age range: 23−81 years) referred to our Department for the surgical removal of GBM were evaluated immunohistochemically for c-Met expression. Progression-free survival (PFS) and overall survival (OS) served as the main outcome measures.
Results: Compared with c-Met− subjects (n = 38), c-Met+ subjects (n = 31) had both a significantly lower OS (15.3±2.3 vs. 22.6±2.5 months, respectively, $p < 0.01$) and PFS (12.3±2.1 vs. 19.1±2.6 months, respectively, $p < 0.05$). After allowance for potential confounders, Cox regression analysis identified c-Met+ as an independent predictors of both OS (hazard ratio = 1.7; 95 % confidence interval = 1.1−1.7, $p < 0.01$) and PFS (hazard ratio = 1.6; 95 % confidence interval = 1.1−2.4, $p < 0.05$).
Conclusions: Our findings suggest that c-Met immunohistochemical expression is an independent predictor of outcomes in patients with GBM treated by standard of care.
No conflict of interest.

3362 POSTER

Microenvironment cues induce invasiveness in acquired temozolomide resistance glioma cells

W. Long Hui[1], H. Yoon Khei[2], T. Heng-Phon[1]. *[1]National University of Singapore, Singapore-MIT Alliance, Singapore, Singapore; [2]National University of Singapore, Department of Biochemistry, Singapore, Singapore*

Background: Glioblastoma multiforme (GBM) is the most malignant form of primary brain tumours and patients diagnosed with GBM have a median survival time of 15 months, even with surgical resection, chemotherapy and radiotherapy. One key reason that prognosis for GBM patients is so poor is that single tumour cells can infiltrate diffusely into the brain parenchyma by aberrant interactions with the extracellular matrix (ECM) components in the brain, rendering complete surgical removal of tumour cells impossible. Temozolomide (TMZ), the most promising chemotherapeutic drug for glioma, has further been proven to be ineffective for GBM treatment due to intrinsic or acquired chemoresistance of the GBM cells. In this study, we attempted to understand the influence of microenvironment cues from the ECM on GBM cells with acquired TMZ resistance.
Material and Methods: Stable TMZ-resistant U251MG cell lines were generated by stepwise exposure of parental U251MG cells to TMZ, with 15 passages between each step. Reconstituted rat tail collagen I was used as the 3-dimensional cell culture.
Results: We found that TMZ-resistant U251MG cells displayed a different morphology and were more invasive compared to parental cells in the collagen gels. We further showed that the increased invasiveness of TMZ-resistant U251MG cells were due to the ability to form strong adhesions with surrounding collagen fibers, resulting in a stiffer local microenvironment, and increased expression of matrix metalloproteinases (MMPs).
Conclusions: Microenvironment cues are necessary to induce the invasive capability of TMZ-resistant glioma cells. We propose that complementary chemotherapeutic treatment with TMZ for GBM should emphasize on specific targets, particularly from the MMPs pathway, to prevent recurrence from invasive TMZ-resistant glioma cells.
No conflict of interest.

Identification of a 19 miRNAs signature distinguishing low grade from high grade gliomas

R. Barbano[1], O. Palumbo[2], B. Pasculli[3], M. Galasso[4], S. Volinia[4], M. Coco[5], L. Dimitri[6], M. Carella[7], V.M. Fazio[5], P. Parrella[1]. *[1]IRCCS Casa Sollievo Della Sofferenza, Oncology Laboratory, San Giovanni Rotondo(FG), Italy; [2]IRCCS Casa Sollievo Della Sofferenza, Laboratory of Medical Genetics, San Giovanni Rotondo(FG), Italy; [3]University of Bari, Department of Biosciences Biotechnology and Pharmacological Sciences, Bari, Italy; [4]University of Ferrara, Department of Morphology Surgery and Experimental Medicine, Ferrara, Italy; [5]IRCCS Casa Sollievo della Sofferenza, Laboratory of Oncology, San Giovanni Rotondo(FG), Italy; [6]IRCCS Casa Sollievo della Sofferenza, Unit of Anatomopathology, San Giovanni Rotondo(FG), Italy; [7]IRCCS Casa Sollievo della Sofferenza, Laboratory of Medical Genetics, San Giovanni Rotondo(FG), Italy*

Background: Gliomas account for approximately 70% of malignant primary brain tumors diagnosed in adults. They represent a disparate group of tumors for which there are no cure. MicroRNAs (miRNAs) are small non-coding RNAs, of 18 to 25 nucleotides in length, involved in the post transcriptional regulation of gene expression. Low grade (LG) and high grade (HG) gliomas share several morphological characteristics and pathways abnormalities but have a completely different clinical behaviour. We hypothesize that the comparison of the miRNAs profile between LG and HG gliomas may lead to the identification of miRNAs associated with the glioblastoma multiforme (GBMs) aggressive phenotype.
Material and Methods: miRNAs profiling of 8 LG gliomas (WHO grade II), 24 HG gliomas (2 WHO grade III and 22 GBMs) and 4 commercially available normal brain tissues (NBT) was performed by using the Affymetrix GeneChip® miRNA Array 1.0. Data analysis was performed with Partek Genomic Suite software, setting as cut offs a significative p-value $\leqslant 0.01$ and a fold change of 2. A relative quantification method with standard curve using specific stem loop primers was used to validate the 22 miRNA signature identified by array analysis. The prognostic performance of the 19 validated miRNAs was evaluated by using the Tumor Cancer Genome Atlas Network (TCGA) dataset which includes only GBMs.
Results: miRNA profiling of the 32 gliomas and 4 NBT allowed us to identify 60 miRNAs differentially expressed in LG and HG versus NBT; 80 miRNAs differentially expressed in LG versus NBT and 71 miRNAs differentially expressed in HG versus NBT. A signature of 22 miRNAs distinguished HG from LG and NBT. qRT-PCR analysis confirmed differential expression in LG versus HG for 19 out of the 22 miRNAs. We evaluated our signature on the TCGA dataset finding 6 miRNAs differentially expressed in the GBM subclasses identified by the TCGA data dataset (astrocytic, neural, neuromesenchimal, oligoneural and radial glial). Two of those miRNAs were associated with worse overall survival in both univariate and multivariate Cox Regression analysis (HR 1.19 95% CI 1.008–1.406 P = 0.04; and 1.183 95%C 1.018–1.375 P = 0.03).
Conclusions: Our study has led to identifying a subset of miRNAs able to distinguish low grade from high grade gliomas. This informations could be exploited for the development of novel methodological tools for innovative diagnostic and therapeutic approaches for this deadly disease.

3364 POSTER

HOXB7 gene expression and growth of glioblastoma xenografts after treatment with 13-cis retinoic acid and thalidomide

D. Milanovic[1], P. Maier[2], A.L. Grosu[1], F. Wenz[2], G. Niedermann[1], C. Herskind[2]. *[1]University Hospital Freiburg, Department of Radiation Oncology, Freiburg, Germany; [2]University Medical Center Mannheim University of Heidelberg, Department of Radiation Oncology, Mannheim, Germany*

Background: 13-cis retinoic acid (RA) and thalidomide (THAL) are biological modulators frequently used as sole agents or in the combination

with different chemotherapeutics or radiotherapy in clinical trials in patients with glioblastomas (GBM). However, induction of homeobox (HOX) gene expression such a HOXB7 by RA may activate basic fibroblast growth factor (bFGF) contributing to tumor progression and thereby potentially limiting its efficacy. The purpose was to test if THAL can inhibit RA-induced HOXB7 and bFGF expression and delay growth of glioblastoma xenografts.
Material and Methods: U343 glioblastoma cells were treated in vitro with RA, THAL and their combination. Quantitative real-time PCR was used to determine changes in HOXB7 and bFGF expression. 1.5×10^6 U251 cells were inoculated s. c. into the right hind limb of NMRI-Foxn1^{nu} nude mice. Animals were randomly assigned in 4 groups (7−11 animals/group): control, RA, THAL and RA + THAL and treated daily (Monday-Friday) via intragastric tube with RA (30 mg/kg), THAL (30 mg/kg) or their combination for 18 days. Tumor growth was determined during the whole treatment period. Animals were sacrificed and tumors resected one day after the last treatment. mRNA was isolated from three tumors selected randomly from each group and transcription of HOXB7 was evaluated by real-time PCR with ACTB as reference.
Results: Treatment of U343 cells with RA *in vitro* caused upregulation of HOXB7 and bFGF gene expression which was significantly inhibited by THAL ($p < 0.0001$ for HOXB7; $p = 0.007$ for bFGF). RA or THAL as sole agents did not influence growth of the xenografts while combined treatment caused a significant decrease in tumor volume ($p = 0.0043$). The final tumor volumes were: control = $1.37 \pm 0.2\,cm^3$, RA = $1.38 \pm 0.23\,cm^3$, THAL = $1.43 \pm 0.5\,cm^3$, RA + THAL = $0.69 \pm 0.075\,cm^3$. Hematoxylin and eosin staining of xenografts revealed marked hypocellularity in the case of combined treatment. No significant difference in HOXB7 expression was found between different treatment groups.
Conclusions: THAL inhibited upregulation of HOXB7 and bFGF expression induced by 13-cis RA in U343 glioblastoma cells. Combined treatment caused significant delay in tumor growth albeit without influence on HOXB7 gene expression. These results indicate a complex mechanism of action of THAL in combination with RA. Microarray analysis of global gene transcription in the tumors is ongoing.

3365 POSTER

Preclinical evaluation of the novel anthracycline derivative aldoxorubicin for human glioblastoma chemotherapy

O. Prakash[1], A.E. Musto[2], D. Wyczechowska[1], L. Marrero[1], A. Zapata[1], H. Vashistha[1], C. Parsons[1], S. Wieland[3], D. Levitt[3], K. Reiss[1]. *[1]LSUHSC, Stanley S. Scott Cancer Center, New Orleans LA, USA; [2]LSUHSC, Neuroscience Center of Excellence, New Orleans LA, USA; [3]CytRx Corporation, Los Angeles CA, USA*

Background: Glioblastoma multiforme (GBM) is the most common and aggressive of the adult brain tumors with a median survival of 12−14 months despite aggressive surgery, radiotherapy, and the use of the chemotherapeutic drug temozolomide. In this study, we evaluated the preclinical efficacy of a novel albumin-binding prodrug of doxorubicin, aldoxorubicin (also known as INNO-206), for the treatment of GBM in a murine model.
Material and Methods: U87MG human glioma cells (5×10^5) expressing firefly luciferase (U87-luc) were stereotactically implanted in the left striatum of nude mice. After 9 days, mice ($n = 8$ in each group) received either vehicle or aldoxorubicin by tail vein injection once weekly for a total 3 weeks. The first two doses were 75% and the third dose was 50% of the maximum tolerated dose of 32 mg/kg in mice. Tumor growth was monitored weekly using bioluminescence imaging, and survival compared using Kaplan–Meier curves.
Results: Although, the relative difference in average tumor sizes between the control and the treatment group after 7 days of tumor cell implantation was non-significant ($p>0.05$), all control mice developed large tumors (median tumor size 4.7×10^8 bioluminescence units) by day 21 and died within 29 days. In contrast, mice receiving aldoxorubicin displayed near complete tumor regression 21 days after implantation (median tumor size 0.57×10^8 bioluminescence units), and remained alive at day 29. Kaplan–Meier survival curves revealed significantly increased survival for mice treated with aldoxorubicin ($p = 0.0006$).
Conclusions: Using an intracranial murine model for GBM tumor progression, we show that systemic administration of aldoxorubicin induces significant tumor regression and prolongs survival. Unlike doxorubicin which has shown limited efficacy in the treatment of brain tumors, our data support the potential utility of aldoxorubicin for GBM therapy.

MGMT promoter methylation status and MGMT and CD133 immunohistochemical expression as prognostic markers in glioblastoma patients treated with temozolomide plus radiotherapy

B. Gonzalez-Astorga[1], R. Luque[1], V. Castellon[1], E. Gonzalez[1], C. Sanchez[1], J. Soberino[1], C. Gonzalez[1], J. Ruiz[1], M. Zurita[2], J.R. Delgado[1]. *[1]Hospital Universitario Virgen de las Nieves, Medical Oncology, Granada, Spain; [2]Hospital Universitario Virgen de las Nieves, Radiotherapy Oncology, Granada, Spain*

Background: The CD133 antigen is a marker of radio and chemo-resistant stem cell populations in glioblastoma (GBM). The O6-methylguanine DNA methyltransferase (MGMT) enzyme is related with temozolomide (TMZ) resistance. Our propose is to analyze the prognostic significance of the markers in a homogenous group of GBM patients uniformly treated with radiotherapy and TMZ.
Methods: Seventy-eight patients with GBM treated with radiotherapy combined with concomitant and adjuvant TMZ were analyzed for MGMT and CD133. MGMT gene promoter methylation was determined by methylation -specific polymerase chain reaction after bisulfite treatment. MGMT and CD133 expression was assessed immunohistochemically using an automatic quantification system. Overall and progression-free survival was calculated according to the Kaplan–Meier method.
Results: MGMT methylation status was methylated in 43% and unmethylated in 57%. A significant correlation was observed between MGMT promoter methylation and patients' survival, the median OS among patients with methylates MGMT promoter was 19 months compared with 13 months in unmethylated MGMT promoter tumors ($P = 0.031$). No correlation was found between MGMT promoter methylation and MGMT expression, or MGMT expression and survival. In contrast with recent results, CD133 expression was not a predictive mark er in GBM patients. Analyses of possible correlation between CD133 expression and MGMT protein expression or MGMT promoter methylation were negative.
Conclusions: Our results support the hypothesis that MGMT promoter methylation status but not MGMT expression may be a predictive biomarker in the treatment of patients with GBM. In addition, CD133 should not be used for prognostic evaluation of thes e patients. Future studies will be necessary to determine its clinical utility.

3367 POSTER

Nanoparticles releasing zoledronic acid have antitumor activity against experimental models of human glioblastoma

C. Leonetti[1], M. Porru[1], S. Artuso[1], S. Zappavigna[2], A. Luce[2], G. Salzano[3], S. Lusa[3], G. De Rosa[3], M. Caraglia[2]. *[1]Regina Elena National Cancer Institute, Experimental Chemotherapy Laboratory, Rome, Italy; [2]Second University of Naples, Department of Biochemistry and Biophysics, Naples, Italy; [3]University "Federico II" of Naples, Department of Chemistry and Pharmaceutical Chemistry Toxicology, Naples, Italy*

Background: Tumours localized in the brain are poorly sensitive to treatments for the intrinsic resistance of tumor cells and for the presence of the blood–brain barrier (BBB). The emerging field of cancer nanotechnology holds promise in the use of nanoparticles to allow the crossing of drugs thorough the BBB. Zoledronic acid (ZOL) is commonly used as antiresorptive agent in the treatment of cancer-related bone disease. On the other hands, ZOL has a direct antitumour activity by inducing apoptosis on different cancer cell types, but it accumulates almost exclusively in the bone not reaching tumour cells. Based on this background, our aim was to study the antitumor efficacy of nanoparticles releasing ZOL against human glioblastoma.
Materials and Methods: Self-assembly PEGylated nanoparticles (NPs), based on calcium/phosphate NPs and cationic liposomes, were optimized to achieve NPs easily prepared before use. The targeting of ZOL in the brain was improved by designing NPs functionalized with transferrin (TRF) able to bind specific receptors on endothelial cells of BBB. The in vitro cytotoxic activity of NPs-ZOL was tested on different glioblastoma cell lines (U373, LN229 and U87-MG) by MTT and clonogenic assay. The antitumor efficacy of NPs-ZOL was evaluated in vivo on heterotopic and orthotopic glioblastoma xenografts by injecting luminescent glioblastoma cells and tumor growth analyzed by an imaging system.
Results: NPs-ZOL strongly inhibited the growth of glioblastoma cells showing an IC50 that was ten times lower than ZOL free and, surprisingly, twenty times lower than Temozolomide. Moreover, this new formulation had higher antitumor efficacy than that one caused by ZOL free in mice-bearing glioblastoma tumors implanted intramuscularly in mice. More interestingly, we observed that i.v injected TRF-NPs were able to overcome BBB since fluorescent NPs were detected in the brain of mice bearing glioblastoma.

Finally, preliminary experiments showed that TRF-NPs-ZOL reduce the growth of orthotopic model of U373-MG-LUC xenografts.
Conclusions: The demonstration of NPs-ZOL to brain tumor localization and assessment of antitumor activity of this formulation opens a new scenario in which NPs-ZOLcould have a strong impact for the treatment of brain tumors, for which a paucity of effective treatments exists.

Impact of crizotinib on patient-reported symptoms and global quality of life (QoL) compared with chemotherapy in a phase III study of advanced alk-positive non-small cell lung cancer (NSCLC)

F. Blackhall[1], V. Hirsh[2], D.W. Kim[3], B. Besse[4], H. Nokihara[5], J.Y. Han[6], K. Wilner[7], A. Reisman[8], S. Iyer[9], A. Shaw[10]. *[1]Christie Hospital NHS Foundation Trust, Department of Medical Oncology, Manchester, United Kingdom; [2]McGill University Health Centre, Department of Oncology, Montreal, Canada; [3]Seoul National University Hospital, Department of Internal Medicine, Seoul, South Korea; [4]Institut Gustave Roussy, Department of Cancer Medicine, Villejuif, France; [5]National Cancer Center Hospital, Division of Internal Medicine, Tokyo, Japan; [6]National Cancer Center, Center for Lung Cancer, Goyang, South Korea; [7]Pfizer Oncology, Medical Oncology, La Jolla, USA; [8]Pfizer Specialty Care, Statistics, New York, USA; [9]Pfizer Oncology, Health Economics and Outcomes, New York, USA; [10]Massachusetts General Hospital, Department of Thoracic Oncology, Boston, USA*

Background: The main objective of our analysis was to compare patient-reported symptom and global QOL improvement rates between crizotinib and standard-of-care chemotherapy (pemetrexed or docetaxel) in previously treated patients with advanced *ALK*-positive NSCLC in the ongoing PROFILE 1007 study (Pfizer; NCT0093283).
Methods: 172 patients were randomized to crizotinib and 171 to standard-of-care chemotherapy. Patient-reported outcomes were assessed at baseline, on day 1 of each cycle, and at the end of treatment using EORTC QLQ-C30 and lung cancer module QLQ-LC13. Higher scores (range 0–100) indicated higher symptom severity or better functioning/QOL. A clinically meaningful change was defined as a $\geqslant$10-point change from baseline. The percentage of patients classified as having improved ($\geqslant$10-point increase for functioning scales and $\geqslant$10-point reduction for symptoms in average of change from baseline scores across cycles for a patient) or worsened ($\geqslant$10-point reduction for functioning and $\geqslant$10-point increase for symptoms in average of change from baseline scores across cycles) was examined. Relative risk ratios were calculated for improvement rates in key lung cancer symptoms and differences in rates between treatment groups were tested for statistical significance using chi-square tests.
Results: Completion rates at baseline were $\geqslant$90% in each group and scores were well balanced. Relative risk ratios (95% CI) for improvement rates favored the crizotinib versus the chemotherapy arm for the following lung cancer symptoms: cough (1.7 [1.3−2.2]), dyspnea (2.3 [1.5−3.4]), and pain in chest (1.8 [1.3−2.6]). A significantly greater percentage of patients in the crizotinib versus the chemotherapy arm showed improvements for global QOL (42.6% vs. 20.7%; $p < 0.001$), physical functioning (27.2% vs. 11.9%; $p < 0.001$), role functioning (30.9% vs. 14.6%; $p < 0.001$) emotional functioning (37.0% vs. 24.0%; $p < 0.05$), fatigue (46.3% vs. 20.5%; $p < 0.001$), pain (43.8% vs.20.5%; $p < 0.001$), cough (55.3% vs. 33.3%; $p < 0.001$), dyspnea (39.1% vs. 17.3%; $p < 0.001$), pain in chest (40.0% vs. 22.3%; $p < 0.001$), and pain in arm or shoulder (33.5% vs. 19.5%; $p < 0.001$). A significantly higher proportion of patients showed worsening of constipation (44.4% vs. 22.5%; $p < 0.001$) and diarrhea (41.4% vs. 19.2%; $p < 0.001$) with crizotinib compared with chemotherapy.
Conclusion: Treatment with crizotinib led to significantly higher improvement rates in global QOL and key lung cancer symptoms compared with chemotherapy.

Updated results of a first-in-human dose-finding study of the ALK/EGFR inhibitor AP26113 in patients with advanced malignancies

D.R. Camidge[1], L. Bazhenova[2], R. Salgia[3], G.J. Weiss[4], C.J. Langer[5], A.T. Shaw[6], N.I. Narasimhan[7], D.J. Dorer[7], J. Zhang[7], S.N. Gettinger[8]. *[1]University of Colorado Denver, School of Medicine, Aurora, USA; [2]University of California San Diego, Moores Cancer Center, La Jolla, USA; [3]University of Chicago, Department of Medicine, Chicago, USA; [4]Virginia G. Piper Cancer Center Clinical Trials at Scottsdale Healthcare, Scottsdale, USA; [5]University of Pennsylvania, Abramson Cancer Center, Philadelphia, USA; [6]Massachusetts General Hospital, Department of Hematology/Oncology, Boston, USA; [7]ARIAD Pharmaceuticals Inc., Cambridge, USA; [8]Yale University, School of Medicine, New Haven, USA*

Background: AP26113 is a novel tyrosine kinase inhibitor (TKI) that potently inhibits mutant activated forms of anaplastic lymphoma kinase (ALK+) and epidermal growth factor receptor (EGFRm), and TKI-resistant forms including L1196M (ALK) and T790M (EGFR). AP26113 does not inhibit native EGFR.
Methods: The dose finding phase (3+3 design) of this phase 1/2 open-label, multicenter study is ongoing in pts with advanced malignancies (except leukemia) refractory to available therapies or for whom no standard treatment exists. Dosing is once daily (QD) or twice daily (BID).
Results: As of 7 March 2013, 49 pts were enrolled: 30 mg (daily dose) n = 3, 60 mg n = 3, 90 mg n = 8, 120 mg n = 13, 180 mg n = 11, 240 mg n = 9, 300 mg n = 2; 59% female, median age 58 yrs; diagnoses: non-small cell lung cancer (NSCLC, n = 42), other (n = 7). 29 pts discontinued: 19 disease progression, 5 adverse event (AE), 4 deaths (2 possibly related: sudden death, hypoxia), 1 withdrawal by subject. The most common AEs were nausea (43%), fatigue (41%), and diarrhea (35%), which were generally grade 1/2 in severity. The most common grade 3/4 treatment-related AE was diarrhea (4%). 2 dose limiting toxicities were observed: grade 3 ALT increase, 240 mg; grade 4 dyspnea, 300 mg. Doses <300 mg are being explored further. 25 pts had ALK+ history (22 NSCLC, 3 other). Among 21 evaluable ALK+ pts, 13 responded. Among ALK+ pts with $\leqslant$1 prior ALK TKI, responses were observed in 2/3 (67%) TKI-naive pts and 11/15 (73%) pts with prior crizotinib therapy. The longest response is 48 wks (ongoing). Among ALK+ NSCLC pts with prior crizotinib only, 10/14 (71%) responded. 4 of 5 ALK+ pts with untreated or progressing CNS lesions at baseline and with follow-up scans had evidence of radiographic improvement in CNS, including 1 pt resistant to crizotinib and LDK378 (overall response = stable disease). 17 pts had EGFRm history (16 NSCLC, 1 SCLC); 15 pts had $\geqslant$1 prior EGFR TKI. Of 12 EGFRm pts with a follow-up scan, 1 pt (prior erlotinib) responded at 120 mg (duration 21 wks, ongoing), 6 pts had stable disease (1 ongoing).
Conclusions: AP26113 has promising anti-tumor activity in pts with ALK+ NSCLC and other ALK+ tumors, with initial evidence of activity in EGFRm pts, and is generally well tolerated. Phase 2 will begin after the recommended phase 2 dose is determined. Cohorts will include: crizotinib-naive NSCLC; crizotinib-resistant NSCLC; EGFR TKI-resistant NSCLC; other tumors. Pemetrexed (PEM) and cisplatin (CIS) with concurrent thoracic radiation after PEM+CIS induction in patients (pts) with unresectable locally advanced (LA) nonsquamous non-small cell lung cancer (NS-NSCLC): primary results of a phase II study

P. Garrido[1], M. Serke[2], S. Novello[3], P. Giraud[4], C. Visseren-Grul[5], S. Ameryckx[6], V. Soldatenkova[7], N. Chouaki[8], W. Engel-Riedel[9]. *[1]University Hospital Ramón Y Cajal, Medical Oncology, Madrid, Spain; [2]Hemer Lung Clinic, Thoracic Oncology, Hemer, Germany; [3]S. Luigi Hospital University of Turin, Oncology, Orbassano, Italy; [4]Georges Pompidou European Hospital, Oncology Radiology, Paris, France; [5]Eli Lilly and Company, Medical Oncology, Houten, Netherlands; [6]Lilly S.A. Eli Lilly Benelux N.V., Clinical Trial Management Oncology, Brussels, Belgium; [7]Lilly Deutschland GmbH, European Statistics Oncology, Bad Homburg, Germany; [8]Lilly France, Medical Oncology, Suresnes, France; [9]Hospital of Cologne, Lung Clinic Merheim, Cologne, Germany*

Background: Concurrent chemo- and radiotherapy (CT+RT) is standard of care for most pts with unresectable LA NSCLC, but no standard regimen has been established. PEM synergizes with ionizing radiation and CIS in preclinical models. PEM+CIS doublets showed efficacy and

favourable toxicity profiles in Phase I/II studies of NS-NSCLC. This single-arm multicenter Phase II study investigated efficacy and safety of PEM+CIS induction followed by full-dose PEM+CIS plus concurrent RT in pts with LA NS-NSCLC.

Materials and Methods: Pts with unresectable Stage IIIA/IIIB NS-NSCLC, ECOG performance status (PS) 0−1 and forced expiratory volume (FEV) >50% of predicted normal FEV received two 21-day cycles of PEM 500 mg/m^2 + CIS 75 mg/m^2 on Day 1. Pts who had not progressed, had no residual neurological toxicity >Grade(G) 2, PS 0−1 and lung V20 <35% then received 2 cycles of the same full-dose PEM+CIS regimen plus concurrent thoracic RT of 2 Gy/fraction, 5d/wk for 7wks (66 Gy total). All pts received vitamin supplementation/dexamethasone prophylaxis as per PEM-label. Primary endpoint was the 1 yr progression-free survival (PFS) rate. A minimum of 53 events was required to provide 90% power to demonstrate an improvement of the 1 yr PFS rate from 45% (historical data) to 60% at a 2-sided alpha level of 5%, resulting in a sample size of 88 pts assuming 10% dropouts. Secondary data presented include tumor response and toxicity.

Results: 90 pts were enrolled in 4 countries: median age 61 yrs, male/female 57%/43%, ECOG PS 0/1 66%/34%, mean (SD) FEV 2.3 (0.62)L, adenocarcinoma 90%, Stage IIIA/IIIB 36%/62% (2 pts had Stage IV and discontinued before starting RT). 75 pts (83.3%) completed induction CT and started concurrent CT+RT. 63 of the 75 pts (84.0%) received all 4 CT cycles and full RT of 66 Gy. Median PEM+CIS dose intensities were >97% during concurrent CT+RT, median RT dose was 66 Gy (range 18−66 Gy). The 1 yr PFS rate was 51.3% (95% CI 42.0–60.5). After a median follow-up of 24 months, median PFS was 10.6 months (95% CI 8.6–17.3). Response data are shown as table. One pt died from study-drug related toxicity (enteritis) during Cycle 4. Four pts discontinued due to non-fatal drug- or radiation related adverse events, 1 on induction CT (renal failure), 3 on concurrent CT+RT (hypoacusis, 2x radiation esophagitis). During induction CT, 18.9% of pts reported G3/4 CTCAEs, only neutropenia (2.2%) and syncope (2.2%) were reported by >1 pt. During concurrent CT+RT, 41.3% of 75 pts reported G3/4 CTCAEs, mainly esophagitis (12.0%), neutropenia (10.7%) and leukopenia (9.3%). One pt experienced G3 mucositis and 1 pt showed G3 acute pneumonitis.

Conclusions: In this study of PEM+CIS induction followed by full-dose PEM+CIS with concurrent thoracic RT, the 1 yr PFS rate (51.3%) was in the same range as previously observed with other CIS-based induction CT followed by CT+RT (40−50%). Of note, 7 pts had CR. Main G3/4 toxicities during concurrent CT+RT included esophagitis, neutropenia and leukopenia.

Conflict of interest: *Ownership: None. Advisory board: Yes: Lilly, Roche, Boeringher, Astra-Zeneca, Celgene. Board of directors: No. Corporate-sponsored research: Yes, this study (Eli Lilly). Other substantive relationships: None.*

Treatment compliance of customized postoperative chemotherapy after NSCLC resection: A toxicity/safety analysis of SCAT (Spanish Customized Adjuvant Therapy) trial − Spanish Lung Cancer Group/GECP

B. Massuti[1], M. Cobo[2], J.M. Rodriguez-Paniagua[3], I.M. Ballesteros[4], T. Moran[5], R. Arrabal[6], J.L. González-Larriba[7], E. Pereira[8], J.M. Sánchez-Torres[9], R. Rosell[10]. *[1]Alicante University Hospital, Medical Oncology, Alicante, Spain; [2]Carlos Haya University Hospital, Medical Oncology, Málaga, Spain; [3]Alicante University Hospital, Thoracic Surgery, Alicante, Spain; [4]La Princesa University Hospital, Medical Oncologyq, Madrid, Spain; [5]Institut Catala Oncologia, Medical Oncologyg, Badalona, Spain; [6]Carlos Haya University Hospital, Thoracic Surgery, Málaga, Spain; [7]Hospital Clínico San Carlos, Medical Oncology, Madrid, Spain; [8]Spanish Lung Cancer Group, CRA, Barcelona, Spain; [9]La Princesa University Hospital, Medical Oncology, Madrid, Spain; [10]Institut Català Oncologia, Medical Oncology, Badalona, Spain*

Background: Adjuvant platinum-based CT improves outcomes in resected NSCLC with nodal involvement but is still insufficient to provide optimal survival. Better risk selection or customized selected therapy needs to be explored. mRNA BRCA1 levels are prognostic in early NSCLC and could be a predictive marker for CT activity. In advanced disease patients with low BRCA1 benefit from cisplatin doublets meanwhile p with high levels attained longer survival with taxanes. Customization is feasible in adjuvant setting (tissue availability). Compliance is a key issue in adjuvant setting.

Methods: Phase III trial testing 4 cycles non-selected vs selected adjuvant CT. Entry criteria: NSCLC, R0 resection, pN1 or pN2, KI >70, recovered from surgery, adequate hematologic, renal and liver functions, no prior CT or RT, age >18 y, informed consent. Stratification: N1 vs N2, histology (squamous vs non-squamous), resection (lobectomy vs pneumonectomy). Central lab mRNA BRCA1 levels and quartile distribution. Primary end-point: DFS. Secondary end-points: OS, toxicity, recurrence pattern. Design: R: 1:3. Control treatment: Cis-Docetaxel (CD). Experimental arm: Q1: Cis-Gemcitabine (CG); Q2−3: Cis-Docetaxel; Q4: Docetaxel (D). PORT in pN2 patients. Analysis adjuvant CT toxicity profile (CTC-AE) and treatment compliance between arms.

Results: 461 included p; 108 control arm, 353 experimental arm. mRNA BRCA1 expression: Q1 162, Q2−3 98, Q4 93. M/F ratio: 82.5/17.5%. Median age: 62 (range 36−80). PS 0/1/2: 55.9/43.1/1%. Histology: Adenocarcinoma 47.5%, Squamous 44.1%. Stages: IIA/IIB/IIIA: 11.1/38.4/50.2%. Surgical procedure: Lobectomy 72.1%; Pneumonectomy 27.9%. Overall low levels BRCA1: 43.8%. Toxicity/compliance assessed in 297 p. G3−4 AE: Neutropenic fever: CD 10% vs D 4.4% vs CG 0%. ($p = 0.0056$); Nausea/vomits: CG 11.1% vs CD 10.4% vs D 0%. ($p = 0.0198$); Hypersensitivity: D 5.97% (NS). Dose-reduction: 34.24% control vs 18.30% experimental ($p = 0.0044$). Full 4 cycles CT compliance: CD control 80.83%, CG 91.2%, CD experimental 79.2%, D 88.1% ($p = 0.052$). PORT compliance 55.31% of planned cases.

Conclusions: Majority of resected NSCLC showed low levels expression BRCA1. Safety profiles differences observed between treatment schedules: neutropenic fever (CD), nausea/vomits (CG). Customized treatment requires less dose-reductions. Trend to poor compliance with Cis-Doc. Low compliance for PORT.

No conflict of interest.

Resistance training in patients with radically treated respiratory cancer: A prospective randomized multi-center study (REINFORCE)

J. Van Meerbeeck[1], B. Salhi[2], C. Haenebalcke[3], S. Perez-Bogerd[4], M.D. Nguyen[5], T. Malfait[2], K.F. Vermaelen[2], V.F. Surmont[2], G. Van Maele[6], E. Derom[2]. *[1]UZA, MOCA-Thoracic Oncology Multidisciplinary Oncological Center Antwerp, Edegem, Belgium; [2]Ghent University Hospital, Respiratory Medicine, Ghent, Belgium; [3]AZ St Jan, Respiratory Medicine, Bruges, Belgium; [4]CHU Sart Tilman, Respiratory Medicine, Liège, Belgium; [5]CHU St Pierre, Respiratory Medicine, Brussels, Belgium; [6]Ghent University, Biostatistical Unit, Ghent, Belgium*

Background: Patients with respiratory cancer improve their post-radical treatment exercise capacity, muscle strength and quality of life (QOL) by conventional resistance training (CRT). Whole body vibration (WBV) is proposed as an alternative to CRT.

Aim: To investigate by a RCT with a 2-tier design, the effect of radical treatment and of 2 post-treatment resistance training programs on functional and maximal exercise capacity, muscle strength and QoL, as measured respectively by the 6 minutes walking distance (6MWD), Wmax, Quadriceps Force (QF), and scores for physical functioning (PF), fatigue (F), pain (P) and dyspnoea (D).

Methods: Patients with clinical stage I−IIIB (non-)small cell lung cancer (N- SCLC) or I−II mesothelioma were evaluated before (M1) and after (M2) completion of either radical surgery (RS) +/− platin-based chemotherapy (PCT) or radiotherapy (RT) or RT +/− PCT, and were randomized to either to usual care (UC), CRT or WBV. 6MWD (primary endpoint), Wmax, QF and PF, F, P and D were measured at M1, M2 and 12 weeks (w) after intervention (M3). A minimal clinical important difference (MCID) in 6MWD was considered 54 m. Within and in-between treatment arm changes in 6MWD were estimated using a linear and logistic regression model.

Results: Of the 121 patients evaluated at M1, 70 were randomized to UC: n = 24, CRT: n = 24 and WBV: n = 22. M1-characteristics were well balanced: male 73%, median age 62 y (29−79); median BMI 25 kg/m^2 (16−42); 40% had COPD, 91% NSCLC and 60% stage I−II. 48% had RS and 6% RT as sole therapy, 46% a combination of RS or RT with PCT and/or PORT; 19% had a pneumonectomy. A median of 28 CRT-sessions (10−36) and 23 WBV-sessions (0−37) were attended with a median M2-M3 interval of 14 w (9−30). Radical treatment significantly decreased all variables at M2: Δ6MWD: 20 m (−295–130); ΔWmax: −18 Watt (−119−34); ΔQF: −12 Nm (−117–102); ΔPF: −7 points (−60−40); ΔF: 2 points (−29−30), ΔP: 1 point (−8−8) and ΔD: 1 point (−7−8), $p < 0.05$ to M2. 6MWD at M3 increased with 95 m (58–132) in CRT ($p < 0.0001$), 37 m (−1−76) in WBV ($p = 0.06$) and 1 m (−34−36) in UC (CRT vs. UC $p = 0.0006$ and WBV vs. UC $p = 0.16$). A significant increase of Wmax and PF in both CRT and WBV

was seen at M3 ($p < 0.05$). Only QF increased significantly ($p = 0.0009$) after CRT and D significantly decreased in WBV patients ($p = 0.009$). M3 values did not significantly exceed M1 ones with either intervention. In multivariate analysis, RS was independently associated with the likelihood to reach the MCID of 6 MWD (OR: 15.6 (1.87 −129, 8) ($p = 0.011$).
Conclusions: Exercise capacity, muscle strength and QOL significantly decrease by any radical treatment and are restored by resistance training. WBV does not substitute for CRT. Surgically treated patients benefit most. CRT should be offered to patients with radically treated lung cancer and mesothelioma. Supported by a research grant of IWT-TBM the Clinical Research Fund of Ghent University Hospital). (clintrials.gov NCT00752700)

Radical surgery as treatment option in advanced NSCLC − a retrospective analyses of 80 NSCLC patients of the TYROL lung cancer registry

G. Gamerith[1], T. Mommertz[1], A. Amann[1], J. Huber[1], T. Schmid[2], M. Nevinny[3], W. Hilbe[1], M. Fiegl[1]. *[1]Innsbruck Medical University, Department of Internal Medicine V Hematology and Oncology, Innsbruck, Austria; [2]Innsbruck Medical University, Department of Visceral and Thoracic Surgery, Innsbruck, Austria; [3]Innsbruck Medical University, Department of Radiooncology, Innsbruck, Austria*

Introduction: In various advanced tumors (e.g. melanoma, colorectal carcinoma, sarcoma), metasasectomy is part of standard treatment for selected patients. The clinical significance of metastasectomy in advanced non-small-cell lung cancer (NSCLC) is still unclear, and scientific evidence is limited. We present a retrospective analysis in 80 advanced NSCLC patients, who underwent radical metastasectomy in an either synchronous or metachronous setting.
Methods: In the TYROL (Twenty Years Retrospective of Lung) Cancer Registry, >2500 lung cancer cases are documented, and 80 patients were subjected to radical surgery in an advanced stage of disease. Using SPSS statistics, clinical characteristics were analyzed descriptively, and outcome in stratified subgroups was calculated by event-time analyses.
Results: 58 patients (73%) were male; at time of palliative surgery, median age was 62 years (range: 36−82). 24/44 evaluable cases were smokers (55%), 10/44 former smokers (23%), and 3/44 never smokers (7%). 37/48 (77%) were in favorable ECOG PS 0−1. Histologically, 41/80 patients had adenocarcinoma (51%), 21 (26%) squamous, 7 adenosquamous (9%) and 11 (14%) other carcinoma. 37/80 (46%) had surgery, the rest combined modality treatment (20 chemotherapy, 12 radiotherapy, 11 chemo- & radiotherapy). 28 (35%) underwent radical resection of primary tumor and limited metastasis ('synchronous'), whereas 52 (65%) had later resection of metastasis ('metachronous': singular pulmonal [n = 17]; pulmonal & mediastinal [12]; brain [12]; 5 renal/suprarenal [5]; liver, chest wall, soft tissue [2 each]). At last follow-up, 46 were dead (58%). Median PFS and OS from palliative resection were 12.1 months and 33.4 months, respectively. In patients with metachronous metastasectomy, PFS was inferior if the interval was <2 years from primary surgery (5.9 vs. 37.9 months; $p < 0.001$) and anemia was present (5.1 vs. 14.9 months, $P = 0.001$). Likewise, OS was inferior in case of an interval <2 years (20.7 vs. 57 months; $p = 0.002$) and anemia (12.6 vs. 33.4 months, $p < 0.001$).
Conclusion: In selected patients with advanced NSCLC, radical surgery might be an attractive option. Especially patients with a long disease free interval from first treatment to progression and without anemia benefited.

Evaluation of protein expression by immunohistochemistry in non-small cell lung cancer (pharmacogenoscan study)

A.C. Toffart[1], J.F. Timsit[2], P.J. Souquet[3], P. Merle[4], D. Moro-Sibilot[1], M. Perol[5], B. Mastroianni[6], N. Girard[6], C. Brambilla[1], E. Brambilla[7]. *[1]Centre Hospitalier Universitaire A. Michallon, Thoracic Oncology Unit, Grenoble, France; [2]Centre Hospitalier Universitaire A. Michallon, Medical Intensive Care Unit, Grenoble, France; [3]Centre Hospitalier Lyon Sud Hospices Civils de Lyon, Respiratory Medicine Service, Pierre Bénite, France; [4]Centre Hospitalier Universitaire G. Montpied, Respiratory Medicine − Thoracic Oncology Unit, Clermont Ferrand, France; [5]Hôpital Croix Rousse Hospices Civils de Lyon, Thoracic Oncology Unit, Lyon, France; [6]Hôpital Louis Pradel Hospices Civils de Lyon, Respiratory Medicine Service, Lyon, France; [7]Centre Hospitalier Universitaire A. Michallon, Department of Pathology, Grenoble, France*

Background: Platinum-based chemotherapy regimens are the standard treatment of metastatic non-small cell lung cancer (NSCLC). In this study, our objective was to identify proteic biomarkers that may predict a benefit from these treatments.
Methods: The 'Pharmacogenoscan' study (NCT 00222404) included 537 patients with chemotherapy-naive NSCLC from each stage between 2005 and 2010 in 6 hospitals in the Rhône-Alpes-Auvergne region in France. We collected tumor tissue samples and evaluated the expression by immunohistochemistry (IHC) of 8 biomarkers: ERCC1, BRCA1, p53, $p27^{kip1}$, class III β-tubulin (TUBB3), Bax, Fas and FasL. High and low expression marker status was determined by the median of intensity x positivity rate score for each protein. Results were correlated with objective tumor response after 2 or 3 cycles of platinum-based chemotherapy using standard RECIST criteria, progression-free survival (PFS) and overall survival (OS). Given the number of statistical tests, the Bonferroni correction was used.
Results: Two hundred twenty nine patients had a suitable tumor tissue specimen for evaluating the expression of at least one biomarker. Only TUBB3 expression levels were significantly higher in adenocarcinoma tumors ($p=8.10^{-4}$). Tumors with under-expression of ERCC1 were more frequently metastatic (ns). No significant association was found between the level of biomarkers' expression and tumor response or survival (PFS or OS). However, patients with TUBB3-negative and FasL-negative tumors had a tendency towards a better response to platinum-based chemotherapy with respectively 89% vs. 79% objective response rate (ORR) in the TUBB3-positive group (ns) and 90% vs. 81% ORR in the FasL-positive group (ns).
Conclusion: Immunohistochemical biomarkers cannot be recommended as predictors of response to chemotherapy. Our negative results on a large cohort do not allow assigning any prognostic or predictive role of these biomarkers.
No conflict of interest.

Does KRAS mutation status predicts for chemoresistance in advanced non-small cell lung cancer (NSCLC)?

M. Macerelli[1], L. Faivre[2], B. Besse[3], D. Planchard[3], C. Caramella[4], V. Polo[5], J.P. Pignon[2], J.C. Soria[3]. *[1]Azienda Ospedaliero-Universitaria Santa Maria della Misericordia, Department of Medical Oncology, Udine, Italy; [2]Institut Gustave Roussy, Department of Biostatistics and Epidemiology, Villejuif, France; [3]Institut Gustave Roussy, Department of Cancer Medicine, Villejuif, France; [4]Institut Gustave Roussy, Department of Radiology, Villejuif, France; [5]Istituto Oncologico Veneto, Department of Second Medical Oncology, Padova, Italy*

Background: Clinical implications of KRAS mutation status in advanced NSCLC remain unclear. While K-RAS mutation seems to be correlated with resistance to EGFR TKI, its predictive value regarding efficacy of chemotherapy (CT) is debated. We retrospectively explored whether KRAS mutations could impact on tumor response during first line platinum-based CT as well as on progression-free survival (PFS) and overall survival (OS).
Methods: Between June 2009 and June 2012, 340 patients with advanced (stage IIIB/IV) NSCLC were retrospectively reviewed in a single institution (Institut Gustave Roussy). Two hundred and one patients had a biomolecular profile and a platinum-based first line CT. Patients with an unknown mutational status or with actionable abnormalities (i.e. EGFR, PI3K, HER2, BRAF, FGFR4, ERBB4, PTEN, NRAS, and STK11 mutations; as well as HER2, FGFR1, and MET amplification; ALK translocation), were excluded. We retained two groups: patients with an exclusive KRAS mutation (MUT) and patients with wild type KRAS and wild-type EGFR (WT). Multivariate analyses with logistic or Cox model were used.
Results: One hundred and eight patients were studied: 39 in MUT group and 69 in WT group. Radiological presentation before 1st line chemotherapy demonstrated an excess of brain and liver metastases in MUT patients (33% vs. 13%, $p = 0.01$; 21% vs. 7% $p = 0.04$, Fisher). The disease control rate (DCR) of 1st line CT was 76% for MUT vs. 91% for WT group ($p = 0.04$, in uni and multivariate analysis), with no difference for type of platinum-based CT (use of pemetrexed or not). In second line setting, no statistically significant difference was observed on DCR ($p = 0.32$) between MUT and WT. At 24 months there was no statistically significant difference in PFS (4.8 vs. 7.3 months; $p = 0.27$) and in OS (10.3 vs 13.2 months; $p = 0.37$) between MUT and WT in uni and multivariate analysis.
Conclusion: KRAS mutant cancer is probably a different disease with greater incidence of hepatic and cerebral metastasis in advanced setting. KRAS mutant patients showed a lower DCR rate in 1st line platinum-based CT (independently of pemetrexed use or not), but this small difference did not translated in a PFS or OS difference in multivariate analysis.
No conflict of interest.

Clinical activity, safety and biomarkers of PD-L1 blockade in non-small cell lung cancer (NSCLC): Additional analyses from a clinical study of the engineered antibody MPDL3280A (anti-PDL1)

J.C. Soria[1], C. Cruz[2], R. Bahleda[3], J.P. Delord[4], L. Horn[5], R.S. Herbst[6], D. Spigel[7], A. Mokatrin[8], G. Fine[9], S. Gettinger[6]. [1]*Institut Gustave Roussy, Medical Oncology, Villejuit, France;* [2]*Vall d'Hebron University Hospital, Medical Oncology, Barcelona, Spain;* [3]*Institut Gustave Roussy, Department of Medicine, Villejuit, France;* [4]*Institute Claudius Regaud, Department of Medicine, Toulouse, France;* [5]*Vanderbilt University Medical Center, Department of Medicine, Nashville, USA;* [6]*Yale School of Medicine, Medical Oncology, New Haven, USA;* [7]*Sarah Cannon Research Institute, Medical Oncology, Nashville, USA;* [8]*Genentech Inc., Biostatistics, South San Francisco, USA;* [9]*Genentech Inc., BioOncology, South San Francisco, USA*

Background: Mutational complexity may be associated with increased tumor immunogenicity. In lung cancer, the antitumor immune response may be inhibited by PD-L1 expression. MPDL3280A, a human monoclonal Ab containing an engineered Fc-domain designed to optimize efficacy and safety, aims to restore tumor-specific T-cell immunity by blocking PD-L1 from binding to its receptors, including PD-1 and B7.1.
Materials and Methods: Pts with squamous or nonsquamous NSCLC received MPDL3280A IV q3w in a Ph I expansion study. Pts were treated for up to 1 y. Objective response rate (ORR) was assessed by RECIST v1.1. Reported ORR includes u/cCR and u/cPR. Cigarette smoking history was captured at baseline.
Results: As of Feb 1, 2013, 53 NSCLC pts were evaluable for safety and treated at doses of 0.03 (n = 1), 1 (n = 1), 10 (n = 10), 15 (n = 19) and 20 mg/kg (n = 22). Pts received treatment for a median duration of 106 days (range 1–450) of MPDL3280A. The incidence of all G3/4 AEs, regardless of attribution, was 34%, including pericardial effusion (6%), dehydration (4%), dyspnea (4%) and fatigue (4%). No G3−5 pneumonitis or diarrhea was reported. 37 NSCLC pts enrolled prior to Jul 1, 2012, were evaluable for efficacy. An ORR of 24% (9/37) was observed in pts with squamous and nonsquamous histologies with a duration of response range of 1+ to 214+ days. All responses were ongoing or improving. Additional pts had delayed responses after apparent radiographic progression (not included in the ORR). The 24-week PFS was 46%. Analysis of biomarker data from archival tumor samples demonstrated a correlation between PD-L1 status and efficacy. Pts with PD-L1-positive tumors showed an ORR of 100% (4/4), while pts who were PD-L1 tumor status-negative had an ORR of 15% (4/26). 84% (31/37) of pts were either former or current smokers, and 16% (6/37) of pts were never smokers. The response rate in the former or current smokers group was 25% (8/31) versus 16% (1/6) in the never smoker group. The median pack year history was 15 pack years for responders versus 5 pack years for pts with PD as best overall response. Updated data will be presented.
Conclusions: Treatment with MPDL3280A was well tolerated, with no pneumonitis-related deaths. Rapid and durable responses were observed, and PD-L1 tumor status correlated with response to MPDL3280A. In addition, preliminary data suggest that the number of responders was numerically higher for former/current smokers versus never smokers.

KG, Oncology, Biberach, Germany;* [3]*ICO-R Gauducheau, Medical Oncology, St Herblain, France;* [4]*St Petersburg State Medical University, Thoracic Oncology, St Petersburg, Russian Federation;* [5]*The Maria Slodowska-Curie Memorial Institute of Oncology, Chest & Thoracic Tumours, Warsaw, Poland;* [6]*Asklepios Fachkliniken München Gauting, Pneumology Clinic, Gauting, Germany;* [7]*Meir Medical Center, Lung Cancer Unit, Kfra Saba, Israel;* [8]*Boehringer Ingelheim Pharmaceuticals Inc, Clinical Development Oncology, Ridgefield, USA;* [9]*Boehringer Ingelheim Pharma GmbH & Co.KG, Global BCA Clinical Biostatistics, Biberach, Germany;* [10]*Lung Clinic Grosshansdorf GmbH, Oncology, Grosshansdorf, Germany*

Background: Nintedanib (N) is an oral inhibitor of VEGFR, FGFR, and PDGFR. LUME Lung 1, a placebo (P) controlled phase 3 trial investigated N + docetaxel (D) in locally advanced/metastatic NSCLC patients (pts) progressing after 1st line chemotherapy (NCT00806819).
Methods: Stage IIIB/IV or recurrent NSCLC pts were stratified by histology, ECOG PS, prior bevacizumab and brain metastases, randomized to N 200 mg bid + D 75 mg/m^2 q21d (n = 655) or P + D (n = 659) and treated until progression or unacceptable adverse events (AEs). 1º endpoint was centrally reviewed progression free survival (PFS) analysed after 714 events; the key 2º endpoint was overall survival (OS) analysed hierarchically after 1121 events first in adenocarcinoma (adeno) pts <9 mo since start of 1st line therapy (T<9 mo; identified as a predictive biomarker [ASCO 2013; ESMO 2013]), followed by all adeno pts and then all pts.
Results: 1,314 pts were recruited (658 adeno, 554 squamous, 102 other histology). Pt characteristics were balanced between the arms. N + D significantly prolonged median (m) PFS vs P + D regardless of histology (3.4 vs 2.7 mo, HR 0.79, 95% CI: 0.68–0.92, p = 0.0019) with a trend for improved mOS (10.1 vs 9.1, HR 0.94; CI: 0.83–1.05; p = 0.272). In adeno pts N + D (n = 322) significantly prolonged mOS vs P + D (n = 336) (12.6 vs 10.3 mo, HR 0.83; CI: 0.70–0.99; p = 0.0359). The treatment effect was observed early and was consistently maintained over time (Table). The greatest mOS improvement was observed in T<9 mo adeno pts randomised to N (n = 206) vs P (n = 199) (10.9 vs 7.9 mo, HR 0.75; CI: 0.60–0.92, p = 0.0073). Common non-haematologic AEs (N vs P) in adeno pts were diarrhea (any: 43.4 vs 24.6%; Gr⩾3: 6.3 vs 3.6%) elevated ALT (37.8 vs 9.3%; 11.6 vs 0.9%) and fatigue (30.9 vs 29.4%; 4.7 vs 4.2%). Incidence of CTCAE Gr⩾3 AEs was 75.9 vs 68.5%. Withdrawals due to AEs (20.9 vs 17.7%) were similar in both arms, as were Gr⩾3 hypertension, bleeding and thrombosis.
Conclusions: 2nd line treatment with N + D improved OS for adeno NSCLC pts significantly and consistently over time. AEs were generally manageable with dose reductions and symptomatic treatment.

Table: OS probabilities in adeno pts over time

Time since study start (mo)	N + D (n = 332)			P + D (n = 336)		
	n at risk*	n (%) events*	OS probability	n at risk*	n (%) events*	OS probability
6	230	86 (26.7)	0.729	219	99 (29.5)	0.692
12	163	149 (46.3)	0.527	139	176 (52.4)	0.447
18	113	196 (60.9)	0.374	88	223 (66.4)	0.293
24	72	231 (71.7)	0.257	55	253 (75.3)	0.191

MARQUEE: A randomized, double-blind, placebo-controlled, phase 3 trial of tivantinib (ARQ 197) plus erlotinib versus placebo plus erlotinib in previously treated patients with locally advanced or metastatic, non-squamous, non-small-cell lung cancer (NSCLC)

G. Scagliotti[1], S. Novello[1], R. Ramlau[2], A. Favaretto[3], F. Barlesi[4], W. Akerley[5], J. Von Pawel[6], D. Shuster[7], B. Schwartz[8], A. Sandler[9]. [1]*University of Turin San Luigi Hospital, Oncology Department, Orbassano (Turin), Italy;* [2]*Poznan University of Medical Sciences, Oncology Department, Poznan, Poland;* [3]*Istituto Oncologico Veneto IOV IRCCS, Medical Oncology Department, Padua, Italy;* [4]*Aix Marseille University Assistance Publique Hopitaux de Marseille, Oncology Department, Marseille, France;* [5]*Huntsman Cancer Institute The University of Utah School of Medicine, Department of Medicine, Salt Lake City, USA;* [6]*Asklepios Fachkliniken München-Gauting, Oncology Department, Gauting, Germany;* [7]*Daiichi Sankyo Inc., Clinical Development Oncology, Parsippany, USA;* [8]*ArQule Inc., Clinical Development, Woburn, USA;* [9]*Oregon Health & Science University, Hematology/Oncology, Portland, USA*

Background: In a randomized phase 2 study, the combination of tivantinib (T), a selective MET inhibitor, plus erlotinib (E) improved progression-free survival (PFS) and overall survival (OS) compared with placebo (P) plus E in the subset of patients with nonsquamous histology, a population enriched for MET overexpression.
Material and Methods: Patients with locally advanced or metastatic nonsquamous NSCLC previously treated with 1 or 2 lines of systemic therapy, including a platinum-doublet, were stratified by number of prior

therapies, sex, smoking history, and *EGFR* and *KRAS* mutation status, then randomized (1:1) to oral T (360 mg twice daily) + E (150 mg once daily) or P+E until disease progression. Prior treatment with an EGFR inhibitor was not allowed. The primary endpoint was OS, with 1 interim analysis and stopping boundaries for futility and superiority. Secondary and exploratory objectives included PFS, OS in molecular subgroups, and safety.
Results: From Jan 2011 to Jul 2012, 1048 patients were randomized to T+E (n = 526) or P+E (n = 522). Baseline characteristics included median age of 62 y (range, 24−89 y), prior therapies =1 (66%) or 2 (34%), ECOG performance status of 0 (32%) or 1 (68%), *EGFR* mutant (10.4%), and *KRAS* mutant (27.1%), and were well balanced between arms. In Sep 2012, the independent data monitoring committee recommended trial discontinuation because the pre-planned interim analysis crossed the futility boundary. At the Dec 2012 data cutoff, median OS was 8.5 mo (95% confidence interval [CI], 7.1−9.3 mo) in the T+E arm and 7.8 mo (95% CI, 7.0−9.0 mo) in the P+E arm (hazard ratio [HR]=0.98; 95% CI, 0.84–1.15; $P = 0.81$). Median PFS was 3.6 mo (95% CI, 2.8−3.7 mo) in the T+E arm and 1.9 mo (95% CI, 1.9−2.0 mo) in the P+E arm (HR = 0.74; 95% CI, 0.62–0.89; $P < .0001$). Overall response rate (ORR) improved to 10.3% in the T+E arm compared with 6.5% in the P+E arm ($P < .05$). Common adverse events (T+E arm vs P+E arm, respectively) included rash (33.1% vs 37.3%), diarrhea (34.6% vs 41.0%), and asthenia/fatigue (43.5% vs 38.1%), which occurred at similar rates between treatment arms; neutropenia (Grade 3/4: 10.0% vs 1.0%) was more common with tivantinib.
Conclusions: Addition of tivantinib to erlotinib did not achieve the primary endpoint of improved OS. However, the combination is well tolerated and biologically active with substantial improvement in PFS and ORR. Analysis of molecular subgroups, including MET expression, is ongoing.

Safety and efficacy profile of crizotinib in the French Temporary Authorization for Use (ATU) of crizotinib in patients (pts) with ALK-positive (+) advanced NSCLC

M. Perol[1], J. Cadranel[2], D. Planchard[3], E. Dansin[4], L. Bigay-Game[5], C. Audigier-Valette[6], A. Scherpereel[7], A. Buturuga[8], D. Moro-Sibilot[9], B. Besse[3]. *[1]Centre Leon Bérard, Pneumologie, Lyon, France; [2]Hôpital Tenon, Pneumologie and GRC-04 Theranoscan, Paris, France; [3]Institut Gustave Roussy, Innovations Thérapeutiques Précoces, Villejuif, France; [4]Centre Oscar Lambret, Medical Oncology, Lille, France; [5]University Hospital Larrey, Pneumologie, Toulouse, France; [6]Centre Hospitalier de Toulon, Pneumologie, Toulon, France; [7]University Hospital of Lille, Pneumologie, Lille, France; [8]Pfizer France, Medical Affairs, Paris, France; [9]CHU Grenoble, Thoracic Oncology Unit and INSERM U823, Grenoble, France*

Background: Crizotinib is a selective tyrosine kinase inhibitor of MET, ALK and ROS1 approved in the US on Aug 2011 for advanced ALK+ NSCLC and in Europe on Oct 2012 for previously treated advanced ALK+ NSCLC. The ATU program is an exceptional measure allowing drug availability before Marketing Authorisation Approval. We report the efficacy and safety data of crizotinib in ALK+ NSCLC pts included in a French ATU. ALK testing was performed by genetics platforms funded by French National Cancer Institute.
Methods: The ATU included pts not eligible for a clinical trial with advanced ALK+ NSCLC (assessed by FISH or immunohistochemistry [IHC]) or other ALK+ tumors. Pts received 250 mg bid crizotinib until disease progression or intolerance. The clinicians were asked to provide data on efficacy and tolerance of crizotinib every 3 months. Data cut-off for the present analysis was Oct 13th, 2012 for efficacy and demographic data and July 12th, 2012 for safety.
Results: From Dec. 1st, 2010 to Oct. 13th, 2012, 254 pts were included in the ATU, among whom 241 metastatic NSCLC pts with a median age of 57 (17−87). Baseline characteristics: 50.2% females, PS 0/1/2/3 (%): 30/46/16/8, 31% with brain metastases; 2%, 45%, 27%, 26% of pts received 0, 1, 2 and ⩾3 previous lines of therapy (up to 6), respectively. Discrepancies between IHC and FISH ALK tests were observed in 12 (7.5%) pts. Median duration of treatment for all pts (not mature) was 3.25 months (range 0.03 months − 14.0 months). 91 pts were assessable for response with CR: 4.4%, PR: 61.5%, SD: 29.7% and PD: 4.4%. 187 pts were assessable for toxicity. Most frequent reported AEs were visual disturbances (n = 15), neutropenia (n = 12), edema (n = 8), nausea (n = 8) and diarrhea (n = 7). Five serious AEs related to hepatitis were observed. Treatment was permanently discontinued for toxicity in 9 pts. Final safety and efficacy are being evaluated, including response rates for PS 3 pts, heavily pretreated pts and pts with brain metastases.
Conclusions: These interim results of efficacy and toxicity of crizotinib in ALK-positive advanced NSCLC patients in routine clinical practice do not differ from data previously reported in clinical trials. Updated results will be presented at the meeting.

3412 POSTER DISCUSSION

Impact of crizotinib on patient-reported general health status compared with single-agent chemotherapy in a phase III study of advanced ALK-positive non-small cell lung cancer (NSCLC)

F. Blackhall[1], V. Hirsh[2], D.W. Kim[3], B. Besse[4], H. Nokihara[5], J.Y. Han[6], K. Wilner[7], A. Reisman[8], S. Iyer[9], A. Shaw[10]. *[1]Christie Hospital NHS Foundation Trust, Department of Medical Oncology, Manchester, United Kingdom; [2]McGill University Health Centre, Department of Oncology, Montreal, Canada; [3]Seoul National University Hospital, Department of Internal Medicine, Seoul, South Korea; [4]Institut Gustave Roussy, Department of Cancer Medicine, Villejuif, France; [5]National Cancer Center Hospital, Division of Internal Medicine, Tokyo, Japan; [6]National Cancer Center, Center for Lung Cancer, Goyang, South Korea; [7]Pfizer Oncology, Medical Oncology, La Jolla, USA; [8]Pfizer Specialty Care, Statistics, New York, USA; [9]Pfizer Oncology, Health Economics and Outcomes, New York, USA; [10]Massachusetts General Hospital, Department of Thoracic Oncology, Boston, USA*

Background: The present analysis compares patient-reported general health status between crizotinib and standard-of-care chemotherapy (pemetrexed or docetaxel) in previously treated patients with advanced *ALK*-positive NSCLC.
Material and Methods: Patients in the ongoing PROFILE 1007 study (Pfizer; NCT00932893) were randomized to crizotinib (n = 172) or chemotherapy (n = 171). Patient-reported outcomes were assessed at baseline, on day 1 of each cycle, and at the end of treatment using EQ-5D, a standardized measure of health status that consists of a descriptive system comprising 5 dimensions: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression rated at 3 levels (no, some, or extreme problems) and a single index score for health status (range 0 [dead] to 1 [full health]) calculated using a standard algorithm. In addition, a visual analog scale (VAS) measured self-rated health status from '0' (worst imaginable) to '100' (best imaginable). Descriptive statistics were reported. Repeated measures mixed-effects analyses were performed to compare overall index and change from baseline VAS scores between the treatments, controlling for baseline.
Results: Completion rates at baseline were ⩾85% in each group. The mean (SD) scores at baseline were comparable between crizotinib and chemotherapy for the VAS (64.09 [21.04] vs 66.76 [20.74]) and the EQ-5D index scores (0.72 [0.25]) vs (0.69 [0.26]). The proportion of patients reporting the presence of a problem at baseline for crizotinib and chemotherapy, respectively, were: mobility (31% vs 32%), self-care (9% vs 14%), usual activities (51% vs 52%), pain (62% vs 67%), and anxiety/depression (49% vs 57%). The overall mean (SD) EQ-5D index scores on treatment were significantly greater ($p < 0.001$) for crizotinib (0.82 [0.01]) compared with chemotherapy (0.73 [0.02]). A statistically significant ($p < 0.05$) improvement in VAS score was observed early and maintained (cycles 2−15) in the crizotinib arm compared with no significant change in the chemotherapy arm. A significantly greater overall improvement from baseline was observed in VAS scores in the crizotinib arm compared with chemotherapy (4.68 vs −6.06; $p < 0.001$).
Conclusion: Treatment with crizotinib leads to a significantly greater improvement in general health status compared with chemotherapy in previously treated patients with advanced *ALK*-positive NSCLC.

3413 POSTER DISCUSSION

Clinical experience with crizotinib in patients (pts) with advanced ALK+ non-small cell lung cancer (NSCLC) and brain metastases

L. Crinò[1], M.J. Ahn[2], S.H.I. Ou[3], B.J. Solomon[4], D.B. Costa[5], S.M. Shreeve[6], R. Wiltshire[7], P. Selaru[8], C. Zhou[9], G.J. Riely[10]. *[1]Azienda Ospedaliera di Perugia, S.C. di Oncologia Medica, Perugia, Italy; [2]Sungkyunkwan University School of Medicine, Samsung Medical Center, Seoul, South Korea; [3]University of California at Irvine School of Medicine, Chao Family Comprehensive Cancer Center, Irvine, USA; [4]Peter MacCallum Cancer Centre, Medical Oncology, Melbourne, Australia; [5]Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, USA; [6]Pfizer Oncology, Medical Oncology, La Jolla, USA; [7]Pfizer Oncology, Medical Oncology, Tadworth, United Kingdom; [8]Pfizer Oncology, Statistics, La Jolla, USA; [9]Shanghai Pulmonary Hospital, Department of Oncology, Shanghai, China; [10]Memorial Sloan-Kettering Cancer Center, Department of Medicine, New York, USA*

Background: Crizotinib is an oral tyrosine kinase inhibitor targeting ALK and is approved in several countries for the treatment of advanced *ALK+* NSCLC. PROFILE 1005 (NCT00932451; Pfizer) is a large ongoing global open-label, single-arm phase II study of crizotinib in pts with *ALK+* NSCLC who have received ⩾1 treatment regimen for advanced/metastatic disease. PROFILE 1007 (NCT00923893; Pfizer) is a global randomized phase III study that compared crizotinib with standard chemotherapy as second-line therapy for advanced *ALK+* NSCLC (Shaw et al, ESMO 2012). To evaluate the clinical outcomes of pts with brain metastases on crizotinib, we conducted a retrospective analysis of pooled data from these studies.
Materials and Methods: Pts with previously treated advanced *ALK+* NSCLC enrolled in either PROFILE 1005 or PROFILE 1007 (and randomized to crizotinib) were included in this analysis. Baseline (BL) brain imaging was required in both studies, and if brain metastases were detected, subsequent brain imaging was required at 6-week intervals. Otherwise, imaging to assess brain metastasis on treatment was performed as clinically indicated. Tumor assessments were evaluated by investigators based on RECIST. The starting dose of crizotinib was 250 mg BID. Three subgroups of pts were evaluated: those with untreated (no prior radiotherapy) asymptomatic brain metastases at BL, those with previously treated asymptomatic brain metastases at BL, and those without detectable brain metastases at BL.
Results: Of 980 pts included in this analysis, 120 had untreated asymptomatic brain metastases at BL. Among these 120 pts, 112 were evaluable for systemic response, 111 for intracranial (IC) response, and 109 for both types of response. 6/111 had complete IC responses and 4/111 had partial IC responses, for an IC ORR of 9%; 78/111 pts (70%) had stable IC disease (SICD). The systemic ORR was 41% (46/112). 54/109 pts had IC responses that matched or exceeded their systemic response. 42/109 pts (39%) had a better systemic than IC response, of whom 27/42 (64%) had SICD ⩾3 months. Additional data on pts with IC responses (e.g., the number, size, and location of lesions) and summaries of pt subgroups with untreated, treated, or no brain metastases at BL will be presented.
Conclusions: Crizotinib appeared to provide clinical benefit in pts who had untreated asymptomatic brain metastases at BL, with an IC disease control rate of nearly 80% in evaluable pts.

3414 POSTER DISCUSSION

Pooled analysis of the European (EUR) and Chinese (Ch) BRCA1-RAP80 Expression Customization (BREC) randomized trials of customized therapy in advanced non-small-cell lung cancer (NSCLC) patients (p) (NCT00617656/GECP-BREC and ChiCTR-TRC-12001860)

R. Rosell[1], B. Liu[2], M. Cobo[3], J. Wei[2], M. Domine[4], X. Qian[2], M. Sánchez-Ronco[5], Z. Zou[2], B. Massuti[6], A. Vergnenegre[7]. *[1]Catalan Institute of Oncology Hospital Universitari Germans Trias i Pujol, Oncology, Badalona (Barcelona), Spain; [2]Drum Tower Hospital, Oncology, Nanjing, China; [3]Hospital Carlos Haya, Oncology, Malaga, Spain; [4]Fundación Jiménez Diaz, Oncology, Madrid, Spain; [5]Alcalá de Henares University, Statistics, Madrid, Spain; [6]Hospital General de Alicante, Oncology, Alicante, Spain; [7]Hôpital du Cluzeau, Oncology, Limoges, France*

Background: Findings from the SLCG phase II customized chemotherapy trial (NCT00883480) showed that RAP80, a component of the BRCA1 complex, influenced outcome both in p with low BRCA1 expression treated with cisplatin (cis)/gemcitabine (gem) and in p with intermediate/high BRCA1 levels treated with cis/docetaxel (doc) or with doc alone. Together with the French Lung Cancer Group, the SLCG performed a prospective, randomized phase III trial comparing non-customized cis/doc with customized therapy in metastatic NSCLC p. A parallel phase II study was carried out in China under the auspices of the SLCG.
Material and Methods: Randomization to the control or experimental arm was 1:1 in the EUR and 1:3 in the Ch trial. p in the control arm receive cis/doc; p in the experimental arm received treatment according to their BRCA1 and RAP80 levels: p with low RAP80, regardless of BRCA1 levels, cis/gem; p with intermediate/high RAP80 and low/intermediate BRCA1, cis/doc; p with intermediate/high RAP80 and high BRCA1, doc alone. The primary endpoint was progression-free survival (PFS).
Results: 382 p are evaluable for PFS and overall survival (OS). PFS was 5.46 months (m) in the control and 3.91 m in the experimental arm (P = 0.08). OS was 11.91 m in the control and 9.64 m in the experimental arm (P = 0.05). Response rate was 34.9% in the control and 28.9% in the experimental arm (P = 0.23). In the multivariate analysis including PS, treatment arm, BRCA1, RAP80, histology, smoking status and metastatic site, only treatment with doc alone was associated with an increased risk of progression (HR, 2.15; P<0.001).
Conclusions: Negative results may be due to the poor predictive capacity of RAP80 and the inclusion of doc alone as a treatment in the experimental arm. In addition, doc/cis may not be the ideal combination for the control arm.
No conflict of interest.

3415 POSTER DISCUSSION

GAIN-(L): Efficacy, safety and biomarker analysis of RG7160 (GA201), a novel dual-acting monoclonal antibody (mAb) designed to enhance antibody-dependent cellular cytotoxicity (ADCC), in combination with 1st line cisplatin and pemetrexed in metastatic non-squamous NSCLC

L. Paz-Ares[1], E. Calvo[2], E. Kalinka-Warzocha[3], F. Cappuzzo[4], J. Corral[1], C. Guizani[5], S. Golding[6], A. Passioukov[7], M.G. Ott[5]. *[1]Hospital Universitario Virgen del Rocio, Servicio de Oncología, Seville, Spain; [2]START Madrid, Centro Integral Oncologico Clara Campal, Madrid, Spain; [3]Wojewodzki Szpital, Regional Oncology Center, Lodz, Poland; [4]Istituto Toscano Tumori Ospedale Civile, Department of Oncology, Livorno, Italy; [5]F.Hoffmann-La Roche Ltd., Oncology Early Development, Basel, Switzerland; [6]F.Hoffmann-La Roche Ltd., Biostatistics, Basel, Switzerland; [7]F.Hoffmann-La Roche Ltd., Oncology Early Development, Schlieren, Switzerland*

Background: GA201, a humanized, engineered IgG1 anti-Epidermal Growth Factor Receptor (EGFR) mAb designed to enhance ADCC, has shown promising clinical activity in phase I and in the neoadjuvant treatment of head and neck cancer. This phase II study (NCT01185847) aimed to demonstrate evidence of superior activity of GA201 added to cisplatin and pemetrexed versus chemotherapy alone in terms of PFS in non-squamous NSCLC.
Methods: In this open-label, multicenter, phase II study, non-squamous NSCLC patients (pts) who had not received prior chemotherapy were randomized (2:1) to treatment arm A to receive GA201 (1400 mg IV on day 1 and 8 then q2-weekly) in combination with cisplatin (75 mg/m^2 IV) and pemetrexed (500 mg/m^2 IV) on day 1 q3-weekly for a maximum of 6 cycles followed by GA201 monotherapy until progression or withdrawal, or arm B to receive chemotherapy alone. Data cut off was 9 months after enrolling the last patient.
Results: 41 pts (15 female) and 21 pts (3) with performance status 0−1 were enrolled in arms A and B respectively. PFS HR was 0.92 (95% CI 0.51, 1.66) for 77% of events. Median PFS (Investigator reported) was

5.4 months (95% CI 4.1, 6.5) in arm A versus 6.0 (95% CI 3.7, 8.1) in arm B. Consistent results were observed with independent review. Median overall survival (OS) (52%) was 9.0 months (95% CI 6.6, 13.5) in arm A versus 11.1 (95% CI 9.0,·) in arm B. Most common adverse events (AEs − all grades) included rash (85% in arm A and 19% in arm B), hypomagnesaemia (63 and 19% respectively), nausea (54 and 52% respectively) and infusion-related reactions (49% in arm A only). AEs of ⩾ grade 3 included rash (49% in arm A only), neutropenia (22 and 33% respectively), hypomagnesaemia (15 and 5% respectively), fatigue (15% in arm A only), infusion-related reactions (7% in arm A only) and pulmonary embolism (7 and 5% respectively). Median time to improvement of rash grade 3 was 15 days (range 3−37). AEs led to treatment discontinuation for 24% of pts in arm A (15% discontinued for rash) and 10% in arm B. Analysis of immune cell densities in the tumor at baseline showed a potential positive correlation of CD16+CD3 cells with improved OS.

Conclusion: The study was negative with respect to the primary efficacy endpoint (PFS). In a recent updated analysis of OS, 12 pts (29%) are censored in the GA201 arm with survival times of 13−20 months. Biomarker analysis showed encouraging data for CD16+CD3 combination associated with GA201 clinical efficacy.

3416 POSTER DISCUSSION

Ganetespib in combination with docetaxel versus docetaxel alone in second line adenocarcinoma patients with KRAS mutations and elevated LDH levels

D.A. Fennell[1], G.D. Goss[2], Z. Andric[3], I. Bondarenko[4], B. Zaric[5], T. Ceric[6], E. Poddubskaya[7], F. Teofilovici[8], W. Guo[8], S. Ramalingam[9]. *[1]University of Leicester, Thoracic Medical Oncology, Leicester, United Kingdom; [2]The Ottawa Hospital Cancer Centre, Medical Oncology, Ottawa, Canada; [3]Clinical Hospital Centre Bezanijska kosa, Medical Oncology, Beograd, Serbia; [4]Municipal Institution Dnipropetrov, Medical Oncology, Dnipropetrov, Ukraine; [5]Institute for Pulmonary Diseases of Vojvodina, Medical Oncology, Novi Sad, Serbia; [6]Clinical Center University of Sarajevo, Medical Oncology, Sarajevo, Bosnia-Herzegovina; [7]Unit of Russian Academy of Medical Sciences, Medical Oncology, Moscow, Russian Federation; [8]Synta Pharmaceuticals, Medical Oncology, Lexington, USA; [9]Winship Cancer Institute of Emory University, Medical Oncology, Atlanta, USA*

Background: Heat shock protein 90 chaperone function is critical for the biological effects of many oncoproteins. Ganetespib (G) is a highly potent 2nd generation Hsp90 inhibitor with a favorable safety profile and synergistic activity with docetaxel (D) in NSCLC xenografts. G has shown single-agent clinical activity in NSCLC patients with tumors harboring ELM4-ALK translocations and KRAS mutations (mKRAS).

Methods: We conducted a randomized, international open-label study of D with or without G (Galaxy-1) in patients with advanced lung adenocarcinoma, one prior systemic therapy, and ECOG PS 0/1. D was given at 75 mg/m^2 on Day 1 of a three-week cycle in both arms. In the combination arm, G was given at 150 mg/m^2 on days 1 and 15. The co-primary endpoints were PFS in patients with elevated LDH (eLDH) levels, or tumors harboring KRAS mutation. Key secondary endpoints were OS and PFS in all adenocarcinoma patients. Target enrollment was 240 adenocarcinoma patients, including 120 eLDH and 80 mKRAS patients. Statistical tests are 1-sided.

Results: Enrollment of 254 adenocarcinoma patients, including 63 mKRAS and 77 eLDH patients, completed in November 2012; enrollment of mKRAS and eLDH patients continues in order to reach recruitment target. In all adenocarcinoma patients, baseline characteristics were balanced between the two arms (median age 60 years, males 57%, PS 0 41% and never-smokers 25%). Median number of cycles delivered were 5 and 4 for D+G and D, respectively. Grade 3/4 adverse events for the D+G and D alone arms were: neutropenia 38% vs. 37%; fatigue 4% vs. 3; anemia 7% vs. 6%; diarrhea 3% vs. 0; fever with neutropenia 8% vs. 2%.

At the time of abstract submission OS HR in the all adenocarcinoma population was 0.69 (90% CI 0.48 to 0.99, p = 0.093). In the mKRAS group OS HR was 0.63 (90% CI 0.31 to 1.28, p = 0.14), and in the eLDH group OS HR was 0.57 (90% CI 0.32 to 1.01, p = 0.05). The PFS HR in the all adenocarcinoma population was 0.70 (90% CI 0.53 to 0.94, p = 0.012). In the mKRAS group the PFS HR was 0.93 (90% CI 0.53 to 1.65, p = 0.58), and in the eLDH group PFS HR was 0.82 (90% CI 0.50 to 1.35, p = 0.75). Updated mKRAS and eLDH results, including ORR, PFS and OS, will be presented at the meeting.

Conclusions: Treatment with D+G showed a favorable safety profile. Encouraging survival improvement was observed in the combination arm in all adenocarcinoma patients, including mKRAS and eLDH patients.

3417 POSTER DISCUSSION

Key survival prognostic factors in NSCLC based on patient reported outcomes of global factors and thoracic symptoms using the LCSS: results of the 622 patient AP-QL trial

R.J. Gralla[1], P.J. Hollen[2], S. Thongprasert[3], H.K. Kim[4], Y. Shi[5], T.C. Hsia[6]. *[1]Albert Einstein College of Medicine Jacobi Medical Center, Medical Oncology, Bronx, USA; [2]University of Virginia, School of Nursing, Charlottesville, USA; [3]Maharaj Nakorn Chiang Mai Hospital, Medical Oncology, Chiang Mai, Thailand; [4]St. Vincent's Hospital, Medical Oncology, Suwon, South Korea; [5]Cancer Institute and Hospital Chinese Academy of Medical Sciences, Medical Oncology, Beijing, China; [6]China Medical University Hospital, Medical Oncology, Taichung, Taiwan*

Background: Reliable prognostic factors assist better trial design and appropriate personalization of care. Clinical factors and molecular testing are commonly used for these purposes but no patient reported outcome (PRO) is routinely used, as performance status is not patient rated.

Methods: This prospective study enlisted 622 patients receiving initial docetaxel-based chemotherapy (80% with cisplatin or carboplatin) and correlated PROs from an electronic LCSS format (eLCSS-QL) every 3 weeks with survival outcomes. The eLCSS-QL requires <3 minutes; it is simple and inexpensive to perform especially with electronic assistance and has high patient and staff acceptance.

Results: Survival and baseline PRO data were available for 96% of patients (70% male; 65% adenocarcinoma; medians: KPS = 90; ECOG = 1, with 27% having ECOG 0 PS); Stages: IV (72%), IIIB (28%). Survival: 12.8 months median; 52% at 1 year. Survival results were analyzed for differences in PRO scores at baseline, assessing survival according to whether patients scored baseline PROs at less than the median (negative finding) or greater than the median (positive finding) for the 3 NSCLC thoracic symptoms (dyspnea, cough, pain) and the 3 LCSS global items (see table). Survival differences for baseline PRO values above or below medians for each global item varied by about 4 months, while differences for the thoracic symptoms were about 2 months on average. Individual symptoms are found only in subsets of patients, while all patients have scores for global factors.

Parameter	Median value at baseline	Survival advantage if baseline value is above the median	p
Dyspnea	78%	2.1 Months	0.33
Cough	75%	1.3 Months	0.26
Pain	81%	2.6 Months	0.05
Symptom distress	68%	3.6 Months	<0.003
Quality of life	60%	4.3 Months	<0.003
Activity level	66%	4.4 Months	0.0006

Conclusions: PRO findings at baseline have strong predictive properties, with global items such as quality of life exceeding any thoracic symptom. An index of these PRO factors is now under analysis. For unselected patients, these parameters can equal or exceed prognostic separations identified by molecular alterations. These results show the value of PRO factors and the need for evaluating global factors as well as symptoms. Use of these factors can assist better trial design and analysis, and can aid in personalizing therapeutic decision making based on individual likelihood of risk and benefit.

3418 POSTER DISCUSSION

Retrospective evaluation of the futility analysis in LUME Lung 2, a randomized, double-blind, placebo-controlled phase 3 trial of nintedanib (BIBF 1120) in combination with pemetrexed in NSCLC patients progressing after one prior first line chemotherapy

N. Hanna[1], R. Kaiser[2], J.H. Kim[3], R. Sullivan[4], O. Aren[5], M.J. Ahn[6], B.J. Tiangco[7], I. Voccia[8], J. Barrueco[9], P. Glomb[10]. [1]*Indiana University, Medicine, Indianapolis, USA;* [2]*Boehringer Ingelheim Pharma GmbH & Co KG, Biberach, Oncology Germany;* [3]*Yonsei Cancer Center, Yonsei University College of Medicine, Medical Oncology;* [4]*Auckland District Health Board/Auckland University, Oncology, Auckland, New Zealand;* [5]*Instituto Nacional del Cancer, Medical Oncology, Santiago, Chile;* [6]*Samsung Medical Center, Medicine, Seoul, Korea;* [7]*National Kidney and Transplant Institute, Internal Medicine, Quezon City, The Philippines;* [8]*Boehringer Ingelheim (Canada) Ltd, Medical, Burlington, Canada;* [9]*Boehringer Ingelheim Pharmaceuticals Inc., Clinical Development Oncology, Ridgefield, USA;* [10]*Boehringer Ingelheim Pharma GmbH & Co KG, Global BCA, Clinical Biostatistics*

Background: LUME Lung 2 was a placebo (PB) controlled phase 3 trial (NCT00806819) of 2nd line nintedanib (N) + pemetrexed (PM) in patients (pts) with advanced/metastatic non-squamous NSCLC. Based on results of a planned futility analysis conducted by the Data Monitoring Committee (DMC), the trial was halted prior to planned completion (no safety concerns).
Methods: Pts with Stage IIIB/IV or recurrent NSCLC were randomised to N 200 mg po bid + PM 500 mg/m^2 iv q21d (n = 353) or PB + PM (n = 360). 1º endpoint was centrally reviewed progression free survival (PFS). The pre-planned DMC analysis used investigator reviewed PFS data (14 Mar 2011; 345 [48%] events) and met futility criteria as defined in the DMC charter. Based on the DMC recommendation to stop the study, ongoing pts were unblinded and follow-up was continued per amended protocol. Using the final study data (9 Jul 2012) a retrospective evaluation of statistical factors such as conditional and predictive power over time was performed for both investigator and centrally reviewed data.
Results: 713/1300 planned pts were entered. Pt characteristics were balanced. Analysis of the 1º endpoint (9 Jul 2012 data) showed a statistically significant improved PFS by central independent review favoring N + PM (median 4.4 vs 3.6 mo, HR 0.83; CI: 0.7–0.99, p = 0.0435). This was confirmed in a follow-up analysis (15 Feb 2013 data, median 4.4 vs 3.4 mo HR 0.84; CI: 0.7–1.00, p = 0.0506). Retrospective analysis of the statistical factors leading to the futility results confirmed that based on investigator reviewed PFS the criteria defined in the DMC charter were met at the time of the original DMC analysis (13.3% conditional and 21.6% predictive power). When analyzed at other times, however, these statistical measures remained above the pre-defined futility criteria. When centrally reviewed PFS was analysed over the same period of time, fluctuations in the statistical measures were noted but remained above the pre-defined futility criteria.
Conclusions: The 1º endpoint was met even though the study was stopped prior to planned completion. Retrospective investigations suggest that had the DMC analysis been performed at another time point or had centrally reviewed data been used, the outcome of the futility analysis may have been different. In general, futility analyses should be repeated at different time points during the study and potential discordances between investigator and centrally assessed PFS need to be considered.
No conflict of interest information specified.

Updated analysis and secondary endpoints with L-BLP25 in unresectable stage III non-small cell lung cancer in the phase III START study

F. Shepherd[1], M. Socinski[2], P. Mitchell[3], N. Thatcher[4], L. Havel[5], M. Krzakowski[6], S. Nawrocki[7], C. Helwig[8], A. Schroeder[9], C. Butts[10]. [1]*Princess Margaret Hospital, Department of Medical Oncology, Toronto, Canada;* [2]*UPMC Cancer Pavilion, Division of Hematology/Oncology, Pittsburgh, USA;* [3]*Austin Hospital, Medical Oncology Unit, Melbourne, Australia;* [4]*Christie Hospital NHS Trust, Department of Medical Oncology, Manchester, United Kingdom;* [5]*Klinika Pneumologie a Hrudní Chirurgie, 3. LF UK, Praha 8, Czech Republic;* [6]*Maria Curie-Sklodowska Memorial Institute, Department of Lung and Chest Cancers, Warsaw, Poland;* [7]*University of Warmia and Mazury, Department of Oncology, Olsztyn, Poland;* [8]*Merck KGaA, Global Biostatistics, Darmstadt, Germany;* [9]*Merck KGaA, Merck Serono Glob. Dev. & Medical, Darmstadt, Germany;* [10]*Cross Cancer Institute, Department of Oncology, Edmonton, Canada*

Background: START is a phase III trial of MUC1-specific cancer immunotherapy L-BLP25 in patients (pts) with stage III unresectable non-small cell lung cancer who did not progress after primary chemoradiotherapy (CRT). While the primary objective of overall survival (OS) prolongation was not met, pre-defined subgroup analyses revealed a clinically meaningful prolongation of OS in pts previously treated with concurrent CRT. Sensitivity analyses suggested the observed treatment effect was underestimated due to a clinical hold. L-BLP25 was well tolerated, with no safety concerns identified. Here we report pre-defined subgroup analyses for secondary endpoints. Updated OS data, available in Q3 2013, also will be presented.
Materials and Methods: From Jan 2007 to Nov 2011, 1513 patients with unresectable stage III NSCLC who did not progress after CRT were randomized (2:1; double-blind) to L-BLP25 (806 μg lipopeptide) or placebo (PBO) SC weekly x 8 then Q6 weeks until disease progression or withdrawal. Cyclophosphamide 300 mg/m^2 x 1 or saline was given 3 days prior to first L-BLP25/PBO dose. Primary endpoint was OS. Secondary endpoints were time to symptom progression (TTSP) (measured by the lung cancer symptom scale, LCSS) and time to progression (TTP).
Results: The primary analysis population (n = 1239) was defined prospectively to try to account for the clinical hold. L-BLP25 extended TTSP and TTP compared with PBO. Analyses of TTSP and TTP in pre-defined subgroups were conducted. In line with OS data, L-BLP25 treatment effects on TTSP and TTP were more pronounced in patients with prior concurrent (n = 806) vs. sequential (n = 433) CRT. For pts with concurrent CRT, TTSP was 16.4 m (L-BLP25) vs. 11.4 m (PBO) (HR 0.81, 95% CI 0.67–0.97, p = 0.023) whilst for pts with sequential CRT, TTSP was 12.3 m (L-BLP25) vs. 11.4 m (PBO) (HR 0.92, 95% CI 0.73–1.17, p = 0.493). Similarly, TTP was 11.9 m (L-BLP25) vs. 9.4 m (PBO) (HR 0.85, 95% CI 0.71–1.02, p = 0.078) for concurrent CRT and 7.7 m (L-BLP25) vs. 7.4 m (PBO) for sequential CRT (HR 0.91, 95% CI 0.72–1.15, p = 0.437). Time to event analysis of each of the 9 single LCSS variables was consistent with the overall TTSP results.
Conclusions: While the primary objective of the trial to prolong survival time significantly was not met, detailed secondary endpoint analyses of pre-defined subgroups support a potential benefit of L-BLP25 in patients receiving prior concurrent CRT (Sponsor, Merck KGaA; ClinicalTrials.gov number, NCT00409188).

Background: Progression-free survival (PFS) and response rate (RR) to EGFR tyrosine kinase inhibitors (TKIs) vary in pts with NSCLC driven by EGFR mutations, suggesting that other genetic alterations may influence oncogene addiction. In our experience, high BRCA1 mRNA expression negatively influenced PFS among EGFR mutant pts treated with erlotinib. We hypothesized that since olaparib can attenuate and/or prevent BRCA1 expression, the addition of olaparib to gefitinib could improve PFS in these pts.
Methods: This is a Phase IB dose escalation study to identify the maximum tolerated dose (MTD), dose limiting toxicity (DLT), pharmacokinetics (PK), and clinical activity of orally administered olaparib in combination with gefitinib in EGFR mutant advanced NSCLC. In a standard 3+3 design

based on toxicity, pts were treated with gefitinib 250 mg once daily plus olaparib at escalating doses ranging from 100 mg BID to 250 mg TDS during a 28-day cycle.
Results: 22 pts have been included across four dose levels of olaparib: 100 mg BID (3), 200 mg BID (6), 200 mg TDS (6) and 250 mg TDS (7). Median age, 65 (range 39−84); male, 6 pts; PS 0−1, 19 pts; EGFR TKI treatment-naive, 14 p; T790M positive (69%), 9 of 13 pts analyzed. Toxicities: anemia (66.6%), leucopenia (33.3%), nausea (33.3%), diarrhea (33.3%), asthenia (27.7%), rash (22.2%) vomiting (11%), decreased appetite (16%), and hyperlipasemia (5.5%). Most toxicities were G1−2; G3 drug-related events included leucopenia (1) and anemia (3). No DLT at dose levels 1, 2, and 3; 2 DLT at dose level 4 (G3 anemia and repeated blood transfusion within 4−6 weeks). Few dose reductions or interruptions for both drugs were needed. 1 pts died due to pulmonary embolism unrelated to study treatment. 19 pts were evaluated for response: Partial responses (PR) were observed in 8 pts (42%), all EGFR TKI-naive; stable disease (SD) in 8 pts (42%), most previously treated; progressive disease (PD) in 2 pts (10.5%), all previously treated. Durable PR and SD were observed in both EGFR TKI-naive and previously treated pts.11 pts are still on treatment.
Conclusions: This phase IB trial of gefitinib plus olaparib, confirms the tolerability of the combination and the activity seen warrants further exploration in treatment-naive patients. The final recommended dose of olaparib is expected to be either 200 mg BID or 200 mg TDS. A phase II randomized trial in treatment-naive EGFR-mutant advanced NSCLC is planned in 2013.
No conflict of interest.

Tissue biomarker analysis in PROSE, a randomized proteomic stratified phase III study of second line erlotinib (E) versus chemotherapy (CT) in patients with inoperable non-small cell lung cancer (NSCLC)

S. Novello[1], S. Barni[2], F. Grossi[3], T.M. De Pas[4], M. Mencoboni[5], F. De Marinis[6], H. Roder[7], V. Gregorc[8], F.R. Hirsh[9], I. Floriani[10]. *[1]University of Turin. AOU San Luigi Orbassano, Oncology, Orbassano, Italy; [2]Ospedale "Treviglio-Caravaggio", Oncology, Treviglio, Italy; [3]Istituto Nazionale per la Ricerca sul Cancro, Oncology, Genova, Italy; [4]European Institute of Oncology, Medical Oncology Unit of Respiratory Tract and Sarcomas, Milano, Italy; [5]Villa Scassi, Oncology, Genova, Italy; [6]San Camillo Forlanini, Oncology, Roma, Italy; [7]Biodesix, Technology Pfficer, Steamboat Springs, USA; [8]Istituto Scientifico San Raffaele, Milano, Italy; [9]University of Colorado Cancer Center, Department of Medicine Division of Medical Oncology and Department of Pathology, Aurora, USA; [10]Istituto di Ricerche Farmacologiche Mario Negri, Laboratory of Clinical Research Department of Oncology, Milano, Italy*

Background: Improved PFS in first line E-treated pts is associated with EGFR sensitizing mutations. However, a test for optimizing treatment in pts with wild-type or unknown EGFR mutation status in second line setting is of clinical value. PROSE is a multicenter prospective randomized biomarker validation trial, designed to evaluate the ability of VeriStrat (VS) serum protein test to predict survival in 2nd line metastatic NSCLC pts treated with E or CT. It is the first completed prospective randomized biomarker validation trial following the MARVEL design.
Methods: 285 pts, stratified by performance status, smoking habits, and blinded pre-treatment VS classification were randomized in a 1:1 fashion to receive E or CT at standard doses. Primary endpoint was overall survival (OS) having as the primary hypothesis a significant interaction between VS status and treatment. Sample size was calculated based on an estimated 65%/35% VeriStrat Good (VSG):VeriStrat Poor (VSP) ratio, and hazard ratio (HR) for interaction of 2.35, with a 2-sided α=0.05 and 90% power.
Results: 263 (129 CT, 134 E) were included in the primary analysis as per protocol: 68% of pts in CT arm and 72% in E arm were classified as VSG. The analysis was performed reaching 226 events. The primary objective was met with a significant interaction between treatment and VS classification (p-value for interaction 0.037). Pts in the VSP group performed worse on E compared to CT (HR: 1.72, 95% CI: 1.08–2.74); there was no significantly different OS between treatments in the VSG group (HR: 1.09, 95% CI:0.79–1.50). Data in subgroup analyses in pts with wild-type EGFR, positive K-RAS mutation status and by histology will be presented.
Conclusions: The results suggest that VS status is predictive of differential OS benefit for E versus CT in the second line setting. The ongoing subgroup analysis will clarify whether VS has prognostic and predictive value independently from other validated variables such as EGFR and K-RAS mutations.

Safe introduction of VATS in the Netherlands: First results of a nation-wide audit

M. Ten Berge[1], P.J. Van Huijstee[2], R.A.M. Damhuis[3], P.H.J.M. Veldman[4], J.P. Eerenberg[5], W.H. Schreurs[6], M.W. Wouters[7], E.J. Veen[8]. *[1]Leiden University Medical Center, Leiden, Netherlands; [2]Haga Ziekenhuis, Surgery, Den Haag, Netherlands; [3]IKNL, Epidemiology, Rotterdam, Netherlands; [4]Tjongerschans Ziekenhuis, Surgery, Heerenveen, Netherlands; [5]Tergooiziekenhuizen, Surgery, Hilversum, Netherlands; [6]Medisch Centrum Alkmaar, Surgery, Alkmaar, Netherlands; [7]Antoni van Leeuwenhoek ziekenhuis, Surgery, Amsterdam, Netherlands; [8]Amphia Ziekenhuis, Surgery, Breda, Netherlands*

Background: In 2006 video-assisted thoracic surgery (VATS) was introduced for anatomical parenchymal resections (segmentectomy, (bi)lobectomy, pneumonectomy) of non-small cell lung cancer (NSCLC) in the Netherlands. Implementation was realised by the formation of dedicated teams and formulating minimum volume requirements. The main objective of this study was to compare surgical outcome between VATS and thoracotomy.
Material and Methods: Patients who underwent resection for NSCLC in 2012 were included in a nation-wide, web-based prospective database, the Dutch Lung Surgery Audit. Patients were stratified in two groups, those who underwent thoracotomy versus those in whom resection was performed by VATS. Patient, tumour and treatment characteristics, as well as outcome, were compared between the two groups using Chi-square tests and multivariate analysis.
Results: The preliminary results comprise 1.580 patients treated in 42 hospitals with general thoracic surgeons. Patient characteristics were similar for the VATS and thoracotomy group, though more advanced tumour stages were found in the thoracotomy group. Near 75% of lobectomies and a small minority of more extensive parenchymal resections (bilobectomies, pneumonectomies) were performed by VATS. For lobectomies, a similar number of resected N1 and N2 lymph nodes were found in both groups. There was no significant difference in 30-day mortality (VATS: 1.6% vs thoracotomy: 3.1%) or reintervention rate (VATS: 4.1% vs thoracotomy: 5.1%). Extensive blood loss was small in both groups. Pneumothorax and air leakage longer than 5 days were more common in the VATS group, although this was not associated with a prolonged length of stay (mean: 6 versus 8 days).
Conclusions: Since its introduction in the Netherlands, the number of resections for NSCLC performed by VATS procedure increased rapidly. Although variation in patient selection criteria does not allow a direct comparison of outcomes between the two techniques, this study suggests that there has been a safe introduction of VATS for the treatment of NSCLC in the Netherlands.
No conflict of interest.

Functional outcome after pulmonary metastasectomy: Video-assisted thoracoscopic surgery versus thoracotomy

R.C. Numan[1], J.A. Burgers[2], V. Vd Noort[3], H.M. Klomp[1], M.W. Wouters[1]. *[1]Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Department of Thoracic Surgery, Amsterdam, Netherlands; [2]Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Department of Thoracic Oncology, Amsterdam, Netherlands; [3]Netherlands Cancer Institute/Antoni van Leeuwenhoek Hospital, Department of Statistics, Amsterdam, Netherlands*

Background: Today, pulmonary metastasectomy is performed as a routine part of clinical practice. Thoracic surgeons use a thoracotomy or a video-assisted thoracoscopic (VATS) approach to enter the thorax and remove oligometastic disease. To a lack of randomized controlled trials it is not clear which approach yields a better postoperative recovery. The main goal of this study is to compare the functional recovery after pulmonary metastatectomy for two distinct surgical approaches (i.e. VATS and thoracotomy) used in current clinical practice.
Material and Methods: From April 2006 to December 2011, 100 eligible patients treated for pulmonary metastasis, were identified through a prospective database incorporated in a multidisciplinary care path for oncological thoracic surgery in the Netherlands Cancer Institute. Patient-, tumour-, treatment- and outcome characteristics were collected. Quality of life (QoL) and painscores were evaluated pre-operative, 1, 3 and 6 months postoperative using the SF-36 questionnaire and a visual analogue scale (VAS), respectively.
Results: QoL 6 months postoperative revealed a physical and mental performance comparable to baseline. Linear regression analysis showed no significant differences in QoL scores 6 months postoperative between the two surgical approaches. No difference in pain, direct postoperative

and 6 months postoperative, between thoracotomy and VATS group was revealed (resp. $p = 0.087$ and $p = 0.402$). Short term outcome showed that VATS is associated with shorter hospital stay ($p<0.001$), shorter duration of chest drainage ($p<0.001$), and shorter duration of epidural analgesia ($p<0.001$).
Conclusion: No differences were found in QoL or painscores 6 months postoperative between the thoracotomy and VATS group. Though, a VATS approach has advantages in short-term outcome: shorter hospital stay, shorter duration of chest drainage and of epidural analgesia.
No conflict of interest.

Characterisation of the tumour microenvironment in non-small cell lung cancer

M. Xenophontos[1], M. Craze[2], D. Onion[2], A. Grabowska[2]. *[1]University of Nottingham, Nottingham, United Kingdom; [2]University of Nottingham, Pre-Clinical Oncology, Nottingham, United Kingdom*

Background: This study set out to characterise the number and localisation of T cells, CD8+ T cells, FOXP3+ T regulatory cells and macrophages in the tumour microenvironment of Non-Small Cell Lung Cancer (NSCLC) and determine whether the number of immune cells is associated with survival.
Methods: Immunohistochemistry was carried out on 32 resected NSCLC tumours using CD3, CD8, FOXP3 and CD68 antibodies to detect T cells, CD8+ T cells, FOXP3+ T regulatory cells and macrophages respectively. The number of immune cells in the tumour islets (intratumoural), tumour stroma, tumour islets and stroma (total) was quantified using a microscope. The number of immune cells was correlated with the clinicopathological data (including survival) of patients.
Results: The number of CD3+ cells was highest in both the stroma and tumour; followed by CD8+ cells, CD68+ cells and FOXP3+ cells. Stage II was associated with a higher number of intratumoural CD3+, CD8+ and FOXP3+ cells compared to stage I. The number of stromal, intratumoural and total immune cells detected using one antibody correlated with the number of stromal, intratumoural and total immune cells respectively detected using the other antibodies. The number of immune cells was not associated with survival using either univariate or multivariate analysis.
Conclusions: The number of immune cells was not associated with survival. The prognostic value of immune cells in the tumour microenvironment of NSCLC should be further investigated in a larger study.
No conflict of interest.

Venom present in *Heteractis magnifica* induces apoptosis in human lung cancer A549 cells

M. Ramezanpour[1], B. Sanderson[2], K. Burke da Silva[3]. *[1]Flinders University, Medical Biotechnology, Adelaide, Australia; [2]Flinders University, Medical Biotech, Adelaide, Australia; [3]Flinders University, School of Biological Sciences, Adelaide, Australia*

Background: Lung cancer is a major cause of cancer deaths through the word but the complexity of apoptosis resistance in lung cancer is becoming apparent. This study defined important roles for inducing apoptosis in A549 human lung cancer cell line with sea anemone venom.
Material and Methods: Cytotoxicity induced by *H. magnifica* venom was investigated through two colorimetric bioassays, the MTT assay (metabolic viability) and the Crystal violet assay (Cell number) on human lung cancer A549 cell line. Apoptosis was also assayed, via annexin V-flourescein isothiocyanate and propidium iodide (PI) staining followed by flow cytometric analysis. Cell cycle progression and mitochondria membrane potential were studied via flow cytometry following PI and JC-1 staining respectively.
Results: This study shows that chemo-preventive action of venom from *H. magnifica* might be due to its ability to induce apoptosis and cell cycle arrest. *H. magnifica* venom inhibited the growth of A549 cells line in a concentration dependent manner. The venom at 40 μg/ml on A549 cell line induced 32.2% apoptosis compared to 2.2% in untreated cells. Caspase 3/7 assay and JC-1staining were conducted to detect increases in the levels of apoptosis-regulating proteins and mitochondrial membrane potential, respectively.
Conclusions: The findings of this study indicate that the crude extracts from *H. magnifica* induce apoptosis in A549 human lung cancer cell line and that is phenomenon is mediated via both the death receptor-mediated and mitochondria-mediated apoptotic pathway. Thus, novel compounds from *H. magnifica* may be developed as effective treatments for lung cancer.
No conflict of interest.

Metabolic activity measured by FDG-PET predicts pathological response in locally advanced NSCLC undergoing trimodality treatment

I. Bahce[1], C.G. Vos[2], C. Dickhoff[2], K.J. Hartemink[2], M. Dahele[3], E.F. Smit[1], R. Boellaard[4], O.S. Hoekstra[4], E. Thunnissen[5]. *[1]VU University Medical Center, Pulmonary Diseases, Amsterdam, Netherlands; [2]VU University Medical Center, Surgery, Amsterdam, Netherlands; [3]VU University Medical Center, Radiation Oncology, Amsterdam, Netherlands; [4]VU University Medical Center, Nuclear Medicin and PET Research, Amsterdam, Netherlands; [5]VU University Medical Center, Pathology, Amsterdam, Netherlands*

Background: Pathological response (pCR) after induction chemoradiation for locally advanced NSCLC is an important prognostic factor. Patients with a pCR or less than 10% vital tumor cells (pR10) have superior outcomes compared to those with >10% vital cells. Post-induction surgery in these patients is questionable. We evaluated whether changes in metabolic activity can predict pCR or pR10 following induction chemoradiation in patients with superior sulcus tumors (SST). Furthermore, we investigated whether the use of post-induction SUV_{peak} (i.e. SUV of a 1cc sphere with highest FDG activity concentration) increases sensitivity of pCR prediction.
Methods: In this prospective cohort study all consecutive patients with SST between January 2010 and January 2012 were included. Routine clinical pre- and post-induction FDG-PET/CT scans were evaluated. FDG uptake was expressed as $SUV_{max,}$ SUV_{TTL} (tumor-to-liver ratio = tumor SUV_{max} / liver SUV_{mean}), SUV_{peak} and SUV_{PTL} (peak-to-liver ratio = tumor SUV_{peak}/liver SUV_{mean}). First, a single pathologist assessed all parts of the tumor for maximal vital tumor cell percentage per cm^2 (C%) and overall residual tumor percentage (T%). Next, tumor regions corresponding to the postinduction SUV_{peak} regions were designated. Then, changes in SUV_{max} and SUV_{TTL} were correlated with T%. Post-induction SUV_{peak} and SUV_{PTL} were correlated with the corresponding C%.
Results: FDG-PET/CT scans from 8 out of 31 treated patients were not usable due to absent postinduction scans or unstandardized PET scans. Sixteen patients had less than 10% remaining vital tumor of which 8 had a pCR. The area under the ROC curve (AUC) for predicting pCR was 0.78 for SUV_{max} ($P = 0.054$) and 0.90 for SUV_{TTL} ($P = 0.007$). The optimal cutoff value for reduction in SUV_{max} was 67% and 77% for SUV_{TTL}. At this cutoff value, sensitivity and specificity was 83% and 70% for SUV_{max} and 83% and 85% for SUV_{TTL}. The AUC for predicting pR10 was 0.96 for SUV_{max} ($P = 0.002$) and 0.96 for SUV_{TTL} ($P = 0.002$). The optimal cutoff value for reduction in SUVmax was 55% and 47% for SUV_{TTL}. At this cutoff value, sensitivity and specificity was 85% and 100% for SUV_{max} and 100% and 83% for SUV_{TTL}. The use of SUV_{peak} and SUV_{PTL} did not improve sensitivity of the prediction of pCR and pR10.
Conclusions: Changes in metabolic activity measured by FDG-PET/CT may predict pathological response in patients with locally advanced NSCLC. The post-induction SUV_{peak} did not improve sensitivity. These findings need confirmation in larger cohorts.
No conflict of interest.

A phase II study of cisplatin and oral vinorelbine concomitantly with radiotherapy in locally advanced non-small-cell lung cancer treatment: Primary objective and safety results

O. Juan[1], A. Sanchez[2], S. Vazquez[3], V. Giner[4], J. Casal[5], J.L. Firvida[6], F. Aparisi[7], J. Muñoz[8], J. Garcia-Sanchez[1], R. Girones[9]. *[1]Hospital Arnau de Vilanova, Medical Oncology Service, Valencia, Spain; [2]Consorcio Hospitalario Provincial de Castellón, Medical Oncology Service, Castellón, Spain; [3]Complexo Hospitalario Xeral-Calde, Medical Oncology Service, Lugo, Spain; [4]Hospital de Sagunto, Medical Oncology Service, Sagunto, Spain; [5]Hospital do Meixoeiro, Medical Oncology Service, Vigo, Spain; [6]Complexo Hospitalario Universitario, Medical Oncology Service, Ourense, Spain; [7]Hospital Virgen de los Lirios, Medical Oncology Service, Alcoy, Spain; [8]Hospital Universitario Dr. Peset, Medical Oncology Service, Valencia, Spain; [9]Hospital Lluis Alcanyis, Medical Oncology Service, Xativa, Spain*

Background: Cisplatin (CDDP) plus oral Vinorelbine (OV) as induction and concomitant regimen with radiotherapy (RT) has shown good efficacy outcomes and safety profile (Vokes, Fournel, Krzakowski). The objective of this study was to evaluate the effectiveness and toxicities of the combination

of CDDP and OV given at full doses concomitantly with RT in locally advanced (LA) non-small-cell lung cancer (NSCLC).
Material and Methods: Between February 2010 and December 2011, 48 chemo-naive patients (p) with histologically confirmed unresectable stage IIIA/IIIB LA NSCLC were treated. Treatment consisted of 4 cycles (cy) of OV 60 mg/m^2 on days 1 and 8 and CDDP 80 mg/m^2 every 3 weeks plus RT 66 Gy starting on day 1, cy 2. The primary objective is the ORR using RECIST 1.0. A standard Fleming two stage design was used. The sample size calculated with a type 1 error of 0.05 and type 2 error of 0.01, taking P_0 20% and P_1 40%.
Results: Patient's characteristics were: Median age 61 years (range 34−72); ⩾65 y 42%; males 89.6%; PS0 42%/PS1 58%; smokers 52%; adenocarcinoma 30%/squamous 64%; stage IIIA 46%/IIIB 54%. Median of days between initial diagnosis and study start was 28 days. 75% p completed the treatment as per protocol. Relative dose intensities of OV and CDDP were 97%/98%, respectively. 14.7% of cy were delayed, 11.8% due to toxicity. Dose of day 8 OV was canceled or delayed in 8.2% of cy. Hematological toxicities (% p): grade (g) 3/4 neutropenia 33.3%; g3 anemia 12.5%; g3/4 thrombocytopenia 16.6%; febrile neutropenia concomitant during CT-RT 14.6%. Non-hematological toxicities (% p): g3 esophagitis 12.5%; g3 dyspnea 4.2%, g3 vomiting 4.2%, g3−4 infection 4.2%. 2 treatment-related deaths were reported, both during cycle 1. 42 p (87.5%) received RT, 7.1% under 60 Gy, 23.8% with RT delays or interruptions due to adverse events. 44 p were evaluable for response. ORR 77.3% [95% CI, 62.2–88.5], DCR 88.6% [CR 2 p (4.5%), PR 32 p (72.7%), SD 5 p (11.4%)]. Median follow-up 6.6 months (range 0.47–23.5). Median OS and TTP not reached. Median PFS 13.3 months (95% CI, 6.4–20.2).
Conclusions: This prospective phase II trial shows that the schedule of CDDP plus OV concomitant with RT from 2nd cy obtains a good efficacy with an acceptable safety profile.
No conflict of interest.

3428 POSTER

Adjuvant treatment of completely resected stage IB−IIIA non-small-cell lung cancer − a retrospective study with cisplatin or carboplatin and oral vinorelbine

W. Engel-Riedel[1], N. Alten[1], A. Bachinger[2], F.S. Magnet[1], C. Ludwig[3], E. Stoelben[3]. *[1]Kliniken der Stadt Köln gGmbH, Pneumology, Köln, Germany; [2]ClinAssess Gesellschaft für Klinische Forschung mbH, Biometry, Leverkusen, Germany; [3]Kliniken der Stadt Köln gGmbH, Thoracic Surgery, Köln, Germany*

Background: Adjuvant chemotherapy is a standardized treatment for early stage non-small-cell lung cancer (NSCLC) patients after complete resection. The most evidence-based data exist for combination of cisplatin (cis) and vinorelbine (vrb), whereas carboplatin (carbo) can be administered as combination partner in cis-unfit patients. To analyze effectiveness and tolerability of platinum-based combination therapy with predominantly oral vrb in daily practice we performed a retrospective study in our hospital.
Material and Methods: Data from 152 patients with completely resected NSCLC (stage IB−IIIA) receiving adjuvant chemotherapy with cis or carbo in combination with intravenous or oral vrb (Navelbine© Oral) between March 2005 and November 2011 were retrospectively analyzed. The primary endpoint was overall survival, secondary endpoints recurrence-free survival and toxicity. Overall survival and recurrence-free survival were estimated with the Kaplan–Meier method.
Results: Patients were on average 61 years old and diagnosed with stage IB (35%), IIA (5%), IIB (38%) or IIIA (22%) NSCLC. 66% of the patients were male, and 93% were former or active smokers. Vrb was predominantly administered orally (89%) and most patients received carbo (74%).
The combination treatment was effective with an estimated 5-year survival of 64% (cis/vrb: 65%, carbo/vrb: 64%) and recurrence-free survival after five years of 60% (cis/vrb: 63%, carbo/vrb: 59%). Toxicities (all grades) related to combination therapy mainly concerned the hematologic system with 70% leukopenia (carbo/vrb: 74%), 32% thrombocytopenia (carbo/vrb: 40%), 40% anemia, 28% neutropenia, and 5% febrile neutropenia. The treatment caused nausea and vomiting in 47% and 23% of the patients (cis/vrb: 59% and 28%), respectively, and fatigue was reported for 23% of the patients. Of note, overall 64% of the patients (carbo/vrb: 71%, cis/vrb: 44%) completed combination therapy with the planned number of cycles.
Conclusions: The results of this retrospective study are in line with clinical trials of cis in combination with intravenous vrb and show that adjuvant chemotherapy of a platinum-based combination therapy with vrb is effective. Carbo was better tolerated than cis resulting in superior treatment compliance and comparable effectiveness.

3429 POSTER

Definitive concurrent chemoradiotherapy for patients over 75 years old with locally advanced non-small-cell lung cancer

T. Kishi[1], M. Kokubo[2], T. Shintani[2], M. Uto[2], Y. Kosaka[2], K. Takayama[3], K. Tomi[4], N. Katakami[5], M. Hiraoka[6]. *[1]Graduate School of Medicine Kyoto University, Radiation Oncology and Image-applied Therapy, Kyoto, Japan; [2]Kobe City Medical Center General Hospital, Radiotherapy, Kobe, Japan; [3]Institute of Biomedical Research and Innovation Hospital, Radiotherapy, Kobe, Japan; [4]Kobe City Medical Center General Hospital, Pulmonary Medicine, Kobe, Japan; [5]Institute of Biomedical Research and Innovation Hospital, Integrated Oncology, Kobe, Japan; [6]Kyoto University, Radiation Oncology and Image-applied Therapy, Kyoto, Japan*

Background: Radiotherapy alone is the standard treatment for elderly patients with locally advanced non-small-cell lung cancer (NSCLC). However, curative thoracic radiotherapy with concurrent chemotherapy may be feasible and contribute to longer survival of selected elderly patients with NSCLC. This retrospective study was aimed to evaluate the tolerability and efficacy of concurrent chemoradiotherapy (CCRT) in patients aged 75 years or older.
Material and Methods: We reviewed the records of 28 consecutive stage III NSCLC patients who were 75 years or older when treated with definitive CCRT from 2006 to 2011. The median age was 79 years, with a range of 75 to 87 years. Twenty-two (78.6%) patients exhibited comorbidity. The median number of Eastern Cooperative Oncology Group (ECOG) performance status of the cases at the beginning of treatment was 1, with a range from 0 to 2. The median delivered radiation dose was 60 Gy. Regional lymph nodes were prophylactically irradiated in 25 patients, while involved-field radiation was applied to the other 3. Concurrent chemotherapy regimens were carboplatin plus paclitaxel, cisplatin plus vinorelbine, carboplatin plus docetaxel, carboplatin plus vinorelbine, paclitaxel alone, pemetrexed alone and S1 alone.
Results: The median follow-up time was 16.9 months (1.7–63.5). The median overall survival and progression-free survival were 19.1 (95% CI 11.5–26.8) and 8.1 months (95% CI 7.4−8.8), respectively. One-year and 2-year survival rates were 76.0 and 44.3%, respectively. Nineteen (67.9%) patients could be evaluated for the initial effects of CCRT. The response rate was 84.6%, namely, 22 patients; 3 (11.5%) experienced stable disease and one (3.8%) disease progression for an overall clinical benefit of 96.2%. During the treatment, 9 patients (32.1%) experienced grade 3−4 neutropenia, three patients (10.7%) grade 3 neutropenic fever, one patient (3.6%) grade 3 anaemia, and no patients thrombocytopenia of grade 3 or higher. Grade 3 radiation pneumonitis and grade 3 drug-induced lung injury were observed in 2 (7.1%) and 1 patients (3.6%), respectively. No treatment-related death occurred. Esophagitis or other non-haematological toxicity of grade 3 or higher was not observed.
Conclusion: CCRT was feasible in selected patients aged 75 years or older with locally advanced NSCLC; it may thus have clinical benefit.
No conflict of interest.

Table: Adverse effects due to definitive concurrent chemoradiotherapy

	Grade 3	Grade 4	Grade 5
Neutrophil count decreased	2 (7.1%)	7 (25.0%)	0
Febrile neutropenia	3 (10.7%)	0	0
Anaemia	1 (3.6%)	0	0
Thrombocyte count decreased	0	0	0
Radiation esophagitis	0	0	0
Radiation pneumonitis	2 (7.1%)	0	0

3430 POSTER

Rotational, intensity-modulated radiotherapy for inoperable non-small cell lung cancer: Long term follow-up and toxicity profile

C. Collen[1], D. Schallier[2], M. De Ridder[1]. *[1]UZ Brussel, Department of Radiotherapy, Brussels, Belgium; [2]UZ Brussel, Medical Oncology, Brussels, Belgium*

Purpose: To report mature results of treatment efficacy and toxicity of rotational, intensity-modulated radiotherapy by means of helical tomotherapy for patients with inoperable, non-small cell lung cancer (NSCLC).
Methods: Between Jan 2006 and March 2012, a total of 144 inoperable NSCLC patients were treated on the Tomotherapy HI-ART II system, in the concurrent (n = 75) or sequential/primary (n = 69) (chemo)radiotherapy approach. Concurrent chemoradiotherapy (CCRT) consisted of weekly administrations of cisplatin and docetaxel at 20 mg/m^2 each in combination

with 30 fractions of 2.24 Gy. Radiotherapy schedule for sequential (SCRT) or primary (PRT) treatment consisted of 30 fractions of 2.35 Gy. Toxicity monitoring was performed using the RTOG and NCI CTCAE version 3.0 criteria. Treatment efficacy was evaluated in terms of in-field progression free, metastasis-free and overall survival using the Kaplan–Meier method. Log-rank testing was used for intergroup comparison.

Results: Mean age was 65 years (range,37−85). AJCC 6th edition was used for staging, clinical stages of the 144 patients were as follows: IIB (n = 3), IIIA (n = 55), IIIB (n = 77), IV (n = 9). The rate of acute ⩾grade 3 esophageal and lung toxicity was 9% and 7%. The rate of late ⩾grade 3 esophageal and lung toxicity was 0.7% and 14%. With a median follow-up time of 14.3 months (range, 3−70 months), 64% of patients experienced disease progression. Site of first failure was distant in 32% and locoregional in 26%. The median overall survival was 25 months, with a 1-year and 2-year overall survival of 71% and 45%, respectively. The 1-year and 2-year in-field progression-free survival rate was 78% and 68% with a median time to in-field progression of 14.7 months. The median metastasis-free survival was 21.5 months with 1-year and 2-year rates of 57% and 37%. No significant statistical difference was observed in survival rates between the three different treatment modalities. A trend towards improved metastasis-free survival was observed between CCRT and SCRT ($p = 0.0625$, log-rank).

Conclusion: Moderate hypofractionated radiotherapy by means of helical tomotherapy in patients with inopearbel NSCLC resulted in accepatable acute and late treatment-related toxicity and encouraging survival results.

No conflict of interest.

3431 POSTER

Reliability of small biopsy samples for determining PD-L1 expression in non-small cell lungcarcinoma, compared with resected specimens using immunohistological staining

K. Satoru[1], Y.F. Fujiwara[1], H.H. Horinouchi[1], S.K. Kanda[1], H.N. Nokihara[1], N.Y. Yamamoto[1], K.T. Tsuta[2], S.W. Watanabe[3], H.A. Asamura[3], T.T. Tamura[1]. *[1]National Cancer Center Hospital, Thoracic Oncology, Tokyo, Japan; [2]National Cancer Center Hospital, Pathology, Tokyo, Japan; [3]National Cancer Center Hospital, Thoracic Surgery, Tokyo, Japan*

Background: Several studies have assessed the expression rate of programmed cell death 1 ligand (PD-L1) in resected specimens of non-small cell lung carcinoma(NSCLC). Although advanced NSCLC is routinely diagnosed by biopsy, expression of PD-L1 in these samples has not been reported.

Materials and Methods: From April 2009 to March 2012, 79 NSCLC patients for whom both resected specimens and biopsy samples for diagnosis were available in our institute were retrospectively enrolled in this study. PD-L1 expression was assessed by immunohistochemistry (IHC) and scored according to hybrid (H) score. Concordance rates for expression of PD-L1 between both the samples were analyzed.

Results: Distribution of disease stage in the patients (52 male, 29 female; median age, 68 years; range, 38−83 years) was stage I in 38, stage II in 8 and stage III in 23. Diagnosis included endobronchial biopsy in 59 cases, transbronchial needle aspiration (TBNA) in 14, and CT-guided needle biopsiy (CTNB) in 6. Positivity rate of PD-L1 in these samples was 45.6% (endobronchial biopsy, n = 27; TBNA, n = 6; CTNB, n = 3) versus 41.8% in resected specimens. Median H-score was 0 (range: 0–170) and mean was 26.7 (standard deviation: 36.2). No association between patient characteristics and expression of PD-L1 was seen. On comparison of biopsy samples and resected specimens, 11 tumors were discordant for expression of PD-L1 and 68 tumors were concordant, giving a concordance rate of 86.1%.

Conclusions: PD-L1 status showed moderate concordance between biopsy samples and resected specimens in NSCLC.

These small samples, even those derived from transbronchial needle aspiration, appeared adequate for assessment of PD-L1 expression.

No conflict of interest.

3432 POSTER

An empirical assessment of non-small cell lung cancer charges by survival

A. Dahal[1], B.K. Bellows[1], D. Stenehjem[1], D. Brixner[1]. *[1]University of Utah, Pharmacotherapy Outcomes Research Center, Salt Lake City UT, USA*

Background: Non-small cell lung (NSCLC) cancer has a high mortality rate and is costly to treat, but it remains unknown if charges differ between patients who die while receiving treatment compared to those who survive. The objective of this study was to assess the mean charges per patient in those diagnosed with NSCLC by survival status.

Material and Methods: The University of Utah Enterprise Data Warehouse was used to analyze patients ⩾18 years with a diagnosis of NSCLC identified by ICD-9 code (initial diagnosis defined as index date) treated at the Huntsman Cancer institute (HCI) from 2002–2010. The HCI Tumor Registry was used to confirm cases and determine stage and histology at diagnosis. Cancer-related death and date of death were captured from the Utah Population Database. NSCLC-related and other charges (US dollars) were identified by ICD-9 code from index date until death or the end of the study period. Patients who died were matched to survivors based upon the Kaplan–Meier probability of survival at the time of death or end of the study period. A generalized linear model (GLM) with gamma distribution and log link function was used to examine charges by survival status, adjusting for stage, histology, year of diagnosis, cancer treatments, demographics, and comorbidities.

Results: A total of 776 patients were included. There were no differences between deceased patients and survivors in age (mean 66 vs. 65) and sex (male 63% vs. 59%). Compared to survivors, more deceased patients were diagnosed with stage IV disease (58% vs. 25%; $p < 0.001$). Additionally, patients who died had more comorbidities ($p = 0.01$) and greater use of radiation ($p < 0.001$). Mean unadjusted NSCLC-related charges were not significantly higher in deceased patients compared to survivors ($66,533 vs. $58,916; $p = 0.12$), but other charges were ($36,666 vs. $20,924; $p < 0.001$). Results from the GLM indicated deceased patients had a non-significant $8,251 increase in adjusted mean NSCLC-related charges ($p = 0.13$), but a significant $23,521 increase in adjusted mean other charges ($p < 0.001$). Being younger and having more comorbidities were associated with an increase in other charges.

Conclusions: When adjusting for confounders, death was associated with higher other charges, but not NSCLC-related charges. Though potential confounders were included in the analysis, patients who died during treatment may have had more aggressive disease leading to higher utilization of ancillary treatments.

No conflict of interest.

Non-small cell lung cancer in women: Description of early stages from the Spanish World07 database

A. Artal Cortes[1], M. Provencio[2], M. Magem[3], P. Garrido[4], E. Felip[5], N. Viñolas[6], D. Isla[7], R. García-Campelo[8], R. De las Peñas[9], E. Carcereny[10]. *[1]Hospital Universitario Miguel Servet, Zaragoza, Spain; [2]Hospital Universitario Puerta de Hierro, Medical Oncology, Madrid, Spain; [3]Hospital Sant Pau, Medical Oncology, Barcelona, Spain; [4]Hospital Universitario Ramon y Cajal, Medical Oncology, Madrid, Spain; [5]Hospital Universitario Vall d'Ebron, Medical Oncology, Barcelona, Spain; [6]Hospital Clinic, Medical Oncology, Barcelona, Spain; [7]Hospital Clinico Universitario, Medical Oncology, Zaragoza, Spain; [8]Hospital Universitario, Medical Oncology, A Coruña, Spain; [9]Hospital Provincial, Medical Oncology, Castellón, Spain; [10]Hospital Germans Trias i Pujol, Medical Oncology, Barcelona, Spain*

Background: Lung cancer is showing an increasing incedence amongst women in most european countries in recent years. As no specific information is available about early stages in this particular population, a descriptive analysis from the Spanish WORLD07 database have been performed.

Material and Methods: From 2007 to December 2012 a total of 2101 women with lung cancer have been included in the database. Data are available from 1,759 NSCLC of them and 477 presented with stages I−IIIa (27.1%).

Results: Stage distribution was (percentages are from overall NSCLC patients (p)): I, 218p (12.4%); II, 83p (4.7%); IIIa, 176 (10.0%). Median age was 61.9 years. Of them 60.7% were current smokers and in other 15.8% second hand smoking could be documented. Most patients (76.9%) were post-menopausal.

Surgery was performed in 343p (71.9%) and in 83.5% of these cases a lobectomy was performed. Adjuvant chemotherapy was administered to 148 of the resected p (43.1%) and adjuvant radiotherapy to 67p (19.5%). Chemotherapy schemes included cis or carboplatin in 136 p (92.1%) and mean number of courses given was 3.7. Survival data are currently under analysis.

Conclusions: NSCLC incidence is rapidly increasing in women and data in this specific situation in lacking. The present data show an example from a wide, women-only, case-series that may shed some ling on the topic. Updated data will be presented.

No conflict of interest.

3434 POSTER

FDG-PET parameters as predictors for outcome in non-small cell lung cancer (NSCLC) treated with stereotactic body radiotherapy (SBRT)

M. Alzouebi[1], M. Subesinghe[1], M. Snee[1], C. Young[1], R. Turner[1], R. Stuart[1], K. Franks[1], S. Ramasamy[1], H. Thygesen[2], K.L. Clarke[1]. *[1]St James University Hospital, Oncology, Leeds, United Kingdom; [2]Leeds University, Statistics, Leeds, United Kingdom*

Background: To identify predictive FDG-PET imaging factors for outcomes following SBRT in early stage NSCLC.
Materials and Methods: Patients with inoperable T1 and T2 NSCLC and a baseline FDG PET-CT at a single centre (Leeds St James University Hospital) treated with SBRT for a single tumour between 2009 and 2012 were included. Scans were reported by a single radiologist. Prospective data was collected on a range of FDG-PET parameters (including SUVmax and TLG − Total lesion glycolysis). Patient characteristics and outcome variables including stage, histology, PTV volume, performance status, dose, time interval between PET and SBRT, maximum response to treatment and patterns of failure collected and analysed. The PET parameters were analysed as a continuous variable.
Results: 125 patients (72 female, 53 male), median age 75.2. 94 were T1 and 31 T2. Median follow up 1.19 yrs (range 0.28−3.3). Histology was available in 40 patients.
In assessable patients maximal response to treatment was Complete Response in 19%, Partial Response in 50%, Stable Disease in 14% and Progressive Disease in 11%.
Relapse free survival at 2 years was 55%. Local, regional and distant relapse-free rates were 94%, 89% and 83% respectively. Overall and cause-specific survival at 2 years was 57% and 81% respectively.
Median SUVmax was 9.2 in patients who had a relapse and 7.35 in those without. On multivariate analysis, pre treatment SUVmax predicted for recurrence ($p = 0.005528$), distant metastases ($p = 0.024081$) and overall survival ($p = 0.000253$). This was consistent amongst patients with and without diagnostic pathology. Median SUVmax for patients with and without histology was 5.85 and 7.65 respectively. SUVmax however did not correlate with local or regional relapse.
Stage was a significant predictor for Overall and Relapse free survival, consistent with previous data. Dose of radiation and time interval from PET to SBRT showed no significant correlation with outcome.
Other PET parameters assessed include TLG 20 which correlates with regional relapse, the significance of this is not clear.
Conclusion: This study identifies that SUV max is the strongest FDG-PET parameter to correlate with outcome following SBRT for NSCLC. This is consistent with previously published data. With SBRT an emerging treatment modality for early stage disease, this may have future implications on the use of adjuvant chemotherapy.
No conflict of interest.

3435 POSTER

Adaptive dose escalation in radiotherapy (RT) for locally advanced non-small cell lung cancer (LA-NSCLC) using serial 4D FDG PET/CT scanning: a planning study

M.L. Yap[1], A. Sun[1], A. Marshall[1], N. Becker[1], J. Higgins[1], L.W. Le[2], D. Vines[1], K. Clarke[1], A. Bezjak[1], J.P. Bissonnette[1]. *[1]Princess Margaret Cancer Centre, University of Toronto, Toronto, Canada; [2]Princess Margaret Cancer Centre, Department of Biostatistics, Toronto, Canada*

Background: There has been recent interest in dose escalation in LA-NSCLC, with the aim to improve loco-regional control and survival. Attempts to dose escalate CT-defined volumes for radiotherapy (RT) for locally-advanced NSCLC have been limited due to organ at risk (OAR) toxicity. We investigated the potential for adaptive dose-escalation using 4DPET/CT scans acquired prior to and during a course of radical chemo/RT (CRT).
Material and Methods: This single institution study prospectively enrolled patients with NSCLC receiving CRT to a dose $\geqslant$60 Gy, delivered in daily 2 Gy treatments. 4DPET/CT scans were acquired prior to (week 0) and at weeks 2 and 4 during RT. RT was delivered to the patients using the intensity modulated RT (IMRT) plan developed from the week 0 scans. Three alternative dose escalated IMRT plans were developed offline based on the week 0, 2 and 4 scans. The PET avid primary (PET-T) and nodal disease (PET-N) volumes were auto-contoured using the 50%SUVmax metric. PET-T and PET-N were dose escalated to as high as possible while respecting OAR constraints and ensuring coverage of the clinical plan PTV. The D95% of the PET-T and PET-N were calculated and compared between week 0, 2 and 4.
Results: Thirty-two patients were recruited, with 27 completing all scans. Sixteen patients were stage IIIA (60%), 9 were IIIB (33%) and 2 were IIA (7%). Eight patients (30%) had been prescribed a clinical dose of 60 Gy, 17 (63%) had 66 Gy, 1 patient 70 Gy and 1 patient 74 Gy. 25 patients (93%) were boosted successfully above the clinical plan doses at week 0; this reduced to 23 (85%) at week 2 and 20 (74%) at week 4. For all weeks combined, the D95 for PET-T was higher than that delivered to clinical PTV by a median of 16.2 Gy. The D95 for PET-N exceeded that delivered to clinical PTV by 13.4 Gy. The median D95% to the PET-T at week 0, 2 and 4 were 74.4 Gy, 75.3 Gy and 74.1 Gy respectively. The median D95% to PET-N at week 0, 2 and 4 were 74.3 Gy, 71.0 Gy and 69.5 Gy.
Conclusions: Using 4DPET/CT, it is feasible to dose escalate PET avid disease in majority of patients, either at the onset or during RT. Though it was possible to escalate the PET-T to higher doses than PET-N, the nodal disease can still be boosted to significant doses. More patients were successfully dose escalated at the onset of RT, however, mid-RT dose escalation allows the additional potential for adaptation.
No conflict of interest.

Local control predicts survival in operable patients receiving stereotactic radiotherapy for early lung cancer: A Japanese–European comparison

O. Suzuki[1], T. Mitsuyoshi[2], M. Miyazaki[2], T. Teshima[2], K. Nishiyama[2], J.F. Ubbels[3], J.A. Langendijk[3], J. Widder[3]. *[1]Osaka University Graduate School of Medicine, Radiation Oncology, Suita, Japan; [2]Osaka Medical Center for Cancer and Cardiovascular Diseases, Radiation Oncology, Osaka, Japan; [3]University of Groningen University Medical Center Groningen, Radiation Oncology, Groningen, Netherlands*

Background: Stereotactic body radiotherapy (SBRT) for early stage lung cancer is increasingly considered standard of care for medically inoperable patients and for patients refusing surgery. This joint analysis aimed at revealing differences in treatment technique and results between a Japanese and a Dutch high-volume stereotactic radiotherapy center.
Material and Methods: Lung cancer patients treated with SBRT for a single lesion (T1−2N0M0) in Osaka (OM) or Groningen (GN) were retrospectively analyzed. Forty to 60 Gy were delivered in 3 to 10 fractions. To correct for differences in planning and dose prescription, all doses were recalculated using collapsed cone or Monte Carlo dose calculation algorithms and expressed as biologically effective dose (BED; alpha/beta = 10) at the margin of the planning target volume (PTV). Survival and local control were analyzed.
Results: Between September 2006 and July 2010, 383 patients were registered (OM, n = 162; GN, n = 221). Patients in GN had a worse WHO performance status (PS) and larger gross tumor volumes (GTV) than in OM ($p < 0.001$). Treatment dose was prescribed at the isoceter in OM, and at the periphery of the PTV in GN. This resulted in a peripheral BED of 102 Gy (+/− 21) and 83 Gy (+/− 5) in GN and OM, respectively. Median follow up was 41 months. At 3 years, actuarial overall survival (OS) was 72% and 52% ($p < 0.001$), and disease specific survival (DSS) was 85% and 76% ($p = 0.1$) for OM and GN respectively. GTV and PS were highly significant prognostic factors for survival. After correction for GTV and PS, OS was no longer significantly different between institutions (HR 0.88; $p = 0.47$). Local control rate at 3 years was better in GN (93% vs 84%, $p < 0.05$) despite larger GTVs; GTV ($p = 0.048$) and BED ($p = 0.014$) were significant factors. While local failure (LF) had a significant effect on OS in operable patients (56/383), that was not observed in inoperable patients: Adjusted for GTV and PS, LF yielded a HR for OS of 7.5 (2−27; $p = 0.003$) for operable and a HR of 1.1 (0.7−1.9; $p = 0.6$) for inoperable patients.
Conclusions: Administration of sufficient dose was confirmed in this international comparison of the European with the Japanese approach towards SBRT. Higher dose yielded better local control, local control in turn was significant for overall survival in operable patients.
This work was supported by the Japan Society for Promotion Science (JSPS) Core-to-Core Program (number 23003).

3437 POSTER

Cost-effectiveness analysis of thoracic radiotherapy in non-operated clinical stage IIIA non-small cell lung cancer

C.R. Chien[1], P.H. Wang[2]. *[1]China Medical University Hospital, Department of Radiation Oncology & Cancer Center, Taichung city, Taiwan; [2]China Medical University Hospital, Department of Cancer Center, Taichung city, Taiwan*

Background: The aim of this study is to use patient-level data to compare the cost-effectiveness of radiotherapy for non-operated clinical stage IIIa non-small cell lung cancer (NSCLC) patients who were treated with chemotherapy.
Material and Methods: We performed a retrospective cohort study for non-operated clinical stage IIIa NSCLC patients diagnosed in 2007, using data

from the Collaboration Center of Health Information Application (CCHIA). CCHIA is a nation-wide database including cancer registry, death registry, and reimbursement data in Taiwan. We identified patients treated with both chemotherapy and radiotherapy (group A) and those were treated with chemotherapy only (group B). We compared the cost and effectiveness of group A vs group B. Effectiveness was measured as survival from diagnosis to either death or censored on Jan 1st, 2010. We compared the survival and cost (both within 2 years after diagnosis) between group A and group B. We used log-rank test, Cox proportional hazard model, t-test, and Chi-square test for the above statistical analysis. We used the net benefit regression to estimate the incremental cost-effectiveness ratio (ICER, in US dollars/life-years (USD/LY)) of radiotherapy after covariates adjustment including characteristics of patients' demographic, comorbidity, health services' provider, and clinical status.
Results: We identified 39 & 92 patients for group A & B respectively. The distribution of the covariates was not statistically different between both groups. Radiotherapy was associated with insignificantly better survival. Radiotherapy was associated with higher mean incremental costs and mean incremental effectiveness (life-days). The mean cost (2011 USD) and effectiveness (days) (both within 2 years from diagnosis) for group A vs group B were 61200 vs 39466 and 497 vs 472 respectively. The unadjusted ICER was 317392 USD/LY. After covariates adjustment, the net benefit analysis revealed that radiotherapy is not likely to be beneficial unless the willingness-to-pay (WTP) is at least around 130000 USD/LY.
Conclusions: In this population based study, we found that radiotherapy might prolong survival for non-operated clinical stage IIIa NSCLC. However, it may not be cost-effective at common WTP threshold.
No conflict of interest.

3438 POSTER

Evaluation of the usefulness of restricted respiratory interval at the time of radiotherapy for non-small cell lung cancer patient

S. Park[1], K.W. Song[1], H.R. Pyo[1], J.H. Ahn[1], J.M. Suh[2], Y.I. Kim[1], J.M. Kim[1], B.K. Choi[1]. *[1]Samsung Medical Center, Radiation Oncology, Seoul, Korea; [2]Daewon University College, Dept. of Radiological Science, Seoul, Korea*

Background: It is essential to minimise the movement of tumour due to respiratory movement at the time of respiration controlled radiotherapy of non-small cell lung cancer patient. Accordingly, this study aims to evaluate the usefulness of restricted respiratory interval by comparing and analysing the treatment plans that apply free and restricted respiration interval respectively.
Subjects and Methods: After having conducted training on 9 non-small cell lung cancer patients (tumour n = 10) from April to December 2011 by using 'signal monitored-breathing (guided-breathing)' method for the 'free respiratory interval' measured on the basis of the regular respiratory interval of the patents and 'restricted respiratory interval' that was intentionally reduced, total of 10 CT images for each of the respiration phases were acquired by carrying out 4D CT for treatment planning purpose by using RPM and 4D CT simulator. Visual gross tumour volume (GTV) and internal target volume (ITV) that each of the observer 1 and observer 2 has set were measured and compared on the CT image of each respiratory interval. Moreover, the amplitude of movement of tumour was measured by measuring the center of mass (COM) at the phase of 0% which is the end-inspiration (EI) and at the phase of 50% which is the end-exhalation (EE). In addition, both observers established treatment plan that applied the 2 respiratory intervals, and mean dose to normal lung (MDTNL) was compared and analysed through dose-volume histogram (DVH). Moreover, normal tissue complication probability (NTCP) of the normal lung volume was compared by using dose-volume histogram analysis program (DVH analyzer v.1) and statistical analysis was performed in order to carry out quantitative evaluation of the measured data.
Results: As the result of the analysis of the treatment plan that applied the 'restricted respiratory interval' of the observer 1 and 2, there was reduction rate of 38.75% in the 3D direction movement of the tumour in comparison to the 'free respiratory interval' in the case of the observer 1, while there reduction rate was 41.10% in the case of the observer 2. The results of measurement and comparison of the volumes, GTV and ITV, there was reduction rate of 14.96±9.44% for observer 1 and 19.86±10.62% for observer 2 in the case of GTV, while there was reduction rate of 8.91±5.91% for observer 1 and 15.52±9.01% for observer 2 in the case of ITV. The results of analysis and the reduction rate of MDTNL 3.98±5.62% for observer 1 and 7.62±10.29% for observer 2 in the case of MDTNL, while there was reduction rate of 21.70±28.27% for observer 1 and 37.83±49.93% for observer 2 in the case of NTCP. In addition, the results of analysis of correlation between the resultant values of the 2 observers.
Conclusion: It was possible to verify the usefulness and appropriateness of 'restricted respiratory interval' as the treatment plan that applied 'restricted respiratory interval' illustrated relative reduction in the evaluation factors.
No conflict of interest.

Pulmonary imaging changes after radiotherapy in patients with lung cancer or oesophageal carcinoma and its correlation to CTC grade 2 or higher radiation pneumonitis

L. Zhou[1], J. Liu[2], Y.J. Zhang[3], Y.L. Gong[1], S. Bai[3], Y. Lu[1]. *[1]West China Hospital of Sichuan University, Department of Thoracic Cancer, Chengdu, China; [2]Chengdu First People's Hospital, Department of Oncology, Chengdu, China; [3]West China Hospital of Sichuan University, Center of Radiation Physics, Chengdu, China*

Background: To retrospectively analyse risk factors for the Common Terminology Criteria for Adverse Events (CTC AE) V3.0 grade 2 or higher radiation pneumonitis (RP) in lung cancer or oesophageal carcinoma patients with pulmonary imaging changes after radiotherapy.
Material and Methods: From January 2011 to May 2012, 60 patients with lung cancer and 17 patients with esophageal carcinoma had pulmonary imaging changes (interstitial inflammation or interstitial fibrosis) after thoracic radiotherapy with no less than 50 Gy/25f in our department. 41 patients received three-dimensional conformal radiation therapy, 15 patients received intensity-modulated radiation therapy, and 21 patients received volumetric modulated arc therapy. There were 53 male patients and 24 female patients, and the median age was 61 (range 31−77). We analysed clinical and dosimetric risk factors for grade ⩾2 RP.
Results: After the median follow-up time of 14 months (6−23 months), the median time to detection of pulmonary imaging changes after radiotherapy was 2 months (0−6 months), and 79.2% (61/77) of patients had their imaging changes in regions receiving ⩾40 Gy. 50.7% (39/77) of patients had grade ⩾2 RP, and the median time to grade ⩾2 RP after radiotherapy was 1 month (0−5 months). Risk factors of grade ⩾2 RP were pulmonary infection (infection *VS.* non-infection: OR=11.48, $P = 0.000$) and lung cancer (lung cancer *VS.* oesophageal carcinoma: OR=4.51, $P = 0.009$). Dosimetric factors including V_5, V_{10}, V_{20}, V_{40}, volumes and mean doses of ipsilateral, contralateral and total lung were found to be not associated with grade ⩾2 RP. Fungous infection and grade 4−5 RP were much higher in patients with imaging changes exceeded regions receiving ⩾40 Gy than those with imaging changes in regions receiving ⩾40 Gy (62.5% *VS.* 8.2%,$P = 0.000$;37.5% *VS.* 0%,$P = 0.000$).
Conclusions: Pulmonary infection and lung cancer were risk factors of grade ⩾2 RP in patients with pulmonary imaging changes after thoracic radiotherapy, and pulmonary imaging changes were predominantly in regions receiving ⩾40 Gy. Furthermore, patients with imaging changes exceeded regions receiving ⩾40 Gy had much higher possibilities to get fungous infection and grade 4−5 RP.

3440 POSTER

Patterns of failure after stereotactic body radiotherapy for histologically proven stage I non-small-cell lung cancer

Y. Kosaka[1], M. Kokubo[1], K. Takayama[2], N. Katakami[3]. *[1]Kobe City Medical Center General Hospital, Division of Radiation Oncology, Kobe, Japan; [2]Institution of Biomedical Research and Innovation, Division of Radiation Oncology, Kobe, Japan; [3]Institution of Biomedical Research and Innovation, Division of Integrated Oncology, Kobe, Japan*

Background: To report patterns of failure after stereotactic body radiotherapy (SBRT) for histologically proven Stage I non-small-cell lung cancer (NSCLC).
Materials and Methods: Between 2003 and 2007, 78 consecutive patients with clinically staged, histologically proven Stage I NSCLC (median age, 79 years; T1N0M0, n = 44; T2N0M0, n = 34) were treated with SBRT at our center in Japan. Twenty-four patients were medically operable but refused surgery, and 54 patients were inoperable because of underlying comorbidities. The histology was adenocarcinoma in 53 patients, squamous cell carcinoma in 23 patients, and others in 2 patients. Stereotactic three-dimensional treatment was performed using non-coplanar, static 4-MV photon beams. Forty-eight Gy in 4 fractions within 4−8 (median = 4) days was prescribed for the isocenter of the planning target volume for all patients. Data were collected and analyzed retrospectively.
Results: Median durations of observation for all patients and survivors as of the final follow-up were 41.1 (range, 2.2–105.9) and 59.9 (range, 9.4–105.9) months, respectively. The 5-year local control, progression-free survival, overall survival, and cause-specific survival were 69.5%, 45.9%, 47.6%, and 63.2%, respectively. Disease progression was observed in 36 patients. The sites of first recurrence were distant only (n = 21), local only

(n = 8), nodal only (n = 5), and nodal and distant (n = 2). First recurrence occurred at a median of 14.0 (range, 4.5–91.5) months, and, in 28 patients (77.8%), first recurrence occurred within 2 years. Finally, after long-term follow-up, local, nodal, and distant failure occurred in 15, 16, and 29 patients, respectively. Local failure occurred at a median 16.4 (range, 5.7–91.5) months, and, in 10 of 15 patients (66.7%), local failure occurred within 2 years. One patient safely underwent salvage surgery and had not developed new recurrence as of the final follow-up (76.5 months). Another patient developed local failure at 91.5 months after SBRT without nodal and distant failure. Univariate analysis showed that a large gross tumor volume was associated with a trend toward high local failure rate, and was a significant factor in cause-specific survival, although no significant factors were correlated with nodal and distant failure.
Conclusions: After SBRT for histologically proven Stage I NSCLC, the predominant pattern of failure was distant failure, followed by local failure. Local failure may occur even after a long-term follow-up. Dose escalation should be considered to prevent local failure, especially for large tumors, as well as systemic chemotherapy to prevent all failures.
No conflict of interest.

3441 POSTER

Stereotactic body radiotherapy (SBRT) for elderly patients with early stage non-small cell lung cancer (NSCLC)

T. Mitsuyoshi[1], Y. Kawaguchi[1], K. Konishi[1], T. Teshima[1], K. Nishiyama[1]. [1]*Osaka Medical Center for Cancer, Radiation Oncology, Osaka, Japan*

Background: SBRT is a standard approach for early stage NSCLC, which is applied for elderly patients that cannot tolerate surgery. The aim of this study is to assess the efficacy and safety of SBRT, especially for elderly patients.
Material and Methods: Since December 2006 through June 2010, 130 patients (94 men and 36 women) of early stage NSCLC (cT1a in 51, cT1b in 53, and cT2a in 26 patients without lymph node and distant metastasis) underwent SBRT at our institution. Histological diagnosis was adenocarcinoma in 58, squamous cell carcinoma in 30, and no evidence of malignancy in 42 patients. Tumors were located in the upper or middle lobes in 87 and in the lower lobes in 43. The median diameter of the tumor was 23 mm(11−47 mm), the median gross tumor volume was 4.9 cm^3(0.8–53.7 cm^3), and the median planning target volume was 28.2 cm^3(6.3–140.4 cm^3). Total doses were 48 Gy in 4 fractions at the isocenter. Local control and overall survival rates were calculated by the Kaplan–Meier method. The median follow-up time after SBRT was 37 months (range: 1−73 months). The endpoints were local control rates. Adverse events were scored using Common Terminology Criteria for Adverse Events version 4.0.
Results: The subjects were 78 years old in median (range: 59−90) and contained 56 patients over 80 years old (43%). The 3-year local control rates were 80.5% for all patients, and 85.7%, 81.3%, and 67.1%, for T1a, T1b, and T2a, respectively. Local control and overall survival rates at 3 years were 82.3% and 82.3% for patients under 80 years old and 77.4% and 67.6% for patients over 80. On univariate analysis for local control, only clinical stage was a significant factor ($p = 0.037$), however, age was an insignificant factor ($p = 0.361$). Concerning adverse events, only one 83-year-old patient developed grade-3 radiation pneumonitis, however, completely recovered after steroid therapy. The other grade-2 or more adverse events were grade-2 rib fractures in 3 patients, all of whom were under 80 years of age.
Conclusions: Our study showed that SBRT achieved equivalent local control even for patients over 80 of age with NSCLC to that for under 80. Overall survival for the elderly patients was lower than that for under 80, however, the difference was insignificant. The incidence of adverse events was minimal for the elderly patients. SBRT for early stage NSCLC provided acceptable local control and was safe for patients over 80 years of age as well.

Hypofractionated (chemo)radiation delivered with helical tomotherapy allows safe dose escalation in stage III unresectable non small cell lung cancer

S. Arcangeli[1], A. Monaco[1], C. Caruso[1], M. Cianciulli[1], C. Chiostrini[1], R. Rauco[2], M.C. Pressello[2], V. Donato[1]. [1]*Azienda Ospedaliera San Camillo-Forlanini, Radioterapia, Roma, Italy;* [2]*Azienda Ospedaliera San Camillo-Forlanini, Fisica Sanitaria, Roma, Italy*

Background: To assess treatment outcome, and toxicity after a moderately escalated hypofractionated radiotherapy delivered with Helical Tomotherapy (HT) in locally advanced stage III unresectable non-small cell lung cancer (NSCLC) combined with sequential or concurrent chemotherapy.
Methods and Materials: Sixty-one eligible patients were treated with combined platinum-based chemotherapy associated with a moderately escalated hypofractionated radiation course delivered with HT. The treatment schedule consisted of 30 daily fractions of 2.25–2.28 Gy each administered in 6 weeks, corresponding to a normalized total dose at 2 Gy per fraction (NTD2) of nearly 70 Gy, applying a/b ratio of 10. The target was considered the gross tumour volume and the clinically proven nodal regions, without elective nodal irradiation. Overall survival and local control were assessed as well as acute and late toxicity using Radiation Therapy Oncology Group (RTOG) grading system.
Results: No Grade $\geqslant$4 acute and late toxicity was reported. Acute Grade 3 treatment-related pneumonitis was detected in 10% of patients. Two patients, both receiving the concurrent schedule, developed a Grade 3 acute esophagitis. The overall incidence of late Grade 3 lung toxicity was 5%. No patients experienced a Grade 3 late esophageal toxicity. The median survival duration was 18 months in the sequential group and 24 months in the concomitant group, with 1-year and 2-year OS rate of 77% and 53% respectively for all patients, 43% of whom were stage IIIB.
Conclusions: Our findings shows that a moderately hypofractionated radiation course delivered with HT is a feasible treatment option for patients with inoperable locally advanced NSCLC receiving chemotherapy (sequentially or concurrently). Hypofractionated radiotherapy with a dedicated technique allows safely dose escalation, minimizing the effect of tumor repopulation that may occur with prolonged treatment time.

3443 POSTER

Pleural lavage cytology is a significant prognostic factor for stage I lung adenocarcinoma patients

D. Hokka[1], Y. Maniwa[1], S. Tauchi[1], S. Tane[1], K. Uchino[2], K. Tane[2], W. Nishio[2], M. Yoshimura[2]. [1]*Kobe University Graduate School of Medicine, Divisions of Thoracic Surgery Department of Surgery, Kobe, Japan;* [2]*Hyogo Cancer Center, Department of Thoracic Surgery, Akashi, Japan*

Background: The result of cytological examination of pleural effusion is important for planning of treatment and prediction of the prognosis in non-small cell lung cancer (NSCLC) patients. Previously, we reported that the positive cytology was detected by carrying out pleural lavage cytology (PLC) at the time of thoracotomy for NSCLC patients with no pleural effusion and its prognostic significance was evaluated. Here, re-examination was performed with additional follow-up survey and new knowledge about the significance of PLC was reported.
Material and Methods: Cytology of pleural lavage immediately after thoracotomy was examined in 1317 consecutive patients with NSCLC with no pleural effusion who underwent pulmonary resections from 1987 to 2004 in Kobe University Hospital and Hyogo Cancer Center. The patients who underwent induction therapy, who underwent CT-guided needle biopsy, and who had pleural dissemination confirmed by pathological examination were excluded from this study.
Results: Forty-six of 1317 patients (3.5%) had positive cytological findings. The prognosis of 46 patients was significantly worse compared with the negative cytology group (26% vs 64% for 5-year survival rate, $p < 0.0001$). In 814 of pathologically stage-I patients, eighteen patients were diagnosed as positive with PLC (2.2%) and the prognosis of them was also significantly worse (25% vs 78%, $p < 0.0001$). The recurrence rate of PLC-positive Patients in stage I was 83% (15 of 18 patients).
Conclusions: Positive finding of PLC is associated with a worse prognosis, and the tendency is significant in stage-I patients. These findings suggested the need of PLC in the staging and treatment of NSCLC patients.
No conflict of interest.

3444 POSTER

Treatment possibilities for local recurrence of surgically treated non-small cell lung cancer

D. Stojiljkovic[1], N. Miletic[1], S. Jokic[1], I. Markovic[1], M. Kocic[1], G. Pupic[2], T. Stojiljkovic[3], I. Spurnic[1], R. Dzodic[1]. [1]*Institute of Oncology and Radiology, Surgery, Belgrade, Serbia;* [2]*Institute of Oncology and Radiology, Patology, Belgrade, Serbia;* [3]*General Hospital Smederevo, Radiology, Smederevo, Serbia*

Background: Reoperation in patients previously operated for lung cancer is practically indicated in two cases. The most common reason is recurrence of disease (relapse), and the other reason is, if previous resection was made incomplete. Relapse of disease is related to the level of radicality on primary operation and is also in relation to the characteristics of the primary tumor.
Materials and Methods: The study was retrospective-prospective and included 114 patients with recurrent disease, primarily operated with the clinical stage of Ia − IV. The patients are collected from the database of

the Institute for Lung Diseases, Clinical Center of Serbia and the Institute for Oncology and Radiology of Serbia in Belgrade from year 2002 to 2010. One patient initially had a solitary metastasis in the CNS (stage IV), which was operatively treated in the beginning of treatment. Operative treatment included all kinds of resections, from minimal atypical (wedge) resection through segmental lobectomies, sleeve lobectomies, pneumonectomies, sleeve pneumonectomies, and if necessary resection of the chest wall.
Results: In the study group of 114 patients, in 42(36.84%) patients surgical resection was possible. Because of poor general condition, symptomatic therapy was applied in 14 (12.8%) patients. For other patients, chemotherapy was applied in (33.33%), radiotherapy (13.16%) and combined chemo-radiotherapy (4.39%). In 42 operated patients, the most common type of surgery was resection of the chest wall in 17 (40.48%) patients. Pneumonectomy or intrapericardial pneumonectomy was performed in 13(30.95%) patients. Mediastinal lymphadenectomy was performed in a total of 22(52.38%) patients. Complications occurred in two patients such as empyema and chronic pain, respectively.
Conclusion: The surgery of local recurrence is justified if the extent of primary operation was less than pneumonectomy.
If local recurrence appears in chest wall on the side where primary operation was done we can certainly say that resection of primary tumor which was in contact with parietal pleura was incomplete. Local recurrence such as pathologically changed lymph nodes in mediastinum more often happens when selective lymphadenectomy was done and not systemic.
Local recurrence on bronchial stump and in lung parenchyma is a sign of positive margins of earlier resection. In our patients it was most common when frozen section was not done.
No conflict of interest.

3445 POSTER

Lymphatic permeation status stratifies the prognosis of pathological node positive patients with clinical stage IA lung adenocarcinoma

T. Mimae[1], Y. Tsutani[2], Y. Miyata[1], T. Yoshiya[1], Y. Ibuki[1], H. Nakayama[3], S. Okumura[4], M. Yoshimura[5], M. Okada[1]. *[1]Research Institute for Radiation Biology and Medicine Hiroshima University, Department of Surgical Oncology, Hiroshima, Japan; [2]Memorial Sloan-Kettering Cancer Center, Department of Surgery, New York, USA; [3]Kanagawa Cancer Center, Department of Thoracic Surgery, Yokohama, Japan; [4]Cancer Institute Hospital, Department of Thoracic Surgery, Tokyo, Japan; [5]Hyogo Cancer Center, Department of Thoracic Surgery, Akashi, Japan*

Background: Logically, lymph node metastasis in lung cancer is thought to be a result of lymphatic permeation in the primary tumor. However, tumors with pathological node metastasis (pN(+)) are not necessarily show lymphatic permeation in pathological examination. The aim of this study is to analyze the prognostic significance of lymphatic permeation in patients with pN(+).
Material and Methods: The present study included 609 clinical T1N0 lung adenocarcinoma patients that consist of 568 pN(−) and 41 pN(+) patients. The association between the prognosis and pathological findings was retrospectively analyzed.
Results: In the pathological factors, pN(+) patients showed a significant lower lepidic growth component ratio (14.0±17.1% v.s. 50.7±36.6%, P <0.001), higher lymphatic, vessel, and visceral pleural invasion rate (68, 59, and 29 % v.s. 11, 14, and 9%, all P <0.001), respectively. In pN(−) patients, both the univariate and multivariate analysis of recurrence free survival (RFS) revealed that lower lepidic growth component ratio, lymphatic, vessel, and pleural invasion had a significant correlation with a poor prognosis. On the other hand, in pN(+) patients, both the univariate and multivariate analysis of RFS showed that only patients with lymphatic invasion (Ly) had an adverse prognosis ($P = 0.024$ and 0.022). Although RFS in the pN(+) patients was significantly worse compared with pN(−) (5 years RFS rate: 51.2% v.s. 88.6%, P <0.001), RFS in pN(+)/Ly(−) patients was significantly better compare with pN(+)/Ly(+) patients, (5 years RFS rate: 68.8 and 41.9%, $P = 0.024$), which was even close to that in pN(−)/Ly(+) patients.(5 years RFS rate: 68.2%, $P = 0.33$).
Conclusions: Even in patients with pathological lymph node metastasis, lymphatic permeation status in the primary tumor stratified the prognosis of patients with clinical stage IA lung adenocarcinoma.
No conflict of interest.

3446 POSTER

Early stage lung cancer treated only with surgery, impact of the 7th AJCC classification

M. Vieito[1], C. Rodriguez Lopez[1], N. Martinez Lago[1], M. Carmona[1], A. Cortegoso[1], F. Vazquez[1], F.J. Barón[1], L. Leon[1], S. Candamio[1], R. Lopez Lopez[1]. *[1]Hospital Clinico Santiago, Oncologia Medica Hospital Clínico Santiago de Compostela Fundación de Investigación Sanitaria Ramón Domínguez, Santiago de Compostela (A Coruña), Spain*

Background: With the high recurrence rates observed in early stage non-small cancer (NSLC) the identification of prognostic factors in this population becomes essential. Adjuvant chemotherapy is the standard treatment for stage IB to IIIA patients since the publication of several randomized controled trials in the early 2000s.
Material and Methods: We have retrospectively reviewed a cohort of patients (characteristics resumed in table 1) treated in our center with radical resection for stage I or II NSLC between March 1999 and March 2003. These patients didn't receive adjuvant chemotherapy.
Results: Median overall survival (OS) was 55 months (m) and the survival rate at 5 and 10 years was 51% and 26% respectively. Differences are found using 6th or 7th edition AJCC classification. Patients with stage I had a better overall survival (69 vs. 43 m) and (73 vs. 39m) although the difference was only statistically significant (p<0, 05) using the 7th edition AJCC classification. Differences between stage IA and stage IB were also numerically superior with the 7th edition (76 vs. 59 m) and(91 vs. 54 m) but neither reached statistical significance (p = 0.4 and 0.08). The existence of previous chronic pulmonary obstructive disease (COPD) was prognostic OS 34 vs. 86 months p < 0.001.
Conclusions: There is little doubt that in some patients NSLC is a systemic disease even when the primary tumor is detected at an early stage, but the current AJCC classification improves the identification of a subset of patients with a good prognosis only.
No conflict of interest.

Table: Characteristics of 41 patients

Gender	92% Male
Age (median)	71(52−86)
Smoking status	56% current smokers, 37% former, 5% never
COPD	46%
Pathological staging 6th AJCC	IA: 43% IB:26% IIA: 5% IIB:25%
Pathological staging 7th AJCC	IA: 34% IB:31% IIA:10% IIB:22% IIIA 2.5%
Histology	56% squamous, 39% adenocarcinoma, 5% large cell
Lymphovascular invasion	21%
Grade	17% well differentiated, 57% moderately, 25% undifferentiated

3447 POSTER

Revision of integrated positron emission tomography value by tumor size is not necessary to evaluate malignancy grade of clinical stage IA lung adenocarcinoma

Y. Miyata[1], Y. Ibuki[2], Y. Tsutani[2], T. Yoshiya[2], T. Mimae[2], H. Nakayama[3], S. Okumura[4], M. Yoshimura[5], M. Okada[2]. *[1]Hiroshima University, Hiroshima, Japan; [2]Hiroshima University, Surgery, Hiroshima, Japan; [3]Kanagawa Cancer Center, Surgery, Yokohama, Japan; [4]Cancer Institute Hospital, Surgery, Tokyo, Japan; [5]Hyogo Cancer Center, Surgery, Akashi, Japan*

Background: Maximal standardized uptake value (maxSUV) on positron emission tomography/computed tomography (PET/CT) is reported to be a surrogate marker of tumor malignancy grade in lung adenocarcinoma. Logically, maxSUV should be revised to correct for partial volume effect, ie, small tumors are thought to be underestimated. In this study, we examined whether revision of maxSUV by tumor size is needed in order to clinically evaluate malignancy grade of clinical stage IA lung adenocarcinoma.
Material and Methods: Consecutive 609 patients with clinical stage IA lung adenocarcinoma who had undergone preoperative PET/CT were enrolled in this study. Tumor diameter from high resolution CT was used to revise maxSUV based on outcomes of study using an anthropomorphic body phantom that conformed to National Electrical Manufacturers Association standards. Measured maxSUV (m-maxSUV) and revised maxSUV (r-maxSUV) by tumor size were compared according to pathological tumor malignancy grade and prognosis.
Results: Recovery coefficient (RC) was determined according to tumor size; 0.2, 0.6, 0.8, 0.9 and 1.0 for tumor diameter (mm) of 10−12, 13−17, 18−22, 23−27 and 20-, respectively. r-maxSUV was calculate using the equation: r-maxSUV = m-maxSUV/RC. Median m-maxSUV was significantly lower than r-maxSUV (1.6 vs 2.4). All receiver operating characteristics area under the curve for predicting ly, v, pl, n, high-grade

malignancy (ly, v, pl or n) and tumor recurrence were larger for m-maxSUV than those for r-maxSUV. Cut-off values of m-maxSUV and r-maxSUVfor predicting tumor recurrence were 3.3 and 2.7, respectively. A significant difference in recurrence free survival (RFS) and overall survival (OS) were identified between patients whose adenocarcinoma had m-maxSUV 3.3 or less (n = 471; 5-year RFS, 95.8%, OS, 96.0%) and greater than 3.3 (n = 138; 5-year RFS, 72.5%, OS, 81.9%. We also found significant differences in RFS and OS between patients whose adenocarcinoma had m-maxSUV 2.7 or less (n = 333; 5-year RFS, 96.7%, OS, 96.7%) and greater than 3.3 (n = 276; 5-year RFS, 83.0%, OS, 88.0%.).
Conclusions: Revision of maxSUV by tumor size is not necessary to evaluate malignancy grade of clinical stage IA lung adenocarcinoma.
No conflict of interest.

3448 POSTER

Our experience of surgical management of rare malignant tumours of lungs: Lessons learned

D. Bazarov[1], V. Parshin[1], U. Biryukov[1], S. Grigorieva[1], D. Fedorov[1].
[1]National Research Centre of Surgery, Thoracic Surgery, Moscow, Russian Federation

Background: The problem of surgical treatment of rare malignant tumours of lungs remains so far insufficiently studied and remain difficult task of modern oncology. To rare malignant tumours of lungs carry tumours as epithelial tumours (carcinoid, adenoid-cystic cancer) and no epithelial tumours (sarcoma, giant cell cancer, etc.).
Aims: To analyse results of surgical management of patients with rare lung tumours.
Materials and Methods: From 1963 to 2012 in our division 4078 operations for primary lung cancer were performed. 388 (9.5%) procedures were performed in patients with rare malignant tumours.
Among rare new growths it is necessary to consider as the most widespread epithelial tumour bronchial lung carcinoid (267 patients) which differentiated on typical (90.5%) and atypical (9.5%) options. Adenoid-cystic cancer was in 28 (7.2%) patients, giant cell cancer in 13 patients. Various histologic types of non-epithelial malignant tumours (sarcoma) in 71 patients. Tactics concerning rare malignant tumours was same as in non-small cell cancer of a lung. Organ-preserving operations including bilobectomy and reconstructive bronchial plastic surgeries were a main type of surgical intervention in cases of typical carcinoids and in cases of adenoid-cystic cancer. When scoping resection atypical carcinoid considered as a non-small cell cancer of a lung and observed the modern principles of a cancer therapy. In the malignant non-epithelial tumours, atypical carcinoids and giant cell cancer expanded operations were performed including pneumonectomy, and also a lob- and bilobectomy with removal of lymph nodes from mediastinum. Postoperative complications observed in 41 patients (10.6%). The hospital lethality made 1.5% − 6 patients died. Long-term results after operations in carcinoid includes five-year survival rate 92.1%, ten-year survival rate 84.2%, in adenoid-cystic cancer: 5 years survival rate was 72.2%, more than 10 y − 27.3% survival rate, more than 15 years − 18% survival rate. In patients operated concerning non epithelial tumours in the II−III stage and with metastasises in lymph nodes (N1−2) the long term results were not very comforting, and only patients with first stage of a disease 5 year survival rate was 52%. Results of treatment of giant cell cancer were worse: 7 patients died in terms till 24 months, the others till 36 months. Only 1 patient lived 61 months.
Conclusion: Since majority of rare lung tumours are resistant to chemotherapy and radiotherapy the surgical management remain single curative option. In patients with high-differentiated tumours in T1N0M0 and T2N0M0 stages surgical treatment is rather effective, but in cases of low-differentiated type of a tumour and as when malignance involving mediastinal lymph nodes results more worse and these patients received combined therapy. Major factors of the prognosis are size of tumour, a condition of intra chest lymph nodes and degree of a differentiation of tumour cells. The long-term results of surgical management of rare malignant tumours of lungs testify to correctness of these tactics.
No conflict of interest.

3449 POSTER

Feasibility of bronchoplastic surgery for bronchial carcinoids

B. Venkitaraman[1], A. Kumar[2], T. Jindal[2], R. Parshad[2], P. Shivanna[1], R. Guleria[3], G.C. Khilnani[3]. *[1]Institute Rotary Cancer Hospital, Department of Surgical Oncology, New Delhi, India; [2]All India Institute of Medical Sciences, Department of Surgical Disciplines, New Delhi, India; [3]All India Institute of Medical Sciences, Department of Pulmonary Medicine, New Delhi, India*

Background: Surgical management of bronchopulmonary carcinoids has evolved significantly over the years. Parenchyma preserving surgery (PPS) has been the preferred management option where ever possible. We share our experience in the management of bronchopulmonary carcinoid tumors at our institute over the last 7 years, with a specific emphasis on parenchyma preserving surgery.
Methods: A retrospective analysis of records of patients diagnosed as bronchopulmonary carcinoid tumors and surgically managed at our institute since 2005 was done to evaluate the outcome of various surgical procedures.
Results: A total of 45 patients with bronchopulmonary carcinoids treated surgically were identified. Among the various surgeries performed, 17 of 45 patients (37.7%) underwent parenchymal preserving surgeries(PPS) − sleeve resection and anastomosis(5), sleeve lobectomy(7), wedge resection (5); while 28 of 45 underwent various parenchymal resection surgeries (PRS) including lobectomy (12), bilobectomy (6) and pneumonectomy (10). 25 patients (8 PPS, 17 PRS) had post operative morbidity, of which 7 patients (3 PPS, 4 PRS) required re-exploration, while 18 patients (5 PPS, 13 PRS) were managed non-operatively. There was no perioperative mortality. One patient had microscopic post margin in PPS group. During follow up (range: 4 months- 80 months), 40/45 patients were doing well(3 − lost to follow-up), with no symptoms or evidence of disease recurrence on bronchoscopy and imaging (including patient microscopic positive margin). Patients with PPS also had a better preservation on lung function in comparison to parenchymal resections on follow up pulmonary function tests.
Conclusion: Parenchyma preserving surgery is feasible in selected patients with bronchopulmonary carcinoids with better preservation of lung function and lesser morbidity.
No conflict of interest.

Treatment	Number of cases
Pneumonectomy	10
Lobectomy	12
Bilobectomy	6
Wedge resection	5
sleeve lobectomy	7
Sleeve resection & Anastomosis	5

Is early 18F-FDG PET useful for predicting pathologic response to EGFR-TKI in resectable non-small cell lung cancer?

M.H. Van Gool[1], T.S. Aukema[2], E.E. Schaake[3], R.A. Valdes Olmos[2], J. Teertstra[4], R. Van Pel[5], J.A. Burgers[3], H. Van Tinteren[6], H.M. Klomp[1], NEL Study group[1]. *[1]NKI-AVL, Surgical Oncology, Amsterdam, Netherlands; [2]NKI-AVL, Nuclear Medicine, Amsterdam, Netherlands; [3]NKI-AVL, Thoracic Oncology, Amsterdam, Netherlands; [4]NKI-AVL, Radiology, Amsterdam, Netherlands; [5]NKI-AVL, Pathology, Amsterdam, Netherlands; [6]NKI-AVL, Biometrics, Amsterdam, Netherlands*

Background: The value of neo-adjuvant therapy in patients with resectable non-small cell lung carcinoma (NSCLC) is limited. Recent advances in targeted therapy have provided novel treatment options for NSCLC with promising results. The Epidermal Growth Factor Receptor (EGFR) is over expressed or may harbour activating mutations in adenocarcinoma in particular. Inhibition of EGFR with tyrosine-kinase inhibitor (TKI) therapy has a favourable outcome in advanced stage patients with activating mutations. Metabolic imaging in (advanced) NSCLC has shown to be valuable in response assessment in the setting of targeted therapy. The purpose of this study was to prospectively evaluate the timing of 18F-FDG-PET to measure metabolic response to neoadjuvant erlotinib, in patients with early stage NSCLC.
Patients and Methods: This study was designed as an open-label phase II trial, performed in 4 hospitals in the Netherlands. Patients received preoperative erlotinib 150 mg once daily for 3 weeks. Response evaluation was performed after 1 week and at 3 weeks using an FDG-PET/CT scan. Tumour FDG uptake and changes were measured by standardized uptake values (SUV). Metabolic response was classified using EORTC criteria. Metabolic response was compared to the histopathological response.
Results: From December 2006 until November 2010, 60 patients with NSCLC eligible for surgical resection were enrolled in this study. In 43 patients (18 male, 25 female), repeated FDG-PET/CT scans and histopathologic response monitoring were available. After 1 week the FDG-PET/CT scan showed partial metabolic response in 10 patients (23%). After 3 weeks, 14 patients (33%) showed partial metabolic response. Relative change in SUVmax at early and at late scan were significantly correlated. Histopathologic examination showed a response in 13 patients (>50% necrosis). Early FDG-PET/CT scan showed an AUC of 64.5% in predicting

histopathologic response, late scan showed an AUC of 72%. No significant difference was seen between these curves.
Conclusion: Response monitoring via FDG PET/CT scan can be performed as early as 1 week after intention of erlotinib.
Conflict of interest: *Corporate-sponsored research: This study was supported in part by an unrestricted educational grant from Roche, The Netherlands.*

3451 POSTER

18F-FDG-PET vs CT in predicting histopathological response to EGFR-TKI treatment in resectable non-small cell lung cancer

M.H. Van Gool[1], T.S. Aukema[2], E.E. Schaake[3], R.A. Valdes Olmos[2], J. Teertstra[4], R. Van Pel[5], J.A. Burgers[6], H. Van Tinteren[7], H.M. Klomp[1], NEL-Study Group[1]. *[1]NKI-AVL, Surgical Oncology, Amsterdam, Netherlands; [2]NKI-AVL, Nuclear Medicine, Amsterdam, Netherlands; [3]NKI-AVL, Thoracic-oncology, Amsterdam, Netherlands; [4]NKI-AVL, Radiology, Amsterdam, Netherlands; [5]NKI-AVL, Pathology, Amsterdam, Netherlands; [6]NKI-AVL, Thoracic Oncology, Amsterdam, Netherlands; [7]NKI-AVL, Biometrics, Amsterdam, Netherlands*

Background: In early stage non-small cell lung cancer (NSCLC) treatment is focused on curative surgery. The value of neo-adjuvant therapy is limited. Recent advances in targeted therapy have provided novel treatment options for NSCLC with promising results. The Epidermal Growth Factor Receptor (EGFR) is over expressed or may harbour activating mutations in adenocarcinoma in particular. Inhibition of EGFR with tyrosine-kinase inhibitor (TKI) therapy has a favourable outcome in advanced stage patients with activating mutations. Several studies demonstrated that FDG-PET is able to identify response to treatment and to avoid (continued) ineffective treatment in advanced stage NSCLC. However, CT has been the clinical standard for response evaluation and discussion has been going on the performance of FDG-PET as compared to CT. In this perspective, a phase II study was designed to monitoring histopathologic response of erlotinib using both diagnostic CT and FDG-PET in patients with NSCLC. The objective was to prospectively evaluate radiologic and metabolic response after 3 weeks of neoadjuvant EGFR-TKI treatment and relate the data to histopathologic response.
Patients and Methods: This study was designed as an open-label phase II trial, performed in four hospitals in the Netherlands. Patients received preoperative erlotinib 150 mg once daily for 3 weeks. CT and FDG-PET were performed at baseline and after 3 weeks of treatment. CT was assessed according to the RECIST criteria 1.1. FDG-PET, tumour FDG uptake and changes were measured by standardized uptake values (SUV). Radiologic and metabolic responses were compared to the histopathological response.
Results: From December 2006 until November 2010, 60 patients were enrolled in this study. In 53 patients (22 male, 31 female) the combination of CT, FDG-PET and histopathological evaluation was available for the analysis. Three patients (6%) had a radiologic response. According to EORTC criteria 15 patients (28%) showed metabolic response. In 11 patients histopathologic response ($\geqslant$50% necrosis) was seen. In predicting histopathologic response, CT had a positive predictive value of 66% (CI 21%-94%) and a negative predictive value of 78% (CI 65%-87%). FDG-PET had a positive predictive value of 46% (CI 25%-70%) and a negative predictive value of 84% (CI 70%-93%).
Conclusion: FDG-PET has an advantage over CT as a predictive tool to identify histopathologic response after 3 weeks of EGFR TKI treatment in NSCLC patients.
Conflict of interest: *Corporate-sponsored research: This study was supported in part by an unrestricted educational grant from Roche, The Netherlands.*

3452 POSTER

Community-based evaluation of determinants for outcome of completely resected non-small cell lung cancer (NSCLC) stage IB receiving adjuvant chemotherapy

S. Wallerek[1], J. Ravn[2], J.B. Sørensen[1]. *[1]Rigshospitalet, Department of Oncology, Copenhagen, Denmark; [2]Rigshospitalet, Department of Thoracic Surgery, Copenhagen, Denmark*

Background: The case for adjuvant chemotherapy following microscopically completely resected NSCLC stage IB is not yet fully illuminated. Adjuvant chemotherapy is currently optional for these patients (pts). We reviewed a consecutive group of unselected completely resected stage IB pts according to 6th staging edition in Copenhagen who received adjuvant chemotherapy and examined subgroups for determinants of overall survival (OS) and disease free survival (DFS).
Materials and Methods: Consecutive pts completely resected 2005–2012 received adjuvant i.v. cisplatin 75 mg/m^2 day 1 and i.v. vinorelbine 30 mg/m^2 day 1+ 8 every third week for 4 cycles. 50 variables including patient characteristics, pathology and surgical records, relapse site and survival were collected. 2- and 5-year OS and DFS were calculated using Kaplan–Meier plots. Differences in OS in subgroups were evaluated using Cox regression analysis.
Results: Among totally 69 pts there were 24 males (34%), median age was 63 years (range 40−78 years). 49 pts (70%) had adenocarcinoma, 14 pts (20%) had squamous cell carcinoma, 5 pts (7%) had large cell carcinoma and 2 pt (3%) had mixed type NSCLC. Median tumor size was 31 mm (7−90 mm), 53 pts (76%) had pleural involvement and 6 pts (9 %) had vascular invasion. Median follow-up was 3.4 years (0.35 −7.3 years). 13 pts (19%) had disease recurrence being local in 46%, distant in 31 % and local + distant in 23%. 11 pts (16%) died. Kaplan–Meier estimates of 2-, and 5-year OS were 90% (CI: 80−96) and 82% (CI: 70−90). 2-, and 5-year DFS were 84% (CI: 73−92) and 74% (CI: 62−83). A multivariate Cox regression analysis including gender, age, histology, tumor size, pleural involvement, vascular involvement, and performance status revealed that pts with a tumor size 5 cm or smaller had significant better OS than pts with tumors larger than 5 cm (p = 0.05). Literature reviews from 2003–2012 revealed 4 articles reporting on OS specifically in stage IB receiving adjuvant chemotherapy with 5-year OS ranging from 60−85% (CI: 52−91) [1−4].
Conclusion: It might be anticipated that selected patients included in randomized trials would experience a better OS than unselected community-based similar pts. This was not the case, supporting application of results to routine daily practice in unselected stage IB pts. Only tumor size was significant in multivariate analysis which corroborates with current 7th staging edition. Biomarkers may clarify which pts in 7th edition stage IB may benefit or not from ACT.

Online validation of survival-associated biomarkers in non small-cell lung cancer using transcriptomic data of 1,715 patients

B. Gyorffy[1], A. Lanczky[1]. *[1]Hungarian Academy of Sciences, Research Group for Pediatrics and Nephrology, Budapest, Hungary*

Background: To decipher the molecular basis of lung cancer and to improve treatment strategies we have to identify genes correlated to therapy response and to survival. Here, we present the development of a new, freely available online tool suitable for the real-time meta-analysis of published lung cancer microarray datasets to validate expression based survival associated biomarker candidates.
Materials and Methods: First we have searched the caBIG, GEO and TCGA repositories to identify datasets with published gene expression data and survival information. In this, three GEO platforms(GPL96, GPL570 and GPL3921) were considered as these possess 22,277 common probes, which were used for constructing the database. All together 1,715 NSCLC samples in ten independent datasets were identified, 85% have overall survival and 45% progression free survival info, one-third adenocarcinomas and one-third squamous cell carcinomas. Cox uni- and multivariate analysis, Kaplan–Meier survival plot, and the hazard ratio with 95%confidence intervals and logrank P value are calculated and plotted in R using Bioconductor packages. To assess the prognostic value of a gene, each percentile (of expression) between the lower and upper quartiles are computed and the best performing threshold can be used as the final cutoff in a Cox regression analysis. The complete meta-analysis tool can be accessed online at http://www.kmplot.com/lung/
Results: We used this analysis tool to validate previously published survival associated biomarkers including 21 individual genes and 7 gene expression signatures. Each of the biomarker candidates was investigated in a cohort having similar clinical characteristics as the patients in which they were originally described. Survival was best predicted by CDK1 (HR = 2.56, p<1e-16), CD24 (HR = 2.45, p=3.6e-10) and CADM1 (HR = 0.38, p=7e-12) in adenocarcinomas and by CCNE1 (HR = 2.44, p=4.8e-08) and VEGF (HR = 1.9, p=3.3e-10) in all NSCLC patients. One of the signatures using 139 genes achieved an even higher power (HR = 3.59, p=8.9e-16) in stage I NSCLC patients.
Conclusions: In summary, by utilizing genome-wide microarray datasets we have successfully integrated a large scale database suitable for the *in silico* validation of biomarker candidates. The presented program is a highly valuable tool for lung cancer research groups enabling to promptly validate genes correlated to survival in order to choose the most robust markers for subsequent analyses.

Poor prognosis of concurrent KRAS and TP53 mutations in patients with resected non-squamous non-small cell lung cancer (NSCLC)

N. Pécuchet[1], P. Laurent-Puig[2], K. Pallier[3], F. Le Pimpec-Barthes[4], M. Riquet[4], A. Cazes[5], E. Fabre[1], H. Blons[2]. [1]*Hôpital Européen Georges Pompidou, Medical Oncology, Paris, France;* [2]*Hôpital Européen Georges Pompidou, Biochemistry Unit of Pharmacogenetic and Molecular Oncology, Paris, France;* [3]*Paris Descartes University, UMR-S775 – Molecular Basis of Response to Xenobiotics, Paris, France;* [4]*Hôpital Européen Georges Pompidou, Thoracic Surgery, Paris, France;* [5]*Hôpital Européen Georges Pompidou, Pathology, Paris, France*

Background: *TP53* and *KRAS* mutations are the most frequent genetic alterations in lung adenocarcinomas but their prognostic impact in early-stage NSCLC remains debated. Here, we addressed the prognostic value of *TP53* inactivating mutations regarding concurrent genetic alterations in *EGFR*, *KRAS*, *CDKN2A*, *CCND1*, *CCND3* and *CCNE1*.
Material and Methods: *TP53* mutations were determined in a surgical series of 140 consecutive non-squamous NSCLC prospectively collected. These tumors were characterized for *TP53* (ex 4−10), *EGFR* (ex 18−21) and *KRAS* (ex 2) mutations by direct sequencing, as for *CDKN2A* homozygous deletions and for *CCND1*, *CCND3*, *CCNE1* amplifications by Q-PCR. Prognostic factors were determined using uni- and multivariate Cox-model analyses on overall survival (OS). Then, we addressed the effect of concurrent mutations on prognostic (ie $TP53_m$ and $KRAS_m$) by testing their interaction in Cox models on OS.
Results: After a median follow-up 7.03 years (CI 6. 67–7.57), 72 events occurred. Pts had a median age of 60 years (range 33−85), included 58 females and 82 males, 123 adenocarcinomas and 17 other histologies, 82 stage I, 27 stage II and 31 stage IIIA tumors. Somatic mutations were: 32% *TP53*, 21% *KRAS*, 17% *EGFR*, 6% had concurrent $KRAS_m$-$TP53_m$; amplifications were: 15% *CCND1*, 12% *CCNE1*, 11% *CCND3*; homozygous deletions were 9% *CDKN2A*. In multivariate analysis, prognostic factors were: tumor stage II (HR 2.14; CI 1.17–3.80), tumor stage III (HR 3.62; CI 2.03–5.71), $TP53_m$ (HR 0.54; CI 0.30–0.94) and $KRAS_m$ (HR 2.13; CI 1.25–3.55). The prognostic of $TP53_m$ was profoundly impacted by the co-occurrence of a $KRAS_m$ (interaction p = 0.001). Indeed, $TP53_m$ was a factor of favorable outcome in $KRAS_{wt}$ tumors (HR 0.32; CI 0.15–0.62), and conversely, a factor of poor outcome in $KRAS_m$ (HR 2.56; CI 0.88–7.23). This interaction was also validated considering disease-free survival (interaction p = 0.02) and cancer-specific survival (interaction p = 0.003). Median OS was 2.14, 4.66, 6.59 and 10.60 years for $TP53_m$-$KRAS_m$, $TP53_{wt}$-$KRAS_m$, $TP53_{wt}$-$KRAS_{wt}$ and $TP53_m$-$KRAS_{wt}$, respectively (log-rank p = 0.0005).
Conclusions: In our series, concurrent *KRAS* and *TP53* mutations conferred a very poor prognostic in patients with resected non-squamous NSCLC. Dedicated targeted therapies are urgently needed to treat this subgroup of patients.
No conflict of interest.

High throughput parallel amplicon sequencing of common driver mutations from FFPE lung cancer samples in molecular pathological routine diagnostics for a regional health care provider network

L. Heukamp[1], K. König[2], M. Peifer[3], K. Stamm[4], M. Bos[5], C. Vollbrecht[6], S. Merkelbach-Buse[6], T. Henkel[7], J. Wolf[5], R. Buettner[6]. [1]*University Hospital Cologne, Institute of Pathology Lung Cancer Group Center for Integrated Oncology, Cologne, Germany;* [2]*University Hospital Cologne, Institute of Pathology, Cologne, Germany;* [3]*University Hospital Cologne, Department of Genomics, Cologne, Germany;* [4]*TARGOS Molecular Pathology GmbH, Cologne, Germany;* [5]*University of Cologne, Lung Cancer Group Cologne Department I of Internal Medicine and Center for Integrated Oncology, Cologne, Germany;* [6]*University of Cologne, Institute of Pathology Lung Cancer Group Center for Integrated Oncology, Cologne, Germany;* [7]*TARGOS Molecular Pathology GmbH, Kassel, Germany*

Background: Treatment paradigms for non-small-cell lung cancer (NSCLC) have shifted from one based only on histology to one that incorporates molecular subtypes. The list of therapeutically targetable lesions is rapidly increasing including mutations in genes such as *EGFR*, *HER2*, *KRAS*, *ALK*, *BRAF*, *PIK3CA*, *AKT1*, *ROS1*, *NRAS*, *FGFR1* and *MAP2K1*. Analysis of these potential targets is becoming a challenge in terms of work load, tissue availability as well as cost. We aimed to reduce 1) the time requirement for comprehensive molecular diagnostics, 2) the minimal amount of formalin fixed paraffin embedded (FFPE) derived input DNA, 3) while at the same time increasing the number of target regions analysed.
Material and Methods: We established a multiplex PCR to amplify up to 190 lung cancer relevant target regions from at least 50ng of FFPE derived tumor DNA. The amplicon libraries were ligated to adapters encompassing medical identifier sequences that allowed multiplexing of up to 48 patients to be sequenced on a benchtop Illumina platform (MiSeq).
Results: So far, we sequenced more than 450 samples of patients diagnosed with NSCLC. We found that the time needed to complete the mutation screening as well as the needed material was significantly reduced. Out of 260 samples of patients diagnosed with squamous-cell carcinoma we could identify six new mutations in the DDR2 gene confirmed by Sanger Sequencing for which a clinical trial at the Network Genomic Medicine Lung Cancer (NGM), a regional molecular screening network of the Center for Integrated Oncology Köln Bonn, is open for the treatment with Dasatinib.
Conclusion: We have established next generation sequencing for FFPE lung cancer samples in routine diagnostics to be able to screen 190 relevant traget regions within 10 working days.
No conflict of interest.

3456 POSTER

Does the "two week wait" target improve the waiting times for specialist review and also waiting time between first seen by lung cancer specialist and diagnosis of lung cancer?

M. Kumari[1], E. Oderuth[2], I. Nikolopoulos[2], K. Thakur[3]. [1]*Queen Elizabeth Hospital, Medicine, London, United Kingdom;* [2]*Queen Elizabeth Hospital, General Surgery, London, United Kingdom;* [3]*Queen Elizabeth Hospital, Breast Surgery, London, United Kingdom*

Background: Incidence and mortality rates for men have fallen sharply since peaking in 1974. Incidence of lung cancer has risen by 76 per cent for women between 1971 and 2000, while mortality rates are falling slightly after peaking in 1994. Lung cancer 5-year survival rates are poor and have been largely static over time. Cancer waiting time targets were introduced to monitor service performance via process improvement. The intention was to improve the outcome (survival) of the disease. The aim of the study was to assess whether the 'two week-wait' target can improve survival in patients with lung cancer.
Materials and Methods: 753 patients were diagnosed with lung cancer between January 2002 and December 2006. Data were retrospectively collected from the cancer database at Queen Elizabeth Hospital, London. Survival was compared in patients that were referred via the' two week-wait' rule (Group 1) and those not referred via this pathway (Group 2).
Results: Only 27% of patients were referred under the' two week-wait' rule and of the remainder a significant proportion came from Accident & Emergency (A&E) or referred from other specialities (221 and 188 patients respectively). Waiting time between referral and first seen by lung specialist for both groups is seen in the upper half of Table 1 and waiting time between first seen by specialist and diagnosis of lung cancer for both groups is seen in the lower half of Table 1.

Table 1.

Waiting time	Group 1, TWR patients	Group 2, Non TWR patients
Between referral and first seen by lung specialist		
Average	22 days	22 days
Median	19 days	17 days
Range	−100 to 161 days	−20 to 429 days
Between first seen by specialist and diagnosis of lung cancer		
Average	9 days	9 days
Median	10 days	5 days
Range	0 to 37 days	−26 to 480 days

Conclusions: There is no difference in the waiting times for specialist review between the two groups and both groups have similar waiting time for diagnosis once they have been examined by the lung specialist.
No conflict of interest.

3457 POSTER

Correlation of fibroblast growth factor-inducible molecule14 (Fn14) expression with mutational profile and clinical outcome in patients (pts) with non-small cell lung cancer (NSCLC)

S. Sahebjam[1], N.A. Pham[2], M. Pintilie[2], T. Jarutat[3], C. To[2], F.A. Shepherd[4], M. DeMario[5], D. Geho[6], L.L. Siu[1], M.S. Tsao[2]. *[1]Princess Margaret Cancer Center, Drug Development Program, Toronto − Ontario, Canada; [2]Princess Margaret Cancer Center, Ontario Cancer Institute, Toronto − Ontario, Canada; [3]Roche Diagnostics GmbH, Pharma Research and Early Development (pRED), Penzberg, Germany; [4]Princess Margaret Cancer Center, Medical Oncology, Toronto − Ontario, Canada; [5]Hoffmann-La Roche Inc, Pharma Research and Early Development, Nutley, USA; [6]Hoffmann-La Roche Inc, Hoffmann-La Roche Inc, Nutley, USA*

Background: Fn14, the cell surface receptor of tumor necrosis factor-like weak inducer of apoptosis (TWEAK), is highly expressed in NSCLC. In pre-clinical models of NSCLC, elevated Fn14 expression has been associated with increased tumor cell migration and invasion. We seek to evaluate the prognostic value of Fn14 in pts with NSCLC.
Methods: We evaluated primary tumor samples (TS) from 114 pts with NSCLC who also had primary tumor xenografts (PTX) generated in NOD-SCID mice from these samples. Expression of Fn14 in tissue microarrays created from TS as well as from corresponding PTXs was assessed by immunohistochemistry using anti-human Fn14 monoclonal mouse antibody MAKM-1.11.17-IgG(SPA) generated by Roche Professional Diagnostics (Penzberg, Germany) and H-score (intensity × percentage) was calculated. Mutational profiling was performed on DNA isolated from formalin-fixed paraffin-embedded TS, using either Sequenom OncoCarta™ v 1.0 or a lab-customized lung cancer panel. Multivariable analyses of disease free survival (DFS) and overall survival (OS) were performed based on TNM stage, histology, mutational status, and Fn14 expression in TS or PTX.
Results: Pt characteristics: Stage I/II vs III/IV = 84:30; squamous vs adenocarcinoma vs other = 52:56:6. Fn14 expression was present in 41 of 84 (49%) of TS with a median H-score of 0 (range: 0–140), and in 76 of 97 (78%) of PTX with a median H-score of 15 (range: 0–250). Sequenom analysis detected mutations in 40.2% (43/107) of samples with *K-RAS* and *EGFR* mutations being the most common (17% and 8.4% respectively). Median Fn14 H-scores were significantly higher in PTX with *K-RAS* mutation than wild-type (56.2 vs. 10, $P = 0.017$). In multivariable analyses, high PTX Fn14 expression (H score>15) was the only independent prognostic factor for DFS when controlled for mutational status, stage, and histology (HR: 2.56, 95% CI: 1.28–5.11, $P = 0.008$). Fn14 expression in TS was not prognostic of DFS or OS in multivariable models.
Conclusions: High expression of Fn14 in PTX confers poor DFS in pts with NSCLC and exhibits a stronger prognostic value than Fn14 in TS.

Highly multiplexed detection of actionable mutations in surgically resected tumor specimens from Japanese patients with lung adenocarcinoma by ultra-deep targeted sequencing

Y. Koh[1], H. Kenmotsu[2], M. Serizawa[1], M. Isaka[3], T. Naito[2], T. Takahashi[2], M. Endo[4], T. Nakajima[5], Y. Ohde[3], N. Yamamoto[2]. *[1]Shizuoka Cancer Center, Drug Discovery and Development, Sunto-gun, Japan; [2]Shizuoka Cancer Center, Thoracic Oncology, Sunto-gun, Japan; [3]Shizuoka Cancer Center, Thoracic Surgery, Sunto-gun, Japan; [4]Shizuoka Cancer Center, Diagnostic Radiology, Sunto-gun, Japan; [5]Shizuoka Cancer Center, Diagnostic Pathology, Sunto-gun, Japan*

Background: Detection of tumor genetic alterations is critically needed for lung cancer clinic as well as for the development of novel molecular targeted therapeutics. This report describes the results of a broad spectrum of genetic alterations identified in Japanese patients with lung adenocarcinoma by ultra-deep targeted sequencing.
Material and Methods: Highly multiplexed amplicon sequencing was performed using genomic DNA extracted from snap-frozen surgically resected tumor specimens. TruSeq amplicon cancer panel (Illumina) was used for the detection of somatic mutations in 48 cancer related genes followed by ultra-deep sequencing (Illumina) at an average coverage of approximately 2800x. *ALK*, *ROS1* and *RET* translocations and *EGFR, MET, PIK3CA, FGFR1* and *FGFR2* amplifications were also detected by multiplex RT-PCR and quantitative PCR, respectively.
Results: The demographics of 140 consecutive patients enrolled in this prospective study at Shizuoka Cancer Center between July 2011 and November 2012 are as follows: median age 69 years (range: 43−89); male 57.9%; never smoker 34.3%; tumor stage: I 62.9%, II 20.0%, III 12.1%, IV 5.0%. *EGFR* mutation was most frequently detected (43.0%) followed by *TP53* mutation (33.8%). In addition, mutations in genes such as *KRAS* (17.6%), *PIK3CA* (14.1%), *STK11* (6.3%), *CTNNB1* (5.6%), *MLH1* (4.9%), *HER2* (2.1%), *BRAF* (1.4%), *MET* (1.4%), *PTEN* (1.4%), *SMAD4* (1.4%), *VHL* (1.4%), *ATM* (0.7%), *GNAS* (0.7%), *HRAS* (0.7%), *JAK2* (0.7%) and *PTPN11* (0.7%) were identified. Gene amplifications in *EGFR* (2.8%), *MET* (0.7%) and *PIK3CA* (0.7%) and fusion genes such as *EML4-ALK* (0.7%) and *KIF5B-RET* (0.7%) were also detected. It is noteworthy that, contrary to previous reports claiming the mutual exclusivity of genetic alterations in lung adenocarcinoma, 40.8% of patients harbored simultaneous actionable mutations in this study, suggesting the genetic complexity of lung adenocarcinoma.
Conclusions: We managed to detect a wide range of genetic alterations and identified additional actionable mutations besides popular driver mutations such as *EGFR*, *KRAS* and *EML4-ALK* mutations in Japanese lung adenocarcinoma patients. This approach may facilitate elucidation of detailed molecular characteristics of lung adenocarcinoma, thereby implementing personalized cancer medicine.
No conflict of interest.

3459 POSTER

Accelerated normofractionation in medically inoperable stage I non-small cell lung cancer yields excellent local control

F. Zehentmayr[1], F. Sedlmayer[2], H. Deutschmann[2], K. Dagn[3], C. Fussl[3], P. Kopp[3], P. Porsch[4], B. Wegleitner[4], M. Studnicka[4], K. Wurstbauer[2]. *[1]Paracelsus Medizinische Privatuniversität, Institute for Research and Development on Advanced Radiation Technologies (radART), Salzburg, Austria; [2]Paracelsus Medizinische Privatuniversität Landeskliniken Salzburg, Universitätsklinik für Strahlentherapie und Radioonkologie and radART, Salzburg, Austria; [3]Paracelsus Medizinische Privatuniversität Landeskliniken Salzburg, Universitätsklinik für Strahlentherapie und Radioonkologie, Salzburg, Austria; [4]Paracelsus Medizinische Privatuniversität Landeskliniken Salzburg, Universitätsklinik für Pneumologie, Salzburg, Austria*

Background: The standard of care for stage I non-small cell lung cancer (NSCLC) is surgery. Due to co-morbidities some patients are medically not operable. These patients are treated with radiotherapy. The best fractionation scheme is a matter of debate. Stereotactic body radiotherapy (SBRT) was successfully introduced in the past decade but is limited to smaller tumor volumes. In this study we used a schedule of dose differentiated accelerated radiotherapy with twice daily fractions of 1.8 Gy (DART-bid).
Material and Methods: Between 07/2002 and 12/2010, 54 patients (36 male, 18 female) with 56 histologically proven tumors were treated for stage I NSCLC. The median age was 71 years (range 53−87 years). The median Karnofsky Performance Score (KPS) was 70 % (range 50–100 %). Total doses were applied based on tumor size measured by the mean of 3 perpendicular diameters: 73.8 Gy for tumors <2.5 cm, 79.2 Gy for 2.5−4.5 cm, 84.6 Gy for 4.5−6 cm, 90 Gy for tumors >6 cm. Lymph nodes were electively irradiated in 16 patients (median 45 Gy, range 45−63 Gy). Toxicity was assessed according to CTC 4.0. A CT scan was performed on each follow up visit. Local failure was defined as enlargement of the lesion compared to the previous CT.
Results: The median follow up of all patients was 28.5 months (range 2–108 months), local control (LC) at five years is 90.9% (51/56). Local failures occur within the first 16 months (median 11 months, range 8−16 months). No regional lymph node failures were observed. In 12.9% (7/54) of the patients distant metastases occurred, the period of time to metastases covered a range of 4 to 52 months. 53.7% (29/54) of the patients died for non-tumor related reasons, 18.5% (10/54) cancer specific deaths occurred, and 15 patients are still alive. In the Cox regression analysis, prognosticators for LC were tumor volume ($p = 0.035$), for DFS tumor diameter ($p = 0.014$) and duration of radiotherapy ($p = 0.029$), for overall survival KPS ($p = 0.008$). Acute esophagitis grade 1 or 2 occurred in 7 cases, which resumed completely after 3 months. No chronic toxicity > grade 1 was detected.
Conclusion: DART-bid is a feasible fractionation scheme that combines high BEDs up to 101.7 Gy ($\alpha/\beta = 10$) with shortened overall treatment time, yielding high LC without significant toxicity. LC is equal to SBRT, with lower toxicity compared to reported incidences. Especially for tumor sizes out of range for SBRT, this treatment regimen serves as radiotherapeutic alternative for Stage I NSCLC patients.
No conflict of interest.

3460 POSTER

Multicenter analysis for prognostic role of high-resolution computed tomography and positron emission tomography/computed tomography in clinical stage IA lung adenocarcinoma

S. Murakami[1], H. Nakayama[1], Y. Tsutani[2], Y. Miyata[2], S. Okumura[3], M. Yoshimura[4], S. Adachi[5], M. Okada[2]. [1]*Kanagawa Cancer Center, Thoracic Oncology, Yokohama, Japan;* [2]*Hiroshima University, Surgical Oncology, Hiroshima, Japan;* [3]*Cancer Institute Hospital, Thoracic Surgery, Tokyo, Japan;* [4]*Hyogo Cancer Center, Thoracic Surgery, Akashi, Japan;* [5]*Hyogo Cancer Center, Radiology, Akashi, Japan*

Background: Although ^{18}F-fluorodeoxyglucose positron emission tomography/computed tomography (PET/CT) is widely and increasingly used to diagnose, stage, and therapeutically assess lung cancer, the malignancy grade of tumors assessed by Maximum standardized uptake values (maxSUV) has not been investigated in detail. This study aimed to investigate the role of PET/CT as well as high-resolution computed tomography (HR-CT) to estimate the malignant behavior and prognosis of early lung adenocarcinomas.
Methods: maxSUV from PET/CT and ground-glass opacity (GGO) ratios on HR-CT before complete resection were measured in 610 patients with clinical stage IA lung adenocarcinoma. Pathological invasiveness and survival were examined in relationship to clinical factors and radiographic findings including the maxSUV, which was adjusted to correct for inter-institutional discrepancies that confer limitations upon multicenter PET studies.
Results: On analyses of receiver operating characteristic curves, optimal cutoffs of maxSUV and GGO ratio were demonstrated to predict recurrence of 2.9 (area under the curve [AUC], 0.816) and 25% (AUC, 0.803), respectively. Significant differences in RFS ($p < 0.001$) were identified between tumors having a maxSUV of $\leqslant$2.9 (5-year RFS ratio, 95%) and >2.9 (72%), and between those with GGO ratios $\geqslant$25% (98%) and <25% (79%). Both the maxSUV and GGO ratio reflected tumor invasiveness, nodal metastasis, recurrence and patient survivals, and were significant prognostic factors not only on recurrence-free and cancer-specific survivals but also on multivariate Cox analysis (all, $p < 0.001$). We grouped the patients based on GGO ratios and maxSUV of $\geqslant$25% and $\leqslant$2.9 (n = 319; Group 1), $\geqslant$25% and >2.9 or <25% and $\leqslant$2.9 (n = 152; Group 2), and <25% and >2.9 (n = 139; Group 3), respectively. The Recurrence-free survival ($p < 0.001$) also significantly differed among the groups (5-year DFS rates in Groups 1, 2 and 3: 99%, 88% and 70%, respectively).
Conclusions: The combination of maxSUV and GGO ratio is a better predictor of malignant tumor grade than either alone in clinical stage IA lung adenocarcinoma and should be considered before choosing therapeutic strategies.

Background: Clinical oncology societies develop and regularly update evidence-based guidelines in order to improve the quality of care of patients with cancer and reduce variability in cancer care. In 2004 AIOM (Italian Association of Medical Oncology) created the RIGHT (Research for the Identification of the most effective and hIGHly accepted clinical guidelines for cancer Treatment) program, successfully applied to colorectal and breast cancer guidelines. The third step of the RIGHT3 program, aims to evaluate the concordance between AIOM 2009 lung cancer guidelines and clinical practice in Italian lung cancer centers.
Materials and Methods: RIGHT3 is a retrospective observational study conducted in a sample of 53 Italian centers for lung cancer care representative of 230 AIOM centers. Site sampling from AIOM database was stratified by presence vs absence of Thoracic Surgery Unit and geographic distribution (North; Center, South). In each stratum sampled site number was proportional to the total number of AIOM sites. 14 indicators were identified to verify the concordance between 2009 AIOM lung cancer guidelines and clinical practice about staging and treatment (surgery, chemotherapy and radiotherapy). Patients with NSCLC diagnosis who had their first visit at the site during 2010 and followed-up for at least 6 months were included in 3 groups defined according to staging: I−II−IIIA, IIIB and IV.
Results: Among the 708 enrolled, 225 I−II−IIIA stage, 156 IIIB stage and 299 IV stage patients were eligible for analyses. Results showed that cyto-histological diagnosis was available for 95% of I−II−IIIA stage patients, 87% for stage IIIB and IV. PET was performed in 64% of I−II−IIIA patients and in 46% of IIIB ones. 88% of I−II stage patients underwent lobectomy and 56% of II−III stage patients undergoing complete surgery were treated with adjuvant chemotherapy.
As regards stage IV patients, 33% of them had a molecular analyses; platinum-based first-line treatment was prescribed to 87% of them, 70% underwent second-line treatment and 94% of older-than-70 y patients were treated with chemotherapy.
Conclusions: RIGHT3 study showed that guidelines adherence is high for stage IV patients and PET is not frequently used for diagnosing. Guidelines adherence monitoring and subsequent update represent crucial activity in order to provide useful instruments for better plan health care interventions.
No conflict of interest.

3462 POSTER

Encouraging outcome of patients with oligometastatic NSCLC through intrathoracic radical approach

D.H. Schanne[1], A. Bunea[1], T. Schimek- Jasch[1], J. Rawluk[2], C. Waller[2], B. Passlick[3], A.L. Grosu[1], U. Nestle[1]. [1]*Albert-Ludwigs-Universitat Freiburg, Radiation Oncology, Freiburg, Germany;* [2]*Albert-Ludwigs-Universitat Freiburg, Hematology and Oncology, Freiburg, Germany;* [3]*Albert-Ludwigs-Universitat Freiburg, Thoracic Surgery, Freiburg, Germany*

Background: Patients with Stage-IV NSCLC are usually subjected to palliative chemotherapy (CTX) and/or radiotherapy (RT). However, more radical treatment approaches are arising, trying to eliminate all tumor manifestations with a radical approach in case of oligometastatic disease. There is prospective data, indicating for a fraction of almost 20% long- term survivors after this regime, underlining the necessity to rethink the current treatment standards (De Ruysscher, 2012). We report supporting data from a retrospective, single-center study of radical treatment of stage-IV NSCLC.
Materials and Methods: 1029 NSCLC patients UICC stage IV were screened, who were discussed in the local Comprehensive Cancer Center and treated between 2008 and 2012. Selection criteria were <5 distant metastases and a radical treatment approach towards all tumor manifestations (surgery, RT and CTX + combinations). Patients were followed using clinical reports, imaging data and external reports. Statistical analysis was performed with SPSS 21.
Results: 16 patients (69% men, 31% women) were identified with a median age of 62 (52−75) years at diagnosis. Median Karnofsky performance index was 90 (70–100) %. Local UICC stadium (ignoring metastases) was: stage I: 20%, II: 20%, IIIA: 27% IIIB: 33%. Staging PET/CT was available in all cases. Sites of metastasis were brain (37%), lung (19%), distant lymph nodes (19%), adrenal glands (7%), and other (19%). Bioptic confirmation showed 56% adeno- and 44% squamous cell carcinomas. Loco-regional thoracic surgery was part of the interdisciplinary treatment in 62% of the cases. All patients received RT, of which 38% were combined chemoradiotherapies of intrathoracic disease. One patient was treated with stereotactic radiation therapy. Other irradiation sites included brain (42%), intrathoracic (53%) and bone (5%). No metastases were treated surgically. 53% of all patients received CTX during their course with mainly platin-based regimens. Median overall survival was 38 months with 1-/2- year rates of 79% and 56%, while median disease- free survival was 10 months with 1-/2- year rates of 41%, 33%, respectively.
Conclusions: This study confirms that radical treatment of NSCLC stage-IV disease can lead to long- term survival. The data show the importance of interdisciplinary cooperation of surgeons, oncologists and radiation oncologists along with selection of appropriate patients. To further improve the outcome of metastasized disease, more prospective data is needed.
No conflict of interest.

Adrenalectomy for adrenal metastases in low-tumor-burden metastatic lung cancer: Results of a single institution experience

L. Zubiri[1], P. Martin Romano[1], A. Gurpide[1], I. Gil Bazo[1], J.L. Perez Gracia[1], F. Rotellar[2], M. Moreno[1], E. Castañon[1], S. Martin Algarra[1], J.M. Lopez-Picazo[1]. *[1]Clinica Universitaria de Navarra, Oncology, Pamplona (Navarra), Spain; [2]Clinica Universitaria de Navarra, General Surgery, Pamplona (Navarra), Spain*

Background: Adrenal gland is a common site of metastasis in lung cancer. Adrenal metastasis (AM) can occur at the time of diagnosis (synchronous AM) or later (metachronous AM). When an AM appears as an isolated site of dissemination it is considered a good-prognosis metastatic disease. Some other times, AM occurs in the presence of other sites of metastasis. Nevertheless, few data are available about the prognosis and the optimal management of these patients and about which is the role of adrenalectomy in this situation.
Methods: Retrospective analysis of the historical series of adrenalectomies in patients treated of lung cancer at our institution.
Results: From April 2002 to April 2011, 30 patients (27m/3f) were diagnosed of AM of lung cancer (16 non-squamous, 8 squamous, 6 small-cell; 21 metachronous AM, 9 synchronous AM). We analysed 19 pts with single AM and 11 pts with AM plus other metastatic sites (8 pts with brain dissemination and 3 pts other sites). All of them were treated with adrenalectomy (26 laparoscopic, 4 open surgery). Median age was 55 years old (range: 42−71). Median size of the AM was 35 mm (range: 12–140). R0 was achieved in 26 pts (87%). Adjuvant teatment was administrated in 13 pts. There were no severe complications of surgery in any patient. All the patients had received radical treatment for the primary tumour and for other metatatic sites (8 patients brain metastases, 3 patients other sites) before adrenalectomy. Median overall survival (OS) and disease-free survival from adrenalectomy for the entire group were 44 (95% CI: 10−78) and 15 (95% CI: 7.6–22.3) months respectively. We found an statistical trend ($p = 0.087$) of better OS from adrenalectomy for patients with non-squamous histology compared with squamous histology: 57 (95% CI: 38.4–75.6) and 21 (18.3–23.8) months respectively. The percentage of alive patients at 2 and 5 years was 59.1% and 36% respectively. No significant differences were observed between matachronous and synchronous AM neither between single AM vs AM plus other sites.
Conclusions: These results add new data about the prognosis of patients with adrenal metastases into the context of low-tumor-burden metastatic lung cancer. Adrenalectomy is a tolerable procedure which plays a role in the management of these patients.
No conflict of interest.

3464 POSTER

Impact of epidermal growth factor receptor mutation status for post recurrence survival of patients with non-small cell lung cancer

T. Takenaka[1], T. Takenoyama[1], E. Inamasu[1], G. Toyokawa[1], Y. Shiraishi[1], Y. Morodomi[1], F. Hirai[1], M. Yamaguchi[1], T. Seto[1], Y. Ichinose[1]. *[1]National Hospital Organization Kyushu Cancer Center, Department of Thoracic Oncology, Fukuoka, Japan*

Background: The survival characteristics and prognosis of patients with recurrent non-small cell lung cancer (NSCLC) after surgical resection have not been well demonstrated. The aim of this study is to identify the prognostic factors associated with the post-recurrence survival after surgical resection of NSCLC, and to examine the best therapeutic strategy for this disease from the view point of the epidermal growth factor receptor (EGFR) status and EGFR tyrosine kinase inhibitors (EGFR-TKIs) therapy.
Patients and Methods: From 2000 through 2011, 1237 consecutive patients with NSCLC underwent pulmonary resection at National Kyushu Cancer Center. Of those, 280 patients experienced a postoperative recurrence before the end of 2012. We retrospectively reviewed these cases and analyzed the post-recurrence survival and predictors of this survival.
Results: Postoperative recurrence developed in 183 males (65%) and 97 females (35%). The mean age of the patients was 66 years. Adenocarcinoma accounted for 68% (n = 189) of the recurrences, followed by squamous cell carcinoma (n = 51, 18%) and other histological types (n = 40, 14%). The EGFR mutation status was examined in 183 cases (65%), and 83 patients (30%) were positive for an EGFR mutation. The median post-recurrence survival time and the five-year survival rate of all cases were 25 months and 20.8%, respectively. As initial treatment for the recurrence, chemotherapy was administered to 152 patients (54%), chemoradiotherapy to 62 (22%), radiotherapy to 32 (12%) and surgical resection was performed in 15 (5%) cases. There have been no significant survival differences based on the initial treatment strategies. A multivariate analysis identified that the Eastern Cooperative Oncology Group (ECOG) performance status (PS), presence of brain metastases, number of recurrent sites and EGFR mutation status were independent prognostic factors for the post-recurrence survival. In all cases, the median post-recurrence survival time according to the use of EGFR-TKIs therapy were as follows: 49 months for EGFR mutation-positive patients treated with EGFR-TKIs therapy, 20 months for EGFR wild or unknown cases treated with EGFR-TKIs and 17 months for those not treated with EGFR-TKIs therapy ($p < 0.01$). With regard to the adenocarcinoma patients, the median post-recurrence survival time according to the EGFR-TKIs therapy were 49 months, 23 months, and 20 months, respectively ($p < 0.01$).
Conclusion: Patients with recurrent NSCLC with an EGFR mutation positive status received some benefit from EGFR-TKIs therapy. It is essential for recurrent NSCLC patients to be examined for their EGFR mutation status, especially those with adenocarcinoma. The therapeutic strategy for recurrent NSCLC should be considered after evaluating the EGFR mutation status.
No conflict of interest.

3465 POSTER

Assessing the role of chemotherapy for solitary fibrous tumors of the pleura in a routine practice setting

O. Bylicki[1], D. Rouviere[2], P. Cassier[3], J. Margery[4], A. Levard[3], L. Chalabreysse[5], J. Mazieres[2], J.Y. Blay[3], N. Girard[6]. *[1]Hôpital d'Instruction des Armées Desgenettes, Respiratory Medicine Department, Lyon, France; [2]Hôpital Larrey Chu De Toulouse Université De Toulouse Iii (Paul Sabatier), Respiratory Medicine Service, Toulouse, France; [3]Leon Bérard Cancer Center, Department of Medicine, Lyon, France; [4]Percy Military Hospital, Respiratory Medicine Department, Clamart, France; [5]Hospices Civils De Lyon, Pathology Department, Lyon, France; [6]Hospices Civils De Lyon, Respiratory Medicine Service, Lyon, France*

Background: Solitary Fibrous Tumors of the Pleura (SFTP) refer as to a heterogeneous group of mesenchymal malignancies with various anatomic and histologic features. Upfront surgical resection is the standard approach, but the outcome of patients is unpredictable. Recurrences may be aggressive and difficult to treat.
The most widely accepted staging system has been proposed by De Perrot et al., and is based on the anatomy of the tumor implantation (sessile/pedunculated), and the presence of histologic signs of aggressiveness, including cellularity with crowding and overlapping of nuclei, cellular pleomorphism, high mitotic count, necrosis, or stromal/vascular invasion. Given the rarity of the tumor, limited evidence is available about the role and the modalities of perioperative and definite chemotherapy for SFTP.
Material and Methods: Multicenter retrospective study of patients (pts) with histologically-proven SFTP with complete follow-up from surgical diagnostic to tumor recurrence and death.
Results: 68 pts (28 males/40 females) were included. Median age at diagnosis was 62 year-old. Tumor stage according to the De Perrot system was 0/I for 29 pts, II for 23 pts, III for 7 pts, and IV for 4 pts. Adjuvant chemotherapy was given to 7 patients, mostly with stage III/IV SFTP, consisting of doxorubicin-based regimen. Recurrence rate and median time-to-progression (TTP) after surgery were 3%, 52%, 71%, and 75% ($p<0.001$), and 107, 70, 29, 11 months ($p = 0.006$) for stage 0/I, II, III, and IV tumors, respectively. Besides tumor stage, predictors of shorter TTP were incomplete resection ($p<0.001$) and a higher number of histologic signs of malignancy ($p = 0.009$). At time of tumor recurrence, 12 pts received chemotherapy. Highest disease control rates were observed with trabectedine (7/9 pts; Disease Control Rate (DCR): 78%; median TTP: 3.4 months), and gemcitabine-dacarbazine combination (2/3 pts, DCR: 66%; median TTP: 1.9 months). Median overall survival of the whole cohort was 56 months.
Conclusion: This study 1) confirms the prognostic value of the De Perrot staging system, 2) indicates a high recurrence rate in patients with stage II tumors, for which perioperative chemotherapy may be considered, and 3) suggests an interest for trabectedine in the setting of recurrent tumors. Besides clinical data, further molecular characterization, including recently identified specific gene fusions, may help to better predict the outcome of patients with SFTP.
No conflict of interest.

3466 POSTER

Impact of doxycycline (doxy) prophylaxis on dermatologic toxicity from dacomitinib (D) for NSCLC, by CTCAE and patient (pt)-reported outcomes (PRO) measures in a placebo-controlled trial

M. Lacouture[1], S. Grunberg[2], D. Keefe[3], S. Sonis[4], J. Ely[2], D. Gernhardt[5], T. Wang[5], J. Doherty[5], J. O'Connell[5], A. Jatoi[6]. [1]*Memorial Sloan-Kettering Cancer Center, Department of Medicine, New York, USA;* [2]*University of Vermont, Fletcher Allen Health Care, Burlington, USA;* [3]*University of Adelaide, Royal Adelaide Hospital, Adelaide, Australia;* [4]*Dana-Farber Cancer Institute, Brigham and Women's Hospital, Boston, USA;* [5]*Pfizer Oncology, Medical Oncology, Groton, USA;* [6]*Mayo Clinic, Medical Oncology, Rochester, USA*

Background: D, an irreversible small molecule inhibitor of human epidermal growth factor receptor (HER) 1, 2 and 4 tyrosine kinases, has shown potential efficacy in NSCLC and is currently in Phase (P) 3 trials. This study (ARCHER 1042: NCT01465802) explores prophylactic interventions to minimize the impact of common adverse events (AEs) associated with EGFR targeted therapy, including select dermatologic AEs of interest (SDAEI; pruritus, dermatitis acneiform, skin exfoliation, exfoliative rash, paronychia, nail disorders, skin fissures, skin lacerations, skin infection, skin ulcers, rash, dry skin, nail discoloration).
Methods: In Cohort 1 of this P2 clinical trial, 104 pts with measurable or non-measurable advanced NSCLC, at least 1 prior chemotherapy, ECOG Performance Status (PS) 0−2, are planned to be randomized (pt blinded) to (a) D 45 mg daily (QD) plus placebo (D+p) or (b) D 45 mg QD plus doxy 100 mg twice daily (BID) x 4 wks (D+d). Primary endpoints include the incidence of all-grade (G) and G⩾2 SDAEI and PRO (Skindex-16 scores) in the first 8 wks. Secondary endpoints include safety and tolerability, concomitant medication use and relative dose intensity of D.
Results: Reported results are for the first 8 wks of treatment. As of 15 Mar 2013, 37 pts were randomized to Cohort 1 D+p and D+d, 30 of whom (median age 65.5 years, 50% male, 70% adenocarcinoma) were evaluable and with data through Day 56 (15 in each arm). All-causality rates for G and G⩾2 SDAEI were 100.0% and 46.7% for D+p vs. 66.7% and 26.7% for D+d. Average compliance with PRO over 8 wks was 97.4% for D+d and 97.0% for D+p. Comparing PRO mean change from baseline scores over the first 8 wks, D+p exceeded the minimum clinically important difference (MCID) of 10 points worse for the PRO Total Score 4/7 visits (v); Symptom subscale 3/7 v; Emotion subscale 5/7 v; and Functioning subscale 2/7 v, whereas D+d exceeded the MCID for only Symptom subscale at 1/7 v. There was no difference in the overall AE profiles between the 2 groups.
Conclusions: This study uses a novel comprehensive approach to assessing the impact of AEs from both provider and pt assessment. Preliminary data suggest prophylactic doxy at onset of D therapy was well tolerated, with a reduced incidence of SDAEI ($p = 0.05$) and better PRO scores compared with reactive treatment. The study is ongoing, with further results available at presentation.

Background: EGFR mutations (M+) predict response to EGFR tyrosine kinase inhibitors (TKI) in NSCLC. The AstraZeneca-sponsored non-interventional studies REASON (Germany, NCT00997230) and MUTACT (France, NCT01167972) aimed to investigate associations between clinicopathological characteristics and EGFR M+ in NSCLC, and record real-world management and outcomes in M+ patients. We present a subgroup analysis of the stage IV adenocarcinoma patients in these studies.
Material and Methods: For this post-hoc analysis, patients ⩾18 years old with stage IV adenocarcinoma and a planned EGFR mutation test were eligible. Baseline demographic and first-line treatment decision data were collected. Associations between patient characteristics and M+ status were evaluated in logistic regression models adjusted for study (REASON vs MUTACT). Heterogeneity tests were performed to assess differences between the effect of characteristics on M+ status between the studies.
Results: 3403 patients were identified (2409 from REASON, 994 from MUTACT; 57% male; 98% Caucasian; 75% current or former smoker; median age 65 years [range 26−93]). M+ frequency was 14% in REASON and 23% in MUTACT, a difference that could be explained at least in part by the inclusion of more non-smoking women in MUTACT. The only characteristic that showed a significantly stronger univariate association with M+ status in MUTACT vs REASON was smoking status (heterogeneity $p = 0.01$). In a multivariate model, M+ status was more frequent in women (odds ratio [OR] 1.9; 95% CI 1.5−2.3; $p < 0.0001$), ex- or non-smokers (OR 1.8; 1.3−2.4; $p = 0.007$ and OR 6.3; 4.7−8.4; $p < 0.0001$), patients with performance status (PS) 0 (0 vs 2: OR 1.6; 1.1−2.3; 0 vs 3: OR 2.2; 1.1−4.1; $p = 0.02$), and patients with brain (OR 1.3; 1.0−1.7; $p = 0.02$) or bone (OR 1.3; 1.1−1.7; $p = 0.01$) metastases. Overall, 74% of patients received first-line treatment; 53% of patients with M+ NSCLC received EGFR-TKI; 60% of patients with M- NSCLC received platin-based agents and 34% received pemetrexed.
Conclusions: Despite the limitations inherent to real-world evidence studies and differences between the studies, this analysis brings important information on EGFR M+ incidence in NSCLC and its predictive factors in a large cohort of Western European patients with stage IV adenocarcinoma.

3468 POSTER

Open label phase II study to establish the efficacy of intravenous loading doses of Ibandronate 6 mg in patients with lung cancer and skeletal metastases experiencing moderate to severe bone pain: NVALT 9 (NTR1602)

A. Dingemans[1], H.J.M. Smit[2], B.E.E.M. Van de Borne[3], H.J.M. Groen[4], B. Biesma[5], A. Vincent[6], O. Dalesio[6], F.M.N.H. Schramel[7]. *[1]University Hospital of Maastricht, Pulmonology, Maastricht, Netherlands; [2]Rijnstate Hospital, Pulmonology, Arnhem, Netherlands; [3]Catharina Hospital, Pulmonology, Eindhoven, Netherlands; [4]University Medical Center Groningen, Pulmonology, Groningen, Netherlands; [5]Jeroen Bosch Hospital, Pulmonology, 's Hertogenbosch, Netherlands; [6]Netherlands Cancer Institute, Biostatistics, Amsterdam, Netherlands; [7]St Antonius Hospital, Pulmonology, Nieuwegein, Netherlands*

Background: Pain due to bone metastases is a frequent problem in non-small cell lung cancer (NSCLC). Loading doses of ibandronate, a potent biphosphonate, rapidly relieve bone metastases related pain in breast and prostate cancer patients (pts).
Material and Methods: In this open label multi-center phase II study pts with NSCLC and painful bone metastases with patient-reported mean 'worst pain score' over the last 7 days on brief pain inventory (BPI) $\geqslant$5 were included. Pts had to be treated with at least a NSAID or a weak opioid based on the WHO analgesic ladder step 2. Pts were treated with 6 mg ibandronate i.v on day 1, 2 and 3. Main efficacy endpoint was bone pain response, defined as 25% decrease in mean pain score over a 3-day period (day 5−7) compared to pain score at baseline as determined by the 'worst pain' scale of the BPI, with no more than a 25% increase in mean analgesic consumption during the same 3-day period. Secondary endpoints were mean 'worst pain' scale of the BPI over time (first 7-days), interference scales of the BPI, analgesic consumption, WHO performance score and QOL (EORTC QLQ-C30).
The study was designed according to Simon's Optimal 2-stage design with 90% power to declare the treatment active when the pain response rate is 80% or more. If in the first 19 pts 12 or less successes are observed the study will be stopped, otherwise 34 additional pts will be included. The treatment will be declared to have sufficient activity if >38 pain responders are observed.
Results: Between 12/2007 and 11/2010 20 pts were enrolled in the study, 2 pts did not start treatment. Patient characteristics: 12 males and 6 females, mean age 58 years. The mean pain score over the last 7 days was 5 in 4 pts, 6 in 2 pts, 7 in 5 pts, 8 in 4 pts, 9 in 2 pts and 10 in 1 pts. All pts completed the 3- day treatment. No related adverse events were reported. In 4 out of 18 pts (22%) >25% decrease of mean pain score over day 5−7 was observed. No change in QoL was observed between baseline and day 7. According to the stopping rule, further enrollment was stopped.
Conclusion: Only 4 out of the 18 pts responded with a rapid reduction of pain to a loading dose ibandronate. In accordance with the Simon 2-stage procedure the trial was stopped at the interim analysis due to insufficient pain relieve of ibrandronate in NSCLC pts with bone metastases.
Conflict of interest: *Advisory board: Roche*

3469 POSTER

Clinical features and outcome differences in patients with thymoma and thymic carcinoma

Y. Okuma[1], Y. Hosomi[1], K. Watanabe[1], T. Hishima[2], K. Karasawa[3], H. Horio[4], Y. Maeda[5], T. Okamura[1]. *[1]Tokyo Metropolitan Cancer and Infectious diseases Center Komagome Hospital, Thoracic Oncology and Respiratory Medicine, Tokyo, Japan; [2]Tokyo Metropolitan Cancer and Infectious diseases Center Komagome Hospital, Pathology, Tokyo, Japan; [3]Tokyo Metropolitan Cancer and Infectious diseases Center Komagome Hospital, Radiation Oncology, Tokyo, Japan; [4]Tokyo Metropolitan Cancer and Infectious diseases Center Komagome Hospital, Thoracic Surgery, Tokyo, Japan; [5]Tokyo Metropolitan Cancer and Infectious diseases Center Komagome Hospital, Medical Oncology, Tokyo, Japan*

Background: Thymic epithelial tumours (TETs), consisting of thymoma and thymic carcinoma (TC), are rare cancers with specific morphological clinical features. The clinical characteristics and outcomes of TETs have not been well investigated because of their rarity.
Methods: The study was a retrospective review of 187 Japanese patients with TETs from 1976 to 2012 at our institution. The clinical features studied included clinical demographics, histology, staging, treatment interventions, and overall survival (OS). Differences in survival were assessed using Kaplan–Meier analysis and uni- and multivariate Cox proportional hazards regression analyses.
Results: The study included 51 patients with stage I, 37 with stage II, 22 with stage III, and 76 with stage IVa/IVb according to the Masaoka-Koga Staging System. On histology, 5 patients had type A, 33 had type AB, 19 had type B1, 39 had type B2, and 15 had type B3; 68 patients with TC included 12 with neuroendocrine carcinomas according to the 2004 WHO classification. Eight patients had either other histological types or missing data. Paraneoplastic syndrome was seen in 26 patients only in the thymoma group (23.4%). Most of the patients who were symptomatic at presentation had myasthenia gravis or TC. Secondary cancers were seen in 25 patients (13.3%). The median OS was 235.2 (95% CI, 137.3-not reached) months for thymoma and 32.4 (95% CI, 23.7–52.2) months ($p < 0.0001$) for TC of all stages. Furthermore, overall survival rates at 5 and 10 years were 85.4% and 33.8%, respectively, for thymoma and 71.5% and 2.3%, respectively, for TC. Immunological complications or secondary cancers in the thymoma group were not always associated with a poor prognosis ($p = 0.24$). OS compared between thymoma and TC in each stage group showed a significant difference for stage IVa. The stage and whether the tumour was thymoma or TC were significant determinants of survival on multivariate analysis.
Conclusions: The role of treatment should be further investigated for thymoma and TC separately because of differences in clinical demographics.
No conflict of interest.

Erlotinib in previously treated NSCLC − a critical appraisal based on multicenter post-marketing analysis

A.C. Palozzo[1], G. Pasello[2], V. Di Iorio[3], E. D'Angelo[4], S. Corridoni[5], D. Bernardi[6], S. Palazzo[7], C. Graiff[8], A. Zuccheri[9], S. Imbevaro[10]. *[1]Istituto Oncologico Veneto IRCCS, Pharmacy Unit, Padova, Italy; [2]Istituto Oncologico Veneto IRCCS, Medical Oncology 2, Padova, Italy; [3]Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori IRCCS, Oncology Pharmacy Unit, Meldola, Italy; [4]Ospedale Civile, Anticancer Drugs Unit, Pescara, Italy; [5]Presidio Ospedaliero "San Salvatore", Drug Unit, L'Aquila, Italy; [6]Unità Locale Socio Sanitaria n.10, Medical Oncology, San Donà di Piave, Italy; [7]Azienda Ospedaliera, Medical Oncology, Cosenza, Italy; [8]Ospedale Centrale, Medical Oncology, Bolzano, Italy; [9]Azienda Ospedaliera Universitaria, Pharmacy Unit, Parma, Italy; [10]Istituto Oncologico Veneto IRCCS, Anticancer Drugs Evaluation Center, Padova, Italy*

Background: Erlotinib is a potent inhibitor of the EGFR (epidermal growth factor receptor) tyrosin-kinase activity and its efficacy has been demonstrated for the treatment of NSCLC in large randomized trials. The registration study BR.21 (N Engl J Med 2005;353:123−32) showed to prolong significantly OS and PFS in Erlotinib arm. The median age of the patients in this study was 61.4 years.
We have conducted a prospective observational study, using institutional data collected through onco-AIFA, a web-based national Italian registry of new oncology drugs.
The aim of our study was to assess median OS and PFS in clinical practice in comparison to outcome values obtained from the registration study.
Materials and Methods: Ten Italian oncology centers (Meldola − 222 pts, Padova − 159, Parma − 145, Pescara − 82, L'Aquila − 64, San Donà di Piave − 61, Cosenza − 42, Bolzano − 38, Trieste − 36, Bassano del Grappa −11) collected data from the registry to establish the real clinical impact of the drug. The observation period was October 2006 − November 2012. Every patient was checked for the length of the treatment and outcomes. For the efficacy/effectiveness comparison assessment we used the RCT outcome measures: OS, PFS with Kaplan–Meier estimates. EGFR wasn't a mandatory status for drug administration.
Results: A total of 860 patients treated with Erlotinib were reviewed (median age = 66.8 years, M= 61%).
Median PFS and OS were 2.4 (95% CI: 2.3−2.6) and 5.3 (95% CI: 4.7−6.3) months respectively compared to Erlotinib arm of the BR.21 study with PFS 2.2 months and OS 6.7 months. We recorded 26 (3%) suspensions of the treatment for toxicity. The median duration of treatment was 2.3 months (range 0.5–49.2) and 1-year survival rate was 33%. Moreover, there was a statistically significant difference in OS between males and females (5.0 *vs* 6.4 months respectively, $P < 0.001$).
Conclusions: The post-marketing studies in real life practice are needed in order to verify effectiveness and safety in general population and test the validity of the randomized trials. Moreover, the post-progression survival assessment may be crucial to determine the real clinical impact of a drug in combination with other treatments as it is usually missed in the approval RCTs.
Our results do not differ particularly from the study BR.21 and the slight difference in OS noticed by us can be explained by the fact that in our study the median age was higher than in the pivotal trial (66.8 *vs* 61.4 years).
No conflict of interest.

Results of the MARS study on the management of antiangiogenics' renovascular safety in lung cancer

F. Goldwasser[1], N. Janus[2], J.F. Morere[3], I. Ray-Coquard[4], J.P. Spano[5], J. Gligorov[6], J.B. Rey[7], C. Daniel[8], E. Fabre[9], V. Launay-Vacher[2]. [1]*Hôpital Cochin, Medical Oncology, Paris, France;* [2]*Hôpital de la Pitié-Salpêtrière, Service ICAR Nephrology, Paris, France;* [3]*Hôpital Avicenne, Medical Oncology, Bobigny, France;* [4]*Centre Léon Bérard, Medical Oncology, Lyon, France;* [5]*Hôpital de la Pitié-Salpêtrière, Medical Oncology, Paris, France;* [6]*Hôpital Tenon, Medical Oncology, Paris, France;* [7]*Institut Jean Godinot, Pharmacy, Reims, France;* [8]*Institut Curie, Medical Oncology, Paris, France;* [9]*Hôpital Européen Georges Pompidou, Medical Oncology, Paris, France*

Background: Anti-VEGF drugs (AVD) are widely used in cancer patients (pts). Hypertension (HTN) and proteinuria (Pu) are class-side-effects of AVD, related to the inhibition of the VEGF pathway. The MARS study has been conducted to assess the renovascular tolerance of these drugs in the clinical setting.
Methods: This multicentric, prospective, observational study evaluated the renovascular safety of AVD in pts naive from any AVD, conducted in 7 centres in France, from 2009 to 2012, with a follow-up (f/u) of 1 year. Data collected included: gender, age, serum creatinine (SCr), diabetes, HTN, hematuria (Hu) and dipstick Pu, at baseline and at each visit.
Results: 1124 pts were included. 104 pts had lung cancer (LC) and all but 3 received bevacizumab (1st line: 57.4%; median durations of treatment: 11.4 months). Median age at inclusion was 56 years (28−80). Visceral, bone and cerebral metastasis frequencies were 71.3, 45.5 and 13.9%, respectively. Diabetes and HTN prevalences were 8.9 and 23.8%, respectively. Baseline renal assessment retrieved: Pu 16.0%, Hu 3.0%, mean aMDRD 97.4 ml/min/1.73m^2 and 7 pts with aMDRD<60. The incidence of *de novo* Pu and HTN during f/u was 72.1 and 22.1% (Table). 88.9% of pts with Pu at inclusion improved or remained stable. Among pts with *de novo* Pu, 40.9% afterwards improved/normalized. No Grade 3/4 Pu has been reported (at inclusion or during f/u). Renal function decreased with a mean aMDRD of 90.6 at the end of f/u. 12.3% had grade 2−3 SCr increase (no grade 4). No thrombotic micro-angiopathy (TMA) was reported.
Conclusion: These results on the renovascular safety of bevacizumab in LC patients showed that 1) TMA is rare, 2) Pu develops in 72.1% of the pts, (no Grade 3/4), 3) 22.1% developed HTN. Furthermore, in case of a renovascular effect, investigators followed the recommendations from the French Society of Nephrology (Halimi JM. Nephrol Ther 2008) and no treatment withdrawal for unmanageable renovascular toxicity occurred.
Conflict of interest: *Other substantive relationships: Merck, Amgen, Novartis, PharmaMar, Sanofi, Roche.*

Treatment decisions for elderly patients with advanced NSCLC in Italian clinical practice

S. Barni[1], M. Di Maio[2], E. Maiello[3], A. Ardizzoni[4], F. Cappuzzo[5], S. Novello[6], A. Ori[7], S. Rizzoli[7], R. Chiari[8], L. Crinò[8]. [1]*Azienda Ospedaliera Treviglio, Oncology, Treviglio, Italy;* [2]*Isituto Tumori Fondazione Pascale, Oncology, Napoli, Italy;* [3]*Casa Sollievo Della Ssofferenza, Oncology, S Giovanni Rotondo, Italy;* [4]*Azienda Ospedaliera Universitaria, Oncology, Parma, Italy;* [5]*Ospedale di Livorno, Oncology, Livorno, Italy;* [6]*AOU S Luigi Università di Torino, Oncology, Torino, Italy;* [7]*Medidata studi e ricerca, Modena, Italy;* [8]*Azienda Ospedaliera di Perugia, Oncology, Perugia, Italy*

Background: In 2004, Italian Association of Medical Oncology (AIOM) created the RIGHT (Research for the identification of the most effective and highly accepted clinical guidelines for cancer treatment) program. The third step of the program, RIGHT3, aimed to evaluate the concordance between AIOM lung cancer guidelines and clinical practice in Italy. Description of treatment decisions for elderly patients with advanced non-small-cell lung cancer (NSCLC) was among the indicators. According to 2009 AIOM guidelines, single-agent chemotherapy with a third-generation agent was a reasonable choice for elderly patients with advanced NSCLC, whilst evidence about use of platinum-based treatment in the elderly population was judged potentially affected by selection bias and not conclusive.
Materials and Methods: RIGHT3 was a retrospective observational study conducted in a sample of 53 Italian lung cancer centers, representative of 230 AIOM centers. Proportion of elderly patients with stage IV disease receiving chemotherapy was among the 14 indicators evaluated. Patients with NSCLC diagnosis who had their first visit at the oncology center during 2010 and followed-up for at least 6 months were included.
Results: Overall, 306 pts with stage IV NSLSC were enrolled, and 299 were evaluable. Of these, 90 (30.1%) were older than 70. In the elderly subgroup, 81 pts (90.0%) were treated with first-line chemotherapy. In detail, a single-agent treatment was administered in 28 (34.6%) of cases, and a combination chemotherapy in the other 53 cases (65.4%). Among pts receiving platinum-containing doublets, carboplatin was more frequently used than cisplatin: carbo–gemcitabine (16 pts), carbo–pemetrexed (12 pts), cisplatin–pemetrexed (8 pts), cisplatin–gemcitabine (7 pts), carbo–vinorelbine (4 pts) were the 5 most frequently used regimens. Thirty pts (33%) received a second-line chemotherapy: single-agent in 23 cases, combination chemotherapy in 7 cases.
Conclusions: First-line platinum-based combination chemotherapy was commonly used in elderly patients with advanced NSCLC in 2010 by the Italian Lung cancer centers involved. First-line single-agent treatment, recommended by AIOM 2009 guidelines as the treatment choice with highest level of evidence, was used only in a minority of patients.
No conflict of interest.

Insights into the management of bone metastases in patients with lung cancer: A comprehensive European survey

P. Woll[1], A. Flinois[2], P. Schoen[3], S. Shepherd[4], I. Haynes[4]. [1]*Weston Park Hospital, Sheffield, United Kingdom;* [2]*Kantar Health/TNS Sofres, Montrouge Cedex, France;* [3]*Amgen (Europe) GmbH, Zug, Switzerland;* [4]*Amgen Ltd., Uxbridge, United Kingdom*

Background: Bone metastases commonly occur in patients with solid tumours including lung cancer. Associated skeletal-related events (SREs; pathologic fracture, radiation or surgery to bone and spinal cord compression), hypercalcaemia and pain can substantially reduce quality of life. Bone-targeted agents (BTAs) may be used to prevent or delay these skeletal complications. We investigated how BTAs are used to treat European patients.
Materials and Methods: Prospective, observational chart audit in France, Germany, Italy, Spain and the United Kingdom. In total, 881 participating physicians completed brief questionnaires on patients with bone metastases examined during the observation period and detailed questionnaires for further patients meeting specific criteria. Patient cases were weighted according to the probability of prospective inclusion in the study. We report data on the subset of patients with lung cancer.
Results: Brief questionnaires were completed for 1646 patients with lung cancer and bone metastases. Detailed questionnaires were completed for a further 1139 patients. Only 56% of patients with lung cancer and bone metastases were receiving bisphosphonates (the only BTAs available at that time), 13% had been previously treated, 8% had treatment planned and 23% were expected never to receive BTAs. The most common reasons cited for not treating with a BTA were short life expectancy (63%), poor risk/benefit profile for the patient (37%) and renal impairment (25%). However, 26% of patients who were never expected to receive bisphosphonates

had a life expectancy of at least 1 year at time of bone metastases diagnosis, and around 74% of these patients were judged by their treating physician to be at moderate to high risk of experiencing an SRE. The main reasons for delaying bisphosphonate treatment were inappropriate patient profile (50%) or bone metastases responding to initial anti-tumour therapies (48%); safety concerns and bone metastasis characteristics each led to treatment delay in 26% of patients.

Conclusions: A substantial percentage of patients with bone metastases secondary to lung cancer do not receive treatment with a BTA, despite the impact that SREs can have on their quality of life. As the life expectancy of lung cancer patients increases with better treatment, there is a need for further awareness of these SREs and increased use of the most appropriate BTAs.

25-OH-vitamin D (vD) serum levels and malignant pleural mesothelioma (MPM) in a highly asbestos-polluted area in Piedmomt, Italy: A case-control study

F. Grosso[1], V. Bianchi[2], M. Bertolotti[3], R. Libener[4], A. Roveta[1], R. Guaschino[5], L. Mazzucco[5], M. Botta[6], F. Bonelli[7], C. Magnani[8]. *[1]SS Antonio e Biagio General Hospital, Oncology, Alessandria, Italy; [2]SS Antonio e Biagio General Hospital, Laboratory Medicine, Alessandria, Italy; [3]SS Antonio e Biagio General Hospital, Scientific Development Unit, Alessandria, Italy; [4]SS Antonio e Biagio General Hospital, Pathology, Alessandria, Italy; [5]SS Antonio e Biagio General Hospital, Transfusional Medicine, Alessandria, Italy; [6]S Spirito Hospital, Oncology, Casale Monferrato, Italy; [7]Diasorin, Scientific Development, Minnesota, USA; [8]University of Piemonte Orientale, Epidemiology, Novara, Italy*

Background: Low serum vD levels are a known risk factor for several diseases, including many types of human cancer. Furthermore in vitro and in vivo studies have demonstrated vD anti-tumor effects. The aim of this study is to identify a potential association between vD serum levels and MPM in a case-control study in the highly asbestos polluted area of Casale Monferrato, in Italy.

Material and Methods: Ninety-one subjects diagnosed with MPM since June 2002 to June 2006 constituted the case group. Two controls per patient (196), matched for age and gender, were randomly selected from the local population. A standard questionnaire was administered to collect information about demographics, life-style, occupational history and asbestos exposure. Serum samples were collected and stored at −20ºC until vD measurements were performed with a chemiolumiscence immunoassay (LIAISON, DiaSorin, Minnesota, USA). After evaluation of factors influencing vD in controls, the association of vD levels with case/control status was assessed, adjusting for the detected variables. Unconditional multivariate logistic regression analysis was mainly used but exploratory analyses using multivariate linear regression (GLM) were also conducted. ORs and 95% CIs were calculated for unit increase of the logarithm of vD and for quartiles of the distribution.

Results: Factors associated with vD variations in controls were age, gender and season, no data were available on nutrition. Median vD concentrations (ng/ml) in cases and controls were 11.50 (IQR: 7.75–19.50) and 20.85 (13.60–28.55), respectively. In both groups vD distribution was skewed and therefore analyses were conducted after logarithm transformation. In GLM multivariate analyses caseness was associated to a lower level of ln(vD) ($p < 0.0001$). In logistic regression analyses adjusted by age, gender, season and occupational exposure, the OR for a unit increase of ln(OR) was 0.298 (95% CI: 0.171–0.521), showing a statistically significant protective effect of vD.

Conclusion: In this series low vD levels strongly associate with MPM case status. Further investigations are ongoing to elucidate whether this striking difference between cases and controls could be involved in the pathogenesis of MPM as it is in other cancers.

3475 POSTER

First-line gefitinib in Caucasian patients (pts) with epidermal growth factor receptor (EGFR) mutation-positive non-small-cell lung cancer (NSCLC): Results from a multinational, prospective, open-label, single-arm Phase IV study

G. Ostoros[1], M. Cobo[2], T. Ciuleanu[3], R. McCormack[4], A. Webster[5], T. Milenkova[6], J.Y. Douillard[7]. *[1]National Korányi Institute, VIII, Budapest, Hungary; [2]Hospital Regional Universitario, Servicio de Oncologia Medica, Malaga, Spain; [3]Institutul Oncologic Prof. Dr. Ion Chiricuta, Medical Oncology, Cluj-Napoca, Romania; [4]AstraZeneca, Personalised Healthcare, Macclesfield, United Kingdom; [5]AstraZeneca, Biometrics and Information Sciences, Macclesfield, United Kingdom; [6]AstraZeneca, Research & Development, Macclesfield, United Kingdom; [7]ICO R Gauducheau, Medical Oncology, St Herblain, France*

Background: Study NCT01203917 (sponsor: AstraZeneca) assessed efficacy and safety/tolerability of first-line gefitinib in Caucasian pts with *EGFR* mutation-positive NSCLC.

Materials and Methods: Pts: Caucasian, ⩾18 yrs, PS 0−2, histologically confirmed Stage IIIA/B/IV *EGFR* mutation-positive NSCLC eligible for 1st-line treatment. Treatment: gefitinib 250 mg/day until disease progression (assessed 6-weekly by RECIST 1.1). Primary endpoint: objective response rate (ORR; investigator assessment; full analysis set [FAS]). Secondary endpoints included disease control rate (DCR), progression-free survival (PFS), overall survival (OS), safety/tolerability. Pre-planned exploratory objectives included the analysis of *EGFR* mutations in duplicate plasma samples (I and II; plasma I data presented).

Results: Of 1060 screened pts with NSCLC, 106 whose tumours harboured activating, sensitising *EGFR* mutations were enrolled (Sep 2010-Feb 2012; FAS). Demographics (FAS): female 71%; adenocarcinoma 97%; never smoker 64%. At data cut off (Aug 2012), ORR was 70% (95% confidence interval [CI] 61−78), DCR 91% (95% CI 84−95), median PFS 9.7 months (95% CI 9−11) and median OS 19 months (95% CI 17-not calculable; 27% maturity). Most common adverse events (AEs; any grade): rash (45%), diarrhoea (31%). Serious AEs (SAEs): 19%. AEs CTC grade 3/4: 15%. SAEs considered related to gefitinib by investigator: 1.9% (2 pts). Of 1033 pts with tumour samples, 859 had known *EGFR* mutation status (118 positive; mutation frequency 14%). Of 106 patients with *EGFR* mutation-positive tumours enrolled, 66% had exon 19 deletions and 31% L858R point mutations. Of 903 pts with baseline plasma I samples, 784 had known *EGFR* mutation status (82 positive; mutation frequency 11%; 68% exon 19 deletions, 31% L858R point mutations). Comparison of *EGFR* M status in matched tumour and plasma I samples and concordance between matched tumour vs plasma I is shown in the table.

Table: *EGFR* mutation status in tumour and plasma I samples (pts evaluable for both)

Tumour	Plasma, n		
	Positive	Negative	Total
Positive	69	36	105
Negative	1	546	547
Total	70	582	652
	n	%	**95% CI**
Concordance	652	94	92−96
Sensitivity	105	66	56−75
Specificity	547	100	99–100
Positive Predictive Value	70	99	92–100
Negative Predictive Value	582	94	92−96

Conclusions: First-line gefitinib was effective and well tolerated in Caucasian pts with *EGFR* mutation-positive NSCLC, consistent with the previous studies in Asian pts. Plasma samples could be considered for mutation analysis if tumour tissue is unavailable.

3476 POSTER

Crizotinib safety profile in elderly and non-elderly patients (pts) with advanced ALK+ non-small cell lung cancer (NSCLC)

F. Blackhall[1], A.T. Shaw[2], P.A. Jänne[3], D.W. Kim[4], K.D. Wilner[5], P. Schnell[6], A. Polli[7], B. Besse[8]. [1]*Christie Hospital NHS Foundation Trust, Department of Medical Oncology, Manchester, United Kingdom;* [2]*Massachusetts General Hospital, Department of Thoracic Oncology, Boston, USA;* [3]*Dana-Farber Cancer Institute, Lowe Center for Thoracic Oncology, Boston, USA;* [4]*Seoul National University Hospital, Department of Internal Medicine, Seoul, South Korea;* [5]*Pfizer Oncology, Medical Oncology, La Jolla, USA;* [6]*Pfizer Oncology, Medical Oncology, New York, USA;* [7]*Pfizer Oncology, Statistics, Milan, Italy;* [8]*Institut Gustave Roussy, Department of Cancer Medicine, Villejuif, France*

Background: Crizotinib is an oral tyrosine kinase inhibitor that targets ALK and has been approved in several countries for treatment of advanced *ALK+* NSCLC. The availability of data from a large number of pts from three ongoing crizotinib studies (Pfizer) allowed us to assess the safety profile of crizotinib in elderly pts (⩾65 y) versus that in non-elderly adult pts (<65 y). PROFILE 1001 (P1001; NCT00585195) is a single-arm study with a treatment-naive or previously treated *ALK+* NSCLC cohort. PROFILE 1005 (P1005; NCT00932451) is a large global single-arm phase II study in pts with previously treated *ALK+* NSCLC. PROFILE 1007 (P1007; NCT00923893) is a global randomized phase III study comparing crizotinib with standard chemotherapy as second-line therapy for advanced *ALK+* NSCLC. Previously reported ORRs with crizotinib in the three studies were 60−65%, and median values for PFS were 7.7−9.7 months.
Materials and Methods: Pts in all three studies received crizotinib at a starting dose of 250 mg BID and were followed for AEs from the first day of study treatment until ⩾28 days after the last dose of study drug.
Results: Pts who received at least one dose of crizotinib were included in this analysis (n = 1255; P1001, 149; P1005, 934; P1007, 172). Among crizotinib-treated pts, 1056 (84%) were aged <65 and 199 (16%) ⩾65 y. The overall frequency of treatment-related (TR) AEs in crizotinib-treated pts was comparable between pts aged <65 and ⩾65 y (93% and 97%). In the two age groups, respectively, the most common TRAEs were nausea (49%, 50%), diarrhea (44%, 45%), visual impairment (43%, 37%), and vomiting (41%, 43%). No TRAEs were reported at frequencies that differed by ⩾10 percentage points between the groups. Only the frequency of visual impairment was ⩾5 percentage points higher in pts aged <65 than ⩾65 y. Peripheral edema, decreased appetite, and edema were reported at frequencies ⩾5 percentage points higher in pts aged ⩾65 than <65 y. TRSAEs were reported in 79/1056 pts aged <65 y (7%) and 30/199 pts ⩾65 y (15%). Among pts aged <65 y, TRSAEs reported in >2 pts were renal cysts (n = 9), increased ALT (n = 6), pneumonitis (n = 6), dyspnea (n = 4), and febrile neutropenia, diarrhea, pneumonia, and ILD (n = 3 each). Among pts aged ⩾65 y, only pneumonitis (n = 4) was reported in >2 pts.
Conclusions: The safety profiles of crizotinib in pts aged <65 and ⩾65 y were similar in terms of types and frequencies of TRAEs. TRSAEs were reported at relatively low frequencies in both age groups.

3477 POSTER

Treatment strategies after failure to reversible tyrosine kinase inhibitors (rTKI) in EGFR mutant (mut) non-small cell lung cancer (NSCLC) patients (p): A retrospective analysis of 41 Spanish patients

M. Gil[1], J. Remon[2], D. Alcaraz[3], L. Capdevila[4], E. Sais[5], N. Reguart[3], T. Morán[6], E. Carcereny[6], R. Porta[7], R. Rosell[6]. [1]*ICO Badalona, Medical Oncology, Badalona, Spain;* [2]*Hospital de Mataró, Medical Oncology, Mataro, Spain;* [3]*Hospital Clinic i Provincial, Medical Oncology, Barcelona, Spain;* [4]*ICO-Badalona, Medical Oncology, Barcelona, Spain;* [5]*ICO-Girona, Medical Oncology, Girona, Spain;* [6]*ICO-Badalona, Medical Oncology, Badalona, Spain;* [7]*ICO-Girona, Medical Oncology, Badalona, Spain*

Background: Different therapeutic approaches have been used in the clinical setting in NSCLC p harbouring *EGFR* mutations progressing to rTKI, although the standard of care in this situation is still not well established.
Methods: A multinstitutional database from four different centers in Spain was review to identify *EGFR* mut p with acquired resistance to rTKI in order to evaluate the therapeutic strategies after rTKI failure and the effect on the post-progression survival (PPS) of these treatments.
Results: 41 p with acquired resistance to rTKI were identified: 63% female; median (m) age 62 ±11 yrs; 95% Caucasian; del19 76%, never or light former smokers 100%; 90.2% adenocarcinomas; 51 % received TKI as first line therapy; 85% were initial stage IV. mPFS for the rTKI was 8.4 months (mo) and mOS was 29.7 mo for the entire population. P were treated with a median of 2 therapeutic strategies after the rTKI failure. 6 therapeutic strategies have been identified. As immediate approach, 16 p were switched to chemotherapy (CT) with a mPPS of 3 mo. 9 p were switched to an irreversible TKI obtaining a mPPS of 3.9 mo. rTKI plus other drug was maintained in 11 p: rTKI plus CT in 9 p with a mPPS of 4 mo and rTKI plus other drug different to CT in 2 with a mPPS of 2 mo. Despite the progression, rTKI was maintained in 2 p considered slow progressors and local therapy, in addition to the rTKI, was administered in 3 p with oligometastatic progressive disease obtaining a mPPS of 1.4 and 36 mo, respectively. 8 p were treated sequentially with ⩾5 strategies. These p attained a mOS of 27.7 mo.
Conclusions: The combination of different strategies when treating *EGFR* mut p after rTKI failure may impact the survival especially when p are candidates to receive some of this treatments sequentially. These strategies may reflect different subsets of *EGFR* mut disease.
No conflict of interest.

3478 POSTER

Individualized dose adjustments facilitate continuous treatment with afatinib, allowing patients (pts) with advanced NSCLC previously treated with chemotherapy and erlotinib or gefitinib to maintain clinical benefit

A. Inoue[1], N. Katakami[2], S. Atagi[3], K. Goto[4], T. Hida[5], T. Horai[6], Y. Seki[7], R. Ebisawa[7], M. Shahidi[8], N. Yamamoto[9]. [1]*Tohoku University, Sendai, Japan;* [2]*Kobe City Medical Center General Hospital, Kobe, Japan;* [3]*National Hospital Organization Kinki-Chuo Chest Medical Center, Osaka, Japan;* [4]*National Cancer Center Hospital East, Chiba, Japan;* [5]*Aichi Cancer Center Hospital, Nagoya, Japan;* [6]*The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, Japan;* [7]*Nippon Boehringer Ingelheim Co. Ltd., Tokyo, Japan;* [8]*Boehringer Ingelheim, Bracknell, United Kingdom;* [9]*Wakayama Medical University, Wakayama, Japan*

Background: Gastrointestinal adverse events (AEs) − in particular, diarrhoea − are characteristic of epidermal growth factor receptor (EGFR)-inhibiting agents and guidance on their effective management can facilitate continuous treatment, allowing pts to obtain maximum therapeutic benefits. Afatinib (A) is an oral, irreversible, ErbB Family Blocker that blocks signalling from EGFR (ErbB1), human epidermal growth factor receptor 2 (HER2; ErbB2) and ErbB4. In LUX-Lung 4, A was effective in third- or fourth-line NSCLC Japanese pts with acquired resistance to erlotinib/gefitinib (median progression-free survival [PFS] of 4.4 months based on central independent review at the primary endpoint analysis [data cut-off 14 Feb 2011]). Here, in a subsequent exploratory analysis, we show that appropriate dose interruptions facilitate continuous A treatment.
Methods: 62 pts received A, which was given until progression or intolerable AEs. The A starting dose of 50 mg could be reduced by 10 mg increments to 40 mg or 30 mg daily.

Table: Japanese pts with PFS ⩾180 days (independent review; data cut-off 14 Feb 2011)

Pt*	Days on A treatment			Total treatment duration	PFS
	50 mg	40 mg	30 mg	(days)	(days)
1	98	370	−	462	423
2	38	48	273	357	197
3	140	16	−	155	183
4	303	−	−	303	192
5	28	156	127	309	252
6	20	10	199	227	195
7	32	50	403	483	421
8	23	51	125	197	232
9	38	148	−	185	184
10	15	27	117	157	181
11	8	341	−	348	191

*6/11 pts dose reduced due to diarrhoea.

Results: Median/mean duration of A treatment was 3.9/4.6 months (data cut-off 14 Feb 2011); the updated mean duration of A treatment was 4.9 months, with a maximum treatment of 25 months (data cut-off 9 Feb 2012). Diarrhoea was the most common AE that led to A dose reduction in 26 pts;

16 pts had grade 3 diarrhoea, and only 2 pts discontinued A due to grade 3 diarrhoea. Dose reduction allowed pts to continue A treatment to prevent disease progression (Table). Eleven pts had durable disease stability for ⩾180 days, two of whom for >400 days (data cut-off 9 Feb 2012) − 759 and 753 days, respectively, based on investigator assessment. One pt remains on A treatment (3.4 years as of 7 Apr 2013). Additional response and safety data will be presented.
Conclusions: In LUX-Lung 4, individualized A dose adjustments allowed pts to remain on treatment for as long as they had clinical benefit.

Identification of a clinical biomarker for 2nd line combination with nintedanib in adenocarcinoma non-small cell lung cancer (NSCLC) patients in two phase III trials

R. Kaiser[1], J.R. Barrueco[2], M. Reck[3], N. Hanna[4], C. Gann[1], P. Glomb[5], B. Gaschler-Markefski[6]. *[1]Boehringer Ingelheim Pharma GmbH & Co.KG, Oncology, Biberach, Germany; [2]Boehringer Ingelheim Pharmaceuticals Inc, Clinical Development Oncology, Ridgefield, USA; [3]Lung Clinic Grosshansdorf GmbH, Thoracic Oncology, Grosshansdorf, Germany; [4]Indiana University, Medicine, Indianapolis, USA; [5]Boehringer Ingelheim Pharma GmbH & Co KG, Global BCA Clinical Biostatistics, Biberach, Germany; [6]Boehringer Ingelheim Pharma GmbH & Co KG, Clinical Biostatistics, Biberach, Germany*

Background: Nintedanib, a triple angiokinase inhibitor, is in advanced development with two pivotal 2nd line NSCLC trials. LUME-Lung 1 (LL1) randomised 1314 patients (all histologies) to nintedanib + docetaxel or placebo + docetaxel, met its primary endpoint of PFS and demonstrated significant OS improvement in adenocarcinoma patients. LUME-Lung 2 (LL2) randomised non-squamous patients to nintedanib + pemetrexed or placebo + pemetrexed, with PFS by central review as the primary endpoint. Based on DMC futility analysis of investigator-assessed PFS, enrolment in LL2 was halted after randomising 713/1300 planned patients. Ongoing patients were unblinded and follow-up was continued per the amended protocol. ITT analysis showed a significant improvement in PFS by central independent review. Analyses to identify a clinical biomarker characterising patients benefitting from nintedanib combination treatment were performed.
Methods: Stepwise selection, using Cox proportional hazards modeling and a recursive partitioning tree, identified baseline variables prognostic for PFS in the LL2 placebo arm. Treatment by covariate interaction tests and HR by treatment interaction plots showed factors predictive of improved PFS in the LL2 nintedanib arm. These methods were applied to the LL2 DMC dataset to develop a hypothesis that was tested internally on final LL2 central PFS data and confirmed using LL2 OS data. External validation of the biomarker was performed on PFS (primary endpoint), interim OS, and final OS data from adenocarcinoma LL1 patients.
Results: Time since start of 1st line was the only prognostic, predictive clinical biomarker for 2nd line nintedanib combination in adenocarcinoma NSCLC patients. These patients progress rapidly after 1st line therapy. Interaction tests and HR 95% CIs led to selection of a 9 month cut-off since the start of 1st line to define the target population (T<9 mo). Benefit in T<9 mo patients (nintedanib vs placebo) was seen in LL2 (mPFS: 4.0 vs 2.8 months, HR 0.73, CI: 0.56–0.96, p = 0.0224; OS: HR 0.84, CI: 0.62–1.14) and confirmed in LL1 (mPFS: 3.6 vs 1.5 months, HR 0.63, CI: 0.48–0.83, p = 0.0008; interim OS: HR 0.79, CI: 0.55–1.14). Validation with final LL1 OS data show mOS: 10.9 vs 7.9 months, HR 0.75, CI: 0.60–0.92, p = 0.0073).
Conclusions: T<9 mo was validated in two independent NSCLC trials as a predictive clinical biomarker of nintedanib benefit for the adenocarcinoma patients most refractory to platinum-based 1st line therapy.

Tyrosine kinase inhibitors (TKI) treatment of non-small cell lung cancer (NSCLC) patients (p) based on EGFR mutations (m) status in serum only

L. Vilà[1], N. Pardo[1], J.L. Cuadra[1], L. Capdevila[1], T. Moran[1], E. Carcereny[1], C. Queralt[2], I. De Aguirre[2], M. Taron[2], R. Rosell[1]. *[1]ICO Badalona, Medical Oncology, Badalona, Spain; [2]ICO Badalona, Molecular Laboratory, Badalona, Spain*

Background: Treatment of EGFR mutated NSCLC p with EGFR TKIs in phase III trials has shown improved efficacy to standard chemotherapy. However, it can be difficult to obtain sufficient tumor tissue for analysis of EGFR m status in a large proportion of p. Nevertheless, so far, no data exists for NSCLC p treated according to EGFR m status in serum alone.
Methods: We reviewed our database to identify EGFR mutated p, excluding those for whom status was available in both serum and tissue. We analyzed p treated with an EGFR TKI for whom EGFR m status was known in serum only (status in tissue unknown due to insufficient material). At the same time, we reviewed p in whom EGFR m status in tissue was available over the same period in order to compare clinical characteristics and efficacy parameters: PFS, ORR and overall survival (OS). EGFR m analysis was performed in cell free circulating DNA (cfDNA)isolated from serum and plasma using the QIAmp DNA blood mini kit.
Results: 9 p with EGFR m detected in serum and 33 p with EGFR m in tissue were included. In EGFR mutated p in serum, median age 63; male 55.6%; non-smokers 33.3%; former smokers 44.4%; ECOG PS 0−1 66.7%; adenocarcinoma 77.8%; deletion19 33.3%, L858R 66.7%; EGFR TKI treatment in 1st line 44.4%; 2nd or 3rd line 55.6%. ORR: complete response (CR) 22.2%; partial response (PR) 22.2%; stable disease (SD) 22.2%; progressive disease (PD) 11.1%. 2p had poor PS and died prior to evaluation. mPFS 4.7 months (mo). mOS 18 mo. In p with EGFR m in tissue, median age 61; male 36.4%; non-smokers 75.8%; former smokers 24.2%; adenocarcinoma 87.9%; deletion19 75.8%; L858R 24.2%; 1st line 54.5%; 2nd or 3rd line 45.5%. ORR: CR 15.2%; PR 57.6%; SD 12.1%; PD 15.2%. mPFS 8.9 mo. mOS 32.7 mo. The multivariate analysis for OS considering EGFR m in serum differed according to PS (PS 0−1 16.6 mo vs PS >2 5.2 mo).
Conclusions: Obtaining sufficient tissue from NSCLC p for analysis of EGFR m status and other molecular alterations can be difficult. Determination of EGFR m in serum alone is feasible, yields similar results to mutation status in tissue, and could permit us to take treatment decisions.

Phase II study of combination therapy with S-1 and irinotecan in EGFR-mutated non-small cell lung cancer (NSCLC) resistant to both platinum-based chemotherapy and EGFR-TKI: NJLCG0804

M. Maemondo[1], S. Sugawara[2], T. Harada[3], S. Fukumoto[4], A. Inoue[5], O. Ishimoto[2], N. Matsubara[1], M. Harada[4], K. Kobayashi[6], T. Nukiwa[7]. *[1]Miyagi Cancer Center, Respiratory Medicine, Natori, Japan; [2]Sendai Kosei Hospital, Respiratory Medicine, Sendai, Japan; [3]Hokkaido Social Insurance Hospital, Respiratory Medicine, Sapporo, Japan; [4]Hokkaido Cancer Center, Respiratory Medicine, Sapporo, Japan; [5]Tohoku University Hospital, Respiratory Medicine, Sendai, Japan; [6]Saitama Medical University International Medical Center, Respiratory Medicine, Saitama, Japan; [7]South Miyagi Center Hospital, Miyagi, Japan*

Background: From the results of recent trials it was considered that both EGFR-TKI and platinum doublet are important for prolonging survival of patients with EGFR mutated NSCLC. However, if both treatments fail, there is no established treatment in NSCLC with EGFR mutation. Some reports showed high sensitivity of TKI-resistant cell lines to 5-FU and a synergistic effect between S-1 (a novel oral fluorouracil derivative) and irinotecan. We therefore conducted a phase II trial to evaluate the efficacy and safety of a combination of S-1 and irinotecan in EGFR-mutated NSCLC that was resistant to both platinum-based chemotherapy and EGFR-TKI.
Methods: Eligible patients had advanced or recurrent NSCLC with an EGFR activating mutation, disease progression (PD) during or after second − or third − line EGFR-TKI therapy, and experience with one or two lines of chemotherapy, including a platinum doublet prior to EGFR-TKI therapy. All patients received S-1 (80 mg/m^2, day 1 to 14) orally and irinotecan (70 mg/m^2, day 1 and 15) intravenously every 3 weeks. The primary endpoint was disease control rate (DCR) at 8 weeks after enrollment. The estimated accrual was 23 patients to confirm a DCR of 60% as a desirable target level and a DCR of 30 % as uninteresting with alpha = 0.05 and beta = 0.10.
Results: From February 2009 to April 2012, 25 patients were enrolled from 6 institutions. The patients comprised 5 males and 20 females with a

median age of 62 years (range, 53 to 78 years). ECOG performance status was PS 0 in 4 patients and PS1 in 21 patients. The histological subtypes were: adenocarcinoma 23 patients (92%), squamous cell carcinoma 1 patient, adenosquamous carcinoma 1 patient. EGFR activating mutations were, exon 19 deletion in 17 patients and exon 21 point mutation termed L858R in 8 patients. The current line of treatment in this study was the 3rd in 22 patients and the 4th in 3 patients. The median cycles of treatment was 4 (range 1−12). The objective responses were CR 0, PR 13, SD 8, and PD 4, giving a DCR at 8 weeks of 84.0% (95% CI, 63.9–95.5%). The overall response rate was 52.0% (95% CI, 31.3–72.2%). The median PFS was 5.0 months, whereas the median overall survival was 17.1 months. There was no significant difference in efficacy between the two types of EGFR mutations. Major grade 3 or worse toxicities included neutropenia (52%), anemia (20%), febrile neutropenia (16%), diarrhea (16%), thrombocytopenia (4%), and pulmonary thromboembolism (4%). No treatment-related death was observed.
Conclusions: This combination therapy with S-1 and irinotecan in EGFR-mutated NSCLC that was resistant to both platinum-based chemotherapy and EGFR-TKI showed promising efficacy with manageable toxicities. Further evaluation of this regimen in comparison with other cytotoxic agents or with irreversible EGFR-TKI is warranted.
No conflict of interest.

3482 POSTER

Phase II study of the 1st line chemotherapy consisting of bevacizumab, docetaxel and carboplatin for patients with non-squamous non-small cell lung cancer: TCOG1001

K. Minato[1], A. Gemma[2], M. Shingyoji[3], K. Yoshimori[4], H. Kuribayashi[5], H. Okamoto[6], M. Ando[7], Y. Takiguchi[8]. *[1]Gunma Prefectural Cancer Center, Ota Gunma, Japan; [2]Nippon Medical School, Tokyo, Japan; [3]Chiba Cancer Center, Chiba, Japan; [4]Double-Barred Cross Hospital Japan Anti-Tuberculosis Association, Tokyo, Japan; [5]Nippon Medical School Chiba Hokusou Hospital, Chiba, Japan; [6]Yokohama Municipal Citizen's Hospital, Yokohama, Japan; [7]Zizankai Medical Foundation Tsuboi Cancer Center Hospital, Fukushima, Japan; [8]Graduate School of Medicine Chiba University, Chiba, Japan*

Background: Although carboplatin is slightly inferior to cisplatin in terms of survival, addition of bevacizumab to carboplatin may overcome this disadvantage. ECOG4599 and some preclinical studies suggested a possible advantage of bevacizumab combined with taxanes. The aim of this study was to explore efficacy and safety of combination chemotherapy consisting of bevacizumab, docetaxel and carboplatin in the 1st line chemotherapy for non-sq NSCLC.
Patients and Methods: Pts who are untreatable with thoracic radiotherapy, with stage IIIB/IV non-sq NSCLC, age ranging from 20 to 74 years, PS 0 or 1, adequate organ functions, measurable lesions, and written IC were eligible. Combination chemotherapy consisting of bevacizumab (15 mg/kg), docetaxel (60 mg/m^2) and carboplatin (AUC=6) on day 1 was administered every 3 weeks up to 6 cycles (induction phase). Unless PD, it was followed by bevacizumab until PD (maintenance phase). The primary endpoint was median PFS to prove its superiority to the previous standard combination chemotherapy consisting of docetaxel and cisplatin with its historical median PFS of 4.6 months. With α=0.05 and β=0.20, calculated minimum sample size was 37, and the final determined sample size was 40. It was registered to the clinical trial registration system with the ID of UMIN000004524.
Results: Among 40 pts enrolled, 39 pts were analyzed because one retracted IC before starting the therapy. They included women in 31%, pts with PS of 0 in 67%, stage IV in 92%, EGFR mutations in 13% and unknown EGFR status in 8%. The median age was 62 years. The induction phase was delivered for 4 cycles in median (range: 1−6), and 21 pts (54%) received maintenance phase with median 4 cycles (range: 2−24). Frequent toxicities $\geqslant$ grade 3 during the induction phase in completely analyzed pts (n = 32) included anemia (9.4%), neutropenia (50.0%), thrombocytopenia (9.4%), febrile neutropenia (25.0%) and hypertension (37.5%). Other toxicities $\geqslant$ grade 3 were cholecystitis, increased ALP, hyperpotassemia, proteinuria, diarrhea, appetite loss, nausea, constipation, infection, stomatitis, and cancer pain in 3.1%, respectively. Interim external reviews of 35 pts revealed ORR of 74% (26/35) and median PFS of 6.4 months (95% CI: 4.8−9.9).
Conclusions: The primary endpoint was met because the lower end of the 95% CI exceeded the threshold of 4.6 months. This combination chemotherapy seems promising in terms of safety and effectiveness, warranting phase III studies.
No conflict of interest.

3483 POSTER

EGFR-TKI re-challenge with erlotinib after gefitinib for central nervous system metastases of EGFR mutated NSCLC

K. Tanaka[1], A. Hata[1], J. Takeshita[1], R. Kaji[1], S. Fujita[1], M. Kokubo[1], N. Katakami[1]. *[1]Institute of Biomedical Research and Innovation, Division of Integrated Oncology, Kobe, Japan*

Background: The re-challenge efficacy of epidermal growth factor receptor-tyrosine kinase inhibitors (EGFR-TKIs) in non-small cell lung cancer (NSCLC) harboring *EGFR* mutations has recently been reported, however there is little data for central nervous system (CNS) metastases.
Methods: We retrospectively screened 46 NSCLC patients with CNS metastases who had already experienced progressive disease (PD) following first EGFR-TKI (gefitinib), and were administered second EGFR-TKI (erlotinib). Among them, we compared the re-challenge efficacy of erlotinib in CNS lesions, between patients whose CNS metastases emerged after gefitinib administration (CNS relapse group; n = 16) and those who had CNS metastases before gefitinib administration (original CNS group; n = 30).
Results: The median CNS progression-free survival (PFS) and overall survival (OS) after initiation of erlotinib were 8.8 months (95% CI: 5.4–12.4) and 18.8 months (95% CI: 12.4–24.0), respectively. CNS relapse group showed better tumor response (response rate: 73.3 vs. 50.0%, $p = 0.192$) and significantly prolonged CNS-PFS (12.4 months [95% CI: 5.4–12.4] vs. 5.5 months [95% CI: 12.4–24.0], $p = 0.019$) compared to original CNS group. There was no significant difference in OS between CNS relapse group at 14.9 months (95% CI, 8.0–29.7) and original CNS group at 19.9 months (95% CI, 6.2–29.6, $p = 0.503$). We observed a significant discrepancy in tumor response between CNS metastases and primary lesions (response rate: 58.1% vs. 6.5%, $p<0.001$). Additionally, PD rate inside CNS was lesser during erlotinib administration in both groups, compared to gefitinib administration (31.0% vs. 76.2%, $p<0.001$).
Conclusion: EGFR-TKI re-challenge with erlotinib is more effective for CNS metastases compared with primary lesions, and corresponds with lesser frequency of PD inside CNS compared with gefitinib. Having CNS metastasis before initial EGFR-TKI administration was a negative predictive factor for re-challenge efficacy of EGFR-TKI inside CNS.
No conflict of interest.

3484 POSTER

Weekly and every 2 weeks cetuximab maintenance therapy after platinum-based chemotherapy plus cetuximab as first-line treatment for non-small cell lung cancer (NSCLC): Randomized, non-comparative, phase IIIb NEXT trial

D. Heigener[1], J.R. Pereira[2], E. Felip[3], J. Mazal[4], L. Manzyuk[5], E.H. Tan[6], O. Merimsky[7], B. Sarholz[8], R. Esser[8], U. Gatzemeier[9]. *[1]Krankenhaus Grosshansdorf, Grosshansdorf, Germany; [2]Instituto do Cancer − Arnaldo Vieira de Carvalho, São Paulo, Brazil; [3]Hospital General Vall d'Hebron, Barcelona, Spain; [4]F.D. Roosevelt Faculty Hospital, Banská Bystrica, Slovak Republic; [5]Russian Cancer Research Centre, Moscow, Russian Federation; [6]National Cancer Centre Singapore, Singapore, Singapore; [7]Tel Aviv Medical Center, Tel Aviv, Israel; [8]Merck KGaA, Darmstadt, Germany; [9]LungenClinic Grosshansdorf GmbH, Grosshansdorf, Germany*

Background: The phase III FLEX trial showed that the addition of cetuximab to cisplatin and vinorelbine chemotherapy (CT) followed by weekly cetuximab maintenance therapy significantly improved survival compared with CT alone in the first-line treatment of EGFR-expressing advanced NSCLC. The multinational, parallel-group phase IIIb NEXT trial (NCT00820755; sponsor, Merck KGaA) investigated in a community practice setting the efficacy and safety of weekly and every 2 weeks cetuximab maintenance therapy in patients with advanced NSCLC.
Material and Methods: Eligible patients with stage IIIB with pleural effusion or stage IV (UICC staging, 6th edition) NSCLC received 4−6 cycles of first-line platinum-based CT + cetuximab. At the end of combination therapy, patients free of disease progression were randomized to cetuximab maintenance therapy, weekly (250 mg/m^2) or every 2 weeks (500 mg/m^2), stratified for tumor histology and response status. The primary endpoint was overall survival (OS), from trial inclusion to death. Secondary endpoints included time to treatment failure (TTF) and response. A planned 1200 patients were to be enrolled to allow for an estimated 480 to be randomized.
Results: Enrollment was stopped prematurely when cetuximab did not gain regulatory approval in this setting. The intention to treat (ITT) population comprised 583 patients, recruited from 136 centers in 28 countries. After completion of the combination therapy phase, 311/583 (53%) patients without progression (ITT maintenance population) were randomized to maintenance therapy; 157 to every 2 weeks cetuximab and 154 to weekly cetuximab. Baseline characteristics were balanced between these two groups and exposure to cetuximab in the maintenance therapy phase was

similar. The 1-year OS rate was 62.8% (95% CI: 54.7–70.0) for every 2 weeks cetuximab and 64.4% (95% CI: 56.2–71.4) for weekly cetuximab. Median OS from inclusion was 16.1 (95% CI 13.6–18.2) and 15.5 (95% CI 13.2–19.7) months, respectively. Median TTF from inclusion was 5.8 (95% CI: 5.6−6.6) and 6.6 (95% CI: 6.1−6.9) months, respectively. Safety profiles in both the combination therapy and the maintenance phase were manageable and in line with expectations.
Conclusions: In patients with advanced NSCLC who were progression-free after 4−6 cycles of first-line CT + cetuximab, weekly and every 2 weeks cetuximab maintenance therapy were associated with similar survival outcomes.
Conflict of interest: *Ownership: Merck KGaA (BS, employment RE, employment and stock ownership). Advisory board: Merck KGaA (UG)*

Natural history of malignant bone disease in non-small cell lung cancer: Final results of a multicenter bone metastasis survey

D.S. Santini[1], S. Intagliata[1], F.P. Pantano[1], D.G. Galetta[2], F.F. Ferraù[3], L.G. Ginocchi[4], L.M. Moscetti[5], S.B. Barni[6], T.I. Ibrahim[7], M.A.S. Satolli[8]. *[1]University Campus Bio-Medico, Medical Oncology, Roma, Italy; [2]Istituto Tumori Giovanni Paolo II, Medical Oncology, Bari, Italy; [3]Ospedale San Vincenzo, Medical Oncology, Taormina, Italy; [4]Azienda Ospedaliero Universitaria Pisana, Medical Oncology, Pisa, Italy; [5]Ospedale Belcolle, Medical Oncology, Viterbo, Italy; [6]Azienda Ospedaliera di Treviglio-Caravaggio, Medical Oncology, Bergamo, Italy; [7]Istituto Scientifico Romagnolo per lo studio e la Cura dei Tumori, Medical Oncology, Meldola, Italy; [8]Ospedale Le Molinette, Medical Oncology, Torino, Italy*

Background: Bone metastases represent an increasing clinical problem in advanced Non-Small Cell Lung Cancer (NSCLC) as disease-related survival improves. This is a multicenter, retrospective survey aimed to explore the impact of bone involvement in this severe, life-threatening disease.
Patients and Methods: Data on clinicopathology, skeletal outcomes, skeletal-related events (SREs), and bone-directed therapies for 591 deceased NSCLC patients (50.8% aged >66 years) with evidence of bone metastasis were statistically analyzed.
Results: ECOG performance status at diagnosis of NSCLC was 0 in 40.1% of patients, 1 in 44.7% and 2 in 12.2%. The most frequent stage at diagnosis was IV (79.5%). Adenocarcinoma was the commonest histotype (66.2%) and EGFR status was unknown in 70.4%. Chemotherapy was the preferred I line treatment in 79%. Bone metastases evident at diagnosis in 57.5% of patients. In the remaining cases median time to bone metastases was 9 months. Patients ECOG performance status when bone metastases were detected was 1 in 51.1% and 2 in 19.6%. In our sample multiple bone metastases were detected in 78.5% of patients and 73.3% were osteolitic. Axial skeleton was interested in 72.6% of cases, pelvic bones in 47.5% and limb bones in 32.3%. Bone metastases related pain was reported by 78% of patients. Median Verbal Numerical Rating Scale (VNRS) for pain was 4 and it measured >4 in 44.3% of cases. Bisphosphonates was administered in 54% of patients, before the first SRE in 26.7% and after in 73.3%; zoledronic acid was mainly used (49.2%). First SRE occurs after 12 months in patients treated with zoledronic acid and after 2 months in those who did not receive. Osteonecrosis of the jaw was reported in only 4.6% of cases. Median number of SREs/patient was one, less than half of the patients (42.3%) experienced at least one SRE, 16.9% experienced at least two SREs, and only 2% experienced at least three SREs. The most common SRE was radiotherapy (69.4%), bone fracture occurred in 16.3%, spinal cord compression in 5%, the need of surgery in 4.8% and hypercalcemia in 4.4% of cases. Median time to first SRE was 2 months. Median survival after bone metastases diagnosis was 8 months and after first SRE was 7 months.
Conclusions: This is the largest study ever presented in literature on natural history of bone metastases in non small-cell lung cancer. These preliminary data suggest that bone metastases are a relevant clinical event in the natural history of patients affected by NSCLC. Final results will be available next ESMO meeting.
No conflict of interest.

3486 POSTER

A pilot phase II trial of cabazitaxel in patients with metastatic NSCLC progressing after docetaxel-based treatment: Preliminary results

A. Kotsakis[1], N. Kentepozidis[2], S. Agelaki[1], E. Kontopodis[1], P. Koinis[1], I. Mountzios[2], V. Karavassilis[3], P. Koliou[4], L. Vamvakas[1], V. Georgoulias[1]. *[1]University General Hospital of Heraklion, Department of Medical Onoclogy, Heraklion, Greece; [2]251 Air Force Hospital, Department of Medical Onoclogy, Athens, Greece; [3]Papageorgiou Hospital, Department of Medical Onoclogy, Thessaloniki, Greece; [4]Agios Georgios General Hospital of Chania, Department of Medical Onoclogy, Chania, Greece*

Purpose: Cabazitaxel, a microtubule inhibitor, is a semi-synthetic derivative of a natural taxoid that has been shown to be active in docetaxel-resistant prostate cancer. We investigated its activity in patients with metastatic NSCLC progressing under or after docetaxel-based regimens.
Material and Methods: Eligible patients had stage IV NSCLC; measurable disease; ECOG performance status 0−2; up to 2 prior chemotherapy regimens for the treatment of metastatic disease from which one containing docetaxel. Treatment consisted of cabazitaxel (25 mg/m^2 iv, every 21 days) until disease progression. G-CSF was administered to the physician's discretion. The primary endpoint was the objective response rate with a planned sample size of 40 eligible patients. A 2-stage design was applied with an interim analysis after enrolment of the first 25 patients (min 2 objectives responses).
Results: At the completion of the first stage (n = 25 patients) 30% had squamous cell carcinoma, 52% adenocarcinoma and 18% a low differentiated NSCLC. Three patients received one and 22 patients two prior regimens. Among the 21 evaluable patients, 4 (19%) patients showed partial response, 8 (38%) stable disease [Disease Control Rate=57%] and 9 (43%) progressive disease. The most common adverse events were anemia (54%); lymphopenia (38%); fatigue (35%). Grade 3/4 adverse events were neutropenia: 2/2; lymphopenia: 6/0; anemia: 1/0; thrombocytopenia: 0/1; diarrhea: 1/0; fatigue: 1/0. There was no treatment-related death. The estimated median PFS is 2.8 months. Treatment compliance was 94% as 1 patient withdrew due to toxicity (fatigue). 5 cycles delayed (6.2%), 3 due to toxicity and 2 for other reasons. Hematologic toxicity was the reason for dose reduction in 3 patients.
Conclusions: These preliminary results further support that cabazitaxel is active in docetaxel-resistant tumors. Its efficacy in pre-treated patients with NSCLC implies the necessity to explore its role in the treatment algorithm either in the first or second-line setting.
No conflict of interest.

3487 POSTER

Activity of gefitinib and erlotinib in pretreated EGFR wild-type NSCLC patients: A pooled analysis of 11 randomised trials

S. Barni[1], V. Gregorc[2], M. Cabiddu[1], M. Ghilardi[1], K. Borgonovo[1], A. Coinu[1], M. Cremonesi[1], M.G. Viganò[2], F. Petrelli[1]. *[1]Azienda Ospedaliera Treviglio, Medical Oncology, Treviglio, Italy; [2]Istituto Scientifico Ospedale San Raffaele, Medical Oncology, Milano, Italy*

Background: The tyrosine kinase inhibitors (TKIs) gefitinib and erlotinib (E) appear to be especially effective in non-small cell lung cancer (NSCLC) patients with activating epidermal growth factor receptor (EGFR) gene mutations. The role of TKIs in EGFR *wild*- type disease is still not well established. We have performed a pooled analysis to evaluate the activity of G and E in pretreated EGFR *wild*- type advanced NSCLC patients.
Material and Methods: PubMed, EMBASE, Web of Science and The Cochrane Library were systematically searched to identify published publications. Studies conducted in advanced NSCLC patients treated with G or E as $\geqslant$ second line therapy, and reporting objective response rate (RR), progression-free survival (PFS), time-to-progression (TTP) and overall survival (OS) of EGFR *wild*-type patients were included in analysis. Data on RRs were pooled by using Comprehensive Meta-Analysis software with a random-effects model. Data on outcome were summarised descriptively as median weighted PFS/TTP and OS.
Results: A total of 12 randomised controlled trials (6 phase III and 6 phase II of which 4 in second line and 8 further lines setting) were analysed for a total of 1801 patients. Five studies included G arms, 6 E arms and one compared E and G directly. Nine were studies in Caucasian population and 3 included Asiatic patients only. The reported overall weighted median PFS/TTP, median OS and pooled objective RR were 1.84 months, 6.4 months and 10.5%. In n = 4 second line trials, (n = 747 patients) median weighted PFS/TTP and OS were 3.1 and 7.6 months. In trials with Caucasian patients only, median weighted PFS/TTP and OS were similar to the overall population (1.84 and 6.4 months respectively). In Asiatic studies, median weighted PFS was 2.8 months while OS was not reported.
Conclusions: In this pooled analysis, the RR and OS outcome with G and E in a population of pretreated, and Caucasian patients also, with EGFR

wild-type NSCLC is in a range of what expected in > second line setting for NSCLC. In particular in the second line, outcome with EGFR TKIs has been nearly identical to that observed with standard docetaxel and pemetrexed chemotherapy.
No conflict of interest.

3488 POSTER

The use of epidermal growth factor receptor tyrosine kinase inhibitors in treatment of advanced EGFR wild-type non-small cell lung cancer: A meta-analysis

K. Wong[1], C. Victor[2], L. Eng[3], S. Verma[1]. [1]*Sunnybrook Odette Cancer Centre, Medical Oncology, Toronto − Ontario, Canada;* [2]*Institute for Clinical Evaluative Sciences, Statistics, Toronto − Ontario, Canada;* [3]*University of Toronto, Faculty of Medicine, Toronto − Ontario, Canada*

Background: The epidermal growth factor receptor (EGFR) oral tyrosine kinase inhibitors (TKIs), gefitinib and erlotinib, improve progression-free survival (PFS) compared to chemotherapy in the first-line treatment of patients with advanced non-small cell lung cancer (NSCLC) with activating EGFR mutation. Previous trials of TKIs in unselected patients suggest that they may have some activity in EGFR wild-type (WT) patients, but the magnitude of benefit is unclear. We conducted a meta-analysis to determine the outcomes of EGFR WT patients with advanced NSCLC treated with gefitinib or erlotinib.
Methods: MEDLINE was searched for phase 2 and 3 clinical trials of gefitinib or erlotinib in advanced NSCLC published between January 2000 and May 2012. Trials using TKI as treatment or control arm or as maintenance therapy were included. In addition, studies must have tested for EGFR mutation by polymerase chain reaction and analyzed EGFR WT patients. Random effects meta-analysis using the DerSimonian and Laird method was performed to pool survival estimates (hazard ratios (HR), risk ratios) and objective response rate (ORR). Placebo- and chemotherapy-controlled phase 3 trials were also evaluated separately in a subgroup analysis.
Results: Six randomized controlled trials (RCTs) with a total of 1,180 EGFR WT patients (709 on TKI, 471 on control with placebo or chemotherapy) were available for meta-analysis. Pooled overall survival (OS) from 5 RCTs was not significantly different for patients in the TKI arm compared to control arm (HR 1.00; 95% CI 0.86 to 1.16). Subgroup analysis according to type of control showed that TKI offered no OS benefit compared to either placebo (HR 0.92, 95% CI 0.63–1.35) or chemotherapy (HR 1.02, 95% CI 0.86 to 1.22) (interaction p = 0.63). Likewise, pooled PFS was similar between TKI and control in 4 RCTs (HR 1.35; 95% CI 0.79 to 2.31). However, the use of TKI significantly increased PFS compared to placebo (HR 0.78, 95% CI 0.63–0.97), but not chemotherapy (HR 1.64, 95% CI 0.96 to 2.79) (interaction p = 0.01). The rate of patients in the control arm who subsequently received TKI upon progression ranged from 3% to 52%. ORR estimated from 51 studies (1,872 EGFR WT patients) was 8.4% (95% CI 6.0–10.8), and was similar for gefitinib and erlotinib. Sensitivity analyses removing studies with estimated effect sizes did not affect these findings.
Conclusions: In this meta-analysis, gefitinib and erlotinib significantly increase PFS compared to best supportive care for advanced NSCLC with EGFR WT status. The lack of OS gain may be explained by significant crossover in these trials. TKIs may have a potential role in the management of EGFR WT patients who are not candidates for chemotherapy in the first-line setting.

3489 POSTER

Metronomic oral vinorelbine as first-line treatment in elderly patients with advanced non-small cell lung cancer: Preliminary results of a phase II trial (move trial)

A. Camerini[1], S. Donati[1], C. Valsuani[1], C. Puccetti[1], M.C. Petrella[1], G. Tartarelli[1], P. Puccinelli[1], D. Amoroso[1]. [1]*Ospedale Versilia, Medical Oncology, Lido di Camaiore, Italy*

Background: Metronomic oral vinorelbine could be a safe option for elderly patient with advanced non small cell lung cancer (NSCLC). Metronomic administration of chemotherapy leads to a cytostatic action shifting treatment target from cancer cell to tumor angiogenesis.
Materials and Methods: 32 chemotherapy naive elderly (⩾70 yrs) PS 0−2 patients with stage IIIB-IV NSCLC were prospectively recruited. Median age was 79 yrs (M/F 27/5) with predominantly squamous histology. PS distribution was 0−1(12)/2(20) with a median of 3.5 serious co-morbid illnesses. Study treatment consisted of oral vinorelbine 50 mg three times weekly (Monday-Wednesday-Friday). Primary endpoints were overall response rate (ORR), clinical benefit (CB) and safety. As per protocol we present the second interim analysis results.
Results: Patients received a median of 6 (range 3−20) cycles. ORR was 12.5% with 3 partial and 1 complete responses; 16/32 experienced stable disease lasting more than 12 weeks leading to an overall CB of 62.5%. Median time to progression was 6 (range 3−18) and median overall survival 8.5 (range 4−23) months. Treatment was well tolerated with rare G3/4 toxicity (two episodes of G3 diarrhoea, one of not-febrile G3 neutropenia and one G3 fatigue). Regardless of severity main toxicities observed were anemia in 40%, fatigue in 38%, diarrhoea 14%, nausea in 10% and vomiting in 7% of patients.
Conclusions: Metronomic oral vinorelbine is safe in elderly patients with advanced NSCLC with an interesting activity mainly consisting in long-term disease stabilization. Study accrual will continue to a total of 43 pts.
No conflict of interest.

3490 POSTER

Treatment-free interval (TFI) after first-line therapy and disease control rate (DCR) during second-line therapy as potential predictors of overall survival (OS) in relapsed malignant pleural mesothelioma (MPM)

A. Bulotta[1], V. Gregorc[1], M.G. Viganò[1], D. Ghio[2], G. Rossoni[1], C. Sallemi[1], A. Lambiase[3], C. Bordignon[3]. [1]*Istituto Scientifico San Raffaele, Department of Oncology, Milan, Italy;* [2]*Istituto Scientifico San Raffaele, Department of Radiology, Milan, Italy;* [3]*MolMed, Clinical Development, Milan, Italy*

Background: Both TFI (the time elapsing from completion of 1st-line to initiation of 2nd-line) and DCR (the nonprogression rate at 1st tumor evaluation) have been found to predict OS in some tumor types.
Methods: We assessed the associations of TFI after 1st-line and DCR during 2nd-line with OS by means of an individual patient pooled analysis of MPM patients (pts) who had failed a pemetrexed-based regimen. Dataset consisted of 261 pts receiving a 2nd-line therapy with single-agent NGR-hTNF (n = 50; phase 2 trial) or single-agent chemotherapy (gemcitabine, vinorelbine or doxorubicin) plus NGR-hTNF/placebo (n = 211; phase 3 trial). In both trials, tumor response was assessed every 6 weeks using MPM-modified RECIST criteria. OS was computed from start of 2nd-line, and median follow-up was 10.2 months (95% CI, 8.8–11.6). By applying a ROC analysis, the cutpoint for estimating TFI in relation to OS was set at 6 months (AUC=0.59; 0.53–0.65). In multivariate analyses, hazard ratios (HR) for OS were derived from Cox models with covariates for baseline factors (age, sex, PS and histology).
Results: After 1st-line therapy, 60 pts (23%) had partial response (PR), 135 (52%) stable disease (SD), for an overall DCR of 75%, and 66 (25%) early PD. Median TFI was 4.4 months (95% CI, 3.8−5.0), with 97 pts (37%) experiencing a TFI >6 months. A TFI >6 months (vs ⩽6) was correlated with improved OS in univariate (HR = 0.59; 0.42–0.84; p = 0.003) and multivariate models (HR = 0.60; 0.43–0.85; p = 0.004). After 2nd-line therapy, 9 pts (3%) had PR, 130 (50%) SD, for an overall DCR of 53%, and 122 (47%) early PD. Among pts responding to 1st-line, one third (23/60, 38%) progressed early during 2nd-line, while among pts progressing early during 1st-line, half (32/66, 48%) experienced disease control during 2nd-line. In a landmark analysis set at the 6-week time point, DCR (vs PD) was significantly associated with OS improvement (HR = 0.43; 0.30–0.60; p < 0.0001), which persisted after adjusting for baseline variables (HR = 0.37; 0.26–0.57; p < 0.0001).
Conclusions: With smaller HRs, an early-look measure such as 6-week DCR shows some advantage over TFI in predicting subsequent OS in relapsed MPM. In 2nd-line trials, TFI as stratification factor and DCR as surrogate endpoint may be considered.
No conflict of interest.

3491 POSTER

Long-term treatment with erlotinib in patients with advanced non-small cell lung cancer (NSCLC): Interim analysis at 1-year follow-up (the TERRA Study)

G. Jeannin[1], P. Fournel[2], C. Chouaid[3], R. Gervais[4], C. Locher[5], D. Moro-Sibilot[6], A. Vergnenègre[7], B. Milleron[8], P.J. Souquet[9], J.L. Mouysset[10]. [1]*CHU de Clermont Ferrand, Medical Oncology, Clermont Ferrand, France;* [2]*Institut de Cancérologie Lucien Neuwirth, Medical Oncology, Saint Priest en Jarez, France;* [3]*Hôpital Saint Antoine, Medical Oncology, Paris, France;* [4]*Centre François Baclesse, Medical Oncology, Caen, France;* [5]*CH de Meaux, Medical Oncology, Meaux, France;* [6]*CHU de Grenoble, Medical Oncology, Grenoble, France;* [7]*Hôpital Le Cluzeau, Medical Oncology, Limoges, France;* [8]*Hôpital Tenon, Medical Oncology, Paris, France;* [9]*CHU de Toulouse, Medical Oncology, Toulouse, France;* [10]*CHU de Lyon, Medical Oncology, Lyon, France*

Background: Patients (pts) with advanced NSCLC may experience long-term benefits with erlotinib, whatever the line of treatment No prospective data on a cohort of long term responder pts to erlotinib are currently

available. We present the results of a non-interventional prospective study after 1 year follow-up. Main disease and pts characteristics were presented earlier.

Patients and Methods: Stage IV pts with advanced NSCLC after platinum based chemotherapy treated for at least 9 months with erlotinib and followed for 24 months were included prospectively. The main endpoint was median PFS. Other endpoints included: pts demographics and disease characteristics, previous treatments and erlotinib therapy, objective response rate, overall survival, long-term safety, compliance and quality of life. PFS is presented.

Results: A total of 217 pts were included in 76 French sites, 213 were analyzed. Pts characteristics were: median age 67 [36−93] years; non-Asian 96.2%; ECOG performance status (PS) 0/1/2/3, 40.2/54.4/3.9/1.5 (%); men 42.3%; current/former/never smokers 5.7/44.8/40.1 (%); adenocarcinoma, 82.4%; stage IV/IIIB, 83.4/16.6 (%). Among 62 pts tested, 56.5% presented activating epidermal growth factor receptor (EGFR) mutation. Erlotinib was administered as first/second/third line treatment in 21.6/49.8/22.5 (%) of pts. As of February 2013, median total duration of erlotinib treatment was 23.4 [9.5–73.6] months and it was definitely discontinued in 43.7% of pts, mainly for disease progression (34.7%). Median total PFS (from erlotinib initiation) was 32 months (95% CI, 27 to 43) in these responder pts. At data cutoff 20.2% of pts had died (mainly disease progression). Most pts (86.8%) were identified as 'high adherers' on the Morisky Medication Adherence questionnaire. Most frequent long-term reported AEs (all grades) during the 12-month follow-up were diarrhea (12.4%), dry skin (6.9%), asthenia (6.5%), rash (5.5%). Most frequent long-term grade 3/4 AEs during the 12-month follow-up were rash (1.4%), folliculitis (0.9%) and dyspnea (0.9%). Grade 3 dry skin occurred in 1.8% pts, Grade 1/2 perionyxis in 4.1% pts.

Conclusion: At 12 months follow-up, interim results of the TERRA cohort study show that patients with advanced NSCLC treated with erlotinib, all treatment lines, can achieve extended PFS results, and most interestingly in patients with or without activated EGFR mutation. Long-term grade 3−4 adverse events were limited and mainly cutaneous.

3492 POSTER

Phase II study of bevacizumab in combination with carboplatin plus paclitaxel as first-line chemotherapy for non-squamous non-small cell lung cancer with malignant pleural effusion

M. Tamiya[1], A. Tamiya[2], K. Asami[2], K. Okishio[3], T. Kawagchi[2], H. Suzuki[4], N. Okamoto[4], I. Kawase[4], S. Atagi[3], T. Hirashima[4]. *[1]Osaka Prefectural Hospital Organization Osaka Prefectural Medical Center, Thoracic Malignancy, Habikino, Japan; [2]Kinki-Chuo Chest Medical Center, Thoracic Oncology, Sakai, Japan; [3]Kinki-Chuo Chest Medical Center, Clinical Research Center, Sakai, Japan; [4]Osaka Prefectural Hospital Organization Osaka Prefectural Medical Center, Thoracic Malignancy, Habikino, Japan*

Background: Vascular endothelial growth factor (VEGF) is involved in non-small cell lung cancer (NSCLC) with malignant pleural effusion (MPE), but little is known regarding the efficacy of bevacizumab (Bev) with carboplatin-paclitaxel (CP) to treat NSCLC with MPE. Therefore, we prospectively evaluated the efficacy and safety of Bev and CP in non-squamous NSCLC patients with MPE.

Methods: Twenty-three chemotherapy-naive non-squamous NSCLC patients with MPE were enrolled. Pleurodesis before chemotherapy was not performed. In the first cycle, patients received only CP to prevent Bev-induced wound healing delay after chest drainage. Subsequently, they received 2−6 cycles of CP with Bev. Patients who completed more than 4 cycles of CP and Bev without disease progression or severe toxicities continued to receive Bev alone as maintenance therapy. The primary endpoint was overall response, although an increase in MPE was allowed in the first cycle. VEGF levels were measured in plasma and MPE at baseline and in plasma after 3 cycles of chemotherapy.

Results: The overall response rate was 60.8%; the disease control rate was 87.0%. Response was not evaluated in 1 patient because of sudden death after 1 treatment cycle. Sixteen patients received maintenance therapy, following a median of 3 cycles. The median progression-free survival and median overall survival were 7.1 months (95% CI, 5.6−9.4 months) and 11.7 months (95% CI, 7.4–16.8 months). Most patients experienced severe hematological toxicities, including ⩾grade 3 neutropenia; none experienced severe bleeding events. Pleural effusions were controlled in 21 of 23 patients (overall MPE DCR, 91.3%). Treatment was successful in 4 of 6 patients in whom the affected lung did not re-expand after tube drainage. The only 2 patients whose MPE could not be controlled demonstrated high MPE levels, and their affected lungs did not re-expand after tube drainage. Furthermore, the control rate of MPE was improved after combination with Bev (CP, 78.3%, 18/23 patients; CP with Bev, 91.3%, 21/23 patients; $P = 0.08$). The median baseline VEGF level in MPE was 1798.6 pg/mL (range, 223.4–35,633.4). Plasma VEGF levels significantly decreased after 3 chemotherapy cycles (baseline, 513.6±326.4 pg/mL, post-chemotherapy, 25.1±14.1 pg/mL, $P < 0.01$), regardless of the efficacy of CP with Bev.

Conclusion: The combination of CP with Bev was confirmed as effective and tolerable in chemotherapy-naive non-squamous NSCLC patients with MPE. To better establish this evidence for patients with MPE, further clinical trials are warranted.

No conflict of interest.

3493 POSTER

Bevacizumab (B) (10 mg/kg) in combination with cisplatin (C) and docetaxel (D) administered every 2 weeks in patients (p) with advanced non-squamous non-Small Cell Lung Cancer (nsNSCLC): GGCP047/10 study

M. Lázaro[1], S. Vázquez[2], M.J. Villanueva[1], J.L. Fírvida[3], B. Campos[2], G. Huidobro[1], C. Senín[1], S. Varela[2], C. Grande[1], N. García-Cid[1]. *[1]CHUVI, Vigo, Spain; [2]HULA, Lugo, Spain; [3]CHOU, Orense, Spain*

Background: B in combination with platinum doublets followed by continuation maintenance with B prolongs survival and delays progression in chemo-naive pts with advanced nsNSCLC. In a phase II trial C, D and B (15 mg/kg) every 3 weeks followed by B showed a promising efficacy, in terms of progression free survival (PFS) and overall survival (OS), and an acceptable toxicity profile. In addition, a biweekly schedule of D and C in p with metastatic NSCLC as a front-line CT has demonstrated effective antitumor activity with a reduction in hematologic toxicity, comparable to the results of previous studies using 3-week schedule. Taken together, these data suggest that the addition of B to C/D administered every 2 weeks could increase the efficacy and reduce the toxicity associated with the other schedules.

Material and Methods: GGCP 047−10 is a multicenter study in chemo- naive p diagnosed with advanced nsNSCLC. Eligible p also have measurable disease according to RECIST criteria; age ⩾18 years; ECOG PS ⩽1; adequate hematological, renal and liver function; life expectancy of at least 2 months and signed informed consent. P receive C (50 mg/m^2), D (50 mg/m^2), and B (10 mg/kg) every 2 weeks for up to 6 cycles, followed by B alone every 2 weeks until disease progression or unacceptable toxicity. PFS is used as the primary efficacy endpoint. Secondary endpoints include safety profile, overall response rate (ORR), disease control rate (DCR) and OS.

Results: 32 p were enrolled in the study. Median age was 60 years (range 44−72; 28.1% ⩾65 years); male/female (%): 81/19; ECOG 0/1/2 (%): 28/63/10; adenocarcinoma (%): 84. Median PFS in overall population was 6.4 months (95% CI, 4.2−8.7). Among the 22 p evaluable for response, the ORR was 63.6% and DCR was 95.4%. Most frequent grade 3/4 hematologic toxicity was neutropenia (40.6%) and grade 3/4 nonhematologic toxicities was asthenia (12.5%) followed by mucositis (6.2%) and diarrhea (3.1%). There were no grade 3/4 hemorrhagic events.

Conclusions: Treatment with B, C and D plus maintenance B every 2 weeks is effective as front-line treatment of p with advanced nsNSCLC with acceptable toxicity. These data provide further evidence that B may be used in combination with multiple standard, platinum-based doublets in this setting.

No conflict of interest.

3494 POSTER

Multicenter trial for assessing tolerability of combination therapy with cisplatin, irinotecan, and Polysaccharide-K in extensive-stage small-cell lung cancer: RNCLC-01 study

T. Kashii[1], T. Miwa[1], S. Kajiura[1], I. Kinoshita[2], S. Oizumi[3], K. Nakagawa[4], S. Nagase[5], Y. Akashi[6], Y. Iwamoto[7], M. Tsuboi[8]. *[1]Toyama University Hospital, Medical Oncology, Toyama, Japan; [2]Hokkaido University, Medical Oncology, Sapporo, Japan; [3]Hokkaido University, First Department of Medicine, Sapporo, Japan; [4]Kanazawa Medical University, Respiratory Medicine, Ishikawa, Japan; [5]Tokyo Medical University, First Department of Surgery, Tokyo, Japan; [6]Nara Hospital Kinki University Faculty of Medicine, Medical Oncology, Nara, Japan; [7]Hiroshima City Hospital, Respiratory Medicine, Hiroshima, Japan; [8]Yokohama City University Medical Center, Respiratory Disease, Yokohama, Japan*

Background: Polysaccharide-K (PSK, Krestin®) is a protein-bound polysaccharide, extracted from culturedmycelium of Coriplus versicolor, and is associated with immunostimulatory activity. Although combinationuse of PSK with chemotherapy has been shown to prolong the response period in patients with small-cell lung cancer (SCLC), the efficacy of PSK in combination chemotherapy including cisplatin has been less examined. In this study, we examined safety and efficacy of combination therapy with cisplatin, irinotecan, and PSK in extensive-stage (ED) SCLC.
Material and Methods: Eligible pts included: histologically confirmed ED-SCLC without prior chemotherapy, age under 75 years, ECOG performance status $\leqslant$1, with evaluable disease and adequate organ function. Treatment: irinotecan 60 mg/m^2 on days 1, 8, and 15 and cisplatin 60 mg/m^2 on day 1 every 4 weeks for 4 to 6 courses, and oral PSK 3,000 mg/body daily. The treatment with PSK was continued after the end of cisplatin and irinotecan administrations, and was combined as a part of second-line therapy after exacerbations.
Results: Between January 2008 and July 2010, 17 patients were enrolled, and the efficacy and prognosis were evaluated in 15 of 17 patients. Response rate was 66.6%, one year survival rate was 66.6%, and two year survival rate was 33.2%. The major toxicities were diarrhea and myelosuppression, and the common toxicity of PSK-containing combination chemotherapy was not observed.
Conclusions: The combination chemotherapy with cisplatin, irinotecan, and PSK was effective and well tolerated in ED-SCLC. Updated survival and toxicity data will be presented at the Meeting.
No conflict of interest.

3495 POSTER

Paclitaxel and irinotecan in platinum refractory or resistant patients with small cell lung cancer: Experience from the Galician Lung Cancer Group

F.J. Afonso-Afonso[1], S. Vázquez Estéves[2], J. Casal Rubio[3], J.L. Fírvida Pérez[4], L.M. De Paz Árias[1], B. Campos Balea[2], M.J. Villanueva Silva[3], M.C. Areses Manrique[4]. *[1]Hospital Universitario de Ferrol, Medical Oncology, Ferrol, Spain; [2]Hospital Universitario Lucus Augusti, Medical Oncology, Lugo, Spain; [3]Complexo Hospitalario Universitario de Vigo, Medical Oncology, Vigo, Spain; [4]Complexo Hospitalario Universitario de Ourense, Medical Oncology, Ourense, Spain*

Background: Patients with Small Cell Lung Cancer (SCLC) whose disease progresses during or shortly after treatment with platinum, have a poor prognosis. Paclitaxel (P) and irinotecan(I) have demonstrated activity both as monotherapy as in combination regimen for this neoplasm. We present preliminary data from our experience in patients with SCLC refractory or resistant to platinum.
Material and Methods: We included patients with measurable disease that had progressed during or within six months of first-line chemotherapy based on platinum, with an Eastern Cooperative Oncology Group (ECOG) performance status <2, adequate liver, renal and bone marrow function. They were treated with (P): 75 mg/m^2 and (I): 50 mg/m^2, both drugs administered on days 1 and 8 of a 21 day cycle. Treatment was maintained until disease progression and/or unacceptable toxicity.
Results: Twenty-four patients have been treated, with a mean age of 59.5 years (43−79) and with metastases in two or more locations in 21 of them (87.5%). A median of 4 cycles of treatment was administered and eight patients (33.3%) received six or more cycles. The main reason for discontinuation of chemotherapy was disease progression, observed in 20 patients (83.3%). Partial response was documented in 16 patients (66.6%), stable disease in three (12.5%) and disease progression in five (20.8%). The median survival time was 24.9 weeks and the 1-year survival time was 22%. There have been no treatment-related deaths. The clinical and hematologic toxicities most frequently observed were grade 1 and 2: nausea (n:7; 29.2%), asthenia (n:7; 29.2%), anorexia (n:6; 25%), diarrhea (n:4; 16.6%), anemia (n:16; 66.6%) and neutropenia (n:12; 50%). There was one (4.1%) grade 4 and two (8.3%) grade 3 neutropenia. There were no cases of grade 4 clinical toxicity and there were eight (33.3%) grade 3: three of diarrhea (12.5%), two hepatic (8.3%) and three of asthenia (12.5%).
Conclusions: This (P) and (I) regimen is an effective and well tolerated option for this subgroup of poor prognosis patients with SCLC.
No conflict of interest.

3496 POSTER

Treatment with cisplatin–etoposide in the high-grade neuroendocrine tumors of the lung: Is histology important?

F. Longo[1], D. Rossini[1], L. De Filippis[1], G. Del Bene[1], S. Capponnetto[1], A. Emiliani[1], V. Lapadula[1], L. Marchetti[1], E. Petrelli[1], D. Vitolo[2]. *[1]Policlinico Umberto I − Roma, Oncologia BMI08, Roma, Italy; [2]Policlinico Umberto I − Roma, Experimental and Pathological Medicine, Roma, Italy*

Background: The optimal treatment for neuroendocrine tumors (NE) of the lung is still a matter of discussion. There is controversy regarding chemotherapy for large cell neuroendocrine carcinoma (LCNEC), in fact is not clear if the optimal treatment for LCNEC is similarly to small cell lung cancer (SCLC) or non-small cell lung cancer (NSCLC). The aim of our study is to analyze the differences in demographic characteristics and survival between SCLC and LCNEC using the same therapeutic strategy in both histological types.
Material and Methods: 33 and 24 patients with a diagnosis of LCNEC and SCLC respectively from 2005 to 2013 received cisplatin 90 mg/m^2 d1q21, etoposide 100 mg/m^2 d1q21 plus octreotide LAR 30 mg every 28 day. Other eligibility criteria were performance status 0 or 1, any stage, no previous chemotherapy and a histologically documented LNEC. The Kaplan–Meier test was used in order to evaluate the progression free survival (PFS) and overall survival (OS).
Results: In our single institution study we retrospective examined 57 patients of whom 50 (87.7%) with smoking history, median age of 64 (range 40−80), 63.2% male. Patients received a median of 6 cycles (range 3−6). For LCNEC the median progression free survival (PFS) was 12.5 months (95% Confidence Interval, CI 5.9–19.0) and the overall survival (OS) was 18.0 months (95% CI 11.3–24.7). For the SCLC the PFS was 16.2 months (95% CI 7.9–24.6) and OS was 25.8 months (95% CI 16.8–34.9).
Conclusion: In our results LCNEC tumors treated with cisplatin and etoposide plus octreotide LAR have a lower PFS (12.5 vs 16.2 months) and OS (18.0 vs 25.8 months) than SCLC.
No conflict of interest.

	PFS, months	OS, months
LCNEC	12.5 (CI 5.9–19.0)	18.0 (CI 11.3–24.7)
SCLC	16.2 (CI 7.9–24.6)	25.8 (CI 16.8–34.9)

3497 POSTER

Cisplatin in combination with etoposide for the first-line treatment of patients with large cell neuroendocrine carcinoma of the lung

F. Longo[1], D. Rossini[1], L. De Filippis[1], G. Del Bene[1], S. Caponnetto[1], A. Emiliani[1], V. Lapadula[1], L. Marchetti[1], E. Petrelli[1], D. Vitolo[2]. *[1]Policlinico Umberto I − Roma, Oncologia BMI08, Roma, Italy; [2]Policlinico Umberto I − Roma, Experimental and Pathological Medicine, Roma, Italy*

Background: Large-cell neuroendocrine carcinoma (LCNEC), 1−3% of all lung cancers, at diagnosis are generally widespread. The prognosis is poor despite an aggressive approach with extensive surgical resection for low stages and multidisciplinary approach with chemotherapy and radiotherapy for advanced stages. In literature there is no optimal treatment for patients with LCNEC. A recent retrospective review (Sun JM et al., Lung Cancer. Aug;77−2:365−70) of 45 consecutive patients with advanced LCNEC assessed that the median PFS durations were 6.1 and 4.9 months (P = 0.41), and the median OS durations were 16.5 and 9.2 months (P = 0.10) depending on whether first-line chemotherapy used regimens designed for SCLC (n = 11) or for NSCLC (n = 34). Our aim is to evaluate the effectiveness of the doublet cisplatin–etoposide plus octreotide in LCNEC as a first-line therapy.
Material and Methods: We retrospective studied 33 patients with LCNEC from 2005 to 2013 who received cisplatin 90 mg/m^2 d 1q21, etoposide 100 mg/m^2 d 1−3q21 and octreotide LAR 30 mg every 28 days. Other eligibility criteria were performance status 0 or 1, any stage, no previous chemotherapy and a histologically documented LNEC. The Kaplan–Meier

test was used in order to evaluate the progression free survival (PFS) and overall survival (OS).
Results: 28 patients (84.8%) had a smoking history, median age was 66 (range 40−80), 60.6% men, 39.4% women. Patients received a median of 6 cycles (range 3−6). The median PFS was 12.5 months (Confidence Interval, CI 5.9–19.0) and the OS was 18.0 months (95% CI 11.3–24.7) respectively.
Conclusions: Results show that patients treated with cisplatin–etoposide and octreotide LAR have a poor prognosis similar to SCLC regardless of the stage of presentation, however our results, if compared to literature, support that cisplatin–etoposide plus octreotide based regimens may be effective against LCNEC.

3498 POSTER

Phase 1b study of capecitabine and erlotinib in advanced non-small cell lung cancer

S. Lu[1], S. Popat[2], M. Puglisi[3], N. Kaudeer[2], S. Gennatas[2], M. Hewish[1], B. Ayite[1], J. Bhosle[2], M. O'Brien[2]. *[1]Royal Marsden NHS Foundation Trust, London, United Kingdom; [2]Royal Marsden NHS Foundation Trust, Lung Unit, London, United Kingdom; [3]Institute of Cnacer Research, London, United Kingdom*

Background: Erlotinib (Tarceva®, T) has been shown to improve overall survival and progression-free survival in second or third line treatment of unselected non-small cell lung cancer (NSCLC) patients (pts) compared to placebo. Thymidylate synthase inhibitors are active in NSCLC. Capecitabine (X) is an oral pro-drug of 5-fluorouracil activated by thymidine phosphorylase which is present in ~30% of NSCLC. T in combination with platinum and X in combination with docetaxel have been tested in NSCLC. Combination of X and T is active and well tolerated with no grade 4 toxicities in advanced pancreatic cancer. This provides the rationale for a phase 1b open-label 2-part study of X combined with T in pts with advanced NSCLC.
Methods: In the first part of the study, pts who received prior chemotherapy with adenocarcinoma histology and a performance status of 0−2 were investigated. The primary objective was to determine the maximum tolerated dose (MTD) and safety profile. X was administered at a starting dose of 500 mg/m^2 twice daily (bd) from day 1−14 and T 100 mg once daily (od) between day 1−21, all orally on a 21-day cycle. Successive cohorts of 3−6 pts were evaluated for dose-limiting toxicities (DLTs), defined as one episode of grade 2 or more toxicity that resulted in dose interruption or reduction. Dose escalation would only commence when all pts in the cohort had completed 42 days (2 cycles) of treatment without DLTs. The MTD was the dose at which $\leqslant$1/6 DLT was observed in that cohort.
Results: 20 pts were enrolled. No DLTs was observed in the first cohort. In the second cohort, 6 pts (3 were replacements due to early progressive disease (PD) before cycle 2) were treated with X 750 mg/m^2 bd and T 100 mg od with no DLTs. In the third cohort, X 1000 mg/m^2 bd and T 100 mg od, 1 patient had DLTs (grade 2 anaemia, grade 3 atrial fibrillation, grade 3 pneumonia) and additional 3 patients were recruited. 2 pts developed DLTs (1 had grade 2 skin toxicity and grade 2 rise in creatinine, 1 received a dose reduction as per protocol due to a drop in creatinine clearance). Dose escalation was stopped and 5 pts were recruited to the previous dose level (1 was replaced due to early PD before cycle 2 and 1 was a screen failure making a total of 6 pts in this dose level) with no DLTs and the MTD was established. Preliminary efficacy data showed 7/15 (47%) attained stable disease at the end of cycle 2 but 2 of the 7 pts went on to achieve partial response (PR) (13.3%). EGFR mutation status was not known in 7 pts and the remaining 8 pts (including 1 pt with PR) had none of the common EGFR mutations in exons 18 to 21 detected.
Conclusions: The combination of X 750 mg/m^2 bd with T 100 mg od is active and generally well tolerated in advanced NSCLC. The second part of the study has started and is recruiting pts at this dose level in the first line setting.

3499 POSTER

Multi-center randomized phase II trial of pemetrexed plus oxaliplatin or pemetrexed alone as the second line treatment for stage IV non-squamous non-small cell lung cancer

Y. Gong[1], L. Ren[1], M. Huang[1], L. Li[1], F. Peng[1], M. Hou[1], W. Li[2], Y. Jia[3], H. Yang[4], Y. Lu[1]. *[1]West China Hospital Sichuan University, Department of Thoracic Oncology and State Key Laboratory of Biotherapy, Chengdu Sichuan, China; [2]Cancer Hospital of Yunnan Province, Dept.of Medical Oncology, Kunming, China; [3]Second Renmin Hospital of Yibin City, Dept.of Medical Oncology, Yibin, China; [4]First Affiliated Hospital of Kunming Medical University, Dept.of Thoracic Surgery, Kunming, China*

Background: Guidelines from ESMO and NCCN indicated that the pemetrexed (Pem) alone was one of the options as the second line treatment for non-squamous NSCLC. While for the patients with a good performance status (ECOG 0−1), whether or not combining with platinum still remains unclear. This multi-center phase II trial was to evaluate the effectiveness and safety of the combination of Pem and oxaliplatin (Ox) as the second line treatment for those patients.
Materials and Methods: 53 pre-treated patients with non-squamous NSCLC were randomly assigned to Pem group (Pem 500 mg/m^2 d1/21 days) or Pem-Ox group (Pem 500 mg/m^2 d1 and Ox 135 mg/m^2 d1/21 days). The primer objective was the time to progression (TTP), and the second objectives included overall survival (OS) and treatment-related toxicities. The Kaplan–Meier analysis was performed in statistical analysis. Toxicities were recorded according to the NCI CTC version 3.0.
Results: The patients aged 42−68 years (median 55 years). The median follow-up period was 34 weeks. 21 and 22 patients was assigned to Pem and Pem-Ox group, respectively. The disease control rate (DCR) were 52.4% and 59.1%, respectively. There was no significant improvement in median TTP (13 weeks) and OS (36 weeks) in Pem-Ox group, comparing to the Pem group (median TTP: 10 weeks and median OS 32 weeks) (p >0.05, respectively). The treatment-related toxicities were similar, except more grade 1−2 peripheral neuritis were observed in the combination of Pem-Ox regimen.
Conclusions: For those patients with non-squamous NSCLC, the combination of pemetrexed and oxaliplatin did not show advantage as the second line treatment in this perspective study, comparing to the pemetrexed alone. Due to the limited study sample, further investigations might be warranted.
No conflict of interest.

3500 POSTER

Biweekly docetaxel/cisplatin vs gemcitabine/cisplatin as first-line therapy for advanced non small cell lung cancer patients who are elderly or poor performance status: Randomized multicenter phase II trial

J. Jang[1], H.K. Kim[2], B.C. Cho[3], K. Lee[4], H. Yun[5], I. Woo[6], K. Park[7], H. Song[8], H. Ryoo[9]. *[1]Chung-Ang University College of Medicine, Internal Medicine, Seoul, Korea; [2]Catholic University St. Vincent Hospital, Internal Medicine, Suwon, Korea; [3]Yonsei University Sevrance Hospital, Internal Medicine, Seoul, Korea; [4]YeungNam University Hospital, Internal Medicine, Daegu, Korea; [5]ChungNam Natl University Hospital, Internal Medicine, Daejeon, Korea; [6]Catholic University St Mary Hospital, Internal Medicine, Seoul, Korea; [7]Sungkyunkwan University Samsung Hospital, Internal Medicine, Seoul, Korea; [8]Keimyung University Hospital, Internal Medicine, Daegu, Korea; [9]Daegu Catholic University Hospital, Internal Medicine, Daegu, Korea*

Background: Docetaxel/Cisplatin (DP) and Gemcitabine/Cisplatin (GP) are standard treatment regimens for advanced NSCLC. In spite of potent efficacy, conventional one-day DP is regarded to have more toxicity compared with GP. There is increasing interest in a biweekly split administration of DP to reduce its toxicity. Hypothesis was that 1st-line biweekly DP is as safe as GP in elderly or poor performance status (PS) patients (pts).
Material and Methods: Chemotherapy naive pts with advanced NSCLC (IIIB/IV) who were elderly(65<) or PS (ECOG 2) were randomized to DP or GP arm by balancing for ECOG (0−1 v. 2), stage (IIIB v. IV) and age (<65 v. 65<). DP composed of docetaxel (35 mg/m^2)/cisplatin(30 mg/m^2) iv on days 1, 8 every 3 weeks. GP composed of gemcitabine (1000 mg/m^2)/cisplatin (30 mg/m^2) iv on days 1, 8 every 3 weeks. Chemotherapy lasted upto 6 cycles or until progression. Primary endpoint was safety (proportion of grade 3/4 toxicities). Planned sample size was 49 pts in each arm.
Results: From Nov. 09 to Jan. 13, a total of 97 pts were randomized (DP 50/GP 47). Adenoca was 58% in DP arm and 51% in GP while that of squamous cell ca 34% in DP and 40% in GP. Stage IIIB/IV was

33%/66% in DP and 42%/59% in GP. In DP arm, a total 228 adverse events (AEs) were reported and 27 were grade 3/4 toxicities while 211 AEs and 21 grade 3/4 toxicities in GP arm. Neutropenia was the most frequent grade 3/4 toxicity in both arm (DP 8.9%; GP 15.9%). In DP arm, grade 3/4 leukopenia(8.9%), hyponatremia(6.7%), anemia(4.4%) and anorexia (4.4%) were observed while anemia (9.1%) and hyponatremia (6.8%) in GP. In total AEs, anemia was the most common in both arms (DP:66.7%; GP:63.6%). Then, in the following order, hyponatremia (53.3%), anorexia (53.3%) and fatigue(40%) were common in DP arm while anorexia, (56.8%), fatigue(36.4%) and neutropenia(45.5%) were common in GP. Death during treatment was occurred in 1 pt in each arm. Both regimen showed similar grade 3/4 toxicities with similar profiles. Survivals seem to be favorable in GP arm compared with DP but with no statistical significance as follows. Progression-free survivals are 3.72 (DP) and 5.56 (GP) months respectively(p = 0.341). Overall survivals are 14.93 (DP) and 20.82 (GP) months respectively(p = 0.209).
Conclusions: This study showed that DP is similar with GP in terms of toxicity and efficacy in treatment of elderly or poor performance patients.
No conflict of interest.

3501 POSTER

ABCB1 polymorphisms as a predictive biomarker of neutropenia induced by amrubicin

O. Takakuwa[1], T. Oguri[1], M. Yokoyama[1], T. Uemura[1], E. Kunii[1], H. Hijikata[1], H. Ohkubo[1], M. Takemura[1], K. Maeno[1], A. Niimi[1]. *[1]Nagoya City University Graduate School of Medical Sciences, Medical Oncology and Immunology, Nagoya, Japan*

Background: Amrubicin is a key drug for small cell lung cancer (SCLC) but its treatment has a high incidence of severe neutropenia. The human *ABCB1* gene encodes multidrug transporter P-glycoprotein (P-gp) and its functional single nucleotide polymorphisms (SNPs) are known to influence to clinical outcome of various anticancer drugs. Amrubicin and its active metabolite, amrubicinol, are substrates for P-gp but the involvement of *ACBC1* SNPs in neutropenia induced by amrubicin has yet to be determined.
Material and Method: In 53 lung cancer patients treated by amrubicin monotherapy, grade of adverse effects and absolute neutrophil count (ANC) at nadir in first line amrubicin treatment were investigated and genotypes of two most major *ABCB1* SNPs (C3435T, G2677T/A) were analyzed by Taqman-probe method. In 18 of them, plasma concentrations of amrubicin and amrubicinol after first administration of amrubicin were measured using high-performance liquid chromatography method and their area under the plasma concentration versus time curve (AUC) values were analyzed.
Results: Patients treated with standard dose of amrubicin (N = 30, 40 mg/m^2) showed a significantly higher incidence of grade 4 neutropenia and percent decrease of ANC compared to 23 patients treated with lower dose of amrubicin (N = 23, *P* = 0.046 and 0.01). In patients treated with standard dose, patients carrying 3435CC (N = 9) showed significantly higher percent decrease of ANC compared to patients carrying 3435CT (*P* = 0.01) and 3435TT *(P*=0.04). Also, there incidence of grade 4 neutropenia was significant higher than that of patients without this genotype (*P* = 0.03). Patients carrying 2677GG (N = 6) showed a significant higher percent decrease of ANC compared to patients without G allele (*P* = 0.04). Meanwhile, in patients treated by low dose treatment of amrubicin, no significant relation between degree of neutropenia and genotypes of *ABCB1* SNPs was seen. In pharmacokinetic analysis, there was a significant positive correlation between AUC value of amrubicinol and percent decrease of ANC (r = 0.589 P = 0.01), but there was no significant correlation between AUC value of amrubicinol and genotypes of *ABCB1* SNPs.
Conclusions: These findings suggest C3435T and G2677T/A SNPs of *ABCB1* associate with amrubicin-related neutropenia and the mechanism is independent of AUC value of amrubicinol. These *ABCB1* SNPs could be a predictive biomarker for severe neutropenia induced by amrubicin.
No conflict of interest.

3502 POSTER

A combination of pemetrexed and carboplatin as first-line treatment for advanced non-squamous non-small cell lung cancer without epidermal growth factor mutation: A multicenter, phase II trial (CJLSG0906)

Y. Kogure[1], T. Kimura[2], H. Saka[3], E. Kojima[4], T. Ogasawara[5], M. Kondo[6], H. Taniguchi[2], H. Saito[7]. *[1]Nagoya Medical Center, Respiratory Medicine, Nagoya, Japan; [2]Tosei General Hospital, Respiratory Medicine and Allergy, Seto, Japan; [3]Nagoya Medical Center, Respiratory Medicine, Nagoya, Japan; [4]Komaki Municipal Hospital, Respiratory and Allergy Medicine, Komaki, Japan; [5]Japanese Red Cross Nagoya Daini Hospital, Pulmonary Medicine, Nagoya, Japan; [6]Nagoya University Graduate School of Medicine, Respiratory Medicine, Nagoya, Japan; [7]Aichi Cancer Center Aichi Hospital, Respiratory Medicine, Okazaki, Japan*

Background: Epidermal growth factor receptor (EGFR) status is very important when selecting treatment for non-small cell lung cancer (NSCLC). We evaluated the efficacy and safety of combination therapy with pemetrexed and carboplatin (PC) for the treatment of patients with advanced non-squamous (non-Sq) NSCLC without EGFR mutation.
Material and Methods: In this multicenter, phase II trial, we recruited patients with non-Sq NSCLC without EGFR mutation. Eligibility criteria were stage IIIB or IV, recurrent disease after surgery, no prior chemotherapy, age 20−74 years, Eastern Cooperative Oncology Group performance status 0−1, and adequate organ function. We evaluated the efficacy and safety of pemetrexed (500 mg/m^2) and carboplatin (area under curve 6), on day 1 of a 21-day cycle for up to 3−6 cycles. The primary endpoint was the response rate (RR), and the secondary endpoints were safety and the disease control rate (DCR). Based on the Simon 2-stage design, the planned sample size of 53 patients (pts) was determined to reject the RR of 15% under the expectation of 30% with a power of 0.80 and type I error of 0.05.
Results: From March 2009 to February 2012, 54 pts were enrolled from 18 centers and 52 pts were analyzable for outcome. The median age of these pts was 65 years (range, 43−73), and the male/female ratio was 40/12. Stage III and IV were noted in 6 and 46 pts, respectively; 46, 3, and 3 pts had adenocarcinoma, large cell carcinoma, and NSCLC, respectively. The median number of cycles was 4. We noted partial response in 19 pts with a RR of 36.5% (95% confidence interval, 23.6–51.0%). Stable disease was observed in 20 pts and the DCR was 75%. Major adverse events of grade 3−4 neutropenia were noted in 19 pts (36.5%). Grade 3−4 infection was observed in 4 cases (7.7%), but grade 3 febrile neutropenia was not noted. Grade 3−4 anemia and thrombocytopenia were observed in 16 pts (30.7%, each). Grade 3−4 nausea and vomiting were seen in 3 (5.8%) and 2 (3.8%) pts, respectively. There was no treatment-related death.
Conclusions: PC was efficacious and well tolerated in pts with advanced non-Sq NSCLC without EGFR mutation. This combination could be a standard regimen option for first-line treatment for advanced non-Sq NSCLC.
Clinical trial: UMIN000003393. This study was sponsored by Central Japan Lung Study Group.

3503 POSTER

Tumor-related symptoms (TRS) assessment in patients (pts) with advanced non-small cell lung cancer (NSCLC) treated with gefitinib or erlotinib: Preliminary results of an observational study

F. Narducci[1], G. Mansueto[1], S. Quadrini[1], L. Mentuccia[1], M. Mauri[2], R. Grande[1], I. Sperduti[3], T. Gamucci[1]. *[1]ASL Frosinone, Oncology Department, Frosinone, Italy; [2]Ospedale "San Giovanni Addolorata", Oncology Department, Rome, Italy; [3]Regina Elena National Cancer Institute, Bio-Statistic Unit, Rome, Italy*

Background: Edmonton Symptoms Assessment Scale (ESAS) is a validated tool in palliative care, which evaluates physical symptoms through a numeric scale (0−10). Symptoms improvement as a predictive factor for response rate (RR) in pts with advanced NSCLC treated with tyrosine-kinase inhibitors (TKIs) has not yet been evaluated. To this purpose, we performed an observational retrospective study.
Methods: Pts with advanced NSCLC treated with gefitinib or erlotinib were eligible. Primary outcome was the association between treatment response and tumor-related symptoms (TRS) (pain, asthenia, dyspnea) improvement. ESAS was performed at day 1 and 14 of each 28-d cycle. Symptoms' scores were divided into: not clinically relevant (0−4, NCR) and clinically relevant (5−10, CR). Sample size estimation was 115 to 165 pts to be needed for the expected difference in the primary outcome. Differences between symptoms' groups were analyzed with the paired-data

McNemar-test. All the associations were estimated using the Chi-Square test. Kaplan–Meier method was used for survival calculation. Uni- and multivariate survival analysis were carried out using the Cox regression model.
Results: Here we report data about 89 consecutive pts; median age: 69 years, males 68%, ECOG PS 0−1 88%, smokers 70%, EGFR-mutated 20%. Treatment was gefitinib (21%) or erlotinib (79%). RR: RC/RP 16%, SD 20%, PD 62%, TE 2%. Median follow-up was 7 months. 63% of pts had at least one CR TRS at baseline. Among these pts, a significant reduction ($p < 0.0001$) of TRS during treatment was observed (Table). Our preliminary data show a significant association between dyspnea/asthenia and RR ($p = 0.01$). At the multivariate analysis, TRS improvement correlates with both PFS and OS. Also related with survival were PS, EGFR status (PFS) and RR (OS).
Conclusions: Our preliminary data show that TRS improvement is significantly associated with treatment response and appears to be a prognostic factor during treatment with TKIs.
No conflict of interest.

TRS	Basal score $\geqslant$5 (%)	Nadir* score (%)
Pain	53	19
Asthenia	66	30
Dyspnea	57	23

*Lower score registered per patient.

3504 POSTER

No improvement in population-based survival of stage IV NSCLC despite increased use of chemotherapy

M. Aarts[1], B.E. Van den Borne[2], B. Biesma[3], J. Kloover[4], J.G. Aerts[5], V.E.P.P. Lemmens[1]. *[1]Eindhoven Cancer Registry/Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands; [2]Catharina Hospital, Pulmonary Diseases, Eindhoven, Netherlands; [3]Jeroen Bosch Hospital, Pulmonary Diseases, 's-Hertogenbosch, Netherlands; [4]St Elisabeth Hospital TweeSteden Hospital, Respiratory Diseases and Tuberculosis, Tilburg, Netherlands; [5]Amphia Hospital, Respiratory Diseases and Tuberc, Breda, Netherlands*

Background: Objective of this study was to investigate which factors were associated with the administration of chemotherapy for patients with stage IV non-small cell lung cancer (NSCLC), and their relation to population-based survival.
Materials and Methods: All patients diagnosed with NSCLC stage IV from 2001 to 2010 in the area of the Eindhoven Cancer Registry (n = 4,091) were included. Logistic and Cox regression analyses were performed to evaluate chemotherapy use and survival, respectively.
Results: Overall, 44% of the patients received chemotherapy. Higher rates were found among younger patients (multivariable odds ratio ($OR_{\leqslant 64\_vs\geqslant 75\_years}$) 1.9 (95% CI:1.6−2.2), in higher socioeconomic status ($OR_{high\_vs\_low}$ 1.7 (95% CI:1.4−2.1)), patients without comorbidity ($OR_{\geqslant 2\_vs\_0}$ 0.6 (95% CI:0.5−0.7)), patients diagnosed in more recent years ($OR_{2001-2003\_vs\_2010}$ 0.5 (95% CI:0.4−0.6)), having adenocarcinoma ($OR_{squamous\_vs\_adenocarcinoma}$ 0.8 (95% CI:0.6−1.0)), and metastasis to bone ($OR_{brain\_vs\_bone}$ 0.5 (95% CI:0.4−0.6)). Also a large hospital variation was observed, up to OR 2.2 (95% CI:1.6−2.9). Survival did not improve over time (median 19 weeks). One-year survival rates were 31% (median 35 weeks) for patients receiving chemotherapy and 8% for those not receiving chemotherapy (median 10 weeks). Prognostic factors were receipt of chemotherapy (hazard ratio (HR) 0.4 (95% CI: 0.4−0.5)), histology ($HR_{other\_vs\_adenocarcinoma}$ 1.1 (1.0−1.2)) and grade ($HR_{poor/undifferentiated\_vs\_well/moderate}$ 1.2 (1.0−1.4), $HR_{unknown\_differentiation\_vs\_well/moderate}$ 1.2 (1.0−1.4)).
Conclusion: The administration of chemotherapy was affected by year and hospital of diagnosis, as well as patient related (i.e. age, socioeconomic status, comorbidities) and tumour related factors (i.e. histology, site of metastasis). Despite increasing administration rates of chemotherapy, population-based survival rates remained low. The role of both patient and doctor preferences in the administration of chemotherapy remains to be explored. There should be more attention for identifying subgroups of patients who benefit from chemotherapy.
No conflict of interest.

3505 POSTER

Gefitinib as first line treatment of locally advanced or metastatic non-small cell lung cancer (NSCLC) in patients with activating epidermal growth factor receptor (EGFR) mutations within a Western population

R. Brooker[1], A. Pope[1], H. Wong[1], J. Gosney[2], P. Jain[1], J.AH. Littler[1]. *[1]Clatterbridge Cancer Centre, Clinical Oncology, Wirral, United Kingdom; [2]Royal Liverpool University Hospital, Histopathology, Liverpool, United Kingdom*

Background: Tyrosine kinase inhibitors are standard of care in first line treatment of advanced NSCLC with activating EGFR mutations. Initially gefitinib (Iressa®) was the only approved drug in the UK following the IPASS study. Majority of evidence for gefitinib is based on patients of Asian origin, female sex, never or former-light smokers with less evidence in Western populations, which prompted this audit in Merseyside.
Methods: Case notes of patients who received first line Gefitinib from September 2010 to December 2012 were reviewed. Cases were identified via electronic patient records and records of Histopathology Department. CTCAE v 3.0 was used to score toxicity and response assessed according to RECIST criteria. Survival was calculated using IBM SPSS Statistics version 19.
Results: 42 patients, 45% male and 55% female, with a mean age of 74 were identified. Performance status (PS) was 0−2 in 83% and 3 in 17%. All had adenocarcinomas with 93% having stage 3/4 disease. The remainder had relapsed disease after radical treatment and 1 patient had stage 1 disease. Most common EGFR mutations were exon 19 deletions (42%) and L858R exon 21 mutations (39%). Improved survival was seen in exon 19 deletions and patients of PS1 (20 vs. 10 months respectively) but this was not statistically significant. Median progression free and overall survival was 9 and 10 months. 1 year survival was 49.4%. A median of 7 cycles (range1−24) were delivered. 34 (81%) had lesions suitable for RECIST evaluation. At first CT scan 65% had stable disease, 26% partial response, 6% complete response, and 3% progressive disease. Of the remainder, 5 died prior to initial scan, 2 had immeasurable disease and 1 failed to have a baseline scan within an acceptable timeframe.
The most common reason for discontinuing gefitinib was disease progression with 29% (12) patients having further treatment. Palliative radiotherapy was administered in 5 and chemotherapy in 6. Common toxicities experienced were rash (56%), diarrhoea (36%), nausea and vomiting (12%) and fatigue (12%). Treatment was stopped due to toxicity in 4 patients; 2 grade 3 nausea, 1 grade 3 mucositis and 1 recurrent pyrexia.
Conclusions: Patients in our local population, of primarily Caucasian origin with advanced NSCLC and activating EGFR mutations benefit from first line Gefitinib. Benefits and toxicities broadly concur with those of the IPASS study though survival is inferior. Updated data on 100 patients will be presented.
Conflict of interest: *Other substantive relationships: Professor J R Gosney works in an advisory capacity for AstraZeneca, Lilly & Co, Boehringer-Ingelhiem and Pfizer. Dr P Jain has received financial support in the past for attendance at meetings from Lilly & Co, Roche and Boehringer-Ingelheim.*

3506 POSTER

Phase I study of oral nintedanib combined with docetaxel in previously treated Japanese patients with advanced non-small cell lung cancer (NSCLC)

I. Okamoto[1], M. Miyazaki[2], M. Takeda[2], K. Azuma[2], H. Hayashi[2], T. Seto[3], K. Konishi[4], A. Sarashina[5], R. Kaiser[6], K. Nakagawa[2]. *[1]Kinki University Hospital & Kyushu University Hospital, Medical Oncology & Center for Clinical and Translational Research, Fukuoka, Japan; [2]Kinki University Faculty of Medicine, Medical Oncology, Osaka, Japan; [3]National Kyushu Cancer Center, Thoracic Oncology, Fukuoka, Japan; [4]Nippon Boehringer-Ingelheim Co Ltd, Oncology Clinical Research, Shinagawa Tokyo, Japan; [5]Nippon Boehringer-Ingelheim Co Ltd, Medical Development Division, Kobe, Japan; [6]Boehringer Ingelheim Pharma GmbH Co KG, Oncology, Biberach, Germany*

Background: Nintedanib is an oral tyrosine kinase inhibitor that targets VEGFRs, PDGFRs and FGFRs, as well as RET and Flt3. This phase I, open-label, dose-escalation study (NCT00876460) was conducted primarily to determine the safety, tolerability, and maximum tolerated dose (MTD) of nintedanib combined with docetaxel in previously treated patients with advanced NSCLC.
Material and Methods: Eligible patients had advanced NSCLC of any histology after failure of first-line platinum-based chemotherapy (not containing docetaxel), an ECOG performance status of 0−1, and adequate organ function. Patients received nintedanib twice daily (bid), given continuously at a dose of 100, 150 or 200 mg bid (days 2−21), combined

with docetaxel 60 or 75 mg/m^2 (day 1) in 21-day cycles. Standard 3+3 dose escalations were performed separately in two pt cohorts with a small body surface area (<1.5m^2) (sBSA) and standard (⩾1.5m^2) BSA (stBSA), respectively. MTD was defined as the highest dose at which incidence of dose-limiting toxicities (DLTs) was ⩽33.3%. Pharmacokinetic (PK) analysis of nintedanib and docetaxel was also performed. Preliminary antitumour activity was evaluated according to RECIST v.1.0.

Results: Forty-two patients, including 17 patients with sBSA (<1.5m^2) and 25 patients with stBSA (⩾1.5m^2), were treated. The MTD of nintedanib, given in combination with 75 mg/m^2 docetaxel, was 150 mg bid in the sBSA cohort and 200 mg bid in the stBSA cohort. All DLTs were grade 3 liver enzyme elevations, which occurred in 12 patients (6 patients each in the sBSAand stBSA cohorts). These liver enzyme elevations were fully reversible and manageable with dose reduction or treatment discontinuation. The other most frequent drug-related adverse events were neutropenia (95%), leukopenia (83%), fatigue (76%), alopecia (69%), and decreased appetite (67%). PK analysis revealed no interactions between nintedanib and docetaxel. Analysis of PKs by BSA is ongoing. Among 36 assessable patients, 10 had a partial response, yielding an overall response rate of 28%.

Conclusion: Continuous daily treatment with nintedanib combined with docetaxel was manageable and showed promising signs of efficacy in previously treated Japanese patients with advanced NSCLC.

Phase II study of bevacizumab, cisplatin and docetaxel plus maintenance bevacizumab as first line treatment for patients with advanced non-squamous non-small cell lung cancer (n-Sq NSCLC) combined with exploratory analysis of circulating endothelial cells (CEC): Thoracic Oncology Research Group(TORG)1016

Y. Nakahara[1], T. Kato[2], N. Masuda[3], F. Oshita[4], Y. Hosomi[1], M. Nishikawa[5], T. Kaburagi[6], H. Okamoto[7], S. Morita[8], K. Watanabe[9]. *[1]Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Department of Thoracic Oncology and Respiratory Medicine, Tokyo, Japan; [2]Kanagawa Cardiovascular and Respiratory Center, Division of Respiratory Medicine, Yokohama, Japan; [3]Kitasato University School of Medicine, Department of Respiratory Medicine, Sagamihara, Japan; [4]Kanagawa Cancer Center, Department of Thoracic Oncology, Yokohama, Japan; [5]Fujisawa City Hospital, Department of Respiratory Medicine, Fujisawa, Japan; [6]Ibaraki Prefectural Central Hospital and Regional Cancer Center, Division of Respiratory Medicine, Kasama, Japan; [7]Yokohama Municipal Citizens Hospital, Department of Respiratory Medicine and Medical Oncology, Yokohama, Japan; [8]Yokohama City University Medical Center, Department of Biostatistics and Epidemiology, Yokohama, Japan; [9]Thoracic Oncology Research Group, Yokohama, Japan*

Background: Bevacizumab has been shown to amplify efficacy against n-Sq NSCLC in combination with platinum doublet, especially taxane including regimens. Docetaxel is one of best taxane composition combined with cisplatin for first line treatment for NSCLC, and known to have anti-angiogenic effect and may act synergistically with VEGF inhibiting agent. The object of this study was to assess the efficacy and safety of bevacizumab, cisplatin and docetaxel combination treatment in patients with chemonaive n-Sq NSCLC patients (Trial Registry: UMIN 000004368).

Methods: Eligible patients had advanced or recurrent n-Sq NSCLC with no prior chemotherapy. Patients having brain metastasis or history of hemoptysis were ineligible. Patients received 4 cycles of docetaxel (60 mg/m^2), cisplatin (80 mg/m^2) and bevacizumab (15 mg/kg) on day1 every 3 weeks followed by Bev alone as maintenance every 3 weeks until disease progression or unacceptable toxicity. The primary endpoint was response rate (RR) and planned sample size of this phase II study was 47 patients (Simon's two-stage minimax design). We measured circulating endothelial cells (CEC) count day1 and 8 of first cycle for exploratory analysis of efficacy and safety prediction.

Results: From Oct 2010 to Apr 2012, 47 patients (28 males/ 19 females, median age, 61 years, 39−73) were enrolled. Stage IIIB/IV/recurrent: 5/39/3, ECOG PS 0/1: 31/16. All patients were adenocarcinoma, EGFR status: mutated/wild/unknown: 13/31/3. Bevacizumab maintenance were administered in 87% (41/47) of the patients and 9 was median number of delivered course, 4 course of induction and 5 course of maintenance. Dose reduction was required in 28% (13/47) of the patients. Thirty-five partial responses and 11 stable diseases were observed among 47 patients, yielding a RR of 74.5% (95% confidence interval: 59.7–86.1%) and disease control rate of 97.9% (88.7–99.9%), respectively. The median progression free survival duration in the patients was 9.0 (7.0–11.3) months. Grade 3/4 leukopenia, neutropenia, hypertension, nausea and febrile neutropenia were observed in 60, 96, 47, 13 and 9% of the patients, respectively. Alveolar hemorrhage (Grade 5) after 4 cycle occurred in one patient.

Conclusions: Bevacizumab, cisplatin and docetaxel combination followed by bevacizumab maintenance treatment was highly effective in patients with n-Sq NSCLC, with acceptable toxicity. Exploratory analysis of CEC is ongoing and will be presented.

No conflict of interest.

3508 POSTER

TSR-011: A potent inhibitor of ALK with activity in crizotinib-resistant tumor models in phase 1−2 development for ALK+ NSCLC

G. Weiss[1], J.C. Sachdev[1], J.R. Infante[2], M. Mita[3], K.M. Wilcoxen[4], V. Kansra[5], D.G. Brooks[5], R.E. Martell[5], S.P. Anthony[6]. *[1]Scottsdale Healthcare, Virginia Piper Cancer Center, Scottsdale AZ, USA; [2]Sarah Cannon Research Institute, Phase 1, Nashville TN, USA; [3]Cedars-Sinai Medical Center, Oncology, Los Angeles CA, USA; [4]TESARO Inc, Scientific Affairs, Waltham MA, USA; [5]TESARO Inc, Medical Research, Waltham MA, USA; [6]Evergreen Hematology & Oncology, Spokane WA, USA*

Background: Significant progress has been made in treatment of the subset of non-small cell lung cancer (NSCLC) driven by the echinoderm microtubule associated protein like 4 (EML4) anaplastic lymphoma kinase (ALK) gene and other fusions. Despite approval of crizotinib for ALK+ NSCLC there are still significant challenges. In order to address limitations of crizotinib, such as resistance mutations in ALK, TSR-011, a potent, small molecule, second generation ALK inhibitor is undergoing clinical evaluation. TSR-011 was specifically designed using X-ray structure based drug design, and hence has very high affinity for the ALK kinase domain (Kd = 0.36 nanomolar, [nM]). TSR-011 inhibits wild type, recombinant ALK kinase activity with an IC50 value of 0.7 nM and exhibits sustained potent inhibition of ALK-dependent tumor growth in mice. ALK amplification and mutations that are important drivers of NSCLC cell growth or crizotinib resistance are inhibited by TSR-011 at low nM (IC50 values of 0.1 to 2.2 nM) concentrations. The (sub)nanomolar potency and activity against clinically observed ALK mutations of make TSR-011 a promising 2nd generation ALK inhibitor.

Methods: A Phase 1−2a dose escalation and cohort expansion study sponsored by TESARO is underway to evaluate safety, tolerability, PK, and efficacy of TSR-011. Phase 1 is evaluating patients with advanced solid tumors and lymphomas of any ALK status. The maximum tolerated or recommended Phase 2 dose will be evaluated in Phase 2a in patients required to have ALK+ tumors (defined by immunohistochemistry and fluorescent in-situ hybridization) including those with NSCLC progressing on, or naive to, ALK inhibitor therapy, as well as, non-lung malignancies. This study was approved by Institutional Review Boards of all participating institutions.

Results: As of April 2013, patients have been enrolled at doses between 30 and 480 mg orally. Tumor types include ALK+ and negative NSCLC, papillary thyroid cancer and neuroendocrine tumors. Once daily dosing resulted in dose responsive pharmacokinetic parameters and human drug exposures in excess of that associated with efficacy in murine models. No DLTs or visual changes have been reported.

Conclusions: Based on tight binding to ALK, potency at inhibiting ALK enzymatic activity, activity in crizotinib resistant cellular models and early clinical data TSR-011 is a promising agent for ALK-dependent malignancies.

3509 POSTER

Final results of a phase II trial evaluating oral vinorelbine as maintenance treatment after first line chemotherapy with cisplatin plus oral vinorelbine for locally advanced or metastatic non-small-cell lung cancer patients

E. Helou[1], J.G. Kattan[2], F. El Karak[1], F. Nasr[3], W. Houhou[4], G. Chahine[1], M. Ghosn[5], C. Mourad[6], F.S. Farhat[4]. *[1]Hotel Dieu de France University Hospital, Hematology-Oncology, Beirut, Lebanon; [2]St Joseph Hospital, Hematology-Oncology, Beirut, Lebanon; [3]Mount Lebanon Hospital, Hematology-Oncology, Beirut, Lebanon; [4]Hammoud Hospital University Medical Center, Hematology-Oncology Department, Saida, Lebanon; [5]Faculty of Medicine Saint Joseph University, Chairman Hematology-Oncology Department, Beirut, Lebanon; [6]Pierre Fabre Medicament, Medical Affairs Department, Beirut, Lebanon*

Background: Vinorelbine (V) plus Cisplatin (CDDP) is a commonly used platinum doublet for the treatment of advanced NSCLC which has

consistent proven efficacy. Maintenance therapy has lately demonstrated significant outcome improvement; nevertheless the high cost of treatment in developing countries remains an issue. The oral form of V is a convenient and cost-effective treatment.
Material and Methods: We conducted a multi-centre phase II trial to evaluate CDDP 80 mg/m^2 D1 in combination with Oral V 60 mg/m^2 D1 & D8 at first cycle increased at 2nd cycle (in the absence of grade III–IV haematological toxicity) to 80 mg/m^2 D1 & D8. Cycles were repeated every 3 weeks for a total of 4 cycles. Patients with objective response or stable disease after 4 cycles received maintenance therapy with Oral V 80 mg/m^2 D1 & D8 every 3 weeks for a total of 4 cycles. Primary objective: progression-free survival. Secondary objectives: objective response, overall survival and safety profile.
Results: n = 39; median age (range) 63 years (42–82); PS at inclusion: 0 (64%) or 1 (36%); number of metastatic sites: 1 (23%), 2 (54%), 3 or more (20%); Histology: non-squamous 82%, squamous (18%). 38 patients were evaluable for efficacy. Objective response was observed in 18 pts (47%) with 2 pts achieving CR (5%). Stable disease was observed in 9 pts (24%). The median duration of response was 6 months (95% CI [3.6–9.2]). 16 patients (41%) received the planned Oral V maintenance treatment. The median progression free survival for the whole population and for the population receiving maintenance treatment was 4.3 (95% CI [2.5–6]) and 7.8 (95% CI [5–9.9]) months respectively while the overall survival was 8.9 (95% CI [5.7–12]) and 10.5 (95% CI [6.6–14.3]) months respectively. Treatment was well tolerated with main observed hematological toxicities being grade 3 anemia (8%) and grade 3 & 4 neutropenia (8%). Grade 3 & 4 nausea/vomiting were observed in 18% of pts and grade 3 asthenia in 5%.
Conclusion: The study results are in line with published data, and reconfirm the efficacy of CDDP + Oral V regimen as first line treatment for advanced NSCLC. Maintenance therapy with single agent Oral V is feasible and well tolerated. Maintenance treatment with V may extend efficacy of the combination regimen, oral form being convenient to the patients for a treatment prolongation.

3510 POSTER

Phase II study of amrubicin and carboplatin for previously untreated patients with extensive-disease small cell lung cancer

M.I. Fukuda[1], T. Kitazaki[1], Y. Nakamura[2], A. Kinoshita[3], M.A. Fukuda[4], H. Takatani[5], H. Soda[6], Y. Soejima[7], S. Nagashima[2], S. Kohno[2]. *[1]Japanese Red Cross Nagasaki Genbaku Hospital, Chemotherapy, Nagasaki, Japan; [2]Nagasaki University Hospital, Second Department of Internal Medicine, Nagasaki, Japan; [3]Nagasaki Prefecture Shimabara Hospital, Internal Medicine, Nagasaki, Japan; [4]National Hospital Organization Nagasaki Medical Center, Respiratory Medicine, Ohmura, Japan; [5]Nagasaki Municipal Medical Center, Internal Medicine, Nagasaki, Japan; [6]Sasebo General Hospital, Internal Medicine, Sasebo, Japan; [7]Ureshino Medical Center, Respiratory Medicine, Ureshino, Japan*

Background: Amrubicin and cisplatin are active in the treatment of small cell lung cancer (SCLC), and carboplatin is an analogue of cisplatin with less nonhematological toxicity. To determine the efficacy and toxicity of amrubicin and carboplatin for previously untreated patients with extensive-disease (ED) SCLC.
Patients and Methods: Thirty-five patients fulfilling the following eligibility criteria were enrolled: chemotherapy-naive, good performance status (PS 0–1), age <76, extensive-disease, and adequate organ function. Based on the phase I study (J Thorac Oncol 4:741, 2009), the patients received amrubicin 35 mg/m^2 i.v. on days 1, 2 and 3, and carboplatin AUC 5 i.v. on day 1. Four cycles of chemotherapy were repeated every 3 weeks.
Results: Thirty-five patients were eligible and 34 patients were assessable for response, toxicity and survival. Patients' characteristics were as follows: male/female = 27/8; PS 0/1 = 4/31; median age (range) = 64 (41–75); stage IV = 35. The overall response was 81% (CR5, PR21, SD4, PD2, NE3). Grade 4 leukopenia, neutropenia, and thrombocytopenia occurred in 11%, 60%, and 11%, respectively. There were no treatment-related death and pneumonitis. Three patients experienced hypotension for amrubicin infusion reaction and two were terminated the study. The median overall survival time, and the 1-, 2- and 3-year survival rates were 15.6 months, 63%, 33% and 8%, respectively. The median progression-free survival time was 6.5 months.
Conclusion: Amrubicin and carboplatin was effective in untreated extensive-disease small cell lung cancer.
No conflict of interest.

3511 POSTER

Biweekly cisplatin and gemcitabine as first line treatment in stage IV non-small cell lung cancer

Y. Günaydin[1], M. Benekli[1], M. Inanç[2], M. Ozkan[2], A. Demirci[3], U. Demirci[3], A. Süner[4], H. Karaca[2], V. Berk[2], S. Büyükberber[1]. *[1]Gazi University Medical Faculty, Medical Oncology, Ankara, Turkey; [2]Erciyes University Medical Faculty, Medical Oncology, Kayseri, Turkey; [3]Dr.A. Y. Ankara Oncology Education and Research Hospital, Medical Oncology, Ankara, Turkey; [4]Gaziantep University Medical Faculty, Medical Oncology, Gaziantep, Turkey*

Background: Cisplatin plus gemcitabine is an option in treatment of stage IV non-small cell lung cancer (NSCLC). Biweekly use of this regimen is effective and more tolerable in a study. We evaluated the efficacy and tolerability of this regimen as retrospective.
Material and Methods: We analyzed patients, who had taken biweekly cisplatin/gemcitabine chemotherapy as first line treatment of NSCLC. Cisplatin 50 mg/m^2 and gemcitabine 1000 mg/m^2 were given on day 1 every 14 days.
Results: 108 patients were evaluated from five centers, 93 men (86%) and 15 women (14%). The median age was 58 (25–82). Most of patients were adenocarcinomas (n = 63, 58%). All of them had $\leqslant$2 ECOG PS. Mean 7 cycles therapy were given (2–12). After every four cycles, patients were evaluated for response. Overall clinical benefit was 68% (40% partial, 28% stable response). Progression free survival was 7.1 months. There were 41 deaths(38%) and overall survival (OS) didn't calculate. Estimated OS was 14.1 months. Six patients had died owing to progression during therapy. Grade 3/4 toxicity was detected in eight (7%) patients. They were four anemias, two neutropenias, one womiting and one nephropathy. In all grades, the most toxicity was anemia (48%). Neutropenia was 21% but only one patient had febrile neutropenia. One patient had changed therapy for grade 2 nephropathy. The predominant nonhematologic side effect were nausea and womiting.
Conclusions: Biweekly administration of cisplatin and gemcitabine as first line treatment in NSCLC is effective and tolerable.
No conflict of interest.

3512 POSTER

Clinicopathological features of non-small cell lung cancer in south India and correlation with epidermal growth factor receptor [EGFR] mutational status

A.D. Bhatt[1], R. Pai[2], G. Rebekah[3], S. Dhananjayan[2], G. ArunNehru[2], A. Samuel[4], A. Singh[4], A. Joel[4], A. Korula[2], R.T. Chacko[4]. *[1]Avinash Cancer Clinic, Medical Oncology, Pune, India; [2]Christian Medical College, Department of Pathology, Vellore, India; [3]Christian Medical College, Department of Biostatistics, Vellore, India; [4]Christian Medical College, Department of Medical Oncology, Vellore, India*

Background: There is scanty information on the prevalence of mutations in the Indian region. A prevalence of 51.8% was reported from single centre in India. We performed a retrospective analysis of 154 patients with carcinoma of the lung for whom formalin fixed paraffin embedded [FFPE] tissues was available. The clinicopathological profile, EGFR mutational status, treatment given and outcomes was collected, analyzed and are described.
Methods: All patients with histopathologically confirmed NSCLC who were treated during the two year period Jan 2008-Dec 2010 and for whom formalin fixed paraffin embedded [FFPE] tissues, on which EGFR mutational analysis could be performed, were available were included in this study. This protocol was approved by the IRB of the centre.
Results: Of the 154 cases included in the study, 48 were excluded since they were either treated elsewhere or the duration of follow up was less than 3 months. FFPE tissues of the remaining 106 patients were analysed for EGFR mutations. Forty two patients (39.6%) included in the study had a mutation in one of the four exons characterized (Table 1). The commonest mutation in exon 19 was a 15 bp deletion (n = 26, del E746-A750). Patients whose EGFR mutational status was not available at presentation prior to start of treatment were started on chemotherapy, n = 46 [43.39%]. If EGFR mutational analysis was available and mutations were present patient were stated on either upfront TKI, n = 15 [14.15%] or if on chemotherapy arm were allowed to finish 6 cycles and then start with maintenance TKIs, n = 26 [24.52%]. The median progression free survival for smokers and non smokers was 10 months (95% CI, 7–12) and 9 months (95% CI, 7–10) respectively. The median progression free survival for patients with and without mutations was 9 months (95% CI, 7–10) and 11 months (95% CI, 7–14) respectively. Better progression free survival was seen in the EGFR mutation positive group who received chemotherapy followed by TKI (log rank test, p = 0.027) as compared to those who received only

TKIs. Progression free survival in chemotherapy followed by maintenance with pemetrexed was (10 months, 95% CI, 8−11).
Conclusion: Our results show relative high prevalence of mutations in EGFR at 39.6% which is higher than the published data in western world and lower than that reported by a previous report from India which found mutations in 51.8% of patients[18]. The response rate of patients with an activating EGFR mutation was 93.3%. There was observed benefit of addition of chemotherapy over TKI in EGFR mutation positive group.
No conflict of interest.

Table 1. EGFR mutation status and its correlates

Variable	Number (%) of patients				
	EGFR mutation present (N = 42, 39.6%)		EGFR mutation absent (N = 64, 60.4%)		
Exon 18 mutation present	1 (2.4%)				
Exon 19 mutation present	32 (76.2%)				
Exon 20 mutation present	2 (4.8%)				
Exon 21 mutation present	7 (16.6%)				
	Response (%)	**Progression (%)**	**Response (%)**	**Progression (%)**	**Total**

3513 POSTER

Malignant pleural mesothelioma: maintenance chemotherapy with pemetrexed

A. Nacci[1], P. Rizzo[2], F. Sponziello[2], E. Mazzoni[2], P. Fedele[2], L. Orlando[2], P. Schiavone[2], N. Calvani[2], A. Marino[2], S. Cinieri[2]. *[1]Presidio Ospedaliero di Summa − Antonio Perrino, Brindisi, Italy; [2]Presidio Ospedaliero di Summa − Antonio Perrino, Oncology, Brindisi, Italy*

Background: Maintenance chemotherapy with pemetrexed is not the standard treatment of choice in patients with locally advanced or metastatic epiteliomorfe malignant pleural mesothelioma (EMPM). We would assess the safety and efficacy of a treatment with pemetrexed until progression disease after 4 or 6 cycles of induction therapy with or without platin.
Methods: From July 2008 to September 2012, 21 patients (18 males and 3 females with a median age of 67 years range 58−84) with locally advanced or metastatic epiteliomorfe malignant pleural mesothelioma (EMPM) were enrolled. In all patients histology was epiteliomorfe malignant mesothelioma. Only 15 patients (71.4%) had a PS 0 whereas 6 (28.6%) had a PS 1. All patients received an induction therapy with or without platin. Each patient received an average of 5.6 cycles of induction chemotherapy. Then all patients received a maintenance chemotherapy with pemetrexed 500 mg/mq intavenously over 10 minutes every 3 weeks. Each patient received an average of 7.3 cycles of maintenance chemotherapy. All patients received folic acid and vitamin B12 supplementation to improve safety.
Results: At the time of analysis all patients were evaluable for response. Fourteen patients (66.6%) had a partial response and two of these underwent surgery and obtained a complete response. Six patients (28.5%) had a stable disease. The median overall survival was 13 months, while median progression-free survival was 11 months. Grade 2−3 of WHO haematological toxicities (anemia and neutropenia) occurred in 4 patient (19%). We also observed grade 2−3 of WHO gastrointestinal toxicities (diarrhea, nausea and vomiting) in 2 patient (9.5%). Grade 2 of lack of appetite and asthenia occurred in 3 patients (14.3%).
Conclusions: Our data show that a maintenance chemotherapy with pemetrexed in EMPM resulted in a moderate overall survival (13 months). These results indicate that patients with EMPM could benefit from a maintenance treatment with pemetrexed.
No conflict of interest.

3514 POSTER

MED12, a component of the transcriptional MEDIATOR complex, and STAT3 influence outcome to platinum-based chemotherapy in patients (p) with advanced non-small-cell lung cancer (NSCLC)

D. Morales-Espinosa[1], C. Costa[2], N. Karachaliou[2], M.A. Molina-Vila[3], A. Gimenez-Capitan[2], L. Bonnano[4], M. Majem[5], B. Massuti[6], J.J. Sanchez[7], R. Rosell[8]. *[1]Instituto Nacional de Cancerologia, Subdirección de Investigación Clínica, Distrito Federal, Mexico; [2]Pangaea, RNA, Barcelona, Spain; [3]Pangaea, DNA, Barcelona, Spain; [4]Istituto Oncologico Veneto, Medical Oncology, Padova, Italy; [5]Hospital de la Santa Creu i Sant Pau, Medical Oncology, Barcelona, Spain; [6]Hospital General de Alicante, Medical Oncology, Alicante, Spain; [7]Autonomous University of Madrid, Departamento Medicina Preventiva y Salud Pública, Madrid, Spain; [8]Catalan Institute of Oncology, Medical Oncology, Badalona, Spain*

Background: MED12 negatively regulates TGF-b receptor signaling. Loss of MED12 induces an EMT-like phenotype associated with chemotherapy resistance. IDO and IL6 activate the JAK2/STAT3 signaling pathway, which − together with NFkB (RelA) signaling − is often altered in lung cancer. BIM could influence response to chemotherapy. We have examined these components and KRAS mutations in NSCLC tumor samples and correlated results with progression-free survival (PFS).
Methods: The mRNA expression of MED12, IDO, JAK2, STAT3, RelA and BIM was examined in microdissected tumor samples from p with stage IV NSCLC. mRNA levels were assessed by RT-PCR and categorized by terciles (high vs low/intermediate). KRAS mutations were assessed by high resolution melting.
Results: A total of 55 p with performance status (PS) 0−1, treated with platinum plus either gemcitabine or pemetrexed: median age, 62 years; 27.6% females; 84.2% smokers; 66% adenocarcinoma; 16% with KRAS mutations. There was no correlation between gene expression levels and KRAS mutation status. In the multivariate analysis, including gene expression levels, histology and PS, only MED12 and STAT3 were associated with PFS (low MED12: HR = 11.6, P = 0.005; high STAT3: HR = 6.5, P = 0.01). HR for low BIM expression was 2.4 (P = 0.16). None of the markers were associated with overall survival.
Conclusions: To the best of our knowledge, this is the first time that low expression of MED12 with significantly shorter PFS in NSCLC p receiving platinum-based chemotherapy. MED12 could be a new biomarker of chemoresistance and inhibition of TGF-bR signaling can restore chemotherapy response in patients with low MED12.
No conflict of interest.

3515 POSTER

Cell-free DNA and tumour burden in advanced NSCLC

A. Dowler Nygaard[1], P.C. Holdgaard[2], K.L.G. Spindler[1], N. Pallisgaard[3], A. Jakobsen[1]. *[1]Vejle Hospital, Department of Oncology, Vejle, Denmark; [2]Vejle Hospital, Department of Nuclear Medicine, Vejle, Denmark; [3]Vejle Hospital, Department of Molecular Biochemistry, Vejle, Denmark*

Background: Cell-free DNA (cfDNA) is fragments of DNA circulating in the bloodstream. Under malignant conditions, the level of cfDNA increases. The biological mechanisms behind this phenomenon remain to be fully understood, but it has been argued that the level of cfDNA is merely reflecting the tumour burden. It has also been suggested that the mechanism is far more complex, including biological pathways reflecting the aggressiveness of the disease. We aimed to examine the correlation between whole-body tumour burden in terms of total metabolic tumour volume (MTV) and total lesion glycolysis (TLG) estimated by PET-CT, and the level of cfDNA.
Material and Methods: Patients with newly diagnosed, non-small cell lung cancer (NSCLC) being candidates for first line chemotherapy were enrolled into a prospective biomarker trial at the Department of Oncology, Vejle Hospital, Denmark. From a pre-treatment blood sample, plasma was extracted and the level of cfDNA determined by an in-house qPCR. The routine staging was supplemented by a PET-CT scan when indicated. PET-scans performed within a month before blood-sampling were evaluated by an experienced nuclear medicine specialist, blinded to the level of cfDNA. The tumour contours were delineated semi- automatically by using a threshold SUV of 2.5. The primary endpoint was correlation between MTV, TLG and cfDNA. Secondary endpoints were progression free survival (PFS) and overall survival (OS) according to MTV, TLG and cfDNA. Correlations were determined by the Spearman's Rank correlation method. Survival data were analysed by the Kaplan–Meier method and the Log Rank test.
Results: Fifty-three patients were included. There was no correlation between MTV and cfDNA (r = 0.1), or TLG and cfDNA (r = 0.1), while there was a high agreement between MTV and TLG (r = 0.98). There was no

correlation between MTV, TLG, cfDNA and PFS, but patients with MTV above the median, had a significantly shorter OS compared with patients below the median (p=0.02). There was no significant difference in OS according to TLG (p = 0.08). cfDNA levels above the 75th percentile were significantly correlated to a shorter OS (p = 0.02) which was confirmed in a multivariate analysis.
Conclusions: Our results indicate that cfDNA does not merely reflect tumour burden, but is a valuable tumour marker of clinical importance.
No conflict of interest.

Phase I study of peptide vaccine targeting indeolamine 2,3 dioxygenase in metastatic lung cancer patients

T. Zeeberg Iversen[1], L. Engell-Noerregaard[1], E. Ellebaek[1], R. Andersen[1], J. Bjoern[1], C. Gouttefangeas[2], A. Mellemgaard[1], P. Thor Straten[1], M. Hald Andersen[1], I.M. Svane[1]. *[1]Center for Cancer ImmuneTherapy, Department of Oncology, Copenhagen, Denmark; [2]University of Tuebingen Interfaculty Institute for Cell Biology, Department of Immunology, Tuebingen, Germany*

Background: To investigate the targeting of indeolamine 2.3 dioxygenase (IDO) enzyme by a synthetic peptide vaccine for patients with metastatic with non small-cell lung cancer (NSCLC).
Material and Methods: In a clinical phase I study we treated 15 HLA-A2 positive patients with stage III−IV NSCLC and disease stabilization (SD) after standard chemotherapy. Patients were treated with Imiquimod ointment and vaccine (100 microg IDO5 peptide, sequence ALLEIASCL, formulated in 900 microL Montanide) subcutaneously. Primary endpoint was toxicity. Clinical benefit and immunity were assessed.
Results: No CTCAE grade 3−4 were observed. One patient developed a partial response (PR) after 1 year of vaccine treatment while long-lasting disease stabilization (SD >8.5 months) was demonstrated in another 6 patients. The median overall survival (OS) was 2.1 years. Patients demonstrated significant improved OS (P = 0.03) when compared to the untreated group of excluded HLA-A2 negative patients. IDO specific CD8+ T-cell immunity were demonstrated by IFN-gamma Elispot and Tetramer staining. Flow cytometry analyses demonstrated a significant reduction in the T-reg population (P = 0.03) and a significant increase in the NK cell population (P = 0.05) after the 6th vaccine (2.5 months) compared to pre-treatment levels. Furthermore, expression of IDO was frequently detected in tumour biopsies by immunehistochemistry staining. High performance liquid chromatography analyses of Kynurenine/Tryptophan ratio in sera suggested stabilization of IDO activity in 10/15 (67%) of patients, with long term stability observed in two clinical responding patients.
Conclusion: The vaccine is safe and well-tolerated with no grade 3/4 toxicity occurring. Long-lasting PR+SD were seen in 47% of the patients demonstrating a median OS of 2.1 years.

Antimetastatic activity of ganetespib: Preclinical studies and assessment of progressions due to new lesions in the GALAXY-1 NSCLC trial

D.A. Proia[1], M. Nagai[1], J.P. Jimenez[1], C. Zhang[1], J. Sang[1], W. Guo[1], M. Sequeira[1], D.L. Smith[1], S.R. Bahcall[1], V. Vukovic[1]. *[1]Synta Pharmaceuticals, Lexington MA, USA*

Background: Heat shock protein 90 (Hsp90) maintains the stability and activity of numerous signaling proteins involved in cancer metastasis. Interim results of the GALAXY-1 trial (NCT01348126) showed an improvement in overall survival in patients with non-small cell lung cancer (NSCLC) treated with an Hsp90 inhibitor, ganetespib (G), plus docetaxel (D) compared to D alone. We evaluated the antimetastatic activity of ganetespib in preclinical models, and compared radiological disease progression due to new lesion formation in the two arms of the GALAXY-1 trial.
Material and Methods: Preclinical effects of ganetespib were investigated on the: (1) migration of cancer cells via Boyden chamber assay, (2) expression of metastatic factors using protein array and gene profiling, (3) architecture of NSCLC xenografts by IHC, and (4) metastasis to the lung in tail vein and orthotopic breast cancer mouse models assessed by bioluminescence. GALAXY-1 is a Synta sponsored randomized, international open-label study of D with or without G in patients with advanced lung adenocarcinoma, one prior systemic therapy, and ECOG PS 0/1. D was given at 75 mg/m^2 on Day 1 of a three-week cycle in both arms. In the combination arm, G was given at 150 mg/m^2 on days 1 and 15. Development of new metastatic lesions was evaluated using serial computed tomography scans. Enrollment completed in November 2012.
Results: Ganetespib blocked the migration of cancer cells and induced the degradation of metastasis drivers including FAK, MET, HIF-1α, and VEGF; significantly reduced tumor angiogenesis and proliferation in NSCLC xenografts; significantly blocked (>8×, p < 0.005) the development of lung cancer metastases in a tail vein model; and significantly reduced multi-organ metastasis in an orthotopic model and blocked extramedullary hematopoiesis induced by the primary tumor. In GALAXY-1 trial patients, the population that exhibited the strongest survival improvement (diagnosis of advanced disease >6 months, N = 175), radiologic progressions due to new lesion formation were 19 (50%) vs. 5 (17%), for D vs. D+G, respectively, at time of abstract submission.
Conclusions: Ganetespib induces the degradation of key drivers of metastasis, resulting in reduced cell migration, tumor angiogenesis and new lesion formation in vivo. Preliminary data from the GALAXY-1 study support reduced frequency of progression due to new metastatic lesion formation in advanced NSCLC patients treated with ganetespib.

Role of circulating endothelial cells in the evaluation of response to chemotherapy in non-small cell lung cancer patients

M. Al Ammar[1], F. Najjar[2], M. Bashour[3], M. Salmoon[3], G. Almassarani[2], Z. Marrawi[3]. *[1]Albeirouni University Hospital, Thoracic Oncology, Damascus, Syria; [2]Atomic Energy Commission, Radiation Medicine, Damascus, Syria; [3]Albairouni University Hospital, Thoracic Oncology, Damascus, Syria*

Background: The majority of NSCLC cases diagnosed in advanced stages, which make the treatment non-curative with high recurrence rate. So it is very important to define a biological marker to aid us as a predictive factor.
When the tumour volume become at 1−2 mm, it begin the stimulation of endothelial cells by a multiple growth factors to generate a new vessels, so the circulating endothelial cells (CECs) increase in the blood stream theoretically. Many methods used to discover these cells as Immunomagnetic Separation (IMS) technique, four-color channels flow cytometry and PCR. The phenotype of these cells can be defined by the positivity of CD146 and CD31 while the CD45 is negative. Increased number of CECs was found in tumours. Many studies confirmed the normalisation of CECs levels in cancer patients after the treatment. Mancuso et al. confirmed the importance of quantify these cells to evaluate the response of chemotherapy in breast cancer.
Materials and Methods: Newly diagnosed patients with non surgical stages III or IV NSCLC have been included. Blood samples have been taken before starting any treatment then after 3 cycles of chemotherapy to evaluate the number of CECs by using IMS techniques with a Nageotte slide by a fluorescent microscope equipped with camera.
Results: 143 naive patients of have recruited. Before treatment the number of CECs was more than 80 cells/ml in 121 patients [45 pts. (81–150 c/ml), 32 pts. (151–300 c/ml) and 43 pts. More than 300 cells/ml] while, just 22 patients with less than 80 cells/ml. (79) patients were valuable after 3 cycles. The difference between CECs accounts before and after treatment was calculated as relative absolute quotient (ΔaCECs) has been considered significant when it was more than 0.1. Accordance between CECs and response to treatment was found in 61 patients (77%). The account of CECs was significantly decreased in 42 patients who showed Partial Response, while 11 patients with progression disease had significant increased number of CECs and 8 patients with Stable disease with no significant changes in CECs number. On the other hand, 18 patients (23%) didn't show accordance between the treatment response and CECs levels.
Conclusions: CECs seem to be a predictive factor in evaluating response to chemotherapy in NSCLC patients. However, further studies are necessary to evaluate the role of CECs levels in the recurrence prediction.

Prognostic impact of central nervous system (CNS) metastases associated with T790M status after acquired resistance to EGFR-TKI

A. Hata[1], N. Katakami[1], H. Yoshioka[2], S. Fujita[1], R. Kaji[1], K. Nagata[3], R. Tachikawa[3], K. Tomii[3], M. Iwasaku[2], T. Ishida[2]. *[1]Institute of Biomedical Research and Innovation, Division of Integrated Oncology, Kobe, Japan; [2]Kurashiki Central Hospital, Department of Respiratory Medicine, Kurashiki, Japan; [3]Kobe City Medical Center General Hospital, Department of Respiratory Medicine, Kobe, Japan*

Background: Patients with *EGFR*-mutant non-small cell lung cancer (NSCLC) can prolong survival with EGFR-TKI. However, approximately

one-third of patients seem to develop CNS metastases such as brain metastases (BM) and leptomeningeal metastases (LM) after initial response to EGFR-TKI. Generally, CNS metastases are associated with poor prognosis in NSCLC, but little is known regarding prognostic impact and T790M status of CNS metastases after acquired resistance to EGFR-TKI.
Patients and Methods: We retrospectively investigated the prognostic impact of CNS metastases in 80 *EGFR*-mutant NSCLC patients whose T790M status had been confirmed. CNS collapse was defined as patient death due to uncontrolled and progressive CNS metastases. Postprogression survival (PPS) after initial EGFR-TKI failure and T790M status were compared in patients with or without CNS collapse. Additionally, PPS and T790M status in BM and LM populations were analysed.
Results: Median PPS in 50 patients without CNS collapse (23.4 months) was significantly longer than in 30 with CNS collapse (16.7 months) ($p = 0.0017$). T790M was detected in 23 (46%) of 50 patients without CNS collapse, and in 4 (13%) of 30 with CNS collapse ($p = 0.0032$). Median PPS in 47 patients without LM (25.6 months) was significantly longer than in 33 with LM (11.4 months) ($p = 0.0007$). Median PPS was 11.2 months in 47 patients without BM, and 24.4 months in 33 with BM ($p = 0.1007$). T790M status was examined in brain tumoral tissues of 5 patients with BM and cerebrospinal fluid samples of 20 with LM. T790M was detected in 4 (80%) of 5 BM, and in 1 (5%) of 20 LM ($p = 0.0019$). In 11 patients, rebiopsies were performed both on the CNS and outside the CNS. Six patients had T790M outside the CNS, without T790M in the CNS, and 5 patients exhibited no T790M, either in or outside the CNS.
Conclusions: CNS collapse was associated with poor prognosis and T790M-negative status. BM and LM appear to have distinct tumour biologies and clinical courses. More effective therapeutic strategies, including high-dose EGFR-TKI for CNS metastases may contribute to better prognosis after acquired resistance to EGFR-TKI.

Impact of polymorphic variants on vascular endothelial growth factor gene and non-small-cell lung cancer prognosis: A prospective study in a South-European Population

R.A. De Mello[1], M. Ferreira[2], F. Soares-Pires[3], S. Costa[4], J. Cunha[5], P. Oliveira[6], V. Hespanhol[3], R.M. Reis[7]. *[1]CROP − Instituto Portugues Oncologia, Department of Medical Oncology, Porto, Portugal; [2]CROP – Instituto Portugues Oncologia, Life and Health Sciences Research Institute (ICVS) School of Health Sciences University of Minho Campus de Gualtar 4710–057 Braga/ 3B's − PT Government Associate Laboratory Braga/Guimarães Portugal, Braga, Portugal; [3]Centro Hospitalar de São João, Pneumology, Porto, Portugal; [4]Life and Health Sciences Research Institute (ICVS) School of Health Sciences University of Minho Campus de Gualtar 4710–057 Braga/ 3B's − PT Government Associate Laboratory Braga/Guimarães Portugal, Braga, Portugal; [5]Hospital São Marcos, Pneumology, Braga, Portugal; [6]ICBAS − Instituto de CIências Biomédicas Abel Salazar Univerrsity of Porto, Department of Populations Studies, Porto, Portugal; [7]Barretos Cancer Hospital Pio XII Foundation, Molecular Oncology, Barretos, Brazil*

Background: Vascular endothelial growth factor (VEGF) gene regulation showed in previous studies that may contribute to lung cancer carcinogenesis. Therefore, this study was performed in order to assess the role of some VEGF variants in non-small-cell lung cancer (NSCLC) prognosis.
Patients and Methods: Prospective study from February 2010 to April 2011. Median follow up was 12 months. NSCLC patient's genotyping was performed using the Sequenom® MassARRAY platform. Kaplan–Meier curve was used to assess overall survival (OS) and progression-free-survival (PFS). Statistical significance was considered for $p < 0.05$.
Results: 144 NSCLC patients were consecutively genotyped in order to assess 11 single nucleotides polymorphisms (SNP). Male were 78.5%. Median age was 61.5 (32−89) years old. Non-squamous cell histology was 77.1% and 91.4% were stages IIIB and IV. The following SNPs showed influence in OS: rs2010963 (*VEGF* + 405 G/C), $p = 0.042$, rs3025010 (*VEGF* intron 5 C/T), $p = 0.047$; and none SNPs showed influence in PFS.
Conclusions: This is the first large study in Portugal involving NSCLC patients and assessment of 11 SNPs on chromosome 6p12. Our study suggests that variants on chromosome 6p12 are potential prognostic biomarker in advanced NSCLC. In future, genome-identified patients may improve NSCLC screening strategies and also therapeutic management.

Metformin inhibits IL-6-induced epithelial–mesenchymal transition (EMT) and metastasis in non-small cell lung carcinoma

B. Zhu[1], Y. He[2], Z. Zhao[3]. *[1]Institute of Cancer, Xinqiao Hospital Third Military Mediacal University, Chongqing, China; [2]Department of Respiratory Diseases, Daping Hospital Third Military Medical University, Chongqing, China; [3]Institute of Cancer, Xinqiao Hospital Third Military Medical University, Chongqing, China*

Background: Metastasis is the major causes of death for non-small cell lung carcinoma (NSCLC). Epithelial–mesenchymal transition (EMT) plays an important role in tumour invasion and metastasis. However, the underlying mechanisms of EMT in NSCLC and how to inhibit this process remain to be explored.
Materials and Methods: Invasion assay, western blotting and immunofluorescence were used to determine EMT after treatment with different dose of recombinant human IL-6 (rh-IL-6) alone, or combined with metformin. IL-6, E-cadherin and vimentin mRNA expression in the tissues of NSCLC were determined by real-time PCR, and their correlations were assayed. We inoculated lung cancer cell line ectopically expressing IL-6 in nude mice to assess the effects of metformin on EMT and metastasis of NSCLC. IL-6/Stat3 signalling pathway in NSCLC cell lines treated with (rh-IL-6) alone, or combined with metformin, or in ectopically IL-6 expressing cell line were evaluated by Western blotting.
Results: We found that IL-6 could promote NSCLC cells invasion via EMT in a dose-dependent manner in vitro, which was further proved by the positively correlation between IL-6 and vimentin mRNA expression, and negatively correlation between IL-6 and E-cadherin mRNA expression in NSCLC tissues. IL-6-induced EMT in NSCLC cells could be inhibited by metformin in a dose-dependent manner in vitro, and metformin could significantly reduce the metastasis in tumour-bearing nude mice. Furthermore, we found that the blockade of STAT-3 phosphorylation might be the underlying mechanisms of metformin on IL-6-induced EMT and metastasis in NSCLC.
Conclusions: We show that enhanced IL-6 expression is a mechanism of EMT and metastasis in NSCLC. Pharmacologically, we found that metformin could inhibit IL-6 induced EMT process by blocking STAT-3 phosphorylation, suggesting the potential clinical use for metformin to reduce metastasis and reverse chemotherapy resistance.

3522 POSTER

The prognostic role of XRCC1, ERCC1, ERCC2 and, TP53 single nucleotide polymorphisms (SNPs) in metastatic non-small cell lung cancer (NSCLC)

M. Artac[1], C. Geredeli[1], S. Yildirim[2], A. Inal[3], T. Guler[1], C. Boruban[1], T. Akkuloglu[2], A. Isikdogan[3], H. Bozcuk[4], A. Demirkazik[5]. *[1]Necmettin Erbakan University Meram Medical Faculty, Department of Medical Oncology, Konya, Turkey; [2]Necmettin Erbakan University Meram Medical Faculty, Department of Genetics, Konya, Turkey; [3]Dicle University Medical Faculty, Department of Medical Oncology, Diyarbakir, Turkey; [4]Akdeniz University Medical Faculty, Department of Medical Oncology, Antalya, Turkey; [5]Ankara University Medical Faculty, Department of Medical Oncology, Ankara, Turkey*

Background: Identification of biomarkers that can be used for the prognostic evaluation of metastatic NSCLC patients is important. The aim of this study was to evaluate the potential prognostic value of XRCC1, ERCC1, ERCC2 and, TP53 SNPs in metastatic NSCLC patients.
Patients and Methods: In total 145 patients, who had been treated for metastatic NSCLC with platinum based chemotherapy regimens between 2000 and 2012, were included in this study. Analysis of SNPs from peripheral blood cells was performed by polymerase chain reaction. XRCC1 Arg399Gln, ERCC1 Asn118Asn, ERCC2 Lys751Gln and, TP53 Arg72Pro polymorphisms were evaluated in conjunction with clinical and pathological parameters and survival. Kaplan–Meier method and Cox regression analysis were used.
Results: The median age of patients was 60 years (range 34−79). The median progression free survival (PFS) and overall survival (OAS) was 5.1 months (95% CI, 4.3−5.8 months) and 30.9 months (95% CI, 28.2–33.6 months), respectively. In the univariate analysis for OAS performance score (HR, 5.25; 95% CI, 1.45–19.04; $p = 0.01$), ERCC1 genotype (HR, 0.26; 95% CI, 0.12–0.57; $p < 0.01$), and XRCC1 genotype (HR, 0.37; 95% CI, 0.16–0.83; $p = 0.01$) were significant parameters. In the multivariate analysis performance score (HR, 4.80; 95% CI, 1.22–18.87; $p = 0.02$), ERCC1 genotype (HR, 0.36; 95% CI, 0.14–0.92; $p = 0.03$), and XRCC1 genotype (HR, 0.37; 95% CI, 0.14–0.98; $p = 0.04$) retained their significance. The median OAS was 45.2 months (95% CI, 25.3–65.0 months) for the ERCC1 normal (CC) and heterozygote (CT) genotypes,

and 25.5 months (95% CI, 9.5–41.5 months) for the ERCC1 mutant (TT) genotype (P<0.01).
Conclusions: In addition to performance score, ERCC1 and XRCC1 genotypes independently predicted OAS in metastatic NSCLC patients. Future prospective studies are needed for the further evaluation of potential prognostic SNPs in metastatic NSCLC.
No conflict of interest.

3523 POSTER

Impact of EGFR status and treatment selection on survival of patients with stage IV non-small cell lung cancer (NSCLC) and liver metastases (LM)

E. Castanon[1], J. Fusco[1], E. Arevalo[1], O. Carranza[1], L. Zubiri[1], P. Martin[1], J.M. Lopez-Picazo[1], M.D. Lozano[2], I. Gil-Bazo[1]. *[1]University of Navarre, Oncology, Pamplona, Spain; [2]University of Navarre, Pathology Anatomy, Pamplona, Spain*

Background: LM appear in 20−30% of patients (pts) diagnosed with NSCLC. LM are considered a poor prognosis feature of NSCLC and they may also involve a more treatment-resistant condition. However, whether the clinical outcome of NSCLC pts with LM harboring molecular alterations in EGFR, KRAS and EML4-ALK genes is substantially different depending on their distinct status is still unknown.
Methods: A total of 268 consecutive stage IV NSCLC pts were included in the analysis. The tumor molecular analysis for EGFR, KRAS and EML4-ALK was available in 205 pts (76.5%), 136 pts (50.7%) and 31 pts (11.6%), respectively. An EGFR mutation was observed in 32 pts (15.6%), KRAS was mutated in 28 pts (20.6%) and an ALK gene rearrangement was observed in three pts (9.6%). We aimed to evaluate the incidence of LM in the last consecutive NSCLC pts treated in our institution and the differences in clinical outcome regarding the status of EGFR, KRAS and EML4-ALK.
Results: Most of the pts were men (71.3%). The most common histologies were adenocarcinoma (59.3%) and squamous-cell carcinoma (23.1%). Overall, 34% of the pts showed LM at any time of the disease course. Among the whole cohort, median overall survival (OS) for LM pts was 16 months vs 42 months for pts with metastases other than LM ($p < 0.001$). Among pts with LM and EGFR mutations, the one-year survival rate was 85.7% vs 54.3% for pts with LM and EGFR wild-type ($p = 0.03$). In the subgroup of pts carrying EGFR mutations and receiving tyrosine-kinase inhibitors (TKIs), the 18-month survival rate was 75% for pts showing liver involvement compared to 80% ($p = 0.44$) for those with no LM. In contrast, in the subgroup of pts with wild-type EGFR receiving standard chemotherapy, the 18-month survival rate was 32.4% for pts showing LM compared to 74.9% for those with no liver involvement ($p < 0.001$).
Conclusions: The presence of LM at any time of the disease curse negatively impacts on the clinical outcome of pts with NSCLC. However, the presence of EGFR activating mutations significantly improves the OS of pts with liver spread of NSCLC, reaching an OS similar to those pts with no LM. Pts with EGFR mutations and LM may light down the detrimental effect of LM on prognosis, when treated with EGFR TKIs.
No conflict of interest.

3524 POSTER

Biological mechanism of acquired resistance to the EGFR irreversible inhibitor BIBW-2992 in EGFR-mutant non small cell lung cancer cell line

F. Grossi[1], S. Coco[1], A. Truini[1], G. Barletta[1], M.G. Dal Bello[1], C. Genova[1], E. Rijavec[1], G. Savarino[1], C. Sini[1], A. Alama[1]. *[1]National Institute for Cancer Research, Lung Cancer Unit, Genova, Italy*

Background: Non-small cell lung cancer (NSCLC) accounts for over 85% of all lung cancers and about 20% of caucasian patients harbor somatic activating mutations in the tyrosine kinase (TK) domain of the epidermal growth factor receptor (*EGFR*) gene. Most of these patients initially respond to the EGFR-TK inhibitors but eventually relapse within one year for the development of acquired resistance due to a second-site mutation (T790M) in the *EGFR gene*. BIBW-2992, an irreversible *EGFR* inhibitor, has demonstrated activity in unselected patients with advanced NSCLC who have failed previous EGFR-TK inhibitor and in EGFR mutated patients. In this study, the H-1975 NSCLC cell line, harboring the T790M mutation, was used as *in vitro* model to generate BIBW-2992 resistant clones in order to investigate the molecular mechanisms of acquired resistance.
Material and Methods: A dose-escalation study was performed to establish an BIBW-2992 resistant (R) cell line. All exons of EGFR and KRAS as well as 10 known hot spots in some genes (5 involved in the EGFR signaling cascade and 5 frequently altered in NSCLC) were sequenced using Cancer panel® by Ion PGM™ Sequencer, while the EGF pathway was studied by qPCR using TaqMan® Array EGF Pathway (Life Technologies). Concomitantly, protein expression of some genes related to the EGF pathway such as EGFR, AKT and ERK (un-phosphorylated and phosphorylated) as well as MRAS and PI3KR1 were more deeply investigated by Western Blot.
Results: Although sequence analysis of R cell line did not reveal any novel mutations, gene expression profiles disclosed an increase of some members of the RAS family (MRAS, KRAS) and PIK3R1, up-regulation of SHC and down-regulation of EGF. R cells showed a higher signal of MRAS and an increase of ERK1/2 phosphorylation compared to the parental cells. This behavior also persisted in absence of EGF stimulation and in cultures maintained in afatinib-free medium for over 6 months.
Conclusions: The absence of novel mutations suggests the implication of other mechanisms implicated in BIBW-2992 resistance. In particular the marked increase of SHC3, an adaptor immediately downstream of EGFR, leads to hypothesize its involvement in the EGFR activation. Furthermore, the EGF down-modulation together with the MRAS increased expression and ERK1/2 phosphorylation, suggest that this cell line may acquire a different way to activate the EGFR pathway.

Racial differences in risk of hematologic malignancies

H. Tran[1], Y. Li[2], D. Baer[2], N. Udaltsova[3], G.D. Friedman[3], A.L. Klatsky[3]. *[1]Kaiser Permanente Oakland Medical Center, Internal Medicine, Oakland, USA; [2]Kaiser Permanente Oakland Medical Center, Hematology and Oncology, Oakland, USA; [3]Kaiser Permanente Oakland Medical Center, Division of Research, Oakland, USA*

Background: There are only sparse data from multiracial population studies detailing race/ethnicity disparities in risk of hematologic malignancies (HM).
Methods: We performed a cohort study in a multiracial population of 126,293 adults that supplied baseline information at health examinations in 1978−85. The largest race/ethnic groups by self-classification were 55% White, 27% Black, and 11% Asian. We used Cox proportional hazards models with seven covariates to study risk of HM, which occurred in 1,244 persons (801 White, 310 Black, and 78 Asian). We studied all HM and major HM sub-types yielding hazard ratios (HR) 95% confidence intervals (CI), and p values.
Results: (See Table). Compared to Whites as referent HRs were similar in Blacks but significantly lower in Asians. The similar risk of Black and White persons for all HM was consistent for men, women and several other strata. However, Blacks were at lower risk for non-Hodgkin's lymphoma (HR = 0.6 [0.5−0.7], $p < 0.0001$) and at higher risk for multiple myeloma (HR = 2.1 [1.6−2.9], $p < 0.0001$); these Black/White disparities were similar for men and for women. The lower Asian vs White risk for all HM was similar for men, women, and strata of age, interval to diagnosis, smoking, and birthplace. The lower risk of Asians was also similar in Asian ethnic subgroups. The HR for Asians was <1.0 for each HM subtype, with p values <0.05 for non-Hodgkin's lymphoma, lymphocytic leukemia, and myelocytic leukemia. Among covariate relationships to risk of any HM, male sex, increased age, and higher body mass index were associated with increased risk, alcohol drinking was associated with decreased risk, and birthplace (US vs non-US) was unassociated with risk.
Conclusions: Compared to whites: (1) Blacks are at lower risk of non-Hodgkin's lymphoma and higher risk of multiple myeloma, and (2) Asians are at lower risk of all HM and of several HM subtypes.
No conflict of interest.

Comparison*	HR (95% CI)	p-value

Study of the correlation of baseline biomarkers and DNA demethylation to clinical responses in a phase 1/2, randomized study of SGI-110, a novel subcutaneous (SC) hypomethylating agent (HMA), in the treatment of relapsed/refractory (r/r) acute myeloid leukemia (AML)

J. Issa[1], D. Rizzieri[2], L. Chen[3], G. Roboz[4], W. Stock[5], C. O'Connell[6], E. Griffiths[7], K. Yee[8], R. Tibes[9], H. Kantarjian[3]. [1]*Fels Institute Temple University, Philadelphia, USA;* [2]*Duke University Medical Center, Raleigh, USA;* [3]*University of Texas MD Anderson Cancer Center, Houston, USA;* [4]*Weill Cornell Medical College, New York, USA;* [5]*University of Chicago Medical Center, Chicago, USA;* [6]*USC Keck School of Medicine University of Southern California, Los Angeles, USA;* [7]*Roswell Park Cancer Institute, Buffalo, USA;* [8]*Princess Margaret Hospital, Toronto, Canada;* [9]*Mayo Clinic Arizona, Scottsdale, USA*

Background: SGI-110 is a novel SC HMA synthesized as a dinucleotide of decitabine (DAC) and deoxyguanosine that has longer plasma half-life and more extended DAC exposure than DAC IV infusion. The differentiated pharmacokinetic profile offers the potential of improved biological and clinical activity and safety over currently available HMAs. Little is known about the correlation between different epigenetic and other biological biomarkers with clinical response to HMA treatment.
Materials and Methods: We completed the Phase 1 dose-escalation stage of a Phase 1−2 study of SGI-110 in r/r AML (Study SGI-110−01). The association between clinical responses and several biomarkers were studied including: global DNA methylation as a surrogate marker using LINE1 assay; baseline miRNA29b involved in methylation control; functional activity of cytidine deaminase (CDA) responsible for deactivation of DAC; and levels of deoxycytidine kinase (dCK) responsible for activation of DAC.
Results: Sixty-three r/r AML patients (pts), median age 67 (29−86), ECOG PS 0/1/2 in 13/41/9 pts, median prior regimens 4 (1−9) were treated with SGI-110 doses from 3–125 mg/m^2 randomized to either QDx5 schedule (35 pts) or QWx3 (28 pts). Thirty-five (56%) had prior HMA and 26 (41%) had secondary AML. A maximum average LINE1 demethylation from baseline of −25.9% was achieved at the 60 mg/m^2 QDx5 dose level. Five complete responses (2 CR, 2CRi, 1 CRp) were achieved at doses $\geqslant$36 mg/m^2 with mean/median duration of response of 217+/114 days (range 42–534+). Two responders had received prior HMA treatment. Clinical responses correlated with post treatment LINE1 demethylation (no responses in 31 pts with demethylation <10%; 5 responses in 19 pts with $\geqslant$10% demethylation; $p < 0.01$). There was no association between baseline miRNA29b and response. CDA functional activity correlated with dose-adjusted DAC plasma exposures (correlation coefficient $p = 0.011$). The most common drug-related adverse events were local injection site reactions (21%) mostly Gr1, and myelosuppression.
Conclusions: In r/r AML pts, SGI-110 was well-tolerated and complete responses were observed in 5/19 pts (26%; 95% CI 19−51%) who achieved adequate DNA demethylation of $\geqslant$10% regardless of prior HMA treatment. CDA activity correlated with DAC exposure ($p = 0.011$). Baseline miRNA29b did not seem to influence clinical responses. The study is supported by Astex Pharmaceuticals, Inc. and Stand Up to Cancer (ID: NCT01261312).

Snail expression confers drug resistance to Abl kinase inhibitors and collateral sensitivity to gemcitabine in Ph-positive leukemia cells

J. Mahajna[1], H. Khamaisie[2], N. Ruimi[2], S. Roitman[2], A.A. Mian[3], M. Ruthardt[3]. [1]*Migal and Telhai College, Cancer Drug Discovery Program and Nutritional Sciences Department, Kiryat Shmona, Israel;* [2]*Migal, Cancer Drug Discovery Program, Kiryat Shmona, Israel;* [3]*J.W. Goethe University, Laboratory for Tumor Stem Cell Biology Department of Hematology, Frankfurt, Germany*

Background: Chronic myeloid leukemia (CML) is a clonal myeloproliferative disorder of the hematopoietic stem cells depends on the Bcr-Abl fusion protein, which displays a constitutive tyrosine kinase activity. Imatinib, a selective inhibitor of Abl kinase was approved for the treatment of chronic phase CML (CP). Imatinib clinical efficacy continuously decreases with the advancement of the disease. Blast crisis (BC) CML or Ph+ ALL patients benefit from the treatment with tyrosine kinase inhibitors only temporarily or not at all. Acquired resistance in the CP is mostly due to the acquisition of point mutations within the Abl kinase domain of Bcr-Abl. In addition, drug resistance also encounter during BC which mainly mediated by Bcr-Abl independent alterations. Second generation inhibitors of Abl kinase activity such as Nilotinib and Dasatinib and recently Ponatinib reported to overcome Bcr-Abl acquired resistance. However, all Abl kinase inhibitors failed to overcome drug resistance during BC.
Methods: In an attempt to develop a model system that resemble CML blast crisis, we introduced EMT modulators, Snail and Twist1, into Ph+ leukemia cells. The characteristics, proliferation, clonigenicity, surface markers and sensitivity to relevant chemotherapeutics drugs were evaluated for Snail and Twist1 overexpressed cells in comparison to parental cells.
Results: Overexpression of Snail, but not Twist1, confers drug resistance to Abl kinase inhibitors (AKIs) up to 600 fold in reduced sensitivity of K562/Snail to Dasatinib when compared to parental cells. Moreover, AKIs fail to inhibit Bcr-Abl auto-phosphorylation as well as other down-stream regulators such as STAT5a. Interestingly, over-expression of Snail in Ph+ leukemia cells confers sensitivity to the nucleoside analog, gemcitabine.
Conclusions: Our data showed that overexpression of snail confer characteristics that resemble blast crisis including drug resistance to AKIs. Experiments are underway to elucidate the mechanisms of AKIs drug resistance and collateral sensitivity to gemcitabine.

Whole exome massive parallel sequencing of splenic marginal zone lymphoma reveals novel somatic mutations in NOTCH2 and SMYD1 genes

J. Peveling-Oberhag[1], F. Wolters[2], L. Sellmann[3], M. Lucioni[4], M. Schubach[5], M. Paulli[4], R. Küppers[6], S. Biskup[5], S. Zeuzem[1], M.L. Hansmann[2]. [1]*J.W. Goethe University, Medicine 1, Frankfurt/Main, Germany;* [2]*J.W. Goethe University, Senckenberg Institute of Pathology, Frankfurt/Main, Germany;* [3]*University of Duisburg-Essen Medical School, Department of Hematology Medical Faculty, Essen, Germany;* [4]*University of Pavia, Department of Human Pathology Fondazione IRCCS Policlinico San Matteo, Pavia, Italy;* [5]*CeGaT GmbH, Tübingen, Germany;* [6]*University of Duisburg-Essen Medical School, Institute of Cell Biology (Cancer Research), Essen, Germany*

Background: Splenic marginal zone lymphoma (SMZL) is an indolent B-cell non-Hodgkin lymphoma and represents the most common primary malignancy of the spleen. Its precise molecular pathogenesis is still unknown and consecutively specific molecular markers for diagnosis or as possible departure point for causal therapies are lacking.
Material and Methods: We performed massive parallel whole exome sequencing using Agilent SureSelect Target Enrichment and SOLid4 platform (Life Technologies) on primary tissue samples of two cases of SMZL. Fresh frozen tumor tissue was extracted by microdissection and CD3 MACS-sorted tissue of the same patient was used as non-tumorous control. After alignment and global filtering using a sequence quality threshold, the generated sequence data was screened for non-synonymous base exchanges only present in the tumor sample. Identified single nucleotide polymorphisms (SNPs) were consecutively validated by Pyrosequencing and Sanger sequencing in an independent cohort. As all detected base exchanges were heterozygos, SNP-Chip microarray analysis (Affymetrix) was performed to identify corresponding major deletions and loss of heterozygosity.
Results: The whole human exome (50Mb/sample), including miRNAs and ncRNAs, was sequenced for two SMZL samples and their respective non-tumorous tissue. Overall, 223 high fidelity SNPs (non-synonymous, high qualitiy score, 20x minimum coverage) were identified. Out of these, 53 base changes have not been described as polymorphisms before. Four high quality SNPs (SNP-call >40 % in tumor tissue and <10% in corresponding non-tumor tissue) in 4 different genes (NOTCH2, SMYD1, MYD88 and SCRN2) were successfully validated. While SCRN2 has been previously described as polymorphism, it has a global minor allele frequency below 1%. MYD88 L265P has been observed in SMZL before, while NOTCH2 Q2364X and SMYD1 C279F are newly identified mutations. We used an independent cohort of 20 SMZL samples to analyze whether the identified mutations were recurrent. While MYD88 L265P missense mutation was found present in three additional samples (12.5%), the other SNPs showed no recurrence in the validation cohort.
Conclusions: Whole exome sequencing of two cases of SMZL revealed three somatic mutations. The mutations in NOTCH2 and SMYD1 were not described before, whereas the recurrent MYD88 mutation has already been described in SMZL (frequency 10−13%). The discovered NOTCH2 nonsense-mutation is located in the PEST domain, where mutations in SMZL have been described previously (20−25% of SMZL). NOTCH2 and MYD88 mutation seem to be the most common mutation detectable in SMZL, but their rather low frequency may likely not enable reliable diagnostic application.

Involved-field three-dimensional conformal radiotherapy vs helical tomotherapy for female patients with early-stage mediastinal Hodgkin lymphoma: A dosimetric comparative study

V. Pernin[1], A. Zygogianni[1], G. Capezzali[1], D. Peurien[1], M. Amessis[1], S. Zefkili[1], Y. Kirova[1]. [1]*Institut Curie, Radiotherapy, Paris Cedex 05, France*

Background: Chemotherapy plus involved-field (IF) three-dimensional conformal radiotherapy (3D-CRT) is the standard treatment for early stage Hodgkin's lymphoma (HL). Reductions in organ at risk (OAR) doses have been shown with intensity modulation radiotherapy. Nevertheless the role of IF helical tomotherapy (HT) in female patients treated for mediastinal HL remains unclear and the present dosimetric study was performed to compare IF HT to IF 3D-CRT.
Material and Methods: Ten young female patients affected with mediastinal stage II HL and treated with IF 3D-CRT after chemotherapy were selected from our database. For each patient, 3D-CRT and HT plans were designed to deliver 30 Gy to the target volume with a complement of 6 Gy in areas suspect of not sterilization on CT-scan simulation. HT planning solutions were optimized by inverse planning with specific dose-volume constraints on target volume and OAR. Dose-volume histograms for target volume and OAR were calculated and then compared between 3D-CRT and HT by a statistical analysis (Wilcoxon's Test).
Results: Conformity index and homogeneity index were not statistically different between HT and 3D-CRT. Mean doses to the breasts were increased with HT compared to 3D-CRT (right breast: 2.83 vs 1.45, $p = 0.006$; left breast: 3.47 vs 1.55, $p = 0.005$) whereas no difference in mean doses appeared for heart, coronary arteries, lungs, thyroid and normal tissues. Maximal doses were reduced with HT for breasts (right breast: 20.83 vs. 30.85, $p = 0.004$; left breast: 25.18 vs 31.53, $p = 0.002$) and spinal cord (20.72 vs 33, $p = 0.002$). Volume exposed to doses $\geqslant$20 Gy was significantly smaller with HT whereas volume exposed to doses $\leqslant$4 Gy was smaller with 3D-CRT for right breast, left breast, lungs, heart and normal tissues. No statistically significant decrease of mean and maximum doses was recorded for origins of coronary arteries with HT when compared to 3D-CRT. Pronounced benefits of HT in terms of heart sparing were observed for patients with lymph nodes anterior to the heart.
Conclusions: Compared to 3D-CRT, HT allowed greater sparing of breasts, heart and lungs from high doses. Nevertheless, increasing low doses especially in the breasts with HT must be taken into account concerning the risk of second malignancies for young women with HL. HT may be considered when the anterior mediastinum is invaded in order to protect large volume of heart from high doses and then decrease the risk of late complications.

Survival analysis of follicular lymphoma in a national registry with over a thousand patients: Impact by treatment groups

A. López-González[1], C. Quero[1], M.A. Cruz[1], P. Sabin[1], D. Aguiar[1], J. Gómez Codina[1], M. Llanos[1], D. Rodríguez[1], J. Lavernia[1], M. Provencio[1]. [1]*On behalf of the GOTEL (Spanish Lymphoma Oncology Group), Medical Oncology, Hospital Universitario Puerta de Hierro, Spain*

Introduction: Chemotherapy regimens containing anthracyclines and rituximab in the treatment of lymphomas CD-20 positive have significantly increased the survival of these patients. The therapeutic approach 'watch and wait' should be a strategy to take greater account in asymptomatic patients with low tumor burden, especially in elderly patients and/or comorbidities.
Material and Methods: 1178 patients diagnosed with follicular lymphoma, between 1986 and 2012, and treated at the Oncology Department of 17 Spanish hospitals were reviewed. A survival analysis were made with the generalized Wilcoxon test.
Results: A total of 1178 patients were analyzed, of whom 51% were women. The mean age at diagnosis was 57.8 years. 23% of the patients received chemotherapy without rituximab (14% based on anthracycline and 9% non-anthracycline) and 69% of the patients received chemotherapy associated with rituximab (59% with anthracycline-based chemotherapy and 10% without anthracyclines). 4.1% of patients received rituximab in monotherapy. The median overall survival was 246 months (95% CI 228 months − 264 months). There are statistically significant differences between the different chemotherapy regimens used, with a longer overall survival in patients receiving anthracyclines (252.15 months vs. 172.38 months, $p < 0.001$, HR 0.54). There is also a longer overall survival in patients treated with rituximab ($p = 0.008$). The 25.8% of patients who received radiation therapy had a significantly longer overall survival ($p < 0.001$, HR 0.51). In only 2.2% of the patients observation at diagnosis was the first approach.
Conclusion: The median overall survival of patients diagnosed of follicular lymphoma is over 20 years in our series. This increase in survival is due to the use of anthracyclines, rituximab and radiotherapy.

Prior autoimmune disease and risk of monoclonal gammopathy of undetermined significance (MGUS) and multiple myeloma: A systematic review and meta-analysis of the literature

C.M. McShane[1], L.J. Murray[1], O. Landgren[2], M.A. O'Rorke[1], N. Korde[2], A.T. Kunzmann[1], M.R. Ismail[3], L.A. Anderson[1]. [1]*Queens University Belfast, Centre for Public Health, Belfast N. Ireland, United Kingdom;* [2]*National Cancer Institute, Multiple Myeloma Section, Bethesda Maryland, USA;* [3]*University of Malaya, Department of Social and Preventive Medicine, Kuala Lumpur Malaysia, United Kingdom*

Background: Chronic antigenic stimulation has been postulated as a potential trigger to the onset of plasma cell disorders monoclonal gammopathy of undetermined significance (MGUS) and multiple myeloma (MM). Several observational studies have investigated the role of antecedent autoimmune disease and risk of MGUS and MM, however findings have been largely inconsistent and hindered by the rarity and heterogeneity of the autoimmune disorders investigated. A systematic review of the literature was therefore undertaken to evaluate the strength of the evidence linking prior autoimmune disease and subsequent risk of MGUS and MM.
Materials and Methods: A broad search strategy using key terms for MGUS, MM and 50 autoimmune diseases was used to search four electronic databases (PubMed, Medline, Embase and Web of Science) from inception through November 2011. To account for the expected heterogeneity between and within the included observational studies, a random effects model was used to generate pooled risk estimates and associated 95% confidence intervals.
Results: A total of 53 studies met the inclusion criteria, of which 36 were suitably comparable to perform a meta-analysis. 'Any autoimmune disorder' was significantly associated with an increased risk of both MGUS [n = 764 patients; pooled relative risk (RR) 1.43, 95% confidence interval (CI) 1.15–1.79] and MM (n = 2,811 patients; RR 1.11, 95% CI 1.04–1.18). This risk was disease dependent with only pernicious anaemia showing an increased risk of both MGUS (RR 1.67, 95% CI 1.21–2.31) and MM (RR 1.39, 95% CI 1.10–1.75). Other autoimmune conditions including autoimmune haemolytic anaemia, ulcerative colitis, polymyositis/dermatomyositis and ankylosing spondylitis were associated with an increased risk of MGUS or MM but not both.
Conclusions: Our findings, which are based on the largest number of autoimmune disorders and MGUS/MM patients reported to date, suggest that autoimmune diseases and/or their treatment may be important in the aetiology of MGUS/MM. The strong associations observed for pernicious anaemia with both MGUS and MM suggests that anaemia, or more precisely its underlying mechanism may be related to the onset of MGUS/MM and that clinically anaemia may be an important biomarker of disease onset.

The association of the VEGFR2 604T/C polymorphism with aggressiveness of multiple myeloma

A. Brito[1], M.T. Delamain[2], L.L. Aguiar[1], C. Oliveira[1], C.B.M. Oliveira[1], C.A. De Souza[2], G.J. Lourenço[1], J. Vassallo[3], C.S.P. Lima[1]. [1]*Laboratory of Cancer Genetic, Department of Internal Medicine Faculty of Medical Sciences University of Campinas Campinas São Paulo Brazil, Campinas SP, Brazil;* [2]*Hematology and Hemotherapy Center University of Campinas Campinas Brazil, Department of Internal Medicine Faculty of Medical Sciences University of Campinas Campinas São Paulo Brazil, Campinas SP, Brazil;* [3]*Department of Pathology Faculty of Medical Sciences University of Campinas Campinas São Paulo Brazil, Department of Internal Medicine Faculty of Medical Sciences University of Campinas Campinas São Paulo Brazil, Campinas SP, Brazil*

Background: Increased angiogenesis (AG) has been demonstrated in the bone marrow microenvironment in multiple myeloma (MM), suggesting its potential pathophysiologic role in the disease. The most important mediators of AG during tumor development are the vascular endothelial

growth factor (VEGF) and the vascular endothelial growth factor receptor 2 (VEGFR2). Both factors are encoded by polymorphic genes and, therefore, their levels or functions are variable in healthy humans. It is known that allele C of the *VEGF* 2578C/A (rs699947) and allele G of the 1154G/A (rs1570360) are related to higher concentration of serum VEGF compared to the remaining alleles. It is also established that the G allele of the *VEGFR2* 1192G/A (rs2305948) has higher binding efficiency and the allele C of the *VEGFR2* 604T/C (rs2071559) has lower transcription activity. Since the roles of these genetic polymorphisms in the risk and clinical manifestation of MM are still unknown, these were the aims of the present study.
Material and Methods: Genomic DNA from peripheral blood of 157 consecutive MM patients and 157 age and race-matched controls was analyzed by real-time polymerase chain reaction for genotyping of the above mentioned polymorphisms. The differences between groups were analyzed by the logistic regression model. Power analysis (PA) was used to verify the effect of sample size on the results obtained in the study.
Results: Similar frequencies of the *VEGF* 2578C/A, *VEGF* 1154G/A, *VEGFR2* 1192G/A, and *VEGFR2* 604T/C, isolated or combined, were seen in MM patients and controls. Individuals with the distinct genotypes of the genes were under similar risks for the disease. In contrast, excesses of the *VEGF* 2578CC+CA (86.1% *versus* 71.8%, $P = 0.02$; PA: 59.3%), *VEGF* 2578CC plus *VEGF* 1154GG (46.0% *versus* 28.6, $P = 0.03$; PA:52.4%), *VEGF* 2578CC plus *VEGFR2* 1192GG (67.7% *versus* 43.3, $P = 0.04$; PA: 52.2%), and *VEGF* 2578CC+CA plus *VEGFR2* 604TT+TC (94.2% *versus* 81.1%, $P = 0.04$; PA: 53.1%) genotypes were seen in male patients compared to female patients. Additionally, the frequency of the *VEGFR2* 604TT genotype was higher in patients with tumors of II and III Durie & Salmon stages than in those with tumors of stage I (29.1% *versus* 10.0%, $P = 0.04$; PA: 60.7%).
Conclusions: The data present, for the first time, preliminary evidence that inherited abnormalities of *VEGF* and *VEGFR2* pathways alter the distribution of MM in distinct genders and the aggressiveness of the disease.
No conflict of interest.

3608 POSTER

Multiple myeloma − toxicity studies of innovative substances

N. Steiner[1], J. Kern[2], G. Untergasser[2], W. Willenbacher[1], G. Gastl[1], E. Gunsilius[1]. [1]*Innsbruck Medical University, Internal Medicine V, Innsbruck, Austria;* [2]*Innsbruck Medical University, Laboratory of Tumor Biology and Angiogenesis, Innsbruck, Austria*

Objective: The prognosis of patients with multiple myeloma (MM) has substantially improved during the last years- due to implementation of novel drugs into the treatment. However, MM is still incurable and novel treatment strategies are needed. Here, we tested novel substances for their anti-myeloma activities.
Methods: 0.1–100[nM] of 11 innovative compounds with unknown activity against MM and bortezomib as a reference substance were applied to the MM cell lines OPM-2, NCI, and U-266 in vitro. Apoptosis was determined by FACS using annexin V FITC/ 7AAD-staining and expressed as IC50. Different adherent cells (foreskin fibroblasts, prostatic adenocarcinoma cells − PC3, colorectal adenocarcinoma cells − HRT, human umbilical vein endothelial cells − HUVEC and breast adenocarcinoma cells − MDA) served as controls.
Results: Viability of untreated cells was >90%. 6/11 compounds with anti-myeloma effects were identified (% apoptosis, IC50).

Table: Concentrations [nM] killing 50% of cells within 24 h of incubation

Compound Nº	1	2	6	7	8	11	Bortezomib
OPM-2	6.8	35.8	2.4	6.2	3.5	40.4	11.8
NCI	5.5	68.1	5.9	1.6	5.0	14.7	5.5
U-266	5.8	31.6	5.9	0.6	4.3	4.4	5.3
Fibroblasts/PC3	>100	>100	>100	>100	>100	>100	>100
HRT	4.0	>100	7.9	4.1	9.6	>100	>100
HUVEC	3.4	26.6	2.4	0.9	3.9	3.9	3.4
MDA	3.3	7.4	4.1	1.6	6.5	9.6	7.4

IC50 was <10[nM] on 4/6 effective substances, suggesting activity similar to bortezomib. Compounds 1, 2, 6, 8 showed relatively uniform activity in all three cell lines, compound 7 and 11 were most active in U-266 cells. Fibroblasts and PC3 are resistant to all compounds, whereas- HUVECs and MDA were similar sensitive to MM cell lines. Moreover, compounds 1, 2, 6, 7, 8 and 11 showed also activity against purified myeloma cells from 3 patients.
Conclusions: We identified new compounds with potential anti-myeloma effects and putative antiangiogenic activities in vitro. Currently, a model is being established to study the antiangiogenic and anti-myeloma effect of these new compounds in vivo.
Acknowledgements: Support for this study was provided by EU Research Project FP7 (OPTATIO) with its clinical, scientific and industry partners and the Innsbruck Medical University (IMU).

3609 POSTER

Expression and activity analysis of mammalian target of rapamycin (mTOR) complexes in human lymphoma cells

N. Nagy[1], A. Márk[1], S. Paku[1], Z.S. Németh[1], N. Buthi[1], L. Kopper[1], A. Sebestyén[2]. [1]*Semmelweis University, 1st Department of Pathology and Experimental Cancer Research, Budapest, Hungary;* [2]*Hungarian Academy of Sciences and Semmelweis University, Tumor Progression Research Group, Budapest, Hungary*

Background: The PI3K/Akt/mTOR pathway plays key roles in the translation of proteins regulating cell survival, proliferation and metabolism; it can be an ideal target of cancer therapy. The mammalian target of rapamycin (mTOR) is a serine-threonine kinase; its activity and sensitivity to mTOR inhibitors (mTORI) are variable in different tumors. This aspect is poorly characterized in lymphomas. mTOR can be localized in two different complexes referred to as mTORC1 and mTORC2. Results of clinical trials with rapalogs (C1 inhibitors) suggest the importance of using new generation dual inhibitors. We examined the effects of different mTORIs and the activity of C1 and C2 complexes in several lymphoma cell lines.
Material and Methods: We investigated the activity and expression of mTOR complexes in Hodgkin (KMH2, L1236 and DEV), Burkitt (HT58, BL41) and diffuse large B-cell (BHD1) lymphoma cell lines and in human lymphoma biopsies by immunocytochemistry, immunohistochemistry (IHC) and Western-blotting (mTOR, p-mTOR, Rictor, Raptor p-p70S6K, p-S6, p-4EBP1). The amount and the activity of C1 and C2 complexes in cell lines were characterized by the Duolink® technique. Cells were treated with rapamycin, NVP-BEZ235 and PP-242 inhibitors in vitro. The biological effects (proliferation, apoptosis) were investigated by AlamarBlue® assay and flow cytometry analysis.
Results: Increased mTOR activity was observed in all lymphoma cell lines and differences were found in the amount and activity of the two complexes (C1 and C2). mTORI treatment inhibited proliferation in all cells; however, in vitro apoptosis induction was detected only in Hodgkin cell lines after long-term treatment. Dual inhibitors were more effective than rapalogs in cells with mTORC2 overexpression. Our IHC study on different human lymphomas supports that mTORC2 related high mTOR activity is a sign of potentially worse prognosis.
Conclusions: Increased mTOR activity in different lymphomas draws attention to the potential therapeutic use of mTOR inhibitors in the future. According to our results, analysis of the expression and activity of proteins related to different mTOR complexes should have great importance before clinical trials with mTORIs are initiated in lymphomas.
Supported by OTKA81624 and OTKA84262.

Exposure to common community acquired infections associated with increased risk of multiple myeloma

C.M. McShane[1], L.J. Murray[1], O. Landgren[2], E.A. Engels[3], L.A. Anderson[1]. [1]*Queens University Belfast, Centre for Public Health, Belfast N. Ireland, United Kingdom;* [2]*National Cancer Institute, Multiple Myeloma Section, Bethesda Maryland, USA;* [3]*National Cancer Institute, Division of Cancer Epidemiology and Genetics, Bethesda Maryland, USA*

Background: The role of infectious pathogens in the development of cancer has been well documented for several sites, including a number of haematological malignancies. However, the impact of such exposures on the subsequent development of multiple myeloma (MM) is less clear.
Materials and Methods: The United States of America, Surveillance Epidemiology and End Results -Medicare dataset was utilised to investigate the impact of fourteen antecedent common community acquired infections and subsequent risk of MM. Logistic regression was used to derive odds ratios (ORs) and associated 95% confidence intervals (CI) adjusted for sex, age and calendar year of selection. The 13 month period prior to diagnosis/ selection was excluded. Crude adjustment for multiple comparisons was undertaken using Bonferonni correction.
Results: In total, 15, 318 MM cases and 200,000 population based controls were identified. An increased risk of MM (ranging from 5−39%) was observed for eight of the fourteen investigated infections. Following

Bonferonni correction, strong associations were observed for a number of respiratory tract infections including bronchitis (adjusted OR 1.14, 95% CI 1.09–1.18), influenza (OR 1.18, 95% CI 1.11–1.25), sinusitis (OR 1.15, 95% CI 1.10–1.20) pneumonia (OR 1.27, 95% CI 1.21–1.33), skin infection herpes zoster (OR 1.39, 95% CI 1.29–1.49) and urinary tract infection cystitis (OR 1.09, 95% CI 1.05–1.14). With the exception of influenza, each of the aforementioned infections remained positively associated with MM following the exclusion of more than 6 years of claims data prior to diagnosis/selection.
Conclusions: The findings may support a role for infections in the malignant transformation to MM. Alternatively, the observed associations may be a manifestation of an underlying immune disturbance which is present several years prior to MM diagnosis, and thereby part of the natural history of disease progression from late stage monoclonal gammopathy of undetermined significance (MGUS) to MM.
No conflict of interest.

3611 POSTER

Common community acquired infections and risk of lymphoplasmacytic lymphoma/Waldenström's macroglobulinemia: A population based study

C.M. McShane[1], L.J. Murray[1], E.A. Engels[2], L.A. Anderson[1]. *[1]Queens University Belfast, Centre for Public Health, Belfast N. Ireland, United Kingdom; [2]National Cancer Institute, Division of Cancer Epidemiology and Genetics, Bethesda Maryland, USA*

Background: The aetiology of lymphoplasmacytic lymphoma/Waldenström's Macroglobulinemia (LPL/WM) remains largely to be elucidated. Emerging evidence supports the role for repeated antigenic stimulation in the development of LPL/WM. Owing to the rarity of LPL/WM, few population-based studies have been conducted investigating exposure to infections and subsequent risk of malignant transformation to LPL/WM.
Materials and Methods: Using the population-based United States of America, Surveillance, Epidemiology and End Results-Medicare database we investigated exposure to fourteen antecedent common community acquired infections and subsequent risk of LPL/WM in 693 LPL/WM cases and 200,000 controls. Logistic regression was used to derive odds ratios (ORs) and associated 95% confidence intervals. All analyses were adjusted for age, gender and calendar year of selection.
Results: Of the fourteen investigated infections, five were significantly associated with an increased risk (ranging from 33−56%) of LPL/WM. Strong associations were observed for respiratory tract infections, bronchitis (OR 1.56, 95% CI 1.32–1.84)), pharyngitis (OR 1.43, 95% CI 1.17–1.76), pneumonia (OR 1.42, 95% CI 1.18–1.72) and sinusitis (OR 1.33, 95% CI 1.12–1.60) and skin infection, herpes zoster (OR 1.51, 95% CI 1.12–2.04). For each of these infections, findings remained significantly elevated following the exclusion of more than six years of Medicare claims data prior to diagnosis/selection.
Conclusions: The findings suggest that exposure to infectious antigens may play a role in the development of LPL/WM. Alternatively, the observed associations may reflect an underlying immune disturbance which is present many years prior to diagnosis and thereby part of the natural history of disease progression.
No conflict of interest.

3612 POSTER

Novel molecular markers for acute myeloid leukaemia disease activity

E. Sittig[1], O. Kauko[2], U. Salmenniemi[3], A. Laiho[1], V. Kairisto[4], J. Johansson[3], M. Itälä-Remes[3], J. Westermarck[5]. *[1]University of Turku and Åbo Akademi University, Turku Centre for Biotechnology, Turku, Finland; [2]University of Turku and Åbo Akademi University, Turku Centre for Biotechnology and Department of Pathology and Turku Doctoral Programme of Biomedical Sciences, Turku, Finland; [3]Turku University Hospital, Department of Medicine, Turku, Finland; [4]Turku University Hospital, Central Laboratory, Turku, Finland; [5]University of Turku and Åbo Akademi University, Turku Centre for Biotechnology and Department of Pathology, Turku, Finland*

Background: Acute myeloid leukaemia (AML) is the most common acute leukemia affecting adults. AML is a disease with marked heterogeneity in both response to therapy and survival. Diagnostic markers used today are poor in explaining the high prevalence of relapses, thus new molecular markers for AML prognosis and minimal residual disease monitoring are needed.
Protein phosphatase 2A (PP2A) is an essential human tumor suppressor whose inhibition has been shown to be a recurrent event in multiple types of malignancies including AML. Although mutations in PP2A have been reported in human cancers, observed mutation frequency is low in general and cannot thus be enough to account for overall inhibition of PP2A in human cancers. Instead, PP2A's growth suppressor activity has shown to be inhibited in many cancers by the endogenous PP2A inhibitor proteins. Goal of this study was to investigate the role of PP2A and its inhibitory proteins in AML and to identify novel molecular markers of AML activity.
Material and Methods: Patient samples consisted of 93 patients aged 18−65 diagnosed with *de novo* or secondary AML at Turku University Central Hospital. Sample collection included diagnosis phase, two remission phase and possible relapse phase samples.
In order to characterize gene expression changes, fusion gene transcripts and splice variants that might predict disease recurrence in AML, RNAseq was conducted for selected core binding factor (CBF) subtype samples. Quantitative real time PCR was used to study prognostic role and gene expression differences of specific genes, including CIP2A, SET, EVI1, WT1, ABL, TIPRL, PME1 and ARPP19, on the whole sample collection.
Results: EVI1 and WT1 gene expression levels within the sample collection could be divided into subgroups as reposted previously for the prognostic role of these genes in AML. As a contrary to published data, CIP2A gene expression levels did not correlate with disease activity. The potential role of other PP2A inhibitory proteins and results from RNAseq are still under investigation.
Conclusions: It is expected that results of this study will reveal novel markers for disease activity and patient stratification in AML.
No conflict of interest.

3613 POSTER

Ponatinib regulates major signaling pathways in imatinib-resistant chronic myeloid leukemia cells

C. Biray Avci[1], C. Kayabasi[1], S. Yilmaz Susluer[1], T. Balci[1], G. Saydam[2], Y. Baran[3], C. Gunduz[1]. *[1]Ege University School of Medicine, Medical Biology, Izmir, Turkey; [2]Ege University School of Medicine, Hematology, Izmir, Turkey; [3]Izmir Institute of Technology, Molecular Biology and Genetics, Izmir, Turkey*

Background: BCR-ABL fusion protein, responsible for developing of leukemic phenotype as a result of (9;22) translocation, is occured in more than 90% of Chronic Myeloid Leukemia (CML) cases. Third generation tyrosine kinase inhibitor ponatinib inhibits both wild type and T315I mutant ABL1 autophosphorylation. The aim of the study was to evaluate effect of ponatinib on imatinib resistant chronic myeloid leukemia cells according to the expression of genes including several signal transduction pathways such as; NF-κB, MAP/MAPK, PI3K-Akt-mTOR.
Material and Methods: An amount of 3μM imatinib resistant cells were generated by our group and named as K562/ima3 cells. Cytotoxic effect of ponatinib in K562 and K562/ima3 cell lines were assessed by WST-1 assay. Total RNA was isolated from cultured cells treated with ponatinib in IC50 doses for 48 hours and control cells. Reverse transcription procedure was performed for cDNA synthesis by using Transcriptor First Strand cDNA Synthesis Kit according to the manufacturers' instructions. For this study, custom design 96-well plates consist of 43 genes which are important in BCR-ABL signaling pathway, 2 housekeeping genes (GAPDH, ACTB), 1 Human Genomic DNA contamination, 1 Reverse Transcription Control, 1 positive PCR control was used for gene expression analysis by using LightCycler 480 real-time PCR. Cytotoxicity analyses were evaluated by GraphPad Prism v5.0 Software. ΔΔCT method was used for data analysis. Statistical analysis was performed by web based RT^2 Profiler PCR Array Data Analysis. The expressions of 43 genes playing roles in NF-κB and MAP/MAPK, PI3K-Akt-mTOR signaling pathways were studied by real time online RT-PCR.
Results: IC_{50} doses of ponatinib were calculated as 0.24 nM and 9.87 nM, in K562 and K562/ima3 cell lines, respectively. At 48th hour, expression of genes that are components of several signaling pathways necessary for leukemia were studied by real time online RT-PCR and down regulation of MAP3K7, MAPK8, IKBKB, mTOR, MAP3K2, IRF7, REL, ERN1 genes were significant in ponatinib treated K562/ima3 cells according to control cells. Fold changes of the above mentioned genes were; 7.90, 6.81, 6.48, 6.20, 6.03, 4.07, 3.72, 2.83, respectively.
Conclusion: Our data suggest that, ponatinib is an attractive target inhibiting cell proliferation via deregulating expressions of genes which are the components of BCR-ABL signaling pathway in imatinib resistant chronic myeloid cell lines.

Recent experience of localized radiotherapy for low grade orbital lymphoma at a tertiary referral centre

H. Kuhan[1], D. Woolf[1], O. Shoffren[1], E. Akinnawo[1], H. Boyce[1], X. Tai[1], E. Perry[1], J. Uddin[2], G. Rose[2], N. Plowman[1]. [1]*Barts Health, Clinical Oncology, London, United Kingdom;* [2]*Moorfields, Opthalmic Surgery, London, United Kingdom*

Background: Orbital lymphoma is a rare diagnosis and is usually of low-grade histology, most commonly marginal zone lymphoma. The majority present at an early stage (IE) and after biopsy and staging imaging to confirm no systemic involvement, will be treated with curative intent. Gold standard treatment for this group of patients is considered to be radiotherapy, although technique varies; a conservative dose of 30 Gy is delivered. We have previously published our data on this disease but here concentrate on low grade disease and partial orbital/ conjunctival radiotherapy.
Material and Methods: All patients diagnosed with histologically proven low grade 1E orbital lymphoma from January 2003 until December 2012 inclusive and treated with primary radiotherapy at St Bartholomew's Hospital, London were included in this review. Data on patient's demographics, radiotherapy regimes including techniques, dose fractionation and toxicity were collected. In addition follow up data including relapse details were collected retrospectively from electronic notes and radiotherapy records.
Results: 77 patients were diagnosed and treated with radiotherapy during this period and data was reviewed for all of them. 44 were female (57%) and 33 were male (43%), with a median age of 64 (range 26−89).
65 patients (84%) were treated with a 6 mega-voltage photon technique to the whole orbit, in a custom-made mask. 12 patients (16%) (whom had conjunctival only disease) were treated with a contact lens, bearing a central lead cylinder that is positioned over the cornea to screen midline ocular structures/ lens. The median dose prescribed was 30 Gy in 15 fractions over 3 weeks (range 30−34 Gy in 15−17 fractions).
The majority of patients experienced grade 1 erythema and/or conjunctivitis. In addition 3 patients experienced cataracts post radiotherapy.
At a median follow up of 3.4 years a total of 3 patients suffered a recurrence or treatment failure. 2 had developed distant disease, 1 had persistent disease in the treated orbit, and 1 had new disease in the contralateral orbit. No patients have died of disease.
Conclusions: This data suggests that patients with low grade, localized orbital lymphoma can be managed with a conservative dose of radiotherapy, demonstrating acceptable toxicity, and a high cure rate. We encountered no cases of localized relapse in the cohort of 12 conjunctival lymphoma treated with localized, lens sparing orthovoltage radiotherapy.
No conflict of interest.

Angiogenesis in chronic myeloid leukemia

K. Kulumani Mahadevan[1], D. Basu[2], K. Kumar Swarup[2]. [1]*JIPMER, Pondicherry, India;* [2]*JIPMER, Pathology, Pondicherry, India*

Background: Angiogenesis is associated with growth, dissemination and metastasis of tumors. Microvascular density (MVD) being one quantitative method of assessment of angiogenesis, demonstrated by immunohistological markers would give a proportional co relate of the angiogenic process in tumors. The aim of this study is to measure MVD using CD34 staining, to co-relate micro vascular densities with the grade of fibrosis, various phases of CML and type of CML (G/GM).
Materials and Methods: Bone marrow biopsy specimens of 30 CML patients and 20 non CML (controls) cases that required bone marrow biopsy were subjected to CD34 staining and H&E staining. The mean MVD in CD34 slides was assessed by selecting hot spots and MVD was measured in these fields in high power (40 x magnifications) and the mean MVD was calculated by taking the average of four hot spots per field. Grade of fibrosis and phase of CML, type(G/GM) were assessed in H&E slides. The controls were matched with respect to age and gender.
Results: Among 30 patients with CML, 21 were in Chronic phase, 5 in accelerated and 4 in blast crisis. A normal distribution was obtained for MVD of both CML cases and controls using tests for normality. Comparison of mean MVD between CML and controls by Student's t test showed a significant increase in MVD of CML cases ($P = 0.00026$). No significant difference in MVD between the three phases viz., Chronic, accelerated and Blast crisis phase ($P = 0.302$) was obtained by using One way ANOVA. Comparison of Grade of fibrosis with MVD using independent t test showed no significant difference in MVD between low (grade 1&2) and high grade (grade 3&4) ($P = 0.805$). No significant difference in MVD was obtained between G and GM types of CML using independent t test ($P = 0.381$).
Conclusion: The study shows that there is significant increase in MVD in CML cases than controls but no significant difference in MVD could be demonstrated between different phases of CML, types of CML and grades of CML. Therefore, although there is increased angiogenesis in CML patients, there is no significant difference in the angiogenetic process with respect to the phases of CML, type of CML and grade of fibrosis.
No conflict of interest.

Methylene tetrahydrofolate reductase gene polymorphism and risk of childhood acute lymphoblastic leukemia

N. Raafat[1], O. Elsafy[1], T. Abdelmonem[1]. [1]*Zagazig Faculty of Medicine Zagazig University, Biochemistry & Molecular Biology, Zagazeg, Egypt*

Background: Childhood acute lymphoblastic leukemia (ALL) is the most common malignancy affecting children, constituting about 30% of all cancers among children. It constitutes about 75% of pediatric acute leukemia with peak incidence between ages 3 and 4. Genetic factors may predispose children to develop leukemia. Recently, genetic variants of the Methylene tetrahydrofolate reductase (MTHFR) gene have been subject to increasing attention in the etiology of leukemia. Gene polymorphism at the nucleotide 677 in MTHFR gene (C677T) (Ala?Val) results in a less stable version of the enzyme. This study aimed at determination of the relationship between MTHFR gene polymorphism (C677T) and increasing susceptibility of childhood ALL among Egyptian children.
Methods: DNA was isolated from 60 pediatric ALL patients (cases) and from 40 healthy donors (controls). We detected the MTHFR C677T genotype in ALL patients and compared it with the genotype of controls by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) using *Hinf I* restriction endonuclease.
Results: T-allele carriers were significantly lower in ALL cases (43.3%) than healthy controls (55%). Reduction in ALL risk was observed for heterozygous (CT) or homozygous (TT) carriers of the MTHFR 677T allele (OR 0.7; 95% CI, 0.5−1.0; $P < 0.05$).
Conclusion: Our data suggest that the MTHFR gene variants are associated with decreased ALL rate and risk. the reduced risk associated with the MTHFR C677T polymorphisms may be the result of changed intracellular folate redistribution.
No conflict of interest.

BETTER follow-up guidelines for Hodgkin lymphoma survivors regarding late adverse treatment effects

N. Dekker[1], M.B. Van 't Veer[1], J. Raemaekers[2], C.P.M. Janus[3], F. Ong[4], P. Lugtenburg[5], L. Dorresteijn[6], G. Van Imhoff[7], B.M.P. Aleman[8], F.E. Van Leeuwen[1]. [1]*The Netherlands Cancer Institute, Epidemiology, Amsterdam, Netherlands;* [2]*Radboud University Nijmegen Medical Centre, Hematology, Nijmegen, Netherlands;* [3]*Erasmus MC University Medical Center Rotterdam, Radiotherapy, Rotterdam, Netherlands;* [4]*Medisch Spectrum Twente, Radiotherapy, Enschede, Netherlands;* [5]*Erasmus MC University Medical Center Rotterdam, Hematology, Rotterdam, Netherlands;* [6]*Medisch Spectrum Twente, Neurology, Enschede, Netherlands;* [7]*University Medical Center Groningen, Hematology, Groningen, Netherlands;* [8]*The Netherlands Cancer Institute, Radiotherapy, Amsterdam, Netherlands*

Background: After the introduction of modern radiotherapy and chemotherapy, Hodgkin lymphoma (HL) has become a highly curable disease. However, survivors have an increased risk of late adverse effects from treatment leading to excess morbidity and mortality and a decreased quality of life. Specific problems include second malignancies, cardiovascular and thyroid disease, fertility issues and premature menopause, neck muscle weakness, and increased risk of infections after splenectomy. The need for long-term follow-up is increasingly recognized, but uniform recommendations are lacking at present. Therefore, the Dutch BETTER consortium (**B**etter care after Hodgkin lymphoma: **E**valuation of long-**T**erm **T**reatment **E**ffects and screening **R**ecommendations) developed follow-up guidelines aimed at reduction of morbidity and mortality due to late adverse treatment effects.
Material and Methods: The BETTER follow-up guidelines were developed according to international standards. The guideline development group consisted of clinicians, methodological experts and patient representatives. Besides literature reviews, experts were consulted for best practice recommendations; consensus was sought during meetings with the national BETTER consortium.
Results: After treatment for HL, long-term screening of specific risk groups is advised for breast cancer (mammography and breast magnetic resonance imaging), cardiovascular disease (blood pressure, lipids, biomarkers, echocardiogram and electrocardiogram), thyroid disease (hormone profile) and osteoporosis after premature menopause (bone mineral density).

Recommendations are given for fertility care and family planning, therapy for neck muscle weakness, and post-splenectomy infection prophylaxis. A healthy lifestyle and awareness of possible late adverse treatment effects are advocated. In the near future guidelines will be implemented among approximately 8,500 HL survivors throughout the Netherlands and evaluated for their diagnostic value and efficacy.
Conclusions: While much literature is available regarding the incidence of late adverse effects after HL treatment, very little evidence was found regarding the diagnostic value and efficacy of various screening tests. The new BETTER guidelines are thus mainly consensus-based. Implementation and evaluation of the guidelines will lead to more evidence-based follow-up practices and hopefully to improved life expectancy and quality of life for HL survivors.
No conflict of interest.

3618 POSTER

Long-term follow-up results of first-line treatment with doxycycline in patients with previously untreated ocular adnexal marginal zone B-cell lymphoma

J.J. Han[1], T.M. Kim[1], Y.K. Jeon[2], M.K. Kim[3], S.I. Khwarg[3], C.W. Kim[2], D.S. Heo[1]. *[1]Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea; [2]Seoul National University Hospital, Department of Pathology, Seoul, Korea; [3]Seoul National University Hospital, Department of Ophthalmology, Seoul, Korea*

Background: Since *Chlamydophila psittasi* infection has been associated with ocular adnexal marginal zone B-cell lymphoma (OAMZL), doxycycline has been used for its treatment. However, there is not enough evidence of long-term outcomes of doxycycline therapy. Therefore, this study was conducted to evaluate long-term results of doxycycline treatment as first-line therapy for OAMZL patients.
Material and Methods: Ninety patients with previously untreated and histologically confirmed OAMZL were enrolled at Seoul National University Hospital between 2004 and 2012. Each patient was treated with two cycles of doxycycline 100 mg bid for 3 weeks and re-evaluated with ophthalmologic examination and radiologic examination (CT or MRI) every 6 months. Doxycycline outcomes were evaluated in patients who were followed for more than six months after completion of therapy. Progression-free survival (PFS) was calculated from the date of start of treatment to relapse, progression, or to the last date of follow-up. All patients were alive at last follow-up.
Results: The median age at diagnosis was 48 years (range, 21−71 years) with a male-to-female ratio of 1:1.6 and all patients had ECOG performance status 0−1. The most common site of presentation was conjunctiva (82%), followed by orbit (13%), eyelid (3%), and lacrimal gland (2%). All patients, except one patient who had bone marrow involvement, had stage IE at diagnosis. Serum lactate dehydrogenase was elevated in 20% of patients and only one patient had B symptom at diagnosis. There was no serious adverse event reported after doxycycline therapy. After a median follow-up period of 40.5 months (range, 8−85 months), the median PFS was not reached and 5-year PFS was 62.2% by intent-to-treat analysis. Twenty-nine patients (32%) showed local treatment failure without systemic spread. In these patients, median time to treatment failure was 4 months (range: 1−56 months) after doxycycline treatment. Twenty patients received CVP (cyclophosphamide, vincristine, and prednisolone in combination) and nine patients received radiation as second-line therapy. All of these patients achieved complete remission to the second-line therapy without any serious complication.
Conclusions: First-line treatment with doxycycline in patients with previously untreated OAMZL is effective without serious toxicity. Patients who failed after doxycycline therapy were successfully salvaged with chemotherapy or radiotherapy without compromising the long-term treatment outcomes.
No conflict of interest.

3619 POSTER

The relationship between transfusion independence and survival outcomes in older patients with newly diagnosed acute myeloid leukaemia (AML) treated with decitabine

J. He[1], L. Xiu[2], P. De Porre[3], R. Dass[4], M. Doyle[4]. *[1]Janssen Global Services LLC, Oncology, Raritan NJ, USA; [2]Janssen R&D, Raritan NJ, USA; [3]Janssen R&D, Beerse, Belgium; [4]Janssen EMEA, High Wycombe, United Kingdom*

Background: Further analysis of transfusion data from the DACO-016 study in patients with newly-diagnosed AML indicated that treatment with decitabine (DACOGEN) resulted in statistically significant reduction in transfusion dependence compared to treatment choice with physician's advice (TC).
Objectives: This post hoc analysis of DACO-016 explored if transfusion dependence at baseline or on-study is a prognostic factor of survival outcomes.
Methods: In Study DACO-016 485 patients ($\geqslant$65 years) with newly diagnosed AML were randomised to decitabine 20 mg/m^2 intravenous for 5 consecutive days every 4 weeks or TC (either supportive care or 20 mg/m^2 cytarabine given subcutaneously once daily for 10 consecutive days every 4 weeks). Patient baseline or on-study transfusion independence as well as survival outcomes were analysed. Log-rank tests were conducted to test the relationship between transfusion independency and survival outcomes.
Results: For platelet transfusions, the odds of a patient treated with decitabine to become transfusion independent were 1.38 as compared to TC. Within the decitabine arm, the hazard ratios (HR) of platelet transfusion independent patients versus dependent patients for overall survival (OS) and progression free survival (PFS) were 0.42 (95% CI (0.28, 0.65), p = 0.0001) and 0.50 (95% CI (0.30, 0.80), p = 0.0031) respectively. For RBC transfusion, the odds of a patient on decitabine to become transfusion independent were 1.53 as compared to TC. Within the decitabine arm, the HRs of RBC transfusion independent versus dependent patients for OS and PFS were 0.54 (95% CI (0.40, 0.74), p = 0.0001) and 0.57 (95% CI (0.40, 0.81), p = 0.0019) respectively.
Conclusions: Decitabine induced transfusion independence in older patients with AML. Transfusion independence was shown to be a strong prognostic factor for disease progression and overall survival.

Analysis of the transformation of follicular lymphoma in a national registry of over a thousand patients

A. López-González[1], M.A. Cruz[1], P. Sabin[1], C. Quero[1], A. Rueda[1], J. Gumá[1], L. De la Cruz[1], J.R. García Arroyo[1], N. Martínez-Benaclocha[1], M. Provencio[1]. *[1]On behalf of the GOTEL (Spanish Lymphoma Oncology Group), Medical Oncology, Hospital Universitario Puerta de Hierro, Spain*

Introduction: The evolution of an indolent non-Hodgkin lymphoma to a more aggressive one is known as histologic transformation. Its frequency in follicular lymphoma varies between 10 and 70% depending on the series. As established risk factors at the time of diagnosis are known: stage III/IV, elevated LDH, high β2 microglobulin, low albumin, grade III, high FLIPI and absence of complete remission after initial treatment. We unknow the impact of treatment on the risk of transformation. The frequency of histologic transformation is so variable in the series due to the histological definition, the follow-up time and the frequency in which biopsies and/or autopsies are performed to document this progression. It should be suspected when there is evidence of rapid progression of lymphadenopathy, atypical infiltration of extranodal sites, onset of systemic symptoms and increased in LDH and/or hypercalcemia.
Material and Methods: 1178 patients diagnosed with follicular lymphoma, between 1986 and 2012, and treated at the Oncology Department of 17 Spanish hospitals were reviewed. An analysis of clinical and pathological variables using SPSS v19 was made.
Results: A total of 1178 patients were analyzed, of whom 51% were women. The mean age at diagnosis was 57.8 years. A 3.5% of the total of the patients underwent a transformation over the evolution of the disease. 67% of them had stage III/IV at diagnosis. A 63.6% of the transformations were to diffuse large B-cell lymphoma and 15% were at high grade follicular lymphoma. Less frequent were Burkitt-like lymphoma, Hodgkin lymphoma, mantle cell lymphoma, T-cell lymphoma and MALT lymphoma. The median time to transformation was 40 months (standard deviation of 33.24). We do not find any statistically significant differences between the treatments that patients had received prior to the transformation; it was similar in patients treated with or without rituximab, with or without anthracyclines.
Conclusion: The different chemotherapy regimens and the use of rituximab are not associated with the risk of histologic transformation of follicular lymphoma. Re-biopsy should always be done in those cases where histologic transformation is suspected.
No conflict of interest.

3621 POSTER

Treatment of mucosa-associated lymphoid tissue (MALT) lymphoma of the ocular adnexa: A retrospective single-centre analysis

B. Kiesewetter[1], S. Wöhrer[2], J. Fischbach[1], J. Lukas[3], M.E. Mayerhoefer[4], L. Müllauer[5], M. Raderer[1]. [1]*Medical University Vienna, Department of Internal Medicine I/Division of Oncology, Vienna, Austria;* [2]*Medical University Vienna, Department of Internal Medicine I/Division of Bone Marrow Transplant, Vienna, Austria;* [3]*Medical University Vienna, Department of Ophthalmology, Vienna, Austria;* [4]*Medical University Vienna, Department of Radiology, Vienna, Austria;* [5]*Medical University Vienna, Department of Pathology, Vienna, Austria*

Background: Ocular lymphomas represent a heterogeneous group of different lymphomas with a rising incidence. Although several histological subtypes may occur, orbital marginal zone B-cell lymphoma (OAMZL) constitutes for the most frequent diagnosis. However, relatively little is known about clinical course, typical features and therapy. We report our experience of patients with OAMZL seen at our institution 1999–2012.
Material and Methods: This retrospective analysis was performed of all MALT lymphoma patients diagnosed and treated at a tertiary referral centre 1999–2012. Diagnosis was made according to the WHO classification. A total of 60 patients (33 female, 27 male) with OAMZL were identified at a median age of 66 years; interquartile range (IQR) 52−75. The median follow-up time was 43 months (IQR 16−92). The study had been approved by the Ethical Board of the Medical University of Vienna.
Results: The majority presented with local disease i.e. stage IE according to Ann Arbor (n = 40/60, 67%), one patient had stage IIE (2%), two patients stage IIIE (3%) and the remaining 17 (28%) stage IVE disease. Seven patients with stage IVE presented with bilateral orbital disease whereas the others showed involvement of further organs. Autoimmune disorders were present in 17 of 47 tested patients and the most frequent diagnosis was autoimmune thyroiditis (7/17).
Treatment data were available in 58 patients. Local treatment with either radiotherapy (24%, 14/58) or surgical resection (5%, 3/58) resulted in complete or partial response (CR or PR) in 82% of patients (CR n = 13, PR n = 1). One patient had stable disease (SD), one progressive disease (PD) and one was lost to follow-up. However, a total of eight patients needed consecutive further therapy. Median time-to-progression (mTTP) in this group was 41 months (IQR 24−58). The majority of patients (47%, 27/58) received systemic treatment with (immuno-)chemotherapy regimens and response rate was identical at 81% (CR n = 16, PR n = 6, SD n = 3, PD n = 1, no data n = 1). Eleven patients warranted further therapy after a mTTP of 16 months (IQR 9−31). Eight patients received antibiotics (doxycycline or clarithromycin) as initial therapy. Two patients achieved CR now ongoing for 6 and 83 months; response rate was 38% (PR n = 1, SD n = 2, PD n = 2, no data n = 1). Median TTP in this group was 15 months (IQR 2−17). Watchful waiting was the initial approach in 6/58 patients (10%), and 4 received systemic therapy after a mTTP of 32 months (IQR 21−73). The remaining two were lost to follow up.
There was no significant difference in mTTP between the treatment arms. A total of 28/58 (48%) patients progressed and were given second line therapy. None of our patients had central nervous system involvement during follow-up.
Conclusion: OAMZL patients were treated first line with radiotherapy, surgery, (immuno-)chemotherapy or antibiotics resulting in high response rates. There was no significant difference in TTP and response rates between local vs systemic therapy, but recent data have suggested a preferential toxicity profile for systemic therapy.
No conflict of interest.

3622 POSTER

Secondary tumors in patients after lymphoma treatment

I. Kriachok[1], A.V. Martynchyk[1], Y.V. Pastushenko[1], A. Gubareva[1], I. Tytorenko[1]. [1]*National Cancer Institute in Ukraine, Oncohematology, Kyiv, Ukraine*

Background: Patients after treatment of non-Hodgkin lymphoma (NHL) or Hodgkin lymphoma (HL) are at risk for secondary tumors (ST). The aim of this study was to assess the rate and risk factors for ST occurring in NHL and HL patients.
Methods: In order to reveal ST cases a total of 3056 patients with NHL or LH were identified who were treated from 1976 to 2010 in the National Cancer Institute, Ukraine.
Results: Eligible cases included 53 patients with ST after initial treatment of NHL or HL. Median age of patients at the moment of ST diagnosis was 41.5 y.o. and 75.5% were females. The majority of HL patients had lymphoma stage II (55%), 42% of patients with NHL had stage III. Patients received 2−8 courses of chemotherapy (CT) (CHOP, CNOP, BHOP, COPP, COP, ABVD, BEACOPP).
24.5% patients received CT alone as initial treatment, radiation therapy (RT) alone − 9.5% patients, combined treatment − 66% patients. RT doses ranged from 30 to 46 Gy to the cervical, axillaries, mediastinal, and inguinal and retroperitoneal regions involved and extended radiation fields. The ST occurred in the region of previous RT in 65.2% of patients. The average time of occurrence was 12.0±0.5 years (1−34).
Median of survival was 140.9 months, average life duration was 147.9±1.9 months. 5-year overall survival was 83%, 10-years survival was 63% and 20-year survival was 30% from the time of lymphoma diagnosis.
The rate of ST was as follow: breast cancer in 17%, head and neck cancer − 13%, lymphoma/leukemia − 13%, gastric cancer − 11%, lung cancer − 8%, cervical cancer − 8%, uterine neoplasm − 6%, skin cancer − 6%, colorectal cancer − 4%, ovarian cancer − 4%, prostate cancer − 2%, others − 8% of cases.
According to Bhatia S., 2003 patients the most common ST in patients after treatment HL were lung cancer, gastric cancer, colorectal, thyroid and breast cancer.
According to Rueffer U., 2001 the most common ST after treatment of NHL were MDS/AML, lung cancer, gastric cancer and breast cancer.
There was a direct correlation of the ST occurrence and previous RT, $\chi^2 = 0.39$ ($p < 0.5$), gender (female), $\gamma = 0.412$ ($p < 0.05$) and there was no correlation of tumors and CT alone ($\gamma = 0.06$), age, stage of lymphoma, type of CT and number of CT cycles.
Conclusion: Breast cancer, head and neck cancer, lymphoma/leukemia and gastric cancer were the most frequent malignancy among these patients. The main risk factor for ST was RT at initial treatment and women had a higher risk compare to men.
No conflict of interest.

3623 POSTER

The avβ3/avβ5 blockage by Cilengitide® disables the osteoclast-like differentiation of malignant plasma cells in multiple myeloma

L.S. Stucci[1], M. Tucci[1], M. Vecchio[1], P. Cafforio[1], F. Silvestris[1]. [1]*University of Bari "A. Moro", Department of Biomedical Sciences and Human Oncology, Bari, Italy*

Background: Hyperactive osteoclastogenesis in multiple myeloma (MM) is primarily promoted by marrow MM cells while the osteoerosive activity is triggered in osteoclasts (OC) by the $\alpha_v\beta_3$ integrin that, however, is also expressed by malignant plasma cells. These cells may undergo to OC-like differentiation in vitro and the inhibition of $\alpha_v\beta_3$ by small interfering RNAs impairs their OC-like erosive activity. $\alpha_v\beta_5$ is also expressed by MM cells in their adhesion to the bone matrix and interacts with $\alpha_v\beta_3$ in driving the hyperactivation of OCs. Cilengitide® (CLG) is an antagonist of $\alpha_v\beta_3/\alpha_v\beta_5$ that restrains the proliferation of high-grade glioma cells both in vitro and in vivo as well as the osteotropism of tumor cells in animal models of breast cancer. In this study we verified its effect in inhibiting the in vitro bone resorbing activity of OC-like MM cells.
Methods: Marrow plasma cells purified from seven MM patients were primarily assessed for both $\alpha_v\beta_3$ and $\alpha_v\beta_5$ expression by flow-cytometry and then cultured up to 24 hours with CLG on vitronectin coated substrates. Cell viability and adhesion were investigated by MTT assay, whereas the cytoskeleton F-actin was visualized by immunofluorescence. Both $\alpha_v\beta_3$ and $\alpha_v\beta_5$ intracellular pathways were explored by western blot (WB), particularly the phosphorylation of Erk1/2, Pyk2, paxillin as well as Akt. Calcium phosphate, as bone resembling substrate, was used to measure the effect of CLG on the bone resorption exerted by MM cells.
Results: Both $\alpha_v\beta_3$ and $\alpha_v\beta_5$ were highly expressed (>98%) by MM cells whose incubation with CLG at 25 μg/ml up to 6-hours promoted the detachment of approximately 50% of cells from the vitronectin coating, whereas the cell viability remained mostly unaffected. However, non adherent cells showed altered and irregular F-actin localization in parallel with minor phosphorylation of ERK1/2, PYK2 and paxillin as compared with untreated cells that showed a well rearranged perimembrane F-actin ring. By contrast, the Akt phosphorylation the cells underwent to significant inhibition in their osteoerosive activity as number of pits, compared to untreated cells (34±13 and 9±2/cm2; $p < 0.05$).
Conclusions: Inhibition of $\alpha_v\beta_3/\alpha_v\beta_5$ signalling by CLG appears functional in disabling the bone resorptive properties of MM cells in our in vitro experimental model. Thus, new preclinical studies are needed to explore its potential for future treatment of the myeloma bone disease.
No conflict of interest.

3624 POSTER

Report on imatinib treated CML patients: Pregnancy outcome

S. Dasgupta[1], A. Mukhopadhyay[2], U.K. Ray[3], F.H. Gharami[4], C.K. Basu[4], S. Mukhopadhyay[1]. *[1]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Molecular Biology, Kolkata, India; [2]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Haematological Oncology, Kolkata, India; [3]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Pathology, Kolkata, India; [4]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Clinical Trial, Kolkata, India*

Background: Now that imatinib is being used to treat thousands of chronic myeloid leukemia (CML) patients for more than 10 year it is highly probable that many patients will get pregnant during its use. Company warns against any such use. But the fact remains that there is need for planned pregnancies in indicated cases. So we selected few cases both male and female for such pregnancies by interrupting treatment and following the pregnancy closely. Their outcome was studied so that we have an idea about what best could be suggested in such instance.
Materials and Methods: From November 2002 to January 2011, 634 patients with CML in any stage of the disease were treated with imatinib at our tertiary cancer research institute. We selected 22 (12 females and 10 males) cases of pregnancies by interrupting treatment. We reported 9 accidental pregnancies and 13 planned pregnancies involving 22 patients who or their wives conceived while receiving imatinib for the treatment of CML.
Results: Among 23 pregnancies there were 3 spontaneous abortions and 4 elective abortions. In case of 8 female patients, 3 and 5 were male and female babies respectably and in case of six male patients 4 and 4 were male and female babies. Two babies were with congenital anomaly such as one Hypospandium and one Mild-Hydrocephalus (in case of unplanned pregnancies and imatinib exposure during the first trimester of organogenesis).
Conclusions: In conclusion, exposure to Imatinib during pregnancy might result in an increased risk of serious fetal abnormalities or spontaneous abortions. Women of childbearing potential should use adequate contraception while using Imatinib. We can suggest that planned pregnancy during therapy should be encouraged but imatinib therapy in unplanned pregnancy can cause spontaneous abortion or minor congenital anomaly.
No conflict of interest.

3625 POSTER

Epidemiological analysis of follicular lymphoma in Spain: Retrospective registry in 17 hospitals

A. López-González[1], P. Sabin[1], C. Quero[1], M.A. Cruz[1], A. Rueda[1], A. Blasco[1], A. Saenz Cusi[1], N. Pérez[1], A. García-Palomo[1], M. Provencio[1]. *[1]On behalf of the GOTEL (Spanish Lymphoma Oncology Group), Medical Oncology, Hospital Universitario Puerta de Hierro, Spain*

Introduction: In Spain, between 3,000 and 5,000 new cases of follicular lymphoma are diagnosed each year. It is the second most common tumor of lymphoid lineage. It represents 22−40% of non-Hodgkin lymphomas. The annual incidence is increasing in recent decades. The development of national registers helps us to understand the clinical and pathological characteristics of the patients in our area. Thus, we can develop the best treatment program for our patients, thereby improving the effectiveness of our clinical practice.
Material and Methods: 1178 patients diagnosed with follicular lymphoma, between 1986 and 2012, and treated at the Oncology Department of 17 Spanish hospitals were reviewed. An analysis of clinical and pathological variables using SPSS v19 was made.
Results: A total of 1178 patients were registered, of which 51% were women. The mean age at diagnosis was 57.8 years with an ECOG of 0−1 over 80%. In 60% of the cases, follicular lymphoma was grade I−II. Regarding prognostic factors at diagnosis, 46% of patients were over 60 years, 22% had hemoglobin <12 mg/dl, 25% an elevated LDH, 46% a stage I−II Ann Arbor, and nearly 40% of patients had more than 4 nodal areas affected. This meant a FLIPI 0−1 in 38.4%, a FLIPI 2 in 29% and $\geqslant$3 FLIPI in 31.7%. Other important features at diagnosis are the extranodal origin in 20%, the elevation of the β2 microglobulin in 32.7%, bone marrow involvement by nearly 40%, the presence of B symptoms in 19.6% of patients and Bulky involvement by 22.8%. Currently, 19.2% of the patients are alive with disease, 59.4% are alive without active macroscopic disease and 21.5% have died.
Conclusion: To our knowledge, this is the largest registry of patients diagnosed with follicular lymphoma. Such records are necessary to determine the characteristics of the patients treated in each health area.
No conflict of interest.

Spinal cord compression in multiple myeloma

H. Jung[1], S.H. Cho[1], C.H. Maeng[1], J.Y. Lee[1], S.H. Im[1], J.H. Jang[1], W.S. Kim[1], C.W. Jung[1], K.H. Kim[1]. *[1]Samsung Medical Center Sungkyunkwan University School of Medicine, Division of Hematology-Oncology Department of Medicine, Seoul, Korea*

Background: Spinal cord compression occurs in 5% of all cancer patients and its prognosis is usually poor. However, the impact of cord compression on the prognosis of myeloma patients is relatively less than that of other cancers because most cases are so sensitive to radiotherapy or chemotherapy that they can be rescued by active treatment. However, there is few data regarding clinical outcomes of spinal cord compression in Korean myeloma patients. In this study, we identified clinical features of cord compression in myeloma patients as well as analyzed its treatment outcome and prognostic impact.
Methods: We reviewed the retrospective cohort of myeloma patients in the Samsung Medical Center between 2001 and 2011. We designated a case of spinal cord compression as a myeloma patient diagnosed with spinal cord compression during or after active treatment by CT or MRI scans or histologic confirmation. We gathered clinical data associated with cord compression and treatment outcomes including functional recovery and overall survival.
Results: Of 542 patients who were diagnosed with symptomatic multiple myeloma, 65 patients (12.0%) had spinal cord compression. The onset of cord compression was variable, but 40 cases were found at diagnosis (61.5%) whereas 25 cases were found during follow up (38.5%). The most common presentation was epidural mass compressing spinal cord (73.8%), and the second common was compression fracture (20.0%). Pain was the most common symptom, occurring in 47 (72.3%) patients and 27 patients (41.5%) had neurologic impairment. Thoracic spine was most common involved site (61.5%) followed by cervical spine (21.5%). The performance status was relatively poor, thus, 46.2% of patients had poor performance (ECOG $\geqslant$2) whereas only 28.0% had poor performance in patients without cord compression ($P < 0.05$). The median overall survival was 42.9 months in patients with cord compression and it was not significantly different from patients without cord compression (53.8 months, $P = 0.23$). Radiotherapy was most commonly used treatment modality ($n = 37$, 56.9%), and 10 patients (15.4%) received surgery for spinal lesion. Among patients with neurologic deficit ($n = 27$), 18 patients received radiotherapy and 6 patients received surgical decompression. The response to treatment in terms of neurologic improvement was 77.8% in radiotherapy group and 100% in surgery group.
Conclusions: The present study is the first study of description of spinal cord compression in Korean myeloma patients, and radiotherapy might be recommended as an effective treatment in terms of neurologic deficit.
No conflict of interest.

3627 POSTER

Safety and efficacy of rituximab based chemotherapy in chronic lymphocytic leukaemia patients: A single centre experience

A. Gogia[1], V. Raina[1], A. Sharma[1], L. Kumar[1]. *[1]All India Institute of Medical Sciences, Medical Oncology, Delhi, India*

Background: Rituximab (anti-CD 20) has been reported to be an effective drug for the treatment of chronic lymphocytic leukaemia (CLL) with combination of fludarabine and bendamustine. Its safety and efficacy in Indian patients has not been studied. We carried out analysis of CLL patients who received two different regimen FCR (fludarabine, cyclophosphamide, and rituximab) and BR (bendamustine and rituximab) for treatment of CLL in upfront and relapsed cases at I.R.C.H, AIIMS, New Delhi, India.
Methods: The records of patients ($N = 320$) with diagnosis of CLL between January 2000 and December 2012 were collected. Rituximab was used in 64 denovo and 25 relapsed cases. Response evaluation was done as per the National Cancer Institute-Working Group guidelines, in those patients who received at least 3 cycles of chemotherapy. Toxicity was graded as per the common terminology criteria for adverse events, version 3.0. Median event-free survival was obtained using Kaplan–Meier survival analysis.
Results: Eighty nine patients (64-upfront/de novo, 25 relapsed) were included in the study and 353 cycles were administered (median: 4 cycles per patient). Fifty-five patients received FCR and 34 received BR. Thirty patients had treatment delay in FCR and 6 patients in BR subgroup due to prolonged myelosuppression. The complete (CR), partial (PR) and overall response rate (ORR) of FCR and BR was 43%, 43%, 86% and 40%, 50%, 90% respectively those treated upfront. ORR was 50% in those with relapsed disease in both subgroup. Grade 3/4 myelosuppression occurred in 65% with FCR and 20% with BR. One third patients had developed overt tuberculosis during treatment period or subsequent follow-up in patients

who received FCR. Four patients died of pneumocystis jiroveci carinii pneumonia (PCP) in FCR group. Median follow-up period was 27 months. Median event-free survival for patients treated upfront with FCR was 24 months and BR was not achieved.
Conclusions: In our patient population, response to FCR and BR is same and similar to that in the published literature but toxicity profile is different. Prolonged myelosuppression (two third of patients leads to treatment delay) and tuberculosis (one third of patients) in FCR regimen. BR is better option to treat CLL patients in our group of population where the prevalence of subclinical tuberculosis is high.
No conflict of interest.

3628 POSTER

Graft-versus-host disease (GVHD) prophylaxis with mesenchymal stem cells transplanted on thalassemia major patients: An experience from Eastern India

B. Chatterjee[1], A. Mukhopadhyay[2]. *[1]Netaji Subhas Chandra Bose Cancer Research Instituite, Calcutta, India; [2]Netaji Subhas Chandra Bose Cancer Research Instituite, Bone Marrow Transplant Unit, Calcutta, India*

Background: Mesenchymal progenitor stem cells (MSCs) have a tremendous potential to self renew and exhibit multiple lineages of cell lines and are known to by inhibiting T cell proliferation and acceleration of hematopoietic stem cell engraftment. MSCs avoid allorecognition, tend to interfere with dendritic cell and T-cell function thus creating an immunosuppressive microenvironment by secreting cytokines. Numerous clinical trials have been reported to use MSCs to prevent graft-versus-host disease (GVHD). MSC therapy offers a safe and a therapeutic method against GVSD to Thallassemia patients without without impairing graft-versus-leukemia effects. Our aim is to see the effect of MSCs in GVHD prophylaxis and result of thalassemia major patients.
Material and Method: 16 thalassemia major patients were selected and they have undergone umbilical cord blood transplants. The age group determined was in the range of 4−15 years, having a mean of 8.5. Messenchymal stem cells were derived from sibling cord blood. We used routine GVHD prophylaxis (methotraxate, cyclosporine and methlprednisolone) on 8 patients. In another 8 patients we added additional cord blood MSCs. MSCs were cultured and administered to the recipients at doses of 0.8−1.3$\times$106/kg when the blood count indicated recovery.
Result: The comparative study of 8 thalassemic patients treated with routine GVSD prophylaxis i.e. with (methotraxate, cyclosporine and methlprednisolone) and another 8 patients with we added additional cord blood MSCs has shown that 6 out of 8 (75%) thalassemia patients had developed GVHD of stage II−IV when administered with routine GVHD prophylaxis; whereas another group of 8 patients have shown 2 (25%) patient has developed grade- III, 1(12.5%) patient grade- II and 5 (67.5%) patients developed grade- I GVHD where additional MSC were used as GVHD prophylaxis.
We have also observed that there was no difference in graft rejection rate, chronic GVHD development or any infections during the transplant. No mortality or morbidity was there in both the groups. But there was a rejection rate of 20% where no MSCs were used in the group.
Conclusion: We have came to precise information that using MSCs on GVHD patients is 100% safe and in future we will look forward to manipulate MSCs to restore the normal functioning of the patients with or without drugs or steroids that cause side effects in regular transplantation. The number is very small. We intend to continue the programme more in Thalassemia transplants as well as in other allogenic transplants.
No conflict of interest.

3629 POSTER

Differences in baseline characteristics and survival rates between GCB and non-GCB diffuse large B-cell lymphoma treated with rituximab based immunochemotherapy

L. Popovic[1], O. Markovic[2], D. Jovanovic[1], D. Marisavljevic[2], D. Petrovic[3], B. Mihaljevic[4], Z. Nikin[5], T. Matkovic[2], G. Matovina-Brko[1], R. Zivkovic[6]. *[1]Oncology Institute of Vojvodina University of Novi Sad, Medical Oncology, Sremska Kamenica Novi Sad, Serbia; [2]Clinical-Hospital Center "Bezanijska kosa" Medical Faculty Belgrade, Hematology, Belgrade, Serbia; [3]Oncology Institute of Vojvodina, Medical Oncology, Sremska Kamenica Novi Sad, Serbia; [4]Clinic of Hematology Clinical Center of Serbia Medical Faculty Belgrade, Hematology, Belgrade, Serbia; [5]Oncology Institute of Vojvodina University of Novi Sad, Surgical Oncology Pathology, Sremska Kamenica Novi Sad, Serbia; [6]Clinical-Hospital Center "Bezanijska kosa", Hematology, Belgrade, Serbia*

Background: In recent years, the emergence of new studies and new drugs, made division of diffuse large non-B lymphoma (DLBCL) on GCB in non-GCB subtypes increasingly important. Previous studies have shown that this distinction has prognostic significance. Addition of rituximab in both subtypes improved treatment results.
Material and Methods: We retrospectively analyzed 111 patients with de novo DLBCL, treated with rituximab-based immunochemotherapy. Division of GCB and non-GCB subtypes was performed with immunohistochemistry, according to Hans's criteria. The baseline characteristics that were correlated with the subtype of DLBCL were: patient age, sex, hemoglobin, lymphocyte count, LDH level, albumin level, Ann Arbor clinical stage, IPI and R-IPI score, percent of Ki-67 expression and expression Bcl-2 and CD5. In addition, we observed differences in response to therapy, EFS and OS.
Results: Sixty-two (56.25%) patients had non-GCB subtype. Analysed groups did not differ in age of patients (median age 56 years in both groups), patient gender (males 63.26% GCB vs non-GCB 66.12%, p = 0.909), hemoglobin <100 g/l (10.2% GCB vs non -GCB 11:29%, p = 0.901), lymphocyte count <1.3 (GCB 45.83% vs non-GCB 50%, p = 0.809) albumin <35 (GCB 22.5% vs. non-GCB 38.18%, p = 0.162), LDH elevation (65.30% GCB vs non-GCB 59.67%, p = 0.682), Ann Arbor clinical stage (I 8:16% GCB vs non-GCB 9.67% p = 0.954, II 34.69% vs. 37.09%, p = 0.95, III 30.61% vs. 27.41%, p = 0.874, IV 26.53% vs. 25.8%, p = 0.896), and IPI/R-IPI score (score 71.42% 0, 1, 2 GCB vs non-GCB 68.84%, p = 0.939). Median Ki67 expression was 70% in GCB and 62.5% in the non-GCB group. Expression of Bcl-2 and CD 5 also was not different among the subtypes. Complete remission was achieved in the group of GCB in 79.16% cases, while in the non-GCB in 67.79% (p = 0.272). Patients with GCB subtype had a longer EFS (median 26 months vs. NR, 3-year EFS 67.6% vs. 47.1%, p = 0.05), and OS (median 53 vs 35 months, 3-year OS 59.6% vs. 44.9%, p = 0016).
Conclusion: Non-GCB subtype is predictor of shorter survival in patients with DLBCL treated with rituximab based immunochemotherapy.
No conflict of interest.

3630 POSTER

CD5-positive versus CD5-negative diffuse large B-cell lymphoma treated with immunochemotherapy: Is there a difference?

L. Popovic[1], O. Markovic[2], D. Jovanovic[1], D. Marisavljevic[2], D. Petrovic[3], B. Mihaljevic[4], M. Popovic[5], T. Matkovic[2], G. Matovina-Brko[1], R. Zivkovic[6]. *[1]Oncology Institute of Vojvodina University of Novi Sad, Medical Oncology, Sremska Kamenica Novi Sad, Serbia; [2]Clinical-Hospital Center "Bezanijska kosa" Medical Faculty Belgrade, Hematology, Belgrade, Serbia; [3]Oncology Institute of Vojvodina, Medical Oncology, Sremska Kamenica Novi Sad, Serbia; [4]Clinic of Hematology Clinical Center of Serbia Medical Faculty Belgrade, Hematology, Belgrade, Serbia; [5]Clinical Center of Vojvodina University of Novi Sad, Nephrology and Clinical Immunology, Novi Sad, Serbia; [6]Clinical-Hospital Center "Bezanijska kosa", Hematology, Belgrade, Serbia*

Background: CD5 is recognized as a marker of poor prognosis in patients with DLBCL. Patients with CD5 + DLBCL treated with rituximab have longer time to disease progression compared to patients treated with chemotherapy alone.
Patients and Methods: We analyzed 121 patients with de novo DLBCL, treated with rituximab-based immunochemotherapy. CD5 positivity was determined by immunohistochemistry. Basic characteristics that correlated with the CD5 status were: patient age, sex, hemoglobin, lymphocyte count, LDH level, albumin level, Ann Arbor clinical stage, IPI and R-IPI score, and the level of Ki-67expression, expression of Bcl-2, and the percentage of GCB/non-GCB phenotypes within the group, based on Hans's criteria. In addition, we observed differences in response to therapy, EFS and OS.
Results: Seventeen patients (14%) in our group were diagnosed with CD5 + DLBCL. Analysed subgroups did not differ in proportion of patients older than 60 years 41.17% vs. 33.65% (p = 0.742), hemoglobin <100 g/l 5.88% vs. 17:47% (p = 0.393), lymphocyte count <1.3 43.75% vs. 44.55% (p = 0.833), albumin level <35 30.76% vs. 24.05% (p = 0.863), LDH level elevation 64.70% vs. 54.80% (p = 0.618) for CD5+ versus CD5− respectively. Groups did not differ in Ann Arbor stage (III + IV CS CD5+ 58.82% vs 52.88% CD5− p = 0.847). Although not statistically significant (p = 0.145), male sex was more frequent in CD5-negative patients (57.49% vs. 35.29%). More patients with CD5+ DLBCL were in poor prognosis group according to R-IPI score (52.94% vs. 28.15%, p = 0.035). Median level of Ki67 expression in CD5+ DLBCL was 60%, compared to 65% CD5− patients. Groups also did not differ according to the expression of Bcl-2 nor the affiliation to GCB/non-GCB phenotype. In our series, there were no differences in the percentage of complete remissions achievement (CD5+ 75% vs. CD5− 71.84%, p = 0.970), EFS (median CD5+ 35 months vs. CD5− NR, 3-year EFS 59.3% vs. 48.8%, p = 0.629) and OS (median CD5+ 44 months vs. CD5− 37 months, 3-year OS 66.12% vs. 52.6%, p = 0.869).

Conclusion: Despite the higher number of patients with poor R-IPI score in our group of patients, the EFS and OS were the same in patients with CD5+ or CD5− DLBCL.
No conflict of interest.

3631 POSTER

International Prognostic Index (IPI) is a stronger predictor of outcome in diffuse large B cell lymphoma (DLBCL) treated with rituximab (R) and CHOP (R-CHOP) compared to revised-IPI (R-IPI)

H. Soudy[1], N. Bakshi[2], A. Darwish[1], M. Abdel Salam[1], A. Rehman[3], T. Elhassan[3], S. Akhtar[1], I. Maghfoor[1]. *[1]King Faisal Specialist Hospital, Medical Oncology, Riyadh, Saudi Arabia; [2]King Faisal Specialist Hospital, Pathology, Riyadh, Saudi Arabia; [3]King Faisal Specialist Hospital, Oncology Research Unit, Riyadh, Saudi Arabia*

Background: Standard IPI was developed in the non-rituximab based chemotherapy era as prognostic tool for risk stratification of aggressive NHL. The revised IPI (R-IPI) was created in the rituximab based chemotherapy era by redistributing the risk factors of IPI; it has been suggested as an alternative and better predictor in this patient population. This is a retrospective study designed to compare the prognostic value of IPI versus (R-IPI) in DLBCL patients treated by R-CHOP.
Material and Methods: The study included 198 patients treated by R-CHOP between (8–2004 till 12–2008) at King Faisal Specialist hospital, Saudi Arabia. Demographics, presentations, stage, therapy, and IPI risk scores and survivals were collected and calculated retrospectively. Data were incomplete in 13 patients. 185 patients form the basis for this report.
Results: There were 113 males/85 females with a median age of 50 year (15−89). At a median follow-up for survivors of 68 months (19–102), the event-free survivals (EFS) and overall (OS) were 55%, 64% respectively. Event free survival and overall survival for four groups according to IPI were 79%, 46%, 47%, 29% and 85%, 59%, 53%, 36% for low, low intermediate, high intermediate and high risk groups respectively. According to R-IPI the EFS and OS were 81%, 63%, 38% and 81%, 74%, 45% for very good, good and poor risk groups respectively. While all the differences were highly statistically significant for IPI, the same did not reach statistical significance for R-IPI (Table 1).

Table 1

Risk Category	OS	HR	p-value	EFS	HR	p-value
Standard International Prognostic Index						
Low (0, 1)	85%	1		79%	1	
Low Intermediate (2)	59%	2.6	0.009	46%	2.8	0.001
High Intermediate (3)	53%	3.6	<0.001	47%	3.3	<0.001
High (4, 5)	36%	5.6	<0.001	29%	5.2	<0.001
Revised International Prognostic Index						
Very Good (0)	81%	1		81%	1	
Good (1, 2)	74%	1.6	0.4	63%	2.2	0.178
Poor (3, 4, 5)	45%	4.2	0.01	38%	5.09	0.006

HR, Hazard Ratio. All percentages are rounded.

Conclusion: Standard IPI remains a valid prognostic tool even in chemo-immunotherapy era and is more robust than R-IPI in predicting prognosis in DLBCL treated with R-CHOP.
No conflict of interest.

3632 POSTER

Incidence of second cancer in patients with chronic lymphocytic leukemia: 13 years experience from single institute

A. Gogia[1], V. Raina[1], A. Sharma[1], L. Kumar[1], R. Gupta[2], M.C. Sharma[3]. *[1]All India Institute of Medical Sciences, Medical Oncology, Delhi, India; [2]All India Institute of Medical Sciences, Lab Oncology, Delhi, India; [3]All India Institute of Medical Sciences, Pathology, Delhi, India*

Background: Chronic lymphocytic leukemia (CLL) is most common malignancy in the west and relatively uncommon in India. Patients with CLL have a higher incidence of second malignancies (two times) than the general population. Our study aims to present the incidence and predicting factor for second cancer in patients of CLL at our institution.
Methods: We retrospective evaluated 320 patients of CLL registered at All India Institute of Medical Sciences (AIIMS), New Delhi over a period of 15 years (2000–2012). A second malignancy was defined as another malignancy at the time of diagnosis or during follow-up.
Results: There were 230 males and 90 females. The median age was 59 years (28−90 years). The common presenting features were lymphadenopathy 63%, fatigue 25%, fever 20%, hepatomegaly 40%, splenomegaly 55%. Median total leucocyte count at presentation was 47×10^9/L. Sixty percent of patients were early (Rai stage 0−10%, stage I − 16%, stage II − 34%) and 40% of cases were in advanced (stage III −20 % and stage IV − 20%) stage. Fifty percent of patients received treatment at presentation (one hundred twelve patients (70%) received chlorambucil and 40 patients (25%) received Fludarabine and eight patients received bendamustine based chemotherapy). With a median follow-up of 40 months, total of 24 cancers were identified (18 hematological and 6 solid tumors). Seventeen cases were transformed to diffuse B cell lymphoma (richter's syndrome) and rest were myelodysplastic syndrome −1, basal cell carcinoma −1, carcinoma of larynx −1, breast cancer −1, adenocarcinoma of lung −1 and locally advanced urinary bladder cancer −1 case each. According to correlation analysis, young age (<55 years, $p = 0.015$) a high expression of CD38 positivity (>30%, $p = 0.001$) and advanced Rai stage (III & IV, $p < 0.001$) were found to be independent predictors of transformation to richter's syndrome (RS). Median time to progression to RS and overall survival was 26 months and 8 months respectively.
Conclusions: The incidence of second cancer is 7.5% in our population, richter's transformation is the most common and accounts for 5% of cases. Young age, advanced stage and high expression of CD 38 predict poor outcome.
No conflict of interest.

3633 POSTER

BAFF, TACI and BCMA receptors expression and their impact on survival of patients with diffuse large B-cell lymphoma

L. Popovic[1], Z. Nikin[2], D. Jovanovic[1], S. Knezevic-Usaj[2], M. Popovic[3], G. Matovina-Brko[1]. *[1]Oncology Institute of Vojvodina University of Novi Sad, Medical Oncology, Sremska Kamenica Novi Sad, Serbia; [2]Oncology Institute of Vojvodina University of Novi Sad, Surgical Oncology Pathology, Sremska Kamenica Novi Sad, Serbia; [3]Clinical Center of Vojvodina University of Novi Sad, Nephrology and Clinical Immunology, Novi Sad, Serbia*

Background: B-cell activating factor (BAFF) is a molecule which affects the survival and maturation of B lymphocytes. BAFF binds to three receptors: B-cell activator maturation antigen (BCMA), transmembrane activator and calcium modulator and cyclophilin ligand interactor (TACI), and BAFF receptor (BAFF-R). Activity of atacicept and tabalumab in multiple myeloma emphasizes the importance of these receptors in hematological malignancies.
Patients and Methods: The study presents the pilot results of 30 patients with DLBCL treated with rituximab-based immunochemotherapy. Receptors BAFF-R, TACI and BCMA were determined by immunohistochemistry using Abcam ® antibodies. We also determined expression of Bcl-2, Bcl-6, MUM-1, CD10, CD5, Ki67 receptors. We correlated the EFS and OS in relation to: age, sex, hemoglobin level, LDH elevation, lymphocyte count, expression of Ki67, Bcl-2, CD5, GCB/nonGCB phenotype (Hans method), and the expression of BAFF-R, TACI and BCMA. We expressed the results of three-year EFS and OS.
Results: BAFF-R were expressed in 22 patients (73.3%), TACI in 19 (63.3%), BCMA in 12 (40%). The median percent expression of BAFF-R was 42.5% (0−95), TACI 52.5% (0−95), BCMA 0% (0−60). Duration of EFS and OS were not significantly influenced by sex, hemoglobin, LDH level, the expression of Ki67, bcl-2, CD5. Patients with IPI score >2 had shorter EFS ($p = 0.002$) and OS ($p = 0.02$). Ann Arbor stage influenced EFS ($p = 0.013$), while had no effect on OS. Patients older than 60 years had shorter EFS ($p = 0.0026$) and OS ($p = 0.032$). Patients with baseline lymphocyte count $\leqslant 1.3$ had statistically marginal shorter EFS ($p = 0.09$) and significantly shorter OS ($p = 0.0072$). Patients with GCB subtype had longer EFS ($p = 0.05$) but GCB/nonGCB subtype had no effect on OS. Expression of BAFF-R on over 80% of cells resulted in longer EFS (100% vs. 58.8%, $p = 0.05$), and statistically marginally significance to the OS (100% vs. 63%, $p = 0.1$). Expression of BAFF-R on over 50% of cells also affects longer OS (93% vs. 53%, $p = 0.05$). TACI receptor had no effect on EFS and OS, while the expression of BCMA receptors showed also statistically marginally effect for longer EFS (84.5% vs. 56.2%, $p = 0.09$) and OS (92.1% vs. 55.9%, $p = 0.09$).
Conclusion: In addition to the standard prognostic parameters, expression of BAFF-R and BCMA receptors influence the outcome of patients with DLBCL. These results warrant further investigation.
No conflict of interest.

3634 POSTER

Causes of death of patients treated for Hodgkin's disease in young adulthood − a population based study

L. Zadravec Zaletel[1], B. Jereb[1]. [1]*Institute of Oncology, Radiotherapy Department, Ljubljana, Slovenia*

Background: Survival of patients treated for Hodgkin's disease (HD) is high, but sequelae of combined treatment, chemotherapy (ChT) and radiotherapy (RT), are frequent and are important cause of morbidity. We studied causes of death in patients treated for HD at the age of 16 to 30 years.
Material and Methods: In Slovenia, 178 patients, 98 women, 89 men, were treated for HD at the age of 16 to 30 (median 24) years between 1980–1995. They have been followed for 17−32 (median 22) years.
Results: Of the 178 patients 65 died, 34 (52%) of HD. Sixteen (25%) died of late sequelae: 13 of second malignant neoplasms (SMN) 11 to 29 (median 22) years after primary diagnosis. The SMNs were: breast cancer in four, lung cancer in 2, AML, MDS, holangiocarcinoma, endometrial cancer, cancer of stomach, pancreas and head and neck cancer one each. Three patients died of cardiac cause 17 to 31 (median 30) years after primary diagnosis; one of dilative cardiomyopathy after ChT with antracycline and mediastinal RT, two of coronary artery disease after mediastinal RT. Eight patients died of other causes: brain hemorrhage, hypothermia, accident, acute pancreatitis, bronchopneumonia and suffocation (in 2). In seven patients the cause of death 1 to 6 (median 5) years after primary diagnosis is unknown, they were lost to follow-up.
Conclusions: SMN and cardiac damage are the most frequent cause of death more than 10 years after treatment for HD in young adulthood. Long-term follow-up of those patients especially in term of SMN screening and cardiac examination is evidently necessary.
No conflict of interest.

3635 POSTER

Prognostic significance of international prognostic index (IPI) individual risk factors in patients with diffuse large b cell lymphoma (DLBCL) treated with rituximab (R) and chop (R-CHOP) based chemotherapy

S. Akhtar[1], H. Soudy[1], A. Darwish[1], M. Abdel Salam[1], T. Elhassan[2], A. Rehman[2], N. Bakshi[3], I. Maghfoor[1]. [1]*King Faisal Specialist Hospital, Medical Oncology, Riyadh, Saudi Arabia;* [2]*King Faisal Specialist Hospital, Oncology Research Unit, Riyadh, Saudi Arabia;* [3]*King Faisal Specialist Hospital, Pathology, Riyadh, Saudi Arabia*

Background: International Prognostic Index (IPI) was developed in the non-rituximab based chemotherapy era as predictive tool for risk stratification of aggressive non-Hodgkin's lymphoma (NHL). This model identified five prognostic factors (Table); all were individually significant for predicting survival in this population. Whether these risk factors retain their prognostic significance in Rituximab based chemotherapy era remains unclear. This retrospective analysis reviewed the ability of these individual prognostic factors to predict prognosis in DLBCL patients treated with R-CHOP based chemotherapy.
Methods: The study included 198 patients treated with R-CHOP from 8–2004 to 12–2008 at King Faisal Specialist hospital, Saudi Arabia. Demographics, presentations, stage, therapy, and IPI risk scores and survivals were collected and calculated retrospectively.

Risk factor	Value	Number	OS %	HR	LL HR	UL HR	*P*-value
Age	<60	133	68.4				
	>60	64	45.3	2.139	1.36	3.36	0.001
Performance status	0−1	146	67.8				
	⩾2	38	34.2	2.89	1.77	4.71	<0.000
Stage	I−II	75	68				
	III−IV	120	57.5	1.4	0.862	2.29	0.172
Extranodal sites	0−1	160	64.5				
	>1	31	41.9	1.95	1.15	3.32	0.014
LDH	Normal	71	71.8				
	Elevated	119	55.5	1.76	1.05	2.95	0.031

OS = overall survival; HR = Hazard Ratio; LL HR = lower limits of HR; UL HR = upper limits of HR.

Results: There were 113 males/85 females with a median age of 50 year (15−89). Median follow-up for all alive patients was 68 months (19–102), the event-free (EFS) and overall (OS) survivals were 55%, 64% respectively. Presence of any of these risk factors revealed a higher hazard of death (HR range 1.4 to 2.89). All of them except advanced stage achieved statistical significance. Lack of statistical significance (p-value=0.174) for higher stage with a HR of 1.4 is likely secondary to inadequate sample size. Details of these results are shown in Table.
Conclusion: All five IPI risk factors of IPI retain prognostic importance in R-CHOP era. Presence of any of these factors carries higher risk of death for patients treated with R-CHOP based chemotherapy. Stage III−IV failed to reach statistical significance likely due to small sample size. These risk factors remain valid prognostic indicators individually even in chemo-immunotherapy era. A larger sample is likely to validate all these risk factors in R-CHOP treated patients.
No conflict of interest.

Early stage diffuse large B-cell lymphoma treated with CHOP with or without rituximab (R): Outcome analysis according to risk stratification

I. Maghfoor[1], H. Soudy[1], A. Darwish[1], T. Elhassan[2], M. Abdel Salam[1], A. Rehman[1], N. Bakshi[3], S. Akhtar[1]. [1]*King Faisal Specialist Hospital, Medical Oncology, Riyadh, Saudi Arabia;* [2]*King Faisal Specialist Hospital, Oncology Research Unit, Riyadh, Saudi Arabia;* [3]*King Faisal Specialist Hospital, Pathology, Riyadh, Saudi Arabia*

Background: Early stage DLBCL is managed either with abbreviated chemotherapy and involved field radiation (IFRT) or full course CHOP chemotherapy. After introduction of rituximab in the management of advanced DLBCL, it has been added to CHOP in management of early stage disease even when 3 cycles of chemotherapy and IFRT are used. Mabthera International Trial included a significant percentage of early stage disease and showed benefit with rituximab in early stage DLBCL, however, no prospective trial has specifically looked at addition of R to CHOP in early stage disease. We aimed to assess the outcome of early stage DLBCL with R-CHOP and compare with therapy without rituximab.
Methods: We identified a total of 168 patients with stages I & II DLBCL and collected data on international prognostic index (IPI), therapy and outcomes. The patients with 0−2 IPI factors were assigned as low risk (LR) and those with 3−4 factors were assigned as high risk (HR). Groups were analyzed to compare for survivals for treatment with CHOP vs. R-CHOP.
Results: Of 168 patients, 75 were treated with R-CHOP and 93 with CHOP alone. Data were incomplete in 19 patients. One hundred thirty eight of the 149 patients analyzed were in LR group (R-CHOP;62 and CHOP;76) while only 11 patients had HR disease (R-CHOP;5 & CHOP;6). Disease free (DFS) survival was 65% vs. 67% (p = 0.5) and overall (OS) survival was 71.3% vs. 79% ($P = 0.1$) for R-CHOP and CHOP treated groups respectively (Table). In LR group, DFS was similar in CHOP and R-CHOP treated patients, however, OS was superior in CHOP compared to R-CHOP. We explored the impact of age, disease specific death, stage I vs. II, presence or absence of hepatitis B or C, and bulky disease in order to analyze inferior survival in R-CHOP treated patients. R-CHOP treated group had significantly more patients with bulky disease: 41.3% vs. 28% in CHOP treated group ($P = 0.036$). In HR group, addition of rituximab resulted in superior DFS and OS but did not achieve significance due to small numbers.
Conclusion: Addition of rituximab to CHOP chemotherapy did not result in improved outcomes in patients with stage I & II DLBCL with 0−2 IPI risk factors. Among those with 3−4 IPI risk factors, outcomes were superior with addition of rituximab but did not attain significance due to small numbers. Lower overall survival with rituximab in low risk group may be due to adverse feature i.e. bulky disease. Further exploration is ongoing.
No conflict of interest.

	Survival (%)		*P*-value	Hazard ratio

The prognostic impact of survivin and REG1A in diffuse large B-cell lymphoma

M. Seker[1], M. Gumus[1], N. Ozdemir Barisik[2], F. Dane[3], S. Uyar Bozkurt[4], A. Bilici[1], S. Seber[3], A. Mayadagli[5], P. Fulden Yumuk[3], S. Turhal[3]. [1]*Dr. Lutfi Kirdar Education and Research Hospital, Medical Oncology, Istanbul, Turkey;* [2]*Dr. Lutfi Kirdar Education and Research Hospital, Pathology, Istanbul, Turkey;* [3]*Marmara University School of Medicine, Medical Oncology, Istanbul, Turkey;* [4]*Marmara University School of Medicine, Pathology, Istanbul, Turkey;* [5]*Dr. Lutfi Kirdar Education and Research Hospital, Radiation Oncology, Istanbul, Turkey*

Background: Non-Hodgkin lymphomas (NHL) are a group of heterogeneous malignant disorders. Diffuse large B-cell lymphoma (DLBCL) is the most common subtype and accounts for approximately 35−40% of cases. This subgroup contains different clinical entities showing different biology and clinical outcomes. Many studies have examined the prognostic and predictive value of various biological parameters in this heterogeneous entity. Several biological markers have been reported to date, some of which provide prognostic and some predictive information about the biology of these different subgroups. In this study, we studied two anti-apoptotic markers, survivin and REG 1, in DLBCL.
Material and Methods: This study included a total of 51 DLBCL.All demographic parameters, presenting symptoms, clinical and histopathological variables, treatment schemas, and responses to the given treatment were obtained from the patients' hospital records. Formalin-fixed, paraffin-embedded lymphoma tissue sections were obtained from the pathology department. The expression of survivin was evaluated according to the IRS by assessing the percentage of marked cancer cells and the staining intensity. Staining intensity was scored as 0, no staining; 1, weak; 2, moderate; and 3, intensive staining. The percentage of positive cells was rated as follows: 0, no staining; 1, less than 10% positive cells; 2, 10−50%; 3, 51−80%; and 4, greater than 80% positive cells. Scores for the percentage of positive cells and scores for expression intensities were multiplied to calculate an IRS. An IRS value of 0−6 was accepted as negative staining; a value of 7−12 was accepted as positive staining. Any case of lymphoma was considered positive for REG1A protein if more than 20% of the cancer cells were positively stained.
Results: Twenty-five (49%) patients were survivin-positive. REG1A expression was observed in 26 (51%) patients. There was no statistical difference in the five-year OS rate between survivin-negative and -positive groups or between REG1A-positive and -negative groups.
Conclusions: In our study we were unable to demonstrate the prognostic value of REG1A in DLBCL patients. Additionally, there was no association between high REG1A expression and any other patient or disease characteristics. Although the survival curves of our negative REG1A patients were better than those of positive REG1A patients, this was not statistically significant. This might be due to the small sample size and short follow-up of our lymphoma patients. Our study is the first study to evaluate the expression and prognostic impact of REG1A in DLBCL patients. Further studies with larger patient groups and longer follow-up are required to validate the expression rates and prognostic values of both survivin and specifically REG1A in DLBCL.
No conflict of interest.

3638 POSTER

Prognostic factors for overall survival in Non-Hodgkin Lymphoma: Nonlinear hazard ratio of some continuous covariates

C. Flores[1], L. Casanova[2]. [1]*Oncosalud, San Borja, Peru;* [2]*Instituo Nacional de Enfermedades Neoplásicas, Medical Oncology, Lima, Peru*

Background: Knowledge of prognostic factors for survival of patients with cancer is very important for the clinical management. Here we analyzed the nonlinear functional form of continuous covariates influencing the overall survival (OS) of patients with non-Hodgkin lymphoma (NHL).
Patients and Methods: We retrospectively analyzed prognostic factors (PFs) for OS in 2160 patients (pts) with NHL, treated at INEN between 1990–2002. PFs were determinate according to Cox model with P-splines.
Results: The median age was 54 years (range 14−96) and 51% were male. The majority of the pts had good performance status (73%, WHO 0−1). The Ann Arbor stage was I−II in 51%, III−IV in 49% and B symptoms were present in 38% of the pts. The hemoglobin (Hb) was low in 48%, leukocytes (WBC), lymphocytes and LDH were elevated in 17.7%, 7.7% and 60% of pts, respectively. Of all patients, 709 (32.8%) pts had died. The median survival was 61.8 months and the survival rate at 5 and 10 years was 51.2% and 41.7% respectively.
PFs identified were: age, sex, zubrod, clinical stage, Hb, leukocytes, lymphocytes and LDH. The following table shows the p-value and hazard ratio (HR). The effect of continuous covariates in the log(HR) is non-linear. The cutoff points of highest (HR >1) match the clinically defined ones, which are: age >60 yrs, Hb<12*g/dl* and LDH >240*UI/L*. Both leukocytes and lymphocytes have two higher risk breakpoints: leukocytes >3$x10^3$ and >10$x10^3$, lymphocytes <20% and >60%.
Conclusion: PFs for OS in our group of pts were similar to other reports in NHL. Age, Hb, leukocytes, and lymphocytes are relevant to OS, which showed a non-linear effect in the log(HR).
No conflict of interest.

Variables	Test of association: p-value	HR (95% CI)	Test of PH p-value
Age: non-linear	0.028	curve	0.510

3639 POSTER

Instrumental diagnosis of bone marrow invasion by Hodgkin's disease: Is it important for therapy planning

S.V. Kanaev[1], M.M. Girshovich[1], S. Novikov[1], L.A. Gukova[1]. [1]*N.Petrov Research Institute of Oncology, Radiation Oncology & Nuclear Medicine, Saint-Petersburg, Russian Federation*

Purpose: In this retrospective study we try to determine how bone marrow (BM) visualisation can influence treatment decision in patients (pts) with advanced Hodgkin's disease (HD).
Material and Methods: Since 1992 in our department whole body bone marrow (BM) visualisation is a part of routine staging for pts with HD. Since that time *632 pts with advanced HD* and whole body BM survey are available for *long term (15 years) follow-up.* All visualized BM lesions were verified by biopsy or additional instrumental examinations during follow-up. All pts had histologically confirmed HD and received 4−8 cycles of MOPP-ABVD or ABVD or BEACOPP chemotherapy. In 45 pts visualised BM lesions were irradiated within 20 Gy-50 Gy (average dose 38.1 Gy). Foci of BM invasion were outside radiation fields in another 30 cases.
Results: BM invasion was revealed in 75 (11.8%) of 632 evaluated pts: 51 pts had one or two BM lesions and another 24 − multifocal BM involvement. Overall (OS) and disease free (DFS) 10 year survival in pts with BM invasion (49% and 45%) were significantly ($p = 0.026$) lower than in other 131 pts with extranodal HD (62% and 65%). In pts with only BM involvement and those with BM and other extranodal lesions OS and DFS were comparable: 50% versus 47.5% and 48.5 versus 41%. On the contrary, OS was significantly different ($p = 0.014$) in pts with 1−2 BM lesions (57%) and multifocal BM disease (26.5%).
Irradiation of BM lesions significantly improve 10 year OS ($p = 0.00005$) and DFS ($p = 0.006$) in pts with HD: from 16% to 68% and from 23% to 58.5% correspondingly. This differences are evident in subgroup of pts with 1−2 detected BM foci: 10 year OS and DFS in pts with irradiated BM lesions are 72.7% and 57.5% versus 13.5% and 25% − for pts with non-irradiated BM lesions ($p = 0.0006$ and $p = 0.054$).
Conclusion: 1. In pts with HD diagnosis and precise characterisation (extent and localisation) of BM invasion is of crucial importance for treatment planning. 2. Possible role of radiotherapy in treatment of pts with BM invasion must be evaluated in randomized trials.
No conflict of interest.

3640 POSTER

Treatment outcomes and patterns of failure in early stage unfavourable Hodgkin's Lymphoma

N. Khanna[1], S. Laskar[1], D. Kumar[1], H. Menon[2], M. Sengar[2], B. Arora[2], S. Gujral[3], T. Shet[3], E. Sridhar[3], S. Banavali[2]. [1]*Tata Memorial Hospital, Radiation Oncology, Mumbai, India;* [2]*Tata Memorial Hospital, Medical Oncology, Mumbai, India;* [3]*Tata Memorial Hospital, Pathology, Mumbai, India*

Background and Purpose: To evaluate the efficacy and outcome of using 4−6 cycles of Doxorubicin, Bleomycin, Vinblastine and Dacarbazine (ABVD) chemotherapy (CTh) and involved field radiation therapy (IFRT) in the management of early stage unfavourable Hodgkin's Lymphoma.

Materials and Methods: One hundred and fifty one patients treated with 4−6 cycles of ABVD followed by IFRT were included. There were 120 (79.5%) males. The commonest histological subtype was mixed cellularity (43%). Majority had stage IIAX disease. The IFRT doses were 25.2 Gy/ 14 fractions and 34.2 Gy/ 19 fractions for adults with complete response (CR) and partial response (PR) respectively, while the doses were 19.8 Gy/ 11 fractions and 30.6 Gy/ 17 fractions respectively for children.
Results: After a median follow-up of 50 months, the 8 year progression free survival (PFS) and overall survival (OS) were 84.5% and 89.5% respectively. On univariate analysis, prognostic factors found to have significant impact on PFS were age more than 20 yrs, nodular lymphocyte predominant histology, presence of extra-nodal disease, response to primary treatment and stage. Presence of extra-nodal disease had a significant impact on OS. On multivariate analysis, nodular lymphocyte predominant histology ($p = 0.008$) and the response at 3 months after treatment ($p = 0.000$) had a significant impact on PFS while none had a statistically significant impact on OS. CTh related acute pulmonay toxicity was documented in 21.4% patients receiving 6 cycles of ABVD compared to 4.8% in those receiving 4 cycles ($p = 0.041$). Grade I and II dermatitis for patients receiving IFRT doses more than 25.2 Gy or less were 79.6% and 76% respectively, while the corresponding incidence of mucositis was 10.5% and 5.6% respectively.
Conclusion: The combination of four cycles of ABVD followed by IFRT results in optimal outcomes in terms of disease control and treatment related toxicities.
No conflict of interest.

3641 POSTER

Role of response evaluation criteria in local disease control after combined therapy of Hodgkin's lymphoma

P. Datsenko[1], T.R. Izmailov[1], S.V. Golub[1], G.A. Panshin[1]. *[1]Russian Scientific Center of Roentgenoradiology, Department of Clinical Oncology, Moscow, Russian Federation*

Purpose/Objective: Study the role of response evaluation criteria after first-line chemotherapy in the subsequent occurrence of nodal recurrence of Hodgkin's lymphoma (HL).
Materials and Methods: Four hundred thirty-nine patients with HL stage I − IV according to the Ann Arbor classification were treated with ABVD or BEACOPP or CEA/ABVD (lomustine, etoposide, adriamycine, bleomycine, vinblastine and dacarbacine) regimen chemotherapy and IFRT or EFRT or STNI radiotherapy. New, effective classification Response Evaluation Criteria in Hodgkin's lymphoma was invented in RSCRR:
– CR or PR⩾80% (adequate response);
– PR 0−79% (an inadequate response);
– Progression after first-line chemotherapy.
The estimation of Percent Response Evaluation is based on a zone with the least effect after chemotherapy. Median doses in initially involved areas were 36 Gy (0−44), in initially uninvolved areas − 0 Gy (0−44).
Results: After a median observation time of 4.1 years, according to logistic regression analysis in group 'CR or PR⩾80%' (after first-line chemotherapy) percent of nodal recurrence in initially involved areas with RT was 1.2 percent (12 of 856), in initially uninvolved areas without RT − 1.4 percent (10 of 844). Probability of nodal recurrence in initially involved areas in patients from group 'PR 0−79%' in comparison with group 'CR or PR⩾80%' was 10.2 times higher in zones with regression more than 80% (95 % CI: 11.750–50.844, $p = 0.000$), in zones with regression: 0−79% − 39.6 times higher (95 % CI: 18.348–85.380, $p = 0.000$), in initially uninvolved areas without RT − 10.2 times higher (95 % CI: 4.738–22.138, $p = 0.000$). Probability of nodal recurrence in patients with progression after first-line chemotherapy was 59.7 times higher (95 % CI: 28.898–123.408, $p = 0.000$) in comparison with 'CR or PR⩾80%' group.
Conclusions: Correct allocation of groups with 'CR or PR⩾80%' and 'PR 0−79%', after first-line chemotherapy, is extremely important for following RT planning. These approach offer wide perspectives for Hodgkin's lymphoma treatment.
No conflict of interest.

3642 POSTER

Could the association of new systemic target treatment with helical tomotherapy become the standard of treatment of solitary plasmacytoma?

N. Wiazzane[1], D. Bouscary[2], C. Plancher[1], J. Tamburini[2], Y. Kirova[1]. *[1]Institut Curie, Radiotherapy, Paris, France; [2]Cochin Hospital, Hematology, Paris, France*

Purpose: To report the preliminary results and the tolerance profile and efficacy of the association of new systemic target treatment and Helical Tomotherapy (HT) in patients with solitary plasmacytoma. This pilot study was conducted with aim to decrease the toxicity (using HT) and improve the therapeutic results.
Patients and Methods: Five males and one woman with biologically, histologically (bone marrow biopsy) and radiological (total body bone magnetic resonance imaging (MRI) and 18 FDG PET scan) confirmed solitary plasmacytoma have been treated in our department between September 2009 and September 2011 using a concomitant HT with a systemic targeted treatment. The total dose was 40 Gy in 20 fractions. Four patients received 4 cycles concurrent lenalidomide-dexamethasone association, 1 patient was treated with concomitant bortezomib-dexamethasone and one patient was treated with bortezomib-dexamethasone and cyclophosphamide. All toxicities were described using the Common Terminology Criteria for Adverse Effects v3.0. Clinical assessment was performed weekly during RT and monthly after the end of irradiation. The evaluation MRI was realized 6 weeks and evaluation PET scan 4 months after the RT.
Results: The tolerance profile was excellent with no higher than grade 1 toxicity observed except for one patient who presented a grade 3 leucopenia related to the systemic treatment. Three patients over six underwent a partial radiological response, four had a complete TEP/FDG response and five over six patients had a complete relief of symptoms 4 months after treatment. With a median follow up of 18 months, five of six patients are controlled clinically, radiologically and biologically.
Conclusion: HT concomitant with bortezomib or lenalidomide has been used in the treatment of solitary plasmacytoma with an excellent response rate and an excellent acute tolerance profile. Longer follow-up is needed to assess the late toxicity and the rate of progression to multiple myeloma.
No conflict of interest.

3643 POSTER

Positron emission tomography guided intensity modulated radiotherapy as a fourth line treatment option for intermediate grade non-Hodgkin's lymphoma

S. Susheela[1], S. Revannasiddaiah[1], M. Gupta[2], A. Basavalingaiah[1], K. Kallur[3], G. Mallarajapatna[4], S. Muzumder[1], N. Madhusudhan[1], R. Bilimagga[1], S. Patil[5]. *[1]HealthCare Global Enterprises Ltd, Radiation Oncology, Bangalore, India; [2]HealthCare Global Enterprises Ltd, Anesthesiology, Bangalore, India; [3]HealthCare Global Enterprises Ltd, Nuclear Medicine, Bangalore, India; [4]HealthCare Global Enterprises Ltd, Radiology, Bangalore, India; [5]HealthCare Global Enterprises Ltd, Medical Oncology, Bangalore, India*

Background: After failure despite three lines of systemic treatments which include chemotherapy and targeted therapy, the prognosis among non-Hodgkin's lymphoma (NHL) patients is dismal. This study explores the outcomes with the use of fluorine-18 fluorodeoxyglucose (^{18}F-FDG) positron emission tomography (PET) guided intensity modulated radiotherapy (IMRT) as a fourth-line treatment option among patients with intermediate grade NHL.
Material and Methods: On a retrospective review of NHL patients' hospital records (excluding stage-IV) treated in the institution from January 1 2010 to December 31 2012, a total of 26 patient records were found eligible for analysis- having been treated with IMRT to atleast 45 Gray (Gy) to the *PET-TV* (PET-treatment volume: computed by adding a 1.5 cm margin over the PET defined gross tumour volume) whilst having relapse/residual disease despite three prior lines of systemic therapies. Also, patients with a PET-TV >500cc had ben excluded from analysis. Responses were classified as per the PERCIST criteria (*Wahl RL et al, J Nucl Med 2009*). Progression free survival (PFS) and overall survival (OS) at 3 months and 6 months were noted. The computed tomography (CT) images of each patients were retrieved and *CT-TV* (CT-treatment volume, computed by adding a 1.5 cm margin over the CT defined gross tumour volume) were calculated so as to facilitate comparisons with the *PET-TV*.
Results: Complete metabolic response was achieved in 88.5% (n = 23) and partial metabolic response was achieved in 11.5% (n = 3) of patients, thus amounting to an overall response rate of 100%. The median followup was 14 months. The PFS at 3 & 6 months were 84.6% & 38.5% respectively. The OS at 3 & 6 months were 100% and 76.9% respectively. The *PET-TV* was significantly larger than the *CT-TV* in terms of mean volume (217cc vs. 126cc, $p<0.0001$; *paired samples t-test*).
Conclusions: After failure of three lines of prior systemic treatment in patients with intermediate grade non-stage-IV NHL, the use of ^{18}F-FDG-PET-guided IMRT with curative intent holds the potential to offer durable responses and meaningful survival benefits. The use of PET for target delineation ensures a more comprehensive coverage of disease foci in comparison to CT based delineation. Prospective trials to confirm these findings are justifiable.
No conflict of interest.

3644 POSTER

Nilotinib vs dasatinib in patients with newly diagnosed chronic myeloid leukaemia in chronic phase: an indirect adjusted comparison of updated 36 months follow-up of ENESTnd and DASISION trials

J. Félix[1], D. Ferreira[2], B. Vandewalle[3]. [1]*Exigo Consultores Lda, Director, Lisboa, Portugal;* [2]*Exigo Consultores Lda, Outcomes Research, Lisboa, Portugal;* [3]*Exigo Consultores Lda, Quantitative Methods, Lisboa, Portugal*

Background: Prognosis for patients with Chronic Myeloid Leukaemia (CML) has evolved dramatically since the introduction of imatinib (IMT) in the market. Nilotinib (NIL) and dasatinib (DAS) are second-generation tyrosine kinase inhibitors inducing deeper molecular responses than IMT in newly diagnosed chronic-phase CML patients. Clinical trials supporting this evidence were titled ENESTnd (NIL 300 mg BID or NIL 400 mg BID or IMT 400 mg QD) and DASISION (DAS 100 mg QD or IMT 400 mg QD). In the absence of head-to-head clinical trials between NIL and DAS the present analysis performs an indirect adjusted comparison of these second-generation tyrosine kinase inhibitors using data from the recently updated 36 months follow-up of DASISION and ENESTnd trials.
Methods: Outcomes analysed were: major molecular response (MMR, $\leqslant$0.1% BCR-ABL); progression to accelerated or blastic phase (PAB); overall survival (OS); discontinuation due to adverse events (AE). The Bucher *et al*. (1999) method for indirect comparison was used to pool results from the DASISION and ENESTnd trials in order to assess NIL 300 mg BID and DAS 100 mg QD relative clinical efficacy and tolerability having IMT 400 mg QD as common comparator. Hazard ratios (HR) and odds ratios (OR) and corresponding 95% confidence intervals (95% CI) are presented for outcomes based on rates and proportions, respectively.
Results: The rate of MMR at 36 months is estimated to be significantly higher in patients CML treated with NIL compared to DAS (HR = 1.36: 95% CI [1.01; 1.85]). The odds of progression to accelerated or blastic phase with NIL is estimated to be 32% lower than in patients treated with DAS (OR=0.68: 95% CI [0.22; 2.10]). Nilotinib is estimated to reduce the risk of death from any cause by 12% relative to dasatinib (HR of OS=0. 88: IC95% [0.33; 2.31]). Discontinuation due to adverse events is also estimated to be lower with NIL treatment (OR = 0.50: 95% CI [0.21; 1.18]).
Conclusion: This indirect adjusted comparison suggests that nilotibib 300 mg BID is more efficacious and better tolerated than dasatinib 100 mg QD for the treatment of patients with newly diagnosed chronic myeloid leukemia in chronic phase.
No conflict of interest.

3645 POSTER

Low dose cytarabine with or without anthracycline in the induction treatment of elderly patients with acute myeloid leukemia

F.M. Abu-Taleb[1], O.M. Mansour[2], O.L.A.M.R. Khorshid[2], A. Abdel Raheem[1]. [1]*Zagazig University Hospital, Medical Oncology & Hematology, Zagazig, Egypt;* [2]*National Cancer Institute Cairo University, Medical Oncology, Cairo, Egypt*

Background: AML is disease of elderly with overall survival (OAS) less than 12 months despite improved supportive care and novel agents due to both host and disease biology that affect the ability to tolerate chemotherapy. Standard remission induction therapy achieve complete remission (CR) rates 40% in older AML adults at a price of a high treatment-related mortality that approaches 25%.
Aim: Comparing the outcome of low dose Cytarabine (LDAC) plus Doxorubicin versus LDAC in elderly AML patients.
Methods: This is a prospective randomized trial where 90 patients with de novo AML aged $\geqslant$60 years, ECOG Performance status $\leqslant$2, left ventricular ejection fraction $\geqslant$60%, adequate liver & renal function were randomized to receive induction either with LDAC 20 mg/m^2 s.c. D1−14 (arm 1) or with LDAC 20 mg/m^2 s.c. D1−14 + Doxorubicin 25 mg/m^2 i.v. D1−2 (2+14 regimen) (arm 2), Patients who achieve CR in both groups received consolidation therapy in the form of three more cycles of the induction regimen 2+14 regimen, with 45 patients in each arm, with a 1ry end point of CR, OAS and 2ry endpoints of quality of life, hospital admission for blood product transfusions. NCCN response criteria were used to define response to induction therapy, toxicity was recorded according to WHO criteria.
Results: Patients characteristics were evenly matched with higher RR 53.4% in arm 2, compared to 26.6% in arm 1 with higher CR 7 (15.6%) patients in arm 2 compared to 2 (4.4%) patients in arm 1 p = 0.027, toxic early death was 2.2% in arm 1 compared to 11% in arm 2, regarding toxicity neutropenia was higher in arm 2 with grade 3 in 66.7%, grade 4 in 33.3% compared to arm 1 where 46.7% had grade 2, 42.2% grade 3, 11.1% with grade 4. The median survival for arm 2 was 9 months, compared to 6 months in arm 1 after a follow up period of 24 months. There were significant reduction in the number of patients who were admitted to the hospital for blood transfusion 8 (17.7%) patients in arm 2 compared to 27 (60%) patients in arm 1. Significantly shorter admission duration for transfusion in favor of arm 2 P<0.001.
Conclusion: We met the 1ry end points with a higher CR and longer OS with the 2+14 arm 2 regimen compared to LDAC arm 1 with improvement in quality of life in form of reduction in hospital admission for blood transfusion.
No conflict of interest.

Effects of haematopoietic stem cell transplantation on clinical presentation of bloodstream infections in neutropenic patients with haematological malignancy

K. Okinaka[1], T. Fukuda[2], K. Tobinai[3]. [1]*National Cancer Center Hospital Tokyo, Division of General Internal Medicine, Tokyo, Japan;* [2]*National Cancer Center Hospital Tokyo, Division of Haematopoietic Stem Cell Transplantation, Tokyo, Japan;* [3]*National Cancer Center Hospital Tokyo, Division of Haematology, Tokyo, Japan*

Background: Febrile neutropenia (FN) is a serious adverse event in patients with haematological malignancy (HM). Haematopoietic stem cell transplantation (HSCT) may affect the presentation and outcomes of bloodstream infection (BSI) in neutropenic HM patients. We investigated the clinical characteristics and outcomes of BSI in these patients on the basis of their HSCT history.
Patients and Methods: We retrospectively reviewed the medical records of FN patients with positive blood cultures at the National Cancer Center Hospital from January 1, 2008 through March 31, 2012. Patients with possibly contaminated cultures were excluded and logistic regression analysis was used to identify factors associated with mortality.
Results: In total, 203 microorganisms were identified in 192 patients (acute myeloid leukaemia, 85; malignant lymphoma, 47; acute lymphocytic leukaemia, 18; and myelodysplastic syndrome, 14) including 70 post-transplant (PT) and 122 non-transplant (NT) patients. The proportion of patients aged <60 years (p <0.01) or with FN duration $\geqslant$10 days (p = 0.01) was significantly higher among PT patients than NT patients. The ratio of Gram-positive cocci to Gram-negative rods (PT, 2.5; NT, 1.5) was comparable between the groups, however, and coagulase-negative staphylococci were the leading pathogens (PT, 32%; NT, 25%) in both groups. Oral mucositis and catheter-related infections were most commonly associated with suspected bacterial entry in PT and NT patients, respectively. Thirty patients died from infections within 30 days of BSI onset with PT patients exhibiting a higher mortality rate (p = 0.10). The mortality rate was significantly higher among PT patients with acute myeloid leukaemia than their NT counterparts. Nine of 37 such PT patients died (24%) compared to three of 48 such NT patients (6%) (p = 0.03). Death-related factors identified in univariate analysis included lower Multinational Association for Supportive Care in Cancer (MASCC) scores (p <0.01), no antacid use (p = 0.02), altered mental status (p <0.01), higher serum total bilirubin (p <0.01) or creatinine (p <0.01) levels, lower serum albumin levels (p <0.01), tachycardia (p <0.01), intensive care unit stay (p <0.01), longer duration between pathogen detection and the onset of neutropenia (p = 0.04), higher European Cooperative Oncology Group performance status (p = 0.03) and steroid (p <0.01) or vasopressor use (p <0.01). Multivariate analysis identified lower MASCC scores (p <0.01; odds ratio [OR] = 1.29; 95% confidence interval [CI]: 1.12–1.49), altered mental status (p <0.01; OR = 8.06; 95% CI: 2.61–24.9) and use of vasopressors (p <0.01; OR = 1.03; 95% CI: 2.22–47.6) as independent mortality predictors.
Conclusion: The clinical presentation of BSI in FN patients with HM may be affected by HSCT history and several risk factors were identified associated with fatal outcomes. Identification of high-risk patients, suspicion of BSI in FN patients and early appropriate therapy will be required to improve mortality rates associated with these infections.
No conflict of interest.

3647 POSTER

Evaluation of safety, tolerability and efficacy of Temsirolimus in patients with relapsed or refractory mantle cell lymphoma (rel/refr MCL) in routine clinical practice

G. Krekeler[1], C. Herzberg[1], M. Dreyling[2], G. Hess[3], D. Kalanovic[1]. [1]*Pfizer GmbH, Medical Affairs, Berlin, Germany;* [2]*Ludwig-Maximilians-Universität, Medizinische Klinik III, München, Germany;* [3]*Johannes-Gutenberg Universität, III.Medizinische Klinik, Mainz, Germany*

Background: Temsirolimus (TEMS), an mTOR-inhibitor, is approved the EU for the treatment of patients (pts) with relapsed or refractory (rel/refr) MCL A pivotal study demonstrated significantly longer progression free survival with TEMS (175 mg weekly for 3 weeks followed by 75 mg weekly) in rel/refr MCL pts compared to investigator's choice therapy (4.8 mo vs 1.9 mo; P =. 0009). To evaluate safety and efficacy of TEMS in an

unselected patient population during clinical routine, a prospective non-interventional study with TEMS in rel/refr MCL pts is useful. Here we report on interim results of the study.
Methods: A German multicenter registry for rel/refr MCL pts treated with TEMS was started in Oct 2009 (NCT00700258). Objectives are evaluation of the safety profile of TEMS, tolerability and anti-tumor activity of TEMS, patients' profile and the sequence of systemic therapies.
Results: From Oct 2012 to Mar 2013, 12 active centers recruited 29 pts. Baseline characteristics are available for 29 pts: 72.4% male; median age 73.0 yrs; ECOG PS 0 or 1 in 79.3%, ECOG PS 2 in 20.7% of the pts; MIPI score: 20.7%, 27.6%, and 51.7% of the pts are classified as low, intermediate and high risk at the time of enrollment, bone marrow involvement: 44.8% of the pts. Median time between diagnosis and start oft treatment with TEMS is 3.1 yrs. The median number of prior therapies is 5 with 65.5% treated in $\geqslant 5^{th}$ line. Most common adverse events are thrombocytopenia, anemia and diarrhea. Severe adverse events (drug related) are general, metabolic, psychiatric disorders and infections, skin and renal/urinary disorders (in 2 pts each).
Efficacy analyses are available for 21 of 27 patients and show an objective response in 5 pts (1CR and 4 PR,18.5%), a clinical benefit in 13 pts (48.1%) and PD in 8 pts (29.6%). Median PFS is 4.1 months.
Conclusions: This registry was started to evaluate the safety and efficacy of TEMS in pts with rez/refr MCL in the clinical routine. Though the here included pts are more heavily pretreated, TEMS shows a predictable, manageable tolerability profile and efficacy remains comparable with phase III data.

Multiple myeloma with light chain-induced acute renal failure − role of bortezomib-dexamethasone & cyclophosphamide-thalidomide & dexamethasone: A prospective randomized study

S. Sahai[1], L. Kumar[1], V. Raina[1], A. Sharma[1], R. Gupta[2], S. Mahajan[3], S. Thulkar[4], A. Dinda[5]. *[1]All India Institute of Medical Science, Medical Oncology, Delhi, India; [2]All India Institute of Medical Science, Lab Oncology, Delhi, India; [3]All India Institute of Medical Science, Nephrology, Delhi, India; [4]All India Institute of Medical Science, Radiology, Delhi, India; [5]All India Institute of Medical Science, Pathology, Delhi, India*

Background: We prospectively compared Cyclophosphamide, Thalidomide and Dexamethasone (CTD) with Bortezomib and Dexamethasone (BD) as induction therapy for patients of Multiple Myeloma (M.M.) with light chain induced renal insufficiency (RI).
Methods: Between February 2011 and September 2012, 43 patients (median age=56 years; range 40−77 years) received either oral Cyclophosphamide 100 mg/m^2 for 7 days, Thalidomide 100 mg daily &oral dexamethasone 40 mg/wk q 4 weekly (n = 21) or Inj. Bortezomib 1.3 mg/m^2 iv and oral dexamethasone 40 mg both weekly q 4 weekly (n = 22). Patients were assessed for renal and myeloma response as per International Myeloma Working Group Criteria. Analysis was done as intention to treat.
Results: Major renal response (CR+ PR) was observed in 58.8% of patients in CTD arm & 45% in BD arm, respectively, p = 0.14. There was a trend for early renal response in BD arm. Major myeloma response was seen in 52.9% in CTD & 80% in BD arm, p = 0.44. 5 out of 11 patients became dialysis free after treatment.

Table 1. Renal & myeloma responses in study group

	CTD Arm (n = 17)	BD arm (n = 20)	p value
Renal response			0.32
CR	5 [29.4%]	5 [25%]	
PR	5 [29.4%]	2 [10%]	
MR	3 [17.6%]	8 [40%]	
Median time to renal response (days)	88 (31–153)	69 (30–125)	0.43
Myeloma response			0.11
CR	5 [29.4%]	5 [25%]	
PR	4 [23.5%]	11 [55%]	
SD	8 [47.1%]	4 [20%]	

Toxicity was not significantly different between two arms. Anemia was commonest hematological toxicity; 23% in CTD & 15% in BD. Non-hematological toxicities included- constipation (53%) in CTD and diarrhea (30%) in BD arm. On Univariate analysis − serum LDH >250 U/L (CTD Arm) was associated with inferior renal response, p = 0.009 & bone marrow plasma cells >40% was associated with inferior myeloma response, p = 0.002. Serum LDH >300U/L was associated with inferior myeloma response in BD arm, p = 0.008. A total of 11 patients died, 6 within 8 weeks of accrual. Patients with ECOG performance status $\geqslant 3$ (p < 0.008) and requirement for dialysis (p < 0.004) were at high risk for early mortality. At a median follow up of 7.5 months, 13 patients are alive in CTD and 16 in BD arm.
Conclusion: Renal and myeloma responses were comparable in CTD and BD arm in present study.
No conflict of interest.

3649 POSTER

Impact of active surveillance, chlorambucil and intensive chemo and immunotherapy on health related quality of life in patients with chronic lymphocytic leukemia in the Netherlands

E. Van den Broek[1], S. Oerlemans[2], E. Posthuma[3], M. Nijziel[4], J.W. Coebergh[5], L. Van de Poll-Franse[2]. *[1]Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands; [2]Tilburg University, Center of Research on Psychology in Somatic Diseases (CoRPS), Tilburg, Netherlands; [3]Reinier de Graaf Group, Internal Medicine, Delft, Netherlands; [4]Máxima Medical Center, Internal Medicine, Veldhoven/Eindhoven, Netherlands; [5]Erasmus Medical Centre, Public Health, Rotterdam, Netherlands*

Background: In the Netherlands, each year, more than 700 patients are diagnosed with Chronic Lymphocytic Leukemia (CLL), 70% of them is older than 65 years. Survival time is highly variable (from a few months up to decades), but as response rates improve, the number of CLL patients that live long after their diagnosis is rising. This underpins health related quality of life (HRQoL) as a relevant endpoint. Few studies have investigated HRQoL in CLL patients, and most were randomized clinical trials. As a consequence, patients with early stage CLL, elderly patients and patients with comorbidities were underrepresented. The aim of the present study was therefore to assess HRQoL in a population-based setting that includes these previously underrepresented patients.
Methods: 175 patients diagnosed with CLL between 2004 and 2011 and registered in the Eindhoven Cancer Registry received a questionnaire regarding HRQoL (which included the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire-Core 30 (EORTC QLQ-C30)). 136 of them responded (78%).
Detailed data on stage, treatment and adverse events were collected within the scope of the Population-based HAematological Registry for Observational Studies (PHAROS); an extension of the Netherlands Cancer Registry.
The outcomes were compared to an age-and sex-matched norm population. Analysis of covariance (ANCOVA) was carried out to investigate the differences in HRQoL between types of treatment and between patients on and off treatment after adjustment for sex, age and comorbidity.
Results: Patients treated for CLL reported significantly worse HRQoL than the norm population (p < 0.01 and clinically important differences (CID)), while no difference was observed between the norm population and patients under active surveillance.
We saw more and larger differences between patients treated with chlorambucil and patients under active surveillance than between patients treated with other chemo- and/or immunotherapy and those under active surveillance.
Both patients on and off treatment scored worse on all functional scales (except cognitive functioning), fatigue and sleeping problems compared to the norm population (p < 0.01 and CID). Cognitive functioning was the only scale on which patients on treatment reported statistically and clinically important worse scores than patients off treatment.
Conclusion: Since starting treatment in CLL patients has a drastic and long-lasting effect on HRQoL, it seems wise to be restrained in starting treatment, especially in asymptomatic patients, despite the recent success in prolonging survival.
No conflict of interest.

3650 POSTER

High expression of Bcl-2 predicts poor outcome in diffuse large B-cell lymphoma (DLBCL) patients (pts) treated with CHOP-based chemotherapy

M. Ahn[1], J. Choi[1], S. Kang[1], J. Han[2], J. Kim[2], H. Lee[1], S. Jeong[1], J. Park[1]. *[1]Ajou University Hospital, Hematology-Oncology, Suwon, South Korea; [2]Ajou University Hospital, Pathology, Suwon, South Korea*

Background: We evaluated the prognostic significance of apoptosis-related proteins in DLBCL pts treated with cyclophosphamide/doxorubicin/vincristine/prednisone (CHOP) chemotherapy with or without rituximab (R).

Methods: Pretreatment tumor biopsy specimens from 111 pts (stage I: 15, II: 29, III: 34, IV: 33 pts) with DLBCL were analyzed for Bcl-2, Bcl-6, Topoisomerase-II (Topo-II), β-tubulin and p53 proteins expression by immunohistochemistry. Thirty-nine pts were treated with CHOP regimen, while 72 pts with R-CHOP.
Results: The median follow-up duration was 77 months (14–136 months) in survivors. In univariate analysis, 5-year OS of pts with high expression of Bcl-2 was significantly inferior compared to that of pts with low expression (42% vs 72%, $p = 0.0013$). In addition, high expression of Bcl-6 ($p = 0.296$), p53 ($p = 0.775$), Topo-II ($p = 0.588$) and β-tubulin ($p = 0.627$) was not associated with outcome of pts. In terms of chemotherapy regimen, high expression of Bcl-2 was associated with poor outcome in R-CHOP group ($p = 0.007$), without significant correlation in CHOP group ($p = 0.264$). In multivariate analysis, high expression of Bcl-2 was a significant independent prognostic factor of poor OS ($p = 0.023$) along with high International Prognostic Index (IPI) score ($\geqslant 3$) ($p < 0.006$) in R-CHOP group. Furthermore, in pts with low IPI score ($n = 71$), high expression of Bcl-2 correlated with poor outcome both in all pts ($p = 0.021$) and R-CHOP group ($p = 0.042$) without significant association in high IPI score pts ($p = 0.253$).
Conclusions: High expression of Bcl-2 may be a useful prognostic factor in DLBCL pts treated with R-CHOP, especially in cases of low IPI score.
No conflict of interest.

3651 POSTER

Prognostic relevance of follicular lymphoma international prognostic index (FLIPI) in Korean follicular lymphoma patients: Comparison of FLIPI and FLIPI2

C.H. Maeng[1], S.W. Ahn[2], S.Y. Ryu[2], S. Han[2], Y.H. Ko[3], W.S. Kim[4], S.J. Kim[4]. *[1]Kyung Hee University Medical Center, Haemato-Oncology, Seoul, Korea; [2]Samsung Medical Center, Division of Education and Training, Seoul, Korea; [3]Samsung Medical Center, Pathology, Seoul, Korea; [4]Samsung Medical Center, Haemato-Oncology, Seoul, Korea*

Introduction: Follicular lymphoma (FL) is one of the most common types of Non-Hodgkin's lymphoma (NHL) among mature B cell neoplasm. The incidence of FL in Korea showed increased frequency. Prognostic index with validity and reproducibility is essential to plan a treatment strategy and mange patients with FL because of its heterogeneity and diverse clinical course. Follicular Lymphoma International Prognostic Index (FLIPI) was first introduced, and FLIPI2 using easily accessible clinical data was newly developed after rituximab-era. Even if there are several studies validating the FLIPI or FLIPI2 for FL, all of the studies were performed using western populations. It is still necessary that validation of FLIPI and FLIPI2 in Korean population where the epidemiology of FL is somewhat different with that of western countries.
Method and Materials: We aimed to evaluate the validity the FLIPI and FLIPI2 on our retrospective cohort of patients with FL. From 1995 to 2012, we collected clinical data for scoring FLIPI and FLIPI2 in Samsung Medical Center, Korea. We stratified patients as three categories according to FLIPI or FLIPI2 scores: low-, intermediate-, and high-risk group. Distribution of each parameter based on risk groups was analyzed. And we searched relevant factors in respect to patients' outcome. Finally Progression-free survival (PFS) and overall survival (OS) were estimated between three groups using Kaplan–Meier curve to evaluate the role of FLIPI/FLIPI2. If there is any statistical significance between any groups, we planned to discriminate which group has statistical significance on survival among three groups.
Results: Total number of target population was 125 patients. Median follow-up duration is 5.1 year (1.3–13.9). Median age was 53 years old. Using FLIPI score, 71 patients (56.8%) were in LR group, 27 patients (21.6%) in the IR group, and 27 (21.6%) in the HR group. In terms of FLIPI 2, 36 patients (28.8%) were in LR group, 39 patients (31.2%) in the IR group, and 12 patients (9.6%) in the HR group. 38 patients were unknown due to unavailable data of 38 patients. Using FILIPI, there was significant longer PFS and OS in LR group compared to IR or HR group ($p < 0.0001$). However, neither PFS nor OS showed statistical difference between IR and HR group ($p = 0.472$ and 0.648, respectively). In terms of FLIPI 2, there were same statistical patterns as in FLIPI, LR group was shown to have longer duration of PFS and OS compared to those of IR group ($p = 0.001$ and 0.025, respectively). There was no statistical difference between IR and HR group, either ($p = 0.41$ and 0.49, respectively). Whether patients received rituximab-based chemotherapy or not was not found to be responsible for discriminating power of FLIPI/FLIPI2.
Conclusions: Based on our study, FLIPI and FLIPI 2 are likely to discriminate LR patients from higher risk populations. However, stratification of IR and HR group is shown to be somewhat ambiguous, suggesting that FLIPI/FLIPI2 has limited role of discriminating patients with or without HR in Korean populations.
No conflict of interest.

3652 POSTER

Efficacy and safety of cladribine: Subcutaneous versus intravenous administration in hairy cell leukemia

T. Yakout[1], G. Mosaad[2], A. Namour[2], R. Malek[3], O. Khorshid[2]. *[1]Cairo Oncology Center, Cairo, Egypt; [2]National Cancer Institute, Medical Oncology, Cairo, Egypt; [3]Faculty of Medicine Cairo University, Clinical Oncology, Cairo, Egypt*

Background: Hairy cell leukemia (HCL) is rare B-cell lymphoproliferative disorder. Its treatment has evolved from splenectomy with time to failure (TTF) of 19 months to Cladribine that increased complete remission (CR) rate to 90%, with only small percentage of patients relapsing at 30 months. Cladribine (CDA) is originally administered intravenously as continuous infusion for 7 days; Subsequently, it was administered subcutaneously. This study aims at comparing efficacy and toxicity of Subcutaneous (SC) versus Intravenous (IV) administration of CDA in treatment of HCL.
Material and Methods: This retrospective study included HCL patients presented to National Cancer Institute and Nasser Institute, Cairo, Egypt, during period 2004–2010. Included patients received CDA as 1st or 2nd line with minimum follow up of 12 months. All files were reviewed for baseline clinical & laboratory parameters, route of administration, response, adverse events and survival.
Results: This study included 49 eligible patients, 41 patients received CDA as 1st line treatment, while 8 patients as 2nd line. Eighteen patients were treated by continuous IV infusion whereas 31 patients by SC injections. Both groups were comparable regarding baseline clinical and laboratory parameters with no statistically significant difference. At median follow up period of 33.5 months, complete remission rate was 94% in IV group versus 97% in SC group ($p = 0.691$); median TTF for IV group was 52.9 months while that for SC group was not reached ($p = 0.035$). The median time to achieve CR in both arms was similar. By analyzing different factors affecting TTF using multivariate analysis, route of administration proved to be the only statistically significant factor ($P = 0.006$). Regarding adverse events, there was no difference between both groups in hematological toxicities. IV route was associated with a significant higher incidence of mucositis ($p = 0.02$) and viral infections ($p = 0.01$). Hepatotoxicity and neurotoxicity were higher in SC group but difference was not statistically significant.
Conclusions: SC administration of cladribine is an alternative route to IV in treatment of HCL with similar response rate, longer time to treatment failure and better tolerability.
No conflict of interest.

3653 POSTER

Combination immunotherapy of indolent B-Cell non-Hodgkin's lymphoma (B-NHL) with R-CHOP regimen and recombinant interleukin-2 (rIL-2) "Roncoleukin®"

O. Kalenik[1], E.A. Zhavrid[1], N.V. Sachivko[1]. *[1]N.N. Alexandrov National Cancer Centre of Belarus, Chemotherapy, Minsk, Belarus*

Background: rIL-2 is the potential agent capable to increase the affect of rituximab in the treatment of indolent CD 20+ B-NHL, which is conformed in a number of pre-clinical and phase 2 clinical trials. However, this issue remains under investigation. The goal of the present study is to evaluate the effect of rIL-2 on the R-CHOP regimen in the first line treatment of indolent B-NHL.
Material and Methods: 39 patients with indolent B-NHL (9 low-grade follicular NHL, 20 lymphocyte NHL, 10 mantle cell NHL) were randomized ether in the group of R-CHOP or R-CHOP in combination with rIL-2. All patients had indications for treatment. 19 patients were treated with standard R-CHOP regimen (rituximab, vincristine, doxorubicin and prednisolone) and 20 patients received R-CHOP in the combination with rIL-2. Patients received rIL-2 at a dose of 0.5 MIU s.c. twice a day during days 1 to 5 or 1 MIU s.c. once a day during days 1 to 5. The primary and point of the study was progression-free survival (PFS).
Results: R-CHOP plus rIL-2 combination therapy was safe and generally well tolerated. The median follow-up in the R-CHOP and R-CHOP plus rIL-2 groups was 33.9 (range, 0.3−73.6) and 34.7 (range, 1.0−74.0) months, respectively. In each group 10 patients experienced clinical progression. The median survival in R-CHOP group was 31.2 months and 27.0 months in R-CHOP with rIL-2. The 5-year PFS rate was 38.0% and 36.5%, respectively.
Conclusion: The combination of R-CHOP and rIL-2 in the first line treatment of indolent B-NHL does not improve PFS.
No conflict of interest.

3654 POSTER

Combination of bendamustine and rituximab as salvage therapy for patients with relapsed or refractory chronic lymphocytic leukemia: Experience of single center in Russia

S. Semochkin[1], V.L. Ivanova[2], A.I. Lukina[3], L.A. Mukha[2], E.G. Arshanskaya[2], I.E. Lazarev[2], S.S. Kulikova[1], M.E. Pochtar[2], N.K. Huazheva[2], V.G. Markaryan[2]. *[1]Russian National Research Medical University n.a. N.I. Pirogov, Pediatric Oncology and Radiation Therapy, Moscow, Russian Federation; [2]City Clinical Hospital n.a. S.P. Botkin, Hematology, Moscow, Russian Federation; [3]Federal Research Center for Pediatric Oncology Hematology and Immunology, Adolescent Hematology, Moscow, Russian Federation*

The patients with fludarabine-refractory chronic lymphocytic leukemia (CLL) have short survival and limited treatment options. Refractory CLL is characterized a high incidence of unfavorable molecular and clinical features. Moreover these patients are also severely immunosuppressed and experience a high rate of infectious complications. Bendamustine is an alkylating agent with high activity against CLL and excellent tolerability. Several limited studies have shown encouraging results have been obtained using combination of bendamustine plusrituximab (BR) in patients with refractory CLL.

The aim of this study was to evaluate safety and clinical efficacy of combination BR in patients with relapsed and/or refractory CLL.

Patients and Methods: Twenty patients (15 males, 5 females) with relapsed and/or refractory CLL were included in this study during 01–09.2012. Seventeen (85%) patients received BR: bendamustine 90 mg/m^2 i.v.on days 1 and 2 combined with rituximab 375 mg/m^2 on day 0 of the first course (cycle 1) and 500 mg/m^2 during subsequent courses (cycles2−6). The doses of bendamustine were increased from 70 mg/m^2 to 90 mg/m^2 compared with previously published studies (Fisher K., et al.J Clin Oncol., 2011). Bendamustine only was administered at a dose of 100 mg/m^{2}on days 1 and 2 every 28 days in 3 (15%) cases of known resistance to rituximab.Treatment was planned for 6 cycles. The efficacy of treatment was assessedaccording to the guidelines International Working Group criteria for CLL.

Results: Median age of patients was 63.4 years (range, 52−77). Binet stage B was diagnosed in 10 (50%) of patients, stage C − 10 (50%). In 2 (10%) cases was documented del17p. Seven (35%) have relapses, that were sensitive to the last line of therapy, and13 (65%) were refractory. A median duration of history of CLL was 6.1 years (range, 1.3 to 12.3 years). The median number of lines of previous therapies was 2 (range, 1−6). The majority of patients previously received fludarabine − 15(75%), rituximab in combination with chemotherapy − 17 (85%) and as maintenance therapy − 9 (45%). The best response to previous therapy was complete response (CR) for 5 (25%), and partial response (PR) − 8 (40%), and stable disease (SD) − 5 (25%). Two (10%) patients were refractory to all previous treatments. With median follow-up time of 5.6 months of therapy with bendamustine all patients were alive. A median number of BR cycle were 4 (range, 2−6). The treatment response was assessed for 17 patients: ⩾ PR achieved 9 (53%), and only SD − 6 (35%). None of toxic deaths were reported. The key grade 3/4 toxicities were neutropenia − 5 (25%), anemia − 3 (15%), thrombocytopenia − 3 (15%) and infection − 1 (5%). Probability of achieving ⩾ PR was higher in patients who received less 3 lines of previously therapy ($r = 0.67$; $p = 0.004$) and in the case of relapse against refractory ($r = 0.61$; $p = 0.01$).

Conclusion: Combination of bendamustine plus rituximab is effective salvage treatment for relapsed or refractory CLL afterfludarabine-containing regimens.

No conflict of interest.

3655 POSTER

Brentuximab vedotin (SGN-35) in Hodgkin's lymphoma patients with relapsed after autologous peripheral blood stem-cell transplantation

G. Erdem[1], N. Karadurmus[1], S. Ozaydin[1], A.O. Karacalioglu[2], C. Yeginer[3], M. Ozturk[1], S. Ataergin[1], O. Nevruz[4], T. Cetin[4], F. Arpaci[1]. *[1]Gulhane School of Medicine, Medical Oncology, Ankara, Turkey; [2]Gulhane School of Medicine, Nuclear Medicine, Ankara, Turkey; [3]Gulhane School of Medicine, Public Health, Ankara, Turkey; [4]Gulhane School of Medicine, Hematology, Ankara, Turkey*

Background: Approximately 15 to 30% of patients with Hodgkin's lymphoma (HL) do not have a long-term remission with conventional therapy. Autologous peripheral blood stem-cell transplantation (APBSCT) represents a potentially curative treatment for some patients with recurrent or progressive HL after failure of initial combination chemotherapy. Unfortunately, APBSCT is only effective in approximately 50% of such patients. Brentuximab vedotin comprises an anti-CD30 antibody conjugated by a plasma-stable linker to the potentantial microtubule agent, monomethyl auristatin. Brentuximab vedotin selectively induces apoptotic death of CD30+ cells.

Methods: We evaluated the efficacy and safety of brentuximab vedotin in patients (pts) with relapsed HL after APBSCT. Pts received brentuximab vedotin1.8 mg/kg q3 weeks (wks) as a 30 minute out patient IV infusion for upto 16 cycles. The primary endpoint was the objective response rate (ORR) and toxicity.

Results: Ten pts were enrolled; eight pts were male and median age was 26 yrs (range, 22−30 yrs). Pts had received a median of 4 (range 3−5) prior cancer-related systemic therapies excluding APBSCT. Fifty percent of pts had primary refractory disease and 80% had not responded to their most recent prior therapy. We evaluated all pts every three cycles. After 6 cycles of therapy, tumor regression occurred in 80% of patients and the overall objective response rate was 80% (n = 8), with partial remissions (PRs) in 7 pts. and complete remissions (CRs) in 1 pt. The most common treatment-related adverse events (AEs) of any grade were alopecia, abdominal pain, fatigue, insomnia and diarrhea. AEs ⩾ grade 3 occurred in ⩾60% of pts were fatigue, insomnia artralgia and diarrhea.

Conclusions: With manageable AEs, single-agent brentuximab vedotin induced objective responses in 80% of pts with relapsed HL after APBSCT. Brentuximab vedotin is effective in the early period of treatment. This agent can be considered as a method of bridge treatment prior allogeneic stem cell transplantation.

No conflict of interest.

Thyroid lymphomas − a study of 32 cases from a single centre

S. Kombath Payini[1], G. Narayanan[1], A. Surendran[1], K. Ratheesan[2]. *[1]Regional Cancer Centre, Medical Oncology, Trivandrum, India; [2]Regional Cancer Centre, Radiation Oncology, Trivandrum, India*

Background: Extra nodal involvement in Non Hodgkin's lymphoma (NHL) can occur in around 25−30 % of cases. But thyroid as an extra nodal site is rare. Here we present our experience with this disease.

Aim: To study the presentation, treatment and survival of patients with NHL of the thyroid gland.

Materials and Methods: Thirty two patients with NHL of the thyroid was seen and treated by us at Regional Cancer Centre, Trivandrum, India during the period 2000–2009. The clinical and treatment details of these patients were analysed and survival data collected.

Results: Among 32 cases, there were 16 males and 16 females. The median age at presentation was 62 years (range 31−77 yrs). The predominant symptoms were swelling of the neck (26), stridor/ dyspnoea (16), and hoarseness (5). The median duration of symptom was 4 months. Lymph nodes of the neck was palpable in 9, and 2 had B symptoms. Bone marrow was positive in 2 cases. The Ann Arbor stage was I in 19, II in 9, III in 2, and IV in 2. The histopathology subtypes were Diffuse Large B cell in 12, MALT in 4, follicular large cell in 3, diffuse mixed in 2 and one each of marginal zone, burkitt and the subtype was not specified in 9 cases. Two patients had NHL in association with Hashimoto's thyroiditis and papillary carcinoma of thyroid. CD20 was positive in 23 cases. Twenty nine patients received treatment, 11 had surgery and chemotherapy, 7 surgery alone, 5 had chemotherapy along with radiation, 3 had chemotherapy alone and 1 radiation alone. Three patients received all 3 modalities. Chemotherapy consisted of combinations of cyclophosphamide, doxorubicin or mitoxantrone, vincristne and prednisolone. Ten patients underwent total thyroidectomy, and 6 subtotal thyroidectomy. Radiation dose ranged from 35−40 Gy. Median survival was 36 months.

Conclusions: NHL thyroid is a disease of the elderly, predominantly of diffuse large B cell subtype and needs multimodality management.

No conflict of interest.

3657 POSTER

Impact of rituximab and IPI on survival in diffuse large B cell Lymphoma (DLBCL) patient treated at tertiary cancer center of Pakistan

S. Athar[1], A.H. Siddique[1], N. Siddique[1], N. Muzaffar[1], M. Ali[1], R. Sulman[1]. *[1]Shaukat Khanum Memorial Cancer Hospital and Research Centre Lahore, Medical Oncology, Lahore, Pakistan*

Background: International prognostic index (IPI) is a tool to predict overall survival and response to treatment in DLBCL. Anti CD 20 Rituximab has a significant impact on survival in patient with DLBCL. The objective of this study is to determine the impact of rituximab and IPI on survival in patient with DLBCL treated at our institution.

Method: 93 patients with DLBCL registered from 2007 to 2010 were included and data was reviewed retrospectively. Their base line IPI score,

stage at presentation and type of chemotherapy i.e. CHOP (Group 1) and R-CHOP (groups 2) were recorded.
Results: Median age was 43 years (range 18−76), with predominantly males 58%. Stage at presentation was Stage-I 15.1%, stage-II 44.1%, stage-III 21.5% and Stage-IV 19.4%. IPI risk categorization, low risk (63.4%), low intermediate risk (24.7%), high intermediate risk (10.8%) and high risk (1.1%). Thirty-one (33%) patients were treated with CHOP chemotherapy and 62(67%) patients with R-CHOP.
Median Survival for all patients not reached. Kaplan Meir estimated overall survival (OS) at 4.5 years in both group was 56%. At 4.5 years, OS for group 1 and group 2 are 45% and 66%, respectively. The difference in OS was statistically non-significant (p = 0.4). At 4.5 years, OS for Low, Low intermediate and high intermediate risk group were 69%, 54% and 15%, respectively and it was statistically significant with p-value of 0.000.
Conclusion: Rituximab had non statistical significant impact on survival in our patients that could be due to small sample size more over most patients belong to low risk group. We merit future controlled trial to assess the effect of Rituximab in our population. However, IPI risk categorization has statistical significant impact on survival in our study.
No conflict of interest.

3658 POSTER

Clinical features and outcome of relapsed refractory aggressive peripheral T-cell lymphoma − a ten-year study from a single institute in India

T. Tilak[1], L. Kumar[1], A. Sharma[1], S. Bakhshi[1], R.K. Sahoo[1], S. Kayal[1], S. Chaudhary[1], V. Raina[1]. *[1]All India Institute of Medical Sciences, Delhi, India*

Background: Relapse or progression is a major determinant of outcome despite initial response to therapy in aggressive peripheral T-cell NHL (PTCL). We analyzed the clinical features and outcome to second-line therapy of patients with aggressive PTCL.
Methods: Medical records of patients with relapsed or refractory aggressive PTCL registered at our institute from Jan 2002 to June 2011 were retrieved and reviewed for demographics, clinical manifestations at relapse, imaging findings, treatment and outcome.
Results: The median age of the cohort of 65 patients, male/female ratio of 3.6:1, was 45 years (range: 1−86 yrs). Baseline histopathological diagnosis comprised of PTCL-NOS (n = 27), ALK +ve ALCL (n = 3), ALK-ve ALCL (n = 7), AITL (n = 4), NK/T-cell (n = 4), SPTCL (n = 2) and T-NHL-unspecified (n = 18). Complete remission to first-line therapy was achieved in 39 (60%) patients. The median duration of CR was 4.9 months (range 1.2−80 months). Twenty-nine patients (46.7%) had 'B' symptoms at progression/ relapse. Lymph node involvement was present in 41 (67.2%). Extranodal site of disease was detected in 34 (55.74%). The commonest site of extranodal disease was skin (n = 10). Liver and spleen involvement was present in 13 (20%) and 16 (24.6%). Forty (61.5%) received second-line therapy, common regimes being MINE (n = 10), ICE (n = 7) and DHAP (n = 7). Complete remission was achieved with salvage therapy in six, 12 had PR and one had stable disease. Ten patients progressed at various periods during therapy. Autologous transplant was done in five patients; four are alive without disease and one died of progression. A total of 22 patients (33.9%) died due to disease progression and 8 are alive. Ten patients were lost to follow- up. Median EFS was 9.9 months. None of the clinical factors (age, sex, 'B' symptoms, extranodal or bulky disease) or laboratory parameters (hemoglobin, albumin, LDH) were significant to predict EFS.
Conclusion: The most common diagnosis for relapse/progression was PTCL-NOS. The median duration of CR prior to relapse was 4.9 months and median EFS was 9.9 months. Complete remission rate with salvage therapy was 9%. None of the clinical or laboratory parameters could predict event free survival.
No conflict of interest.

3659 POSTER

Ifosfamide, methotrexate, and etoposide (IMVP) as a salvage therapy for transplant-ineligible aggressive non-Hodgkin lymphoma patients − long term surveillance

N. Milanovic[1], D. Ristic[1], M. Puric[1], Z. Tomasevic[1]. *[1]Institute of Oncology and Radiology of Serbia, Haematology, Beograd, Serbia*

Background: Conventional salvage regimens without high dose therapy (HDT) with platinum- containing regimens, are associated with poor long-term disease control and significant toxicity in relapsed aggressive lymphoma.
Long-term results of gemcitabine and oxaliplatin +/− rituximab as salvage treatment, showed continuous relapses without a clear plateau on survival curves. Results were particularly disappointing in non − Rituximab cohort (42 mts. FFS and OS, 7% and 7%) (Corazzelli G. et al., 2009).
Due to contradictory reports on the outcomes of IMVP regimen (ifosfamide, methotrexate, and etoposide), the aim of study was to evaluate retrospectively the results of long term surveillance of those patients in our institution.
Patients and Methods: Patients with refractory/relapsing aggressive B-cell lymphoma (16 diffuse large B cell and 5 follicular G III), were treated with IMVP regimen (ifosfamide 1000 mg/sqm, d 1. − 5., methotrexate 30 mg/sqm, d. 1. and 5., etoposide 100 mg/sqm, d. 1. − 3.), q 21 d., G-CSF (ESMO guidelines).
Major endpoints of the study were: response to therapy (RR) and time to progression (TTP).
Results: From April 2007 y. to January 2013 y., twenty one (21) patients were enrolled: M = 28.6%, F = 71.4%, median age 63. y. (range, 47. − 78.); clinical stages II = 23.8%, III/IV = 76.2%; previous chemotherapy lines 1= 61.9%, 2= 38.1%; PS ECOG 0 = 23.8%, 1= 61.9%, 2= 14.3%; relapse = 85.7%, refractory = 14.3%.
Overall (RR) and complete response (CRR) rates were 66.6% and 4.7%.
At 59 months, median time to progression (TTP) was 11 months (95% CI), respectively, with curve plateau forming.
76 cycles of therapy were delivered with median 3.6 cycles (range: 1−6).
Grade 3/4 toxicities were rare and manageable. One episode of granulocytopenia gr. IV, one episode of trombocytopenia gr. III (WHO), and one episode of non − hematological toxicity, mucositis gr. III (WHO), were recorded.
Conclusions: IMVP regimen is to be considered as an alternative for transplant-ineligible patients with refractory/relapsing aggressive B-cell lymphoma.
Our proposition is to 'restart' IMVP +/− Rituximab in a randomized study.
No conflict of interest.

Phenotyping TILs in situ: Automated enumeration of FOXP3+ and CD69+ T cells in follicular lymphoma

J.R. Mansfield[1], C. Van der Loos[2], L.S. Nelson[3], C. Rose[3], H.E. Sandison[3], S. Usher[3], J.A. Radford[3], K.M. Linton[3], R.J. Byers[3]. *[1]PerkinElmer, Life Sciences & Technology, Hopkinton, USA; [2]Academic Medical Center, Pathology, Amsterdam, Netherlands; [3]University of Manchester, Manchester, United Kingdom*

Background: In many cancers, tumor-infiltrating lymphocytes (TILs) indicate levels of tumor immunogenicity and predict survival. In particular, increased levels of regulatory T cells (Tregs) are associated with poorer prognosis, whilst CD69+ T-cells may also be prognostic. Understanding the phenotype and pattern of TILs in situ within tumors would be advantageous. However, visual TIL assessment cannot easily determine the type of lymphocyte in situ and multimarker quantitation is difficult with standard methods. We present a multi-marker, computer-aided event-counting method for determining the phenotypes of lymphocytes in follicular lymphoma using a multispectral imaging (MSI) automated tissue segmentation and counting approach.
Material and Methods: A tissue microarray containing follicular lymphoma (FL) cores from 70 patients was chromogenically immunostained for CD3, CD69 and FOXP3, counterstained with hematoxylin, of which 40 cores were informative for both triplex staining and clinical follow-up. Each core was imaged using MSI and the individual staining of each marker separated from each other using spectral unmixing. Images were analyzed using software trained to recognize different tissue compartments based on morphology, specifically based on CD3 rich (extra-follicular) and poor (intra-follicular) areas. The FOXP3 or CD69 status of each CD3+ TIL was then determined and number Treg (FOXP3+/CD3+) and CD69+ T-cells counted in the intra- and extra-follicular areas.
Results: The intra-follicular (CD3 poor) and extra-follicular (CD3 rich) regions were accurately recognized within each core, based on abundance of CD3 cells. MSI enabled the accurate quantitation of CD3, CD69 and FOXP3 without crosstalk. The number of FOXP3+/CD3+ Tregs and CD69+ T-cells were counted in each core and used in Kaplan–Meier survival analysis, which demonstrated association of FOXP3+/CD3+ Tregs with favourable outcome in both the intra- (p = 0.0173) and extra-follicular (p = 0.0173) areas, as well as CD69+ T-cells in intra-follicular (p = 0.0175) areas; CD69+ T-cells were not prognostic in extra-follicular areas (p=4509).
Conclusions: This study demonstrates use of an automated method for counting Tregs in follicular lymphoma, showing association of FOXP3+ Tregs with good outcome. Given the generic nature of the method automated multiplexed tissue cytometry analyses are feasible for routine clinical studies and work with many multiplexed IHC staining methodologies, of importance for translational cancer studies in general.

mTOR inhibition in MDR acute myeloid leukemia

P. Sengupta[1], A. Karmakar[1], S. Gangopadhyay[1], A. Mukhopadhyay[2]. *[1]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Cell Biology, Kolkata, India; [2]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Haematological Oncology, Kolkata, India*

Background: Signaling through the PI3K/PTEN/AKT/mTOR pathway is aberrantly activated in several human cancers, including Acute Myeloid Leukemia (AML) patients where it contributes to leukemic cell proliferation, survival and drug resistance. In leukemia patients treated with drugs such as anthracyclines, vinca alkaloids, chemo-resistance one of the major problems contributing to therapeutic failure, where all this drugs are modulated in their intracellular retention by a 170 kDa Phosphoglycoprotein, an mdr-1 gene product. The role of mTOR in various processes such as proliferation, growth, has been comprehensively described in many reviews, following its inhibition by rapamycin. Thus inhibition of mtor signaling in AML blasts could account for enhancing their sensitivity to cytotoxic agents. This study is to embrace the effect of Rapamycin, an allosteric mTOR inhibitor on MDR AML patients.
Materials and Methods: We selected samples of 30 MDR AML patients isolated from bone marrow or peripheral blood and cultured *in vitro*. The effects of Rapamycin and Evarolimus (EvarTOR) on fresh AML samples were analyzed by treating the cells with intermediate drug concentrations (100 nM) for 24 h,48 h, 72 h, 96 h respectively followed by cytotoxicity assay (MTT assay). The effects of the drug on proliferation of cells were analyzed also by cell counting.
Results: A marked reduction in cell viability at 96 h was detected in 25 samples treated with Rapamycin and Evarolimus. Out of the 30 analyzed samples, 16 were sensitive to Rapamycin, 19 to Evarolimus where it was observed that the leukemic cell count came down to almost 2% whereas 11 samples displayed various degree of resistance to the drug. Overall, these findings demonstrated that Rapamycin and Evarolimus have a cytotoxic activity against primary cells from AML patients with up-regulated mTOR signaling.
Conclusion: We have evaluated the *in vitro* effects of Rapamycin on AML patient samples where reduced cell viability primary cells from AML patients were observed. However, further studies of the additional effects of Rapamycin and Evarolimus will be of the supreme importance, as they could help in designing more efficient curative protocols, for the treatment of acute leukemia patients.
No conflict of interest.

3662 POSTER

Increased leukemia-specific CTL induction by dendritic cells matured with cocktails of TLR agonists

F. Masoumi[1], M. Nourizadeh[2], J. Hadjati[1]. *[1]Tehran University of Medical Sciences, Department of Immunology School of Medicine, Teheran, Iran; [2]Tehran University of Medical Sciences, 2Immunology Asthma and Allergy Research Institute Children Medical Center, Teheran, Iran*

Background: Despite consolidation chemotherapy, relapse occurs in majority of patients with acute myeloid leukemia (AML) because of the presence of minimal residual disease. Dendritic cell (DC) based immunotherapy can help to maintain patients in remission. In spite of apparent progress in DC-based immunotherapy, some differences were reported in generating potent DCs. The aim of this study was to determine the best combination of TLR agonists with the synergistic effect on maturation of human monocyte-derived DCs for immunotherapy of acute myeloid leukemia.
Methods: Here we generated DCs by culturing isolated peripheral blood monocyte in the presence of GM-CSF and IL-4 for 5 days. Then, immature DCs were cultured in the presence of different TLR ligand cocktails for an additional day. The morphology, expression of key surface molecules and allostimulatory activity were assayed on DCs. Moreover, the ability of DCs in induction of CTLs specific for Leukemia blasts was determined.
Results: Our results revealed that among 10 different TLR agonists and their combinations, cocktails containing R848 (a ligand for TLR7/8) could efficiently produce DCs with increased expression of costimulatory molecules such as CD83, CD86, HLA-DR and CCR7. Such potent DCs also showed great capacity to stimulate allogeneic T cells. Finally, enhanced killing of leukemia blasts was observed by CTLs induced in the presence of regarding DCs.
Conclusions: In conclusion, combination of TLR agonists containing R848 could be considered as an appropriate maturation cocktail for DC production and its potential use for immunotherapy of AML patients.
No conflict of interest.

Ultrasound (US) − guided fine needle aspiration cytology (FNAC) of the sentinel node (SN) in 1000 consecutive melanoma patients

C.A. Voit[1], S. Gooskens[2], A.C.J. Van Akkooi[2], A.M.M. Eggermont[3]. *[1]Charite Humboldt University of Berlin, Department of Dermatology, Berlin, Germany; [2]Erasmus University Medical Center − Daniel den Hoed Cancer Center, Department of Surgical Oncology, Rotterdam, Netherlands; [3]Institut de Cancérologie Gustav Roussy, Department of Surgery, Paris-Sud/Villejuif, France*

Background: The surgical Sentinel Node (SN) procedure is currently considered standard of care worldwide for the staging of AJCC stage I/II melanoma patients (pts). It remains unclear if SN followed by early completion lymph node dissection (CLND) in case of metastasis can lead to a survival benefit. Unlike other types of cancer, US-guided-FNAC has not been proven to be effective in melanoma. We use the Berlin Morphology criteria for US-FNAC, a low threshold for the performing of a FNAC and overnight cytology reports. Now we report sensitivity (sens), specificity (spec), positive (PPV) and Negative (NPV) predictive values from our expanded experience from our prospective database.
Methods: Between 2001 and 2013 over 1500 stage I/II consecutive melanoma patients have undergone US-FNAC prior to SN. We report on the first 1000 consecutive pts. All patients underwent lymphoscintigraphy prior to US-FNAC. Peripheral Perfusion (PP), Loss of Central Echoes (LCE), Balloon Shaped (BS) are the Berlin Morphology Criteria, which were registered. FNAC was performed in case of presence of any (one or all) of these factors. SN tumor burden was measured according to the Rotterdam Criteria. All patients underwent SN or LND in case of positive FNAC. All patients with neg FNAC underwent a SN.
Results: Mean/median Breslow thickness was 2.58/1.57 mm (0.2−44 mm). Mean/median follow-up was 56/53 months (1–132). Ulceration was present in 24%. SN positivity rate was 20.8% (208/1000). Sens was 51%. Spec, PPV and NPV were 99%, 99% and 89%. Sensitivity was highest for T4 tumors (76%) and in ulcerated melanomas (63%). PP, LCE, BS had sens of 69%, 24%, 24%. Sens of US-FNAC increased with increasing SN tumor burden (17% in <0.1 mm to 61% in >1 mm). PP was an early sign of metastasis (58% in <0.1 mm mets). Threshold for positive FNAC was 0.3 mm in maximum diameter. 5-yr survival correlated to US-FNAC status (95% in neg, 59% in pos). Survival of patients with PP was 89% vs. 57% in BS vs. 96% in negative patients (P = 0.001).
Conclusions: US-FNAC according to the Berlin Morphology criteria can correctly identify half of the positive SNs. PP is an early sign of metastasis, BS is a late sign. US-FNAC can significantly reduce the amount of unnecessary surgical SN procedures. US-FNAC sensitivity correlated with increasing T-stage, increasing SN tumor burden and ulceration. US-FNAC can accurately predict survival. A multi-observer validation study is necessary to confirm our results.
No conflict of interest.

The prognostic significance of sentinel node tumour burden in melanoma patients: A European-Australian multicenter study

S. Van der Ploeg[1], A.C.J. Van Akkooi[1], L.E. Haydu[2], C. Verhoef[1], R.A. Scolyer[2], J.F. Thompson[2], A.M.M. Eggermont[3]. *[1]Erasmus MC − Daniel den Hoed Cancer Center, Surgical Oncology, Rotterdam, The Netherlands; [2]Melanoma Institute Australia, Sydney, Australia; [3]Institut de Cancerologie Gustav Roussy, Villejuif/Paris-Sud, France*

Prognosis of patients with sentinel node (SN) positive melanoma is heterogeneous. Patient characteristics, primary tumour and SN parameters, and models for risk stratification of SN-positive patients have been assessed in numerous studies with respect to prediction of non-SN (NSN) status and survival. The aim of the current study was to evaluate the prognostic significance of SN tumour burden parameters and classification schemes in the largest database on positive SNs to date.
In 1539 SN-positive patients treated between 1993 and 2008 at 11 melanoma treatment centers in Europe and Australia, indices of SN tumour burden (intranodal location, tumour penetrative depth (TPD) and maximum SN tumour size) were evaluated.
Non-subcapsular location, increasing TPD and increasing maximum size were all predictive factors for NSN status and were independently associated with poorer melanoma-specific survival. (Table 1) Patients with subcapsular micrometastases <0.1 mm in maximum dimension had the lowest frequency of NSN metastasis (5.5%). Despite differences in SN biopsy protocols and clinicopathologic features of the patient cohorts

(between centers), most SN parameters remained predictive in individual center populations. Maximum SN tumour size >1 mm separated the 1539 patient cohort into two large groups of similar size and was the most reliable and consistent parameter independently associated with higher NSN positivity, poorer disease-free and poorer melanoma-specific survival. In this large retrospective, multicenter cohort study, several parameters of SN tumour burden including intranodal location, TPD and maximum size provided prognostic information, but their prognostic significance varied considerably between the different centers. This could be due to sample size limitations or to differences in SN detection, removal and examination techniques. Prospective studies employing consistent SN assessment protocols are required to establish a classification system for SN tumour burden that accurately and consistently stratifies patients into prognostic groups.

No conflict of interest.

A meta-analysis of randomized, controlled trials in metastatic melanoma establishes progression-free survival as a surrogate for overall survival

K.T. Flaherty[1], S.J. Lee[2], R. Dummer[3], A. Hauschild[4], M. Hennig[5], G.V. Long[6], P. Lorigan[7], C. Robert[8], D. Schadendorf[9]. *[1]Massachusetts General Hospital Cancer Center, Developmental Therapeutics, Boston, USA; [2]Dana-Farber Cancer Institute, Biostatistics, Boston, USA; [3]University Hospital Zurich, Department of Dermatology, Zurich, Switzerland; [4]University of Kiel, Department of Dermatology, Kiel, Germany; [5]GlaxoSmithKline, Biostatistics and Epidemiology, Munich, Germany; [6]University of Sydney, Melanoma Institute Australia and Westmead Hospital, Sydney, Australia; [7]Christie's Hospital, School of Oncology, Manchester, United Kingdom; [8]Institute Gustave Roussy, Department of Dermatology, Villejuif Paris, France; [9]University Hospital Essen, Department of Dermatology, Essen, Germany*

Background: Four randomized, phase 3 metastatic melanoma trials have shown a statistically significant overall survival (OS) benefit over the last few years. This provides the first opportunity to investigate progression free survival (PFS) as a potential surrogate for OS, taking into account a large number of recently conducted melanoma trials.

Materials and Methods: A meta-analysis was performed of 10 randomized controlled trials enrolling 4,215 metastatic melanoma patients. From initially 48 published trials identified, those were selected which included DTIC as control arm, reported both PFS and OS, conform to the convention of reporting hazard ratio (HR) demonstrating benefit as <1. Experimental arm therapies included vemurafenib, dabrafenib, trametinib, sorafenib, ipilimumab, intetumumab, bosentan, oblimersen, temozolomide, and nab-paclitaxel. HRs for OS and PFS were correlated using several weighting strategies: by sample size or by precision of the HR estimate assuming fixed and random effects. Sensitivity analysis was performed including or excluding trials with crossover upon progression, phase 3 trials only, large trials, and only those with DTIC 1,000 mg/m^2 dosing.

Results: There was a statistically significant correlation between PFS and OS regardless of weighting strategy. Correlation coefficients (R) ranged from 0.74 (95% CI 0.26–0.93) for random effects assumption to 0.90 (95% CI 0.66–0.97) for sample size weighting. Considering only trials without crossover, R was 0.97 (95% CI 0.82−1.0) and only slightly lower after including 2 additional trials with less than 50% crossover (R = 0.94; 95% CI 0.74–0.99). Similarly, the correlation strength was non-significantly affected by restricting to phase 3, large, or DTIC 1,000 mg/m^2 (0.95, 0.94, and 0.92, respectively). Only inclusion of mature follow-up data after >50% crossover (vemurafenib and dabrafenib phase 3 trials) significantly weakened PFS/OS correlation (R=0.58; 95% CI −0.03–0.88). We considered the inclusion of trials with no or limited crossover using the random effects assumption to yield a conservative and appropriate statement of the PFS/OS correlation: R=0.93 (95% CI 0.70–0.99).

Conclusions: Based on a meta-analysis of all reported randomized trials in melanoma for which DTIC was the control arm therapy, we found a strong correlation between PFS and OS regardless of mechanistic class of therapy. PFS should be considered as a robust surrogate for OS in subsequent randomized trials.

Vemurafenib (VEM) and MEK inhibitor, cobimetinib (GDC-0973), in advanced BRAFV600-mutated melanoma (BRIM7): dose-escalation and expansion results of a phase IB study

G. McArthur[1], R. Gonzalez[2], A. Pavlick[3], O. Hamid[4], I. Puzanov[5], T.F. Gajewski[6], A. Daud[7], M. Yin[8], N. Choong[8], A. Ribas[9]. *[1]Peter MacCallum Cancer Centre, Research Division, Victoria, Australia; [2]University of Colorado Comprehensive Cancer Center, School of Medicine Division of Oncology, Aurora CO, USA; [3]New York University Medical Center, Departments of Medicine (Cancer Center) and Dermatology, New York NY, USA; [4]The Angeles Clinic and Research Institute, Translational Research and Immunotherapy Melanoma Therapeutics, Los Angeles CA, USA; [5]Vanderbilt-Ingram Cancer Center, Division of Hematology/Oncology, Nashville TN, USA; [6]University of Chicago, Department of Pathology and Department of Medicine Section of Hematology/Oncology, Chicago IL, USA; [7]University of California San Francisco, Department of Medicine Hematology/Oncology, San Francisco CA, USA; [8]Genentech Inc., Biotechnology, South San Francisco CA, USA; [9]The Jonsson Comprehensive Cancer Center at University of California Los Angeles, Department of Medicine Hematology/Oncology, Los Angeles CA, USA*

Background: Combined inhibition of BRAF and MEK delays the emergence of resistance in preclinical models. BRIM7 evaluated safety and efficacy of VEM + cobimetinib. The combination was shown to be tolerable when delivered at the respective single-agent maximum tolerated doses (MTDs; ESMO 2012 LBA28). We report updated safety and efficacy data.

Materials and Methods: Eligible patients (pts) had advanced *BRAF^{V600}*-mutated melanoma and ECOG performance status 0−1 and were BRAF inhibitor (BRAFi)-naive or had disease progression on VEM (VEM-progressor). Pts in the dose-escalation portion received VEM 720 or 960 mg BID continuously and cobimetinib 60, 80, or 100 mg QD 14 days (d) on/14 d off (14/14); 21 d on/7 d off (21/7); or continuously (28/0). Two dose levels were expanded: VEM (720 mg and 960 mg BID) + cobimetinib 60 mg QD 21/7.

Results: Of the 115 pts treated with VEM + cobimetinib as of 25 Jan 2013, 58% were male, median age was 54 y (19−76), 76% were M1c, and 54% were BRAFi-naive. Median no. of cycles to date was 5 (1−20). Dose-limiting toxicities (DLTs) were observed in 4 pts including DLTs of mucositis (1 pt) and arthralgia (1 pt) in 4 pts treated in the VEM 960 mg BID + cobimetinib 60 mg QD 28/0 cohort. The most common treatment-related adverse events (AEs; n = 115) were non-acneiform rash (58%), diarrhea (52%), fatigue (37%), liver laboratory test abnormality (37%), and photosensitivity/sunburn (37%). Most frequent treatment-related grade ⩾3 AEs were liver laboratory test abnormality (10%), non-acneiform rash (7%), arthralgia (5%), diarrhea (4%), and fatigue (4%). Cutaneous squamous cell carcinoma occurred in 3 pts (3%). Dose reduction was required for VEM in 9 pts (8%) and cobimetinib in 7 pts (6%). BRAFi-naive pts attained 73% confirmed response rate (RR); median progression-free survival (PFS) is immature due to the short follow-up time with only 11 pts (19%) having a

PFS event to date. VEM-progressor pts attained 14% confirmed RR, stable disease of 49%, and median PFS of 2.8 months. Updated PFS analysis will be presented.
Conclusions: VEM + cobimetinib can be safely administered at the respective single-agent MTDs of VEM (960 mg BID) and cobimetinib (60 mg 21/7). Preliminary efficacy of the combination is encouraging in BRAFi-naive patients.

Survival analysis with 5 years of follow-up in a phase III study of ipilimumab and dacarbazine in metastatic melanoma

M. Maio[1], I. Bondarenko[2], C. Robert[3], L. Thomas[4], C. Garbe[5], A. Testori[6], H. Lu[7], K. Chin[8], J. Wolchok[9]. *[1]Azienda Ospedaliera Universitaria Senese − Istituto Toscano Tumori, Medical Oncology and Immunotherapy, Siena, Italy; [2]Dnepropetrovsk Medical Academy, Oncology and Medical Radiology, Dnepropetrovsk, Ukraine; [3]Institute Gustave Roussy, Dermatology, Villejuif Paris Sud, France; [4]Lyon 1 University, Dermatology − CHLS, Pierre Bénite, France; [5]University Medical Center, Department of Dermatology, Tuebingen, Germany; [6]Istituto Europeo di Oncologia, Melanoma and Sarcoma Division, Milan, Italy; [7]Bristol-Myers Squibb Company, Global Biometric Science, Wallingford, USA; [8]Bristol-Myers Squibb Company, Global Clinical Research, Wallingford, USA; [9]Memorial Sloan-Kettering Cancer Center, Medicine, New York, USA*

Background: Prior to the recent approval of new therapies, patients with metastatic melanoma (MM) had a 5-year survival rate of ~10%. Increasingly, clinical trial data suggest long-term survival (beyond 5 years) for some MM patients who received ipilimumab (Ipi). An analysis of 177 pts from 3 phase I/II Ipi studies conducted at the US National Cancer Institute demonstrated 5-year survival rates of 13−25%. In 4 other phase II trials, the 5-year survival rate was ~20% for previously treated patients who received Ipi monotherapy. In the phase III trial, CA184–024, Ipi plus dacarbazine (DTIC) significantly improved overall survival (OS) versus DTIC alone in treatment-naive patients with MM. Long-term safety data for patients who survived >2 years have been previously reported for this study. In the current survival analysis, we report the 5-year survival rates from study 024.
Methods: Patients with treatment-naive MM were randomized to receive either Ipi (10 mg/kg) plus DTIC (850 mg/m^2) or placebo plus DTIC (850 mg/m^2) given at weeks 1, 4, 7, 10 followed by DTIC every 3 weeks through week 22. Patients with stable disease or better could receive Ipi or placebo as maintenance therapy, every 12 weeks from week 24. This analysis reports survival data captured 5 years beyond the last enrolled patient, current as of March 2013.
Results: The table summarizes median OS, previously reported survival rates up to 4 years, and current analyses for 5-year survival rates by treatment group. Median follow-up for OS in months (range) was 11.0 [0.4–71.9] for Ipi plus DTIC and 8.9 [0.1–73.2] for placebo plus DTIC. Seven patients continued to receive Ipi maintenance therapy at the cut-off date for this survival analysis, and 6 patients currently remain on Ipi maintenance therapy.

Treatment group	Median OS, months	Overall survival rate, % [95% CI]				
	[95% CI]	1-year	2-year	3-year	4-year	5-year
Ipi + DTIC	11.2	47.6%	28.9%	21.3%	19.1%	18.2%
N = 250	[9.5–13.8]	[41.2–53.7]	[23.3–34.7]	[16.3–26.6]	[14.4–24.3]	[13.6–23.4]
Placebo + DTIC	9.1	36.4%	17.8%	12.1%	9.7%	8.8%
N = 252	[7.8–10.5]	[30.4–42.4]	[13.3–22.8]	[8.4–16.5]	[6.4–13.7]	[5.7–12.8]

Conclusions: The results of this landmark survival analysis for phase III study 024, with 5 years of follow up, continue to demonstrate a long-term survival benefit for patients treated with Ipi plus DTIC compared to placebo plus DTIC. Consistent with the results of phase II studies, survival rates appear to plateau beginning at 3 years.

3705 POSTER

Specific roles for BRAF and CRAF in NRAS-induced mouse melanoma

C. Dorard[1], M. Larcher[1], C. Pouponnot[1], F. Beermann[2], M. Baccarini[3], L. Larue[1], A. Eychène[1], S. Druillennec[1]. *[1]Institut Curie, Orsay Cedex, France; [2]Swiss Institute for Experimental Cancer Research, Lausanne, Switzerland; [3]Center for Molecular Biology, Vienna, Austria*

Background: The RAS/RAF/ERK pathway plays a key role in melanoma, with BRAF and NRAS mutations in 50% and 15% of cases, respectively. The development of chemical inhibitors specifically targeting mutated ^{V600E}BRAF represents a major breakthrough in the treatment of metastatic melanoma, although resistance often develops quickly following treatment. Furthermore, such compounds cannot be used to treat half of melanoma patients, especially those mutated on NRAS. In this study, we evaluated the contribution of BRAF and its closely related kinase CRAF downstream of NRAS during tumoral progression in mouse models.
Material and Methods: We developed NRASQ61K-induced mouse melanoma models in which single or compound ablation of BRAF and CRAF genes can be achieved in the melanocyte lineage upon tyrosinase promoter-driven Cre or Cre^{ERT2} expression. These models allowed us investigating the role of both RAF kinases at each step of tumoral progression, from tumor initiation (formation of benign nevi) to metastatic melanoma.
Results: Temporally-controlled concomitant ablation of BRAF and CRAF abolished nevi formation and melanoma progression and maintenance, showing that RAF signaling is absolutely required for NRAS-induced melanoma development. However, we will present data showing that BRAF and CRAF play specific roles during the different steps of melanoma progression. In addition, using primary cultures of melanomas, we show that ablation of RAF kinases often lead to the emergence of resistant cells showing reactivation of ERK in the absence of BRAF and CRAF.
Conclusions: Our results disclose specific and complementary functions for BRAF and CRAF in NRAS-induced mouse melanoma, and pave the road for further studies on treatment and resistance mechanisms.

New polymorphisms in the ERP29 and LEF1 genes associated with increased risk for cutaneous melanoma

C. Oliveira[1], J.A. Rinck-Júnior[1], G.J. Lourenço[1], E.F.D. Costa[1], A.M. Moraes[1], C.S.P. Lima[1]. *[1]State University of Campinas Faculty of Medical Sciences, Department of Internal Medicine, Campinas SP, Brazil*

Background: Recently, we found that genetic polymorphisms in tumor suppressor *ERP29* c.293A>G (rs7114) gene and in gene of DNA transcription *LEF1* c.1213+480C>T (rs2107028) and g.127267C>T (rs4245926) alter the oropharynx cancer risk. Since the roles of these genetic polymorphisms in the risk and clinical manifestation of cutaneous melanoma (CM) are still unknown, these were the aims of the present study.
Material and Methods: For this case-control study, the genomic DNA from peripheral blood of 179 consecutive CM patients (aged 20−89 years; 90 males, 89 female, 167 Caucasians, 12 non-Caucasians) and 199 healthy subjects matched to patients by gender and race were genotyped using real-time PCR. The differences between groups were analyzed by the logistic regression model. Power analysis (PA) was used to verify the effect of sample size on the results obtained in the study.
Results: The frequencies of the *ERP29* AA and the *LEF1* 127267TT genotypes were higher in patients than in controls (80.4% *vs* 69.3%, $P = 0.03$, PA: 68%) and (76.0% *vs* 65.3%, $P = 0.02$, PA: 74%), respectively. Carriers of these genotypes had a 1.77 (95% CI: 1.05–2.98) and 1.80

(95% CI: 1.09–2.96)-fold increased risks for CM than those with the remaining genotypes, respectively. *LEF1* 127267TT plus *LEF1* 1213+480CC and *ERP29* AA plus *LEF1* 127267TT plus *LEF1* 1213+480CC combined genotypes were also more common in patients than in controls (77.6% *vs* 66.7%, $P = 0.03$, PA: 74%) and (92.8% *vs* 80.0%, $P = 0.02$, PA: 93%). Carriers of these genotypes had a 1.81- (95% CI: 1.05–3.12) and 2.92-fold (95% CI: 1.13–7.54) increased risks for CM than others, respectively. Additionally, the *ERP29* AA genotype was more common in patients with advanced tumours than in those with localized tumours (91.5% *vs* 77.2%, $P = 0.04$, PA: 58%). The frequency of *ERP29* AA in patients with advanced CM was also higher than that found in controls (91.5% *vs* 69.3%, $P = 0.001$, PA 99%). Individuals with the *ERP29* AA genotype had a 4.75 (95% CI: 1.63–13.82)-fold increased risk for aggressive CM than others.

Conclusions: The data suggest, for the first time, that *ERP29* and *LEF1* polymorphisms, alone or in combination, alter consistently the risk for CM, particularly of the advanced form of the disease. We believe that healthy carriers of specific genotypes of the genes should receive additional recommendation to avoid exposition to sunlight and periodic follow-up by dermatologist for CM prevention and early diagnosis.

3707 POSTER

Hyaluronan fragments, a novel modulator of tumor progression in squamous skin carcinomas

K. Röck[1], B. Kellner[1], A. Hippe[2], B. Homey[2], J.W. Fischer[1].
[1]*Universitätsklinikum Düsseldorf, Institut für Pharmakologie und Klinische Pharmakologie, Duesseldorf, Germany;* [2]*Universitätsklinikum Düsseldorf, Hautklinik, Duesseldorf, Germany*

Squamous cell carcinoma (SCC) is the second most common skin cancer and strongly associated with chronic UVB exposure of the skin. UVB induced changes of the extracellular matrix contribute to phenotypic responses of tumour and stroma cells. Hyaluronan (HA), as a main component of the dermal extracellular matrix, is synthesized by HA-synthase isozymes (HAS1−3) and is known to be involved in the regulation of several cellular mechanisms like proliferation and migration. Aim of the present study was to evaluate the contribution of HA on tumour progression of UVB-induced SCCs.

Human skin samples from healthy skin and SCCs were analysed via qRT-PCR. mRNA levels of HAS1 and 2 showed no regulation, whereas HAS3, Hyaluronidases (HYAL) 1 and 2 were clearly upregulated. In vitro comparison of normal human keratinocytes and SCC cells (A431) showed the same expression patterns (HAS3 1.951±0.386; HYAL1 74.28±22.1; HYAL2 4.229±1.680 fold of keratinocytes). The amount of HA in the supernatant of SCC cells was significantly increased in comparison to keratinocytes, however HA size was drastically reduced to HA-fragments (sHA) as shown by size exclusion chromatography. To evaluate the influence of HA on tumour progression in vivo, mice were UVB irradiated (80mJ/cm^2) three times a week for 20 weeks. During the experiment the mice received either chow with an inhibitor of HA synthesis, 4-Methylumbelliferon (4-MU), or control chow. Mice treated with 4-MU developed significantly less tumours compared to non treated animals (18.25±2.22 vs. 33.3±4.1 tumours). In vitro 4-MU reduced the amount of HA in the supernatant of SCC cells (0.567±0.1083 fold of control). [H^3−thymidine] incorporation revealed reduced proliferation of SCC cells in response to 4-MU (0.421±0.216 fold of control). Furthermore, time-lapse microscopy as well as PARP and AnnexinV analysis showed a more apoptotic phenotype after 4-MU treatment. Incubation of SCC cells with external sHA let to no additional phenotype. However, treatment of keratinocytes with sHA resulted in a drastic reduction of IL6 expression. Futhermore it could be shown that IL6 induced cell death in SCC cells.

In conclusion, the present data show that SCC cells extrude more HA, possibly related to increased levels of HAS3, in comparison to keratinocytes. Increased amounts of HA appear to be essential for the UVB induced tumour progression of SCCs in mice. Biological active HA fragments derived from HA degradation by hyaluronidases (Hyal1, 2) are thought to be pro-angiogenetic and pro-inflammatory. Furthermore they might, by a paracrine mechanism, reduce IL6 levels in the microenvironment of the tumour thus possibly also promoting tumour survival and malignancy.

MicroRNA-medited loss of ADAR1 enzyme in metastatic melanoma promotes tumor growth

Y. Nemlich[1], E. Greenberg[1], R. Ortenberg[2], E. Galun[3], D.C. Bennett[4], I. Barshack[5], M. Bar-Eli[6], G. Rechavi[7], J. Schachter[1], G. Markel[1].
[1]*Sheba Medical Center, Ella Institute of Melanoma, Ramat-Gan, Israel;* [2]*Sheba Medical Center, Ella Institute of Melanoma, Ramat Gan, Israel;* [3]*Hadassah Medical Organization, Gene therapy, Jerusalem, Israel;* [4]*St George's University Hospital, Cell Biology, London, United Kingdom;* [5]*Sheba Medical Center, Pathology, Ramat Gan, Israel;* [6]*MD Anderson Cancer Center, Cell Biology, Houston, USA;* [7]*Sheba Medical Center, Cancer Research Center, Ramat-Gan, Israel*

Background: RNA editing is a post transcriptional modification in which adenosine is deaminated into inosine. Decreased RNA editing was reported several years ago in various cancers, but the significance and underlying mechanisms are still elusive. Here we study the mechanistic significance of loss of ADAR1 in the pathogenesis of melanoma.

Methods: ADAR1 expression was tested with qPCR, western blot and immunohistochemistry. Proliferation was tested with XTT. Tumorigenicity was tested in SCID mice. miRNAs were quantified with qPCR or northern blot. Protein-protein interactions were tested with co-immunoprecipitation. Genomic copies were quantified with qPCR. Methylation and RNA-editing was quantified with sequenome MassArray.

Results: We show that the main RNA-editing enzyme, Adenosine Deaminase Acting on RNA-1 (ADAR1) is silenced in many metastatic melanoma cultures. In-depth studies on melanoma samples and progression tissue microarrays point on substantial ADAR1 downregulation during the metastatic transition. Accordingly, ADAR1 suppresses several cancer features, as its downregulation alters cell morphology, facilitates cell-cycle and proliferation in-vitro, and dramatically enhances the tumorigenicity in-vivo. ADAR1 controls the expression of >100 microRNAs, which regulate hundreds of genes that account for the observed phenotype. Importantly, ADAR1 fundamentally regulates the course of miRNA processing in the cell in an RNA-binding dependent yet RNA-editing-independent manner. ADAR1 regulates the expression of Dicer at the level of translation via let-7. In addition, it creates a complex with DGCR8, which is mutually exclusive with the DGCR8-Drosha complex that processes pri-miRNAs in the nucleus. Cancer cells silence ADAR1 by overexpressing miR-17 and miR-432, both of which directly target ADAR1 and operate additively. Both of their genomic sequences are frequently amplified to increase expression, but uniquely, an aberrant hypomethylation of the imprinted DLK1-DIO3 region in chromosome 14 accounts for the miR-432 overexpression.

Conclusion: ADAR1 loss plays a fundamental role controlling melanoma growth by regulating the biogenesis pathway of microRNAs at several stages. Epigenetic and genetic mechanisms account for this loss. This might pave the way for the development of novel technologies.

3709 POSTER

The effect of in vitro NK cell and K562 tumor cell contact on NK cell subset distribution and changes in activation and inhibitory receptor expression in melanoma patients

G. Konjevic[1], A. Vuletic[1], K. Mirjacic Martinovic[1]. [1]*Insitute of Oncology and Radiology, Dept. of Immunology, Belgrade, Serbia*

Background: NK cell cytotoxicity against malignant cells is regulated by functionally opposing, activating and inhibitory receptors whose balance determines whether target cells will be lysed. Thus, ligation of activating receptors to stress-induced ligands stimulates, while binding of inhibitory, KIR receptors to MHC class I molecules on tumor cells inhibits NK cell cytotoxicity. Based on CD16 receptor expression, NK cells are divided into two functionally distinct subsets: cytotoxic $CD16^{bright}$ and regulatory $CD16^{dim}$ subset. K562 human erythromyeloid tumor cell line is MHC class I deficient and sensitive to NK cell lysis, and it expresses stress induced protein MICA, a ligand for NKG2D activating NK cell receptor. The aim of this study was to investigate the effect of co-culture of melanoma patients' NK cells with K562 tumor cell line on the expression of several receptors on $CD3^-CD16^+$ NK cells and their subsets.

Material and Methods: PBL obtained from 15 metastatic melanoma patients (MM) were co-cultured with K562 cell line in target to effector ratio 2:3. Samples were incubated for 4 h at 37ºC in a humidified atmosphere in CO_2 incubator. The expression of NK cell receptors was performed by flow cytometry after staining with CD3PerCP, CD16FITC, NKG2DPE, CD161PE, CD158a/bFITC, CD107aPE mAbs and analyzed on $CD3^-CD16^+$ NK cells and on $CD3^-CD16^{bright}$ and $CD3^-CD16^{dim}$ NK subsets.

Results: Contact with K562 target cells increased CD107a expression on NK cells and $CD16^{bright}$ NK cell subset indicating degranulation characteristic of NK cell cytotoxicity, as well as CD16 shedding leading to a

decrease in the percent of $CD3^-CD16^+$ NK cells and subsequent $CD16^{bright}$ to $CD16^{dim}$ NK cell subset transition. Target cell induced NK cell functional activation led to lower post-contact NKG2D receptor expression on NK cells and $CD16^{bright}$ NK cell subset due to ligand-induced NKG2D internalization and degradation. Furthermore, the shown post contact increase in KIR and CD161 inhibitory receptors on $CD16^{dim}$ NK cell subset may be due to target cell induced $CD16^{bright}$ to $CD16^{dim}$ NK cell subsets transition.
Conclusions: Considering the scarce data of the effect of cell-cell contact between NK and tumor cells on NK cell receptor expression, we show in MM patients the dynamics of NK cell subset distribution characterized by a decrease in the cytotoxic $CD3^-CD16^{bright}$ NK cell subset and in NKG2D activating receptor expression, as well as a significant post-activation KIR up regulation on $CD3^-CD16^{dim}$ subset. These results give data for novel therapeutic options in MM patients including cytokines and KIR antibody immunotherapy to potentiate innate NK cell-mediated antitumor activity.

3710 POSTER

Lipid raft adhesion receptors recruitment mediated by major histocompatibility complex (MHC) class II signalling in melanoma cells

G. Barbieri[1], F. Costantini[1], M.A. Costa[1]. [1]*Istituto di Biomedicina e Immunologia Molecolare (CNR), Palermo, Italy*

Background: The lipid rafts are enriched in freely diffusing, stable assemblies of sphingolipids and cholesterol that are implicated in the selective protein–protein interactions as well as in the assembly of transient signalling platforms. The lipid raft proteins play important roles in cell–cell interaction and are docking site for the proteins involved in focal adhesion and cancer metastasis such as the adhesion receptors. Indeed, the alteration of adhesion receptors expression is related to metastatic progression of melanoma through the deregulation of adhesive functions, the subsequent detachment of tumour cells from the primary tumour site and the tissue borders. Interestingly, in different tumour cell lines has been reported that the signalling activated by the MHC class II molecules is associated to the lipid raft localization of these molecules but only reduced knowledge are available in this field for melanoma. In the aim to understand the molecular mechanisms used by melanomas for the progression to an invasive-metastatic state, we studied in MHC class II constitutive expressing melanoma cell lines, the membrane localization of adhesion receptors as well as the activated signalling.
Material and Methods: The class II constitutive expressing melanoma cells (A375 and HT144 cell lines) were stimulated with a specific anti-HLA-DR mAb (L243) that mimics the TCR interaction with the class II molecules for 24 h and 48 h or left unstimulated. The lipid rafts of stimulated and unstimulated melanoma cells were isolated and analysed by western blot. Exosomes secreted by stimulated and unstimulated melanoma cells were purified and analysed by western blot.
Results: In the lipid rafts domains of stimulated A375 and HT144 cells we observed an increased localisation of HLA-DRa, Integrin b1, MCAM, ICAM as well as FAK kinase. Therefore, we compared the expression of HLA-DRa, MCAM and ICAM receptors in exosomes secreted by stimulated and unstimulated A375 and HT144 melanoma cells.
Conclusions: Therefore, our results underline the role played in melanoma cells by the MHC class II dependent signalling on motility and exosomes functionality. The signalling activated by class II molecules assembling class II, Integrins and CAMs receptors as well as the FAK kinase in the lipid rafts fraction, could elucidate the mechanisms of melanoma cells metastatic dissemination as well as the role of exosomes on the microenvironment of tumour sites.

3711 POSTER

The tamoxifen active metabolites endoxifen and 4-hydroxytamoxifen present superior antitumor activity over the pro-drug in malignant melanoma

M.P.C. Ribeiro[1], A.E. Santos[1], J.B.A. Custódio[1]. [1]*Center for Neuroscience and Cell Biology University of Coimbra Portugal, Faculty of Pharmacy University of Coimbra, Coimbra, Portugal*

Background: Tamoxifen (TAM) is a selective estrogen receptor modulator used routinely in the treatment of breast cancer. TAM has also been used in malignant melanoma, particularly in combination with other chemotherapeutic agents. However, the inclusion of TAM in melanoma therapeutic schemes remains controversial, as the studies in humans performed so far provided contradictory results. TAM is a pro-drug that is metabolized by cytochrome P450 (CYP) enzymes, namely CYP3A4 and CYP2D6, generating the two active metabolites, 4-hydroxytamoxifen (OHTAM) and endoxifen (EDX), which are considered responsible for the anticancer activity of TAM in breast cancer. In fact, several studies have demonstrated an association between CYP2D6 phenotype and clinical outcome in women with breast carcinoma taking TAM. Additionally, several drugs that influence the enzymatic activity of CYP2D6 have also been shown to limit the biological activity of TAM. As the levels of EDX and OHTAM achieved *in vivo* seem to be closely related with the treatment efficacy and the utilization of TAM metabolites allows avoiding the variability on TAM metabolism, we investigated the effects of EDX and OHTAM on melanoma cells and compared to those promoted by TAM, in order to clarify whether TAM metabolites are an effective alternative to TAM in malignant melanoma.
Materials and Methods: Cell proliferation was measured by sulforhodamine B and bromodeoxyuridine (BrdU) incorporation assays, and cell death by the lactate dehydrogenase assay and by cell count with trypan blue staining. The effects on cell cycle were evaluated by flow cytometry.
Results: The antiestrogens decreased melanoma cell biomass in a concentration-dependent manner, but the effects of TAM metabolites were much more pronounced than those of TAM. The antiestrogens did not increase cell death, but TAM metabolites significantly decreased BrdU incorporation, whereas the same concentration of TAM did not exert significant effects.
Conclusion: These results suggest that TAM metabolites induce a superior cytostatic activity in melanoma cells relatively to TAM, suggesting that, as observed in breast cancer, the steady-state levels of EDX and OHTAM may also have an impact on the treatment efficacy of TAM in melanoma. Additionally, the individual variability in TAM metabolism can contribute to explain the discrepant outcomes observed in melanoma patients taking TAM. These observations should be taken into consideration in future trials.
This study was supported by a PhD grant (SFRH/BD/65130/2009) attributed to M.P.C. Ribeiro by FCT.

Real-time assessment of TORC1 suppression following RAF inhibitor treatment can predict responsiveness in BRAF-mutant melanoma patients

R.B. Corcoran[1], S.M. Rothenberg[1], A. Piris[1], R.M. Nazarian[1], S. Maheswaran[1], J. Settleman[2], J.A. Wargo[1], K.T. Flaherty[1], D.A. Haber[1], J.A. Engelman[1]. [1]*Massachusetts General Hospital, Cancer Center, Boston Massachusetts, USA;* [2]*Genentech, Discovery Oncology, South San Francisco California, USA*

Background: RAF inhibitors such as vemurafenib have transformed treatment for *BRAF*-mutant melanoma. Still, most responses are partial and short-lived, and many patients still fail to respond. Thus, biomarkers predicting which patients are more or less likely to benefit would have important clinical applications.
Material and Methods: To identify potential biomarkers of response, *BRAF*-mutant melanoma cell lines were characterized before and after treatment with vemurafenib. Potential biomarkers were evaluated in tumor biopsies obtained before and after vemurafenib treatment in *BRAF*-mutant melanoma xenografts. Paired biopsies obtained from *BRAF*-mutant melanoma patients before and ~2wks after initiation of RAF inhibitor were assessed by IHC for a change in phosphorylation of ribosomal protein S6 (P-S6), and suppression of P-S6 following treatment was correlated with progression-free survival (PFS). Using a novel multiplexed quantitiative immunofluorescence approach, serial fine-needle aspiration (FNA) biopsies obtained from patients before and 1−2wks after initiation of RAF inhibitor were assessed for P-S6 suppression, and results were correlated with radiographic tumor response.
Results: Suppression of TORC1 activity in response to RAF inhibitors, as measured by decreased P-S6, effectively predicted sensitivity in *BRAF*-mutant melanoma cells. In resistant melanomas, P-S6 was maintained, in some cases despite robust suppression of MAPK signaling by RAF inhibitors. In xenografts, P-S6 suppression by RAF inhibitors was necessary for induction of apoptosis and tumor response in vivo. In paired biopsies obtained from *BRAF*-mutant melanoma patients before and 1−2wks after initiation of RAF inhibitor, P-S6 suppression predicted significantly improved PFS [HR = 0.19, 95% CI 0.01–0.84; p = 0.03]. A change in P-S6 could be readily monitored in real-time by serial FNA biopsies in patients initiating RAF inhibitor therapy. In this small prospective test cohort, a decrease in P-S6 following initiation of RAF inhibitor therapy correlated with objective tumor response.
Conclusions: P-S6 suppression following initiation of RAF inhibitor therapy is a promising functional biomarker to predict sensitivity of *BRAF*-mutant melanomas, predicting improved PFS. Therapy-related changes in P-S6 can be effectively and quantitatively monitored in real-time in *BRAF*-mutant melanoma patients by serial FNA biopsies, providing an early and minimally-invasive means of evaluating therapeutic efficacy.

Synergistic effects of glutamate receptors antagonists combined with antiestrogens on melanoma cells

M.P.C. Ribeiro[1], A.E. Santos[1], J.B.A. Custódio[1]. [1]*Center for Neuroscience and Cell Biology University of Coimbra Portugal, Faculty of Pharmacy University of Coimbra, Coimbra, Portugal*

Introduction: In the last years the role of glutamate outside the central nervous system has garnered significant attention and the use of glutamate receptors antagonists in the treatment of several malignancies has been evaluated. Previous studies performed in our laboratory have demonstrated that *N*-methyl-D-aspartate receptors (NMDAR) antagonists memantine and MK-801 exert a cytostatic action on melanoma cells. Recently, it has been reported that MK-801 decreases melanoma cell motility and that it can also decrease melanoma growth *in vivo*. The antiestrogen tamoxifen (TAM) has been used routinely in the treatment of breast carcinoma, but it has also been shown to decrease melanoma cells proliferation and invasion. TAM is a pro-drug that is activated by cytochrome P450 (CYP) enzymes to 4-hydroxytamoxifen (OHTAM) and endoxifen.
The metabolites present therapeutic advantages comparing with the use of TAM, as their efficacy is not limited by variable CYP enzymes activity or by co-administration of CYP2D6 inhibiting medication. Therefore, we investigated the effects of a combined therapy of memantine or MK-801 with TAM and its active metabolite OHTAM on melanoma cells proliferation and migration.
Materials and Methods: Cell proliferation was measured by sulforhodamine B (SRB) and bromodeoxyuridine (BrdU) incorporation assays, and cell death by the lactate dehydrogenase (LDH) assay and by cell count with trypan blue staining. The effects on cell migration were monitored by the wound healing assay.
Results and discussion: The combinations of memantine or MK-801 with antiestrogens exhibited synergistic antiproliferative effects on melanoma cells, as shown by SRB assays. The effect on tumor cell proliferation was not due to increased cell death, since the combinations did not enhance LDH release neither trypan blue stained cells. Measurements of BrdU incorporation suggest that the combinations of NMDAR channel blockers and antiestrogens decrease cell division. Additionally, the combinations of memantine or MK-801 with OHTAM significantly decreased melanoma cells migration relatively to control.
Conclusion: Altogether, these findings support a combined therapy of NMDAR channel blockers memantine or MK-801 with antiestrogens as a new strategy for melanoma treatment.
This study was supported by a PhD grant (SFRH/BD/65130/2009) attributed to M.P.C. Ribeiro by FCT.

Removing barriers to patient detection of early stage melanoma

T.K. Pandian[1], V. Krishnamurthy[2], T.J. Hieken[1]. [1]*Mayo Clinic, General Surgery, Rochester Minnesota, USA;* [2]*Rush University Medical Center, Surgery, Chicago Illinois, USA*

Background: The incidence of and death rate from cutaneous melanoma (CMM) continue to increase. More than half of CMM are detected by patients or their close contacts. Outcome is directly related to stage at presentation. Patient-detected melanomas (PDM) present at higher stage than those found by physicians. We undertook this study to identify strategies to improve timely patient detection of early CMM.
Methods: We reviewed demographic, tumor, and prospective questionnaire data obtained at surgical oncology consultation for 488 CMM in 435 patients. Data were analyzed with SAS statistical software.
Results: 248 CMM (51%) were PDM. As shown in the table, factors associated with patient detection included female sex, younger age, non-Caucasian race, no prior skin cancer, non-truncal site, anterior location, and nodular or acral lentiginous histology, but not with family history or CMM diameter. PDM was associated with greater tumor level and thickness, ulcerated, amelanotic and node-positive CMM (all $p < 0.005$). Mean (median) tumor thickness was 1.66 (0.75) vs 0.72 (0.35) mm for PDM vs physician-detected CMM ($p < 0.001$); 66% of CMM>2 mm thick were PDM. The main symptoms prompting patients to seek care were change in size (32%), color (31%) and bleeding (10%).
Conclusions: We identified modifiable barriers that hinder patient detection of early melanoma. Screening programs, which have decreased mortality from breast and colon cancer, may also lower CMM mortality. Our data suggests that public health efforts and novel educational tools are needed to improve awareness among high-risk patients who are unlikely to detect their own CMM. Skin examinations during routine physician visits for these patients may improve early diagnosis and have a meaningful impact upon melanoma incidence and mortality.
No conflict of interest.

Intra-arterial hepatic chemoembolization with CPT-11 charged microbeads (TACE) combined with systemic fotemustine in metastatic uveal melanoma

S. Valpione[1], C. Aliberti[2], J. Pigozzo[1], E. Midena[3], R. Parrozzani[4], S. Stragliotto[1], P. Pilati[5], L.G. Campana[6], V. Chiarion-Sileni[1]. [1]*Veneto Oncology Institute, Melanoma Cancer Unit-SSD, Padova, Italy;* [2]*Veneto Oncology Institute, Interventional Radiology, Padova, Italy;* [3]*University of Padova, Department of Ophthalmology, Padova, Italy;* [4]*GB Bietti Foundation-IRCCS, Department of Ophthalmology, Rome, Italy;* [5]*University of Padova, 6Surgery Branch Department of Oncological Gastroenterological and Surgical Sciences, Padova, Italy;* [6]*Veneto Oncology Institute, Melanoma and Sarcoma Unit, Padova, Italy*

Background: Uveal melanoma (UM) is the most frequent tumor of the eye (70%), and represents 5% to 6% of all melanoma diagnoses. Approximately 50% of patients with UM will develop metastatic disease within 15 years from the treatment of primary tumor and the liver is the first or prevalent site of metastatic disease in up to 95% of the recurring patients. Without treatment the median survival time is generally poor: larger published case series reported a median life expectancy from 3.6 to 15 months, with rare cases of long-term survivors. Notwithstanding the efforts made to improve the outcome of metastatic UM, no standard therapy is established so far.
Material and Methods: A total of 143 patients (73 women and 70 men) were identified from a prospectively maintained database queried under IRB approval for uveal metastatic melanoma patients undergoing clinical treatments and procedures for their disease from September 1990 to October 2012. Data of patients who were treated with TACE combined with systemic fotemustine as first line treatment for stage IV disease were analyzed and compared with data of patients who didn't.

Table 1. Toxicity data of the combination of the1st TACE concomitant with systemic fotemustine, and duration of hospitalization after 1stTACE.

Toxicity (*N*=32)	No pain	Mild	Moderate	Severe	Very severe	Requiring sedation
Pain	5	10	12	5[a]	0	0
	No toxicity	**G1[b]**	**G2[b]**	**G3[b]**	**G4[b]**	**G5[b]**
Nausea/vomiting	27	3	1	1	0	0
Thrombocytopenia	21	6	1	2	2	0
Duration of hospitalization (nights)	**1 (Day Hospital)**	**2**	**3**	**4**	**5**	**6 or more**
	26	3[c]	2[d]	1[e]	0	0

Results: Out of 143 patients who were treated for metastatic uveal melanoma, 32 received TACE combined with systemic fotemustine as first line therapy. Fotemustine was administrated as outpatient chemotherapy. TACE was performed in day-hospital regimen, patients were usually discharged after an observation of 24 hours. Discharge was delayed after 1st TACE for 6 patients because of infection (*N*=1), and pain (*N*=5). Most frequent adverse event related to the procedure was pain (35 patients experimented pain, any grade), that was mostly epigastric and was eased by ranitidine in patients with mild-moderate pain and needed ranitidine plus morphine solphate (up to 40 mg i.v. per day) administration in 5 patients.

Nausea and vomiting were controlled with dopamine antagonists. Most serious adverse event was protracted G4 thrombocytopenia, that required transfusion of platelets for 2 patients. We observed 1 case of fever (peak 38.7ºC) with normal neutrophil count and augment of C reactive protein, the patient was treated with ceftriaxone and discharged after 3 nights. No life-threatening adverse events or procedure-related deaths were observed. Patients who received the combined treatment of TACE and fotemustine had a survival advantage (18.1 vs 14.6 months, $p = 0.039$).
Conclusions: Combined treatment with TACE and systemic fotemustine improves survival in metastatic melanoma patients and is well tolerated. It could be proposed for further studies, also combined with new drugs.

Melanoma risk-takers: "Fathers and sons"

F. Eisinger[1], J.F. Morère[2], X. Pivot[3], F. Grange[4], C. Lebbé[5], L. Mortier[6], C. Robert[7], P. Saiag[8], B. Sassolas[9], J. Viguier[10]. *[1]Institut Paoli Calmette, Marseille, France; [2]Hôpital Paul Brousse, Oncologie, Villejuif, France; [3]Hôpital Jean Minjoz, Oncologie, Besançon, France; [4]Hôpital Robert Debré, Service de Dermatologie, Reims, France; [5]Hôpital Saint Louis, Service de Dermatologie, Paris, France; [6]Hôpital Claude Huriez, Service de Dermatologie, Lille, France; [7]Institut Gustave Roussy, Service de Dermatologie, Villejuif, France; [8]Hôpital Ambroise Paré, Service de Dermatologie, Boulogne Billancourt, France; [9]Hôpital de la Cavale Blanche, Service de Médecine Interne, Brest, France; [10]Hôpital Trousseau, Centre de Coordination des Dépistages des Cancers, Tours, France*

Background: The fast growing rate of the incidence of skin cancers, especially melanoma, has resulted in the recommendation of sun protection measures. The aim of this survey was to analyse the compliance of the general population with these guidelines.
Methods: This French nationwide observational survey, EDIFICE melanoma, was conducted through phone interviews of a representative sample of 1,502 subjects aged $\geqslant$18 years old, using the quota method. The survey took place shortly after the summer from 28 September 2011 to 20 October 2011. Sun protection behaviours were defined by the frequent or systematic use of clothes or sunscreens. Out of the people who reported exposure to the sun (n = 1,172), the group of risk-takers (n = 442) was compared with those who used sun protection (n = 730).
Results: The risk-takers versus those who used sun protection were significantly more often men than women (62% vs. 44%, $p < 0.01$), had a lower level of education (40% vs. 26%, $p < 0.01$), lower incomes (2587 euros vs. 2948 euros), and smoked more often (42% vs.31%, $p < 0.01$). On the other hand, age, being in a relationship and sunbed use were similar in both groups. Interestingly, risk-takers have less melanoma risk factors (number of naevi and skin phototypes). They have less knowledge about high risk exposure timelines and optimal use of sunscreen protection. Sun protection measures for their children were less stringent in comparison to the group who used sun protection: wearing of sun glasses systematically or often (42% vs. 59%, $p < 0.01$), systematic use of sunscreen (77% vs. 86%, $p < 0.01$), frequency of renewal (69% vs. 82%, $p < 0.01$) high protective factors (46% vs. 56%, $p < 0.01$), using clothing (84% vs 92%, $p < 0.01$) and hats (88% vs. 92%, $p < 0.01$).
Conclusions: The risk-taker population is characterised by a lower level of knowledge of sun protection tools and behaviours. Their children benefit less from protective measures than those of people who use sun protection. If improving knowledge improves behaviours, this will be critically important since it will impact on both their own behaviour and on the use of protection methods for their children.

Melanoma risk in a subfertile population: Results from a large Dutch cohort study

M. Spaan[1], A.W. Van den Belt-Dusebout[1], T.M. Mooij[1], G.M. Ouwens[1], C.W. Burger[2], F.E. Van Leeuwen[1]. *[1]Netherlands Cancer Institute, Department of Epidemiology, Amsterdam, Netherlands; [2]Erasmus University Medical Center, Department Obstetrics and Gynecology, Rotterdam, Netherlands*

Background: Associations between hormonal factors and melanoma have been suggested based on associations with parity or exogenous hormone use. Therefore, we investigated whether subfertile women have an altered risk of melanoma.
Methods: In 1996, a nationwide cohort study (the OMEGA-cohort) was set-up to examine the risk of cancer in a subfertile population receiving ovarian stimulation for in-vitro fertilization (IVF). The cohort includes 19,119 women who received IVF and 6,911 subfertile women not treated with IVF. Cancer incidence was ascertained through linkage with the Netherlands Cancer Registry. Melanoma risk in the cohort was compared with the general population and between the IVF group and the non-IVF group.
Results: The risk of melanoma was not increased in the IVF group compared with the non-IVF group (hazard ratio (HR) = 1.02; 95% CI: 0.61–1.72). In addition, no increased risk was found for the IVF group compared with the general population. Nulliparous women had a significantly increased risk for melanoma (HR = 1.63; 95% CI: 1.04–2.56).
Conclusion: In a subfertile population with 38% nulliparous women we found that nulliparity was associated with increased melanoma risk, while IVF does not appear to affect melanoma risk.

Comparison between two widely used laboratory methods in BRAF V600 mutation detection rate in FFPE clinical samples of stage III cutaneous melanoma metastases to the lymph nodes

A. Gos[1], M. Jurkowska[2], J.A. Siedlecki[1], W. Michej[1], K. Wiater[1], T. Switaj[1], H. Kosela[1], P. Rutkowski[1]. *[1]Maria Sklodowska-Curie Memorial Cancer Center, Warsaw, Poland; [2]Institute of Rheumatology, Warsaw, Poland*

The aim of the study was to compare detection rates of somatic oncogenic *BRAF* mutations in a homogenic group of cutaneous melanoma stage IIIB/C patients by the Cobas® BRAF V600 Mutation Test and direct Sanger sequencing.
Material and Methods: The study group consisted of 236 FFPE melanoma lymph node metastases, collected during regional lymphadenectomy in one cancer center in the period 1994–2012. All samples were re-analysed by a pathologist. The majority had a tumour content of >90% and none <40%. *BRAF* mutational status was verified by 1.) an in-house PCR/Sanger sequencing test, using the BigDye® Terminator v3.1 Cycle Sequencing Kit and a ABI3731 instrument (Applied Biosystems) and 2.) the Cobas® 4800 BRAF V600 Mutation Test (Cobas®) with respective equipment (Roche Diagnostics).
Results: Considered as a gold standard in mutation analysis, Sanger sequencing approach enabled us to obtain results for 230/236 samples. In 140, the mutation in codon 600 of *BRAF* (60.9%) was found, additionally 4 mutations outside codon 600 were identified. The 86 remaining samples were wild type (WT). V600E accounted for 91.4% of all mutated cases (128 samples) followed by V600K substitution (9 samples, 6.4%), V600E2 (double substitution) in two cases and one V600D. Cobas® generated results in all 236 cases, point mutations changing codon V600 were detected in 144 of them (61.0%). Among 6 cases that were not amplifiable by the standard sequencing approach, 5 turned out to be positive and 1 was negative for the V600 mutation. Additionally the Cobas® test detected mutations in 5 samples that were negative by the other method.
Interestingly, sequencing allowed us to detect codon 600 mutations in 6 cases negative as assessed by Cobas®, 2 V600E samples and 4 that were V600K. In total, both tests provided us with the same *BRAF* mutational status in 215 out of 230 cases (93.5%).
Conclusions: Frequency of *BRAF* V600 mutations differed depending on the test applied, with 93.5% conformity. Sequencing was a powerful method to detect mutations other than V600, while Cobas® proved to be less susceptible to poor DNA quality or investigator bias.
The study was supported by the Polish National Science Centre grant no. 2011/03/B/NZ5/04513.
No conflict of interest.

Table 1. Sanger sequencing vs Cobas® test

Mutations as by Sanger sequencing	Cobas® 4800 BRAF V600 Mutation Test	
	mutation detected	mutation not detected
V600E	126	2
V600K	5	4
V600E2	2	0
V600D	1	0
WT	5	81

A novel companion diagnostic assay for BRAF V600E/K detection in melanoma: High clinical concordance of patient outcomes for trametinib and debrafenib treatment

L. O'Donnell[1], W. Sweet[1], X. Lu[1], F. Meynier[2], A. Derome[3], L. Ganee[3], F. Poyet-Gelas[3], A. Martin[4], M. Casey[5], N. Kertesz[6]. *[1]BioMerieux Inc., Clinical Affairs, Durham NC, USA; [2]BioMerieux Inc., BioMath, Grenoble, France; [3]BioMerieux Inc., R&D, Grenoble, France; [4]GSK, Oncology, Collegeville, USA; [5]GSK, Statistics, Collegeville, USA; [6]Response Genetics Inc., Pharmaceutical Liaison, Los Angeles, USA*

Background: THxID™-BRAF Assay was developed to detect BRAF V600E/K in formalin-fixed paraffin-embedded (FFPE) melanoma samples. The clinical performance of this assay has been evaluated in GSK-sponsored Phase III clinical trials MEK114267 (Trametinib) and BRF113683 (Dabrafenib) for subjects with BRAF V600E/K (mut+) melanoma. This study was incorporated in both trials to evaluate clinical concordance between the THxID™-BRAF Assay and the Investigational Use Only (IUO) assay from Response Genetics Inc. (RGI) on mut+ patients treated with Trametinib and Dabrafenib respectively.
Materials and Methods: Samples from subjects enrolled in MEK114267 and BRF113683 were tested retrospectively using THxID™-BRAF Assay and comparisons were made to the results from RGI IUO. Clinical outcomes were evaluated for the subjects randomized for treatment. For Trametinib trial (MEK114267), a total of 288 samples were tested with 282 reported mut+ by both assays and 6 samples with discordant results. For Dabrafenib trial (BRF113683), a total of 229 subjects were reported mut+ by both assays and 8 samples with discordant results. All subjects with mut+ by both assays were included in the clinical concordance analyses.
Results: For both Trametinib and Dabrafenib, the hazard ratio (HR) for progression free survival (PFS) for the subset of THxID™-BRAF mut+ subjects (Trametinib HR = 0.43; Dabrafenib HR = 0.32) was similar to that from the randomized population (Trametinib HR = 0.45; Dabrafenib HR = 0.30) respectively; both analyses were statistically significant. Median PFS was the same regardless of assay (Trametinib: 4.8 months for Trametinib and 1.5 months for Chemotherapy; Dabrafenib: 5.1 months for Dabrafenib and 2.7 months for DTIC). To help establish concordance, a 95% CI around the difference of the point estimates of the natural logarithm of the hazard ratio (ln[HR]) in the randomized and THxID™-BRAF Assay mut+ populations was constructed. There was no significant difference between ln[HR] (difference between ln[HR] estimates was 0.046 from Trametinib and −0.012 from Dabrafenib).
Conclusions: The THxID™-BRAF Assay demonstrated high clinical concordance with the RGI IUO assay for detecting BRAF V600E/K mutations. Similar efficacy results were seen between the randomized population and the subset of THxID™-BRAF mut+ subjects.

Metastatic basal cell carcinoma in the U.S. Veterans Affairs population

S.L. DuVall[1], O.V. Patterson[2], T.B. Forbush[3], A.W.C. Kamauu[4], Y.M. Yim[5], C. Reyes[5], G.M. Bowen[6]. *[1]VA Salt Lake City Health Care System, Informatics and Computing, Salt Lake City Utah, USA; [2]University of Utah, College of Pharmacy, Salt Lake City Utah, USA; [3]University of Utah, School of Medicine, Salt Lake City Utah, USA; [4]Anolinx LLC, Healthcare Informatics, Salt Lake City Utah, USA; [5]Genentech Inc., Health Economics and Outcomes Research, South San Francisco CA 94080, USA; [6]Huntsman Cancer Institute, Department of Dermatology, Salt Lake City Utah, USA*

Background: Metastatic BCC (mBCC) is rare, occurring in 0.0028% − 0.55% of BCC cases, not well characterized, and less than 400 cases have been reported in medical literature. The objective of this study is to describe the clinical, treatment and survival outcomes of mBCC patients (pts) in the Veterans Health Administration (VHA), the largest integrated healthcare system in the U.S.
Methods: Natural language processing (NLP) was used to identify mBCC pts treated at the VHA between 1999–2011 due to lack of BCC-specific ICD-9 codes. Pts with other primary cancers within 12 months of 1st documentation of BCC were excluded. mBCC was defined as pts with metastases to a distant organ or lymph nodes. All NLP-identified cases were confirmed for mBCC diagnosis (Dx) through chart review. The index date was the 1st documented Dx of mBCC. Baseline demographic, treatment, and survival outcomes were summarized. Due to limitations with NLP, ICD-9 codes occurring post-mBCC index date were used as a proxy to summarize lesion location (173.xx) and sites of metastases (196.xx–198.xx). Date of death was obtained through linkage with the National Death Index.
Results: A total of 475 mBCC pts were identified with median follow-up of 17.5 months, representing 0.13% of BCC cases. Median age was 72.0 yrs, 97.9% male, and 76.4% non-Hispanic white. Prevalent comorbidities were diabetes without complications (14.1%), chronic pulmonary disease (11.4%), congestive heart failure (7.0%), cerebrovascular disease (6.5%), and renal disease (6.5%). The most commonly coded lesion sites were unspecified (64.8% pts), unspecified parts of the face (28.0% pts), ear and external auditory canal (13.1% pts), and scalp and skin of neck (13.1% pts). Based on NLP, 28.8% pts indicated lymph node involvement. ICD-9 codes for site of metastases were reported in only 30% of pts. mBCC pts were treated with chemotherapy (24.2%), radiation (11.4%), and surgical treatment (37.5%). At end of observation, 272 mBCC pts (57.3%) were deceased. Amongst the subgroup of deceased pts, the median interval between mBCC Dx and all-cause death was 11.8 months [range 0–138.1 months].
Conclusions: In this study, demographic and disease characteristics of large cohort of mBCC pts from a U.S. military veteran population are presented. mBCC prevalence and time to death is consistent with reported literature. Additional research is warranted to further characterize this patient population.

Frequency and characteristics of familial melanoma in Spain: Preliminary results of the FAM-GEM-1 study

I. Márquez Rodas[1], M. Martín-González[2], P. Cerezuela[3], T. Puértolas[4], S. Martín-Algarra[5], E. Godoy-Gijón[6], I. Gil-Arnaiz[7], C. Maldonado-Seral[8], M. González-Cao[9], A. Martín-Carnicero[10]. *[1]Instituto de Investigación Sanitaria Gregorio Marañón, Medical Oncology, Madrid, Spain; [2]Hospital Ramón y Cajal, Dermatology, Madrid, Spain; [3]Hospital General Universitario Santa Lucía, Medical Oncology, Cartagena, Spain; [4]Hospital Universitario Miguel Servet, Medical Oncology, Zaragoza, Spain; [5]Clínica Universidad de Navarra, Medical Oncology, Pamplona, Spain; [6]Hospital de Cabueñes, Dermatology, Pamplona, Spain; [7]Hospital Reina Sofía, Medical Oncology, Pamplona, Spain; [8]Hospital Central Asturias, Dermatology, Oviedo, Spain; [9]Instituto Oncológico Rossell, Medical Oncology, Barcelona, Spain; [10]Hospital San Pedro, Medical Oncology, Logroño, Spain*

Background: It is estimated that 5−10% of melanoma cases occur in a familial setting. The most known high and intermediate susceptibility genes are CDKN2A and M1CR respectively, but they explain less than 1/3 of the cases. The classic definition for familial melanoma (FM) is the presence of 2 or more first degree relatives with melanoma. Multiple melanoma, early age and family history of pancreatic cancer (PC) are also risk factors for carrying a mutation in CDKN2A. In Spain there are no studies that cover all the territory.
Methods: FAM-GEM-1 is a national, observational, 2 years-registry study (2011–2013), conducted by the Spanish Multidisciplinary Melanoma Group (GEM), whose principal objective is to assess the rate of melanoma patients with family history of melanoma in Spain. Secondary objectives are to analyze whether patients with family history are different from sporadic melanoma in terms of clinical, pathological and molecular features; and to constitute a registry of FM in order to deeper characterise these patients in further studies. We present the exploratory results of the first 274 patients registered.
Results: We did not find any significant differences in clinical or pathological characteristics between patients with family history of melanoma or PC and melanomas without family history. There were higher rate of presence of multiple nevi in patients with family history of PC (41.7%) versus patients without it (19.4%) ($p = 0.07$). BRAF mutation was detected in 4 of 5 (80%) cases analysed in the melanoma with melanoma family history.
Conclusions: In our study, almost 11% of patients have family history of melanoma (63% fulfil classic FM criteria) and 4% of PC. There were no significant differences in clinical or pathological characteristics between groups, although there was a trend for higher rate of history of multiple nevi and the presence of PC in the family. BRAF mutation in melanomas with FM has been detected in a high rate, needing further study.

3723 POSTER

Relevance of indoleamine 2,3-dioxygenase as prognostic biomarker in melanoma patients

T. Palomares[1], M. De Lecea[2], D. Armesto[3], M. Cavia[3], D. Al Kassam[4], A. Alonso-Varona[5]. *[1]University of the Basque Country (UPV/EHU), Surgery and Radiology, Leioa (Bizkaia), Spain; [2]Burgos University Hospital, Plastic Surgery, Burgos, Spain; [3]Burgos University Hospital, Research Laboratory, Burgos, Spain; [4]Burgos University Hospital, Clinical Analysis, Burgos, Spain; [5]University of the Basque Country (UPV/EHU), Biology and Histology, Leioa (Bizkaia), Spain*

Background: Previous studies have suggested the value of indoleamine 2,3-dioxygenase (IDO), a tryptophan-catabolizing enzyme with immune-regulating activities, as prognostic factor in melanoma. In this study, we analyze the lactate dehydrogenase (LDH) and S100B serum levels (the most commonly markers used in melanoma) and the IDO expression in melanoma patients, in order to determine the useful prognostic relevance of IDO in comparison with LDH and S100B.
Material and Methods: For a period of four years, 201 melanoma patients with a median age of 59 years at the time of diagnosis (range: 25−91) were enrolled in this study. Healthy controls were also included (n = 43). The study was approved by the medical ethical committee of Burgos University Hospital. All patients signed written informed consent. We analyzed serum levels of LDH, S100B, and IDO (measured as levels of kynurenine in peripheral blood) at the moment of diagnosis and in the course of the disease (every 3 months). In order to detect relapse and distant metastases, clinical/radiological evaluations were scheduled every 3, 4 or 6 months in first, second and thereafter years, respectively.
Results: At the time of diagnosis, only patients with stage IV presented a significant increase in LDH and S100B serum levels with respect to controls. However, IDO serum levels were increased in a clinical stage-dependent fashion, being the difference statistically significant in patients with stage II, III and IV (1.3-, 1.4- and 1.5-fold increase, respectively, with respect to control values; $p < 0.001$). In relapse patients, the three biomarkers were significantly increased with respect to the values performed at the time of diagnosis. In addition, IDO levels were higher in patients with lymphatic dissemination ($p < 0.001$). In fact, we found that IDO values above 1.45-fold of the controls is correlated with lymphatic dissemination (80% sensitivity; 83% specificity; area under the receiver operating characteristic curve, ROC-AUC 0.85), and with a significant decrease in overall survival ($p = 0.011$).
Conclusions: Our results suggest that IDO could be a good prognostic marker for melanoma and useful to predict recurrences or metastatic disease.
This study has been supported by grants from the University of the Basque Country (UPV/EHU), SACYL, Caja Burgos and Mutua Madrileña.

Predictive factors for the development of brain metastases in patients with malignant melanoma: A study by the Anatolian Society of Medical Oncology

O. Gumusay[1], T. Akman[2], A.S. Ekinci[3], M. Kocar[4], O.B. Erceleb[5], M.A. Kaplan[6], O. Yazici[7], V. Berk[8], B. Cetin[1], U. Coskun[1]. *[1]Departments of Medical Oncology Gazi University Faculty of Medicine, Ankara, Turkey; [2]Dokuz Eylul University Faculty of Medicine, Departments of Medical Oncology, Izmir, Turkey; [3]Dr. Abdurrahman Yurtaslan Education and Research Hospital, Departments of Medical Oncology, Ankara, Turkey; [4]Marmara University Faculty of Medicine, Departments of Medical Oncology, Istanbul, Turkey; [5]Kartal Education and Research Hospital, Departments of Medical Oncology, Istanbul, Turkey; [6]Dicle University Faculty of Medicine, Departments of Medical Oncology, Diyarbakir, Turkey; [7]Ankara Numune Education and Research Hospital, Departments of Medical Oncology, Ankara, Turkey; [8]Erciyes University Faculty of Medicine, Departments of Medical Oncology, Kayseri, Turkey*

Background: The development of brain metastases (BMs) were associated with poor prognosis in melanoma patients. Patients with BMs have a median survival of <6 months. Solitary BMs are more common in melanoma compared with other solid malignancies. Our aim was to identify factors predicting development of BMs and survival.
Patients and Methods: We performed a retrospective analysis of 520 melanoma patients between 2000 and 2012. After eliminating patients who had BMs at the time of melanoma diagnosis and patients who had dropped out of follow up, 470 remaining patients were analyzed. The logistic regression analysis were used to identify the clinicopathological features of primary melanoma that are predictive of BMs development and survival after a diagnosis of brain metastases. Clinical variables such as the presence of neurological symptoms, and the extracranial disease at the time of BMs diagnosis were also assessed.
Results: There were 52 patients (11.1%) who developed melanoma BMs during the study period. The ages of patients with BMs, ranged from 28 to 82 with a median age of 51, and 73.1% of the patients were male. At the time of BMs diagnosis, 61.5% (n = 32) of patients had evidence of extracranial disease. The majority of patients with BMs had neurological symptoms (89.4%). The median post-BMs survival was 4.1 months (range 2.9−5.1 months). On logistic regression analysis site of the primary tumor on the head and neck ($p = 0.002$), primary tumor thickness (Breslow $\geqslant$4 mm) ($p = 0.008$), ulceration ($p = 0.007$), pathologically N2 and N3 disease ($p = 0.001$), were found to be significantly associated with the development of BMs. In univariate analysis, tumor thickness, mitotic index, AJCC stage, performance status had a significant influence on post-BMs survival. In multivariate analysis, these clinicopathologic factors were not remained as significant predictive factors.
Conclusions: Our results revealed the importance of primary tumor characteristics associated with the development of BMs. Ulceration, primary tumor thickness, anatomic site, and pathologic $\geqslant$N2 disease were found to be significant predictors of BMs development.

3725 POSTER

Increasing number of melanoma in situ in Serbia due to media campaign − experience of melanoma center

D. Nikolic[1], V. Stanimirovic[2], A. Nikolic[3], J. Gacic[4]. *[1]Medical Faculty of Belgrade University Medical Center Bezanijska Kosa, Oncosurgery, Beograd, Serbia; [2]Medicine and Medical Devices Agency of Serbia, Human Medicines Center, Beograd, Serbia; [3]Medical Faculty of Belgrade Cardiovascular Institute Dedinje, Non Invasive cardiology, Beograd, Serbia; [4]University Medical Center Bezanijska Kosa Belgrade, Oncosurgery, Beograd, Serbia*

Background: Melanoma is the most serious type of cancer of the skin and is becoming increasingly common, worldwide. The incidence rates in Australia and New Zealand (between 30−40 per 100,000) are about four times higher than those found in North America and the United Kingdom, though in Serbia incidence is about 5 per 100,000. The incidence of melanoma in situ is growing significantly. Detection at the stage provides the highest cure rate for melanoma, but reliable detection with digital epiluminesence microscopy may allow more precise detection of melanoma in situ.
Material and Methods: During the period of five years, from the beginning of opening Melanoma Center, we examined 11,352 patients with the total number of 354,785 evaluated digital images with an integrated system for digital epiluminescence microscopy based on a new concept of illumination.This system combines an easy to use microscope with excellent optical quality and modern computer technology for efficient

data storage and retrieval.Therefore, simultaneous dermatologist/patient on screen observation of potential mole alteration is made possible. The integrated system has capability to recall and display stored images.
Results: In total, 354,785 pigmented lesions from 11,352 selected patients were evaluated using digital epiluminescence microscopy. Comparison with histology was performed on the 1022 surgically excised lesions.Epiluminescence microscopy sensitivity, specificity, positive and negative predictive values as well as agreement for the different risk levels of the lesions were determined. Of the 1022 cutaneous pigmented lesions removed and histological examined, *232 (22.7%)* were non-melanocytic lesions and *790 (77.3%)* were melanocytic lesions. Sensitivity and specificity of digital epiluminscence microscopy in the analysis of melanocytic lesions with a pigment network were both very high (99.8% and 98.7%, respectively). Forty-seven new case of *thin melanoma* (Clark I and II, Breslow I) were identified from one hundred seventy six new cases of all types of melanoma *(26.7%)*. A remarkable proportion of melanoma *in situ* (21 out of 176; *11.9%*) was diagnosed exclusively by digital epuluminescence microscopy.
Conclusions: The prognosis of melanoma can be improved if the tumor is recognized and treated in its early phase.Our study clearly shows that a nationwide public melanoma education campaign significantly reduces the mean Breslow invasion thickness of all melanomas in patients seen in one institution. Although this phenomenon persisted in the post campaign year, the Breslow thickness increased in the years thereafter. Nevertheless, the increased number of patients with earlier stages of the disease during the campaign proves the value of melanoma education campaigns. The immediate worsening of the prognostic features in the post campaign years strongly indicates the need for a permanent education of professionals and the public.

3726 POSTER

Sentinel lymph node biopsy is less frequently performed in melanoma patients with a low socioeconomic status

M. Niebling[1], A.M. Huismans[1], K.P. Wevers[1], M.S. Schuurman[2], H.J. Hoekstra[1]. *[1]University Medical Centre Groningen, Surgery, Groningen, Netherlands; [2]Comprehensive Cancer Centre the Netherlands (IKNL), Department of Research, Groningen, Netherlands*

Background: Sentinel lymph node biopsy (SLNB) is a widely accepted procedure and is recommended for patients with a cutaneous invasive melanoma with a Breslow thickness larger than 1 mm. However, in the United States this procedure is only performed in approximately half of these patients. Performing a SLNB in the US is associated with patient factors including high socioeconomic status and possession of a private health care insurance. The latter of these factors is not applicable in the Netherlands since every patient is insured for health care. Therefore the aim of the present study was to analyse whether socioeconomic status of melanoma patients had an influence on the frequency of performing SLNB.
Material and Methods: Patients who were diagnosed with a cutaneous invasive melanoma of $\geqslant$1 mm between 2004 and 2011 from the north-eastern part of the Netherlands were selected from the Netherlands Cancer Registry (n = 2428). An estimate of the socioeconomic status was defined by income, employment, and level of education. Patients were equally divided over five groups based on socioeconomic status. The Chi square test was used to analyse the association between socioeconomic status and the use of SLNB, for this association odds ratios were defined using univariate logistic regression. Furthermore, the chi square test was also used to analyse if the frequency of SLNB had significantly increased during the past 8 years.
Results: SLNB was performed in 1014 of the 2428 patients (41.8%) The frequency of performing SLNB increased from 24.9% in 2004 to 55.2% in 2011, which was a significant increase (P<0.01). There was a significant association between socioeconomic status and the frequency of performing SLNB (P = 0.05). The group of patients with the highest socioeconomic status had an odds ratio of 1.4 (95% confidence interval: 1.05–1.75) for undergoing a SLNB compared to the group of patients with the lowest socioeconomic status.
Conclusions: In 2011 SLNB was only performed in 55.2% of the patients with a cutaneous invasive melanoma $\geqslant$1 mm, while it has become a recommended staging procedure for these patients. The frequency of performing SLNB has increased over the last 8 years. SLNB is less frequently performed in melanoma patients with a low socioeconomic status and this will have an impact on their disease free and overall survival.
No conflict of interest.

3727 POSTER

Sentinel lymph node biopsy improves regional disease control for selected patients with thin melanomas

T.K. Pandian[1], B.C.L. Trull[2], V. Krisnamurthy[3], T.J. Hieken[1]. *[1]Mayo Clinic, Surgery, Rochester Minnesota, USA; [2]Royal College of Surgeons in Ireland, Medical School, Dublin, Ireland; [3]Rush University Medical Center, Surgery, Chicago Illinois, USA*

Background: Recently updated clinical practice guidelines suggest that sentinel lymph node biopsy (SLNB) only be offered to selected patients with thin melanomas as these patients generally have an excellent prognosis and a low incidence of SLN metastasis. Yet, nearly 25% of all melanoma-related deaths result from thin primaries. It is unclear whether SLNB with selective LN dissection (LND) represents an opportunity to cure patients with high-risk thin melanoma or whether LN disease in these patients lacks the clinical significance of nodal metastasis in patients with thicker tumors.
Methods: From our Melanoma Registry, we identified 339 consecutive thin (clinical stage T1 N0) melanoma cases in 301 patients. Data were verified by pathology and record review. Median patient follow up was 61 months.
Results: Thirty-seven patients (12.2%) underwent SLNB. Patients selected for SLNB were younger (median 57 vs 69 years, p = 0.03), with thicker (median 0.68 vs 0.25 mm), more often level IV/V (43.2 vs 5.3%), ulcerated (15.3 vs 0.3%) and mitotically active (67.6 vs 22.3%) melanomas, all p < 0.001. Three patients (8.1%) were SLN-positive: one patient had isolated tumor cells in a solitary SLN, one had several 0.1 mm metastatic foci in one of 2 SLNs, and one had 2.0 and 0.2 mm foci in 2 of 2 SLNs. None had additional positive LNs detected at completion LND. After a median of 32 (IQR 19−82) months, disease recurred in 6/37 patients after SLNB (16.2%) and 20/264 non-SLNB patients (7.5%). Isolated regional recurrence was the site of first relapse in 9/264 non-SLN patients (3.4%, or 45% of recurrences in non-SLN patients) but in none of the SLN biopsy patients, p < 0.001. Melanoma specific survival was governed by tumor thickness.
Conclusions: SLNB with selective LND appears to provide excellent regional disease control for selected patients with thin melanomas. For the few patients with thin melanoma found to harbor SLN metastasis, completion LND is advised although the likelihood of identifying additional nodal metastatic disease is small. Whether some early melanoma patients have even microscopically occult nodal disease which may be cured with SLNB alone is an intriguing hypothesis that warrants further investigation.
No conflict of interest.

3728 POSTER

Residual melanoma after an excisional biopsy is an independent prognostic factor for local relapse and overall survival

M. Hocevar[1], Z. Dragonja[1], G. Pilko[1], B. Peric[1], B. Gazic[2], J. Zgajnar[1]. *[1]Institute of Oncology Ljubljana, Department of Surgical Oncology, Ljubljana, Slovenia; [2]Institute of Oncology Ljubljana, Department of Pathology, Ljubljana, Slovenia*

Background: Excisional biopsy with a 1−3 mm margin of normal skin and a cuff of subcutaneous fat is a preferable method of biopsy for any suspicious pigmented skin lesion. After micro staging of a primary melanoma a wide (re)excision with/without a sentinel lymph node biopsy (SLNB) should be performed according to the thickness of the primary melanoma. There is a very few data about the impact of residual melanoma on frequency of a local relapse and on overall survival.
The aim of this study was to evaluate the effect of a residual melanoma after an excisional biopsy on prognosis of patients with cutaneous melanoma.
Material and Methods: Between 2000 and 2007 SLNB with/without wide reexcision of a primary melanoma site was successfully performed in 692 patients (315 male and 377 female; mean age 55.7 years) at the Institute of Oncology Ljubljana, Slovenia. Clinicopathological data of all patients were extracted from a prospective institutional melanoma database and the frequency of local relapses and survival were compared between patients with residual melanoma and those without it. For a statistical analysis univariate and multivariate analyses were used.
Results: Only 25 (3.6%) patients had a residual melanoma. There was no difference in mean tumour thickness (3.91 and 2.79 mm) and ulceration (40% and 34%) of the primary melanoma between patients with and without residual melanoma. However, a number of local relapses (16% versus 2.7%) and a number of metastases in sentinel lymph nodes (44% versus 22%) were significantly higher and a 5-year survival was significantly lower (64% versus 87.5%) in patients with residual melanoma. Breslow thickness, ulceration, positive SLNB and residual melanoma were independent prognostic factor for overall survival.
Conclusions: Residual melanoma is very rare after an excisional biopsy of the primary melanoma. However, when present it indicates a higher probability of local relapse and a worse overall survival.
No conflict of interest.

3729 POSTER

The number of metastatic foci in positive sentinel nodes with a tumor burden <0.1 mm does not affect prognosis of melanoma patients

A. Maurichi[1], R. Patuzzo[1], G. Gallino[1], R. Ruggeri[1], I. Mattavelli[1], G. Baffa[1], M.C. Tinti[1], G.P. Castelli[1], M. Santinami[1]. [1]*Fondazione IRCCS Instituto Nazionale Tumori, Surgery, Milano, Italy*

Background: Controversies exist in order to perform a routine completion lymph node dissection (CLND) in melanoma patients with Sentinel Lymph-Node (SLN) metastases <0.1 mm, showing they similar survival rates of SLN-negative patients. The aim of the present study was to investigate this population of patients in order to define factors affecting survival.
Material and Methods: A SNL positivity was found in 348 of 2013 stage I/II patients consecutively treated from 2000 to 2006. The analysis categorized topography of SN-metastases, amount of SN tumor burden and number of metastatic foci. Non-SLN positivity and Melanoma Specific Survival (MSS) were evaluated.
Results: Mean Breslow thickness was 2.1 mm; mean FU was 46 months. Cases with SLN metastasis <0.1 mm were 33 (9.5%). Patients were shown to have similar estimated 5-year MSS rates in the subgroup with one metastatic focus as well as in that with more than one (93% and 91%). Similar rates were found in the two subset of patients relatively to non-SLN positivity (6% and 7%). Topography of SLN involvement had impact on MSS whereas patients with sub-micrometastases present in the subcapsular area only did not show non-SLN positivity and had an estimated 5- and 10-year MSS of 98%.
Conclusions: Our data suggest that patients with SLN sub-micrometastases (<0.1 mm) could be judged as those SLN-negative irrespectively from the number of metastatic foci located in the subcapsular area.
No conflict of interest.

3730 POSTER

Isolated limb perfusion in the management of in-transit melanoma metastases: A monoistitutional experience

R. Patuzzo[1], R. Ruggeri[1], G. Gallino[1], A. Maurichi[1], I. Mattavelli[1], G. Baffa[1], M.C. Tinti[1], G.P. Castelli[2], M. Santinami[1]. [1]*Fondazione IRCCS Istituto Nazionale dei Tumori, Surgery, Milan, Italy;* [2]*Ospedale di Siracusa, Dermatology, Siracusa, Italy*

Background: The Isolated Limb Perfusion (ILP) is an established treatment for melanoma *in transit* metastases (ITM) but the use of tumour necrosis factor (TNF) α is not uniformly accepted. This study reports on a monoinstitutional experience in performing TNF and melphalan-based ILP.
Patients and Methods: A total of 377 ILP were performed on 343 patients with stage IIIB/IIIC melanoma between 1991 and 2012. Melphalan doses were 10−13 mg/l (leg and arm, respectively); TNF was performed at high doses of (3−4 mg) up to 2004 (n = 199) and at low doses of TNF (1−2 mg) from 2004 to 2012 (n = 144) under mild hyperthermic conditions (38ºC-39.5ºC.).
Results: Median follow up was 92 months. Five-year overall survival (OS) was 40% and median survival was 42 months. Stage IIIB and IIIC patients had a 5-year OS rate of 49% and 27%, respectively. Complete, partial and minor responders had a 55%, 33% and 20% 5-year OS, respectively. A second ILP was performed in 30 patients, a third ILP in 4 patients. Treatment-related mortality was observed in 3 patients (0.9%). Severe or grade V toxicity occurred in 6 patients (1.8%). A second or a third ILP performed in the same patient did not cause increased morbidity and provided improved local control. Stage of disease and the extent of immediate response are two significant prognostic factors.
Conclusions: ILP with Melphalan and TNF was an effective treatment modality for melanoma with ITM, in order to obtain a loco-regional disease control.
No conflict of interest.

3731 POSTER

The UK sentinel lymph node biopsy service in stage 1B cutaneous melanoma

S. Yao[1], P.T.H. Brackley[1]. [1]*Whiston Hospital, Plastic Surgery, Liverpool, United Kingdom*

Introduction: Sentinel Lymph Node Biopsy (SLNB) has been advocated as part of the diagnostic and prognostic process in the 2010 updated guidelines for management of cutaneous melanoma. However, there remains some discrepancy in practice across the UK regarding offering SLNB in patients with 1B melanoma (ulceration or mitotic rate $\geqslant 1/mm^2$).
Materials and Method: Fifty-two plastic surgery units from the UK were identified and contacted via telephone and email. Responses were predominantly obtained from skin cancer specialist nurses and consultants interested in skin cancers.
Results: Of the 52 units surveyed, 40% provide a SLNB service within their trust. Of these, 71% offer the surgery to stage 1B patients with either ulceration or high mitotic rate. Specifically, 57% routinely offer SLNB to patients with stage 1B disease due to ulceration; and 62% to stage 1B disease due to a high mitotic rate.
Conclusions: Despite recommendations from the UK guidelines, variation in management of melanomas remains. The risk of a positive SLNB in <1 mm melanoma is quoted at between 5 and 10%. Further studies are therefore warranted to look at the relationship between SLNB outcomes and Stage 1B disease, to guide us in formulating a more united approach to patient management across the UK.
No conflict of interest.

3732 POSTER

Gastrointestinal melanoma metastases surgery in the age of targeted therapy

G. Gallino[1], R. Patuzzo[1], A. Maurichi[1], R. Ruggeri[1], I. Mattavelli[1], G. Baffa[1], M.C. Tinti[1], G.P. Castelli[1], S. Signoroni[2], M. Santinami[1]. [1]*Istituto Nazionale Tumori, Surgery, Milan, Italy;* [2]*Ospedale di Siracusa, Dermatology, Milan, Italy*

Background: Malignant melanoma is the most common tumour metastatic to the gastrointestinal tract. The aim of this study is to assess in a large series of patients the clinical outcomes following therapeutic or palliative surgery of gastrointestinal tract melanoma metastases. The significance of the prognostic factors who affect the prognosis will be evaluated too.
Material and Methods: From 1985 to date 106 patients affected by Stage IV melanoma underwent surgical resection for gastrointestinal metastases at the Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy. The surgical procedure performed was radical or incomplete resection of intestinal metastases. Post operative outcomes were collected and studied by a multivariate analysis. In a small subgroup of patients recently treated gene BRAF mutational status was also evaluated.
Results: In 62/106 (58.5%) patients who underwent surgical resection for gastrointestinal metastases the primary melanoma was nodular type. All patients usually showed symptoms due to anemia and/or bowel obstruction. The intent of surgery was palliative in 61 (57.5%) and therapeutic in 45 (42.5%). Surgical procedure performed was ileal resection in 57 patients, digiunal resection in 31 patients, large bowel resection in 11 patients and duodenal resection in 7. 37 operations involved multiple small bowel resection and/or another intraabdominal organ. The 5-year survival in the group of patients who received a complete resection was significantly higher than in the incomplete resection group. A multivariate analysis identified as important prognostic factors for survival the complete surgical resection of the recurrence (P = 0.0001) and the single site visceral metastases (P = 0.0001). Preliminary and observational data in 35 patients seem to correlate a higher presence of BRAF mutation to long survivor patients.
Conclusion: In highly selected patients with melanoma metastatic to intra abdominal solid organs an aggressive attempts at complete surgical resection may improve the 5-year and disease free survival. The prognostic value of presence of BRAF V600 mutation will be evaluated in a larger series of patients as possible biomarker for patients management.
No conflict of interest.

3733 POSTER

Secondary endpoints from OPTiM: A multicenter, randomized phase 3 trial of talimogene laherparepvec vs GM-CSF for the treatment of unresected stage IIIB/C and IV melanoma

H. Kaufman[1], R.H.I. Andtbacka[2], K. Harrington[3], F. Collichio[4], T. Amatruda[5], N. Senzer[6], J. Chesney[7], K.A. Delman[8], A. VanderWalde[9], R. Coffin[10]. [1]*Rush University Medical Center, Chicago, USA;* [2]*University of Utah Huntsman Cancer Institute, Salt Lake City, USA;* [3]*Royal Marsden Hospital, London, United Kingdom;* [4]*University of North Carolina Medical Center, Chapel Hill, USA;* [5]*Hubert Humphrey Cancer Center, Robbinsdale, USA;* [6]*Mary Crowley Cancer Research Center, Dallas, USA;* [7]*University of Louisville, Louisville, USA;* [8]*Emory University, Atlanta, USA;* [9]*Amgen Inc, Thousand Oaks, USA;* [10]*Amgen Inc, Woburn, USA*

Background: Talimogene laherparepvec (T-VEC) is a novel oncolytic immunotherapy derived from herpes simplex virus type-1 designed to selectively replicate within tumors and to produce GM-CSF to enhance locoregional and systemic antitumor immune responses. OPTiM evaluated T-VEC or GM-CSF for the treatment (tx) of unresected regionally or distantly metastatic melanoma (CT #NCT00769704). Key secondary

endpoint results are reported in addition to the primary results previously reported at ASCO 2013.

Materials and Methods: Patients (pts) had age ⩾18 yrs; ECOG PS ⩽1; unresectable melanoma Stage IIIB/C or IV; injectable cutaneous, subcutaneous (SC), or nodal lesions; LDH ⩽1.5X upper limit of normal; ⩽3 non-lung visceral lesions, and no lesion >3 cm. Pts were randomized 2:1 to T-VEC (initially ⩽4 mL $\times 10^6$ pfu/mL then after 3 wks, ⩽4 mL $\times 10^8$ pfu/mL Q2W) intralesionally or GM-CSF (125 $\mu g/m^2$ qd $\times$ 14 days q28d) SC. *BRAF* status at baseline was collected if known. The primary endpoint was durable response rate (DRR): partial or complete response (CR) continuously for ⩾6 mos starting within 12 mos. Responses were per modified WHO by blinded central review. Key secondary endpoints included OS, objective response rate (ORR) by central review, and time to treatment failure and time to and duration of response (DoR) per investigator.

Results: 436 pts are in the ITT set: 295 (68%) T-VEC, 141 (32%) GM-CSF. Male 57%; median age 63 yrs, Stage IIIB/C 30%, IVM1a 27%, IVM1b 21%, and IVM1c 22%. DRR (95% CI) for T-VEC was 16% (12%-21%) and 2% (0%-5%) for GM-CSF, p < 0.0001. ORR (95% CI) was 26% (21%-32%) with 11% CR for T-VEC, and 6% (2%-10%) with 1% CR for GM-CSF. In an interim analysis of OS there was a trend in favor of T-VEC (HR = 0.79 [95% CI: 0.61–1.02]). With T-VEC, the most common adverse events (AEs) were fatigue, chills, and pyrexia. No grade ⩾3 event occurred in ⩾3% of pts; 26% of T-VEC and 13% of GM-CSF pts had serious AEs. Among responders, DoR was longer with T-VEC (HR = 0.30 [95% CI: 0.13–0.68]; p = 0.003). Responses ⩾12 mos were estimated to occur in 53% (95% CI: 42%-63%) of T-VEC responders. Baseline *BRAF* mutation status was known for 31% of pts in the T-VEC arm; DRR was 11% in both wild-type and mutant pts and 19% in the *BRAF* unknown set.

Conclusions: DRR and ORR are significantly improved with T-VEC in pts with unresectable Stage IIIB-IV melanoma. More than half of T-VEC responses lasted ⩾12 mos and T-VEC treatment was tolerable with an interim trend toward improved OS.

Combined nivolumab (anti-PD-1, BMS-936558, ONO-4538) and ipilimumab in the treatment of advanced melanoma (MEL) patients (pts): Safety and clinical activity

M. Sznol[1], M.K. Callahan[2], H. Kluger[1], M.A. Postow[2], M. Burke[3], Q. Hong[4], M. Selby[5], A. Korman[5], A. Gupta[6], J.D. Wolchok[2]. *[1]Yale University School of Medicine and Yale Cancer Center, Internal Medicine, New Haven CT, USA; [2]Memorial Sloan-Kettering Cancer Center, Medicine, New York NY, USA; [3]Yale University School of Medicine and Yale Cancer Center, Yale Melanoma Unit Smilow Cancer Hospital, New Haven CT, USA; [4]Bristol-Myers Squibb, Global Biometric Sciences, Princeton NJ, USA; [5]Bristol-Myers Squibb, Discovery Research, Redwood City CA, USA; [6]Bristol-Myers Squibb, Discovery Medicine and Clinical Pharmacology, Princeton NJ, USA*

Background: The immune checkpoint receptors PD-1 and CTLA-4 have non-redundant immunologic functions. Antibody blockade of PD-1 with nivolumab or CTLA-4 with ipilimumab demonstrated substantial activity in pts with MEL. Concurrent treatment with anti-PD-1 and anti-CTLA-4 resulted in synergistic antitumor activity in syngeneic murine tumor models. Therefore, we conducted a phase 1 study of nivolumab combined with ipilimumab in MEL pts.

Materials and Methods: Pts received IV nivolumab concurrently with ipilimumab q3 wk $\times$ 4 doses, followed by nivolumab alone q3 wk $\times$ 4 doses (Table). At wk 24, combined treatment was continued q12 wk $\times$ 8 in pts with disease control and no DLTs. In sequenced cohorts, pts with prior ipilimumab therapy received nivolumab q2 wk $\times$ 48.

Results: Fifty-three and 33 pts received concurrent and sequential nivolumab/ipilimumab, respectively. In the concurrent/sequential cohorts, 57%/55% of pts were stage M1c and 38%/100% received prior systemic treatment. In concurrent cohorts 1−3, treatment-related AEs (rAEs) were qualitatively similar to those observed in published monotherapy studies, although some occurred more frequently. Grade 3−4 rAEs occurred in 53% of pts; the most common were lipase, AST, and ALT elevations. AEs were generally reversible and in some pts required immunosuppressants. Cohort 3 exceeded the MTD (3/6 pts with asymptomatic grade 3−4 lipase elevation) and cohort 2 was the MTD. For cohorts 1−3, aggregate clinical activity rate (aCAR; N = 52 evaluable) was 65%, objective response rate (ORR) was 40%, and 31% of all pts had ⩾80% tumor reduction at 12 wk (Table). In cohort 2 (MTD), aCAR was 65%, ORR was 53%, and all 9 responding pts had ⩾80% tumor reduction at their first assessment. ORR was similar among pts with positive vs. negative baseline tumor PD-L1 expression and among pts with normal/high vs. low (<1000/μL) ALC at wk 5−7 with concurrent therapy. With sequenced therapy, 18% had grade 3−4 rAEs; the most common was lipase elevation; aCAR was 43%, ORR was 20%, and 13% of pts had ⩾80% tumor reduction at 8 wk.

Conclusions: Concurrent nivolumab/ipilimumab had a manageable safety profile and produced clinical activity that appears distinct from published monotherapy data. The data also support the potential activity of the combination therapy irrespective of the explored biomarkers. Based on these results, a phase 3 randomized trial in MEL pts of concurrent nivolumab/ipilimumab vs. each monotherapy will be initiated in 2013.

Vemurafenib treatment in patients with BRAF mutated melanoma failing MEK inhibition with trametinib

H. Gogas[1], D. Schadendorf[2], R. Dummer[3], C. Garbe[4], C. Lebbe[5], P. Nathan[6], J. Larkin[7], A. Haydon[8], D. Bafaloukos[9], C. Robert[10]. *[1]Hellenic Cooperative Oncology Group (HeCOG), Data Office, Athens, Greece; [2]University Hospital Essen, Department of Dermatology, Essen, Germany; [3]University Hospital Zurich, Department of Dermatology, Zurich, Switzerland; [4]University Hospital Tubingen, Department of Dermatology, Tubingen, Germany; [5]Hopital Saint Louis University, Department of Dermatology, Paris, France; [6]Mount Vernon Cancer Centre Northwood and National Cancer Research, Department of Medical Oncology, London, United Kingdom; [7]Royal Marsden Hospital, Department of Medical Oncology, London, United Kingdom; [8]The Alfred Hospital, Department of Medical Oncology, Melbourne, Australia; [9]Metropolitan Hospital, 1st Department of Medical Oncology, Athens, Greece; [10]Institut Gustave Roussy, Department of Dermatology and INSERM Unit 981, Villejuif, France*

Background: Trametinib was shown to improve progression-free and overall survival in patients with metastatic melanoma with a BRAF V600E or V600K mutation as compared with chemotherapy in the METRIC trial. However, the median duration of response was 5.5 months and median progression-free survival was 4.8 months in the Trametinib group. Vemurafenib and Ipilimumab were still investigational when this trial was initiated but were available in clinical trials for post-protocol treatment.

Material and Methods: In this phase III trial 87 patients out of the 322 patients of the intent to treat population who had metastatic melanoma with a V600E or V600K mutation received vemurafenib (960 mg twice daily orally). We present data on 60 patients with complete information on vemurafenib clinical efficacy subsequently to trametinib failure.

Results: The median progression free survival was 3.6 months with 95% CI 2.8−4.3 and a range of 0.5–12.1 months. The 2 months PFS was 76.7%, the 4 months PFS was 43.3% and at 6 months 18.3% of patients remained without disease progression. Data on progression free survival on the total number of patients receiving vemurafenib post trametinib and survival data will presented at the meeting.

Conclusions: Some patients who developed a resistance to MEK inhibitor trametinib in first or second line of therapy for BRAFV600 mutated metastatic melanoma seem to benefit from vemurafenib treatment. Sequencing BRAF inhibitors with MEK inhibitors are currently under investigation.

3736 POSTER

Phase I trial evaluating concurrent vemurafenib and ipilimumab in patients with advanced BRAF-mutant melanoma

A. Ribas[1], F.S. Hodi[2], M. Callahan[3], B. Chmielowski[4], D. Lawrence[5], C. Konto[6], M.B. McHenry[7], N. Choong[8], J. Wolchok[3]. *[1]University of California Los Angeles, Medicine, Los Angeles, USA; [2]Dana-Farber Cancer Institute, Medical Oncology, Boston, USA; [3]Memorial Sloan-Kettering Cancer Center, Medicine, New York, USA; [4]University of California Los Angeles, Division of Hematology-Oncology, Los Angeles, USA; [5]Massachusetts General Hospital, Cancer Center, Boston, USA; [6]Bristol-Myers Squibb Company, Oncology Global Clinical Research, Wallingford, USA; [7]Bristol-Myers Squibb Company, Global Biometric Sciences, Wallingford, USA; [8]Roche, Product Development Oncology, South San Francisco, USA*

Background: Ipilimumab (Ipi), a fully human monoclonal antibody that blocks cytotoxic T-lymphocyte antigen-4 to augment antitumor immune responses, and vemurafenib (Vem), a potent inhibitor of BRAF V600-mutated kinase, are both approved for the treatment of advanced melanoma. The phase I/II trial, CA184–161, was designed to evaluate concurrent Vem and Ipi in patients (pts) with advanced BRAF-mutant melanoma.
Methods: An escalating 3+3 dose design was planned to determine the maximum tolerated dose of the combination. The first cohort received Vem and Ipi at the full approved monotherapy doses: Vem was initially given alone for 28 days at 960 mg (po bid), followed by Vem in combination with Ipi at 3 mg/kg (IV q 3 weeks x 4). Pts who experienced tumor stabilization or regression received Vem (po bid) + Ipi maintenance treatment (q 12 weeks beginning at Week 24). The second cohort was planned with Vem at 960 mg and Ipi increased to 10 mg/kg in the absence of dose-limiting toxicities (DLTs) in less than one-third of pts in the first cohort. If the first dose level was not tolerated, a dose de-escalated cohort was planned with Vem at 720 mg and Ipi at 3 mg/kg.
Results: A total of 12 pts received Vem, and 10 received Ipi concurrently with Vem, until the trial stopped accruing pts following DLTs in the liver. The first cohort was expanded to 6 pts due to liver DLTs, and overall 4 developed DLTs of grade 3 elevations in aminotransferase levels. These occurred within 2 to 5 weeks after the first dose of Ipi in combination with Vem, and resolved in all 4 pts in 4−12 days with temporary interruption of Vem and use of corticosteroids. The dose de-escalated cohort was explored in 3 pts and expanded to 6 pts. Of the 4 pts who received concurrent Ipi and Vem, 3 had DLTs of elevations in aminotransferase levels within 3 weeks of starting Ipi (two of grade 3, one of grade 2). The remaining 2 pts received only Vem (one pt withdrew consent). One pt in each cohort had an elevation of total bilirubin (grade 2−3) with concomitant grade 3 transaminitis.
Conclusions: Concurrent administration of Vem and Ipi at the approved doses, or with a lower dose of Vem, resulted in hepatotoxicity that was greater than expected for either agent alone. These safety analyses demonstrate the risk of using Vem and Ipi concurrently, and these drugs should not be used in combination outside of a clinical trial. Further investigation should focus on the optimal sequencing of these agents.

3737 POSTER

A phase III trial of nab-paclitaxel vs dacarbazine in chemotherapy-naive patients with metastatic melanoma: Analysis of patients with M1c stage disease

A. Testori[1], E.M. Hersh[2], M. Del Vecchio[3], M.P. Brown[4], A. Clements[5], C. Loquai[6], C. Robert[7], A. Ko[8], I. Elias[9], A. Hauschild[10]. *[1]European Institute of Oncology, Milan, Italy; [2]University of Arizona Cancer Center, Tucson Arizona, USA; [3]Department of Medical Oncology Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy; [4]Royal Adelaide Hospital, Adelaide, Australia; [5]Westmead Hospital and Melanoma Institute Australia, Westmead NWS, Australia; [6]Universitatsmedizin der Johannes Gutenberg-Universitat Mainz, Mainz, Germany; [7]Institute Gustave Roussy, Villejuif, Fiji; [8]Celgene Corporation, Summit NJ, USA; [9]Celgene, Toronto ON, Canada; [10]Universitatsklinikum Schleswig-Holstein, Kiel, Germany*

Background: In a phase III trial, *nab*-paclitaxel significantly improved progression free survival (PFS; 4.8 vs 2.5 months; P =. 044) vs DTIC and demonstrated a trend toward prolonged interim overall survival (OS; 12.8 vs 10.7 months; P =. 094) for the treatment of chemotherapy-naive patients with metastatic melanoma. Patients with metastatic M1c stage disease or an elevated lactate dehydrogenase (LDH) level have a particularly poor prognosis. Here we report on the outcomes of M1c patients.
Methods: Chemotherapy-naive patients with stage IV melanoma and ECOG PS 0−1 were randomized to *nab*-paclitaxel 150 mg/m^2 on days 1, 8, and 15 of a 28-day cycle (n = 264) or DTIC 1000 mg/m^2 on day 1 of each 21-day cycle (n = 265). Before randomization, patients were stratified by region, metastatic stage, and LDH levels. The primary endpoint was PFS by independent radiologic review; secondary endpoints included OS and safety.
Results: The majority of patients had a baseline metastatic stage of M1c (9% M1a, 26% M1b, 65% M1c), 28% had elevated LDH, and 26% had $\geqslant$5 lesions (median 4; range, 0−18). As expected, patients with M1c stage disease had the shortest PFS and OS in either treatment arm vs patients with M1a or M1b stage disease (Table). However, *nab*-paclitaxel conferred a significant PFS advantage compared with DTIC in patients with M1c stage disease (3.7 vs 2.0 months; HR, 0.734; P =. 028). At the interim OS analysis, a trend in favor of *nab*-paclitaxel vs DTIC was also observed in patients with M1c stage disease (Table). The estimated 1-year survival for patients with M1c was 46% for *nab*-paclitaxel vs 40% for DTIC. The incidence of treatment-related grade $\geqslant$3 peripheral neuropathy for M1c patients was 26% for *nab*-paclitaxel vs 0% for DTIC, similar to that observed in the intent-to-treat population.
Conclusions: In this trial of *nab*-paclitaxel vs DTIC, patients with advanced disease (M1c) and poor prognosis showed clinically relevant benefits with acceptable toxicity with *nab*-paclitaxel treatment.

3738 POSTER

Phase 2 study of nivolumab (Anti-PD-1; ONO-4538/BMS-936558) in patients with advanced melanoma

N. Yamazaki[1], H. Tahara[2], H. Uhara[3], Y. Moroi[4], Y. Kiyohara[5]. [1]*National Cancer Center Hospital, Dermatologic Oncology, Tokyo, Japan;* [2]*The University of Tokyo, Department of Surgery and Bioengineering Advanced Clinical Research Center Institute of Medical Science, Tokyo, Japan;* [3]*Shinshu University School of Medicine, Department of Dermatology, Nagano, Japan;* [4]*Graduate School of Medical Science Kyushu University, Department of Dermatology, Fukuoka, Japan;* [5]*Shizuoka Cancer Center Hospital, Dermatology Division, Shizuoka, Japan*

Background: A fully human monoclonal IgG4 antibody, nivolumab (ONO-4538/BMS-936558), which blocks human programmed death-1 (PD-1) receptor expressed on activated T cells, is therefore expected to be a new treatment option for several types of cancers. We evaluated the efficacy and safety of nivolumab in this phase 2 study (ONO-4538−02) with Japanese patients (pts) who had previously been treated for advanced melanoma (MEL) as of December 2012. Potential biomarkers (BMs) were also explored in this study.
Methods: Nivolumab (2 mg/kg IV Q3W) was given to pts until observing unacceptable toxicity, confirmed progression or complete response. Clinical responses were assessed by investigators according to RECIST 1.1 and immune-related RECIST, and were preliminarily analyzed for this presentation. Potential predictive BMs associated with the efficacy and/or safety of nivolumab were explored by assessing tumor tissue, serum and peripheral blood mononuclear cells (PBMC).
Results: Nivolumab was given to 35 MEL pts with an average of 2.1 prior therapies whose responses were evaluable at the time of this analysis. Twenty-seven and 8 pts had ECOG PS 0 and 1, respectively. The ORR and immune-related ORR (irORR) were 23% (8/35 pts) and 28.6% (10/35 pts), respectively. Responses were durable with 172 days of median PFS. Median overall survival had not been reached at the time of this report. The incidence of drug-related AEs was 45.7%. Grade (G) 3/4 drug-related AEs were reported for 17.1% of pts. Relatively frequent AEs consisted of an increase in GGT, anemia, decreased Ht, Hb and RBC counts, and decreased appetite. G3 hepatitis and G2 pneumonitis were reported in 2 and 1 pts, respectively. Psoriasis arthropica was reported in 1pt. No G3/4 pneumonitis or drug-related deaths were reported. Flow cytometric analysis of PBMCs revealed that the number of PD-1-positive CD4 and CD8 T cells decreased from the baseline with nivolumab treatment. The pts are still being followed up in order to identify OS and PFS. Biomarker analysis is underway.
Conclusions: Administration of nivolumab was associated with a durable clinical benefit in approximately one fourth of Japanese pts with advanced MEL without serious safety concerns. These results do not considerably differ from the efficacy and safety profile observed in preceding/ongoing nivolumab clinical studies of Caucasian pts. Thus, further clinical development of nivolumab for MEL pts is warranted.
Conflict of interest: *Advisory board: Ono Pharmaceutical Co.,Ltd*

Single agent panitumumab in patients with incurable cutaneous squamous cell carcinoma: A single centre phase II study

M. Foote[1], M. McGrath[2], A. Guminski[3], B. Hughes[4], J. Meakin[5], D. Thomson[2], F. Simpson[6], S. Porceddu[1]. [1]*University of Queensland Princess Alexandra Hospital, Radiation Oncology, Brisbane Queensland, Australia;* [2]*Princess Alexandra Hospital, Medical Oncology, Brisbane Queensland, Australia;* [3]*Royal North Shore Hospital, Medical Oncology, Sydney New South Wales, Australia;* [4]*University of Queensland The Prince Charles Hospital and Royal Brisbane and Womens Hospital, Medical Oncology, Brisbane Queensland, Australia;* [5]*Princess Alexandra Hospital, Clinical Trials Research Unit, Brisbane Queensland, Australia;* [6]*University of Queensland, Diamantina Institute, Brisbane Queensland, Australia*

Background: The incidence of advanced cutaneous squamous cell carcinoma (CSCC) is increasing. The objective of this study was to investigate the efficacy of single agent panitumumab in the treatment of incurable CSCC.
Material and Methods: Eligibility included ECOG 0−2 patients deemed to have incurable CSCC not suitable for local therapy or chemotherapy. Prior chemotherapy was permitted. Patients received panitumumab at a dose of 6 mg/kg every 14 days for a maximum of nine cycles, with response assessed after every third cycle prior to proceeding to the next 3 cycles. The primary endpoint was the best overall response rate (ORR) as assessed by RECIST version 1.1.
Results: Between May 2010 and May 2012, 16 patients were recruited. Fourteen patients were male and the median age was 69. Fourteen patients had locoregionally recurrent disease with 15 patients receiving previous radiotherapy and 4 patients receiving previous cytotoxic chemotherapy. The best overall response rate (partial or complete response, PR or CR) was 37.5% (4/16 PR, 2/16 CR) with a further 5 of 16 patients achieving stable disease. The duration of overall response was a median of 8 months. Grade 3 or 4 events were observed in 5 patients (all skin toxicity) with 1 patient ceasing due to skin toxicity. With a median follow up of 11 months, 9 patients died due to progressive disease, 7 are alive, 1 patient with no evidence of disease at the time of analysis.
Conclusions: Single agent panitumumab is a safe and effective agent in the management of incurable CSCC.
Conflict of interest: *Corporate-sponsored research: Amgen − provided panitumumab free of charge and provided research support.*

The Italian Network for Tumor Biotherapy (NIBIT)-M1 study: 2-years survival update for metastatic melanoma patients treated with ipilimumab in combination with fotemustine

A.M. Di Giacomo[1], P.A. Ascierto[2], P. Queirolo[3], L. Pilla[4], R. Ridolfi[5], M. Santinami[6], A. Testori[7], D. Giannarelli[8], G. Parmiani[9], M. Maio[1]. [1]*Medical Oncology and Immunotherapy, University Hospital of Siena, Siena, Italy;* [2]*Medical Oncology and Innovative Therapy, National Cancer Institute, Naples, Italy;* [3]*Medical Oncology A, National Institute for Cancer Research, Genoa, Italy;* [4]*Molecular Oncology/ Medical Oncology A, San Raffaele Scientific and University Institute/National Cancer Institute, Milan, Italy;* [5]*Immunotherapy and Somatic Cell Therapy Unit, Scientific Institute of Romagna, Meldola, Italy;* [6]*Surgical Oncology, National Cancer Institute, Milan, Italy;* [7]*Melanoma and Soft Tissue Sarcoma Division, European Institute of Oncology, Milan, Italy;* [8]*Statistical Unit, Regina Elena National Cancer Institute, Rome, Italy;* [9]*Molecular Oncology, San Raffaele Scientific and University Institute, Milan, Italy*

Background: In spite of limited objective tumor responses, ipilimumab (IPI) significantly improves the survival of metastatic melanoma (MM) patients (pts). The efficacy of IPI, alone or in novel combinations, is being explored also in sub-sets of MM pts, including those with brain metastases (mts). We recently reported the efficacy of IPI in combination with fotemustine (FTM) in MM pts with or w/o brain mts enrolled in the phase II NIBIT-M1 trial. The immune-related Disease Control Rate (ir-DCR) was 46.5%, with a median OS of 13.3 months (mo) (8.9–19.9), and a 1-year survival rate of 52.6% (Di Giacomo, et al. Lancet Oncol, 2012). We now report the up-dated efficacy from the NIBIT-M1 study, with the assessment of *BRAF* mutation status and its correlation with clinical outcome.
Material and Methods: MM patients received an induction therapy with IPI 10 mg/kg every 3 weeks (Q3W) for four doses and FTM 100 mg/m^2 weekly for 3 weeks, as first or second-line treatment. IPI and FTM maintenance therapy was administered Q12W from Week 24 and Q3W from Week 9, respectively. This analysis reports the median OS and PFS (mo, 95% CI), 1- and 2-yrs survival rates, and ir-Duration of Response (DOR) (mo, 95% CI) for the global population, and for the subpopulation of pts with brain disease. The *BRAF* V600E mutation status was retrospectively determined by PCR-based assay.
Results: Eighty-six pts with unresectable Stage III (3 pts) or Stage IV (83 pts) MM were treated in 7 NIBIT Centers; 20 pts had asymptomatic brain mts at baseline. With a median follow-up of 23.7 mo, median OS was 12.7 mo (7.2–18.2), 1- and 2-year survival rates for the whole study population were 51.2% and 30.7%, respectively; in pts with brain mts, median OS was 12.7 mo (2.7–22.7), 1- and 2-year survival rates were 55.0% and 38.9%, respectively. Median PFS was 4.5 mo (3.1−5.9) and 3.4 mo (2.3−4.5) for the whole study population and for pts with brain mts. Median ir-DOR was 23.9 mo (15.5–46.5). The ir-DCR for BRAF mutant melanoma was 46.3% (19/41) compared with 60% (18/30) in pts with *BRAF* wild-type (WT) gene ($p = 0.25$). Median OS for *BRAF* mutant melanoma and WT pts were 10.0 mo (5.5–14.5) and 17.3 mo (10.3–24.3), respectively ($p = 0.23$).
Conclusions: The combination of IPI and FTM explored in the NIBIT-M1 trial continues to demonstrate effective in MM pts with or w/o brain mts. No significant association between *BRAF* V600E mutation status and clinical outcome was detected.

3741 POSTER

A prognostic model for metastatic melanoma treated with ipilimumab

S. Valpione[1], L. Piccin[2], S. Stragliotto[1], J. Pigozzo[1], L.G. Campana[3], V. Chiarion-Sileni[1]. [1]*Veneto Oncology Institute, Melanoma Cancer Unit-SSD, Padova, Italy;* [2]*University of Padova, Medicine and Surgery, Padova, Italy;* [3]*Veneto Oncology Institute, Melanoma and Sarcoma Unit, Padova, Italy*

Background: Metastatic melanoma usually has a dismal prognosis, also because its treatment options have been deluding for long time: until recently, systemic therapies were limited, with poor response rates and short survival advantage. Ipilimumab is a monoclonal anticytotoxic T-lymphocyte antigen 4 antibody that was demonstrated to improve survival of metastatic melanoma patients, but may be associated with immunological toxicities and may impact on National Health Service costs. This is an independent pilot study aimed to design a prognostic model of response to therapy with ipilimumab in the metastatic melanoma setting, with the purpose to improve the identification of patients who would benefit most from therapy.
Materials and Methods: Prospectively collected data of 75 consecutive patients with metastatic melanoma, who received therapy with ipilimumab in the Italian expanded access program (3 mg/kg, q3w), were analysed under a Cox regression model to identify prognostic factors and biomarkers. We analyzed clinical data (sex, melanoma localization and stage at diagnosis, patients' age at first diagnosis and metastatic recurrence, relapse-free interval (RFI), site and number of metastases, previous chemotherapies) and baseline biological data (blood levels of LDH, C-reactive protein, beta-2-microgloulin, VEGF, interleukin-2, interleukin-6, S-100, ALP, transaminases, total circulating leucocytes and subpopulations of lymphocytes and granulocytes analyzed with cytofluorometry). The Wald test was used to assess the significance of each variable included in the full Cox model, only variables with $p \leqslant .05$ were maintained in the final Cox model after fast backward variable selection. Validation was performed with bootstrap method.
Results: After a median survival of 9.9 months from first ipilimumab administration, 7 patients were alive. Covariates that resulted associated with prognosis were sex (HR = 5.01 for female, 95% CI 1.52–16.56), RFI (protective effect of long RFI, HR = 0.60, 95% CI 0.37–0.99), M1a metastatization (HR = 0.23, 95% CI 0.07–0.73), total blood leucocytes (worse prognosis for higher levels of leucocytes, HR = 3.02, 95% CI 1.62–5.63). Among the granulocyte and lymphocyte subpopulations, high baseline levels of T-helper/inducer lymphocytes and of T-suppressor/cytotoxic lymphocytes resulted protective (HR = 0.03, 95% CI 0.01–0.36 and HR = 0.04, 95% CI 0.01–0.68, respectively), while a high percentage of total mature T-lymphocyte was associated with worse prognosis (HR = 12.97, 95% CI 1.46–115.21). The model was validated with the bootstrap method (100 replacements). C-index was 0.71.
Conclusions: The covariates that were significant predictors of survival are feasible for every centre and could be proposed for further validation. The identification of patients who would benefit most from therapy with ipilimumab could help clinicians to better allocate resources, avoiding costs and toxicities for patients who are not to benefit.

Effectiveness and safety of first-line ipilimumab (IPI) 3 mg/kg therapy for advanced melanoma (AM): Evidence from a U.S. multisite retrospective chart review

K. Margolin[1], S.L. Wong[2], J.R. Penrod[3], J. Song[4], I. Chang[5], T. Hebden[2], D.B. Johnson[6], S. Jang[7], J. Clark[8], D. McDermott[9]. [1]*Seattle Cancer Center Alliance, Medical Oncology, Seattle, USA;* [2]*Bristol-Myers Squibb, Health Services U.S. Medical, Plainsboro, USA;* [3]*Bristol-Myers Squibb, Global Health Economics and Outcomes Research, Lawrenceville, USA;* [4]*Bristol-Myers Squibb, Global Biometric Sciences, Wallingford, USA;* [5]*Bristol-Myers Squibb, Oncology Medical, Paris, France;* [6]*Vanderbilt University Medical Center, Hematology Oncology, Nashville, USA;* [7]*MedStar Washington Hospital Center, Medicine, Washington D.C., USA;* [8]*Loyola University Medical Center Cardinal Bernardin Cancer Center, Medicine, Maywood, USA;* [9]*Beth Israel Deaconess Medical Center, Hematology/Oncology, Boston, USA*

Background: In March 2011, the U.S. FDA approved ipilimumab (Yervoy®) for the treatment (Rx) of Rx-naive or pretreated advanced (unresectable or metastatic) melanoma (AM) based on prolongation of overall survival (OS) in a Phase III randomized, double-blind, multicenter study in previously treated AM patients (pts). Ipilimumab (IPI) at 3 mg/kg every 3 weeks for 4 doses was superior to a melanoma peptide vaccine. This study (CA184338) describes the pt and disease characteristics, patterns of care, safety, and outcomes of the same IPI dose and schedule in Rx-naive AM pts. The cohort (target n = 300) will be observed for 4 years.
Material and Methods: Adult pts with unresectable stage III or IV AM were identified retrospectively from 27 U.S. sites. Pts had received $\geqslant$1 dose of first-line IPI 3 mg/kg during April 2011 − Sept 2012. This interim analysis reports on pts (n = 120) for whom $\geqslant$12 months (mo) had elapsed since IPI initiation. Data were collected from medical records.
Results: The 120 pts were 65.8% male, median age was 63 years (range 26−91). The primary site was cutaneous (86.7%), ocular (4.2%), and mucosal (2.5%). Most pts were stage M1c (55%), 11.7% had unresectable stage III AM and 7.5% had brain metastases at AM diagnosis. Among the 97 pts with known BRAF status, 21.6% had an activating mutation. Prior to IPI, 40.8% and 51.7% of pts had ECOG PS 0 and 1 respectively, and 36.7% had LDH > institutional upper limits of normal. The median number of IPI doses was 4, 75.8% of pts completed 4 doses, and 5% experienced one dose interruption. From IPI initiation, median OS was 14.3 mo (95% CI 12.1, −). The 1-year survival rate was 59.5% (95% CI 50.1–67.8%). Overall median follow-up was 12.0 mo (range 0.5–21.7). One-year OS rates for BRAF-mutated, wild-type, and untested pts were 71.4% (95% CI 47.2–86.0%), 58.9% (95% CI 47.0–69.1%) and 50.5% (95% CI 28.4–69.0%), respectively. The most frequent drug-related adverse events were immune-related adverse events (irAEs) that occurred in 53% of pts; 27.5% of irAEs were cutaneous, 24.2% were gastrointestinal. Grade 3−4 irAE occurred in 13.3% of pts. Fifty-eight (48.3%) pts died. No deaths were attributable to drug-related AEs or irAEs.
Conclusions: This observational data is the largest study of IPI 3 mg/kg monotherapy in Rx-naive AM and provides clinical practice evidence of the OS benefit and safety profile of IPI. While BRAF status did not appear to impact OS in these pts, this finding warrants further investigation.

A phase III trial of nab-paclitaxel (nab-P) vs dacarbazine (DTIC) in chemotherapy-naive patients with metastatic melanoma: Analysis of patient (pt) characteristics and treatment patterns by region

C. Robert[1], E. Hersh[2], M. Del Vecchio[3], M.P. Brown[4], A. Clements[5], C. Loquai[6], A. Testori[7], A. Ko[8], I. Elias[9], A. Hauschild[10]. [1]*Institut Gustave Roussy, Villejuif, France;* [2]*University of Arizona Cancer Center, Tucson AZ, USA;* [3]*Department of Medical Oncology Fondazione IRCCS Istituto Nazionale dei Tumori, Milan, Italy;* [4]*Royal Adelaide Hospital, Adelaide, Australia;* [5]*Department of Medical Oncology Westmead Hospital and University of Sydney, NSW, Australia;* [6]*Universitatsmedizin der Johannes Gutenberg-Universitat Mainz, Mainz, Germany;* [7]*European Institute of Oncology, Milan, Italy;* [8]*Celgene Corporation, Summit NJ, USA;* [9]*Celgene, Toronto ON, Canada;* [10]*Universitatsklinikum Schleswig-Holstein, Kiel, Germany*

Background: In a phase III trial, *nab*-P significantly improved progression-free survival (PFS) vs DTIC (4.8 vs 2.5 mo; HR, 0.792; *P* =. 044) and demonstrated a trend toward prolonged interim overall survival (OS; 12.8 vs 10.7 mo; HR, 0.831; *P* =. 094) for the treatment of chemotherapy-naive pts with metastatic melanoma. This analysis examined geographic variations in baseline (BL) demographics, treatment patterns, and outcomes.
Methods: Chemotherapy-naive pts with stage IV melanoma, LDH $\leqslant 2 \times$ ULN, and ECOG PS 0−1 were randomized to *nab-P* 150 mg/m^2 on days 1, 8, and 15 of a 28-day cycle or DTIC 1000 mg/m^2 on day 1 of each 21-day cycle. Before randomization, pts were stratified by region, M stage, and LDH. The primary endpoint was PFS by independent radiologic review; secondary endpoints included OS and safety.
Results: Of the 529 pts in this trial, 231 (44%) were from North America (NA), 228 (43%) were from Western Europe (WE), and 70 (13%) were from Australia/New Zealand (ANZ). Although treatment arms were balanced for BL characteristics, minor differences were noted among regions. The WE cohort had more pts with ECOG PS 0 (85% WE, 62% NA, 56% ANZ); the ANZ cohort had more male pts (76% ANZ, 66% NA, 62% WE), M1c stage disease (73% ANZ, 66% NA, 62% WE), LDH >1.1−2 $\times$ ULN (30% ANZ, 20% WE, 18% NA), and wild type *BRAF* (67% ANZ, 43% NA, 34% WE). PFS was significantly higher with *nab*-P vs DTIC in pts from WE and trended in favor of *nab*-P in pts from NA and ANZ (Table). An exploratory multivariate analysis of PFS adjusting for BL LDH found that HRs for all regions were <1.0, favoring *nab-P*. Interim OS trended in favor of *nab-P* for all regions. The median number of *nab*-P treatment cycles (2 ANZ, 3 NA, 4 WE) and pts with $\geqslant$1 *nab*-P dose reduction (43% NA, 25% WE, 15%

ANZ) varied between regions. More pts in the WE cohort used second-line ipilimumab therapy (25% WE, 13% ANZ, 15% NA) and BRAF inhibitor therapy (11% WE, 7% ANZ, 1% NA).
Conclusions: Regional variations in pt characteristics and treatment patterns were noted in this trial, which may have influenced outcomes. Overall, *nab*-P showed a greater clinical benefit over DTIC among pts with metastatic melanoma irrespective of region.

Immunotargeting melanoma stem cells with Hyper-IL6 modified whole cell therapeutic vaccine (AGI-101H) in patients with advanced melanoma − a joint analysis of two phase 2 studies

J. Mackiewicz[1], P. Wysocki[2], A. Karczewska-Dzionka[3], E. Kwiatkowska-Borowczyk[4], A. Kozlowska[5], T. Burzykowski[6], S. Rose-John[7], M. Wiznerowicz[3], A. Mackiewicz[4]. *[1]Wielkopolska Cancer Centre, Poznan, Poland; [2]Wielkopolska Cancer Center University of Medical Sciences Poznan, Dept of Chemiotherapy Tumor Immunology Dept, Poznan, Poland; [3]Wielkopolska Cancer Center, Tumor Immunology Dept, Poznan, Poland; [4]Wielkopolska Cancer Center University of Medical Sciences Poznan, Tumor Immunology Dept, Poznan, Poland; [5]University of Medical Sciences Poznan, Tumor Immunology Dept, Poznan, Poland; [6]Hasselt University, Interuniversity Institute of Biostatistics and Statictial Bioinformatics, Diepenbeek, Belgium; [7]Kiel University, Institute of Pathophysology, Kiel, Germany*

Background: AGI-101H consists of two human melanoma cell lines modified with molecular adjuvant Hyper-IL-6 (H6) cDNA. Secreted H6 at the site of vaccine injection provides co-stimulatory signals to immune system by inhibiting T regulatory (FoxP3 +) cells formation, activation of maturation and presentation of cryptic antigens by dendritic cells, activation of T CD8+ and NK cells. Moreover, H6 during the culture stimulates vaccine cells via binding gp130 subunit of IL-6-type cytokines receptor complex. It leads to activation of JAK-kinase and chronic phosphorylation of STAT3 and results in altering vaccine cells towards melanoma stem cells (MSCs)-like phenotype. Up to 92% of AGI-101H cells have ALDH activity − a MSCs marker and loose differentiation antigen SSEA-1.
Methods: Non-selected 77 and 35 patients with unresectable stage IIIB, IIIC or IV melanoma were enrolled into trial 2 and 4, respectively. In November 2008 all alive patients were transferred into **E**xtended **T**reatment for **A**dvanced **M**elanoma Transferred from Trials 2−5 (ETAM 2−5) studies (EnduraCT No 2008–003373−40). Among 112 enrolled pts., 22 (19%) received prior chemotherapy. WHO performance status was 0−1/2/3−4 in 45/58/9 pts., respectively. AGI-101H was administered 8 times every 2 weeks (induction) and then every month (maintenance) until patient's death. At progression, maintenance was continued or induction was repeated and followed by maintenance. The primary endpoint was overall survival (OS), with clinical tumor response used as the secondary endpoint.
Results: Median length of follow-up in trial 2 and 4 was equal to 139.3 and 94.9 months, respectively. There were 102 deaths in total. Among the 112 enrolled pts. 6.3% had IIIB, 22.3% IIIC and 71.4% IV. Complete response (CR) and partial response (PR) was observed in 18.7% and 8.9% of pts., respectively. Disease control rate (CR, PR, or SD − stable disease) was noted in 52.6% of pts. The estimated median objective response (CR+PR) duration was equal to 32 months [95% CI 6.5–56.9]. The observed median OS in was equal to 13.3 months [95% CI 11.9–18.1]. The observed median OS in patients with WHO 0−1 was equal to 21.3 months [95% CI 12.9–34.4]. No grade 3/4 adverse events were observed.
Conclusions: Treatment with AGI-101H in patients with advanced melanoma is safe and effective. Phase 3 study is warranted. Long-term survival of high-risk melanoma patients with resected stage IIIB-IV treated with AGI-101H was recently published (Mackiewicz A et al.).
No conflict of interest.

Spanish Melanoma Multidisciplinary Group (gem): Long term survivors (LTS) treated with ipilimumab (IPI) in the expanded access programme (EAP)

A. Berrocal[1], J. Valdivia[2], S. Martin Algarra[3], E. Espinosa[4], T. Curiel[5], T. Puertolas[6], P. Mut[7], M. Ochoa[8], A. Ballesteros[9], I. Marquez[10]. *[1]Hospital General Universitari de València, Oncologia Medica, Valencia, Spain; [2]Hospital Virgen de las Nieves, Oncologia Medica, Granada, Spain; [3]Clinica Universitaria Navarra, Oncologia Medica, Pamplona, Spain; [4]Hospital La Paz, Oncologia Medica, Madrid, Spain; [5]Complejo Hospitalario Arquitecto Marcide, Oncologia Medica, A Coruña, Spain; [6]H Miguel Servet, Oncologia Medica, Zaragoza, Spain; [7]Hospital Son Llatzer, Oncologia Medica, Palma de Mallorca, Spain; [8]ICO Hospitalet, Oncologia Medica, Barcelona, Spain; [9]Hospital Universitario de la Princesa, Oncologia Medica, Madrid, Spain; [10]Hospital Gregorio Marañon, Oncologia Medica, Madrid, Spain*

Background: Advances in metastatic melanoma treatment have demonstrated improvement in survival. After 5 year follow-up of clinical trials with IPI, LTS have been reported. Current follow-up of patients treated within IPI EAP in Spain is 2 years.
Methods: Retrospective review of LTS included in the IPI-EAP experience in Spain. Patients (pts) were treated with IPI at 3 mg/kg q 3 w x 4. Data was registered using a socio-demographic and therapeutic questionnaire, collecting overall response (RR), OS and toxicity (T). LTS was defined as those patients with ⩾12 months overall survival (OS). Pts characteristics in the LTS were compared with the overall Spanish EAP population.
Results: We collected data of 138 treated pts, resulting in 48 LTS (34.5%). These 138 pts represent 47.9% of all EAP treated pts. 15 pts were alive at 12 months (M), 18 pts between 13−19 m and 9 pts, 20−24m. Median age was: 59.5 (30−81). Gender: Male 54.2%. Female 45.8% Stage: IVa 27.1%, IVb 20.8%, IVc 51.1%. Primary tumor site: skin 60.5%; accral 10.4%; mucosal 8.3%; ocular 10.4%; rest unknown. Metastases (mts): soft tissue 41.7%, lung 31.3%, visceral 25%. Median number of prior treatments: 1 (1−5), 18.8% received more than one chemotherapy (chx) line. 97.9% of total pts population has completed induction phase (4 IPI doses). Response assessment: Complete Response 14.6%; Partial Response 35.4%; Stable Disease 35.4%; Progressive disease 10.4%. Mean duration of response: 13 m. Mean survival: 16.5m. 54.2% received thx after IPI: 31.3% chx; 12.5% radiotherapy; 12.5% B-RAF inhibitor. 18 pts (50%) presented T: 10.5% Grades (G) 3−4 were reported; 18.8% G2; 10.4% G1. The most frequent T was cutaneous (18.8%). When compared with the overall EAP pts LTS have less visceral disease, lower median LDH, more objective responses and completion of the 4 induction ipilimumab doses.
Conclusions: Ipilimumab within Spanish EAP experience in pretreated pts has shown long term survival consistently with clinical trials in pts with advanced melanoma. Further research and analysis are needed to identify which pts are most likely to achieve a long term survival benefit with ipilimumab.
Conflict of interest: *Advisory board: Alfonso Berrocal and Salvador Martin Algarra have been advisors for Bristol Meyers*

Results of a phase 1 study of MEK162, an oral MEK inhibitor, in Japanese patients with advanced solid tumors

T. Shimokata[1], K. Watanabe[2], T. Shibata[1], M. Inada-Inoue[1], K. Shirao[2], Y. Hirashima[2], S. Fukuhara[3], K. Tokushige[3], A. Zubel[4], Y. Ando[1]. *[1]Nagoya University Hospital, Department of Clinical Oncology and Chemotherapy, Nagoya, Japan; [2]Oita University, Department of Medical Oncology, Oita, Japan; [3]Novartis Pharma K.K., Oncology Business Unit, Tokyo, Japan; [4]Novartis AG, Oncology Translational Medicine, Basel, Switzerland*

Background: MEK162 (ARRY-162), a small molecule MEK1/2 inhibitor, has shown broad antiproliferative activity in preclinical and early clinical studies in advanced solid tumors and melanoma.

Materials and Methods: The primary objective of this multicenter phase 1 trial (NCT01469130; sponsored by Novartis) is to determine the maximum tolerated dose (MTD) and/or the recommended phase 2 dose of MEK162 in Japanese patients. The study consists of a dose-escalation part in patients with advanced solid tumors and an expansion part in patients with *BRAF*/*RAS*-mutant tumors. Adaptive dose escalations, determined by the investigators and the sponsor, were guided by a Bayesian logistic regression model with overdose control.
Results: As of January 7, 2013, 17 patients have been treated, 14 in the dose-escalation and 3 in the expansion part (6 at 30 mg BID; 11 at 45 mg BID). The median age was 59 y (range, 27−77), 11 (65%) were male, and the most common cancers were lung (n = 4), rectal (n = 3), and bile duct (n = 3). No dose-limiting toxicities (DLTs) were observed in the 5 evaluable patients treated at 30 mg BID. Based on safety, PK data, and the Bayesian inference of DLT rate, the dose level (DL) was increased to 45 mg BID. Two DLTs were reported in 6 evaluable patients at the 45-mg DL (both grade 2 central serous retinopathy [CSR]-like events). The most common treatment-related AEs (>30% of patients) of any grade (G) at either DL were CSR-like events (n = 15; 88%), increased creatine phosphokinase (CPK; n = 12; 71%), diarrhea (n = 10; 59%), increased AST (n = 9; 53%), rash (n = 8; 47%), increased lipase (n = 7; 41%), acneiform dermatitis (n = 6; 36%), decreased appetite (n = 6; 36%), and stomatitis (n = 6; 36%). CSR-like events were all G1/2. Increased CPK was the only G3/4 AE reported in >1 patient (n = 5; 29%; 1 had G4). Four patients discontinued treatment, and 16 patients required a dose reduction/interruption due to an AE. Based on these data and the Bayesian inference of DLT rate, 45 mg BID was determined as the MTD and selected as the dose for the ongoing expansion part. Orally administered MEK162 was rapidly absorbed, with a median T_{max} <2 hours. Plasma concentrations of MEK162 increased with dose and were similar to those seen in studies with Caucasians.
Conclusions: In the dose-escalation part of the study, MEK162 administered orally up to 45 mg BID was well tolerated, and the MTD of MEK162 was identified at 45 mg BID for Japanese patients. This DL is being tested in the expansion part.

The utility of BRAF inhibitors in metastatic melanoma to brain

A. O'Reilly[1], C.G. Gleeson[2], H.P.R. Redmond[3], J. Fitzgibbon[4], K.O.R. O'Regan[5], J.B. Barry[5], D.G.P. Power[1]. *[1]CUH, Oncology, Cork, Ireland; [2]SIVUH, Dermatology, Cork, Ireland; [3]CUH, Surgery, Cork, Ireland; [4]CUH, Cork University Hospital, Cork, Ireland; [5]CUH, Radiology, Cork, Ireland*

Background: About 40−50% of patients with metastatic melanoma will develop symptomatic brain metastases. Median survival following a diagnosis of brain metastases is less than 6 months. BRAF mutation status has become core to modern treatment of melanoma. We report our experience with BRAF inhibitors in the setting of brain metastases from melanoma.
Materials and Methods: A retrospective analysis of all patients diagnosed with metastatic melanoma, from January 2011 − March 2013, was undertaken. Clinicopathologic data and BRAF status was collected. Our specific focus was on patients with the V600E mutation who had brain metastases prior to any therapy for metastatic disease.
Results: Sixty-one patients with metastatic melanoma had documented BRAF status and 16 of these patients had brain metastases. Overall 22 patients were found to harbour the V600E (V600E+) mutation and 10 (45%) of these patients had brain metastases prior to any therapy for metastatic disease. One V600E+ patient developed brain metastases during primary therapy. Five BRAF- patients developed brain metastases, representing 31% of patients with brain metastases.
Fifty-five percent (n = 6) of V600E+ patients and 40% of BRAF wild type (wt) patients (n = 2) were female. Median age at diagnosis of metastatic disease was 64 years (37−71) and 45 years (30−68) in the BRAF- and BRAF+ groups respectively.
Seventy percent of BRAF+ patients with brain metastases and 55% of BRAF- patients with brain metastases had symptomatic brain metastases at presentation.
All BRAF wt patients had solitary brain metastases, 2 V600E+ patients had solitary brain metastases. The mean number of brain metastases per BRAF+ patient was 3 (range 1−8).
Six patients with brain metastases and who were V600E+ were treated with a BRAF inhibitor (5 patients with dabrafenib). Four patients were treated with WBRT prior to commencing a BRAF inhibitor. All patients had a partial response on MRI after 2 months of drug. Progression of disease was noted in 2 patients after a median of 7.6 months (range 6.7−8.5 months). Four patients continue to respond (1 patient has had a complete response) after a median of 4.4 months, (range 3−9 months) on a BRAF inhibitor.
All patients experienced at least a grade 2 skin toxicity while on a BRAF inhibitor. Two grade 3 toxicities occurred; a grade 3 skin toxicity and a grade 3 temperature and rigors in the absence of infection.
Conclusion: In our retrospective analysis, patients with V600E+ disease were more likely to develop multiple metastatic brain deposits. BRAF inhibitors have reported activity in this setting. Our experience highlights the utility of BRAF inhibitors in brain metastases. Toxicity was minimal and the median OS of our small group was superior to historic survivals prior to the advent of BRAF inhibitors.
No conflict of interest.

3748 POSTER

Oncogenic BRAF mutation in cutaneous melanoma in Argentina

G. Boggio[1], A. Falco[1], J. Maur Perotti[1], V. Videla[1], H. García Rivello[2], M. Gutierrez[3], M. Nuñez[4], M. Chacon[1], M.G. Pallotta[1], A. Romero[1]. *[1]Asociación Argentina Oncología Clínica, Clinical Oncology, Buenos Aires, Argentina; [2]Hospital Italiano de Buenos Aires, Pathology, Buenos Aires, Argentina; [3]Stamboulian Servicios de Salud, Molecular Biology, Buenos Aires, Argentina; [4]Universidad de Buenos Aires, Facultad de Ciencias Exactas, Buenos Aires, Argentina*

Background: BRAF is a protein critical in the mitogen-activated protein kinase (MAPK) pathway, and is mutated in approximately 50% of melanoma patients. A single substitution (V600E) account for 80% of BRAF mutations. The aim of this study was to assess the frequency of oncogenic *BRAF* mutations in cutaneous melanoma and to correlate *BRAF* status with clinicopathological features in Argentinian melanoma patients.
Patients and Methods: Tumor tissue from 93 consecutive patients with primary/metastatic cutaneous melanoma, from 12/2011 to 3/2013 was analyzed in 2 referral centers using real time polymerase chain reaction (RT-PCR) assays for *BRAF* mutation (cobas® 4800 System, v2.0). Clinical (age, gender, ethnics, primary tumor location) and pathological (Breslow, ulceration, histopathological subtype, mitotic rate, AJCC stage) features were correlated with BRAF mutation status. Study population was 52% female. Median age 58 ys (35% <50 years). 100% Caucasian. Primary tumor location was 39% trunk, 36% limbs, 12% head and neck, 13% other. 18% were metastatic at diagnosis.
Results: Twenty-nine patients (32%) had BRAF mutation (100% V600E genotype). Other than age at diagnosis (median age, 51 *v* 62 years for *BRAF*-mutant *v BRAF* wild-type patients, respectively; *P* <0.01) there was no significant difference in clinical features by mutation status. Among histopathologic features of the primary melanoma, BRAF wild-type was significantly associated with the presence of ulceration (31% v 21% in for *BRAF*-wild type *v BRAF* mutant patients) (p = 0.05).
Conclusion: This is the first report of BRAF mutation status using RT-PCR COBAS in Argentina. The frequency of BRAF mutation is lower than that reported in medical literature, and only the presence of ulceration and age at diagnosis were significantly different in *BRAF*-mutant and *BRAF* wild-type patients.
No conflict of interest.

3749 POSTER

Desmoplastic small round cell tumor: Multimodal approach with aggressive cytoreductive and hyperthermic intraperitoneal chemotherapy

A. Morales Taboada[1], L.U.I.S. Gonzalez Bayón[2], F. Atahualpa[2], A. Fernandez Nuñez[2], M.A. Steiner[2], J. Rodriguez del Campo[2], E. Sagarra[2], J.M. Asencio Pascual[2], W. Vasquez[2], J.L. García Sabrido[2]. *[1]H.G.U.G.M, Cirugia genearl III, Madrid, Spain; [2]H.G.U.G.M, Cirugia Genearl III, Madrid, Spain*

Background: Desmoplastic small round cell tumor (DSRCT) is a rare and highly aggressive type of sarcoma, which mainly develops in the intra-abdominal cavity of adolescents, and young adults with a strong male predominance. The prognosis is poor, with median survival from 17 to 25 months.
The management may include, a multimodal approach with polychemotherapy, whole abdominal radiation, and currently radical cytoreductive surgery plus hypertermic intraperitoneal chemotherapy (HIPEC) is being evaluated to improve outcomes.
Material and Methods: We present two cases with peritoneal sarcomatosis (DSRCT), treated with optimal cytoreductive surgery associated with HIPEC, as part of a multimodal treatment.
Results: The patients were young male adults presented very advanced peritoneal disease (PCI: 28 and 39 respectively). The diagnosis was confirmed by FISH technique, showing typical reciprocal translocation (EWRS1−22q12).

The treatment strategy was initially based on a multimodal therapy:First neodjuvant systemic chemotherapy (Kushner's scheme).
Second extensive and radical cytoreductive surgery: Peritonectomies, several organs, hundreds nodules resection and electrovaporization nodules. 1 to 2 high risk anastomosis were performed respectively.
Optimal cytoreduction (CC1), and HIPEC with cisplatin (100 mg/m^2) and adriamycin (15 mg/m^2) for 90 minutes, at a high temperature to 42 degrees centigrade, was achieved.
After overcoming a complicated postoperative with high morbidity, but no mortality, it evaluated in a multidisciplinary committee, adjuvant treatment with systemic chemotherapy and/or whole abdominal radiation (IMRT), similar to some recently published papers.
Conclusions: DSRCT is a very rare and aggressive entity, which is mainly reported, in young male patient with abdominopelvic malignancy. The diagnosis and treatment needs an aggressive and multimodal approach. The extensive cytoreductive surgery is currently accepted to have a primary role in the achievement of long-term survival.
The cases presented show that it is possible to achieve optimal cytoreduction (residual tumor less than 2.5 mm), requiring that the neoadjuvant and adjuvant and chemotherapy could prolong disease-free time.

Endocrine toxicities after treatment with ipilimumab

S. Zovato[1], P. Sartorato[1], V. Camozzi[1], V. Chiarion[2], J. Pigozzo[2], S. Faoro[3], G. Opocher[1]. *[1]Veneto Institute of Oncology IOV − IRCCS, Familiar Cancer Clinic- Oncologic Endocrinology, Padova, Italy; [2]Veneto Institute of Oncology IOV − IRCCS, Medical Oncology-IOV-Padova, Padova, Italy; [3]Veneto Institute of Oncology IOV − IRCCS, Pharmacy-IOV-Padova, Padova, Italy*

Background: Ipilimumab (IPL) is a MAB directed against the CTLA-4 which promotes activation of cytotoxic lymphocytes and augments an immune-mediated anti-tumour response. IPL is now licensed for the treatment of unresectable or metastatic malignant melanoma. A host of immune-related adverse events are associated with the anti CTLA-4 therapy. The endocrinologist may be involved in the management of IPL treated patients in whom may arise secondary hypophysitis with hypopituitarism in 1−6 % of patients, followed by hypo-and hyperthyroidism secondary to thyroiditis in 2.7 and 0.3%, respectively and primary adrenal insufficiency in 2.1%.
Patients and Methods: We studied 8 patients (age: 51±7; M/F:6/2) with metastatic melanoma enrolles in different trials with IPL. They presented hypophysitis symptoms after a median time of 11 weeks (range 7−16). All patients presented fatigue and asthenia and 4 also severe headache.
Results: All 8 patients had biochemical evidence of secondary adrenal insufficiency (median random cortisol level 105 ±112 nmol/L with undetectable ACTH levels); four patients presented also low FT3 (mean 2.86 pmol/L) and FT4 levels (mean 11.1 pmol/L) with low TSH in 3 cases (mean 0.245 mU/L) and in normal range in one (2.59 mU/L). 3 male patients also presented with a severe deficiency of testosterone (6±3 nmol/L). Three cases had also very low values of IGF-1 (65±22ug/L). One patient had the MRI which documented diffuse enlargement of the pituitary gland. All patients, as required by trial safety procedures, started with prednison 1 to 2 mg/kg orally once per day with gradual tapering and then substituted with cortison acetate. 3 patients also started thyroxine treatment.1 patient experienced a concomitant autoimmune hyperthyroidism that still requires thyrostatic treatment. Long term follow-up of our patients (11±8 months after IPL discontinuation) showed a persistent need for glucocorticoid replacement, while 2 patients recovered the thyroid axis function after 4 months from hypothyroidism and 2 patients the gonadal axis after 2 months.
Conclusion: The prevalence of IPL induced hypopituitarism may be higher than that previously thought and the effects on adrenal axis may be irreversible. This emphasizes the clinical relevance of endocrine toxicity and the importance of warning for early screening of pituitary insufficiencies in these patients.
No conflict of interest.

3751 POSTER

A community-based, real-world, study of treatment-naive advanced melanoma (AM) patients treated with 3 mg/kg ipilimumab (IPI) in the United States

D. Patt[1], S.L. Wong[2], T. Juday[2], J.R. Penrod[3], C. Chen[4], T. Hebden[2]. *[1]The U.S. Oncology Network McKesson Specialty Health, Health Informatics, The Woodlands, USA; [2]Bristol-Myers Squibb, Health Services U.S. Medical, Plainsboro, USA; [3]Bristol-Myers Squibb, Global Health Economics and Outcomes Research, Lawrenceville, USA; [4]McKesson Specialty Health, Health Economics and Outcomes Research, The Woodlands, USA*

Background: In March 2011 the U.S. FDA approved ipilimumab (Yervoy®) at 3 mg/kg monotherapy for the treatment of treatment-naive or pretreated advanced (unresectable or metastatic) melanoma (AM) based on prolongation of overall survival (OS) in a Phase III randomized, double-blind, multicenter study of previously treated AM patients (pts) treated with ipilimumab (IPI) 3 mg/kg every 3 weeks for 4 doses. We have initiated a four year study (CA184332) to describe pt and disease characteristics, patterns of care, and outcomes in treatment-naive AM pts initiating the approved IPI dose and schedule in a U.S. community-based setting. We currently report interim baseline demographics, pt characteristics, and overall survival (OS) for the first 61 pts.
Material and Methods: Adult pts with unresectable stage III or stage IV melanoma who had received ⩾1 dose of first-line IPI 3 mg/kg during April 2011 − September 2012 were identified retrospectively in U.S. Oncology practices utilizing the iKnowMed electronic medical record system. Clinical data were obtained using programmatic queries in iKnowMed and medical chart abstraction. This interim analysis reports on the subset of pts for whom at least 12 months had elapsed since IPI initiation.
Results: The majority of the 61 pts were male (65.6%) with a mean age of 64 years (SD=14) at IPI initiation. Primary sites at initial melanoma diagnosis were cutaneous (95.1%), anorectal (3.3%) and ocular (1.6%). BRAF mutational testing occurred in 63.9% of pts and of those tested, 20.5% were BRAF mutation positive. At AM diagnosis, 32.8%, 37.7%, and 29.5% of pts were stage M1a, M1b, and M1c, respectively; none had unresectable stage III AM. By IPI initiation, brain metastases were identified in 32.8% of pts. At AM diagnosis, 63.9% and 26.2% of pts had ECOG PS 0 and 1, respectively, and 29.5% had LDH > upper normal limit. From IPI initiation, median OS was 11.5 months (95% CI 6.6, −) with a 1-year survival rate of 49.3% (95% CI 35.6–61.6%). Overall median follow-up was 8.5 months (range 0.4–19.0).
Conclusions: This community-based study is one of the largest studies of IPI 3 mg/kg monotherapy in treatment-naive AM and provides 'real world' evidence of the overall survival benefit of IPI in first-line AM pts.
Conflict of interest: *Ownership: Wong, Juday, Penrod, and Hebden have stock ownership in Bristol-Myers Squibb. PTEN loss correlates with shorter time to brain metastasis and overall survival in stage IIIB/C melanoma patients

A.D. Bucheit[1], R.W. Joseph[2], D. Milton[3], P. Fox[3], R. Bassett[3], J.E. Gershenwald[4], M.T. Tetzlaff[5], V.G. Prieto[5], A.J. Lazar[5], M.A. Davies[1]. *[1]M.D. Anderson Cancer Center, Melanoma Medical Oncology, Houston Texas, USA; [2]Mayo Clinic, Medical Oncology, Jacksonville Florida, USA; [3]M.D. Anderson Cancer Center, Biostatistics, Houston Texas, USA; [4]M.D. Anderson Cancer Center, Surgical Oncology, Houston Texas, USA; [5]M.D. Anderson Cancer Center, Pathology, Houston Texas, USA*

Background: Patients [pts] with stage IIIB/C melanoma have variable outcomes. Risk assessment in these pts is currently based on clinical and pathological factors. We hypothesized that integrated analysis of prevalent oncogenic drivers (BRAF, NRAS, PTEN) would improve risk assessment.
Materials and Methods: Under an IRB-approved protocol, regional metastases from stage IIIB/C melanoma pts (n = 137) who underwent surgery at MD Anderson Cancer Center were collected. Tumor DNA from FFPE tissue was tested for *BRAF* and *NRAS* mutations by mass-spectroscopy based genotyping. PTEN protein expression was determined by a CLIA-certified immunohistochemical assay. PTEN loss was defined as <10% of cells with (+) staining, based on correlation with increased AKT activation. Molecular features were compared to clinical characteristics and outcomes. Time-to-event measures and overall survival [OS] from stage III diagnosis were assessed using the Kaplan–Meier method and group differences were assessed using the log-rank test.
Results: Both time-to-distant metastasis [TTM; p = 0.047] and OS [p = 0.005] correlated with clinical stage (IIIB vs IIIC), consistent with validated models. Mutation status was 40% BRAF mutant, 9% NRAS mutant, and 50% no mutation in BRAF or NRAS [WT]. PTEN loss (evaluable in 125 pts) occurred in 25% of pts overall: 31% of BRAF, 23% of WT, and 8% of NRAS pts, respectively. Neither mutation status (p=1.00) nor PTEN loss (p=1.00) correlated with clinical stage. Tumor mutation status did not correlate significantly with TTM (p = 0.37) or OS (p = 0.89). In the cohort with evaluable PTEN, pts with PTEN loss had significantly shorter OS (median 1.88 vs 3.05 yrs, p = 0.03) but not TTM (p = 0.34). Evaluation of patterns of metastasis demonstrated that PTEN loss correlated with markedly shorter time-to-brain metastasis [TTBM] (median 1.84 vs 4.87 yrs, p = 0.03), but not to lung (p = 0.92), liver (p = 0.52), or bone (p = 0.10) metastasis. By genetic subgroup analysis, PTEN loss in BRAF pts correlated with significantly shorter TTBM (median 1.15 vs 4.19 yrs, p = 0.001) and OS (median 1.63 vs 3.60 yrs, p = 0.001), but not in WT pts (TTBM, p = 0.59; OS, p = 0.94). In a multivariate Cox

proportional hazards model of the BRAF pts incorporating stage, PTEN, age, vemurafenib treatment [tx], and ipilimumab tx, PTEN loss was the only significant risk factor for TTBM (HR 4.71, p = 0.004) and for OS (HR 2.99, p = 0.003).
Conclusion: PTEN loss in BRAF-mutant stage IIIB/C melanoma pts correlates with shorter TTBM and OS. These data implicate PTEN loss as a novel molecular risk factor for brain metastasis, add to the evidence supporting the clinical significance of PTEN loss in BRAF-mutant melanomas, and have implications for the management of, and clinical trials for, stage IIIB/C melanoma pts.

3753 POSTER

Circulating tumor DNA (ctDNA) in metastatic uveal melanoma patients (MUM): Clinical results and correlation with outcome in 87 patients from Institut Curie

S. Piperno-Neumann[1], J. Madic[2], P. Mariani[3], A. Rampanou[4], V. Servois[5], F.C. Bidard[1], M. Milder[4], L. Desjardins[3], M.H. Stern[6], O. Lantz[7]. *[1]Institut Curie, Medical Oncology Department, Paris, France; [2]Institut Curie, INSERM U830 Laboratory of Circulating Biomarkers, Paris, France; [3]Institut Curie, Surgery Department, Paris, France; [4]Institut Curie, Laboratory of Circulating Biomarkers, Paris, France; [5]Institut Curie, Radiology Department, Paris, France; [6]Institut Curie, INSERM U 830 Tumor Biology Department, Paris, France; [7]Institut Curie, Tumor Biology Department, Paris, France*

Background: ctDNA can be detected in the plasma of MUM patients using a real-time PCR based on the pyrophosphorolysis-activated polymerization (bi-PAP) able to detect the most frequent GNAQ and GNA11 point mutations (codon 626) which are present in 85% of UM with high specificity and sensitivity (Madic et al., 2012).
Methods: From May 2011 to March 2013, 87 MUM patients were included in 3 prospective studies to assess the bi-PAP assay. We report here the analysis of clinical and outcome correlations using this new molecular tool.
Results: 87 patients (43 M/44 F), median age 57 (range 23−84), primary tumor: median diameter 15 mm (range 5−25), local treatment: enucleation (32), proton beam (52), iodine disk (3). Enucleated eyes showed mostly mixed histotype and genomic high risk tumors by array-CGH (8q gain and/or 3p loss). With a median disease free interval of 39 months, 83 patients developed liver metastases first, with radiological miliary disease in 55; 4 had extra hepatic lesions without liver involvement. The median number of lesions was 5, the median size 20 mm. 35 patients were enrolled at the time of metastasis diagnostic, LDH was in normal range in 61/87 and performance status (WHO) 0/1/2 in 45/36/6 patients respectively. With a median follow-up of 8 months (range 0−22), 28 patients had disease progression and 34 died of metastasis. The median survival was 13 months (range 2 −115). Tumor samples were available in 82 patients, genotyping is ongoing for 8. GNAQ 626A>T, GNAQ 626A>C and GNA11 626A>T mutations were found in 9, 19 and 26 tumors respectively; rare mutations were present in 6 tumors, and 14 were GNAQ/11 wild-type tumors. Finally, ctDNA was quantitatively detected in 51/54 plasma samples (median 30 copies/ml, range 1–11421) and correlated with the metastatic tumor burden as assessed by liver MRI (median 64 cm^3, range 0.2–7384). Correlation with progression-free and overall survival will be presented.
Conclusion: ctDNA is a promising tool to assess the tumor burden and detect the micrometastatic dissemination of uveal melanoma, and a potential biomarker to evaluate the efficacy of targeted therapies in metastatic patients carrying GNA Q/11 mutated tumors.
No conflict of interest.

3754 POSTER

New DNA repair inhibitors Dbait in combination with radiation therapy to treat melanoma: A preclinical study

J. Biau[1], F. Devun[2], J.S. Sun[2], M. Dutreix[1], Y. Kirova[3]. *[1]Institut Curie, Research Center, Orsay, France; [2]DNA Therapeutics, Research, Evry, France; [3]Institut Curie, Radiation Therapy, Paris Cedex 05, France*

Background: Melanoma is the fifth and sixth leading cause of cancer in men and women, respectively. It is characterized by symptomatic locoregional recurrence, distant metastasis, and a poor response to systemic drugs and particularly radioresistance. The cytotoxicity of radiation therapy (RT) is mainly due to DNA double-strand breaks (DSBs). Dbait are innovative molecules that mimic 'false' DSBs that trap DNA repair proteins and prevent their recruitment thereby inhibiting their repair. This inhibitory effect is partly driven through deregulated activation of DNA-PK kinase (key enzyme of DSB repair). Interestingly, DNA-PK is known to be overexpressed in metastatic melanoma. We assessed the efficacy and safety of combining RT with Dbait in a model of human melanoma.
Material and Methods: Initially, the cytotoxic efficacy of Dbait in combination with RT was evaluated *in vitro* by clonal survival. We further assayed the capacity of Dbait to inhibit RT-induced DNA damage repair over time. Subsequently, nude mice subcutaneously engrafted with human melanomas (SK28) were treated with Dbait (n = 10), 'palliative' (10x3 Gy in 2 weeks; n = 18) or 'radical' (20x3 Gy in 4 weeks; n = 12) RT, a combination of Dbait and RT for 2 (n = 12) and 4 (n = 11) weeks or left untreated (n = 21). Tumor growth and survival of untreated and treated animals were monitored for 250 days.
Results: *In vitro*, Dbait enhanced RT-induced cytotoxicity (67% *vs* 51%; $p < 0.05$). In Dbait and RT treated cells, initially the level of DNA damage was not greater than in RT treated cells, however persisted for longer ($p < 0.05$). Mice treated with Dbait and RT combination treatment had significantly better tumor growth control and longer survival compared to RT alone (median survival: 119 vs 67 days for the 'palliative' protocol, $p < 0.001$; 221 vs 109 days for the 'radical' protocol, $p < 0.001$). Interestingly, only animals receiving the combined 'radical' protocol showed complete responses in 7/11 tumors. No toxicity was observed in Dbait-treated groups.
Conclusions: This preclinical study provides encouraging results for a combination of a new DNA repair inhibitor, Dbait, with RT, in the absence of toxicity. A first-in-human phase I study is currently underway in the palliative management of melanoma in-transit metastases (DRIIM trial).
Conflict of interest: *Other substantive relationships: Sun JS is co-funder of DNA Therapeutics, the company holding the pattent of Dbait and Flavien D is employee of DNA Therapeutics*

3755 POSTER

Locoregional disease control in metastatic melanoma: Exploratory analysis from phase 2 testing of intralesional rose bengal

S. Agarwala[1], J.F. Thompson[2], B.M. Smithers[3], M.I. Ross[4], B.J. Coventry[5], D.R. Minor[6], C.R. Scoggins[7], J.M. Singer[8], E.A. Wachter[8]. *[1]St Luke's University Hospital and Temple University, Oncology & Hematology, Bethlehem, USA; [2]Melanoma Institute Australia, Oncology, Sydney, Australia; [3]Princess Alexandra Hospital, Oncology, Wooloongabba, Australia; [4]MD Anderson Cancer Center, Surgical Oncology, Houston, USA; [5]Royal Adelaide Hospital, Surgical Oncology, Adelaide, Australia; [6]California Pacific Medical Center, Oncology, San Francisco, USA; [7]University of Louisville, Surgical Oncology, Louisville, USA; [8]Provectus Pharmaceuticals, Clinical Development, Knoxville, USA*

Background: PV-10 (10% rose bengal disodium) is a small molecule immuno-chemoablative agent that has completed phase 2 testing in 80 AJCC Stage IIIB-IV(M1c) subjects in clinical trial PV-10-MM-02 (ClinicalTrials.gov ID NCT00521053, sponsored by Provectus Pharmaceuticals, Inc.). Upon intralesional injection, PV-10 elicits selective ablation of injected lesions and a tumor-specific, immune-mediated bystander response in untreated lesions in which T cells are implicated.
Materials and Methods: In the phase 2 trial, up to 10 cutaneous or subcutaneous target lesions and up to 10 additional non-target lesions received intralesional PV-10 at day 0 and could be reinjected as necessary at weeks 8, 12 and 16 if tumor tissue remained. Up to 2 additional cutaneous or subcutaneous lesions were left untreated to assess bystander response. The primary endpoint in the single arm trial was best overall objective response rate (BORR) judged by RECIST in each subject's target lesions.
Results: For all subjects, BORR was 51% (26% CR, 25% PR) with the amount of tumor burden accessible to PV-10 injection prognostic for outcome. In the majority of subjects (66%) the lesions treated with PV-10, together with up to 2 untreated bystander lesions, constituted all disease present, and these subjects achieved a BORR of 62%, while when all disease was treated (33% of subjects) BORR further increased to 73%. Locoregional blistering was observed in 40% of subjects, occurring within 7 days of PV-10 injection but with no clear pattern of incidence, and generally resolving without sequelae within 4 weeks. Occurrence of this potentially immune mediated phenomenon was strongly prognostic for outcome, with 66% BORR in subjects with blisters vs. 42% in those not developing blisters. Locoregional disease control correlated stronger still: 90% of subjects with blisters achieved stable disease or better vs. 54% of subjects without blisters.
Conclusions: In this patient population refractive to other local treatments such as surgery and radiation, intralesional PV-10 provided a viable strategy to maintain, with minimal intervention, locoregional control of the disease with the potential to delay, reverse or prevent progression to life-threatening visceral disease.
Conflict of interest: *Ownership: Provectus Pharmaceuticals (Singer, Wachter). Advisory board: Provectus Pharmaceuticals (Agarwala, Thomp-*

son, Ross, Scoggins). Corporate-sponsored research: Provectus Pharmaceuticals (Agarwala, Thompson, Smithers, Ross, Coventry, Minor, Scoggins). Other substantive relationships: Employee, Provectus Pharmaceuticals (Singer, Wachter)

3756 POSTER

Identification of markers prognostic of survival in lymph node metastases from stage III melanoma patients

S. Mactier[1], K.L. Kaufman[1], P. Wang[2], B. Crossett[1], E. Yang[1], R.A. Scolyer[3], J. Yang[2], G.J. Mann[4], R.I. Christopherson[1]. *[1]The University of Sydney, School of Molecular Bioscience, Sydney NSW, Australia; [2]The University of Sydney, School of Mathematics and Statistics, Sydney NSW, Australia; [3]The University of Sydney, Tissue Pathology and Diagnostic Oncology, Sydney NSW, Australia; [4]The University of Sydney, Westmead Millennium Institute, Westmead NSW, Australia*

Background: The present American Joint Committee on Cancer staging system for Stage III melanoma stratifies patients into heterogeneous groups, with widely varied outcomes and responses to available therapies. Average 5-year survival following surgical lymph node removal is about 30%. Panels of accurate biomarkers prognostic of survival are urgently needed for more personalised melanoma patient management.
Methods: Complementary quantitative proteomics approaches, 2D fluorescence difference in-gel electrophoresis (DIGE) and isobaric tags for relative and absolute quantitation (iTRAQ) coupled with 2D liquid chromatography tandem mass spectrometry (LC-MS/MS), were used to identify differentially abundant proteins in extracts from melanoma lymph node metastases, surgically excised from Stage III patients with poor (n = 14, <1 year survival) and good (n = 19, >4 years) survival outcomes. Potential prognostic markers were verified by selected reaction monitoring (SRM) mass spectrometry (MS).
Results: Overall, 83 proteins were differentially abundant between patients with good and poor survival outcomes ($p < 0.05$). Subsequent SRM analysis verified 21 proteins as potential biomarkers for survival after surgical treatment of lymph node metastasis. The MS-based analyses, iTRAQ 2DLC-MS/MS and SRM, were highly concordant with a median Pearson's correlation value of R = 0.74. Enhanced protein metabolism/folding, nucleic acid metabolism and angiogenesis, deregulation of cellular energetics and methylation processes, and decreased levels of apoptosis and immune response-related proteins were associated with a poor prognosis. Our panel of significant, differentially abundant proteins include biomarkers previously associated with prognosis in metastatic melanoma.
Conclusions: This is the first report of comprehensive quantitative proteomics used to identify proteins predictive of survival in lymph node metastases from Stage III melanoma patients. Collectively, this panel of identified proteins offers insight into important aspects of melanoma biology and next-generation prognostication that may enable better stratification of Stage III patients.
No conflict of interest.

3757 POSTER

Metalloproteinase pregnancy associated plasma protein-A (PAPP-A) promotes melanoma progression in vitro

P. Prithviraj[1], A. Jayachandran[1], M. Anaka[1], J. Cebon[1]. *[1]Ludwig Institute for Cancer Research, Joint Ludwig-Austin Oncology Unit, Melbourne, Australia*

Background: Melanoma is a common and highly aggressive form of skin cancer with a high propensity to metastasise. Metastatic melanoma is a fatal disease with poor prognosis. Insulin-like Growth Factor (IGF1) promotes melanoma metastasis and plays an important role in disease progression. Bioavailability of IGF1 is known to be regulated by IGF-binding proteins (IGFBPs). IGFBP4 forms a complex with IGF1 and inhibits release of active IGF1. IGFBP4 is cleaved by metalloproteinase Pregnancy-Associated Plasma Protein-A (PAPP-A) resulting in release of bioactive IGF1.
Methods: PAPP-A mRNA expression was analysed by quantitative RT-PCR in forty-eight metastatic melanoma patient tumour samples, and in thirty-eight melanoma cell lines developed in our institute. PAPP-A secretion was quantified by commercial ELISA in twelve melanoma patient sera and eleven melanoma cell lines. Efficient knockdown of PAPP-A expression and secretion (down to <90%, $p < 0.01$) was achieved with siRNA transfection lasting for 72 hrs. Functional studies at various timelines were performed post PAPP-A siRNA knockdown, which included proliferation (MTS), invasion (matrigel) and migration (wound healing assay). PAPP-A gene expression was analyzed in melanoma cells resistant to BRAF inhibitor (BRAFi) and cytotoxic chemotherapy (cisplatin & paclitaxel).
Results: PAPP-A was noted to be widely and variably expressed in tumour tissue samples and melanoma cell lines,with some melanoma cell lines expressing PAPP-A as high as 900 copies/10^5 copies of Bactin. PAPP-A protein was secreted in varying concentration by melanoma cell lines, with 3/11 melanoma cell lines secreting PAPP-A as high as 17.5ng/ml. Quantification of PAPP-A in metastatic melanoma patient sera did not reveal elevated levels as compared to normal. PAPP-A knockdown resulted in significant decrease in invasive capability of melanoma cells, with a statistically significant 60% reduction in invasion (paired t-test, p value<0.01). Migration was noted to be markedly inhibited in PAPP-A depleted cells. Proliferative ability of melanoma cells did not change with PAPP-A knockdown. A significant increase in PAPP-A expression was noted in melanoma cells resistant to cytotoxic chemotherapy (upto 20 fold). PAPP-A mRNA levels were noted to be up-regulated in BRAFi resistant cells (upto 3 fold), along with up-regulation in expression of IGF1 receptor (IGFR1) and IGF receptor substrates (IRS1 & IRS2), indicating role of PAPP-A in acquired resistance to BRAFi via modulation of IGF signalling.
Conclusion: Our data suggests that PAPP-A proteolytic activity plays an important role in melanoma progression and treatment resistance to BRAF inhibitors. Targeting PAPP-A could be a novel therapeutic strategy to limit disease progression and holds a promise in overcoming resistance to BRAFi in melanoma patients. In addition, PAPP-A has a potential to be an important biomarker for IGF targeted therapy.
No conflict of interest.

3758 POSTER

BRAF V600 mutations and pathological features in Japanese melanoma

N. Yamazaki[1], R. Tanaka[1], A. Tsutsumida[1], K. Namikawa[1], H. Eguchi[1], W. Omata[1], K. Oashi[1], K. Tsuta[2]. *[1]National Cancer Center Hospital, Dermatologic Oncology, Chuo-kuTokyo, Japan; [2]National Cancer Center Hospital, Pathology and Clinical Laboratories, Chuo-kuTokyo, Japan*

Background: *BRAF* V600 mutations are frequently found in melanomas and result in constitutive activation of BRAF. Recently, the BRAF V600 kinase inhibitor vemurafenib, which has antitumor activity in patients with *BRAF* V600-mutated melanoma, was developed in conjunction with the cobas® 4800 BRAF V600 Mutation Test. The frequency and most common site of melanoma are different among races and it assumed that the *BRAF* mutation rate is also different. In Japan, since the occurrence of melanoma is rare, the frequency and distribution of *BRAF* V600 mutations has not been elucidated. We investigated the frequency of the *BRAF* V600 mutation in Japanese patients with melanoma as a primary end point. A secondary end point demonstrated the relationship between the mutation and clinical or pathologic features.
Material and Methods: Eighty formalin-fixed, paraffin embedded tumors diagnosed with melanoma were collected by the National Cancer Center Hospital from 2006–2012. DNA was extracted with the cobas® DNA preparation kit. The *BRAF* V600 mutations were detected with the cobas®4800 system z480 and the cobas® 4800 BRAF V600 Mutation Test reagents.
Results: *BRAF* V600 mutations were detected in 41.8% of the tested tumors and the invalid rate was found in 1.3%. The mutation rate was found to be over 50% in patients age <60 or with stage III/IV disease without gender differences. Based on tissue subtypes, mutations were detected in 18.8% of acral lentiginous (ALM), 64.7% of superficial spreading (SSM), 50.0% of lentigo maligna (LMM) and 20.0% of nodal melanoma (NM). Although the mutation ratio was low in ALM, 36.4% were mutation positive at stage III/IV.
Conclusions: The frequency of the BRAF mutations is reported to be high in SSM but low in ALM. Therefore we predicted the mutation ratio would be low because ALM was common among Japanese (about 45%) compared with SSM (about 25%). However, this study showed that the patients with SSM had almost the same rate as ALM (43.0% and 40.5%, respectively). Thus the mutation was detected in 41.8% of specimens. Since the 80 specimens were collected for the last 6 years, patients with SSM might be increasing. Interestingly, the frequency of the BRAF mutation in advanced ALM was 36.4% but 9.5% in early stages. As genetic information accumulates relative to molecularly targeted drugs, these genetic insights are expected to provide better treatment predictions for melanoma patients.
No conflict of interest.

The dioxin receptor suppresses melanoma growth and metastasis by differentially acting on the tumor cell and the microenvironment

M. Contador[1], A.B. Alberto[2], B.A. Eva[1], E. Rico Leo[1], R.B. Xose[3], S.S. Javier[4], F.S. Pedro María[1]. [1]*University of Extremadura, Biochemistry and Molecular Biology, Badajoz, Spain;* [2]*University of Extremadura, Servicio de Técnicas Aplicadas a las Biociencias, Badajoz, Spain;* [3]*Cancer Center of Salamanca, Biochemistry and Molecular Biology, Salamanca, Spain;* [4]*Hospital Infanta Cristina, Pathological Anatomy, Badajoz, Spain*

Background: Melanoma is a highly metastatic and malignant skin cancer having poor rates of patient survival. Since the incidence of melanoma is steadily increasing in the population, finding prognostic and therapeutic targets appears a crucial task in cancer. The dioxin receptor (AhR) is well known for its role in xenobiotic-induced toxicity and carcinogenesis and for its contribution to cell and organ homeostasis. Yet, the mechanisms by which AhR affects tumor growth and dissemination are still largely uncharacterized.
Methods: To address the tumor-intrinsic and the stromal-related AhR functions in melanoma, we have used two approaches. Firstly, we have molecularly engineered B16F10 mouse melanoma cell lines to either down-modulate or to constitutively activate AhR in order to investigate how variations in AhR signaling affect melanoma growth and metastasis. Secondly, we have transplanted those cell lines on *AhR*+/+ or *AhR*−/− immunocompetent mice to explore the contribution of stromal AhR on melanoma tumorigenesis and metastasis. This scheme allowed us to investigate the interaction between intrinsic (melanoma-dependent) and microenvironmental (mouse stromal-dependent) AhR activities in melanoma.
Results: We report here that AhR contributes to the tumor–stroma interaction, inhibiting melanoma growth and metastasis when expressed in the tumor cell but supporting melanoma when present in the stroma. B16F10 cells engineered to lack AhR (sh-AhR) displayed exacerbated melanoma primary tumorigenesis and lung metastasis when introduced in immunocompetent *AhR*+/+ recipient mice but not when injected in *AhR*−/− mice or when co-injected with *AhR*−/− fibroblasts in an *AhR*+/+ microenvironment. Contrary, B16F10 cells having a constitutively active AhR (CA-AhR) had reduced tumorigenicity and invasiveness in either AhR genetic background. The tumor suppressor role of AhR in melanoma cells correlates with reduced migration and invasion, with lower numbers of cancer stem-like cells and with altered levels of β1-integrin and caveolin1. Consistently, human melanoma cell lines with highest AhR expression also had lowest migration and invasion potentials. Moreover, AhR expression was significantly reduced in malignant melanomas from human patients with respect to nevi lesions.
Conclusion: We conclude that AhR knock-down in melanoma cells requires stromal AhR for maximal tumor progression and metastasis. Thus, AhR can be a molecular marker in melanoma and its activity in both tumor and stromal compartments should be considered.

Prevalence of BRAF V600E mutation in metastatic melanoma of Mexican Mestizo population

E. Ruiz-Garcia[1], A. Meneses[1], H. Martinez-Said[1], J.L. Aguilar-Ponce[1], A. Mohar[1], A. López[1], O. Alonso-Luna[1], J.A. Guadarrama-Orozco[1], D. Green[2], H. Astudillo-de la Vega[3]. [1]*National Cancer Institute, Traslational Medicine, Mexico D.F, Mexico;* [2]*Médica Sur, Medical Oncology, Mexico D.F, Mexico;* [3]*Centro Médico Nacional Siglo XXI IMSS, Traslational Cancer Research Unit, Mexico D.F, Mexico*

Background: The BRAF mutation V600E have been described in Caucasian, European and Asian melanomas. However the status and clinical significance of BRAF mutation in Mexican population have not been investigated on large scale.
Methods: Consecutive BRAF-tested Mexican patients with metastatic Melanoma (n = 146) were analyzed for mutations in exon 15 of the BRAF gene in genomic DNA by Real time polymerase chain reaction (RT-PCR, Cobas) amplification. The results were correlated with clinic pathologic features of the patients. All the samples were collected from the whole country, most of the analyzed tissue were from private office.
Results: For the total population 53% were females and the rest males. The age range in males was 28−82 years, meanwhile in women was 26−89 years. Median age, was 56 years in both groups BRAF-mutant and BRAF wild-type patients. The incidence of somatic mutation V600E within the BRAF gene was 30.13% (44/146). Nodular melanoma were the most prevalent subtype in our population, and showed BRAF mutations in 36.3% (16/44). The second subtype was superficial spread were BRAF mutation was 47% (8/17). Other clinic-pathological features were assessed to correlate with the mutation status.
Conclusions: The most prevalent BRAF mutation type in melanoma is V600E. This mutation has been studied in Caucasians, Europeans and Asians. The information reveals than in México Nodular Melanoma is the most prevalent type for metastatic presentation, this could be explained because most of the patients comes with advanced disease, meanwhile, superficial spread melanoma normally is diagnosticated in early stages. In Caucasian population the most frequent type of MM with BRAF mutations is usually superficial spread, and in Asiatic used to be acral. This is the first study in Latin America in a mixed population.

Randomized phase II trial of doxorubicin vs. trabectedin plus doxorubicin in first line treatment of patients with advanced non-resectable or metastatic soft tissue sarcomas: a Spanish Group for Sarcoma Research (GEIS) study

J. Martin-Broto[1], A. Lopez-Pousa[2], X. Garcia del Muro[3], R. De Las Peñas[4], J. Martinez-Trufero[5], J. Cruz[6], R. Alvarez[7], R. Cubedo[8], A. Redondo[9], A. Poveda[10]. [1]*Son Espases University Hospital, Medical Oncology, Palma de Mallorca, Spain;* [2]*Hospital Sant Pau, Medical Oncology, Barcelona, Spain;* [3]*Instituto Catalan de Oncologia (ICO), Medical Oncology, Barcelona, Spain;* [4]*Hospital Provincial, Medical Oncology, Castellon, Spain;* [5]*Hospital Miguel Servet, Medical Oncology, Zaragoza, Spain;* [6]*Hospital Universitario de Canarias, Medical Oncology, La Laguna, Spain;* [7]*Hospital Gregorio Marañon, Medical Oncology, Madrid, Spain;* [8]*Hospital Puerta de Hierro, Medical Oncology, Madrid, Spain;* [9]*Hospital La Paz, Medical Oncology, Madrid, Spain;* [10]*Instituto Valenciano de Oncologia (IVO), Medical Oncology, Valencia, Spain*

Background: Doxorubicin, 25 years later, is still the standard upfront systemic treatment for metastatic STS patients whereas trabectedin has been recently approved as second line of therapy in STS. The combination of both drugs was hypothesized to be advantageous based on the following rationale: It was found to be synergistic in sarcoma cell lines culture and additive in murine xenograft sarcoma model. In addition, the toxicity profile of both drugs is different so that no serious summative adverse effects were expected as previous phase I trial indicated. The aim of the present study was to compare, in a randomized phase II trial, the efficacy and toxicity of trabectedin plus doxorubicin vs doxorubicin in first line of STS patients.
Methods: Eligible patients were defined as follows: non-resectable locally advanced or metastatic STS, adequate marrow, hepatic, cardiac and renal function and performance 0−2 (most patients were 0−1 after amendment). Patients with HBsAg positive and replicative positive phase as well as CNS metastases were excluded. Trabectedin 1.1 mg/m^2 in 3-h e.v plus doxorubicin 60 mg/m^2 in 20-min perfusion were given through central venous catheter in experimental arm (EA) and doxorubicin 75 mg/m^2 in 20-min perfusion was administered in control arm (CA). Oral dexametasone 4 mg/12 h was given from −1 day in EA. Cycles were given every 21 days for a maximum of 6 in both arms. Main endpoint was progression free survival (PFS) and interim analysis was planned around the occurrence of 62 events of progression. Disease free interval (⩽12 m vs >12m) was used as stratification factor.
Results: From November 2009 to July 2012, 114 patients were enrolled with a median age of 53 y (21−74). There was 33%/67% and 22%/78% of locally advanced/metastatic cases in CA and EA respectively. There were 4 toxic deaths (2 in each arm) mainly in ECOG 2 patients. Most relevant grade 3/4 toxicity was leukopenia 23% in EA vs 9% in CA and febrile neutropenia 11% in EA vs 8% in CA. Grade 3 nausea found in 8% for EA vs 0% for CA and grade 3 asthenia found in 20% for EA vs 7% for CA were significantly different between both arms. Overall, 469 cycles were administered, 242 in CA and 227 in EA. Median of PFS was 5.8 m (3.6−8) in CA and 5.7 m (2.9−8.5) in EA with HR (IC95%) of 1.32 (0.87−2), p = 0.18. The overall survival rate at one year was 53% in CA and 54% in EA. From 107 evaluable patients, RECIST response rate was distributed as follows: partial response 20% in CA vs 13% in EA, stable disease 47% in CA vs 54% in EA and progressive disease 33% in both arms (p = 0.63). The trial was stopped for futility after interim analysis since the results showed a risk reduction for PFS of less than 9.64% for experimental arm.
Conclusions: Combination of trabectedin plus doxorubicin did not show superiority over doxorubicin alone in first line of STS patients failing to demonstrate, at least with the current scheme, the synergistic effect found in preclinical studies.
No conflict of interest.

NGR-hTNF given at low dose (LD) or high dose (HD) with or without doxorubicin (D) in soft-tissue sarcomas (STS)

S. Ferrari[1], P.G. Casali[2], J.Y. Blay[3], A. Le Cesne[4], G. Tonini[5], N. Ali[6], V. Perfetti[7], A. Lambiase[8], C. Bordignon[8]. [1]*Istituto Ortopedico Rizzoli, Medical Oncology, Bologna, Italy;* [2]*Fondazione IRCCS Istituto Nazionale dei Tumori, Medical Oncology, Milan, Italy;* [3]*University Claude Bernard Lyon I Centre Léon Bérard, Medical Oncology, Lyon, France;* [4]*Institut Gustave Roussy, Medical Oncology, Villejuif, France;* [5]*Università Campus Bio-Medico, Medical Oncology, Rome, Italy;* [6]*Clatterbridge Cancer Centre, Medical Oncology, Bebington, United Kingdom;* [7]*Policlinico San Matteo, Medical Oncology, Pavia, Italy;* [8]*MolMed, Clinical Development, Milan, Italy*

Background: NGR-hTNF, a tumor-targeted antivascular agent, exhibits a biphasic dose-response curve with activity shown at LD or HD. Vascular effects at LD are driven by early vessel stabilization, which improves intratumor D uptake, and late vessel damage, while at HD by rapid vessel disruption.
Methods: After stratification for prior D dose (> vs $\leqslant$300 mg/m^2), patients (pts) with advanced STS were randomly assigned to receive NGR-hTNF alone at LD (0.8 μg/m^2/d1/q1w) in arm A and at HD (45 μg/m^2/d1/q1w) in arm B, or combined with doxorubicin (60 mg/m^2/d1/q3w/max 6 cycles) at LD in arm C and at HD in arm D. This 4-arm phase II trial had progression-free survival (PFS) as primary endpoint, with tumor response assessed q6w until progressive disease (PD). Using a 2-stage study design, each regimen was rejected if $\leqslant$2/14 and $\leqslant$7/24 pts were PD free at 3 months after 1st and 2nd stage, respectively (β=20%; α=10%; n = 96). Secondary endpoints comprised adverse events (AEs), response rate by RECIST criteria and early metabolic response (MR), as quantified by fractional changes in SUV using FDG-PET according to EORTC criteria.
Results: Globally, 69 pts (median age 55 years; male 38; PS $\geqslant$1 31; leiomyosarcomas 14; median prior lines 2, range 0−7) received 678 weekly cycles (mean 10; range 1−46). Main grade 3/4 treatment-related AEs were neutropenia (18%) and chills (7%). After 1st stage, primary endpoint was met only for arm C (LD NGR-hTNF plus D), with 7/14 pts PD free at 3 months. At the end of 2nd stage (arm C, n = 28), median PFS was 1.3 months (95% CI, 1.1−1.5) for arm A, 1.5 (1.1−1.8) for B, 3.6 (1.1−6.1) for C and 1.6 (0.9−2.3) for D (p = 0.01 for trend). As best response by RECIST, 25/59 evaluable pts (42%) had stable disease (SD), including 1/12 in arm A, 6/12 in B, 14/23 in C and 4/12 in D. Median SD duration in arm C was 4.8 months (range 1.6–22.8). By FDG-PET imaging done at 3 weeks, 7/37 assessable pts (19%) had partial MR (4 SD/3 PD per RECIST), with mean change in SUV of −34% (SD $\pm$ 12), while 23 pts (62%) had stable MR (7 SD/16 PD per RECIST), with mean change in SUV of 2% ($\pm$10). Median PFS was 4.1 months in pts who achieved partial MR and 1.4 months in pts who did not (HR = 0.58).
Conclusion: LD NGR-hTNF can be safely given with D, showing promising activity.
No conflict of interest.

PICASSO 3: A phase 3 international, randomized, double-blind, placebo-controlled study of doxorubicin (dox) plus palifosfamide (pali) vs. dox plus placebo for patients (pts) in first-line for metastatic soft tissue sarcoma (mSTS)

C.W. Ryan[1], P. Schoffski[2], O. Merimsky[3], M. Agulnik[4], J.Y. Blay[5], S.M. Schuetze[6], J.Y. Buck[7], X. Garcia del Muro[8], I.R. Judson[9], R.G. Maki[10]. [1]*Oregon Health & Science University, Knight Cancer Institute, Portland, USA;* [2]*University Hospitals Leuven, Department of General Medical Oncology KU Leuven, Leuven, Belgium;* [3]*Tel Aviv Sourasky Medical Center, Unit of Soft Tissue & Bone Oncology Division of Oncology Tel Aviv Medical Center, Tel Aviv, Israel;* [4]*Northwestern University, Feinberg School of Medicine, Chicago, USA;* [5]*Centre Leon Berard, Lyon, France;* [6]*University of Michigan, Ann Arbor, USA;* [7]*ZIOPHARM Oncology Inc, Boston, USA;* [8]*Instituto Catalan Oncologia, Barcelona, Spain;* [9]*The Royal Marsden NHS Foundation Trust, London, United Kingdom;* [10]*Mount Sinai School of Medicine, New York, USA*

Background: Pali is a potent bi-functional DNA alkylating agent with activity against multiple tumors including mSTS, and as the active metabolite of ifosfamide, bypasses resistance pathways and toxic metabolites associated with prodrug activation.
Materials and Methods: Eligible pts had measurable mSTS and had not received previous chemotherapy for metastatic disease. Disease histology was centrally confirmed by independent pathology review. Pts were stratified by histological type (synovial, leiomyosarcoma, other sarcoma) and age (<65, $\geqslant$65 yrs), then randomly assigned 1:1 to receive dox 75 mg/m^{2}IV (day 1) plus either pali 150 mg/m^2 IV or placebo (days 1, 2, 3) every 21 days for up to 6 cycles. No cross-over was allowed. The primary endpoint of progression-free survival (PFS) per RECIST v1.1 was assessed by independent, blinded radiographic review. Secondary endpoints included overall survival, response rate, quality of life, and safety and tolerability.
Results: Between Sept 2010 and Jul 2012, 447 pts with mSTS at 113 centers worldwide were randomly assigned to receive pali+dox (n = 226) or placebo+dox (n = 221); 6% had synovial, 34% leiomyosarcoma, 60% other sarcomas; and 26% were $\geqslant$65 years. Median PFS was 5.98 months (95% CI 5.31–6.20) for pali+dox compared with 5.23 months (4.13–5.90) for placebo+dox (HR = 0.87, 95% CI 0.70–1.07; p = 0.18). At interim analysis, median overall survival was 15.91 months for pali+dox vs 16.89 months for placebo+dox (HR = 1.05, 95% CI 0.79–1.39; p = 0.74). Subgroup analysis is ongoing. Adverse event (AE) profiles were similar in both treatment arms, with the rate of febrile neutropenia of 17.8% for pali+dox v 9.8% for placebo+dox. Common AEs were nausea, constipation, fatigue, vomiting, diarrhea, and anemia. Grade $\geqslant$3 AEs were neutropenia, febrile neutropenia, nausea, anemia, constipation and dehydration. Pt-reported health-related QoL was maintained with pali+dox.
Conclusion: PICASSO 3 did not meet its primary endpoint, although pali+dox showed 3.1 weeks improvement in median PFS compared with placebo+dox in the first-line setting for mSTS. Pali+dox had a comparable toxicity profile compared with dox alone in this setting.

A comparison of isolated limb perfusion with surgery to surgery with radiotherapy for large high grade soft tissue sarcomas of the lower limb

A.J. Hayes[1], J. Jacob[2], M. Wilkinson[1], T. Pencavel[1], D.C. Strauss[1], L. Pilz[2], P. Tunn[3], J.M. Thomas[1], P. Hohenberger[2]. [1]*Royal Marsden Hospital − NHS Trust, Sarcoma and Melanoma Unit, London, United Kingdom;* [2]*University Medical Center Mannheim, Department of Surgery, Mannheim, Germany;* [3]*Sarcoma Center Berlin-Brandenburg, Department of Orthopedic Oncology, Berlin, Germany*

Aims: Isolated Limb Perfusion (ILP) with melphalan and TNFα is an effective induction treatment prior to surgery for locally advanced extremity sarcomas. It is used widely in mainland Europe for large tumours that are considered to be not easily compatible with functional limb conserving surgery. However the outcome of patients undergoing this treatment has never been directly compared to patients with equivalent tumours undergoing standard treatment of surgery and radiotherapy. We conducted a retrospective case matched cohort study comparing patients treated by ILP prior to surgery in two German sarcoma centres with patients with similar tumours treated by surgery and radiotherapy at a sarcoma centre in the UK.
Methods: Patients with intermediate or high grade STS of leg, exceeding 10 cm in size were identified from 2 prospectively maintained databases. Three independent sarcoma surgeons from separate sarcoma centres viewed anonymised MRIs of tumours from patients in each cohort and scored the tumours in terms of compatibility with limb preserving surgery on a linear scale (1−10). Primary outcome measures were local recurrence free survival and local failure rate.
Results: The two cohorts comprised 44 (ILP and surgery) and 80 (surgery and radiotherapy) patients. Twelve patients in the ILP cohort received additional postoperative radiotherapy. In the standard therapy cohort, all patients underwent resection and 66 received adjuvant radiotherapy. Tumour size, grade, histological subtype and compatibility with limb preserving surgery as assessed by independent review were identical between cohorts (Table). There were three amputations because of complications post ILP and surgery. No treatment related amputation occurred in the surgery and radiotherapy group. There were less local recurrences in the ILP cohort although this did not achieve significance (4/44 (9%) versus 13/80 (16%), p = 0.16). Local failure rate (local recurrence or amputation due to complications) was identical between cohorts (7/44 (16%) versus 13/80 (16%)). The rate of distant metastasis was also identical. (43/80(54%) vs 24/44(55%).
Conclusions: This case matched cohort analysis showed that ILP prior to surgical resection may have a lower local recurrence rate for large high grade sarcomas of the leg when compared with surgery and radiotherapy alone. However when treatment related complications are included the

overall local failure rate is identical between treatment groups. Therefore ILP and surgery is not superior to surgery and radiotherapy alone for limb preservation.
No conflict of interest.

Soft tissue sarcoma care in The Netherlands: Epidemiology, patterns of care and outcome data

H.J. Hoekstra[1], B.G.H. Bongers[1], W.T.A. Van der Graaf[2], R.L.M. Haas[3], C.S.P. Van Rijswijk[4], S. Siesling[5], A.J.H. Suurmeijer[6], C.J.H. Van de Velde[7], C. Verhoef[8], V.K.Y. Ho[5]. *[1]University Medical Center Groningen, Surgical Oncology, Groningen, Netherlands; [2]University Medical Center Nijmegen, Medical Oncology, Nijmegen, Netherlands; [3]Netherlands cancer Institute, Radiation Oncology, Amsterdam, Netherlands; [4]Leiden University Medical Center, Radiology, Leiden, Netherlands; [5]Comprehensive Cancer Center The Netherlands, Utrecht, Netherlands; [6]University Medical Centre Groningen, Pathology, Groningen, Netherlands; [7]Leiden University Medical Centre, Surgical Oncology, Leiden, Netherlands; [8]Erasmus Medical Center, Surgical Oncology, Rotterdam, Netherlands*

Introduction: This report presents the results of a nationwide soft tissue sarcoma (STS) survey conducted on behalf of the Dutch Cancer Society. Insight in the incidence, patterns of care and outcome may function as starting point for further improvement of STS patient care.
Methods: STS data from the national population based Netherlands Cancer Registry (NCR) were used to study STS pts in the period 2006–2011 with respect to epidemiology and treatment, excluding Kaposi sarcoma, GIST, uterine sarcoma and sarcoma of the skin. Descriptive statistics were applied to analyze patterns of care and outcomes on selected indicators measuring quality aspects of soft tissue sarcoma care.
Results: Overall, a total of 2,709 pts were diagnosed with STS, 1,495 men (55%) and 1,214 women (45%). The age-standardized incidence rate (2.7/100,000) did not change over time, and the same is true for the 5-yrs relative survival rate (60%). Median age at diagnosis was 63 (range 18–100) years; 47% were elderly pts (>65 years). Considering anatomical localization, 11% head and neck, 43% trunk or retroperitoneal cavity, 33% lower limbs, and 14% in upper limbs. Most often diagnosed histology: leiomyoarcoma (21%), NOS (20%), liposarcoma (19%), fibrosarcoma (10%) and undifferentiated sarcoma (10%). With respect to pattern of care: 2,215 pts (82%) were surgically treated (excluded those with metastatic disease), 892 of these pts (40%) received additional radiation therapy and overall 133 pts received adjuvant chemotherapy (5%). In pts left with an R1-status following surgery, the proportion receiving adjuvant radiotherapy was 53%. Resection status remained unknown in 25% of surgically treated pts (excluding those with metastasized disease), and in one third of the STS pts the tumor was not graded according to Coindre. Only systemic or radiation treatment was given in 4% and 3% respectively. Surgical treatment was fairly concentrated in a few centers: in 2010, 20% of all Dutch hospitals accounted for 60% of surgical procedures performed as STS treatment, with 7 centers (8% of hospitals) treating more than 10 pts per yr.
Conclusion: The incidence and relative survival of STS did not change in The Netherlands. Our findings suggest that there is room for improvement in Dutch STS diagnosis and care. Central pathology review may improve definitive histopathology, grading and reporting of resection status. Sarcoma treatment in 4−5 sarcoma centers with clinical and translational research, preferably within the EORTC Soft Tissue and Bone Sarcoma group, may improve overall sarcoma care and alter the disease outcome in the next decade.
No conflict of interest.

Presentation, treatment, and prognosis of recurrent osteosarcoma: The EUropean RELapsed OsteoSarcoma Registry (EURELOS)

S. Bielack[1], B. Sorg[1], M. Cesari[2], K. Sundby-Hall[3], E. Marchesi[2], M. Kevric[1], G. Friedel[4], R. Schwarz[5], S. Smeland[3], S. Ferrari[2]. *[1]Klinikum Stuttgart-Olgahospital, Pediatric Oncology Hematology Immunology, Stuttgart, Germany; [2]Istituto Ortopedici Rizzoli, Chemotherapy Department of Musculoskeletal Oncology, Bologna, Italy; [3]Norwegian Radium Hospital, Department of Oncology, Oslo, Norway; [4]Klinik Schillerhoehe, Thoracic Surgery, Gerlingen, Germany; [5]University Hospital Hamburg-Eppendorf, Radiation Therapy, Hamburg, Germany*

Background: A significant proportion of osteosarcomas relapse following multimodal treatment, yet prospectively gathered data on relapse presentation and outcomes is scarce. In order to fill this void, three multi-institutional osteosarcoma groups representing 10 European countries joined to form the EUropean RELapsed OsteoSarcoma Registry (EURELOS).
Material and Methods: EURELOS registers Cooperative Osteosarcoma Study Group (COSS), Italian (ISG) and Scandinavian (SSG) Sarcoma Group patients with recurrent osteosarcoma. Details on demographic, tumor, and treatment-related variables are collected according to a predefined common dataset.
Results: As of 03/13, 470 patients registered: 327 COSS, 120 ISG, 23 SSG; 305 male, 165 female; 423 primary extremity tumor, 47 axial; 381 initially localized, 87 metastatic (2?). Median interval diagnostic biopsy to 1st relapse: 1.66 years (range: 0.2–20.4), 432 within 5 years, 34 later (4?). First suspicion of relapse: symptoms 105, routine imaging 301 (64?). 375 recurrences metastatic, 60 local, 34 combined (1?). Metastases: lungs 353, bones 82, other sites 31. Median follow-up from first relapse: 1.26 years (0−9.4) for all 470, 1.69 years (0−9.4) for 229 survivors, 146 patients in 2nd (109) or later (37) CR. Actuarial 2-/5-year overall survival (OS): 48%/30%. 2-year OS isolated local relapse 63%, metastases 49%, combined 24%. 2 year OS with 2nd complete surgical remission (CR) 71%, without 14%. Factors correlating with better OS in univariate analysis: No primary metastases, good histologic response to 1st line chemotherapy, relapse detection by imaging, disease-free interval >median, solitary lesion at recurrence. Overall, neither 2nd line chemotherapy nor the use of immuno- or targeted therapies nor that of radiotherapy predicted for better OS, but all of these were much more likely to be used in patients with brief disease-free intervals and multiple lesions at relapse and particularly in patients not achieving a 2nd CR ($p < 0.001$).
Conclusions: International collaboration in relapsed osteosarcoma is feasible but demanding. Results obtained from the first 470 EURELOS patients confirm those from retrospective analyses and add novel information. Data from EURELOS may be used to help further delineate standards of care.

3806 POSTER

Delay in diagnosis and treatment of soft tissue sarcomas (STS): Causes of late intervention and their role in prognosis − a prospective, multidisciplinary group study

A. Comandone[1], E. Giubellino[1], A. Boglione[1], P. Bergnolo[1], G.C. Gino[1], R. Piana[1], C. Oliva[1], E.M. Brach Del Prever[1], M. Turbiglio[1], A. Linari[1]. *[1]Piedmontese Group for Sarcomas/Italian Sarcoma Group, Torino, Italy*

Background: STS are 1% of malignant tumors in adults. Rarity, heterogeneity in presentation, low expertise in Primary Care Physicians (PCP) or in general hospitals, organisation problems in Specialized Centres may cause a delay in both diagnosis and treatment. Aim of this study is to acknowledge the barriers to optimal care and the consequences of the delay on prognosis.
Material and Methods: Patients with STS of the extremities, trunk, retroperitoneum treated and followed from 1999 to 2011 by the same multidisciplinary group were included.
Time and pattern of symptoms onset, anatomic site, tumor volume, patients' age, gender and home, interval between diagnosis and surgical treatment or neoadjuvant chemotherapy; time to start adjuvant RT or CT were considered in a univariate − multivariate analysis.

Results: 449 adult patient (53% F, 47% M, median age 55 years) were followed for a median time of 116.38 months. 65.7% of STS were at the extremities, 17.6% retroperitoneal, 16.7% at the trunk wall. Median volume at diagnosis was 8 cm for trunk and extremities; 15 cm for retroperitoneum. Commonest histologies: liposarcoma. 18.2%; leiomyo 16.8%; mixofibro 13.6%. Increasing mass, pain and abdominal disconfort were the main revealing signs of diseases. Median time of delay were: from onset of symptom to first medical visit 68 days for trunk and extremities, 82 for retroperitoneum; 104 days from symptoms to histological diagnosis; 129 days from symptoms to start of therapy. Time to surgery after definitive diagnosis was 12 days in extremities and 21 in abdomen. Adjuvant CT started 22 days after surgery for extremities, 25 in trunk, 35 in retroperitoneum. RT initiated after 78 days. Longer delay in treatment lead to worse prognosis: MS 89.95 months if delay was >3 months; 190.40 months if wait was <3 months (p 0.007).
Conclusions: Low self consciousness of the patient; misdiagnosis or inadequate approach in general hospitals; late referral to specialized centres are 75% of the cause of wasted time. Organization problems at the referral Centre concur for 25% of delay. Guidelines implementation and educational programme among general population and PCP are necessary.

3807 POSTER

Hyperthermia-mediated BRCA2-degradation and cytotoxicity of trabectedin in human soft-tissue sarcoma (STS) cells

D. Harnicek[1], E. Kampmann[2], A. Tanovic[3], A. Martins[1], B. Eppink[4], E. Gallmeier[5], L. Lindner[2], R. Kanaar[4], R. Issels[2]. *[1]Clinical Cooperation Group Hyperthermia, Helmholtz Zentrum München, München, Germany; [2]Medizinische Klinik und Poliklinik III, Klinikum der Ludwig-Maximilians-Universität, München, Germany; [3]Medical Affairs, PharmaMar, Barcelona, Spain; [4]Cancer Genomics Center, Erasmus Medical Center, Rotterdam, Netherlands; [5]Medizinische Klinik und Poliklinik II, Klinikum der Ludwig-Maximilians-Universität, München, Germany*

Background: Regional hyperthermia combined with chemotherapy improves treatment response and survival of patients with high-risk STS (Issels, Lancet Oncol 2010). Trabectedin (Yondelis®) is approved in Europe for the treatment of advanced STS after failure of anthracyclines and ifosfamide or for patients unsuitable to receive these drugs. Its cytotoxicity is associated with the induction of DNA double-strand breaks (DSB). The rationale to combine trabectedin with hyperthermia is that heat-exposure inhibits the repair of DSBs by degradation of BRCA2 which is crucial for homologous recombination (HR) DNA-repair by Rad51 recombinase (Krawczyk, PNAS 2011).
Methods: Combination of trabectedin and hyperthermia was analyzed in four different human cell lines: osteosarcoma (U2Os), liposarcoma (SW872), synovial sarcoma (SW982) and colorectal cancer (DLD1). For investigation of BRCA2 deficient cells, DLD1 mutant ($^{-/-}$BRCA2) cells and U2Os cells treated with siRNA knock-down were used. Trabectedin (500–4000 pM) was applied for 3 hours with hyperthermia (41.8ºC and 43ºC) for 90 or 150 min either before, during or after trabectedin. Cytotoxicity was assessed by clonogenic survival, expression of BRCA2 by Western Blot (WB). The amount of γH2AX positive DSB-repair-foci and recruitment of Rad51 were analyzed by immunocytochemistry (ICC).
Results: Cell lines showed a dose dependent reduction of clonogenic survival after trabectedin. Treatment with hyperthermia enhanced cytotoxicity of trabectedin with strongest effects when combined simultaneously. According to WB analysis, a heat-dependent reduction of BRCA2 expression was observed. ICC showed a reduced recruitment of Rad 51 to DSBs after 41.8ºC, which was abolished after 43ºC. Combined treatment also significantly increased the amount of cells with DNA damage (>50 γH2AX-foci per nucleus). In cells deficient for BRCA2, heat-dependent enhancement of trabectedin cytotoxicity was nearly abolished.
Conclusions: Concomitant treatment with trabectedin and hyperthermia resulted in enhanced cytotoxicity, which was accompanied by elevated DNA-damage. Heat-mediated BRCA2-degradation and impairment of HR dependent DSB-repair seem to be related mechanisms for the thermosensitization of trabectedin.

3808 POSTER

Brain metastases from sarcoma: Identification of prognostic factors and analysis of treatment impact − a retrospective analysis from the French Sarcoma Group (GSF/GETO)

L. Chaigneau[1], A. Patrikidou[2], I. Ray-Coquard[3], T. Valentin[4], C. Linassier[5], M. Laigre[6], J.O. Bay[7], A. Le Cesne[8], J.Y. Blay[9], N. Isambert[10]. *[1]CHRU Hospital Jean Minjoz, Oncology, Besangon, France; [2]Intitut Gustave Roussy, Oncology, Villejuif, France; [3]centre Leon Berard, Oncology, Lyon, France; [4]Institut Claudius Regaud, Oncology, Toulouse, France; [5]CHRU Bretonneau, Oncology, Tours, France; [6]Institut Val d'Aurelle, Oncology, Montpellier, France; [7]CHRU Clermont Ferrand, Oncology, Clermont Ferrand, France; [8]Institut Gustave Roussy, Oncology, Villejuif, France; [9]Centre Leon Berard, Oncology, Lyon, France; [10]Centre Georges François Leclerc, Oncology, Dijon, France*

Background: Brain metastases (BM) from adult soft tissue sarcomas or bone sarcomas are rare and only limited data exist on their prognostic factors and treatment.
Material and Methods: A retrospective study in 16 centers of the French Sarcoma Group was conducted to identify prognostic factors and determine the impact of chemotherapy, radiation therapy and surgery on outcomes. The median number of patients per center was 9.5 (range, 2−74).
Results: Between 1992 and 2012, 246 pts (139 men and 107 women) with a median age of 50 (range, 16−86) were managed for BM. BM included 221 cerebral and cerebellal metastases and/or meningeal sarcomatosis (n = 40) and among them 87 patients with only one. Histological subtypes were leiomyosarcoma (n = 46; 18.7%), Ewing sarcoma/primitive neuroectodermal tumor (n = 30; 12.2%), liposarcoma (n = 19; 7.7%), alveolar soft-part sarcoma (n = 14; 5.7%), osteosarcoma (n = 14; 5.7%), rhabdomyosarcoma (n = 14; 5.7%), angiosarcoma (n = 14; 5.7%), synovialosarcoma (n = 13; 5.3%) and others (n = 82; 33.3%). Pathological grades were low, intermediate and high grade in 4.2%, 24.7% and 71.1% of cases, respectively. Patients developed BM at 18 months (0–215) after diagnosis of primary tumour and 9 months (0–110) after diagnosis of others metastases (pulmonary, hepatic and bone metastases in 72.8%, 12.6% and 23.2% respectively). Surgery of BM was carried out for 38 (15.5%) of patients. Radiotherapy to the whole brain and stereotactic radiotherapy were carried out in 144 (58.5%) and 24 (9.8%), respectively. Chemotherapy (the most frequent protocols were doxuribicin +/− ifosfamid, etoposid alone or in association, trabectedin) was carried out in 91 (37.0%) and palliative care in 46 (18.7%). Whatever the treatment, BM have been controlled in 49 pts (19.9%), including 31 partial (12.6%) & 18 complete (7.3%) response. Stable disease, disease progression and no evaluable status were observed in 64 (26.0%), 120 (48.8%) and 13 (5.3%) patients respectively. One hundred and ninety six patients (79.7%) died with a median overall survival (OS) from diagnosis of brain metastasis of 2.7 months (0.-133). In multivariate analysis, the following parameters influenced OS: chemotherapy (Hazard ratio (HR) = 0.38 [95%-CI: 0.26–0.48]), surgical removal (HR = 0.40 [95%-CI: 0.22–0.72]), stereotactic radiotherapy (HR = 0.41 [95%-CI: 0.19–0.90]), whole brain radiotherapy (HR = 0.51 [95%-CI: 0.35–0.76]) and grade (HR = 0.65 [95%-CI: 0.43–0.98]). In univariate analysis, 2 others clinical factors seemed to influence the OS: age (less or plus 50 years (HR = 0.64 [95%-CI: 0.48–0.85])) and number of BM (alone or multiple (HR = 0.76 [95%-CI: 0.56−1])).
Conclusion: BM of adult sarcomas are rare with poor prognosis. Our results suggest the positive impact of chemotherapy, radiation therapy and surgery on outcomes.
Conflict of interest: *Advisory board: Novartis, Pfizer, Pharmamar, GSK*

3809 POSTER

A novel model of skull osteosarcoma in athymic mice

G.C. De Miguel[1], M. Laranjo[2], A.M. Abrantes[2], M. Gracia[1], K. Santos[2], T. Rocha[1], M. Marques Ferreira[3], M.F. Botelho[2], D.G. Priolli[1]. *[1]São Francisco University, Postgraduate Program in Health Science, Bragança Paulista, Brazil; [2]Biophysics Unit − IBILI − CIMAGO, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [3]Department of Dentistry, Faculty of Medicine of University of Coimbra, Coimbra, Portugal*

Background: Osteosarcoma (OS), a malignant tumor characterized by direct formation of bones or osteoid, is the second most common primary bone neoplasm. This type of cancer affects both children and adults and it grows predominantly on metaphyseal region in young adults or flat bones on patients over 50 years. It has an unknown etiology, and the clinical symptomatology comprises local pain and in surrounding area, such as adjacent joint, unrelieved by rest or analgesic. Furthermore, it is a tumor with low response to chemotherapy, leading to a variety of tumor cell necrosis, with a better prognosis of surgery for complete removal of the tumor. Frequently, tumors are located on so-called hard to access locations

or in areas impossible to access surgically. Therefore, the development of new therapeutic strategies is mandatory, based on appropriated model assay to pursue the success on OS treatment. Consequently, the aim of this work was to develop an orthotopic animal model of skull OS. This model might be of paramount importance to evaluate new therapy options as well as to study this disease.
Material and Methods: Human OS cell line MNNG/HOS, purchased at American Type Culture Collection (ATCC), was cultured according to manufacturer's procedure. Eight athymic nude mice (Balb/c nu/nu), with 20−24 g weight were split in two groups: control and test. $1x10^6$ cells were inoculated directly onto the surface of the skull of test group, right after a scarification was made with the needle. Nuclear imaging studies with ^{99m}Tc-MIBI were performed in two different timeframes: in the day of tumor implantation and 30 days later before sacrifice of the mice. Nuclear medicine images allowed the drawing of ROIs at the skull and in quadriceps muscle projections leading to the tumor/muscle ratio calculation. After the sacrifice, RX were made using a Genoray PORT-X II, a portable dental X-ray, analyzed with Gx Vin Wix Pro software, and a conventional histopathological study was performed.
Results: All mice recovered well from the procedure without signs of pain or discomfort. Three days after the surgery the animals does not have any signal of tumor, but ate the fifth day it started to show a small taint at the skull. All five animals submitted to the procedure developed a tumor which volume increased slowly till the tenth day, when it achieved volumes of $424.25\pm243.54\ mm^3$. Tumor/muscle ratio was of 3.7 ± 0.4. At day twenty the animals were subjected to RX. In the control group no alterations were found. However, in the test group the animals presented clearly signs of bone aggression with cortical destruction and lytic lesion in both side views, just below the tumor area.
Conclusion: It was possible to successfully develop an orthotopic animal model of skull osteosarcoma. Imaging studies showed that the tumor cells implanted had continuity with bone area and thus modifying bone structure. The orthotopic model of OS is feasible, allows noninvasive monitoring of the tumor growth and is suitable for studying new therapies.

3810 POSTER

Factors related to the early toxicity of hypofractionated preoperative radiotherapy in treatment of localized extremity/trunk wall soft tissue sarcoma (STS)

M. Kolodziejczyk[1], H. Kosela[1], T. Morysinski[1], K. Wiater[1], S. Falkowski[1], W. Dziewirski[1], A. Pienkowski[1], K. Ptaszynski[1], M. Zdzienicki[1], P. Rutkowski[1]. *[1]Maria Sklodowska-Curie Memorial Cancer, Department of Soft Tissue/Bone Sarcoma and Melanoma, Warsaw, Poland*

Background: The aim of this prospective study is to assess the rate and factors influencing early toxicity in the group of patients localized extremity/trunk wall soft tissue sarcoma (STS) who underwent preoperative hypofractionated radiotherapy.
Methods and Materials: Two hundred and twenty patients with operable STS treated between 2006 and 2010 received preoperative 5×5 Gy short-term irradiation and surgery performed within 5 days. The neoadjuvant chemotherapy was given for the subset of patients with high grade tumors. The potential impact of factors on early toxicity, such as gender, age, addition of chemotherapy, pathological subtype, anatomical site, grade and size of tumor, was analyzed.
Results: The early toxicity after 5×5 Gy was noted in 62/220 (28%) patients: 17.2% had prolonged wound healing >1 month, 12.7% had wound dehiscence, 4% needed prolonged evacuation of lymphatic fluid and 2.7% had grade 3 skin toxicity. Ten patients required reoperation (4%). Only tumor grade, lower limb localization and addition of neoadjuvant chemotherapy were significant risk factors for early toxicity.
Conclusion: The 5×5 Gy regimen in preoperative treatment of STS had acceptable rate of early toxicity. The addition of chemotherapy especially in lower limb sarcomas may increase risk of complications.
No conflict of interest.

3811 POSTER

Early 18F-FDG-PET monitoring during long-term treatment of desmoids (aggressive fibromatosis) with imatinib mesylate

P. Hohenberger[1], A. Dimitrakopoulou-Strauss[2], B. Kasper[3], F. Menge[1], L.G. Strauss[2]. *[1]University Hospital Mannheim, Division of Surgical Oncology and Thoracic Surgery, Mannheim, Germany; [2]German Cancer Research Center, Medical PET Group − Biological Imaging, Heidelberg, Germany; [3]University Hospital Mannheim, Interdisciplinary Sarcoma Center, Mannheim, Germany*

Background: We used early dynamic 18F-FDG PET (dPET) in patients with unresectable aggressive fibromatosis undergoing treatment with imatinib to analyse whether treatment was affecting tumor perfusion and phosphorylation indicating treatment efficacy. The goal of the study was to evaluate whether parametric imaging could serve as a decision element to continue with the drug and await tumor shrinkage at a later stage.
Methods: Out of 224 patients treated with desmoids since 2004, 32 patients with progressive AF were not amenable to surgical resection without significant functional deficit and received imatinib with a target dose of 800 mg per day. Patients were examined using PET prior to the start of therapy and and 4 weeks after reaching the target dose, typically at week 6 to 10. Patients (25 f, 7 m; median age of 28 yrs, range, 16−48 yrs) were characterized by recurrent disease (n = 20), residual tissue (n = 4), or primary disease (n = 8). Median duration of imatinib therapy was 28 mos. (range, 3−66 months).
Parametric images were calculated based on the dPET data by fitting a linear regression function to the time-activity data and for each voxel. Images of the slope and the intercept of the time-activity data were calculated and the resulting parameters of the FDG kinetics [blood volume (VB), k1-k4] were compared with the volume-of-interest-based slope and intercept data. The evaluation of the parametric images was performed visually and quantitatively.
Results: 27 of 32 tumors could be visualized in the SUV images with a moderate uptake, in locations known from the MR images. 23/32 of the tumors demonstrated a clear enhancement in intercept images, whereas 5 tumors showed an intermediate enhancement and another 4 tumors did not show any enhancement. The comparison of slope revealed the highest correlation to the SUV ($r = 0.56$, $P < 0.05$). In median, a 28% decrease in the average standardized uptake value (SUV) of the sequential PET examinations was demonstrated in all evaluable patients. Patients showing a decrease in SUV of more than 40% (n = 15) subsequently developed at least a PR of their disease (PPV of 72%). No patient showed a substantial increase in SUV during imatinib therapy. Four patients developed a CR, three of them after more than 1 year of treatment, in one case it took 5 years to develop after an initial tumor size of 22 cm. Five patients had to stop imatinib therapy for tumor progression.
Conclusion: Our data indicate that the use of regression-based parametric PET allows to identify responders to imatinib treatment early, thus helping to decide whether therapy should be continued or not.

3812 POSTER

Evaluation of outcome and prognostic factors in primitive neuroectodermal tumor of adults: A single institutional experience of 112 cases with uniform chemotherapy protocol

B. Biswas[1], S. Rastogi[2], S.A. Khan[2], S. Agarwala[3], N.K. Shukla[4], S.V.S. Deo[4], B.K. Mohanti[5], D.N. Sharma[5], V. Srineevas[6], S. Bakhshi[1]. *[1]All India Institute of Medical Sciences, Medical Oncology, Delhi, India; [2]All India Institute of Medical Sciences, Orthopedics, Delhi, India; [3]All India Institute of Medical Sciences, Paediatric Surgery, Delhi, India; [4]All India Institute of Medical Sciences, Surgical Oncology, Delhi, India; [5]All India Institute of Medical Sciences, Radiation Oncology, Delhi, India; [6]All India Institute of Medical Sciences, Biostatistics, Delhi, India*

Purpose: To evaluate prognostic factors and treatment outcome in primitive neuroectodermal tumour (PNET) of adults.
Materials and Methods: This is single institutional data review of PNET patients with >18 years of age treated between June 2003 and November 2011 with uniform chemotherapy protocol and evaluated on intent to treat analysis. All patients received neoadjuvant chemotherapy (NACT), surgery and/or radiotherapy as local treatment followed by adjuvant chemotherapy.
Results: Of 374 patients with PNET, 112 (30%) were adult PNETs with median age of 22 years (range: 19−55) and male: female of 80:32. Most common regions included extremity in 50 (45%), thorax in 24 (21%); 44 (39%) had metastatic disease. Thirty-eight patients underwent surgery; 39 patients received radical radiotherapy following NACT. After median follow up of 21.8 months (range: 1.6–108.5), 5-year EFS, OS and local control rate (LCR) were $29.6\pm5.8\%$, $49.6\pm8\%$ and $66.5\pm8.5\%$, respectively for entire cohort, and $40.2.6\pm7.8\%$, $61.6\pm9.6\%$ and $72.3\pm8.7\%$, respectively for localized disease (n = 68). On multivariate analysis, skeletal primary ($p = 0.03$), albumin $\leqslant 3.4$ g/dl ($p = 0.008$) and metastatic disease ($p = 0.006$) predicted inferior EFS. Primary of head and neck, thorax and extremities ($p = 0.02$) and white blood cell count (WBC) $>11\times10^9$/L ($p = 0.04$) predicted inferior OS on multivariate analysis, whereas WBC$>11\times10^9$/L ($p = 0.03$) independently predicted LCR. Adult PNETs had lower systemic symptoms (20% versus 34%, $p = 0.007$), longer symptom (7.9 months versus 5.4 months, $p = 0.004$), lager tumour (10.6 cm versus 9.4 cm, $p = 0.05$), and lower haemoglobin level (12 versus 10.8 g/dl, $p < 0.0001$) as compared to paediatric cohort. In comparison to paediatric PNET (n = 262), adult cohort has superior EFS (21.9% versus 29.7%, $p = 0.11$) and OS (39.5% versus 49.6%, $p = 0.04$).

Conclusions: Adult PNET formed 30% of the all PNETs with 39% patients presenting with metastatic disease. We identified novel prognostic factors including tumour origin, tumour location, WBC count, hypoalbumenia ($\leqslant$3.4 g/dl) and metastatic disease as independent prognostic factor to affect outcome. Patients with localised disease and WBC$\leqslant 11\times 10^9$/L had best prognosis. Those with metastatic disease and high WBC or hypoalbuminemia may merit aggressive therapy. Local treatment modality didn't affected outcome. Adult cohort has marginally superior EFS, but significantly superior OS as compared to paediatric PNET.
No conflict of interest.

3813 POSTER

A non-comparative phase II study of dose intensive chemotherapy with doxorubicin and ifosfamide followed by high dose ICE consolidation with PBSCT in non-resectable, high grade, adult type soft tissue sarcomas (STS)

J. Hartmann[1], M. Horger[2], T. Kluba[3], A. Königsrainer[4], P. DeZwart[5], C. Hann von Weyhern[6], E. Eckert[7], W. Budach[7], C. Bokemeyer[8]. *[1]University Hospital Schleswig-Holstein Kiel, Haematology and Medical Oncology, Kiel, Germany; [2]Eberhard-Karls-University Tuebingen, Orthopedic Surgery, Tuebingen, Germany; [3]Eberhard-Karls-University Tuebingen, General Surgery and Transplantation, Tuebingen, Germany; [4]BG Klinik Tuebingen, Accident and Reconstructive Surgery, Tuebingen, Germany; [5]City Hospital of Munich, Institute of Pathology, Munich, Germany; [6]Heinrich-Heine University of Duesseldorf, Dept. of Radiation Oncology, Duesseldorf, Germany; [7]Eberhard-Karls-University of Tuebingen, Dept. of Radiation Oncology, Tuebingen, Germany; [8]University Hamburg-Eppendorf, Oncology Hematology and Bone Marrow Transplantation, Hamburg, Germany*

Background: To determine the feasibility and effectivity of dose intensive induction chemotherapy (CTh) in patients (pts) with STS that was considered as either unresectable or resectable only with mutilating surgery.
Materials and Methods: Treatment consisted of at least 2 cycles of DOX (75 mg/m^2) on day 1 and IFO (12 g/m^2 as a 72 h infusion). In responding and stable pts, this was followed by one cycle of HD-ICE), ETO 500 mg/m^2, Carbo 500 mg/m^2 and IFO 4 g/m^2 (days −4 to −2, peripheral blood-derived hematopoietic stem-cell support on day 0. Pts with a single distant metastasis deemed resectable were allowed.
Results: 30 out of 631 consecutive pts, age 46 years (range, 21−62), were included, 5 of whom had a single lung (4) or liver (1) metastasis. 29 pts completed at least 2 cycles of DOX/IFO. While 16 pts (55%) remained stable, 7 pts (24%) showed a PR, 1 pt (3%) a CR, and 5 pts (17%) progressed. HD-ICE was withheld because of PD in 5 pts, neurotoxicity in 6, insufficient PBSC mobilization, CR and refusal in 1 pt each. Thus, 16 pts received HD-ICE, which was associated with non-hematological grade III toxicity including emesis, mucositis, fever, neurotoxicity, and transaminase level elevation. Two additional pts attained a PR after HD-ICE. Overall, 24 of 30 (80%) pts underwent surgery, with complete tumor resections in 19 pts (63% of all pts, 79% of the operated subgroup); however, 2 of whom required amputation. After a median follow up period of 50 mos in surviving pts (range, 26–120), 5-yr DFS and OS rates were 39% and 48%, respectively. Pts with shrinking STS becoming resectable after pretreatment had a markedly improved DFS (median, 50 vs. 3.5 mos; HR: 7.22 (95% CI, 1.52–34.29), $p < 0.01$) and survival (median, 73 vs. 9 mos; HR: 9.11 (95% CI 1.82–45.59), $p < 0.007$). Early response to CTh was associated with improved OS. Negative margins and grade III had an impact on DFS. Tumor size was associated with an improved OS (trend only). Extent of necrosis in the resected specimen did not impact survival neither did age, gender and late response to CTh.
Conclusion: Induction chemotherapy plus consolidation HD-ICE is generally feasible, but is associated with significant neurotoxicity. In an intent-to-treat-analysis, complete (R0) resection as the primary end point of the study was achieved in approx. 60% of pts initially considered as not R0 resectable. The advantage of HD-ICE over conventional dose CTh plus EBRT in non-resectable disease remains unproven.
No conflict of interest.

3814 POSTER

Poor clinical outcome in patients with retroperitoneal/intra-abdominal Ewing sarcoma

K. Yonemori[1], M. Kodaira[1], H. Yamamoto[1], M. Yunokawa[1], C. Shimizu[1], K. Tamura[1], A. Kawai[2], H. Chuman[2], A. Yoshida[3], Y. Fujiwara[1]. *[1]National Cancer Center Hospital, Breast and Medical Oncology, Tokyo, Japan; [2]National Cancer Center Hospital, Orthopedic Oncology, Tokyo, Japan; [3]National Cancer Center Hospital, Pathology, Tokyo, Japan*

Background: Ewing sarcoma can arise in either bone or soft tissue locations. Extraskeletal Ewing sarcoma, especially in the origin of retroperitoneal/*intra-abdominal*, is rare in the form of soft tissue sarcoma. We sought to investigate if patients characteristics, treatment strategies, and prognosis differ between skeletal Ewing sarcoma and retroperitoneal/ intra-abdominal Ewing sarcoma (R/I-ES).
Material and Methods: Clinicopathological features and patient outcomes were reviewed retrospectively for Ewing sarcoma patients receiving treatment in our institution between September 1978 and August 2012. We evaluated based on retroperitoneal/intra-abdominal vs skeletal site of origin. Patients characteristics were compared using Fisher exact tests. Overall survival was estimated by Kaplan–Meier methods and compared using log-rank tests and Cox models.
Results: Of the 134 patients identified, primary site of retroperitoneal/ intra-abdominal were 19 (14.1%), skeletal were 95 (70.9%), and the others were 20 (15%). The site of origin of R/I-ES were retroperitoneal 8, kidney 4, small intestine 2, and omentum, peri-anal, pelvis, uterus that were one case each. Patients with R/I-ES had a higher median age (32 vs 19 years; $P<0.001$). At the first visit, 10 patients with R/I-ES had metastatic or invasive lesions and 10 patients with skeletal site of origin (52.3% vs 10.5%; $P<0.001$), mean tumor size was 104 mm and 88.6 mm (n.s.). Radical surgery were performed 15 patients with R/I-ES, and 59 patients with skeletal site of origin and recurrence were confirmed 12 patients with R/I-ES and 25 patients with skeletal site of origin (recurrence rate: 85% vs 42%; $P<0.001$). 15 patients with R/I-ES had received chemotherapy (7: adjuvant settings, 8: after recurrence). Patients with R/I-ES had poor prognosis significantly compared with skeletal site of origin (MST: 2.6 vs 7.8 years: $P<0.004$).
Conclusions: R/I-ES patients had poor prognosis compared with skeletal site of origin. The reason why regardless of tumor size, tumor was diagnosed progression state, and that made it difficult to curative resection, but it was not clear resection rate in this study. It is necessary to increase the cure rate, carrying out multimodality treatment effectively, also cases that curative resection was not performed.
No conflict of interest.

Long survivors with brain metastases from sarcomas: A retrospective analysis from the French Sarcoma Group (GSF/GETO)

N. Isambert[1], J. Domont[2], M.P. Sunyach[3], L. Moureau-Zabotto[4], E. Bompas[5], S. Piperno-Neumann[6], N. Penel[7], T. Alcindor[8], C. Guillemet[9], L. Chaigneau[10]. *[1]Centre Georges François Leclerc, Oncology, Besangon, France; [2]Institut Gustave Roussy, Oncology, Villejuif, France; [3]Centre Leon Berard, Oncology, Lyon, France; [4]Institut Paoli Calmette, Oncology, Marseille, France; [5]centre René-Gauducheau, Oncology, Nantes, France; [6]Institut Curie, Oncology, Paris, France; [7]Centre Oscar Lambret, Oncology, Lille, France; [8]McGill University Health Centre, Oncology, Montreal, Canada; [9]Cente Henry Becquerel, Oncology, Rouen, France; [10]CHRU Jean Minjoz, Oncology, Besançon, France*

Background: Brain metastases (BM) from adult soft tissue or bone sarcomas are rare with poor prognosis. The aim of this retrospective study was to describe the characteristics of long survivors (overall survival (OS) greater than 2 years).
Material and Methods: Data of 246 patients (pts) with BM of sarcomas from 16 centers of the French Sarcoma Group were collected from 1992 to 2012.
Results: Among the 246 pts, 17 (6.9%) − 11 men and 7 women − with a median age of 31 years (range: 17−65) had an OS greater than 2 years. BM included 14 cerebral and cerebellal metastases and/or meningeal sarcomatosis (n = 4) and among them 9 (53%) patients with only one metastasis. Histological subtypes included leiomyosarcoma (n = 4), Ewing sarcoma/primitive neuroectodermal tumor (n = 3), alveolar soft-part sarcoma (n = 3), rhabdomyosarcoma (n = 1), synovialosarcoma (n = 1) and others (n = 4). Pathological grades were low, intermediate, high grade and unknown in 2, 4, 4 and 7 pts, respectively. Interval between diagnosis of sarcoma and BM, and between diagnosis of others metastases and BM were 73 months (range: 0–204) and 10 months (range: 0−88) respectively. Surgery of BM was carried out for 7 patients. Radiotherapy to the whole brain and stereotactic radiotherapy were carried out in 10 and 3 cases,

respectively. Eleven patients received cytotoxic chemotherapy. The most frequent protocols were doxuribicin +/− ifosfamid, etoposid alone or in association, trabectedin. Whatever the treatment, BM have been controlled in 12 pts, including 3 partial & 9 complete response. Stable disease was observed in 5 patients. Nine patients died with a median overall survival (OS) from diagnosis of brain metastasis of 47 months (range, 24–133).
Conclusion: Long survivals with BM of adult sarcomas are rare. Half of these patients had a single metastasis. Our results suggest the positive impact of chemotherapy, radiation therapy and surgery on outcomes.
Conflict of interest: *Advisory board: Novartis, Pfizer, Pharmamar, GSK*

3816 POSTER

Biological features, prognostic factors and outcome of 114 patients with GISTs: A single institution experience

C. Messina[1], L. Gristina[2], G. Badalamenti[3], S. Provenzano[3], G. Maltese[3], M. Messina[4]. [1]*University of Palermo, Oncology, Palermo, Italy;* [2]*University of Palermo, Radiology, Palermo, Italy;* [3]*University of Palermo, Oncology, Palermo, Italy;* [4]*San Raffaele Giglio, Oncology, Cefalu', Italy*

Background: To retrospectively analyse the distribution of biological features and their impact on clinical outcome in a cohort of 114 patients with gastrointestinal stromal tumour (GIST) treated at the GIST Unit of Palermo University between 2000 and 2012.
Methods: We retrospectively analysed 114 patients with GIST treated at the GIST Unit of Palermo University during the past 12 years. Patients with localised disease were stratified according to Fletcher and Miettinen criteria. Patients were treated according to NCCN guidelines. Biological features on tumour specimens, treatment and clinical outcome were recorded and compared with published data.
Results: Among 114 patients, 88 had resectable disease, 26 had metastasis at diagnosis. Ninety GISTs were examined for mutational analysis of KIT or PDGFRα, resulting KIT exon 11 mutation in 59%, KIT exon 9 mutation in 16%, PDGFRα mutation in 11% while 14% were wild type. Median 5-years recurrence-free survival of 88 patients with localised disease undergoing radical resection was 60 months. Adjuvant imatinib 400 mg daily was delivered in 21 cases; 5 patients recurred and received standard treatment for advanced disease while 16 are still free of disease. Clinical outcomes were significantly poorer for 19 patients with exon11 deletion. Miettinen criteria better predicted the risk of recurrence than Fletcher criteria ($p = 0.0046$ vs $p = 0.1$). In patients with metastatic disease undergoing standard I and II line therapy with imatinib and sunitinib ($n = 29$ and $n = 18$) median progression-free survival was respectively 36 and 6 months. Six patients progressing prior treatment with TKI were enrolled in a randomized multicenter phase III trial of regorafenib, experiencing 7 months mPFS. This result was comparable to data from the phase II trial of regorafenib (mPFS=10 months).
Conclusions: All data from our retrospective analysis reproduced those from published literature. Mutational analysis allows risk stratification, predicts response to TKI and should be routinely performed at diagnosis. Our experience demonstrates that GIST Unit guarantees a high standard for diagnosis, biological assessment for risk stratification, staging and treatment delivery, providing clinical outcomes that are comparable to published data. Therefore is essential for patients with rare tumours to be addressed to highly specialised multidisciplinary centers.

Guidelines for time-to-event endpoint definitions in randomized cancer trials for sarcomas and GIST: Results of the DATECAN initiative (Definition for the Assessment of Time-to-event Endpoints in CANcer trials)

C. Bellera[1], M. Ouali[2], N. Pénel[3], S. Litière[4], P. Casali[5], S. Bonvalot[6], O.S. Nielsen[7], M. Delannes[8], S. Mathoulin-Pélissier[1]. [1]*Institut Bergonié Comprehensice Cancer Center, Clinical Epidemiology and Clinical Research, Bordeaux, France;* [2]*Institut Claudius Régaud Comprehensice Cancer Center, Biostatistics, Toulouse, France;* [3]*Centre Oscar Lambret, Medical Oncology, Lille, France;* [4]*European Organization for Research and Treatment of Cancer, Biostatistics, Brussel, Belgium;* [5]*Istituto Nazionale Tumori, Medical Oncology, Brussel, Belgium;* [6]*Insititut Gustave Roussy Comprehensice Cancer Center, Clinical Epidemiology and Clinical Research, Villejuif, France;* [7]*Aarhus University Hospital, Aarhus, Denmark;* [8]*Institut Claudius Régaud Comprehensice Cancer Center, Radiotherapy, Toulouse, France*

Background: With the necessity of reducing randomized clinical trial (RCT) duration, cost and number of patients, potential surrogate endpoints of overall survival (OS) are increasingly being used as replacements for OS in cancer RCT. However, most of these endpoints lack standardized definitions enabling comparison between RCT. Some recommendations have been proposed for specific cancer sites but they do not rely on formal consensus methodologies. The objective of the **DATECAN** initiative (**D**efinition for the **A**ssessment of **T**ime-to-event **E**ndpoints in **CAN**cer trials) is to provide guidelines to standardize definitions of time-to-event (TTE) endpoints in RCT for different cancer sites. We present results for sarcoma and GIST (similar abstract submitted for breast cancer).
Methods: We relied on the modified Delphi consensus method, a validated formalized consensus process for the development of practice guidelines. International experts with various backgrounds and expertise were involved. First, the coordinating committee, a group of statisticians and epidemiologists involved in the design and conduct of RCT, led a comprehensive literature review to identify TTE endpoints and clinical events of interest. The steering committee, which included additional medical experts, prepared the questionnaire sent for rating to international experts from the rating committee.
Results: The consensus process involved two rounds of rating (28 international experts) and one in-person meeting (Chicago 2012). Each expert had to rate on a 1−9 scale if s/he agreed to include clinical events (e.g. toxicity) in the definition of TTE endpoints. Consensus was reached for 73% of the events after the rounds of rating and was finalized at the meeting for the remaining events. Guidelines for the definitions of 13 TTE endpoints were established (e.g. progression-free survival, disease-free-survival, time-to-treatment failure, etc.) across different settings (adjuvant, metastatic, both).
Conclusions: The DATECAN guidelines should help standardize definitions of commonly used TTE endpoints. They should (i) facilitate the comparison of RCT, (ii) improve the quality of trial reporting and (iii) improve the quality of future RCT. We acknowledge that these guidelines will be presented at ASCO 2013. However, communicating about these recommendations at ESMO/ECCO is also a key step towards wide scale dissemination and implementation of these guidelines.
No conflict of interest.

Regional variation and challenges in studying the epidemiology of giant cell tumour of the bone (GCTB)

A. Liede[1], B.A. Bach[2], S. Stryker[1], R.K. Hernandez[3], P. Sobocki[4], B. Bennett[5], S. Wong[5]. [1]*Amgen, Center for Observational Research, South San Francisco, USA;* [2]*Amgen, Clinical Development, Thousand Oaks, USA;* [3]*Amgen, Center for Observational Research, Thousand Oaks, USA;* [4]*Pygargus, Stockholm, Sweden;* [5]*Plan A, Mountain View, USA*

Introduction: Population-based sources of data on the epidemiology of benign bone tumours are limited. The relative frequency of such tumors, including GCTB, can be estimated from published case series of bone cancers and extrapolated to broader populations, a method recommended by the US Bone and Joint Initiative (BMUS 2011). The primary goal of this study was to compare approaches to estimate incidence of GCTB in the US, France, Germany, Italy, Spain, UK, Sweden, Australia, Canada, and Japan in 2013.
Methods: GCTB incidence was calculated using 3 different scenarios consistent with the BMUS method using the relative index (RI) of GCTB to osteosarcoma from case series. The low scenario represents the literature where GCTB accounts for 5−7% of primary bone tumors. The base scenario reflects the Dahlin-Unni series RI of GCTB to osteosarcoma of 32%, and the high scenario corresponds to the Ward series RI of 84%. Differences between the 2 series reflect center of excellence (Mayo clinic) vs. community referral, respectively. To validate the approaches, we compared estimates to the latest incidence of benign GCTB reported by registries in Sweden (1993–2011), Australia (1972–1996), and Japan (2008). United Nations population estimates were used to project to 2013.

Table: Incidence in 2013.

	Bone cancer	GCTB					
		By scenario			Per registry		
		Low	Base	High	Australia	Japan	Sweden
US	2659	133	332	873	424	357	358
France	704	35	77	203	83	70	70
Germany	1213	61	133	351	107	90	90
Italy	841	42	92	243	81	69	69
Spain	426	21	47	123	62	52	52
UK	604	30	66	174	83	70	70
Japan	850	43	93	245	164	138	138
Australia	249	12	27	72	31	26	26
Canada	338	17	38	99	46	39	39
Sweden	88	4	10	25	12	11	11

Results: Three estimation scenarios were compared relative to latest bone cancer incidence (Table). Because osteosarcoma represented 39% of bone cancer incidence in the US in 2013, the base scenario thus reflects a 12% RI (39% x 32%) of GCTB to bone cancer incidence. Similarly, the high scenario corresponds to 33% RI relative to bone cancer. Registry data reflected an incidence rate of GCTB as 1.33 per million in Western Australia, 1.12 per million in Japan, and 1.12 per million in Sweden. If survival is assumed to resemble life expectancy in the general population, 5-year prevalence is the cumulative incidence over 5 years.
Conclusions: The findings highlight challenges in estimating the incidence of GCTB, resulting in a wide variance in the point estimates under different scenarios. Nonetheless, all scenarios reflect that GCTB is a rare disease. Estimates derived from registries in Australia, Japan, and Sweden represent GCTB incidence consistent with the base scenario (which equates to 1.04 new cases per million in the US in 2013).

Perceptions of participants and professionals in bone sarcoma clinical trials: Implications for study design and conduct

S. Pearce[1], V. Lavender[2], A. Brownsdon[3], F. Gibson[4], L. Fern[1], J. Whelan[1]. *[1]UCLHospitals NHS Foundation Trust, Medical Oncology, London, United Kingdom; [2]Oxford Brookes University, Nursing, Oxford, United Kingdom; [3]UCL Hospitals NHS Foundation Trust, Cancer Clinical Trials Unit, London, United Kingdom; [4]Great Ormond Street Hospital for Sick Children and London Southbank University, Nursing, London, United Kingdom*

Background: Under-representation of teenagers and young adults (TYA) in cancer trials is internationally recognised. Compared to children and older adults, this cohort have gained the least improvements in survival from cancer: this is particularly so for bone sarcomas?. Reasons for low trial entry for young people have so far focussed on structural and organisational barriers. There is little understanding of TYA's perceptions of trial entry and those of healthcare professionals caring for them. The aim of this study was to understand the perceptions of TYA who were approached about participation in bone sarcoma trials and health professionals involved in their recruitment and associated care.
Methods: Semi-structured interviews using narrative inquiry were undertaken at a supra regional sarcoma centre between November 2011 and February 2012. Twenty-one young people between 15 to 24 years at diagnosis who were eligible for two bone cancer trials and eighteen associated healthcare professionals were recruited.The transcripts were read and reread; using memoing, coding and constant comparison, categories and themes were developed. Analytical frameworks developed for both data sets were then integrated into a combined framework.
Results: Emergent themes are: the perceptions of clinical trials; the contrasting experience of being asked to register and later consent to randomised treatment on a clinical trial; weighing up burdens and benefits in decision making; the role of communication with, and support from, professionals, family and peers, together with the centrality of autonomy in decision making; and lastly the importance of a culture of expert care.
Conclusion: This study provides new understandings about the experience of young people invited to participate in bone cancer clinical trials, and the factors that influence decision-making. The intensity and longevity of treatment, and the impact of cancer during TYA years, commonly negatively influenced decisions made. The professionals had a good understanding of what it meant to young people to participate in a trial.
The findings have the potential to contribute to interventions to facilitate decision-making and to inform education and training of health professionals. Our study reinforces the need for patient involvement in the design of clinical trials. This is essential to positively influence recruitment of TYA to clinical trials and ultimately improve the outcomes of disease such as bone sarcoma.
No conflict of interest.

3820 POSTER

What is the price of cure for the treatment of pelvic Ewing Sarcoma?

C. Hoffmann[1], C. Winter[2], A. Ranft[1], U. Dirksen[1], D. Rosenbaum[2], H. Juergens[1]. *[1]University Hospital Muenster, Pediatric Hematology and Oncology, Muenster, Germany; [2]University Hospital Muenster, Institute of Experimental Musculoskeletal Medicine, Muenster, Germany*

Objective: Substantial progress has been made in the management of childhood bone tumors over the last 25 years. However, survivors of childhood pelvic tumors are at risk of developing long-term functional restrictions and late sequelaes. So far no data are available concerning the effect of multimodal therapy on the level and quality of physical activity. The aim of this study was to objectively quantify the level of activity in 80 long-term survivors of pelvic Ewing-Sarcoma using a continuous measurement device. All patients were treated according to the Ewing sarcoma trial guidlines, set by the German Society of Pediatric Hematology and Oncology (GPOH).
Methods: The frequency and intensity of physical activity were objectively assessed for 7 consecutive days by means of a uniaxial accelerometer, the Step Activity Monitor (SAM). In addition, function was assessed using the TESS (Toronto Extremity Salvage Score) questionnaire. All patients were asked about long-term late-effects by questionnaire. The median age at diagnosis was 15.4 years (range 0.7−45), median age at time of assessment was 32.8 years (range 10.6–57.1). Initial local therapy was surgery in only 10/78 patients (12.8%), surgery and irradiation in 50 patients (64.1%) and radiotherapy alone in 28 patients (23.1%).
Results: Participants with initial pelvic Ewing-Sarcoma averaged 4650 gait cycles/ per day (SD=1897gait cycles; median: 4443; range: 1887–10738) which had to be considered as somewhat active. (7,500–10,000 steps/day) 30/80 patients reached an active lifestyle (>10,000 steps/day) however 9/80 patients were sedentary (<5000 steps/day). The TESS score (0–100) for tumors located in the pelvis was 90.7 SD = 11.8), suggesting the achievement of moderate to good function following multimodal tumor treatment.
Conclusions: Data indicate that patients can achieve good step activity following pelvic tumor treatment. However, most patients limit themselves to low intensity activity. SAM can be used to capture activity levels in long-term Ewing-sarcoma survivors. It may be advantageous to consider the use of a combination of outcome measures, including SAM, for objective functional mobility assessment. Parallel recording of physical activity (SAM) and TESS provides a better measure reflecting the complex situation of the patients by combining objective and subjective parameters.
Further investigations must identify discriminating factors that influence the degree of recovery following intensive treatment of disease.

Population study of the gastrointestinal stromal tumors based on the data from the clinical registry − Czech and Slovak Republic

B. Bencsikova[1], A. Jureckova[1], I. Kocakova[1], J. Strenkova[2], P. Brabec[2], Z. Bortlicek[2], R. Vyzula[1]. *[1]Masaryk Memorial Cancer Institute, Department of Complex Oncology Care, Brno, Czech Republic; [2]Masaryk University, Institute of Biostatistics and Analyses, Brno, Czech Republic*

Background: Gastrointestinal stromal tumors (GIST) are quite rare mesenchymal tumors mostly presenting typical expression of thyrosinkinase receptor c-Kit (CD117). In the past years, especially before 2001, there have been problems with identification and understanding of GIST and therefore a lack of significant population data and clinical studies focusing on patients with these uncommon malignancies.
Material and Methods: The online registry called 'reGISTer' has been compiled and maintained since December 2006. It involves relevant epidemiological data, pathology results and molecular analysis, clinical information and treatment results on patients with GIST from the Czech and Slovak Republic. Until November 2012 there have been included adequate dataset on 845 patients.
Results: Most of the tumors belong to the high-risk group (50.4%, n = 426), most common location is jejunum and stomach. More than 70% of the tumors are resectable at the time of diagnosis. Median overall survival is 9.2 years. In cases of inoperable and metastatic disease targeted therapy is used, ie. imatinib mesylate in the first line, sunitinib in the second line or regorafenib in the third line.

Table: Results of treatment with imatinib in the palliative setting (n = 399 patients)

Overall survival	
All	65.2 months
Non-metastatic/non-resectable at beginning of treatment	80.3 months
Metastatic at the beginning of treatment	63.3 months
Progression free survival	
All	32.3 months
Non-metastatic/non-resectable at beginning of treatment	43.0 months
Metastatic at beginning of treatment	28.1 months
2-year survival − all	82.2%
Median treatment length	20.1 months
Best treatment response (CR+PR+SD*)	82.6%

*CR: complete response; PR: partial response; SD: stable disease.

Conclusions: The poster comprises up-to-date analysis of the register. Presented data are generally similar to those from the world-wide clinical studies published recently.
Acknowledgments: Authors thank all centers participating in the reGISTer project both in the Czech and Slovak Republic.

3822 POSTER

Carbon ion radiotherapy for unresectable sacral chordomas

H. Akamatsu[1], R. Imai[1], T. Kamada[1]. *[1]National Institute of Radiological Science, Research Center Hospital for Charged Particle Therapy, Chiba, Japan*

Background: Clinical trials on carbon ion radiotherapy for intractable malignancies have been conducted since 1994 at National Institute of Radiological Sciences in Chiba, Japan. As of March 2013, over 7000 patients had been enrolled into studies to analyze toxicity and local tumor response. Since a clinical study for unresectable sarcomas started in June 1996, over 1000 sarcomas have been treated with carbon ion radiotherapy. In this study we evaluated the effectiveness and safety of carbon ion radiotherapy in patients with unresectable sacral chordomas.
Material and Methods: The standard protocol for the treatment consists of 16 irradiation sessions for 4 weeks. The basic eligibility was as follows; 1) unresectable tumors judged by their orthopedic surgeons, 2) pathological confirmation, 3)15 cm in maximum size, 4) no metal instrumentation, 5) no urgent systemic metastasis. We performed a retrospective analysis on 175 patients with unresectable sacral chordomas treated with carbon ion radiotherapy between June 1996 and February 2012. All of the patients in this analysis presented without prior treatment. All patients were observed for at least 12 months from the initial date of radiotherapy. The applied carbon ion dose ranged from 64.0 GyE to 73.6 GyE (Gray equivalent, median 70.4 GyE) in a total of 16 fixed fractions over four weeks.
Results: The median age of the patients was 67 ranging from 26 to 87. The study group consisted of 55 females and 120 males. The cranial extension of tumor was at S2 or higher level in 70% of the patients. The median clinical target volume was 340 cm^3 ranging from 42.4 to 1497. The median follow up period was 58 months. Five-year overall survival and 5-year local control rates were 81% and 79%, respectively. Of the tumors 30 % showed local recurrences over 5 years later after the treatment. The ambulatory in 97% of the patients remained with or without supportive devices. Two patients experienced severe late skin/soft tissue complications requiring skin grafts.
Conclusion: Carbon ion radiotherapy appears effective and safe in the management of patients with unresectable sacral chordomas and offers a promising alternative to surgery.
No conflict of interest.

3823 POSTER

Role of radiation therapy in the conservative management of sarcoma within irradiated field

A. Modesto[1], T. Filleron[2], C. Chevreau[3], C. Le Péchoux[4], P. Rochaix[5], S. Le Guelec[5], A. Ducassou[1], D. Gangloff[6], G. Ferron[6], M. Delannes[1]. *[1]Institut Claudius Regaud, Radiation Oncology, Toulouse, France; [2]Institut Claudius Regaud, Biostatistics, Toulouse, France; [3]Institut Claudius Regaud, Medical Oncology, Toulouse, France; [4]Institut Gustave Roussy, Radiation Oncology, Villejuif, France; [5]Institut Claudius Regaud, Pathology, Toulouse, France; [6]Institut Claudius Regaud, Surgery, Toulouse, France*

Background: Sarcoma within irradiated field (SIF) is a rare but severe complication of radiation therapy (RT). Complete tumoral resection remains the cornerstone of localised SIF management, but clear margin surgery is often difficult to obtain in previously irradiated tissues. Residual disease enhances the risk of local failure and SIF mortality, partly explaining their poor prognosis. Thus, in our institution, we perform adjuvant or exclusive RT when unresectable, gross or microscopically positive-margin SIF. We hereby report on the long-term outcomes and toxicity profile of this combinative approach.
Patients and Methods: Individual clinical data from all consecutive patients diagnosed and treated for a localized SIF between January 2000 and October 2011 at the Institut Claudius Regaud, Toulouse, France, were retrospectively reviewed.
Results: Twenty-seven patients were eligible for this study. Twenty-four patients underwent surgery. Adjuvant or definitive RT was performed in 10 patients. The median follow-up was 3.8 years. Interestingly, there is a trend toward longer survival and better local control in the subgroup of patients who received adjuvant or definitive RT compared to the rest of the cohort with a 4-year overall survival and relapse free survival estimated to 66%, 53% vs 40% and 27% (ns) respectively, whereas the rate of unresectable, gross or microscopically positive-margin disease among this subgroup is significantly higher than the rest of the cohort ($p < 0.001$). The long-term moderate and severe complication's rates were 30% and 40% respectively but allowed a conservative management.
Conclusion: Re-irradiation might improve local control of unresectable localised SIF or after suboptimal surgery. Its non-negligible toxicity has to be balanced with the worse prognosis of SIF particularly when ineligible to surgery or if residual tumour left. RT should be discussed in some cases, as part of intensified local management with a curative intent.
No conflict of interest.

3824 POSTER

Surgery for recurrent gastrointestinal stromal tumors (GIST): A retrospective study of patients in a tertiary institution

J. Wong[1], G.H.C. Tan[2], R. Quek[3], B.K. Goh[4], S.Y. Pan[5], M.C.C. Teo[6]. *[1]National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore; [2]National Cancer Centre, Surgical Oncology, Singapore, Singapore; [3]National Cancer Centre, Medical Oncology, Singapore, Singapore; [4]Singapore General Hospital, General Surgery, Singapore, Singapore; [5]National Cancer Centre, Division of Clinical Trials and Epidemiological Sciences, Singapore, Singapore; [6]National Cancer Centre, Surgical Oncology, Singapore, Singapore*

Background: Surgical resection of primary gastrointestinal stromal tumours (GIST) is associated with recurrence rates of up to 50% at 2 years. The mitotic activity, size and location of the tumor are known risk factors for postoperative recurrence. At recurrence, tyrosine kinase inhibitor (TKI) therapy is recommended, and has been shown to confer survival of up to 55 months. Several studies have also shown that patients with TKI-responsive recurrent GIST benefit from surgery, compared to patients who do not respond to TKI. However, there are no studies which compare surgery plus imatinib therapy vs. imatinib alone. Hence, the role of surgery in recurrent GIST still remains unclear. We review our institutional experience with the management of recurrent GIST and evaluate the overall and disease-free survival rates in this group of patients.
Materials and Methods: Data was retrospectively collected from patients with recurrent GIST treated at the Department of General Surgery at the Singapore General Hospital during a 12 year period. The patients were divided into 2 groups: patients who had underwent a second surgical resection vs. patients who did not have surgery. A comparison of prognostic factors was made between the two groups. Our primary end points were disease-free and overall survival.
Results: A total of 187 patients underwent curative surgery between Jan 2000 and June 2012. Of the 187 patients, 58 (31%) had recurrent disease of which 31 (16.5%) underwent a second surgery; The surgical intent was curative in 28 patients, and palliative in 3 patients. Of the remaining 27 recurrent GIST patients, 20 received palliative TKI therapy, while 7 patients were managed conservatively. In the group of patients who underwent a second surgery, the median disease free survival (DFS) was 2.33 years (95% CI 1.44-undefined). The overall survival (OS) for all recurrent GIST patients was 6.98 years, with 1-, 2- and 3-year OS of 88%, 77% and 62% respectively. The median OS for patients who underwent a second surgery was 8.36 years, with 1-,2- and 3-year OS of 96%, 81% and 71% respectively vs. 3.87 years, with 1-, 2- and 3-year OS of 76%, 70% and 49% respectively for patients who had palliative TKI and conservative management. Patients who underwent a 2nd surgery were more likely to have a primary tumor arising from the small intestine with a lower mitotic rate & of a smaller size than patients who were not subjected to a 2nd surgery.
Conclusion: Our study shows that in a select group of patients with recurrent GIST, curative surgery confers acceptable DFS and OS.
No conflict of interest.

3825 POSTER

The off-label use of targeted therapies in rare disease as sarcomas: The OUTC'S program

L. Eberst[1], C. Cropet[2], A. Le Cesne[3], P. Pautier[3], N. Penel[4], A. Adenis[4], C. Chevreau[5], F. Bertucci[6], J.Y. Blay[1], I. Ray-Coquard[1]. *[1]Centre Léon Bérard, Medicine, Lyon Cedex 08, France; [2]Centre Léon Bérard, Biostatistics, Lyon Cedex 08, France; [3]Institut Gustave Roussy, Medicine, Villejuif, France; [4]Centre Oscar Lambret, Medicine, Lille, France; [5]Institut Claudius Regaud, Medicine, Toulouse, France; [6]Institut Paoli Calmettes, Medicine, Marseille, France*

Background: Few targeted therapies (TTs) are registered for sarcoma treatment, despite numerous phase II studies, but they are potential treatment options for patients after standard treatment escape. The French Sarcoma Group − Bone Tumor Study Group created a national registry to evaluate the outcome of patients treated with off-label TTs.

Table 1 (abstract 3825).

Targeted therapy	N	%	Histotype 1	n (%)	Histotype 2	n (%)	Histotype 3	n (%)	Histotype 4	n (%)	Histotype 5	n (%)
Sorafenib (1)	125	45	GIST	31 (25)	LMS	22 (18)	AS	14 (11)	uterine LMS	8 (6)	liposarcoma	8 (6)
Sunitinib (2)	67	24	LMS	9 (13)	Ewing	8 (12)	SS	8 (12)	unclassified S	8 (12)	uterine LMS	4 (6)
Imatinib	23	8	chordoma	8 (35)	AF	4 (17)	DFSP	4 (17)	epithelioidS	2 (9)	–	–
Sirolimus-cyclophosphamide	18	6	osteoS	8 (44)	chondroS	5 (27)	AS/chordoma/lipoS/ Ewing/SFT	1 each (6)	–	–	–	–
Everolimus (3)	10	4	GIST	3 (30)	LMS	3(30)	KS/MPNST/SS	1 each (10)	other	1(10)	–	–
Bevacizumab (4)	9	3	other	5 (56)	SFT	2 (22)	AS	1 (11)	epithelioidS	1 (11)	–	–
Sirolimus alone	5	2	osteoS	2 (40)	PEComa	1 (20)	other	1 (20)	–	–	–	–

AF: aggressive fibromatosis; AS: angiosarcoma; DFSP: dermatofibrosarcoma protuberans; epithelioidS: epithelioid sarcoma; GIST: gastro-intestinal stromal tumor; KS: kaposi sarcoma; LMS: leiomyosarcoma; MPNST: malignant peripheral nerve sheath tumor; OsteoS: osteosarcoma; SFT: solitary fibrous tumor; SS: synovial sarcoma.

Patients and Methods: Every consecutive sarcoma-patient receiving off-label TT outside a clinical trial was included. The objective was to describe these patients' efficacy and safety data in routine practice.
Results: From October 2008 to October 2011, 249 patients in 24 centers received 278 treatment lines with TTs. Decision of treatment was made under control of multidisciplinary tumor board in 76%. Twenty-five histological subtypes were included: most frequent were leiomyosarcoma (n=48, receiving sorafenib in 63%, sunitinib in 27%), GIST (n=39, receiving sorafenib in 79%), and angiosarcoma (n=18, receiving sorafenib in 78%). The overall response rate to TTs was 15% (95% CI [10.6–20.2]), the disease control rate was 65.4% (95% CI [58.9–71.5]). The median progression-free survival was 4.1 months (95% CI [3.2−4.8]). Three complete responses (CRs) were observed: for a PEComa with temsirolimus, for a Ewing sarcoma with sunitinib, and for a Dermatofibrosarcoma with imatinib. No toxic death occurred, grade 3 and 4 toxicities were reported in 74 (27%) and 14 (5%) patients respectively.
Conclusion: Off-label TTs can be used for sarcoma-patients in routine practice with an acceptable toxicity profile and efficacy similar to that reported in uncontrolled clinical trials. With 3 CRs in rare subtypes, this approach is interesting to identify therapeutic niches.

Table 2. Targeted therapy by histotypes

Histotype	Targeted therapy
1	Alone in 120 cases, combination in 5 cases
2	Alone in 66 cases, combination in 1 case
3	Alone in 7 cases, combination in 3 cases
4	Alone in 3 cases, combination in 6 cases

Targeted therapies with less than 5 patients are not listed in this table.

3826 POSTER

Final results of sequential phase 2 studies of palbociclib (PD0332991) in CDK4-amplified liposarcoma

M. Dickson[1], W.D. Tap[2], C.R. Antonescu[3], J. Landa[4], L.X. Qin[5], A.M. Crago[6], S. Singer[6], G.K. Schwartz[2]. *[1]Memorial Sloan-Kettering Cancer Center, New York, USA; [2]Memorial Sloan-Kettering Cancer Center, Medicine, New York, USA; [3]Memorial Sloan-Kettering Cancer Center, Pathology, New York, USA; [4]Memorial Sloan-Kettering Cancer Center, Radiology, New York, USA; [5]Memorial Sloan-Kettering Cancer Center, Biostatistics, New York, USA; [6]Memorial Sloan-Kettering Cancer Center, Surgery, New York, USA*

Background: The oncogene cyclin-dependent kinase 4 (CDK4) is amplified in >90% of well-differentiated/de-differentiated liposarcomas (WD/DDLS). Palbociclib is a selective CDK4/CDK6 inhibitor that inhibits growth and induces senescence in liposarcoma cell lines and xenografts.
Methods: We performed two sequential phase 2 studies of palbociclib in patients with advanced WD/DDLS, evaluating two dosing schedules: 2/1 schedule (200 mg PO daily x 14d, every 21d) and 3/1 schedule (125 mg PO daily x 21d, every 28d). Participants were adults with advanced WD/DDLS, measurable disease by RECIST 1.1 and progression on $\geqslant$1 systemic therapy. All had CDK4 amplification by fluorescence in situ hybridization and retinoblastoma protein expression by immunohistochemistry ($\geqslant$1+). The primary endpoint was progression-free survival (PFS) at 12 weeks. Based on historical data, a promising result was defined as a 12-week PFS of $\geqslant$40% and not promising as $\leqslant$20%. The study was approved by the Institutional Review Board of Memorial Sloan-Kettering Cancer Center and all patients provided written informed consent. The study was registered at Clinicaltrials.gov (NCT01209598) and was sponsored by Pfizer.
Results: 29 evaluable patients were treated on 2/1 schedule and 25 on 3/1 schedule. PFS at 12 weeks was 66% (90% CI 51–100%) on 2/1 schedule and 56% (90% CI 41–100%) on 3/1 schedule. Median progression-free survival was 18 weeks on 2/1 schedule and 24 weeks on 3/1 schedule. There was one partial response on each schedule. Grade 3−4 toxicity on 2/1 schedule: neutropenia 50%; thrombocytopenia 30%; anemia 17%. On 3/1 schedule: neutropenia 34%, thrombocytopenia 10%, anemia 21%.
Conclusions: In patients with WD/DDLS with CDK4 amplification, palbociclib treatment was associated with a favorable PFS and objective tumor responses. Both dosing schedules are active but the 3/1 schedule is associated with less hematologic toxicity. Updated survival and response data will be presented. The 3/1 schedule has been selected for a randomized phase 3 study.

3827 POSTER

Time course of adverse events in the phase III GRID study of regorafenib in patients with metastatic gastrointestinal stromal tumors (GIST)

J. Blay[1], P.G. Casali[2], P. Reichardt[3], Y.K. Kang[4], P. Rutkowski[5], H. Gelderblom[6], P. Hohenberger[7], C. Kappeler[8], I. Kuss[9], G.D. Demetri[10]. *[1]Centre Régional Léon Berard, Medecine INSERM U590, Lyon, France; [2]Istituto Nazionale Tumori, Adult Mesenchymal Tumour Medical Oncology Unit, Milan, Italy; [3]HELIOS Klinikum Berlin-Buch, Interdisciplinary Oncology Sarcoma Center Berlin-Brandenburg, Berlin, Germany; [4]Asan Medical Center University of Ulsan College of Medicine, Department of Oncology, Seoul, Korea; [5]Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Department of Soft Tissue/Bone Sarcoma and Melanoma, Warsaw, Poland; [6]Leiden University Medical Center, Department of Clinical Oncology, Leiden, Netherlands; [7]Mannheim University Medical Center, Div. of Surgical Oncology & Thoracic Surgery, Mannheim, Germany; [8]Bayer HealthCare, Global Clinical Development Clinical Statistics Europe, Berlin, Germany; [9]Bayer Pharma AG, Global Clinical Development Therapeutic Area Oncology Ophthalmology & Neurology, Berlin, Germany; [10]Dana-Farber Cancer Institute and Harvard Medical School, Ludwig Center, Boston, USA*

Background: Regorafenib (REG), a unique oral multikinase inhibitor, has demonstrated significant improvement in progression-free survival *vs* placebo (P; HR 0.27, p < 0.0001) in the international phase III GRID study (NCT01271712, sponsored by Bayer HealthCare). To better characterize the safety profile of REG in GRID, we investigated adverse events (AEs) and the dose intensity tolerated over time.
Materials and Methods: Adults with metastatic GIST after treatment with imatinib and sunitinib were randomized 2:1 to receive oral REG 160 mg or matching P once daily for the first 3 weeks of each 4-week cycle. Treatment-emergent AEs and biochemical abnormalities were assessed at each cycle.
Results: The safety population comprised 198 patients (pts): REG n = 132; P n = 66. The median treatment duration was 22.9 weeks (range: 9.3–50.9) in the REG group and 7.0 weeks (5.1–25.9) in the P group.
Treatment-emergent AEs of any grade occurred in all of the REG pts and 92% of P pts, at grade 1/2 in 24% and 53%, respectively, at grade 3 in 64% and 29%, respectively, and at grade 4 in 7% and 6%, respectively. AE-related deaths occurred in seven REG and four P pts. The most frequent AEs occurring in REG pts were hypertension (59%), hand–foot skin reaction (HFSR) (57%), fatigue (50%), diarrhea (47%), and oral mucositis (41%). The frequency of these AEs over time is shown in the Table. The incidence of all of these AEs peaked in cycle 1 and tapered to relatively stable lower incidence rates over later cycles.
AEs led to dose modification in 72% of REG pts and in 26% of P recipients. The proportion of planned REG dose actually administered decreased between cycles 1 and 4 (89% of planned dose received in cycle 1 and 77% of planned dose received in cycle 4), and dose intensity was relatively stable in subsequent cycles (planned dose received remained above 72%).
Conclusion: In the GRID trial, the incidence of the most common AEs in the REG group peaked early during treatment, and was manageable with

dose modification so that lower levels of AEs occurred in later treatment cycles, with no evidence of cumulative toxicity. Few pts (6% REG, 8% P) required discontinuation from study due to AEs.

3828 POSTER

Safety of trabectedin versus doxorubicin-based chemotherapy (DXCT) as first-line therapy in patients with translocation-related sarcoma (TRS)

S.P. Chawla[1], A. Italiano[2], S. Patel[3], P. Hohenberger[4], A. Santoro[5], A.P. Staddon[6], P. Lardelli[7], J. Gomez[7], C. Kahatt[7], J.Y. Blay[8]. *[1]Sarcoma Oncology Center, Santa Monica, USA; [2]Institut Bergonie, Oncology, Bordeaux, France; [3]University of Texas MD Anderson Cancer Center, Houston, USA; [4]Universitätsklinikum Mannheim, Mannheim, Germany; [5]Humanitas Cancer Center Istituto Clinico Humanitas IRCCS, Oncology, Rozzano, Italy; [6]Pennsylvania Hospital, Pennsylvania, USA; [7]PharmaMar, Madrid, Spain; [8]University Claude Bernard Lyon I Centre Léon Bérard, Oncology, Lyon, France*

Background: The safety profiles of trabectedin and DXCT, given as 1st therapy in a randomised phase III trial in patients with locally advanced, or metastatic TRS, were analysed.

Methods: Patients were randomised (1:1) to receive trabectedin (1.5 mg/m^2 in 24 h iv infusion q3wk) vs doxorubicin alone (75 mg/m^2 q3wk), or doxorubicin (60 mg/m$^{2)}$ plus ifosfamide (6−9 g/m^2 q3wk). Descriptive statistics were used to evaluate safety, including adverse events (AEs), serious AEs (SAEs), deaths, and laboratory data.

Results: 121 patients were randomised, 61 were treated with trabectedin and 57 with DXCT (36 with doxorubicin single-agent, and 21 with doxorubicin plus ifosfamide). The safety profile observed was expected for both trabectedin and DXCT. Safety is summarised in the tables.

Table 1. Adverse events

Most common AEs	Trabectedin (%)		DXCT (%)	
	G1−2	G3−4	G1−2	G3−4
Nausea	68.9	1.6	64.9	–
Fatigue	57.4	6.6	61.4	1.8
Vomiting	42.6	1.6	26.3	–
Anorexia	23.0	1.6	21.1	–
Alopecia	1.6	–	43.9	–
Mucositis	4.9	1.6	26.3	8.8

Table 2. Laboratory disorders

Laboratory disorder	Trabectedin (%)	DXCT (%)
Neutropenia grade 3−4	55	75
Febrile neutropenia	1.6	12.3
Thrombocytopenia grade 3−4	16.4	14.3
ALT increase grade 3−4	53.3	1.9

General and gastrointestinal disorders were balanced between both treatments. Severe neutropenia was more frequent in the DXCT arm. However, it was generally controlled with G-CSF (61.4% of patients), while in the trabectedin arm it was more frequently managed with dose delay until recovery (49.2% of patients received G-CSF). Drug related discontinuations were slightly higher in the trabectedin arm: 16.4% vs. 10.5%. Nevertheless, patients receiving trabectedin were able to be treated for prolonged periods of time due to lack of cumulative toxicities: 25% of patients received ⩾10 cycles of trabectedin (max. 8 cycles of DXCT, per protocol). Transient transaminases increase occurred more frequently in the trabectedin arm. SAEs incidence was similar (18.0% with trabectedin; 19.3% with DXCT); most frequent SAEs were extravasation (4.9%) in trabectedin arm and febrile neutropenia (12.3%) in DXCT. One drug related death occurred in each arm: rhabdomyolysis in trabectedin arm and pneumonia in DXCT.

Conclusion: Trabectedin and DXCT were generally well tolerated with limited incidence of severe side effects. No new safety signals have emerged from this trial.

No conflict of interest.

3829 POSTER

Results of a multivariate analysis for potential factors affecting outcome in translocation related sarcomas (TRS) treated with trabectedin or doxorubicin-based chemotherapy (DXCT) as first-line therapy

S.P. Chawla[1], M.G. Leahy[2], A. Italiano[3], S. Patel[4], N. Penel[5], S. Piperno-Neumann[6], P. Lardelli[7], A. Soto-Matos[7], A. Nieto[7], J.Y. Blay[8]. *[1]Sarcoma Onc Ctr, Oncology, Santa Monica, USA; [2]The Christie NHS Foundation Trust, Oncology, Manchester, United Kingdom; [3]Institut Bergonié, Bordeaux, France; [4]University of Texas MD Anderson Cancer Center, Oncology, Houston, USA; [5]Centre Oscar Lambret, Lille, France; [6]Institut Curie, Paris, France; [7]PharmaMar, Clinical Oncology, Madrid, Spain; [8]University Claude Bernard Lyon I Centre Léon Bérard, Lyon, France*

Background: A Phase III randomized clinical study was conducted to evaluate trabectedin (1.5 mg/m^2 in 24 h iv infusion q3wk) *versus* doxorubicin, either single agent 75 mg/m^2 q3wk, or 60 mg/m^2 combined with ifosfamide (6−9 g/m^2 q3wk) as first line treatment in locally advanced or metastatic TRS. Primary efficacy endpoint was progression free survival (PFS). A pre-planned multivariate analysis was conducted to analyze the potential factors which may influence the PFS, assessed by independent review, in both arms.

Methods: A Cox proportional hazard model was performed including the variables: treatment arm (trabectedin *vs* DXCT), gender, age, age at diagnosis, race, baseline ECOG, BMI, height, weight, BSA, histology: myxoid/round cell liposarcoma (MRCL) *vs* other TRS, time from diagnosis and from last progression to study entry, primary site (limbs *vs* other), locally advanced/metastatic, prior surgery, prior radiotherapy, number of sites involved, liver metastases, LVEF, presence of bulky lesions (<50 mm *vs* ⩾50 mm), sum of all target lesion diameters, and region (Europe *vs.* other). In the stepwise analysis, the significance level chosen to enter an explanatory variable was 0.05 (for all variables not included, the one with the smallest p-value was entered if the p-value was less than or equal to the specified significance level). The significance level to remove a variable was 0.05 (for all variables included, the one with the largest p-value was removed if the p-value exceeded the significance level).

Results: 88 patients integrated the efficacy population. The only significant covariate found to influence the PFS was the histological type: MRCL *vs* other TRS subtypes.

Analysis of maximum likelihood estimates

Parameter	DF	Parameter estimate	Standard error	χ^2	PR > χ^2	HR (95% confidence limits)
MRCL *vs.* other TRS	1	2.23478	0.62750	12.6837	0.0004	9.344 (2.732, 31.965)

DF, degrees of freedom; HR, hazard ratio.

PFS at 12 months for MRCL was 84.9% (trabectedin) *vs* 79.6% (DXCT). For other TRS it was 28.8% *vs* ~20%.

Conclusions: Of all the covariates included, only histological subtype showed up as prognostic factor for PFS with significant difference in favour of MRCL patients. In addition, according this analysis, no significant difference between the two treatment arms was detected.

Conflict of interest: *Advisory board: Novartis, GSK, J&J, PharmaMar*

3830 POSTER

Health-related quality of life (HRQoL) of patients with advanced gastrointestinal stromal tumors (GIST) treated with regorafenib (REG) vs placebo (P) in the phase III GRID trial

J. Chang[1], P.G. Casali[2], P. Reichardt[3], Y.K. Kang[4], J.Y. Blay[5], Y. Wu[6], D. Odom[6], I. Kuss[7], G.D. Demetri[8]. *[1]Bayer HealthCare Pharmaceuticals, Global Health Economics & Outcomes Research, Montville NJ, USA; [2]Istituto Nazionale Tumori, Adult Mesenchymal Tumour Medical Oncology Unit, Milan, Italy; [3]HELIOS Klinikum Berlin-Buch, Interdisciplinary Oncology Sarcoma Center Berlin-Brandenburg, Berlin, Germany; [4]Asan Medical Center University of Ulsan College of Medicine, Department of Oncology, Seoul, Korea; [5]Centre Leon Berard, Department of Medecine French Sarcoma Group, Lyon, France; [6]RTI Health Solutions, Biostatistics, Durham NC, USA; [7]Bayer Pharma AG, Global Clinical Development Therapeutic Area Oncology Ophthalmology & Neurology, Berlin, Germany; [8]Dana-Farber Cancer Institute and Harvard Medical School, Global Clinical Development Therapeutic Area Oncology Ophthalmology & Neurology, Boston MA, USA*

Background: The GRID trial (NCT01271712, sponsored by Bayer HealthCare) demonstrated significant improvement in progression-free survival (PFS) for REG *vs* P in patients with metastatic GIST after progression on at least imatinib and sunitinib. Exploratory analyses were conducted to assess the effect of treatment on HRQoL.
Materials and Methods: The HRQoL analyses were selected *a priori* based on clinical relevance; the global health status/QoL (QL) and the physical functioning (PF) scales of the EORTC QLQ-C30 questionnaire were used during the double-blind treatment period. Patients who completed a baseline and at least one post-baseline HRQoL assessment were included. A linear mixed-effects model was used to examine the treatment effect on HRQoL and trends over time, assuming that missing data were missing at random. Pattern-mixture models were applied to assess the treatment effect while accounting for potentially informative missing data. Time-to-deterioration (TTD) of HRQoL and responder analyses were conducted to determine the treatment effect based on timing and proportion of patients reaching a minimal important difference (MID) change in QL/PF ($\geqslant$10 points).
Results: The QL and PF changes over time were numerically similar between REG and P based on the linear mixed-effects model. The pattern-mixture models grouped patients based on timing of last HRQoL assessment (<4 or $\geqslant$4 cycles) and suggest that the missing data (presumably due to disease progression/death) might not be missing at random and are therefore informative, especially for the P group. As such, the results from the linear mixed-effects model should be interpreted with caution and alongside the results from the TTD analysis, where disease progression/death was considered as a deterioration in HRQoL. For the TTD analysis, when an event was defined as the earliest MID decrease in QL/PF, disease progression or death, REG showed significantly longer median TTD than P (QL: 6.5 *vs* 4.0; PF 8.0 *vs* 4.0 weeks, respectively). Median TTD was comparable between treatments after removing disease progression from the definition. The responder analyses showed that a similar proportion of patients achieved an improvement in MID in REG *vs* P (QL: 26.2% *vs* 25.4%; PF: 18.0% *vs* 15.3%, respectively).
Conclusion: The findings of this exploratory analysis demonstrate that HRQoL is similar for REG and P groups, indicating that REG prolongs PFS *vs* P while maintaining at least comparable HRQoL.

Exposure-efficacy analysis of regorafenib (REG) and its metabolites M-2 and M-5 in the phase III GRID study in patients (pts) with metastatic gastrointestinal stromal tumor (GIST)

G. Demetri[1], J.M.W. Smeets[2], P.G. Casali[3], P. Reichardt[4], Y.K. Kang[5], H. Joensuu[6], P. Rutkowski[7], J.Y. Blay[8], I. Kuss[9], Z. Jirakova Trnkova[10]. *[1]Dana-Farber Cancer Institute, Senior Vice President for Experimental Therapeutics Dana-Farber Cancer Institute, Boston MA, USA; [2]LAP&P Consultants BV, PK-PD, Leiden, Netherlands; [3]Istituto Nazionale Tumori, Adult Mesenchymal Tumour Medical Oncology Unit, Milan, Italy; [4]HELIOS Klinikum Berlin-Buch, Interdisciplinary Oncology Sarcoma Center Berlin-Brandenburg, Berlin, Germany; [5]Asan Medical Center University of Ulsan College of Medicine, Department of Oncology, Seoul, Korea; [6]Helsinki University Central Hospital, Department of Oncology, Helsinki, Finland; [7]Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Department of Soft Tissue/Bone Sarcoma and Melanoma, Warsaw, Poland; [8]Centre Leon Berard, Department of Medecine French Sarcoma Group, Lyon, France; [9]Bayer Pharma AG, Global Clinical Development Therapeutic Area Oncology Ophthalmology & Neurology, Berlin, Germany; [10]Bayer Pharma AG, GDD Clinical Sciences Clinical Pharmacology Oncology, Berlin, Germany*

Background: REG, an oral multikinase inhibitor, demonstrated significant progression-free survival (PFS) improvement *vs* placebo (HR 0.27, $p < 0.0001$) in the phase III GRID study. We examined the relation between drug levels (i.e. exposure) and efficacy outcomes in GRID by correlating individual exposure estimates to the study efficacy endpoints (PFS, disease control rate (DCR), and overall survival (OS)) and tumor dynamics (size/time).
Materials and Methods: Plasma concentrations of REG parent and two pharmacologically active metabolites M2 and M5 were evaluable in 80 of 133 GRID pts on REG. The exposure estimates were derived from a previously developed population pharmacokinetic (PK) model (Jirakova Trnkova *et al*, ESMO WCGI 2013). Exposure parameters: 1. nominal average concentration over a 24 h dosing interval after 21 daily doses of 160 mg REG (Cav_{md}; primary) and 2. average concentration over the treatment period ($Cav(t1\text{-}t2)_{md}$; secondary). Covariates included age, gender, BMI, ECOG, country, duration of prior imatinib Rx, *KIT* mutation (Exon 9 or 11), and baseline total target lesion size (TTL). For tumor dynamics analysis, TTL measured 414 target lesions from 80 pts with available exposure data. Stepwise Cox proportional hazard or logistical regression methods were used. Sensitivity analyses were performed on tumor dynamics.
Results: Three exposures were defined: REG parent (R*p*), aggregate (R*p* +M2+M5 corrected for unbound fraction), and total (bound and unbound R*p* +M2+M5), resulting in six exposure parameters tested. There was no significant association between any exposure parameter or covariates and PFS, DCR or tumor dynamics. OS data are immature, but the preliminary analysis of only 13 uncensored events indicated longer OS for patients with higher total Cav_{md} and smaller baseline TTL. Tumor dynamics analysis showed that REG caused initial tumor shrinkage, decreasing after 9.2 weeks in a typical pt. Drug exposure was not significantly different between pts who discontinued REG within the first 2 cycles vs later.
Conclusions: Exposure-efficacy analysis in GIST pts treated with REG in the GRID study did not reveal any significant relationship between drug exposure and PFS, DCR or tumor dynamics. REG dosing induced tumor shrinkage, with less continuing decrease after 9 weeks. Early preliminary analysis revealed longer OS for patients with higher REG exposure and smaller total target lesion size.

3832 POSTER

Hypertension (HTN) as a biomarker of efficacy in pazopanib-treated patients (pts) with advanced non-adipocytic soft tissue sarcoma (STS)

F. Duffaud[1], S. Sleijfer[2], S. Litière[3], I. Ray-Coquard[4], A. Le Cesne[5], Z. Papai[6], I. Judson[7], R. Hodge[8], S. Marreaud[3], W. Van der Graaf[9]. *[1]Assistance Publique − Hôpitaux De Marseille − Hôpital de la Timone, Marseille, France; [2]ERASMUS MC − Daniel Den Hoed Cancer Center, Rotterdam, Netherlands; [3]EORTC Headquarters, Brussels, Belgium; [4]Centre Léon Bérard, Lyon, France; [5]Institut Gustave Roussy, Villejuif, France; [6]Military Hospital − State Health Centre, Budapest, Hungary; [7]Royal Marsden Hospital, London, United Kingdom; [8]GSK, Uxbridge, United Kingdom; [9]Radboud University Medical Centre, Department of Medical Oncology, Nijmegen, Netherlands*

Background: Reliable biomarkers of pazopanib's efficacy in STS pts are lacking. HTN is an on-target effect of vascular endothelial growth factor pathway inhibitors such as pazopanib. We evaluated the association of pazopanib-induced HTN with antitumor efficacy in pts with advanced/metastatic non-adipocytic STS.
Methods: Associations between pazopanib-induced HTN and survival (PFS and OS) were retrospectively assessed across 2 studies (EORTC study 62043 and 62072) in pts with metastatic STS who received oral pazopanib starting at 800 mg daily. Only eligible pts with baseline blood pressure (BP) <150/90 mmHg, were considered in this analysis. Anti-hypertensive medication (AHM) to control baseline BP was allowed. BP was measured at monthly clinic visits (in 62072 study bi-monthly after first 3 months). HTN was reported according to NCI-CTC AE grading (v3.0) and assessed as absolute differences compared to baseline.
We first compared the outcome of pts with medically controlled BP at baseline vs. those without baseline AHM in a multivariate Cox model. The cumulative incidence of HTN in pts without baseline AHM was assessed subsequently.
The effect of HTN was assessed on PFS and OS using a landmark analysis stratified by study; univariately using the Kaplan–Meier method and a log-rank test, and in a multivariate Cox regression model after adjustment for important prognostic factors.
Results: Of the 337 eligible pts eligible for this study, 21.7% received AHM at baseline. PFS and OS did not differ significantly between pts using baseline AHM vs. those who did not. In pts without baseline AHM, 38.6% developed HTN. As the vast majority of pts developing HTN did so within 5 weeks (wks) after initiation of pazopanib (68.6%), this time point was used as landmark. Univariately, there was no effect on PFS or OS from occurrence of HTN within 5 wks of treatment expressed either in NCI-CTC AE criteria or as maximal differences from baseline in systolic and diastolic BP. Also in multivariate analysis, after adjusting for important prognostic factors, the occurrence of HTN expressed in the different parameters was not associated with PFS and OS.
Conclusions: In this retrospective analysis, pazopanib-induced HTN did not correlate with outcome in pazopanib-treated non-adipocytic STS pts. The occurrence of HTN cannot serve as an early biomarker in this setting.
No conflict of interest.

3833 POSTER

Trabectedin in patients with advanced soft tissue sarcoma (STS): importance of maintenance therapy in responding patients after 6 cycles of trabectedin

A. Le Cesne[1], I. Ray-Coquard[2], F. Duffaud[3], C. Chevreau[4], N. Penel[5], B. Bui[6], S. Piperno-Neumann[7], C. Even[1], P. Cousin[2], J.Y. Blay[2]. *[1]Institut Gustave Roussy, Department of Medical Oncology, Villejuif, France; [2]Centre Léon Bérard, Department of Medical Oncology, Lyon, France; [3]Hôpital La Timone, Department of Medical Oncology, Marseille, France; [4]Institut Claudius Regaud, Department of Medical Oncology, Toulouse, France; [5]Centre Oscar Lambret, Department of General Oncology, Lille, France; [6]Institut Bergonie, Department of Medical Oncology, Bordeaux, France; [7]Institut Curie, Department of Medical Oncology, Paris, France*

Background: Trabectedin (Yondelis®) is the first marine-derived antineoplastic drug approved in EU for the treatment of patients with recurrent advanced STS (ASTS) or for patients unsuited to receive anthracyclines and ifosfamide. We retrospectively analyzed the RetrospectYon database with patients' data treated with trabectedin between Jan 2008-Dec 2011.
Material and Methods: Trabectedin was given at the approved dose of 1.5 mg/m^2 as a 24-h infusion every 3 weeks. Patients who achieved partial response (PR) or stable disease (SD) after 6 cycles could receive maintaining trabectedin treatment. Uni- and multivariate analyses of prognostic factors were performed.
Results: A total of 885 patients with ASTS (486 women) from 26 French centers with a median age of 54 years (range 12−84) were included. Most patients had leiomyosarcoma (36%), liposarcoma (18%) or synovial STS (11%). At baseline, performance status (PS) was 0 in 26%, 1 in 47% and >1 in 27% of patients. A median of 4 cycles of trabectedin (range 1−28) was administrated as a 2nd (41%), 3rd (39%) or $\geqslant$4th (20% of patients) treatment line. Toxic death and unscheduled re-hospitalization occurred in 0.5% and 8% of patients, respectively. The objective response rate was 15% (6 complete and 127 PR), and SD was 45.5% (n = 403). After a median follow-up of 22.6 months (range 0.03–51.0), the patients who received trabectedin as 2nd, 3rd or $\geqslant$4th line had the median PFS of 4.3, 4.2 and 3.4 months, and the median OS of 12.9, 12.3 and 9.5 months respectively,. Multivariate analysis identified liposarcoma, leiomyosarcoma, angiosarcoma, undifferentiated pleomorphic sarcoma (UPS) and trabectedin line as independent prognostic factors for PFS, and UPS, angiosarcoma, rhabdomyosarcoma, gender, PS and trabectedin line for OS. After 6 cycles, 205 of the 273 (75.1%) patients with non-progressive disease received trabectedin as maintenance treatment and obtained a superior PFS (median 11.0 *vs.* 7.2 months, $p = 0.0001$) and OS (median 25.1 *vs.* 16.9 months, $p<0.0001$) compared to patients who stopped trabectedin after 6 cycles.
Conclusions: The results of this real-life study have demonstrated that patients with ASTS treated with trabectedin had PFS and OS comparable or better to those observed in clinical trials. Trabectedin maintenance beyond 6 cycles is associated with improved PFS and OS and warrants further exploration.
No conflict of interest.

LMS-02: A Phase II single-arm multicenter study to determine the efficacy of doxorubicin in combination with trabectedin as a 1st line treatment of metastatic and/or locally advanced leiomyosarcoma of uterine (U-LMS) or soft tissue (ST-LMS) origin: results of the soft tissue group

P. Pautier[1], C. Chevreau[2], A. Le Cesne[3], N. Penel[4], B. Bui[5], C. Guillemet[6], C. Delcambre[7], A. Rey[8], F. Duffaud[9]. *[1]Institut Gustave Roussy, Medecine, Villejuif Cedex, France; [2]Institut Claudius Régaud, Medecine, Toulouse, France; [3]Institut Gustave-Roussy, Medecine, Villejuif, France; [4]Centre Oscar Lambret, Medecine, Lille, France; [5]Institut Bergonié, Medecine, Bordeaux, France; [6]Centre Henri Becquerel, Medecine, Rouen, France; [7]Centre François Baclesse, Medecine, Caen, France; [8]Institut Gustave Roussy, Biostatistics, Villejuif, France; [9]Hôpital La Timone, Medecine, Marseille, France*

Background: U-LMS and ST-LMS are rare tumours with poor prognosis when metastatic or locally advanced, presenting moderate chemosensitivity mainly to doxorubicin (doxo), ifosfamide (ifo), cisplatin, gemcitabine (gem) and trabectedin (trab). Overall response rates (ORR) in combination therapies (1st line) does not exceed 50% for U-LMS and 35% for ST-LMS. The most active are doxo combinations (mostly with ifo or dacarbazine) and gem plus docetaxel (in particular in U-LMS) with mean response durations of 3−6 months. Trab demonstrated a definite activity on pre-treated LMS with an ORR of ~20%. In view of these encouraging results in LMS, a study combining trab with doxo seems to be of interest. Herein, we present the results in patients (pts) with ST-LMS.
Material and Methods: The primary objective was to determine the disease control rate (DCR) (ORR+SD). Secondary objectives included: PFS at 12 wks, ORR by RECIST, duration of response, overall survival (OS) and safety. Stratification by U-LMS/ST-LMS was carried out, 107 patients planned (45 U-LMS and 62 STS). Treatment: at d1 doxo 60 mg/m^2 followed by trab 1.1 mg/m^2 3-h and pegfilgrastim 6 mg d2 q3wks, 6 cycles. Surgery for residual disease was permitted.
Results: A total of 61 pts (40 women) were included until January 2013, with a median age of 60. Among 42 pts with data for at least 1 cycle, 35 had metastatic disease (mostly lung 26/35); 27 pts had received 6 cycles. For 36 pts with at least 1 evaluation (2 cycles), there were 1 CR, 13 PR, 20 SD for a DCR of 94%, and 2 PD. Progression free survival at 12 weeks is currently 95% [95%IC:84−99]. Common grade 3/4 toxicities in 208 cycles were neutropenia (40.7%), febrile neutropenia (4.3%), thrombopenia (19.7%), anemia (9%), fatigue (6.3%) vomiting (3.8%), and ALAT elevation (9%). One patient died after the second cycle due to a pulmonary oedemia associated to a prolonged febrile aplasia.
Conclusions: Despite expected toxicity observed, doxorubicin in combination with trabectedin seems to be an effective first line treatment in ST-LMS. Final data of the overall population will be available in September 2013.
No conflict of interest.

3835 POSTER

Multicenter phase II study of everolimus in patients with metastatic or recurrent bone and soft tissue sarcomas after failure of anthracycline and ifosfamide

C. Yoo[1], J.H. Ahn[1], J. Lee[2], S.Y. Rha[3], K.H. Park[4], T.M. Kim[5], Y.J. Kim[6], H.J. Lee[7], K.H. Lee[8]. *[1]Asan Medical Center, Oncology, Seoul, Korea; [2]Samsung Medical Center, Medicine, Seoul, Korea; [3]Yonsei Cancer Center, Internal Medicine, Seoul, Korea; [4]Korea University Anam Hospital, Medicine, Seoul, Korea; [5]Seoul National University Hospital, Internal Medicine, Seoul, Korea; [6]Seoul National University Bundang Hospital, Internal Medicine, Seongnam, Korea; [7]Chungnam National University Hospital, Internal Medicine, Seoul, Korea; [8]Yeungnam University Hospital, Internal Medicine, Seoul, Korea*

Background: This multicenter, phase II trial evaluated the efficacy and safety of everolimus, mTOR inhibitor, in patients with metastatic or recurrent bone and soft tissue sarcoma after failure of antracycline- and ifosfamide-containing regimens.
Materials and Methods: Everolimus was given orally as 10 mg once daily. The primary endpoint was progression-free survival (PFS) at 16 weeks, assessed by computed tomography scan according to RECIST 1.0.
Results: Between July, 2010, and May, 2011, 41 patients were enrolled in this study. Among them, 83% received two or more lines of chemotherapy prior to study entry. In 38 patients who the primary endpoint was evaluable, 11 patients reached 16 Week progression-free (one with partial response and 10 with stable disease), indicating PFS at 16 weeks of 27% (95% confidence interval [CI], 16−42%). The PFS rate at 16 weeks was highest in patients with angiosarcoma (2 of 3, 67%). There was a patient with metastatic hemangiopericytoma that everolimus induced prolonged disease stabilization for approximately 18 months with 20 cycles of study treatment after progression on anthracycline/ifosfamide-combination and gemcitabine/docetaxel-combination regimens. With a median follow-up of 10.9 months (range, 2.3–23.9 months) in living patients, the median PFS was 1.9 months (95% CI, 1.3−2.4 months) and median OS was 5.8 months (95% CI, 3.6−8.0 months). Most adverse events were generally mild and tolerable. Grade 3/4 toxicities included hyperglycemia (15%), stomatitis (7%), pain (5%), and asthenia (5%). Grade 3/4 hematologic toxicities were not observed.
Conclusions: Everolimus showed substantial antitumor activity with manageable toxicities in heavily pretreated patients with bone and soft tissue sarcoma.
No conflict of interest.

3836 POSTER

Very late relapse in osteosarcoma: Experience of the Cooperative Osteosarcoma Study COSS

B. Kempf-Bielack[1], B. Sorg[1], M. Kevric[1], K. Helmke[2], D. Branscheid[3], G. Jundt[4], M. Werner[5], L. Kager[6], T. Kühne[7], S. Bielack[1]. *[1]Olgahospital – Klinikum Stuttgart, Paediatric Oncology/COSS, Stuttgart, Germany; [2]Altonaer Kinderkrankenhaus, Pediatric Radiology, Hamburg, Germany; [3]Evangelisches Krankenhaus, Thoracic Surgery, Bielefeld, Germany; [4]Kantonsspital Basel, Institute of Pathology, Basel, Switzerland; [5]HELIOS Klinikum Emil von Behring, Orthopedic Pathology, Berlin, Germany; [6]St.Anna Kinderspital, Hematology & Oncology, Vienna, Austria; [7]University Childrens Hospital, Hematology & Oncology, Basel, Switzerland*

Background: If osteosarcoma (OS) recurs following multimodal treatment, it most frequently does so within the first three years after diagnosis. Most follow-up programs end after 5 to 10 years. We searched the Cooperative Osteosarcoma Study Group COSS database for recurrences detected after more than 10 years.
Material and Methods: Prior to 01.01.03, 2.405 patients with a diagnosis of a non-pretreated OS of the extremity or trunk (excl. craniofacial and extraskeletal variants) were registered with COSS, of whom 789 (752 high grade (HG), 37 low grade (LG)) were followed for 10 years without recurrence. These were searched for OS manifestations arising thereafter. Data of affected patients was analyzed for demographic, tumor, and treatment-related variables and outcomes.
Results: As of 03/13, 14 very late 1st recurrences >10 years from initial diagnostic biopsy were detected (median: 14.2 years; range: 10.1–22.7; 6 x >15). Median patient age: 17.8 years (3.8–44.8) at initial diagnosis, 33.0 (18.1–60.8) at recurrence; 8 males, 6 females; initial site: limb 13, pelvis 1; all 14 without primary distant metastases. Initial histology: HG central OS 10, HG surface OS 1, LG central OS with areas of HG dedifferentiation 1, dedifferentiated HG parosteal OS 1, LG parosteal OS 1. All had received 1st line chemotherapy (4 good, 8 poor responders, 1 primary surgery, 1?). Recurrences first detected by symptoms (8), lab (1), (?5); histology available for 13/14. Recurrences local (2, both LG above), metastatic (11) or combined (1); 1 lesion 8, >1 6. Metastases: lung (8, only: 3, all 3 involving the pleura), bone (4, only: 2); other sites (5, only: 1). Treatment of late relapse (data: 13/14): surgery 9, chemotherapy 10, radiation 2. Median follow-up from late relapse: 1.8 years (0.3–14.2) for all 14, 2.6 years (same range) for 10 survivors; 6/10 in 2nd (5) or later (1) CR, 4 with disease. 4 fatalities (2 osteosarcoma, 1 cardiomyopathy, 1 unknown cause with progressive disease).
Conclusions: OS can recur after >10 years in 1st CR. This is often detected only through symptoms and at an advanced stage. Some (bone) lesions may represent 2nd primary tumors, but other manifestations are true recurrences. Tumor directed follow-up should not be terminated prematurely.
No conflict of interest.

3837 POSTER

Doxorubicin plus dacarbazine (DD) in advanced leiomyosarcoma: A retrospective review of Gustave Roussy Institute

C. Rahal[1], J. Domont[1], O. Mir[1], S. Bonvalot[1], C. Le Pechoux[1], L. Vilcot[1], P. Terrier[1], L. Faivre[1], A. Rahal[1], A. Le Cesne[1]. *[1]Institut Gustave Roussy, Medecine, Villejuif, France*

Background: Advanced leiomyosarcomas represent a group of rare malignant chemo-resistant tumors with dismal survival. Single agent Doxorubicin remains the gold standard first line treatment in palliative setting.
Methods: Patients (Pts) with recurrent/advanced leiomyosarcoma with no prior chemotherapy were included in this retrospective review. Pts received Doxorubicin /Dacarbazine (60 mg/m^2 Day 1/450 mg/m^2 Day 1, 2 Q 3 weeks) for up to 7 cycles.
Results: Between March 2006 and January 2012, twenty two chemo-therapy naive pts (M=6, F=16), with a median age of 47 years (range 28−70) were treated with DD. Tumor grades being G1−2 (n = 10), G3 (n = 9), Gx (n = 3). Primary tumor sites included extremities (n = 4), abdomen/retroperitoneum (n = 12), uterine (n = 4), and others (n = 2).
Sixteen pts had metastases, 8 pts with more than one site. A total of 105 cycles were administered with a median number of 6 cycles (range 3−7) per pt. Best response according to RECIST criteria were PR (n = 6, 27%) with a median duration of response of 17 months (range: 8−42), disease stabilisation (SD) was achieved in further 15 subjects, resulting in a clinical benefit rate (CBR) of 95%.
Only 1 pt progressed while on chemotherapy. 4 pts underwent surgery of residual tumor after DD, 3 of those achieving anR0 resections. Major toxicities (grade 3−4) included, febrile neutropenia (n = 5), anemia (n = 2), asthenia (n = 2), and thrombocytopenia (n = 1).
The median PFS and OS for the whole population were 15.1(95% CI:10.1–16.5) and 33.9 (CI:25.3–50.1) months, respectively.
Second line therapy (Gemcitabine or Trabectedin or clinical trials) was offered to 17 pts, third line to 13, a fourth line and beyond to 12 pts.
Conclusion: DD seems to be one of the best front-line out-patient chemotherapy regimen in advanced leiomyosarcoma, with a CBR of 95% after 3 cycles with tolerable side effects. Patients achieving at least SD had a significantly prolonged PFS and OS.
Conflict of interest: *Corporate-sponsored research: honoraria: Pfizer, Novartis, Pharmamar, GSK*

3838 POSTER

Phase I and pharmacokinetic study of trabectedin in Japanese patients with soft tissue sarcoma

K. Yonemori[1], T. Ueda[2], H. Sugiura[3], A. Kawai[4], M. Ando[5]. *[1]National Cancer Center, Breast and Medical Oncology Division, Tokyo, Japan; [2]Osaka National Hospital, Department of Orthopedic Surgery, Osaka, Japan; [3]Aichi Cancer Center Hospital, Orthopedics, Aichi, Japan; [4]National Cancer Center Hospital, Division of Musculoskeletal Oncology, Tokyo, Japan; [5]National Cancer Center Hospital/Aichi Cancer Center Hospital(Current Affiliation), Breast and Medical Oncology Division/Department of Clinical Oncology(Current Affiliation), Aichi, Japan*

Background: Trabectedin is a novel anticancer agent isolated from the ascidian *Ecteinascidia turbinata*. This phase I dose-escalation study of trabectedin administered as a 24-hour continuous infusion every 21 days was performed to define the phase II recommended dose (RD) and pharmacokinetic profile in soft tissue sarcoma (STS) patients in Japan.
Materials and Methods: Patient inclusion criteria were the following: pathologically proven STS, no history of receiving more than 4 anticancer regimens, unresponsiveness or intolerability to anthracycline-containing chemotherapy regimens, age⩾18, and ECOG PS 0−1.
Patients received trabectedin as a 24-hour continuous infusion repeated every 21 days. The starting dose was 0.9 mg/m^2 with escalation to

1.2 mg/m^2 and then to 1.5 mg/m^2 using a '3 + 3' cohort expansion design. Plasma samples were collected in the first cycle from all patients for pharmacokinetic analysis.
Results: Fifteen patients received one of three dose levels of trabectedin: 0.9, 1.2 and 1.5 mg/m^2. DLTs were not observed up to 1.2 mg/m^2; however 2 out of 3 patients experienced DLT at 1.5 mg/m^2. Observed DLT toxicities were Grade 4 CPK increased, Grade 3 anorexia and Grade 4 thrombocytopenia. Grade 3/4 adverse events (AEs) that occurred with high incidence included ALT increased, AST increased, and neutropenia. Frequency and severity of AEs were clearly higher at 1.5 mg/m^2 than at lower doses. With the pharmacokinetic analysis of trabectedin in Japanese patients, it was expected that the area under the concentration-time curve at 1.2 mg/m^2 was sufficient to show antitumor activity. Partial response (PR) to trabectedin was observed in 3 out of 9 patients at 1.2 mg/m^2 by RECIST. These 3 PR patients (1 Myxoid liposarcoma, 1 Synovial sarcoma, 1 Extraskeletal Ewing sarcoma) were diagnosed as translocation-related sarcomas (TRS). Progression-free rate 12 weeks was 80.0% (12 of 15 patients).
Conclusions: In Japanese STS patients, 1.5 mg/m^2 was the maximum tolerated dose and 1.2 mg/m^2 the RD. In consideration of the pharmacokinetic and efficacy results promising efficacy and tolerability was expected especially in TRS patients.
A randomized, controlled phase II study of trabectedin versus best supportive care (BSC) in TRS patients is ongoing to evaluate the Progression free survival benefit of trabectedin.
Conflict of interest: *Corporate-sponsored research: This phase I clinical study is sponsored by TAIHO Pharmaceutical Co.,LTD.*

3839 POSTER

Soft tissue sarcoma treatment: Results from the drug shortage era

M. Salamoon[1], T. Hussein[2], F. Ahmad[3], M. Daghlawi[3], M. Nassar[3], A. Mahmoud[4], M. Bachour[5]. *[1]Bairouni University Hospital, Damascus, Syria; [2]Tishreen Hospital, Pathology, Damascus, Syria; [3]Bairouni University Hospital, Pathology, Damascus, Syria; [4]Bairouni University Hospital, Soft Tissue Sarcoma Department, Damascus, Syria; [5]Bairouni University Hospital, Medical Oncology Department, Damascus, Syria*

Background: Soft tissue sarcomas are mesodermal malignancies affecting trunk, extremities and abdomen. As a group, it is treated by surgery whenever it is possible; otherwise, chemotherapy is applied using a combination of ifosfamide and anthracyclines.
Objective: The objective of this study was to evaluate the impact of drug shortage (anthracyclines in our study) on response rate especially in locally advanced and metastatic disease.
Material and Methods: The study was done at Al Bairouni University Hospital in Damascus (SYRIA). In 2012, there was a shortage of doxorubicine, therefore the former agent was replaced by cisplatin in combination with ifosfamide. The new combination was: ifosfamide 2gr/m^2 $\times$ 3 days + cisplatin 35 mg/m^2 X 3 days with G-csf support given for 3 cycles every 21 days. The former combination was employed for both neoadjuvant setting and metastatic disease. Patients were evaluated by means of CT-Scan, MRI and physical exam.
Results and discussion: 236 patients were included in the study, 87 patients of which presented with metastatic disease (pulmonary, osseous and abdominal). Evaluation after 3 cycles revealed a complete response in 62 out of 87 (71%) with a P.value of 0.72, while only 34 out of 149 (22%) became resectable after neoadjuvant chemotherapy with a P.value of 0.87.
Conclusions: Results showed that the new combination of ifosfamide and cisplatin seems to be a good choice in metastatic soft tissue sarcomas even a larger number of patients is needed to confirm such results. However, the same combination showed to have a poor efficacy on locally advanced soft tissue sarcomas raising the issue of drug shortage as a negative factor on such disease. Furthermore, this study should alert health professional worldwide to the risk lying behind drug shortage in developing countries and to some extent in developed ones and its negative impact on cancer treatment.
No conflict of interest.

	Patients	Responders	P-value
Neoadjuvant	149	34	0.87
Metastatic	87	62	0.72

3840 POSTER

LOGIST − A Local Observational GIST registry: First interim analysis after a mean observation time of 14.3 months. A non-interventional registry to observe patients with gastrointestinal stroma tumours (GIST) after R0/R1 resection − with or without adjuvant therapy with imatinib (CSTI571BDE77)

P. Reichardt[1], P. Stübs[2], J. Fahlke[3], U. Stölzel[4], D. Quietzsch[4], A. Pustowka[5], A. Reichardt[6], K. Krajinovic[7]. *[1]HELIOS Klinikum Berlin-Buch, Sarkomzentrum Berlin-Brandenburg, Berlin, Germany; [2]Otto-von-Guericke Universität Magdeburg, Universitätsklinikum Magdeburg Klinik für Allgem.Viszeral- u. Gefäßchirurgie, Magdeburg, Germany; [3]Johanniter-Krankenhaus, Klinik für Allgemeine Chirurgie, Stendal, Germany; [4]Klinikum Chemnitz gGmbH, Klinik für Innere Medizin II, Chemnitz, Germany; [5]Novartis Pharma GmbH, Oncology, Nürnberg, Germany; [6]HELIOS Klinikum Berlin-Buch, Klinik für Interdisziplinäre Onkologie, Berlin, Germany; [7]Julius-Maximilians-Universität Würzburg, Universitätsklinikum Würzburg Klinik für Allgem.- Viszeral Gefäß-und Kinderchirurgie, Würzburg, Germany*

Background: Management of GIST is complex and quickly evolving. The SSG XVIII/AIO Phase-III-study on adjuvant therapy of GIST showed significant benefit for patients after a treatment phase of 36 months compared to 12 months (Joensuu et al., 2011). The objective of the LOGIST registry is the long-term evaluation of trends regarding approaches in diagnosis, therapy and outcome of GIST patients.
Methods: Up to 400 non-metastatic GIST patients after R0/R1 resection with or without adjuvant imatinib therapy are followed up for a duration of 60 months or until progression. Documentation is based on local routine. Patient- and center specific data are summarized descriptively and analyzed epidemiologically.
Results: 215 patients with a median follow up of 14.3 months were included in the first interim analysis. For 199 patients GIST was the primary diagnosis. Most GIST were localized in the stomach (64%) or small intestine (23%). In 12.6% of the patients the tumour size was <2 cm, 39.5% had a tumour size >2 cm and $\leqslant$5 cm, 33.5% >5 cm and $\leqslant$10 cm, in 14.4% a tumour >10 cm was found. R0 resection was achieved in 94.4% of the patients. Based on Fletcher and/or Miettinen, 5.1% of all patients had no risk of relapse, 47.2% of patients had a very low or low risk, while 47.1% had an intermediate or high risk. Mutation analysis was obtained for 61.4% of patients. In most cases, c-Kit and PDGFRa mutations (68.2 and 18.2%) were detected.
Of 98 patients with a follow up of $\geqslant$1 year, a mutation analysis was obtained for 71 and 50 were treated with imatinib. Presence of a c-Kit mutation resulted in an imatinib treatment more frequently compared to no therapy (78.4% vs. 52.9%). A risk classification was performed for 90 patients. Of those patients who received imatinib 37.0% had intermediate and 52.0% had high risk of relapse. 2 high risk patients (4.5%) did not receive imatinib, while 5 low or very low risk patients were treated with imatinib.
Dose modifications or treatment interruptions occurred predominantly due to toxicities in 14 cases. Severe adverse events (SAEs) ocurred in 10.6% of patients, however, the number of SAEs was reduced to 1.5% by case-based analysis. A causality between imatinib intake and an SAE (grade 1−2) was found only in one 1 case.
Conclusion: This first interim analysis shows that patients with an intermediate or high risk of relapse according to Fletcher/Miettinen method and a c-Kit mutation are treated with imatinib in accordance with current guidelines.
Conflict of interest: *Advisory board: Novartis. Corporate-sponsored research: Novartis*

3841 POSTER

Symptoms and health related Quality of Life in patients receiving first line palliative chemotherapy for advanced Soft tissue sarcoma: a longitudinal study

N.J. Gough[1], J.R. Ross[1], J. Koffman[2], K. Khabra[3], J. Riley[1], I. Judson[4]. *[1]Royal Marsden Hospital, Palliative Care, London, United Kingdom; [2]King's College London Cicely Saunders Institute, Department of Palliative Care Policy and Rehabilitation, London, United Kingdom; [3]Royal Marsden Hospital, Statistics, London, United Kingdom; [4]Royal Marsden Hospital, Sarcoma, London, United Kingdom*

Background: The main aims of systemic chemotherapy in advanced soft tissue sarcoma (STS) are to increase overall survival and palliate i.e. control symptoms and maintain or improve health related quality of life (HRQoL). There is little evidence demonstrating survival benefit.
Aim: To examine HRQoL and symptom change over time among people living with advanced STS in receipt of first line palliative chemotherapy.
Methods: Forty-one consecutive patients were recruited and followed up at baseline, 2, 6, 12, and 18 weeks post chemotherapy using the

EORTC-QLQ-C30 questionnaire. The 6-week (post 2 cycle) primary end point was considered the earliest time a patient may derive benefit: questionnaires were completed prior to the scheduled 6-week CT scan. Patients not reaching the primary end point had their 2-week results carried forward. The proportion of patients with a clinically significant change (+/− 10 /100 point scale) in overall HRQoL score was calculated. The changes in mean functional and symptom scores were also calculated. An exploratory analysis comparing radiological responders (stable disease or partial response by RECIST) at 6 weeks to those who progressed was also conducted.
Results: 30/41 (73%) patients reached the 6-week primary end point with 11 progressing on CT performed early due to clinical deterioration. 8 patients (19%: 95% CI: 10−34%) experienced a 6-week clinically significant improvement in overall HRQoL,13 (32%: CI: 19−47) experienced no change and 20 (49%: CI: 34−64) a significant reduction.
The mean overall HRQoL score (n = 41) declined at 6 weeks with both clinical and statistical significance (mean ±SD reduction: 10.2±24.1 points, p = 0.01).
Symptomatically fatigue worsened (11.1±28.3, p = 0.02)?? Sleep disturbance improved (14.6±30.8, p = 0.004) possibly related to an improvement in pain (9.4±29.1, p = 0.046). There were no changes in functional scales. At 6-weeks, there was a clinical improvement in pain and sleep disturbance in the radiological responders (n = 25) but a deterioration in fatigue. In the non-responders (n = 16) overall HRQoL and diarrhoea clinically worsened. Only sleep disturbance showed statistical difference between the groups. There was no correlation with scan result and overall HRQoL change.
Conclusion: At 6-weeks after 2 cycles of palliative chemotherapy, HRQoL and fatigue deteriorate. However, pain and sleep disturbance improve enhancing the patient experience.
No conflict of interest.

3842 POSTER

Treatment of synovial sarcoma with high dose ifosfamide: A retrospective single center analysis

V. Fonseca De Jesus[1], M. Santos Alves[1], P. Schettini Iennaco[1], U. Ribaldo Nicolau[1]. *[1]Hospital AC Camargo, Clinical Oncology, São Paulo SP, Brazil*

Background: Synovial sarcoma is a rare neoplasm, accounting for 5−10% of all adult soft-tissue sarcomas. Previous studies have shown this histology to be especially sensitive to ifosfamide in a dose-dependent manner. We sought to analyse the outcome of patients with synovial sarcoma treated with high dose ifosfamide (HDIFO) at our institution.
Material and Methods: Between 2008 and 2013, 17 patients were identified in our database as been treated with HDIFO for synovial sarcoma. Information regarding clinical features, efficacy and toxicity could be retrieved from charts of 13 of those patients. They were treated in both neoadjuvant and metastatic setting with doses ranging from 12 to 15.2 g/m^2/cycle every 3 weeks.
Results: Median age was 32 years (range: 21−59). Seven patients were males and 6 were females. All of them had a diagnosis of synovial sarcoma established by a pathologist with sarcoma expertise. Seven patients had primary extremity tumors. Ten patients had metastatic disease at onset of cycle one of high dose ifosfamide. The remaining three patients were treated in the neoadjuvant setting. All patients with metastatic disease had already been exposed to a combination of anthracycline and standard dose ifosfamide. A median of 3 cycles (range: 2−8) were administered. Chemotherapy cycle delays were observed for a median of 1 cycle per patient.
Chemotherapy dose reduction was necessary in 6 patients. Seven patients received HDIFO through continuous infusion regimens and 6 patients through a bolus infusion regimen. All were treated with prophylactic G-CSF. Nine patients were treated with methylene blue starting prophylactically on the first cycle. Grade 3−4 hematological toxicity was observed in 11 out of 13 of patients, mostly anemia and leukopenia. Ten patients experienced febrile neutropenia (only one case of life-threatening febrile neutropenia). Fanconi syndrome, G3−4 acute renal failure and persistent G2−4 renal function loss were observed, each one of them, in 3 patients. Three patients experienced G3−4 non-hematological non-renal toxicity (2 cases of G3 encephalopathy). There were no treatment related deaths. After a median of 2 cycles, a radiological response rate of 53% (all partial responses) was recorded. Subjective clinical benefit was observed in 84% of patients. Median duration of response for the 9 (one still on treatment) patients with metastatic disease who had completed treatment with HDIFO was 143 days (range: 0–255 days). Median progression free survival for the same patients was 193 days (range: 56–287 days). Median overall survival among patients treated for metastatic disease was 450 days (range: 137–717 days). All 3 patients treated with neoadjuvant HDIFO with curative intent remain disease free at 733, 819 and 906 days of follow up.
Conclusions: HDIFO seems to be a highly active regimen in patients with synovial sarcoma. However it must be emphasized the relevant toxicity attributed to this regimen, with an elevated incidence of grade 3 or higher adverse events.
No conflict of interest.

3843 POSTER

Neutrophil to Lymphocyte Ratio (NLR) as predictive factor in patients with metastatic soft tissue sarcoma (STS) treated with trabectedin (T)

R. De Sanctis[1], V. Quagliuolo[2], A. Viganò[3], A. Bertuzzi[4], F.R. Lutman[5], S. Marchetti[1], P.A. Zucali[1], A. Santoro[1]. *[1]Humanitas Cancer Center, Medical Oncology, Milan, Italy; [2]Humanitas Cancer Center, Surgical Oncology, Milan, Italy; [3]"Sapienza" University, Morphometry and Dynamics Laboratory, Rome, Italy; [4]St Vincent's University Hospital, Medical Oncology, Dublin, Ireland; [5]Humanitas Cancer Center, Radiology, Milan, Italy*

Background: Recent data indicate that tumour microenvironment, which is influenced by inflammatory cells and mediators, has a crucial role in cancer progression and clinical outcome of patients with several cancer type (i.e., STS, colorectal and breast neoplasms). In the present study, we investigated the predictive value of basal NLR in metastatic STS patients treated with T.
Material and Methods: Since March 2008 through April 2013, 51 pts with advanced anthracycline-pretreated STS received T at a dose of 1.5 mg/m^2 every 3 weeks by continuous 24 h infusion. Best response rate was evaluated according to RECIST criteria and basal NLR (before the first trabectedin cycle) as well as demographics, clinical and histopathological data were analyzed. Patients were divided in two subgroups according to a NLR cut-off $\geqslant$3. Clinical results were considered positive if patient had disease control, ie complete response (CR), partial response (PR) or stable disease (SD) vs. negative in the presence of progressive disease (PD). Fisher's test was used to compare relative frequency of positive vs. negative results in the two subgroups.
Results: Median age was 46 years (range, 20−61) with a median ECOG PS of 0. The median number of previous chemotherapy regimens was 1 (range, 0−5). Median number of T cycles was 2 (range 1−6). 44/51 (86%) pts were evaluable for response: positive results were achieved in 22 pts (6 pts (13%) PR and 16 (36%)SD) while negative results were obtained in 22 pts. Basal NLR $\geqslant$3 was significantly associated to a double risk of progressive disease ($p < 0.03$), while the association between NLR inferior to 3 and objective responses is not clearly defined.
Conclusions: Our findings suggest that an elevated NLR ratio may serve as a cost-effective, negative predictive factor in metastatic STS patients undergoing trabectedin.
No conflict of interest.

A retrospective analysis of trabectidin infusion in an outpatient setting by peripherally inserted central venous catheters (PICC): a multicentric Italian experience

F. Martella[1], V. Salutari[2], C. Marchetti[3], C. Pisano[4], M. Di Napoli[4], F. Pietta[5], D. Centineo[1], A. Caringella[6], A. Musella[3], L. Fioretto[1]. *[1]Azienda Sanitaria Firenze − Istituto Toscano Tumori, Dipartimento Oncologico − Struttura Complessa Oncologia, Firenze, Italy; [2]Policlinio Gemelli − Università Cattolica, Gineologia Oncologica, Roma, Italy; [3]Policlinio Umberto I − Università Sapienza, Dipartimento di Scienze Ginecologico-ostetriche e scienze urologiche, Roma, Italy; [4]Istituto Nazionale Tumori, Dipartimento Uroginecologico − Oncologia Medica, Napoli, Italy; [5]Azienda Ospedaliero-Universitaria, Policlinico, Modena, Italy; [6]Azienda Ospedaliera, Policlinico Universitario, Bari, Italy*

Background: Trabectidin (T) is approved as a 24-h intravenous infusion for patients (pts) with advanced sarcomas and, in association with pegilated doxorubicin, for pts with ovarian partially-sensitive cancer. A central venous line is highly recommended for T administration. Central venous catheters (CVC) provide many benefits for pts, but they also put them at risk of catheter-related complication and have a significant budget impact for oncology department. The most frequently used CVC are subcutaneously implanted PORT-chamber catheters (PORT), while peripherally inserted central venous catheters (PICC) are relatively new. PICC are of special interest in the outpatient setting, mainly when a poor survival is expected. In recent years, oncology departments all over Italy have been supporting the development of a nurses' team for PICC management.
Methods: Between November 2009 and March 2013, T became available in Italy. We reviewed the data of T treated pts to evaluate the cost efficient ratio between the use of PORT and PICC in 6 italian centers.
Results: 102 pts received T, 20 for advanced sarcoma, 2 for cervical cancer and 80 for ovarian cancer. Median age was 55 years (range,

31−78). In 45 pts T was infused by a PICC, inserted by trained nurses with an ultrasound-guided technique at the bed-side, while in 57 pts a PORT, requiring a day surgery procedure in the hospital by a surgeon, was used. Device's dislocations and infections were reported in 4 pts, equally distribute between pts with PORT or PICC. Thrombosis occurred only in a single pt with a PORT. Complications requiring devices removal were not reported during any of the 509 cycles of therapy (median 5, range 1−20). Nor PICC misplacement nor early malfunctions were experienced during T infusion. These data are in line with Azienda Sanitaria Firenze-oncology department experience with nearly 500 PICC inserted since 2009, with misplacement occurring in 5% of pts with only 0.5% needing removal, and rare major complications (8%). Based on budget data, cost efficient ratio favor PORT over PICC but only when the device is used for more than 1 years. Pts showed a good acceptance of PICC, but data on quality of life have not been specifically collected.
Conclusions: Our data suggest that T infusion by PICC in an outpatient setting is safe and well accepted. PICC showed a preferable cost efficient ratio than PORT in pts requiring a short standing of the device.
No conflict of interest.

Systemic palliative treatment of patients with inoperable/metastatic L-sarcomas (liposarcoma and leiomyosarcoma)

H. Kosela[1], K. Wiater[1], A. Klimczak[1], T. Switaj[1], S. Falkowski[1], P. Rutkowski[1]. [1]*Maria Sklodowska-Curie Memorial Cancer, Soft Tissue and Bone Sarcoma and Melanoma, Warsaw, Poland*

Background: The current outcomes of systemic palliative therapy in metastatic soft tissue sarcomas (STS) are still poor with median overall survival (OS) about 12 months. We conducted a retrospective analysis of inoperable/metastatic L-sarcoma patients treated in one tertiary center.
Material and Methods: One hundred twelve patients (48 women, 58 men; median age 50 years) with diagnosis of inoperable/metastatic leiomyosarcoma LMS (67 patients), liposarcoma LPS (45 patients) were treated between 1997 and 2010. The most common primary localization of the tumor were extremities. 28 patients at the time of the first visit in our center had a diagnosis of metastatic disease.
Results: The most common site of metastatic disease were lungs. 56 patients had three or more lines of chemotherapy. 71 patients had the first line of chemotherapy based on doxorubicin. 29 patients (26%) underwent a metastasectomy. At the time of the analysis 85 patients (75%) died because of the disease. The median OS from the time of the diagnosis of inoperable/metastatic disease was 23 months (26 months for LMS, 18 for LPS, $p = 0.7$). For the patients who underwent metastasectomy OS was 30 months. Approximately 67% and 45% of patients lived more than one and two years, respectively. Progression-free survival on the 1st line chemotherapy was 6 months, and on the 2nd line 3 months. The clinical benefit of the 1st line chemotherapy (complete, partial regression or stable disease >3 months) was observed in 58 patients (51%).
Conclusions: The patients with advanced L-sarcomas have still poor prognosis, although the use of chemotherapy demonstrated clinical benefit in substantial group of patients. Surgical resection of the metastases is related to prolonged survival but is feasible in a small percentage of them.
No conflict of interest.

Efficacy of trabectedin for advanced soft tissue sarcoma: A retrospective single center analysis

J. Martinez Trufero[1], I.P. Isabel Pajares[1], A.H. Alba Hernandez[1], A.C. Ana Cebollero[1], L.C. Lourdes Calera[1], A.A. Antonio Antón[1]. [1]*Hospital Universitario Miguel Servet, Servicio de Oncología Médica, Zaragoza, Spain*

Background: Trabectedin (Yondelis®) is the first marine-derived anti-neoplastic drug approved in Europe for the treatment of patients with recurrent advanced soft tissue sarcoma (ASTS) or for patients unsuited to receive anthracyclines and ifosfamide. In this study the patients with ASTS treated with trabectedin from Nov. 2006 to April 2012 were retrospectively analyzed.
Methods: Trabectedin was given at the approved dose of 1.5 mg/m^2 as a 24-h infusion every 3 weeks. An analysis of response rate, time to progression (TTP) and overall survival (OS) and univariate analyses of prognostic factors were performed.
Results: Overall, 39 patients (24 men) with mostly high-grade ($n = 29$) ASTS with a median age of 57 years (range 20−81) were included in the analysis. Most had L-type sarcoma (leiomyosarcoma $n = 10$; liposarcoma $n = 3$), undifferentiated pleomorphic sarcoma ($n = 11$), sarcoma not otherwise specified ($n = 5$), or synovial sarcoma ($n = 2$). Eight had one of 6 very rare sarcomas. At baseline patients had metastatic ($n = 21$), bulky ($n = 4$) or metastatic/bulky ($n = 14$) disease and were pretreated with a median of 2 prior chemotherapy lines (range: 0−3; 4 patients received adjuvant chemotherapy only), including anthracycline-based chemotherapy ($n = 30$), gemcitabine plus dacarbazine (GEM-DTIC; $n = 18$), other ($n = 20$). Patients received a median of 4 trabectedin cycles (range 1−34). Among 37 evaluable patients best responses as per RECIST were partial response (PR, $n = 7$), stable disease (SD >3 months, $n = 9$, 5 had SD >6 months) and disease progression ($n = 19$), while 5 patients had a decrease in tumor density. Responses to trabectedin and GEM-DTIC did not exclude responses to the other regimen suggesting the feasibility of sequential treatment. After a median follow-up of 9.37 months, median TTP and OS were 4.4 months (95% CI: 3.5−5.4) and 9.7 months (95% CI: 4.5–14.9), respectively. Univariate analyses identified low/medium-grade STS and growth modulation index >1.13 as independent favorable prognostic factors for TTP, and retroperitoneal/visceral localization, L-type and rare STS and low/medium-grade STS for OS.
Conclusions: The results of this real-life retrospective analysis confirmed the findings of previous trials showing that trabectedin is active drug for ASTS.
No conflict of interest.

The value of high-dose chemotherapy with autologous stem cell transplantation in relapsed Ewing sarcoma patients

M. Rasper[1], S. Jabar[1], A. Ranft[1], U. Dirksen[1], H. Jürgens[1]. [1]*University Hospital, Pediatric Hematology and Oncology, Münster, Germany*

Background: The prognosis of patients (pts) with relapsed Ewing sarcoma (ES) is poor with a 5-year overall survival (OS) of 13%. We analyzed the value of high-dose chemotherapy (HDtx) with autologous stem cell transplantation and conventional chemotherapy (CHtx) in relapsed ES.
Material and Methods: Data from 239 pts with first relapse of ES registered during 2000–2011 in the ES relapse registry of the Cooperative Ewing Sarcoma Study Group (CESS) were analyzed. Patients were treated first line according to cooperative Ewing sarcoma phase III protocols.
Results: 200 of 239 pts received various non-HDtx second-line CHtx regimens, 73 pts had HDtx followed by autologous stem cell rescue. Among those 73 pts, 15 received busulfan–melphalan (bu-mel), 38, treosulfan-melphalan (treo-mel) and 20, other regimens. The 2-year event-free survival (EFS) was 10% in pts treated without HDtx, 47% in pts treated with bu-mel, and 44% in pts treated with treo-mel HDtx. In a second step, we focused on those pts with partial or complete remission (PR/CR) after 4−6 cycles of second-line CHtx ($n = 68$). In this cohort, the 2-year EFS were 44% with HDtx compared to 31% without HDtx ($p = 0.093$). The multivariate analysis revealed HDtx treatment, with a risk ratio (RR) of 0.35 (95% CI 0.17–0.71), and early relapse, with a RR of 4.76 (95% CI 2.31–9.78), as independent prognostic factors for EFS.
Conclusions: Patients with relapse Ewing sarcoma responded to second line chemotherapy appear to benefit from consolidation with high-dose chemotherapy and autologous stem cell transplantation.
No conflict of interest.

A new therapeutic combination in sarcomas: RG7112, a small-molecule inhibitor of MDM2, enhances trabectedin response

A. Obrador-Hevia[1], S. Calabuig-Fariñas[1], R. Ramos[1], R. Alemany[2], J. Martín[1]. [1]*Hospital Universitari Son Espases, Clinical and Translational Oncology, Palma de Mallorca, Spain;* [2]*Universitat de les Illes Balears, Clinical and Translational Oncology, Palma de Mallorca, Spain*

Background: The objective of this study was to evaluate the antitumor efficacy of Trabectedin in combination with MDM2 inhibitors in several sarcoma cell lines, representing two different histologic subtypes of sarcomas, both aggressive and chemoresistant. MDM2 is a critical negative regulator of the p53 tumor suppressor protein. Nutlin-3A and the novel compound from the Nutlin series, RG7112, are small-molecule MDM2 inhibitors that fill the p53-binding pocket on MDM2. RG7112 is now under phase I trials in patients with hematologic neoplasms and advanced solid tumors.
Materials and Methods: Using 6 human sarcoma cell lines (2 fibrosarcomas and 4 liposarcomas), the antitumor effects of Trabectedin, Nutlin-3A and RG7112 as single agents or in combination were examined *in vitro*. Cell viability (Cell Titer Cell Proliferation Assay) and cell cycle analysis (FACS) were performed. Changes in cell growth and viability were Real Time monitored using the xCELLigence System. Apoptosis induction as means of Caspase 3 and 7 activity was also measured (Caspaser-Glo 3/7 Assay).
Results: Trabectedin (0.01−5 nM) showed significant antitumor activity in all sarcoma cell lines studied. We used two different MDM2 inhibitors,

Nutlin-3A and RG7112 (0.01−50 μM), to treat cells in combination with the standard therapeutic agent in sarcomas, Trabectedin. When comparing Nutlin-3A and RG7112, the novel drug RG7112 was more potent in inhibiting cell proliferation and inducing cell cycle changes than Nutlin-3A, especially in those cell lines harbouring wild type p53. We therefore studied the combination of RG7112 with Trabectedin in a well-differentiated liposarcoma (WDLS) cell line that has amplified MDM2 and wild type p53 (93T449), which was the scenario with a better potential response. The results were compared to those obtained with a liposarcoma cell line with mutated p53 (SW872). Using drug concentrations that did not have a great *in vitro* effect in both liposarcoma cell lines when used alone, RG7112 (2.5 μM) in combination with (0.01−5 nM) significantly increased the antitumor response compared to Trabectedin alone in liposarcoma 93T449 cells, exhibiting a moderate effect in liposarcoma SW872 cells.
Conclusion: Our results demonstrated that Trabectedin in combination with the novel MDM2 inhibitor, RG7112, represents a promising new therapeutic strategy for the treatment of sarcomas with amplified MDM2.
No conflict of interest.

3849 POSTER

Inhibitory effect of Yangzheng Xiaoji on the ARK/Aurora pathways and in vivo tumour growth of human osteosarcoma

W. Jiang[1], L. Ye[2], K. Ji[2], F. Ruge[2], P.H. Sun[2], J.F. Ji[3], Y. Gao[4], Y.L. Wu[4], M.D. Mason[5]. *[1]Cardiff University, Wales College of Medicine Metastasis and Angiogenesis Research Group, Cardiff, United Kingdom; [2]Cardiff University, School of Medicine, Cardiff, United Kingdom; [3]Peking University, Cancer Hospital, Beijing, China; [4]Yiling Medical Research Institute, Department of Research, Shijiazhang, China; [5]Cardiff Univesity, School of Medicine, Cardiff, United Kingdom*

Background: *Yangzheng Xiaoji* (*YZXJ*) is a traditional Chinese medicinal formula and in the past few years has been used for treating patients with certain solid tumours including primary liver cancer, gastric and lung cancer. The treatment has survival benefit and improve the quality of life of the patients. In a recent study, we have identified that osteosarcoma is one of the tumour types that are highly sensitive to *Yangzheng Xiaoji.* In the present study, we tested the potential effects of *YZXJ* on cellular functions including migration, adhesion and *in vivo* growth on human osteosarcoma and explored the impact on the ARK/Aurora signalling pathway.
Materials and Methods: Human osteosarcoma cell line, MG63 was used. A *YZXJ* extract, named DME25 was prepared from *Yangzheng Xiaoji.* Cell migration, cell adhesion and cell growth was tested *in vitro* respective cellular models. The effect of DME25 on the *in vivo* growth was evaluated using a tumour xenograft model. ARK1 (Aurora-A) and ARK2 (Aurora-B) were evaluated in cells and tumours by immunofluorescent methods.
Results: Using a traditional cell-matrix assay and electric cell-substrate impedance sensing assay (ECIS), it was found that DME25 had a significant effect on the cell-matrix adhesion and cellular migration of MG63 cells. This effect was further strengthened when an ARK2/Aurora-B inhibitor was used together with DME25 in the system. DME25 had little effects on the *in vitro* growth of MG63 cells. Using an athymic mouse tumour model, it was demonstrated that DME25, given orally and intraperitoneally, significantly inhibited the tumour growth of osteosarcoma. It is noteworthy that DME25 also increased the sensitivity of the tumours to ARK2/Aurora-B inhibitor. Treatment of MG63 and tumour bearing mice markedly inhibited the phosphorylation of the ARK proteins.
Conclusions: *Yangzheng Xiaoji* has a profound effect on the adhesion and migration of osteosarcoma cells. It also has an anti-tumour growth effect. The ARK/Aurora pathway is a key pathway targeted by *Yangzheng Xiaoji*.
