MOLECULAR INTELLIGENCE™

Evidence-Guided Tumour Profiling Services

EQUIPPED WITH
NEXT-GENERATION SEQUENCING

Decode each patient's tumour – individualise cancer treatment.

- Provides a rationale for making your next treatment decision
- Helps determine which drugs to avoid
- Identifies therapies which may not have been considered

HELPING YOU INDIVIDUALISE THERAPY DECISIONS FOR YOUR PATIENT

For example when:

- Choosing amongst standards treatments
- Standard treatments are not enough
- Faced with rare or aggressive tumours

Integrate

Streamline

Optimize

Be Integrated

ARIA® Oncology Information System

ARIA is a comprehensive information system and image management solution that addresses the clinical, administrative, and imaging needs of the oncology department. ARIA forms the foundation of Varian's integrated oncology environment and streamlines the workflow in the department. Its full integration with the Eclipse™ treatment planning system eliminates redundant data entry, and makes the treatment process faster and easier by providing a single user interface. ARIA v11 allows for automatic task assignments, checklist support and customizable user home screens.

With ARIA you can leverage the power of technology to assist you in providing quality and personalized care for each of your patients.

European Journal of Cancer

including EJC Supplements

Aims and Scope

The *European Journal of Cancer* (*including EJC Supplements*) is an international multidisciplinary oncology journal that publishes original research, editorial comments, review articles and news on basic and preclinical research, clinical oncology (medical, paediatric, radiation, surgical), translational oncology and on cancer epidemiology and prevention.

For a full and complete Guide for Authors, please go to http://www.ejcancer.com

Publishing & Advertising Offices: Elsevier Ltd, The Boulevard, Langford Lane, Kidlington, Oxford OX5 1GB, UK. (01865 843000).

Advertising information. Peer Review Policy for the *European Journal of Cancer (EJC)*

The practice of peer review is to ensure that only good science is published. It is an objective process at the heart of good scholarly publishing and is carried out by all reputable scientific journals. Our reviewers therefore play a vital role in maintaining the high standards of the *European Journal of Cancer (EJC)* and all manuscripts are peer reviewed following the procedure outlined below.

Initial manuscript evaluation

The Editors first evaluate all manuscripts. In some circumstances it is entirely feasible for an exceptional manuscript to be accepted at this stage. Those rejected at this stage are insufficiently original, have serious scientific flaws, have poor grammar or English language, or are outside the aims and scope of the journal. Those that meet the minimum criteria are passed on to experts for review.

Authors of manuscripts rejected at this stage will be informed within 2 weeks of receipt.

Type of Peer Review

The *EJC* employs single blind review, where the reviewer remains anonymous to the authors throughout the process.

How the reviewer is selected

Reviewers are matched to the paper according to their expertise. Our reviewer database contains reviewer contact details together with their subject areas of interest, and this is constantly being updated.

Reviewer reports

Reviewers are asked to evaluate whether the manuscript:

- Is original
- Is methodologically sound
- Follows appropriate ethical guidelines
- Has results which are clearly presented and support the conclusions
- Correctly references previous relevant work

Reviewers are not expected to correct or copyedit manuscripts. Language correction is not part of the peer review process. Reviewers are requested to refrain from giving their personal opinion in the "Reviewer blind comments to Author" section of their review on whether or not the paper should be published. Personal opinions can be expressed in the "Reviewer confidential comments to Editor" section.

How long does the peer review process take?

Typically the manuscript will be reviewed within 2-8 weeks. Should the reviewers' reports contradict one another or a report is unnecessarily delayed a further expert opinion will be sought. Revised manuscripts are usually returned to the Editors within 3 weeks and the Editors may request further advice from the reviewers at this time. The Editors may request more than one revision of a manuscript.

Final report

A final decision to accept or reject the manuscript will be sent to the author along with any recommendations made by the reviewers, and may include verbatim comments by the reviewers.

Editor's Decision is final

Reviewers advise the Editors, who are responsible for the final decision to accept or reject the article.

Special Issues / Conference Proceedings

Special issues and/or conference proceedings may have different peer review procedures involving, for example, Guest Editors, conference organisers or scientific committees. Authors contributing to these projects may receive full details of the peer review process on request from the editorial office.

Becoming a Reviewer for the *EJC*

If you are not currently a reviewer for the *EJC* but would like to be considered as a reviewer for this Journal, please contact the editorial office by e-mail at ejcancer@elsevier.com, and provide your contact details. If your request is approved and you are added to the online reviewer database you will receive a confirmatory email, asking you to add details on your field of expertise, in the format of subject classifications.

We see
people before patients

Cancer supportive care may significantly increase quality of life in patients specifically addressing the most dreaded consequences and complications of cancer and anticancer treatment, including pain, emesis, and cachexia. We do research on cancer supportive care. We work not just for the health of the patient, but for the quality of life of the Person.

WHERE CAN I GET THE HELP I NEED?

If you have advanced or metastatic breast cancer, go to advancedbreastcancercommunity.org.

There's a lot on your mind, whether you're newly diagnosed or have been living with your disease for a while. You have decisions to make, options to consider. But your breast cancer is not early stage cancer, and you may not be able to find help in the usual places. You have your doctors, but you need other support too. So where can you turn?

You'll find the information and inspiration you're looking for at advancedbreastcancercommunity.org. It's a place where you can be counted, a place that helps bring much-needed awareness to metastatic breast cancer and those living with this disease.

COUNT Us — Sign up and join the others who have already been counted

KNOW Us — Learn important information about metastatic disease

Astellas has made a commitment to change tomorrow – a commitment that we are bringing to the field of oncology. We aim to create innovative treatments that will genuinely improve the lives of cancer patients. To do this we are focusing our R&D and partnership efforts into precision medicine that will create first-in-class or best-in-class programmes. This has resulted in no fewer than 12 separate therapies under clinical development into conditions including prostate cancer, other solid tumours like pancreatic cancer, breast cancer and advanced renal cell carcinoma, as well as haematological malignancies.

These are the challenges we have set ourselves because CHANGING TOMORROW is more than just words – it is what we must do to give cancer patients real hope of a tomorrow worth looking forward to.

Limitation and Indication of Minimally Invasive Surgery for Gastric Cancer

1 INVITED

Limitation and indication of minimally invasive surgery for gastric cancer

K. Maruyama[1]. [1]*University of Health and Welfare Sanno Hospital, Department of Surgical Oncology, Tokyo, Japan*

Early stage gastric cancer is remarkably increasing by development of diagnostic methods and mass-screening system. Proportion of Stage-I cancer increased from 22.5% (1963–66) to 57.3% (2008) in Japanese Nationwide Registry.
According to the increase of early stage cancer and demand for high quality of life, the surgical treatment was shifted from "high radicality" to "minimally invasive surgery with enough curability, high safety, and high quality of life". Such attitude leads to wide variation of the surgical treatments as follows. Intention of "endoscopic mucosal resection" and "endoscopic submucosal dissection" is to avoid disadvantages and risks of gastric resection and to get quick recovery. The indication is for a cancer with definitely no node metastasis. The requirements are a) mucosal cancer, b) no ulcer scar and elevated or flat lesion, c) 2.0 cm or less in diameter, c) well or moderately differentiated carcinoma. Accurate preoperative diagnosis is essential. And we never hesitate to shift gastric resection if the requirements are not met. Intention of "laparoscopic resection" is to avoid disadvantages and risks of open gastric resection and to get quick recovery and cosmetic advantage. This procedure includes "laparoscopic wedge resection", "laparoscopic resection", and "robotic surgery". The indication was for an early stage cancer, but it is now expanded to advanced cancer according to development of the instruments and surgical skills. In the Japanese Nationwide Survey, more than 7,000 patients were treated every year in 2009, 2010, and 2011. Proportion of distal gastrectomy with D2 standard lymphadenectomy was 51.8%, distal gastrectomy with D3 extended lymphadenectomy was 20.6%, and total gastrectomy was 16.5% in 7400 cases (2011). Robotic surgery showed high accuracy and radicality in surgical procedures, and is now remarkably increasing in Korea and Japan.
"D2 systematic lymphadenectomy" was the gold standard for Japanese and most world leading surgeons, but the attitude was changed to "lymphadenectomy with limited or reasonable extent". The Intention is to reduce postoperative complications and nutritional disadvantages. Intention of "sentinel node navigation" is to detect metastatic nodes and to avoid disadvantages by unnecessary node dissection. This technique is indicated for potentially curatively resectable cancer, and most trials are now for early cancer during laparoscopic resection. The tracers are blue dye, fine carbon particle emulsion, oil contrast media, radioactive mm99 Tin colloid, and CEA antibody. The high detectability was reported; 96% of metastatic nodes were found in the hot nodes. The essential progress are to "develop cancer specific tracer" and to "improve accuracy of frozen histological examination".
We have to know that the most important patient's demand is "cure from cancer". We have to understand the scientific base of minimally invasive surgery and should avoid increase of recurrence caused by the indication expansion.
No conflict of interest.

Opening Session (Sat, 28 Sep, 09:00–11:00)
Biological Basis of Personalised Cancer Therapy

2 INVITED

Lgr5 stem cells in self-renewal and cancer

H. Clevers[1]. [1]*Hubrecht Institute, Royal Netherlands Academy of Arts and Sciences & University Medical Centre Utrecht, Utrecht, Netherlands*

The intestinal epithelium is the most rapidly self-renewing tissue in adult mammals. We originally defined *Lgr5* as a Wnt target gene, transcribed in colon cancer cells. Two knock-in alleles revealed exclusive expression of *Lgr5* in cycling, columnar cells at the crypt base. Using an inducible Cre knock-in allele and the Rosa26-*LacZ* reporter strain, lineage tracing experiments were performed in adult mice. The *Lgr5*$^{+ve}$ crypt base columnar cells (CBC) generated all epithelial lineages throughout life, implying that it represents the stem cell of the small intestine and colon. Similar obserations were made in hair follicles and stomach epithelium.
Single sorted *Lgr5*$^{+ve}$ stem cells can initiate ever-expanding crypt-villus organoids in 3D culture. Tracing experiments indicate that the *Lgr5*$^{+ve}$ stem cell hierarchy is maintained in these organoids. We conclude that intestinal crypt-villus units are self-organizing structures, which can be built from a single stem cell in the absence of a non-epithelial cellular niche. The same technology has now been developed for the *Lgr5*$^{+ve}$ stomach stem cells.
Intestinal cancer is initiated by Wnt pathway-activating mutations in genes such as APC. As in most cancers, the cell of origin has remained elusive. Deletion of APC in stem cells, but not in other crypt cells results in progressively growing neoplasia, identifying the stem cell as the cell-of-origin of adenomas. Moreover, a stem cell/progenitor cell hierarchy is maintained in early stem cell-derived adenomas, lending support to the "cancer stem cell"-concept.
Fate mapping of individual crypt stem cells using a multicolor Cre-reporter revealed that, as a population, Lgr5 stem cells persist life-long, yet crypts drift toward clonality within a period of 1–6 months. Lgr5 cell divisions occur symmetrically. The cellular dynamics are consistent with a model in which the resident stem cells double their numbers each day and stochastically adopt stem or TA fates after cell division. Lgr5 stem cells are interspersed between terminally differentiated Paneth cells that are known to produce bactericidal products. We find that Paneth cells are CD24+ and express EGF, TGF-a, Wnt3 and the Notch ligand Dll4, all essential signals for stem-cell maintenance in culture. Co-culturing of sorted stem cells with Paneth cells dramatically improves organoid formation. This Paneth cell requirement can be substituted by a pulse of exogenous Wnt. Genetic removal of Paneth cells in vivo results in the concomitant loss of Lgr5 stem cells. In colon crypts, CD24+ cells residing between Lgr5 stem cells may represent the Paneth cell equivalents. We conclude that Lgr5 stem cells compete for essential niche signals provided by a specialized daughter cell, the Paneth cell.
No conflict of interest.

3 INVITED

The genetic basis for cancer therapy – the opportunity and the challenges

W.R. Sellers[1]. [1]*Novartis Institutes for BioMedical Research, VP/Global Head of Oncology, Cambridge, USA*

Cancer is fundamentally a disease driven by the acquisition and clonal selection of genomic alterations. These genetic changes result in the gain- and loss-of-function of oncogenes and tumor suppressor genes that together cooperate to induce and maintain the transformed state. Therapeutics directly targeting these underlying perturbations have now shown marked single-agent clinical activity in a diverse set of solid and hematologic malignancies well beyond the initial genetically targeted therapy paradigm established by imatinib in CML. Indeed, the efficacy of inhibitors of BRAF, MEK, ALK, EGFR, PDGFR, KIT and ABL mark the emergence of a new generation of highly active cancer therapeutics all taking advantage of the link to the underlying genetic drivers. There is now a significant opportunity to see greater clinical benefit by the utilization of targeted therapeutics in combination both within this space and with chemotherapy and immunotherapy.
Nonetheless, there are significant challenges to more fully realizing this paradigm broadly across all cancers. First, we remain hampered by an incomplete understanding of the genetic alterations characteristic of human cancer. Here, the advent of Next Gen Sequencing promises to allow us to probe the cancer genome at sufficient depth to understand the genetic combinations that enact each cancer type, to understand disease progression from benign to highly refractory states and to understand disease heterogeneity. Second, there have been significant hurdles in developing therapeutics that reverse the activity of non-kinase oncogenes (e.g. RAS and MYC) or reverse the activity of tumor suppressor mutations (e.g. p53, RB1). Third, the development of resistance to targeted therapy remains a problem for the field and this is related to the fourth issue, specifically the need to rapidly identify highly active novel combination therapy regimens and test these early in clinical development. Finally, there has been a chronic lack of a robust pre-clinical translational infrastructure that would allow for the more accurate prediction of human clinical trial results and hence improve the overall clinical trial success rate while shortening the time to maximizing patient benefit.
The aforementioned challenges to this promising field can be met, however, by an increasingly sophisticated set of experimental and therapeutic approaches. Examples of these approaches will be highlighted in the presentation.
Conflict of interest: *Ownership: Novartis Pharmaceuticals. Other substantive relationships: Employee of Novartis Pharmaceuticals*

4 INVITED

Intratumour heterogeneity and cancer evolution

C. Swanton[1]. [1]*London Research Institute, Translational Cancer Therapeutics Laboratory, London, United Kingdom*

Despite advances in genomic technologies, most advanced solid tumors remain incurable and drug resistance is almost inevitable with limited biomarkers available to personalize therapy. Two important lessons have emerged from the comprehensive genomic analyses of cancers, which may provide an explanation for difficulties that have been encountered in biomarker development. First, each tumor contains an individual assortment of multiple genomic aberrations, few of which are shared between patients with the same histopathological tumor subtype. Second, emerging evidence suggests that these anomalies appear to vary both spatially and temporally within the tumor, indicating substantial intratumor heterogeneity. Increasingly, molecular evidence suggests that intratumor heterogeneity may contribute to tumor growth through a branched (polytypic) rather than a linear pattern of tumor evolution. Branched evolutionary growth and intratumor heterogeneity results in coexisting cancer cell subclones with variegated genotypes and associated functional phenotypes that may be regionally separated within the same tumor or distinct within one biopsy. Furthermore, the dynamics of tumour subclonal architectures are seen to alter in dominance over time.
Variegated phenotypes, resulting from intratumoral genetic heterogeneity and the emergence of new subclones at relapse, are likely to have important implications for developing novel targeted therapies and for preventing the emergence of drug resistance. Intratumor heterogeneity and tumour sampling bias, resulting from single biopsy-driven biomarker discovery and validation approaches, may also contribute to the recently reported failures in implementation of robust biomarkers in the clinical setting.
In this talk, evidence for intratumour heterogeneity, impacting upon signal transduction pathway heterogeneity will be reviewed. Darwinian models for biomarker discovery will be discussed based on trunk and branched tumor growth models that may improve drug discovery and clinical outcome prediction. Initiation of longitudinal clinical cohort studies to define the dynamics of tumour subclonal architectures during the disease course and defining drivers of tumour branched evolution and genomic instability are discussed as priority areas for development.
Conflict of interest: *Other substantive relationships: Novartis and Illumina: Research funding support.*

Opening Session (Sat, 28 Sep, 09:30−11:00)
Oncology Nursing Opening and Award Session

5 INVITED

Diversity in cancer care − the importance of transcultural nursing

M. Johnson[1]. [1]*De Montfort University, Leicester, United Kingdom*

Professor Johnson will discuss the importance of recognising ‘diversity’ in the design and provision of cancer services, with special reference to issues related to nursing care. He will examine the evidence base relating to ethnicity and the experiences of migrant/minority people in health care, focussing on the epidemiology and experience of cancer as mediated through culture, religion, language and family, and the implications for service provision.
Based largely on a review of the literature and ‘good practice’ examples, drawing on the experiences of colleagues in UK and EU and USA, he will make recommendations for the training and management of cancer nurses and other health professionals, and the implications for hospitals and clinics delivering services to multicultural and diverse populations. Other aspects of ‘diversity’ may be included as benefitting from the same sort of attention to the user’s identity, needs and experiences.
The approach needs to acknowledge that the ‘cancer journey’ begins with prevention, and recognition of symptoms, through diagnosis and ‘breaking bad news’, to end of life care and rituals associated with death. A whole-of-life approach enhances life and improves care but needs to be approached in a positive manner that recognises ethnic, religious and cultural diversity and the realities of life for migrants and their descendants.
In the absence of best practice evidence, there is a need to develop better practice, drawing on experience in other clinical fields, and to embed these in cancer care, including improved record keeping of salient characteristics, or ‘ethnic monitoring’, to enable better research and audit that will contribute in future to such evidence becoming available.
No conflict of interest.

Scientific Symposium (Sat, 28 Sep, 11:15−13:15)
The Impact of Cancer − Exploring Complexity and Special Needs in Specific Cancers

6 INVITED

Life beyond cervical cancer

C. Hughes[1]. [1]*London Cancer Alliance, Middx, United Kingdom*

More people are living for longer following a cancer diagnosis. Currently, in the UK this equates to about 2 million people. However, this figure is increasing at a rate of 3.2% per year, which means that by 2030 this number will have doubled. We also know that cancer survivors have significant unmet needs and suffer worse health than those who have never had the disease. Current methods of cancer follow-up were developed when the concepts of long term follow-up and chronic disease management were not generally associated with cancer.
The Cancer Reform Strategy (2007) in England saw the creation of the National Cancer Survivorship Initiative (NCSI) with the aim of increasing our understanding of the issues facing cancer survivors, and developing and testing solutions to improve care and support, in a changing healthcare environment. The vision for survivorship involved a cultural shift to focus on recovery, health and wellbeing; the provision of individual and personalised holistic assessment; care based on a model of self-management; follow-up and support tailored to individual need; and patient reported outcome measures.
There are about 19,000 women in the UK who are alive 10 years following a diagnosis of cervical cancer; 66% of women diagnosed with the disease will be alive 5 years following diagnosis and three quarters of these will be younger women aged 25−64 years. The first peak incidence is in women aged 30−34 years. Improvements in cervical screening have resulted in a reduction in the number of women diagnosed with the disease. Although initiatives to promote screening and earlier diagnosis remain important, current models of care following diagnosis and treatment do not meet the needs of patients for living beyond cancer and the effects of what is often radical treatment, and are not sustainable given the changes in the way the disease is managed.
The recent NSCI publication (Living With and Beyond Cancer: Taking Action to Improve Outcomes) brings together the evidence for the improvements tested as part of the initiative. This session will examine the changes recommended in the NCSI document in relation to the care of women with cervical cancer. This will include the use of formalised models of assessment and care planning to encompass holistic needs that include considerations such as access to work and childcare; templates for treatment summaries that support primary care in the management of women post treatment; the provision of a health and well being event to facilitate the transition from treatment to living with and beyond cancer, including the role of physical activity and a healthy lifestyle; risk stratification of follow-up to ensure women with low risk disease have information about the effects of treatment, what to look for in the event of recurrence and access to services but who are encouraged to self-manage, and women with complex needs get more intensive and appropriate support.
No conflict of interest.

7 INVITED

Life beyond head and neck cancer

M. Wells[1]. [1]*University of Dundee, School of Nursing and Midwifery, Dundee, United Kingdom*

Head and neck cancer is the 6th most common cancer worldwide. In the European Union more than 90,000 people are diagnosed with head and neck cancer every year and about 40,000 die from the disease. Rates are highest in Western, Southern and Eastern Europe and the incidence of oral and oropharyngeal cancer, in particular, is rising due to a significant increase in HPV related disease. Although still relatively ‘rare’, head and neck cancers have a profound impact on all aspects of life. Patients are increasingly treated with combined modality therapy which is associated with significant treatment morbidity. During and after cancer treatment, patients experience major challenges with eating and drinking, body image, psychological wellbeing, social and work life. However, public awareness about head and neck cancer and its impact has, until recently, been limited. This paper will draw on evidence from a recent systematic review of qualitative research on living with head and neck cancer, and on focus groups with patients and carers which highlight the ways in which treatment and care experiences can affect their ability to get on with life. Findings from a cross-sectional survey conducted in Scotland will be used to illustrate the most prominent concerns, quality of life issues and unmet needs expressed by survivors in the first five years after treatment. Finally, data from a record-linkage study will highlight those who are at highest risk of poor outcomes.

Nurses and multidisciplinary colleagues face enormous challenges in meeting the complex needs of an increasing number of people who live with the after effects of head and neck cancer, including the emergence of two distinct groups of patients − those who are socially disadvantaged and have poor health behaviours including smoking and drinking, and those with HPV related cancers who tend to be younger and more affluent. This paper will draw attention to some neglected issues in research and practice, and will summarize current initiatives and interventions to support people who live with this highly challenging cancer.
No conflict of interest.

8 INVITED

Beyond lung cancer

A. Serena[1], M. Eicher[1]. [1]*School of Health University of Applied Science, Research Development & Services, Fribourg, Switzerland*

Background: Lung cancer is the most frequent cancer affecting both men and women in the world. Lung cancer patients experience significant physical and psychosocial distress and have many unmet supportive care needs impacting quality of life for patients with lung cancer.
Method: Review of innovative models of care and emerging trends for nurses as members of a multidisciplinary team caring for lung cancer patients and their families. Current evidence related to use of non-pharmacologic interventions aimed at improving quality of life in lung cancer patients is provided.
Results: Given the often-short disease trajectory of lung cancer and the fact that patients are typically symptomatic at the time of diagnosis, early assessment of supportive care needs of patients and families is imperative. A growing number of studies support the beneficial role of Lung Cancer Nurse Specialists (LCNs) in assessing and meeting the health needs of patients. A number of LCNs innovative care programs have shown enhanced health-related outcomes. Targeted therapeutic education focusing on self-management of symptoms (i.e. shortness of breath) has demonstrated effectiveness. Nurse-led models for follow-up care are associated with improved physical and psychosocial patient outcomes, contribute to continuity of care and are viewed positively by both patients and providers. These growing bodies of evidence indicate that novel models of care delivery should integrate early assessment and therapeutic education programs for patients and families. Developing patient knowledge and expertise on their illness, treatment, symptom management and available support can help promote self-management. Such interventions are critical for empowering patients as there is significant stigmatisation related to lung cancer and often self-blame linked to tobacco use.
Conclusion: Available literature supports the importance and promise of several approaches for patients with lung cancer: 1) a key role for early needs assessment; 2) a role for LCNs consultation at diagnosis, through treatment and continued through follow-up care; and 3) targeted therapeutic education to promote self-management. These emerging models of care have shown promising initial results and warrant further investigation as components of a multidisciplinary approach to patients with lung cancer.

Scientific Symposium (Sat, 28 Sep, 11:15−13:15)
Induction Chemotherapy in the Treatment of Squamous Cell Head and Neck Cancer

9 INVITED

The current status of induction chemotherapy in head and neck squamous cell carcinoma

Abstract not received.

10 INVITED

Assessment of response after induction chemotherapy as the basis of subsequent local therapy

R. De Bree[1]. [1]*VUMC, Amsterdam, Netherlands*

The use of induction chemotherapy in the management of locally advanced head and neck squamous cell carcinoma (HNSCC) is growing. An understanding of the effects of induction chemotherapy on the biology of the tumour prior to delivery of chemoradiation is paramount to provide as much information as possible to tailor the treatment plan to the individual tumour: planning a radiation dose boost or reassessing the modality of treatment.
Contrast-enhanced computed tomography (CT) and magnetic resonance imaging (MRI) provide the mainstay of imaging for treatment response assessment. Both rely on morphology to evaluate the disease whereas functional imaging such as positron emission tomography (PET) and diffusion weighted (DW) MRI provide complementary information on the underlying biology such as metabolic activity and cellularity.
Functional imaging potentially provides an earlier indication of the response to treatment than conventional imaging and allows for potential adaptation of treatment by changing the intervention at a time when this is still possible. Especially changes in 18-fuorodeoxyglucose (FDG) uptake (determined by standardized uptake values: SUV) and microscopic water motion (determined by apparent diffusion coefficient: ADC) are useful for assessment of treatment response. Other techniques include dynamic contrast-enhanced and perfusion CT and MRI. Optimal timing and interpretation criteria for use of functional imaging in daily practice have to be developed.
Several small studies showed that early therapeutic response on FDG-PET and DW-MRI after two cycles of induction chemotherapy in patients with advanced stage HNSCC seems to be a predictive factor for recurrent free survival after subsequent chemoradiation. Marked changes in functional imaging parameters following induction chemotherapy may guide adaptation of individualised treatment regimens.
The use of these imaging techniques and recent studies on assessment of response after induction chemotherapy in HNSCC patients will be discussed.
No conflict of interest.

11 INVITED

Role of induction chemotherapy in the treatment of nasopharyngeal carcinoma

A. Lee[1]. [1]*University of Hong Kong − Shenzhen Hospital, Center of Clinical Oncology, Shenzhen, China*

An overview of the therapeutic benefit of induction chemotherapy for nasopharyngeal carcinoma will be presented.
Nasopharyngeal cancer is a chemo-sensitive cancer; the effectiveness of induction chemotherapy followed by radiotherapy was first reported in the 1980s. The initial results showed conflicting conclusions. Despite the common experience of good initial response, only one of five randomized trials achieved significant improvement in event-free survival and none showed benefit in overall survival. Interests in induction chemotherapy waned in the late 1990s when the Intergroup-0099 Study made the first breakthrough by using concurrent-adjuvant chemoradiotherapy (CRT). A meta-analysis in 2006 confirmed that concurrent chemotherapy is the most potent sequence for combining with radiotherapy (RT) and the only sequence that showed significant survival benefit; induction chemotherapy per se could significantly reduce the risk of both locoregional failures and distant failures, but the impact did not translate into significant benefit in overall survival. Although subsequent trials did confirm the efficacy of regimens using cisplatin in concurrence with radiotherapy followed by combination of cisplatin and fluorouracil, controversy remains about the contribution of the adjuvant phase which is often poorly tolerated. Furthermore, there are concerns that improvement in distant failure remains unsatisfactory.
Hence, there are interesting interest to explore the benefit of induction-concurrent sequence, The induction phase is generally well-tolerated, full dose of potent chemotherapy combination could theoretically be more effective in eradicating micro-metastases. Furthermore, shrinkage of advanced locoregional disease, particularly those abutting neurological tissues, could enable wider margin for subsequent RT. Single-arm Phase II studies all reported encouraging early results, but two randomized Phase II trials showed conflicting results as to whether induction-concurrent CRT is superior to concurrent CRT. Five randomized Phase III trials are now on-going to confirm the therapeutic benefit, while four trials used concurrent CRT as the standard arm, the NPC-0501 Trial used the Intergroup concurrent-adjuvant CRT as the standard arm, 803 patients have been accrued and the preliminary results are being analyzed.
In conclusion, induction chemotherapy per se using cisplatin-based regimen with adequate dosage can achieve modest but significant improvement in tumor control. Adding induction chemotherapy to concurrent CRT is a promising strategy, confirmation by randomized trials is awaited.
No conflict of interest.

12 INVITED

Function-sparing radiation in curable head and neck cancer

H. Langendijk[1]. [1]*University Medical Center Groningen, Radiation Oncology, Groningen, Netherlands*

Introduction: The last decade, major progress has been made in the treatment of head and neck squamous cell carcinoma (HNSCC). There is growing evidence that more aggressive treatment regimens, either the delivery of radiotherapy with concomitant chemotherapy or altered fractionation schedules, improve tumour control and survival. However,

these new treatment regimens have come to the expense of increased morbidity, such as radiation-induced swallowing dysfunction, trismus and xerostomia. As health-related quality of life is particularly affected by these side effects, prevention may improve the therapeutic ratio of treatment for HNSCC.
NTCP-models: Several authors investigated the relationship between the dose distributions in potential organs at risk and side effects. These studies retrieved different results, which may be due to a number of methodological problems, including the relatively small number of patients in most of these studies, differences in eligibility criteria among the different studies, differences in study design and endpoints chosen and differences in the definition and delineation of the organs at risk.
To overcome these problems, we performed well-designed prospective cohort study are required in which all possible relevant pre-treatment, treatment and outcome determinants are prospectively collected according to well defined guidelines.
We developed a number of multivariable Normal Tissue Complication Probability (NTCP) models for different endpoints related to function. These multivariable NTCP-models can be used to:
1. Identify the most important anatomical structures that should be spared to obtain maximal sparing of function after curative radiation or chemoradiation;
2. Identify the dose-volume parameters that are most predictive for the development of functional problems;
3. Develop advanced and emerging radiation technology that enables sparing of the most important organs at risk, and
4. To identify patients who may benefit most from these new technologies.

Clinical validation: After completing the aforementioned steps, we performed a prospective study in which the efficacy of multiple function sparing IMRT was validated. In addition, we performed in silico planning comparison studies to investigate the potential benefit of protons to reduce functional problems.
The results of these studies will be presented.
No conflict of interest.

Society Session (Sat, 28 Sep, 11:15−13:15)
European Society of Surgical Oncology (ESSO)

13 INVITED

2013 a year of challenges in the technique of TME

R. Heald[1]. [1]*North Hampshire Hospital, The Ark Basingstoke & North Hampshire NHS Foundation Trust, Basingstoke, United Kingdom*

The concept of TME is important because it reflects the embryological determination of an envelope of tissue which represents a standard optimal oncological resection specimen. The basis of the detailed anatomy of the insertion of the lower part of this envelope into the pelvic floor, remains an area of challenge for surgeons and anatomists alike. Furthermore MRI radiology and 3-dimensional MRI based imaging have further contributions to make to all the disciplines involved.
Late in 2012, I was introduced by Antonio Lacy to the potential of dissection conducted transanally under positive gas pressure after circumferential incision around the rectum and purse string closure of the distal margin of the specimen. This has led to a number of established laparoscopic and open surgeons seeking to improve their dissection techniques in the low distal insertion of the mesorectal package into the pelvic floor. The essential claim from surgeons conducting the early series, which now encompass more than 200 patients in Europe alone, is that the dissection of this challenging part of a TME operation is actually EASIER. If this proves to be so then patients with middle third and lower third rectal cancer throughout the world may look forward to better outcomes with less nerve damage than in the past.
No conflict of interest.

14 INVITED

Training in cancer surgery across Europe: The trainees perspective

E. Vicini[1], J.R. Van der Vorst[2], I. Montroni[3], D.B.Y. Fontein[4], J.S.D. Mieog[4], S. Partelli[5], K. Polom[6], N.A. Malyshev[7], P. Mordant[8], L. Wyld[9]. [1]*Fondazione IRCCS Policlinico San Matteo, Department of General Surgery, Pavia, Italy;* [2]*Groene Hart Hospital, Department of Surgery, Gouda, Netherlands;* [3]*Policlinico S. Orsola-Malpighi Università di Bologna, Department of General Surgery Emergency Surgery and Organ Transplantation, Bologna, Italy;* [4]*Leiden University Medical Centre, Department of Surgery, Leiden, Netherlands;* [5]*Azienda Ospedaliera Universitaria Ospedali Riuniti di Ancona, Department of Pancreatic Surgery, Ancona, Italy;* [6]*Greater Poland Cancer Center, First Surgical Oncology and General Surgery Department, Poznan, Poland;* [7]*Technical University Munich, Frauenklinik Klinikum Rechts der Isar, Munich, Germany;* [8]*Georges Pompidou European Hospital, Department of Oncology, Paris, France;* [9]*University of Sheffield Medical School Royal Hallamshire Hospital, Academic Unit of Surgical Oncology, Sheffield, United Kingdom*

Background: The European Parliament resolution on combating cancer in the European Union (2008) calls on the Member States to make nationwide provision for multidisciplinary oncology teams to give optimal individual treatment to all patients. Surgical oncologists lead the multi-disciplinary management of most forms of cancer and the increasing complexity of cancer management means that trainees in surgical oncology require a high level of specialist training. This training needs to encompass both generic oncology knowledge about the role of genetics, radiation and medical oncology but also they must achieve a high level of technical expertise in surgery relevant to their field of practice. Standards of training across Europe must be harmonized at the highest level to ensure patients across the Union have equal access to best practice and outcomes converge across Europe. The ESSO Young Surgeons and Alumni Club (EYSAC) was founded in 2010 to facilitate surgical oncology training across Europe. A survey of the members of this association has recently been undertaken to gain better understanding of their training needs and the challenges they face.
Material and Methods: A bespoke online questionnaire was sent out to all EYSAC members in early 2013; questions were related to training needs, perceived problems with training, careers and expectations.
Results: The main finding of the survey provisional results is that trainees perceive that surgical oncology training is still fragmented and poorly developed. The formal European Board of Surgical Qualification (EBSQ) examination in surgical oncology remains the only specific qualification but lacks National or European recognition as a formal certification. There is no single recognized training accreditation across Europe which hinders internal mobility across Europe. Many European countries still don't recognize surgical oncology as an independent discipline.
Conclusions: Since 1996 the EU law guarantees the right to practice of EU trained doctors and specialists in all EU member states, EYSAC will continue to make efforts to promote the harmonization and the quality of training in surgical oncology across Europe in order to optimize and standardize cancer patients' care and to open new avenues for surgical oncology.

Targeting the Microenvironment

17 INVITED

Lysyl oxidases in cancer progression

J.T. Erler[1]. [1]*University of Copenhagen, Biotech Research and Innovation Centre (BRIC), Copenhagen, Denmark*

Background: Metastasis is strongly influenced by the tumour microenvironment, in particular by hypoxia (low oxygen) and increased matrix stiffness.

Materials and Methods: We have identified two key mediator molecules, lysyl oxidase (LOX) and lysyl oxidase-like2 (LOXL2). These are hypoxia-induced secreted enzymes that increase matrix stiffness through mediating the crosslinking of collagens and elastin in the extracellular matrix. We have investigated their role in metastasis using a variety of *in vitro* and *in vivo* models.
Results: We showed that LOX expression is clinically correlated with hypoxia, metastasis and poor patient survival. Furthermore, inhibition of LOX through genetic, chemical or antibody means significantly reduces invasion and metastasis in several *in vivo* models of solid tumour metastasis. LOX enhances invasion through increasing matrix stiffness, thereby activating integrins, Src and FAK. LOX additionally enhances formation of distant metastases by playing a role in formation of pre-metastatic niches through recruitment of CD11b+ cells, which greatly enable metastatic colonisation. More recently, we have found LOX to mediate fibrosis-enhanced metastasis through matrix remodelling in response to chemical- or irradiation-induced fibrosis.
We have also investigated the role of LOXL2 in breast cancer metastasis and normal mammary tissue function. Like LOX, LOXL2 is clinically correlated with metastasis and poor patient survival. LOXL2 enhances invasion through regulation of matrix remodeling. Inhibition of LOXL2 through genetic, chemical or antibody means prevents invasion and metastatic dissemination *in vivo*. We further show that LOXL2 activity is highest during mammary gland involution, consistent with its role in matrix remodelling. More recently, we have found LOXL2 to regulate tumour–stromal interactions that drive cancer progression, and to drive abnormal mammary epithelial cell acinar formation.
Conclusions: These findings demonstrate pre-clinical effectiveness of anti-LOX/LOXL2 therapy, which may have important clinical implications.
No conflict of interest.

18 INVITED

Putting cancer stem cells in context

I. Malanchi[1], A. Santamaria-Martinez[2], J. Huelsken[2]. [1]*London Research Institute, London, United Kingdom;* [2]*EPFL, ISREC, Lausanne, Switzerland*

Metastatic growth in distant organs is the major cause of cancer mortality. Formation of metastasis is a multi-step process with several rate-limiting steps. While dissemination of tumour cells appears to be an early and frequent event, successful initiation of metastatic growth, a process termed “metastatic colonization”, is rather inefficient for many cancer types and accomplished only by a minority of cancer cells that reach distant sites. Prevalent target sites are characteristic for many tumour entities.
We found that a small population of cancer stem cells (CSCs) in a model of mammary gland tumour is critical for metastatic colonization. These CSCs represent a stable population of tumour cells which selectively survive and proliferate upon metastatic seeding and thereby drive the initial expansion of cancer cells at the secondary site. In contrast, non-CSCs fail to grow, are rapidly lost and do not de-differentiate into CSCs.
Furthermore, we find stromal niche signals to be crucial for this process. We identify the extracellular matrix (ECM) component POSTN to be expressed by fibroblasts in the normal tissue exclusively in response to tumour cell infiltration. Infiltrating tumour cells induce stromal POSTN expression in the secondary target organ via TGFb3 secretion. Importantly the induction of POSTN at the target site is essential for the metastatic process. Indeed, generation of a POSTN null mouse revealed that the metastatic process is heavily compromised in the absence of POSTN.
We show that this ECM protein is required to allow maintenance of cancer stem cells: the cells driving the metastatic process. We found that POSTN is able to bind Wnt ligands and therefore increase Wnt signaling. *In vivo* we observed Wnt signaling activity selectively in the CSCs population and this activity is abrogated in absence of POSTN. Thus, POSTN acts as a niche component that can promote stem cell maintenance and metastatic colonization by augmenting Wnt signaling.
In conclusion, this study suggests that the inefficiency of the metastatic process might be due to both: an intrinsic differential potential of the disseminated cancer cells to grow at the secondary sites and inadequate extrinsic signals to support metastasis establishment from distant tissues. We suggest that the education of stromal cells by infiltrating tumour cells is an important step in metastatic colonization and that preventing de-novo niche formation may represent a novel treatment strategy against metastatic disease.
No conflict of interest.

19 INVITED

Tumor elicited inflammation and malignant progression in colorectal cancer

M. Karin[1]. [1]*University of California San Diego, Laboratory of Gene Regulation and Signal TransductionDepartment of Pharmacology, La Jolla CA, USA*

Colorectal cancer (CRC) is the third leading cause of cancer related deaths in the US and other Western countries. Whereas 2% of CRC arises in the context of pre-existing inflammatory bowel disease (IBD), especially ulcerative colitis (UC), and is known as colitis associated cancer (CAC), most CRC, including familial and sporadic cases, is found in individuals that do not show any signs of IBD. Yet, expression profiling has revealed the same inflammatory gene signature, which depends on activation of NF-κB and STAT3, in both CAC and CRC, findings that generate a question regarding the origin of the CRC-elicited inflammatory response. In early experiments we have shown that activation of NF-κB, which leads to production of the pro-inflammatory cytokine IL-6, a potent activator of STAT3, plays a critical role in the development of CAC. More recently we investigated the origin and role of inflammation in the development and progression of sporadic CRC, most of which is driven by loss of the tumor suppressor APC and activation of the β catenin signaling pathway. We focused our studies on IL-23, a heterodimeric cytokine, composed of a unique p19 subunit and a p40 subunit which it shares with IL-12. As observed by others, we also found that IL-23 expression is strongly elevated in CRC relative to adjacent non-tumor tissue and have extended these findings to the CPC-APC mouse model of colorectal tumorigenesis. In CPC-APC mice, the major source of IL-23 expression in colorectal adenomas are tumor associated macrophages (TAM). Importantly, ablation of IL-23 p19 either in all cells or only in bone marrow (BM)-derived cells attenuates the development and slows down the progression of CRC in CPC-APC mice and similar results were observed upon ablation of IL-23 receptor (IL-23R). As IL-23R is not expressed on adenoma epithelial cells, IL-23 must exert its pro-tumorigenic effect via an indirect mechanism. Indeed, IL-23 signaling promotes the polarization of IL-17 producing T cells (Th17) and the production of IL-6, both of which contribute to the development and progression of sporadic colorectal tumors in mice. Importantly, molecular epidemiological studies carried out by Galon, Fridman and their co-workers have revealed that an ‘IL-23-Th17’ signature that is upregulated in about 10% of human CRC patients, and that the presence of this signature in stage I/II CRC is associated with very poor prognosis and a marked decrease in disease free survival. We investigated the mechanism responsible for the specific induction of IL-23 in TAM and found it to depend on Toll like receptor (TLR) − MyD88 signaling, which appears to be activated in response to components of the colonic microflora that permeate the adenomas. We also detected eubacterial 16S RNA in both mouse and human colonic adenomas, as well as increased penetrance of bacterial endotoxin (LPS) into adenomas relative to surrounding non-cancerous tissue. The development of colorectal adenomas in both mice and men is associated with loss of protective mucins and junctional adhesion proteins and this is likely to be the primary mechanism that accounts for the selective entry of microbial products into the tumor and induction of the tumor promoting “IL-23−Th17” signature. Future studies should focus on the therapeutic value of anti-IL-23 or anti-IL-17 interventions and the genetic or environmental causes of the large variation in the magnitude of IL-17 production amongst human CRC patients.
No conflict of interest.

Advances in Preclinical Research

21 INVITED

Frontiers of phase-contrast imaging

P. Coan[1]. [1]*Ludwig Maximilian University Munich, Faculty of Physics/Medical Physics, Garching, Germany*

Background: X-ray imaging has been the most important and widespread diagnostic tool in Medicine over the last century. Despite its huge success, for example in imaging bone structure, X-ray diagnostics ultimately reaches its limits in the examination of soft tissues, such as small tumours in healthy tissues, lungs or articular cartilage. Moreover, medical diagnostic imaging requires high contrast at low radiation dose: a condition that often limits

the sensitivity of the method. In this scenario, the application to biomedical imaging of coherent X-ray phase-contrast imaging (PCI) methods, which explicitly utilize the wave character of X-ray light, has attracted a vivid interest in medical imaging.
Material and Methods: PCI employs the dual property of X-rays of being simultaneously absorbed and refracted while passing through a tissue. Different PCI modalities have been developed (based on X-ray interference or diffraction mechanisms). The produced image contrast is a combination of X-ray absorption, refraction and ultra-small angle scattering. Whole or portions of human tissues such tumour-bearing breasts, pathological livers and osteoarthritic joints provided by the Ludwig Maximilians University (LMU, Phatology and Forensic medicine departments) were imaged in computed tomography (CT) mode. Blinded radiologists quantitatively evaluated the visual aspects of the PCI-CT images with respect to sharpness, contrast and the discrimination of different structures/tissues. IRB-approval for this study was granted by the ethics committee of the LMU.
Results: Low dose, high resolution PCI-CT images of clinically interesting specimens were obtained. Comparative studies in which PCI images were correlated to results produced with clinical diagnostic imaging tools (i.e. CT scans, magnetic resonance imaging, histology). The radiological blinded evaluation showed a statistically relevant difference in image quality in PCI-CT against conventional diagnostic images.
Conclusions: PCI-CT enables depiction of fine tissue changes previously not detectable by conventional diagnostics techniques. Results suggest that PCI-CT has the potential of becoming a valuable method in clinical imaging providing a 3D investigation of whole specimens and quasi-histological information of tissues at clinically compatible doses. In addition, PCI may represent a powerful tool in animal models investigations allowing for the longitudinal follow up of cancer evolution or therapeutical effects.
No conflict of interest.

22 INVITED

Intravital microscopy of tumor invasion and CTL effector function: Mapping and targeting niches of the tumor microenvironment

B. Weigelin[1]. [1]*Radboud University Nijmegen Medical Centre, HB Nijmegen, Netherlands*

Cancer progression, including growth, invasion and immunological control of the tumor are complex processes which depend upon both, cell intrinsic mechanisms and the tumor microenvironment. Using multiphoton excited three-fluorescence and higher harmonic generation microscopy (second and third harmonic) of B16F10 melanoma and HT1080 fibrosarcoma grafts, the niches responsible for tumor invasion, interaction with cytolytic T cells, and tumor therapy response were monitored over time. Invading tumor cells preferentially exploited preformed least-resistance tracks of complex, multi-interface topography, which determined single-cell or collective migration modes, without immediate anatomic tissue remodeling or destruction. The geometric tissue organization included 1D, 2D and 3D topology, which each resulted in unique invasion routes, patterns and efficacy. These invasion zones showed strongly enhanced resistance to radiation therapy, but were particularly sensitive to immunotherapy with adoptively transferred antigen-specific cytolytic T cells (CTL), suggesting that regimen-specific resistance is microenvironmentally controlled. Targeting beta1/beta3 integrins prompted enhanced radiosensitization of invasion strands, implicating integrin-mediated adhesion and/or anti-apoptotic signaling (anoikis) as key mediators of the radioresistance niche. In a different mechanism, improved elimination of invading tumor cells by cytotoxic T lymphocytes was mediated by enhanced migration and accumulation of CTL within the tissue guidance tracks, which locally enhanced serial CTL conjugations and consequently lead to increased tumor cell killing rates.
Thus, intravital microscopy represents a powerful approach to identify and mechanistically address niches of invasion, metastasis and therapy resistance, delivering innovation and new therapy concepts to preclinincal cancer research.
No conflict of interest.

23 INVITED

A dedicated small animal radiotherapy research platform

F. Verhaegen[1], P.V. Granton[1], S. Van Hoof[1], D. Trani[1], L. Dubois[1]. [1]*Maastricht University Medical Centre, Maastricht, Netherlands*

Background: New technology and treatment strategies have often been implemented in the past without thorough preclinical verification. Examples are intensity modulated radiotherapy, stereotactic body radiotherapy, proton radiotherapy etc. Recently it has been realized that useful knowledge may be gained from conducting preclinical radiotherapy studies in e.g. mice, to fully explore new forms of therapy. Examples are synergistic studies between radiotherapy and drugs (to enhance tumor damaging efficacy or normal tissue protection), or other forms of cancer therapy. In the past radiobiology studies were often performed with non-precise radiation beams, bearing little resemblance to modern highly precise targeted irradiation in clinical practice. To enable more precise preclinical irradiation studies, novel technology has been developed recently.
Materials and Methods: Several groups have made efforts towards developing precision irradiators for small animals, combined with x-ray imaging equipment to provide image-guidance, in analogy with what is available for human radiotherapy. The irradiation and imaging technology was downscaled to the spatial resolution of small animals. Also the energy of the photon beams was downscaled. To enable irradiation of small structures with complex spatio-temporal radiation patterns, the development of a dedicated treatment planning system for small animals was necessary.
Results: In our department a small animal irradiation system equipped with a high-resolution cone beam CT imaging system was fully commissioned and optimized. A treatment planning system, SmART-Plan was developed, based on Monte Carlo dose calculations. It was verified that planned doses agreed with delivered doses. A dose verification system, based on the onboard imager, was developed. First preclinical studies are now being performed on this system.
Conclusions: New technology is becoming available for preclinical research with an unprecedented accuracy and precision. It is expected that studies on this type of equipment may help to elucidate radiation interaction mechanisms in normal and cancerous tissues. New knowledge may be gained on the efficacy of complex spatio- temporal radiation patterns, the synergy of radiation with drugs (not restricted to chemotherapy), the influence of organ motion, and much more. It is hoped that this knowledge could then be translated to cancer patients; it is herein that the greatest challenge lies.
No conflict of interest.

24 INVITED

Monochromatic radiotherapy: From first experimental glioma bearing rat therapy up to the first clinical trial

F. Estève[1], J.F. Adam[1], J. Balosso[1], P. Berkvens[2], A. Bravin[2], H. Elleaume[2], J.F. Le Bas[1], C. Nemoz[2], A. Tessier[2], M. Renier[2]. [1]*Grenoble Institute of Neurosciences, CR U836, Grenoble, France;* [2]*ESRF, Grenoble, France*

In the early 80's, Norman's group proposed to treat brain tumors, after loading them with iodinated contrast agents, by using scanners as therapy machines to enhance the local dose deposition determined by the higher X-rays absorption of the iodine atoms. Theoretically, such physical conditions are optimal in the energy range 50 to 80 keV produced with synchrotron sources.
After several years of preclinical radiotherapy research mainly developed at the European Synchrotron Radiation Facility (ESRF), we have built a radiation therapy clinical trial. The clinical protocol has been submitted and approved by the DRRC (Direction de la Recherche Clinique) of the Grenoble CHU. We then obtained the agreement from the AFSSAPS* for medical purposes and from the ASN for the radiation safety aspects. In these clinical trials we wish to translate up to human patients what has been studied at the ID17 beamline on preclinical studies including dose computation on realistic human phantoms.
The first radiotherapy clinical trial currently being performed, is based on the dose enhancement that occurs when a tumor is loaded with heavy iodinated contrast agent. This technique has been studied for years in different places on patients and on animal models using conventional X-ray sources. The medical goal is to perform a phase I and phase II clinical trials to demonstrate the feasibility and acceptance of radiation treatment using a synchrotron X-ray source on patients. Furthermore, the secondary medical objectives are (in relation to phases I and II)
– To assess the onset of adverse effects, early and late effects related to the treatment.
– To assess the survival time without on site relapse, (survival criteria).
– To assess the survival time without cranial tumor relapse (no new metastasis).
– To assess the treatment efficiency using the RECIST criteria: evaluation of treated target lesions response is done with the measurement of the biggest diameter or sum of the diameters of the different metastasis.

To now, we have evaluated the accuracy of the ESRF CT technique on four patients by measuring the iodine distribution in brain metastasis, in comparison with conventional CT scanners. This imaging procedure has been followed by a 5 Gy single synchrotron fraction dose delivery, considering the iodine dose enhancement.

Specialist care for teenager and young adults with cancer

A. Ferrari[1]. [1]*Istituto Tumori Milano, Medical Pediatric Oncology, Milano, Italy*

Background: The last 5 years have been a key time in Italy for the development of projects dedicated to adolescents and young adults with cancer.
Material and Methods: National actions, taken in an effort to implement specific programs tailored to these patients arose from the pediatric oncology community, including the creation of the national Committee on Adolescents of the Associazione Italiana Ematologia Oncologia Pediatrica (AIEOP), founded with the mission of ensuring that Italian adolescents with cancer have prompt, adequate and equitable access to the best care, in order to optimize their treatment outcome and quality of life.
Results: A first study of the Committee compared the number of patients treated at AIEOP-affiliated pediatric oncology centers to the number of cases expected to occur in Italy based on incidence rates obtained from population-based cancer registries. The ratio of observed to expected (O/E) was 0.10 for 15−19 year-old patients, as opposed to 0.77 for 0−14, emphasizing that the AIEOP network was far less effective in serving adolescents than children. A second study showed the existence of rigid upper age limits (as low as 16, 15, or even 14 years) for admission to pediatric cancer units. Further studies confirmed the problem of referral to specialized centers for adolescents, showing that they often arrived at the diagnosis after a considerable delay (as compared to children). The AIEOP Committee defined as priorities: increasing the number of adolescents referred to pediatric oncology units, improving awareness, improving cooperation with adult medical oncologists.
Conclusions: A more ambitious and forward-thinking national program is now necessary, requiring the following actions: a) fully involve adult medical oncology groups in the project, evolving from a pediatric oncology Adolescents Committee to a national broad-based Task Force which forms the official structure which may be accessed by the public authorities; b) achieve the formal support of the Ministry of Health and include in the next National Oncologic Plan the the required facilites to allow centers (no matter if they are pediatric or adult units) to treat adolescents with cancer: e.g. no restricted age cut-offs, multidisciplinary team, clinical trials availability, adequate setting and staff, fertility preservation program, transition program; c) establish cooperation with other international groups involved in the field.
No conflict of interest.

27 INVITED

Developing multi-professional education for TYA with cancer

D. Stark[1], S. Smith[2], S. Morgan[3]. [1]*St James's University Hospital, Medical Oncology Department, Leeds, United Kingdom;* [2]*Teenage Cancer Trust, London, United Kingdom;* [3]*St James's University Hospital, Leeds, United Kingdom*

Background: TYA with cancer have specific requirements, which place specific skills upon professionals working with them. Professionals need to understand the diseases they develop, the physiology at that age, the primacy of clinical trials for many young people, and the wider context of the young person including commmunication to support care and their role alongside their peer group and family.
Methods: We will present the TYA multiprofessional education opportunites and plans within the European Network for Cancer in Children and Adolescents (ENCCA) and their collaboration with ECCO, ESMO, the European Cancer Patients Coalition (ECPC) and others, as well as national-level TYA cancer care specialist groups.
Results: There are a growing number of professional education opportunities for learning these skills, for medics, nurses, and other professionals, and several further are developing within ENCCA and its wider collaborations. These will be described and discussed, and the audience challenged to contribute to overcoming barriers to develop this skill set.
Conclusion: There is much progress in this field, but much remains to do.
No conflict of interest.

28 INVITED

Improving access to clinical trials for teenagers and young adults

L. Brugieres[1]. [1]*Institut Gustave Roussy, Pediatric and Adolescent Oncology, Villejuif, France*

The significant advances in survival for patients with cancer over the last 20 years can be attributed to the improvement of treatment through clinical trials. Survival of children as well as adults with cancer has increased dramatically in the last decades. At the same time, progress in treating adolescents and young adults (AYAs) has stagnated. All the studies focusing on the rate of accrual of AYA in clinical trials show a lack of enrollment as compared to patients under 15 years.
Several reasons can explain this gap, mainly:
1. low number of clinical trials available for AYA even at major cancer comprehensive centres,
2. lack of a coordinated AYA program with patients treated anywhere (most patients not treated at academic centers offering the few clinical trials for AYAs)
3. lack of cooperation among paediatric and medical oncologists developing programs for malignancies involving both adults and children

The consequences of the low inclusion of AYA into clinical trials are a great heterogeneity in the care delivered to these patients; little progress on the biology specificities due to obstacles to tumor samples access.
Several strategies have to be developed in order to overcome these barriers:
- to develop a network involving the disease-, and age-based expertise achieved by the cooperative groups involved in each tumour on a national/international basis. This network relying on pediatric and adult communities should allow to design clinical trials accessible for patients in this age group independently of the site of care
- to set biologically appropriate age eligibility criteria for clinical trials reflecting the disease. These eligibility criteria should allow the inclusion on young adults with paediatric tumours in protocols designed for children as well as paediatric patients in trials designed for adults.
- to improve accessibility of AYA to clinical trials through international policy with a key recommendation from the community of AYA oncologist allowing each AYA with cancer to be offered entry to any clinical trial for which they are eligible
- to create specific care structures for AYA able to offer enrolment of patients on clinical trials as well as offering an environment that is supportive to that group of patients.

The diverse needs of these patients may be addressed only by people dedicated to a new discipline; AYA oncology with dedicated research strategies that are not available through either pediatric or adult programs.
No conflict of interest.

29 INVITED

Role of patients and advocacy groups

Abstract not received.

Special Session (Sat, 28 Sep, 14:15−15:15)
Multidisciplinary Approach to Castration-Resistant Prostate Cancer

30 INVITED

Sequencing post-docetaxel therapy in CRPC − Identifying which agent for which patient

Abstract not received.

31 INVITED

Hormonal therapy and cytotoxic treatment in elderly men with CRPC: Factors to be considered

B. Tombal[1]. [1]*Cliniques Universitaires Saint Luc, Department of Urology, Brussels, Belgium*

The incidence of prostate cancer (PCa) increases with age, with a median age at diagnosis in the late sixties. Due to the increased life expectancy in developed countries, PCa represents a major public health problem. As a consequence of the "global aging" of the population, treatment of PCa in elderly adults (>75 years old) has become a critical issue.
In addition, the landscape of treatment for advanced PCa has been dramatically evolving, bringing the possibility of increasing overall survival and improving quality of life significantly beyond castration. The question of the risk/benefit profile of these drugs in elderly patients is a matter of controversy. It appears indeed that many older men are denied

chemotherapy based on their chronological age, not their health status. Each of the registration trials have included sub-analysis on age but have not generally included specific recommendations for use in the elderly. The SIOG (International Society of Geriatric Oncology) has developed general guidelines for these men. Overall, they conclude that treatment decisions for advanced prostate cancer in senior adult men should be adapted to health status and that specific prospective studies in senior adults men with metastatic prostate cancer are warranted.
Conflict of interest: *Ownership: None. Advisory board: Amgen, Astellas, Dendreon, Sanofi-Aventis, Ferring, Bayer. Board of directors: None. Corporate-sponsored research: None. Other substantive relationships: None*

32 INVITED

Role of palliative surgery and radiation therapy in locally advanced, non-metastatic CRPC

A. Heidenreich[1]. [1]*RWTH Aachen University Hospital, Universitätsklinikum der RWTH Aachen, Aachen, Germany*

Medical treatment with abiraterone acetate plus prednisone, docetaxel plus prednisone ± bone targeting agents while maintaining androgen deprivation represent the therapeutic approach in patients with even non-metastatic castration resistant prostate cancer (CRPC). A significant proportion of patients, however, suffer from locally progressive CRPC with consecutive subvesical obstruction, recurrent gross hematuria and bladder clotting, supravesical obstruction with hydronephrosis and the potential need for endoluminal or percutaneous stenting. In the majority of cases, medical treatment does not result in clinically meaningful remissions as it is observed in metastatic deposits. Therefore, various palliative surgical and radiooncological measures need to be discussed individually in order to improve quality of life. The presentation will discuss the various surgical options in detail.
In case of locally advanced CRPC infiltrating the bladder neck associated with or without gross hematuria, palliative transurethral resection of the prostate (TUR-P) followed by local radiation therapy represents the treatment of choice. Palliative TUR-P is associated with low morbidity, low frequency of complications and immediate relief of micturition symptoms. However, about one third to half of the patients will experience a local relapse so that surgery should be combined with radiation therapy. In case of significant local progression with infiltration of the bladder, the rectum and the pelvic floor, palliative radical surgery including anterior and posterior exenteration with an urinary diversion and/or a permanent colostomy might be indicated resulting in a symptom-free survival time which covers about 80% of the remaining lifetime. Patients have to be selected very carefully and surgery should be performed in experienced centres only. With regard to supravesical obstruction, diversion of the kidney becomes necessary in cases of symptomatic hydronephrosis or in uremia. Diversion can be performed ureteral reimplantation or a subcutaneous pyelovesical bypass in patients with a life expectancy >2 years. For palliative indications insertion of endoluminal stent or a percutaneous nephrostomy is more appropriate.
No conflict of interest.

Special Session (Sat, 28 Sep, 14:15−15:15)
Dilemma of Crossover in Clinical Trial Design of Agents With 'Obvious Activity'

33 INVITED

Crossover in clinical trials is not required

D. Cameron[1]. [1]*Edinburgh Cancer Research Centre, Edinburgh, United Kingdom*

This talk will introduce the subject from a clinician's perspective. Clinical trials are designed to answer specific questions, and when the results of a clinical trial could lead to changes in clinical practice, the trial design has to be mindful of this. In particular, in an age where new drugs may be required to pass both regulatory and health technology hurdles, the implications of cross-over may not always be what is intended and so may not be appropriate. Examples of clinical trials which have and have not allowed cross-over will be used to illustrate the possible consequences.
Patients enrolling in a randomised clinical trial know that there is no guarantee that they will get a more active therapy: even if the new therapy has "obvious activity". In randomised trials there has to be sufficient equipoise between arms to justify the study, so that if it is felt that it would be unethical to deny the patient the new treatment at cross-over then the primary question will be about sequence, not about added efficacy.
Options for how to deal with cross-over when it is felt essential will also be discussed, and the question of trials designed for primary health economic, rather than clinical efficacy, endpoints will also be considered.
No conflict of interest.

34 INVITED

Correcting for partial crossover to the experimental drug in a clinical trial

D.M. Finkelstein[1]. [1]*Massachusetts General Hospital/Harvard University, Biostatistics Department, Boston, USA*

Background: When patients on a clinical trial are selectively crossed over to the experimental arm, it becomes challenging to assess the impact of the experimental therapy on overall survival. In fact, if the therapy is effective, then those who cross over may receive survival benefit, thus diluting the test for comparison of the arms on this important outcome.
Material and Methods: Since a crossover can be necessary on ethical grounds, statistical methods must be applied that allow an assessment of what would have occurred had patients remained on their assigned treatment until death. We will discuss examples of trials that faced this challenge and explain the statistical approach using the inverse probability of censoring weighted (IPCW) method which attempts to remove the bias caused by treatment crossover.
Results: The IPCW method has been applied to assess the effects of treatment on survival in the context of clinical trials that allowed discretionary cross-over. We will describe the IPCW method and discuss the assumptions required for its use, as well as the interpretation of the results.
Conclusions: In the context of trials where patients selectively cross over to the experimental arm, statistical methods such as IPCW can provide insights to the interpretation of the results particularly on overall survival.
No conflict of interest.

35 INVITED

Cross over in oncology trials: Considerations for endpoints and trial design − arguments pro and contra

J. Bogaerts[1]. [1]*European Organisation for Research and Treatment of Cancer, Statistics Department, Brussels, Belgium*

In many cancer settings, the activity of later treatment lines has improved over time.
As a result, obtaining differences in overall survival in comparative phase III trials becomes a challenge.
In the future, more and more effort will need to be devoted to collecting more detailed information on later treatment lines. Regulators (e.g. EMA) have already opened this discussion, asking for Progression Free Survival 2 (PFS 2) data under certain circumstances. PFS 2 can be freely defined as the time from progression on the study drug until progression on the next (off-protocol) treatment line.
Interpretation of the impact of such further heterogeneous treatment lines, and their effect on the OS comparison for the original comparison, will be a daunting task.
A currently significant example of such undertaking is the class of trials where trialists allow patients progressing on the control treatment arm to 'cross over' to the experimental drug. The decision to allow this cross-over, and the difficulty of interpreting the resulting OS data, has far-reaching consequences for such varying interest groups as: trialists (accrual impact), clinical research, patients on the trial, future patients not on the trial, and HTA assessment.
In absence of a significant OS treatment effect, the question then becomes "what would the treatment effect have been in absence of cross-over?"
Attempts to answer this question have ranged from dismissive (there is no effect seen because the crossover to the experimental works so well), over statistically defective (exclude patients who cross over), to methods that are open to severe criticism.
These methods include censoring at time of cross-over, and inverse weighting methods.
The extent of the problem, and the possible misinterpretation by using some of these methods, will be further illustrated by some simulations.
No conflict of interest.

Special Session (Sat, 28 Sep, 14:15−15:15)
Young People Facing Cancer

36 INVITED

Evidence of a prolonged diagnostic journey for young people with cancer: What do we know now?

L. Fern[1]. [1]*Cancer Research UK, London, United Kingdom*

Cancer in teenagers and young adults is uncommon and overall five year survival rates are an impressive 80%. Despite this, cancer is the leading cause of disease death in developed countries. Whilst overall survival rates are high, this figure varies considerably by cancer type, around 99% for thyroid cancers but diseases such as soft tissue sarcoma conferring five year survival rates of 55% for males, and 58% in females.
Survival for some cancers in young people is less than in children and older adults, notably bone sarcomas. This may be related to a prolonged period to diagnosis, differences in cancer biology, lesser involvement in clinical trials and place of care. Young people frequently report a prolonged period to diagnosis and have strong perceptions of a perceived 'delay' in their diagnosis. Evidence from the UK is now supporting this with young people having more general practitioner consultations prior to referral to secondary care compared to adults and a higher frequency of accident and emergency admissions compared to adults.
Young people and often secondary healthcare professionals frequently point to primary care as a simplistic solution to improving the diagnostic journey for young people. However there are multiple components of the diagnostic pathway where actual or perceived 'delays' can occur. These range from appraisal and recognition of potential symptoms by young people, accessing appropriate healthcare services, referral from primary care and also system processes within secondary care.
This presentation will discuss current evidence suggesting a prolonged period to diagnosis for young people with cancer and importantly the need to determine whether it is related to poorer outcomes.
No conflict of interest.

37 INVITED

Quality of life in children and adolescents surviving cancer

M. Eilertsen[1], T. Jozefiak[2], T. Rannestad[1], M.S. Indredavik[2], T. Vik[3]. [1]*University College of Sør-Trøndelag, Faculty of Nursing, Trondheim, Norway;* [2]*NTNU and St. Olav's University Hospital, Department of neuroscience Regional Center of Child and Adolescent Mental Health and Department of Child and Adolescent Psychiatry, Trondheim, Norway;* [3]*NTNU, Department of Laboratory Medicine Children and Women's Health, Trondheim, Norway*

Background: Childhood cancer involves a crisis for the child and their family. The aim of this study was to explore subjective and proxy reported QoL (Quality of Life) in children and adolescents surviving cancer at least three years after their cancer diagnosis compared with healthy controls.
Material and Methods: Case-control study included 50 children and adolescents diagnosed with cancer between January 1, 1993 − January 1, 2003 and treated at the Paediatric Department of St. Olav's University Hospital in Trondheim, Norway. Data was collected by using The Inventory of Life Quality in Children and Adolescents Questionnaire (ILC) and the KINDL QoL questionnaire (parent and self reports), as well as by collecting data for any somatic late effects and psychological symptoms from the medical records of children surviving cancer.
Results: Adolescents surviving cancer as a group assessed their QoL as similar to that of their peers. However, adolescents surviving brain tumours or those with late effects reported lower QoL and an increased number of QoL domains perceived as problematic, even many years after diagnosis and treatment. Parents generally reported a poorer QoL for their children surviving cancer and a greater number of QoL domains experienced as problematic compared with parent controls.
Conclusion: To improve the child's total functioning and well-being we conclude that when planning long-term follow-up care and rehabilitation of children and adolescents with cancer, especially for survivors with brain tumours and with late effects, it is important to particularly take into account their subjectively perceived and proxy reported QoL, in addition to their psychological problems and psychosocial functioning.
No conflict of interest.

38 INVITED

Delivering age appropriate care for teenagers and young adults with cancer

S. Smith[1]. [1]*Teenage Cancer Trust, London, United Kingdom*

Background: Historically teenagers and young adults (TYA) within healthcare have been treated with younger children or much older adults. In contrast, TYA age- specific units in cancer care have developed over the past twenty years with TYA cancer care now recognized as a distinct speciality within its own right the UK. TYA's are now cared for within purpose built environments and by teams who are experts in the delivery of TYA care.
Material: Teenage Cancer Trust is a UK Charity recognized for being the catalyst in the development of age appropriate cancer services. The charity opened its first specialist Unit in 1990 and over the past twenty years has opened 27 further units across the UK. Centralization of care within Units has enabled a growing body of clinical expertise to develop through years of experience and a multidisciplinary approach. Particularly within nursing, the UK is now seen as a worldwide leader in TYA cancer care.
Results: The best standard of care for TYA patients is undoubtedly provided by those who have been specifically trained or have significant experience in managing this particular client group. The UK's experience in delivering age-appropriate, multidisciplinary and nursing care for the past twenty years has recently been captured within A Blueprint of Care (2012). This Blueprint provides guidance to professionals planning and providing services for young people with cancer and will assist those who are in the early stages of developing care for this age group.
Conclusion: Providing tailor made holistic care for TYA cancer patients requires a multidisciplinary approach and nurses who are highly trained, experienced and knowledgeable. Teenage Cancer Trust believes that investment into nursing is essential to ensure patients have access to the best quality of care, environment and support possible. The charity funds a growing number of specialist nurses and provides funding to support national educational and training programs for professionals. The UK is seen as leading TYA cancer care development and TYA specialist cancer nursing. International colleagues are now starting to develop TYA cancer care within their own countries. This is an exciting time, with TYA cancer care as a distinct specialty now developing beyond the UK and this provides an ideal opportunity for sharing best practice and international collaboration, to ensure the unique needs of this vulnerable patient group are met.
No conflict of interest.

39 INVITED

Developing a model of care for young cancer survivors: An Australian perspective

K. Thompson[1], L. Holland[1], S. Van Staalduinen[1], J. Zalcberg[2], L. Orme[1]. [1]*Peter MacCallum Cancer Centre, ONTrac at Peter Mac, Melbourne Victoria, Australia;* [2]*Peter MacCallum Cancer Centre, Cancer Medicine, Melbourne Victoria, Australia*

Background: Each year in Australia approximately 1000 new adolescent and young adult (AYA) patients, aged 15−25 years, are diagnosed with cancer. While much of the attention to date has focused on the diagnosis and disease management of this population group, the focus is now turning to developing models of care which prioritise young peoples' ongoing development, health, well-being and quality of life beyond the period of treatment completion.
In 2011 the ONTrac at Peter Mac Victorian Adolescent & Young Adult Cancer Service received funding to pilot a model of AYA Survivorship care. This model was informed by international research and clinical advances in the field of survivorship; Victorian government cancer care policy and an emerging understanding of patient experience and need during the post treatment period.
Aim: The aim of this project was to develop, implement and evaluate the efficacy and sustainability of a phase 1 model of survivorship care for young people with cancer in Victoria, treated in both metropolitan and rural centres.
Method: The project involves: a nurse/allied health-led intervention; care-coordination; the development of acute/primary partnerships; developmentally appropriate screening; care-planning and patient review. A total of 100 patients will be recruited over 12 month period from three sites across the Australian state of Victoria. Evaluation comprises the analysis of: patient reported outcome measures, including quality of life, distress and need; qualitative interviews with patients, carers and healthcare professionals in both acute and primary sectors who are involved in the project and; assessment of health economic sustainability.
Discussion: This presentation will describe the experience of the ONTrac at Peter Mac Victorian Adolescent & Young Adult Cancer Service in the delivery of AYA specific cancer care. It will discuss the current model of Survivorship Care being piloted and some preliminary learning to date; specifically in relation to transferability, sustainability and the unique, emerging post treatment survivorship issues for young people within the Australian context.
No conflict of interest.

Special Session (Sat, 28 Sep, 14:15−15:15)
The Role of Biological Imaging in the Assessment in Head and Neck Cancer

40 INVITED

BiGART: Integration of biological imaging in treatment planning, adaptation and treatment strategies for radiotherapy of head and neck cancer

C. Grau[1]. [1]*Aarhus University Hospital, Department of Oncology, Aarhus, Denmark*

Primary radiotherapy plays an important role in the management of squamous cell carcinoma of the head and neck. With novel technology (IMRT, IMPT) it is technically possible to increase the radiation dose, at least to smaller target volumes, without violating normal tissue constraints. Since head and neck tumors are known to be heterogeneous, a logical next step in IMRT is therefore to incorporate more biological features into the initial treatment planning (dose painting) and systematically adapt the treatment as the anatomical and biological features change during the course of treatment. This emerging concept is called Biology-Guided Adaptive RT (BiGART). Relevant biological features for BiGART include hypoxia, proliferation, cell density and intrinsic radioresistance. The principle in dose painting is redistribution and escalation of the radiation dose to these radioresistant parts of the tumour. Hereby, a biologically more effective dose distribution might be achieved while simultaneously sparing normal tissues. Functional imaging modalities for BiGART include dynamic CT with contrast, diffusion weighted MRI, dynamic contrast enhanced MRI, and PET/CT with various tracers. A number of studies have shown that functional imaging imaging information on e.g. hypoxia is prognostic for the outcome of radiotherapy.
The main challenges in BiGART are *resolution* and *dynamics:* The biological features are likely to be more heterogeneous on a microscopic level than what current imaging can pick up. If so, our current imaging and delivery techniques are probably too coarse to fully address the biological distribution. The dynamics of the biological features of interest determines how frequent the patient needs to be subjected to repetitive imaging during radiotherapy. A few early studies have shown that dose-painting and BiGART in principle is possible, although not yet practical nor cost-effective on a daily or even weekly basis.
No conflict of interest.

41 INVITED

Diagnostic biological imaging of early relapse

W.J.G. Oyen[1]. [1]*Radboud University Medical Centre, Department of Nuclear Medicine, Nijmegen, Netherlands*

Molecular imaging with positron emission tomography (PET) has become increasingly important for assessment of patients with head and neck cancer.Although a wide variety of radiopharmaceuticals depicting a variety of tumor characteristics has been studied, the vast majority of the clinical evidence has been established with PET using F-18-fluorodeoxyglucose (FDG). Nowadays, FDG-PET is almost exclusively performed on integrated PET/CT scanners. Integrated PET/CT was a major step forward for adequate evaluation of anatomically complex areas like the head and neck, especially in case of distorted anatomy or the presence of posttherapy changes. FDG-PET/CT is currently used e.g. for detection of unknown primaries, staging, radiation treatment planning, and response assessment and prediction.
Although there is little, if any, evidence to support routine PET/CT surveillance in low risk patients with complete clinical, radiological and PET/CT response after treatment, FDG-PET/CT may have an important role in the evaluation of patients suspected of disease recurrence. Due to its high negative predictive value, there is increasing evidence that FDG-PET/CT is very useful to stratify patients clinically suspected of local recurrence. A negative FDG-PET/CT may therefore prevent unnecessary invasive diagnostic procedures like panendoscopy. However, nonmalignant activity on FDG-PET due to previous treatment negatively affects its positive predictive value. Although timing of the procedure and careful assessment of the exact localization of the increased FDG-uptake may help to avoid treatment-related false-positive findings, histological conformation of PET-positive findings remains the gold standard for decision making on major therapeutic interventions or change of management. Additionally, whole body imaging allows simultaneous assessment of the presence of second primaries or distant metastases, both findings having a significant impact on patient management.
In conclusion, when used appropriately FDG-PET/CT has a significant impact on the management of head and neck cancer patients as it provides important information on disease activity when relapse is clinically suspected.
No conflict of interest.

Special Session (Sat, 28 Sep, 14:15−15:15)
Immune System Radiation Interactions

42 INVITED

Radiation-induced TGFβ suppresses immune cells in the tumor microenvironment

M.H. Barcellos-Hoff[1], I. Pelliccotta[1], S. Du[1], S.C. Formenti[1]. [1]*New York University School of Medecine, Dept Radiation Oncology, New York, USA*

Transforming growth factor-β (TGFβ) has a broad range of pro-tumorigenic and immunosuppressive effects that provide the rationale for strategies to block its activity in cancer. Our recent studies reveal that concurrent radiation is a novel means of unleashing the potential of TGFβ inhibitors in cancer therapy. We have shown that radiation induces TGFβ and that TGFβ is necessary for an effective DNA damage response. Pre-clinical experiments in syngeneic breast, brain and lung cancer models show that TGFβ inhibition compromises DNA damage repair, increases tumor cell kill and significantly improves tumor growth control. Here we show that TGFβ inhibition during fractionated radiotherapy concomitantly alleviates detrimental effects on antigen-presenting cells, reduces the abundance of host tumor associated macrophages (TAM) and suppresses systemic production of myeloid derived suppressor cells (MDSC). As TGFβ inhibition promotes radiation-induced tumor cell death, an immunogenic signal, and blocks radiation effects that suppress immune cells in the tumor microenvironment, we propose that concurrent TGFβ inhibition and radiotherapy provides an innovative therapeutic combination to improve tumor control and activate anti-tumor immune responses.
No conflict of interest.

43 INVITED

Immune modulation and radiotherapy: Ipilimumab and melanoma

M. Postow[1]. [1]*Memorial Sloan-Kettering Cancer Center, New York, USA*

Ipilimumab is a human antibody that blocks the normally negative T cell regulator, cytotoxic T lymphocyte antigen (CTLA-4) and has improved the overall survival of patients with advanced melanoma. Additional research is necessary to improve upon the number of patients who benefit from treatment. Investigations are ongoing to evaluate whether combining ipilimumab with other cancer treatments such as chemotherapy and targeted therapy can be effective in increasing the efficacy of ipilimumab. One equally promising, yet underexplored possibility, involves combining ipilimumab with radiotherapy. Preclinical investigations suggest that radiotherapy can result in immunologic effects that are important for tumor eradication. Murine models have also demonstrated synergy when CTLA-4 blocking antibodies were combined with radiotherapy. Anecdotal cases of synergy between ipilimumab and radiotherapy such as the abscopal effect have also been described in patients. This talk will introduce the preclinical rationale for combining radiotherapy with CTLA-4 blockade and share our experience performing a detailed immunologic assessment of one patient who experienced an abscopal effect. We will also discuss ongoing prospective trials evaluating various aspects of the combination of ipilimumab and radiotherapy.
Conflict of interest: *Advisory board: Participate as a non-paid advisor for Bristol-Myers Squibb. Corporate-sponsored research: Receive research funding from Bristol-Myers Squibb*

Special Session (Sat, 28 Sep, 14:15−15:15)
Minimally Invasive Cancer Surgery: What is the Benefit?

44 INVITED

Robotic surgery

D. Jayne[1]. [1]*St James's University Hospital, Professor of Surgery, Division of Clinical Sciences, Leeds, United Kingdom*

Robotic surgery was introduced into clinical practice in 1999. It quickly found a niche in radical prostatectomy and subsequently attracted attention in other pelvic procedures, including rectal cancer surgery and gynaecological malignancy. In this presentation the evolution of robotic colorectal surgery will be scrutinized with particular focus on rectal cancer.

The evidence base will be considered in addition to the knowledge gaps in an attempt to rationalise its implementation into routine clinical practice. The benefits of robotic assistance as put forward by protagonists will be presented alongside criticisms of wider adoption. An update on the MRC NIHR ROLARR trial (robotic versus laparoscopic surgery for rectal cancer) will be presented.
No conflict of interest.

45 INVITED

NOTES − Natural Orifice Transluminal Endoscopic Surgery

R. Cahill[1]. [1]*Beaumont Hospital, Department of Colorectal Surgery, Dublin, Ireland*

Since its advent in 2008, Natural Orifice Transluminal Endoscopic Surgery (N.O.T.E.S.) has proved a very provocative concept and has spawned very considerable technical and technological innovation. In basic principle, the ability to perform abdominal or thoracic intervention without parietal wall injury is intuitively appealing at least in terms of patient postoperative convalescence and cosmesis. However, its clear that simple replication of procedures already well performed by conventional laparoscopy may not provide large clinical benefit and perhaps may be associated with increased complication rates especially during the learning curve. To develop as a useful and important innovation and step-advance, N.O.T.E.S. needs its own niche application and should be best viewed as a compliment rather than as a competitor to more established operative approaches. Especially interesting in this regard is the recent advent into clinical practice of the PerOram Endoscopic Myotomy (POEM) technique for achalasia and Transanal Proctectomy for benign and malignant conditions of the rectum. In both these cases, N.O.T.E.S. concepts and practice prove additive value to the standard operative portfolio of practicing surgeons and represent prototypicaland template natural orifice procedures for the future.
No conflict of interest.

46 INVITED

Laparoscopic surgery

M. Cuesta[1]. [1]*VU University Medical Center, Department of Surgery, Amsterdam, Netherlands*

Since the systematic introduction of Minimally Invasive Surgery (MIS) beginning 1990, questions continue to arise whether MIS for digestive cancers compares to conventional surgery in terms of efficacy and safety. Minimally invasive techniques to resect the oesophagus in patients with cancer were confirmed to be safe and comparable to an open approach with respect to postoperative recovery and cancer survival.
The only randomized study on this subject, the TIME trial, compared the thoracoscopic in prone position (and laparoscopy) versus the conventional transthoracic (and laparotomy) with intrathoracic or cervical anastomosis. In conclusion, this randomized trial comparing open oesophagectomy for cancer with minimally invasive oesophagectomy shows that MIO results in a lower incidence of pulmonary infections, a shorter hospital stay, and a better short-term quality of life without compromise of the quality of the resected specimen.
Hulscher et al. published the randomized study titled: Laparoscopic versus open subtotal gastrectomy for distal gastric cancer: five-year results of a randomized prospective trial.
They concluded that Laparoscopic radical subtotal gastrectomy for distal gastric cancer is a feasible and safe oncologic procedure and that its short- and long-term results are similar to those obtained with an open approach. Additional benefits for the LG were reduced blood loss, shorter time to resumption of oral intake, and earlier discharge from hospital.
The first published randomized study comparing laparoscopic versus open approach for segmental colon cancer was the “Barcelona trial” by Lacy et al., published in the Lancet in 2002. The astonishing result was that a stage III colon cancer showed a better survival rate in the laparoscopic group than in the open group. This finding positively triggered an increasing use of laparoscopic colon approach to colon cancer in daily surgery all over the world.
Since then, additional multicentric trials have been published, such as the CLASSIC study, the COST study, the COLOR I study, and the Transatlantic study.
The COLOR II trial, has been designed for determining the safety of minimally invasive surgery for patients with rectal cancer. Primary goal of the study was to observe if there were differences in local recurrence between the laparoscopic and open group at three years postoperatively. The interpretation of the results has been that in selected patients with rectal cancer treated by skilled surgeons, laparoscopic surgery resulted in similar safety, resection margins, and completeness of resection to that of open surgery, and recovery was improved after laparoscopic surgery.
No conflict of interest.

Special Session (Sat, 28 Sep, 14:15−15:15)
Treatment of Chronic Lymphocytic Leukaemia

47 INVITED

Genetics of chronic lymphocytic leukemia

P. Ghia[1]. [1]*Vita-Salute San Raffaele University, Milan, Italy*

The heterogeneous biological and clinical profile of Chronic Lymphocytic Leukemia (CLL) has long been appreciated but only over the last decades the genetic complexity hidden by its homogenous phenotype started being unraveled.
First hints derived from immunogenetic and cytogenetic studies in the 1990s, demonstrating that immunoglobulin heavy variable (IGHV) gene mutational status identifies two main subsets, with a clear prognostic implication, as mutated cases usually follow a favourable clinical course while the unmutated ones show a dismal outcome.
Along the same line, studies on genomic aberrations by fluorescence-in situ hybridization (FISH) were able to identify four most frequent alterations and led to a hierarchical model where patients with 13q deletion>normal karyotype>trisomy 12>11q deletion>17p deletion show a progressively worsening disease course. In terms of molecular pathogenesis, the favourable prognosis of patients bearing del13q has been recently linked to specific microRNAs (miR15a/16−1) loss. These two non-coding RNA molecules act as epigenetic negative regulators of several genes, including the pro-apoptotic protein BCL2. Interestingly, the 13q deletion was found in CLL-like monoclonal B-cell expansions (so-called MBL) even in clones with <1 cell/μl, suggesting a potential association of this lesion with the acquisition of a CLL-phenotype rather than with a true leukemic condition. On the other side the unfavourable clinical outcome of patients with 17p deletion is explained by the loss of TP53, a well-known tumour-suppressor gene.
Interestingly, recent next generation sequencing studies gave additional insights into the genetic landscape of CLL. Beside the previously known alterations of the TP53 gene, novel mutations involving different pathways (NOTCH1 or non-canonical NFkB signalling, the spliceosome machinery) were reported and showed to play a relevant role in chemoresistance and disease transformation. None of these mutations seem to explain early events in disease pathogenesis, being mostly related to advanced phases of the disease.
Future research efforts will be focussed on dissecting the genetic complexity of CLL in relationship with the microenvironmental interactions occurring in the disease. This will help to reach a better understanding of CLL pathogenesis and to the identification of univocal molecular signatures able to define progression risk and likely to guide a tailored treatment approach.

48 INVITED

First-line treatment of chronic lymphocytic leukaemia

Abstract not received.

49 INVITED

Treatment of relapsed chronic lymphocytic leukaemia

S. Stilgenbauer[1]. [1]*Uniklinik Ulm, Ulm, Germany*

Chronic lymphocytic leukemia (CLL) is characterized by a highly variable clinical course. Among the biological features underlying this heterogeneity, genetic lesions and the mutational status of the immunoglobulin heavy chain variable genes (*IGHV*) are of importance. Therapeutic options in CLL have been considerably expanded during recent years. The combination of fludarabine, cyclophosphamide and rituximab (FCR) has become gold standard in the first-line treatment of physically fit patients. Bendamustine plus Rituximab (BR) is currently evaluated in comparison to FCR and chlorambucil is still of relevance for elderly patients with comorbidities. Alemtuzumab is an alternative for high-risk patients (refractory CLL, 17p deletion, *TP53* mutation). Allogeneic stem cell transplantation (allo-SCT) offers the only chance of cure but not without substantial mortality. Innovative approaches focus on individualized, targeted therapies. A number of novel agents are in clinical trials and show marked efficacy combined with good tolerability. This review provides an overview of the current therapeutic options and of promising novel approaches.

DNA methylation alterations: Promising biomarkers for diagnosis and treatment response in cancer

J. Tost[1]. [1]*CEA- Institut de Genomique Centre National de Genotypage, Laboratory for Epigenetics & Environment, Evry, France*

Cancer is probably the best-studied disease with a strong epigenetic component. The recent advances in microarray- and sequencing-based technologies for the analysis of high-resolution genome-wide DNA methylation patterns have led to an exponential growth in the number of genes and genomic regions reported as being differentially methylated in specific cancers and has demonstrated a crucial role for epigenetic changes in cancer initiation, progression and treatment.
As a stable nucleic acid based modification with limited dynamic range that is technically easy to handle, DNA methylation is a promising biomarker for many applications. DNA methylation can be detected and quantified by a number of technologies including genome-wide screening methods as well as locus- or gene-specific high resolution analysis in different types of samples such as frozen tissues and FFPE samples, but also in body fluids such as urine, plasma, and serum obtained through non-invasive procedures. The knowledge of epigenetics in drug response is still in its infancy. However, the analysis of DNA methylation patterns for treatment response, also termed pharmacoepigenomics, is expected to identify novel biomarkers that can be useful for understanding response to chemotherapy as well as resistance to drugs before the beginning of the treatment. DNA methylation might help to predict the clinical phenotypes in individual patients and may be a proper biomarker to optimize individualized cancer treatment. In some cases, DNA methylation-based biomarkers have already proven to be more specific and sensitive than commonly used protein biomarkers, which could clearly justify their use in clinics. However, very few of them are at the moment used in clinics and even less commercial tests are currently available.
The objective of this presentation is to discuss the advantages of DNA methylation as a biomarker, the practical considerations for their development, and their use in disease detection, prediction of outcome or treatment response, through selected examples.

52 INVITED

Genomic instability − relevance for progression and outcome in breast cancer

A. Børresen-Dale[1]. [1]*The Norwegian Radium Hospital, Department of Genetics, Oslo, Norway*

Patterns of genomic aberrations have been defined that underlie specific expression subgroups of breast cancer (BC) that may infer paths of tumor progression and shed light on mechanisms involved. Classifications built on levels of genomic distortion have been shown to have prognostic value. We have developed two platform-independent algorithms to explore genomic architectural distortion using aCGH data to measure whole-arm gains and losses [whole arm aberration index (WAAI)] and complex rearrangements [complex arm aberration index (CAAI)]. By applying CAAI and WAAI to data from 595 BC patients, we were able to separate the cases into eight subgroups with different distributions of genomic distortion. Within each subgroup data from expression analyses, sequencing and ploidy indicated that progression occurs along separate paths into more complex genotypes. Histological grade had prognostic impact only in the luminal-related groups, whereas the complexity identified by CAAI had an overall independent prognostic power. The results emphasized the relation among structural genomic alterations, molecular subtype, and clinical behavior and showed that objective score of genomic complexity (CAAI) is an independent prognostic marker. We have recently validated the prognostic power of the CAAI index in a large series of breast cancers from the METABRIC cohort.
To investigate the significance of altered gene dosage on expression, both in-cis and in-trans, a stepwise gene selection method was developed, aiming to identify gene dosage that are strongly associated to expression and associated in-trans to specific biological processes. Several potentially new cancer genes were identified and their biological relevance supported by enrichment analysis of their in-trans correlated genes. These include known breast cancer driver genes (e.g. ATAD2), known oncogenes not yet associated with breast cancer (e.g SETDB1) and novel candidates (e.g. MTL5).

Scientific Symposium (Sat, 28 Sep, 16:00−18:00) **Therapeutic Implications for New Targets in Lung Cancer**

53 INVITED

Immune-checkpoints (PD1, PDL1)

Abstract not received.

54 INVITED

PI3K-AKT-mTOR

B. Besse[1]. [1]*Institut Gustave Roussy, Service Gard +7, Villejuif, France*

Due to successful therapeutic development (and partly to biomarker discovery), recent clinical developments in non small cell lung cancer (NSCLC) have mainly focus on EGFR targeted drugs and anti-angiogenic agents. The mammalian target of rapamycin (mTOR) is a protein kinase of the phosphatidylinositol 3-kinase (PI3K)/Akt signaling pathway with a central role in the control of cell proliferation, survival, mobility, and angiogenesis. In more than 50% of lung carcinomas, AKT and mTOR are activated. In response to growth factor stimulation, PI3K is activated, leading to the recruitment of AKT to the plasma membrane where it is activated by phosphorylation. AKT phosphorylates many effectors including TSC (tuberous sclerosis complex)-1/2, leading to its inactivation. The inactivation of TSC2 leads to the activation of mTOR. Mutations in these components or in PTEN, a negative regulator of PI3K, may result in the upregulation of this pathway.
mTOR inhibitors are a class of signal transduction inhibitors with anti-cancer activity that were initially developed as immunosuppressive agents. Temsirolimus and everolimus are both approved in metastatic kidney cancer. Everolimus has been actively developed in NSCLC. It has limited efficacy as a single agent (10 mg/d). In a phase I/II, daily or weekly everolimus has been combined to 150 mg/d erlotinib and dose limiting toxicities were stomatitis, diarrhoea and skin rash. There was no improvement of overall survival compared to erlotinib alone. No predictive factor of mTor inhibitor efficacy has been reported so far. In particular, the efficacy of the mTOR inhibitor ridafolimus in the subgroup of *KRAS* mutated tumors has not been confirmed. Pan-PI3K inhibitors target the catalytic domain of the class IA PI3K p110 subunits, the class most widely implicated in cancer. Combination with second line or first line chemotherapy implies various Pi3K inhibitors such as BKM120, SAR245408 (XL147), PX-866, GDC-0941, and BAY-80–6946. BKM120 is been evaluated as a single agent in the subgroup of *PI3KCA* mutated (2−5%) or PTEN loss (24−44%) NSCLC. The catalytic domains of the p110 subunits and mTOR1/2 share a structural homology. Dual inhibitors are under investigation as BEZ235, SAR245409, GDC-0980, and GSK2126458. Finally, AKT inhibitors are being developed in early trials. mTOR, PI3K and ALK inhibitors share the same pattern of toxicities, including hyperglycemia, hypertriglyceridemia, hepatotoxicity, mucositis, and fatigue.
No conflict of interest.

55 INVITED

Ras-Raf-MEK Pathway

J. Schellens[1]. [1]*The Netherlands Cancer Institute, Medical Oncology, Amsterdam, Netherlands*

The Ras-Raf-MEK, i.e. the MAPK pathway is “hot” in the treatment of non-small cell lung cancer (NSCLC) and other solid tumors. KRAS mutations (KRASm) have been associated with NSCLC since many years and recently also mutations downstream of KRAS especially BRAF, albeit at low frequency, have been detected in NSCLC. Besides, NRAS mutations have been identified as well in NSCLC. About a decade ago attempts to block KRAS signalling by farnesyltransferase inhibitors turned out to be ineffective, confirming the wrong concept behind this approach. Recently novel inhibitors of KRAS signalling have been presented acting through impairment of the interaction between the prenyl-binding protein PDEδ and KRAS. Clinical studies testing MAPK inhibition downstream of KRASm at the level of MEK have shown promise. Combinations of a MEK inhibitor (MEKi; for example selumetinib) and docetaxel have been selected for pivotal studies. Furthermore, in clinical proof of principle studies the concepts of dual intrapathway and interpathway inhibition in the case

of KRASm is tested. Dual intrapathway inhibition of tyrosine receptor kinase activity (TKI) downstream of KRASm by combining BRAFi and MEKi was found to be active in preclinical models. Clinical validation is warranted. In view of crosstalk with other pathways dual interpathway inhibition by MEKi plus IGF1Ri is of interest as well. Epigenetic therapy by combining azacitidine at relatively low dose and entinostat, inhibitors of DNA methylation and histone deacetylation, was found to be active in phase I/II studies, however activity in patients with mutations in the MAPK pathway needs to be established. These novel concepts hold promise for patients with NSCLC and well established biomarker profile of the tumor.
No conflict of interest.

ALK and HSP90

Abstract not received.

Scientific Symposium (Sat, 28 Sep, 16:00−18:00) **Castration Resistant Prostate Cancer Targeting Cancer Cells, Microenvironment and Stem Cells**

57 INVITED

Targeting stem cells in castration-resistant prostate cancer

N. Maitland[1]. [1]*University of York, Department of BiologyYCR Cancer Research Unit, York, United Kingdom*

Fatal, therapy-resistant cancers like castration-resistant prostate cancer (CRPC) arise from an adaptive process, by which a cell develops the intracellular signalling mechanism(s) to resist or even thrive in the new environment induced by the therapeutic agent. Most cells, and stem cells in particular, are programmed with salvage pathways to preserve integrity in the face of mutagenic insults. The cancer stem cell (CSC) hypothesis states that the resistant tumours arise from a therapy resistant stem cell, rather than by adaptive mutation of a mature cancer cell. The CSCs are now proven to have a quiescent and undifferentiated phenotype, closely related to that of the normal stem cell. Stem cell quiescence is maintained until a tissue is damaged, when it participates in the repair process. In a cancer this corresponds to therapy-induced cytotoxicity. The success of therapy resistance is therefore measured by the restoration of tumour bulk, but the true 'founder changes' which permit the tumour to establish at metastatic sites and resist elimination of aberrantly proliferating cells, should also be present in the CSCs.
I will present evidence that the bulk of tumour cells in prostate cancers i.e. the tumour component against which current therapies are directed, have no or minimal tumour inducing properties, and that lower Gleason grades (<7) of prostate cancer are unable to initiate tumour growth in an improved xenograft model of invasive prostate cancer. Furthermore, the identification of changes in the expression of cancer-specific, cell surface genes in primary cell cultures enriched for CSCs, has provided new therapeutic targets. When expression of these genes is eliminated by SiRNA treatment, the greatest effect on colony formation is seen in the castration resistant cancer cell line PC3, compared to benign and non-malignant cell lines. The SiRNA knockdowns had fewer effects on cell growth: the usual paradigm for an anti-cancer agent. When used *in vivo*, prior inhibition of cancer-specific gene expression in the CSCs, from both cancer cell lines and near-patient human xenografts, eliminated cancer induction, even after inoculation of up to 10^6 viable cells. The *in vivo* model corresponds most closely to the initiation of metastasis, the fatal lesion in CRPC.
We also find that application of such agents has only minimal effects on established xenograft tumour growth in vivo, in agreement with the absence of the treatment targets in the bulk tumour cells, but preliminary data suggests that secondary tumour growth, upon re-transplantation, is severely impaired. The challenge in applying such therapies for clinical trials will be to achieve discrete endpoints. We propose that CSC cytotoxic treatments should be combined with traditional therapies to achieve the desired clinical efficacy. Alternatively, based on the outcome of experimental treatments which indicate that many agents achieve a loss of clonogenicity by differentiating the CSCs rather than killing them, that such agents (some of which have already been approved for clinical use) should be used to modify the fate of the SC into mature differentiated tumour cells. The general applicability of CSC therapies in CRPC could nevertheless be confounded by the presence of oligoclonal disease in which the resistant CSC has solved the problem of resistance by perturbation of multiple different signalling pathways. Furthermore, our strategy of identifying cancer-specific changes in CSCs, which are essential for CSC maintenance, has real advantages over inhibition of signalling associated with 'stemness' as a therapeutic strategy, which could have unwanted effects in other stem cell compartments.
No conflict of interest.

58 INVITED

Targeting immunosystem

W. Gerritsen[1]. [1]*Radboud University Nijmegen Medical Centre, Department of Medical Oncology, Nijmegen, Netherlands*

Sipuleucel-T (dendritic cells loaded with prostate acid phosphatase/GM-CSF) was the first immunotherapy product, which was registered for CRPC and even for all solid tumors. Sipuleucel-T guided us that progression free survival (PFS) and PSA responses were not reliable end points for immunotherapy trials. Overall survival is the only significant endpoint of clinical trials. Toxicity is very mild. Sub analyses have indicated that this product prolonged survival especially in elderly men. Functional T-cell studies have not yet revealed immunomarkers predictive for survival or prognosis.
Prostvac (vaccinia/fowl pox virus transduced with PSA gene) did not induce significant responses or PFS, but a remarkable survival advantage of 9 months over placebo in a phase II study. Toxicity is mild. In a small study patients with a T-cell response against PSA had a superior survival compared to those who did show any T-cell response. Encouraging phase II studies have indicated that Prostvac works well in combination with other agents, such as the radio-isotope samarium. A large phase III trial is accruing patients.
Ipilimumab (monoclonal antibody against the checkpoint CTLA-4) have shown anti-tumor activity in CRPC in several phase II studies with some long lasting survival. Toxicity is mild in most patients. Two phase III studies (one in chemo-naive patients and one in patients pretreated with docetaxel) have finished accrual. The results of the phase III study combining irradiation of metastases and Ipilimumab will be presented at this meeting.
Targeting the immune system, we should learn from all the immunotherapy trials; which patient to treat with immunotherapy (low versus high tumor burden, low versus high Gleason score), when can you expect a clinical response, and what is the influence of subsequent treatments on the outcome of an immunotherapy trial.
Inducing an immune response is a first step in immunotherapy. Both Sipuleucel-T and Prostvac are designed for this critical first step. However, the next step is more crucial; elimination of tumor cells within the microenvironment. At present, we learn more and more about immunosuppressive cells, like the myeloid derived suppressor cells and T-regs, and immunosuppressive cytokines which play an essential role at the effector phase of immunotherapy. Drugs, such as Ipilimumab, play an important role to change the microenvironment within a tumor, but also chemotherapy and other agents could be applied to boost the effector phase of immunotherapy.
Conflict of interest: *Advisory board: Amgen, BMS, Sanofi, Astellas, Johnson & Johnson, BNIT*

59 INVITED

Targeting bone microenvironment

F. Saad[1]. [1]*CHUM − Notre-Dame Hospital, Montreal Quebec, Canada*

Bone metastases will occur in over 90% of men with lethal castration-resistant prostate cancer (CRPC). Due to the combined effect of bone fragility due to ADT and the presence of bone metastases almost all patients will experience some form of morbidity related to bone metastases prior to succumbing from the disease. Complications include severe pain, pathologic fracture, the need for palliative radiation or surgery and spinal cord compression. These events impair quality of life and place a significant burden on health-care resources.
Zoledronic acid is the only bisphosphonate that has shown a protective effect against skeletal-related events (SRE) in patients with metastatic castration-resistant prostate cancer. The phase 3 study showed a 48% reduction in the mean annual incidence of SRE ($P = 0.005$), 5 months prolongation in the median time to first SRE ($P = 0.009$) and 36% reduction in the ongoing risk of SRE's at 24 months. **Denosumab** is a fully human monoclonal antibody that specifically targets RANKL thus effectively inhibiting osteoclastic function and bone resorption, In the setting of metastatic CRPC, denosumab (120 mg SC every 4 weeks) compared to zoledronic acid (4 mg IV every 4 weeks) significantly improved the time to first SRE (20.7 vs 17.1 months; $P<0.001$ for non-inferiority; $P = 0.008$ for superiority). Overall survival and progression free survival were similar for both drugs. Hypocalcemia was more common with denosumab (13%) than with zoledronic acid (6%) ($P<0.0001$) and a non-significant trend toward higher osteonecrosis of the jaw was seen with denosumab (2.3% vs 1.3%; $P = 0.09$) (12).
In a placebo controlled trial in non metastatic CRPC, denosumab significantly increased the bone-metastasis-free survival in patients with non-metastatic CRPC by a median of 4.2 months (29.5 vs 25.2 months; HR, 0.85; 95% CI, 0.73–0.98; $P = 0.028$) [18]. Although hypocalcemia was much lower in the setting of non-metastatic CRPC the risk of ONJ was higher given the longer exposure time to denosumab.

A recently completed phase III study of patients with metastatic CRPC were randomized on a 2:1 basis to either **radium-223** (an alpha emitting bone seeker) or placebo. To be eligible for the study patients had to have bone metastases and have progressed after chemotherapy or were not eligible to receive chemotherapy. Patients received 6 cycles of either radium 223 or placebo every 4 weeks. Median survival was 14 months for the treated patients as opposed to 11.2 months for those who received a placebo, conferring an approximate 30% improvement in OS (HR 0.699, p 0.0022). The study also showed a 5 month delay in time to skeletal related events. This agent has recently been approved by the FDA and is the first bone targeted agent to demonstrate a survival advantage.

60 INVITED
Cancer cells in general and specific pathways

J. De Bono[1]. [1]*The Royal Marsden NHS Foundation Trust and Institute of Cancer Research, Drug Development Unit & Institute of Cancer ResearchSection of Medicine Sycamore House, Sutton, United Kingdom*

Prostate cancer is the commonest cancer in men in the Western world and remains the second commonest killer from cancer. Increasing evidence is mounting that this disease is at least in part generated by double strand DNA breaks induced by androgen driven transcription involving topoisomerase 2 beta. This leads to the common occurrence of hormone driven rearrangements, involving androgen response elements driving potent oncogenes including ETS genes, RAS and RAF. The loss of key tumour suppressors activating the PI3K/AKT pathway is also implicated as being critical to prostate carcinogenesis. Whole genome sequencing efforts have identified multiple aberrations involving AR and its co-regulators, its pioneer factor FOXOA1 as well as other genes including SPOP and MED12, DNA repair genes and other genes. These studies are fuelling hope for an improved understanding of prostate cancer disease biology and castration resistance, with an increasing volume of functional data elucidating the mechanisms of castration resistance. This presentation will focus of the recent advances in therapeutics including abiraterone, cabazitaxel, enzalutamide, radium 223 and sipuleucel T as well as how our improved understanding of prostate cancer disease biology can impact therapeutic advances for this disease.
No conflict of interest.

Scientific Symposium (Sat, 28 Sep, 16:00−18:00)
New Classification of Melanoma and its Consequences for Treatment

61 INVITED
New developments in the inherited molecular epidemiologic field

J. Newton Bishop[1]. [1]*University of Leeds, Leeds, United Kingdom*

Cutaneous melanoma is strongly genetically determined as the majority of cases occur in pale skinned peoples. Within these pale skinned populations, furthermore, inherited phenotypes are strong predictors of risk (skin which tends to burn in the sun and large numbers of melanocytic nevi. Progress in the identification of common but relatively low risk susceptibility genes using genome wide association studies (GWAS) has been rapid in recent years: 16 single nucleotide polymorphisms (SNPs) associated with risk are described and some of these are (predictably) associated with skin type (*MC1R, Tyr, Agouti, SLC45A2 and IRF4*). Others are associated with nevus number (*PLA2G6*, a SNP on chromosome 9 and *TERT*). Some are in or near to genes which are as yet of unknown function with respect to melanoma evolution, such as in the *FTO* gene (normally associated with obesity) and efforts are currently being expended to understand their role because of what more this will tell is about melanomagenesis.
Intermediate to high penetrance susceptibility genes have also recently become better understood. Inherited mutations in the *CDKN2A* gene (which codes for two proteins p16 and p14ARF) were first identified many years ago and it has taken some time to identify additional genes. *CDK4* mutations (at the p16 binding site) have been identified in 17 families worldwide, and more recently an intermediate penetrance variant in *MITF* was described by two groups simultaneously. Most recently of all a rare familial promoter mutation in the *TERT* gene coding for telomerase reverse transcriptase was described in a large family with 14 melanoma cases.
A number of these gene associations support the model developed by Dot Bennett and others, in which the control of cell growth in cells of the melanocyte lineage was postulated to be dependent upon tumor suppressor proteins such as p16 (leading to senescence) and that growth inhibition could be overcome by telomerase: highlighting the particular role of p16 and the telomere in melanoma carcinogenesis.

63 INVITED
Towards an integrated taxonomy of melanocytic neoplasia

B. Bastian[1]. [1]*UCSF Comprehensive Cancer Centre, San Francisco, USA*

Melanomas are comprised of multiple biologically distinct categories, which differ in cell of origin, age of onset, clinical and histologic presentation, pattern of metastasis, ethnic distribution, causative role of UV radiation, predisposing germ line alterations, mutational processes, and patterns of somatic mutations. Neoplasms are initiated by gain of function mutations in one of several primary oncogenes, typically leading to benign melanocytic nevi with characteristic histologic features. The progression of nevi is restrained by multiple tumor suppressive mechanisms. Secondary genetic alterations override these barriers and promote intermediate or overtly malignant tumors along distinct progression trajectories. Some types of melanomas arise without a recognizable benign stage. The current knowledge about pathogenesis, clinical, histological and genetic features of primary melanocytic neoplasms is reviewed and integrated into a taxonomic framework.
No conflict of interest.

64 INVITED
BRAF and RAS signalling in melanoma: From basic biology to clinical exploitation

R. Marais[1]. [1]*Paterson Institute for Cancer Research, Manchester, United Kingdom*

The BRAF protein controls cell growth, differentiation and survival. The *BRAF* gene is mutated in ~45% of melanomas, and its upstream activator, the small G-protein NRAS is mutated in a further ~20% of cases. Drugs that inhibit BRAF can achieve impressive clinical responses in BRAF mutant melanoma patients. However, general these responses are short lived and most patients develop resistance after a short period of disease control. Thus, improved knowledge of melanoma biology is essential to underpin the development of personalised/precision treatments for melanoma patients. We have found that in some patients resistance to BRAF drugs is mediated by increased EGF receptor (EGFR) signalling and that BRAF and EGFR drugs cooperate to suppress the growth of resistant tumours. Thus, a combination of BRAF and EGFR drugs may suppress the emergence of resistance in some patients.
We are also developing mouse models of melanoma to study the role of BRAF and NRAS in melanomagenesis. Oncogenic BRAF induces melanoma when expressed in adult mice, but not when expressed in embryonic mice. However, our data also shows that although BRAF can be an initiating event in melanomagenesis, it is not sufficient and other cooperating events are required. Notably, oncogenic NRAS does not induce melanoma when expressed adult mice, but does induce melanoma of the brain that resembles leptomeningeal melanocytosis in children. Thus, the different populations of melanocytes appear to display distinct susceptibility to transformation by the individual oncogenes from this pathway.

Scientific Symposium (Sat, 28 Sep, 16:00−18:00)
Cancer Pain Management Barriers: Can We Overcome Them?

65 INVITED
Patient-related barriers

S. Gunnarsdottir[1]. [1]*Landspitali University Hospital, Research and Development, Reykjavik, Iceland*

Pain management remains a challenge in patients with cancer. The reasons are numerous, among them attitudinal barriers that have been found to negatively affect the quality of pain management and in turn quality of life. These attitudinal barriers include fatalistic beliefs about cancer pain,

fear of addiction, concerns about tolerance and side effects, concerns that strong pain medication mask changes in one's body, and harm the immune system, the belief that 'good patients' do not complain about pain, and that reports of pain may distract physicians from treating the underlying disease. Such barriers are prevalent among patients, family members, the general public and health care professionals including physicians and nurses. Prior research suggests that patients' who have attitudinal barriers to cancer pain management use less potent analgesics than those who do not have such barriers. In turn these patients have more pain, experience more pain related interference with life activities and more impairment in QOL. Numerous interventions have been tested to overcome patient related barriers, some of which have shown promising results. The focus of this presentation will be on interventions aimed at patients to overcome patient related barriers to cancer pain management.
No conflict of interest.

66 INVITED
Nurse-related barriers

Abstract not received.

67 INVITED
Nursing interventions

S. Piskorjanac[1]. [1]*University Hospital Osijek, Department of Radiotherapy and Oncology, Osijek, Croatia*

As a nursing diagnosis pain is defined as: "The state in which an individual experiences and reports the presence of severe discomfort or an uncomfortable sensation." The most frequently cited definition of pain is from pain management pioneer Margaret McCaffery, RN: "Whatever the experiencing person says it is, existing whenever he says it does."
Sadly, pain is all too often undertreated. The WHO describes cancer pain as "commonly undertreated and frequently neglected as health care problem". The reasons for this are multifactoral; poor identification of just how much pain the patient is experiencing, reluctance on the part of the sufferer to admit to pain and, most frequently, a poor understanding of analgesics.
The nurse is in a prime position to allay the patient's fears, to educate him and to ensure that effective pain control is integrated into the complete programme of healthcare provided for the patient. In particular, when nursing patients for whom the prospect of cure is remote or non-existent, putting pain control at the forefront of palliative care is crucial. Nurses have more constant contact with patients than other healthcare professionals and this places them in a unique position to assess patient's needs for pain control and to monitor the success of interventions in bringing pain relief. They need to understand the physiology of pain, the pharmacology of analgesic drugs, the nursing management of pain and complementary (or alternative) techniques which are available for pain control. Nurses need to be familiar with scales for measuring pain and be aware of other factors that are important in assessing patient distress. The nurse will need to explain treatment and strategies to patients and their families and be able to make informed contributions to discussions of patient care with other members of the healthcare team.
Despite these considerations, pain control is given low priority in nursing training.
No conflict of interest.

Novel Targets in Radiation Oncology

69 INVITED
In vitro and In vivo discovery of novel therapeutic targets using functional genomics

B. Wouters[1]. [1]*Ontario Cancer Institute, Toronto Ontario, Canada*

Radiotherapy is used as a curative treatment in many types of cancer with tumour control rates that vary significantly by disease type and tumour stage. Several known biological factors adversely influence treatment efficacy in a patient specific manner, including DNA repair mechanisms, tumour cell proliferation, and tumour hypoxia. These biological phenotypes have served as the basis for development of alternative therapeutic approaches incorporating alternative treatment schedules and/or addition of chemotherapy or molecularly targeted agents. However, it is clear that each of these biological mediators of tumour radioresistance is influenced by a large number of underlying genes and cell signaling pathways, many of which are altered during carcinogenesis. Thus, there is a need for development of investigational approaches that are able to interrogate the potential of targeting individual genes and pathways to improve radiation sensitivity in a high throughput manner. To do so, we have initiated a series of functional genomic screens to identify genes that play essential roles in promoting cellular resistance to hypoxia and cellular radiosensitivity. Our approach utilizes lentiviral delivered shRNA libraries ranging in size from 200–80,000 unique shRNAs. Highly complex shRNA pools targeting ~16,000 human genes have been used to discover a series of novel genes and pathways that confer sensitivity to hypoxia and to radiation treatment in vitro. In addition, smaller focused pools targeting receptor tyrosine kinases, or the entire human kinome have been interrogated both under in vitro conditions as well as in xenografts growing in vivo. Our results reveal a number of novel targets that function in a contextual synethetic lethal manner to increase tumour radiosensitivity and which are thus potential new targets for combination therapy.

Reprogramming metabolism with metformin improves tumor oxygenation and radiation response

M. Koritzinsky[1]. [1]*University Health Network, Princess Margaret Cancer Center, Toronto, Canada*

Background: Tumor hypoxia contributes to poor outcome in patients treated with radiotherapy due in part to the high radiation resistance of hypoxic cells. Oxygen gradients form around perfused vessels due to oxygen consumption, and at distances of 100–150 μm reach levels low enough to cause profound resistance to radiation. Inhibition of oxygen consumption therefore represents a potential strategy to increase the diffusion distance of oxygen in tumor tissue, reduce tumor hypoxia and increase radiation response. Metformin is a commonly prescribed anti-diabetic drug that reduces cellular oxygen consumption by inhibiting complex I in the mitochondrial electron transport chain. We therefore hypothesized that metformin can reduce therapeutically relevant hypoxia in tumors.
Materials and Methods: Oxygen consumption rates were measured in a panel of cancer cell lines exposed to various concentrations of metformin. We investigated whether an acute dose of metformin could reduce levels of hypoxia in established colon cancer xenografts in vivo. To that end, we used a double labelling approach with the hypoxia markers pimonidazole and EF5 detected by immunohistochemistry (IHC) and flow cytometry. We also measured tumor hypoxia by non-invasive 18F-FAZA-PET imaging in the same tumor models. Finally, we administered metformin immediately prior to a subcurative irradiation dose of 15 Gy and measured tumor growth delay and ex vivo clonogenic survival.
Results: We observed a dose- and time-dependent reduction in oxygen consumption in response to metformin, with some sensitive cell lines responding acutely to concentrations that are similar to the steady-state plasma levels in diabetic patients. Metformin administration resulted in rapid tumor reoxygenation in two colon cancer xenograft models as measured by IHC, flow cytometry or 18F-FAZA-PET. Furthermore, metformin substantially potentiated radiation-induced tumor growth delay, consistent with less hypoxic, more radiosensitive tumors. Data from in vitro and ex vivo clonogenic assays confirmed that metformin increases radiation response of tumors by decreasing the fraction of radiation resistant hypoxic cells.
Conclusion: Metformin inhibits oxygen consumption, reduces tumor hypoxia and consequently increases tumor radiation response. These data suggest that a commonly prescribed, affordable and safe drug, metformin, can be repurposed as a cancer therapeutic in order to improve outcomes after radiotherapy.

72 INVITED
Focal adhesion as important determinant of radiation survival

N. Cordes[1]. [1]*Oncoray, Medical Faculty Carl Gustav Carus, Dresden, Germany*

Background: A plethora of intra- and extracellular factors coact for therapy resistance of malignant tumors. Major points of intersection of prosurvival signaling are focal adhesions. Located at the cell membrane and composed

of cell adhesion molecules, growth factor receptors, protein kinases and adapter proteins, these structures act as most upstream and powerful sources of promitogenic biochemical cues, on the one hand, and, on the other hand, serve as easily druggable and frequently overexpressed cancer targets. In this overview, the latest findings about focal adhesion function in cancer, how potent preclinical approaches are and what we have learnt about recent clinical failure of inhibition of integrin cell adhesion receptors (e.g. Cilengitide) will be discussed.
Conclusions: Focal adhesion proteins, especially integrins and growth factor receptors, co-regulate cancer progression and therapy resistance. Combined therapeutic targeting of these cell surface receptors simultaneously with conventional radio- and chemotherapy might substantially improve cancer cure rates.

74 INVITED
Challenges and opportunities to develop novel drugs on the backbone of radiotherapy

V. Gregoire[1], S. Rivera[2], C. Vens[3]. [1]*Université catholique de Louvain St-Luc University Hospital, Department of Radiation Oncology, Brussels, Belgium;* [2]*Gustave Roussy Institute, Department of Radiation Oncology, Villejuif, France;* [3]*The Netherlands Cancer Institute, Department of Radiation Oncology, Amsterdam, Netherlands*

Radiotherapy is one of the most effective modality to cure cancer at a loco-regional stage, and its use as a primary modality or in the post-operative setting has been recognized in a variety of tumor types. Furthermore, with the introduction of modern way of delivering dose such as Intensity Modulated Radiation Therapy (IMRT), radiotherapy has proven to be not only effective, but also much less toxic than in the past. However, despite these improvements it is estimated that on average around 20% of patients may ultimately die of a lack of loco-regional tumor control, and in this setting, there is a growing appreciation of the potential value of combining novel targeted drugs with radiotherapy. Such approaches have the potential to further improve loco-regional disease control and cure rates across a diverse range of tumor types.
Combining radiation with novel drugs requires the appreciation of how these agents could potentially affect key cellular pathways involved in response to ionizing radiation, and then, how they should be properly combined with radiotherapy to maximize tumor interaction and minimize normal tissue toxicity. Such objective requires the development of research programs starting from pre-clinical proof of concept studies, moving quickly to clinical phase I−II trials, and ending with validation phases-III studies. However, such studies will have to be launched early on in the development phase of a new agent, and embark comprehensive translational biological and imaging surrogates of efficacy and/or toxicity aiming at individualizing those patients that are the most likely to benefit from the new concept, and thus on whom dedicated validation studies will have to be conducted.
In conclusion, despite the challenges, radiation therapy combinations with novel drugs present a significant opportunity to further improve cancer cure. In this framework, as an international infrastructure combining high methodological and quality assurance standards, together with a network of dedicated investigators, EORTC is an ideal platform to conduct such research programs in a new collaborative model with the pharma sector.

75 INVITED
Challenges and opportunities for surgical trials, the role of quality assurance

M. Den Dulk[1], G.J. Poston[1], C.J.H. Van de Velde[2]. [1]*Aintree University Hospital, Surgery, Liverpool, United Kingdom;* [2]*Leiden University Medical Center, Surgery, Leiden, Netherlands*

For almost all solid organ cancers, randomised trials have been performed to study different treatment strategies. For these tumours, surgery is the most important variable for recurrence and survival. For example in rectal cancer 5 year overall survival was 48% without preoperative radiotherapy before the introduction of TME surgery, but increased to 64% with TME surgery if no preoperative treatment was given. This large improvement of survival was mainly attributed to a change in surgical technique.
The effect of surgery on recurrence and survival for solid organ tumours has been neglected in many earlier trials aiming to evaluate the efficacy of systemic treatment and radiotherapy. In a trial for e.g. breast cancer preoperative radiotherapy has been shown to decrease locoregional recurrence from 32 to 9% for high risk women treated with mastectomy and adjuvant chemotherapy. However, the high local recurrence rates question surgical quality. Besides, a treatment effect of a (neo)adjuvant treatment found in patients with inadequate surgical treatment should be doubted. In rectal cancer e.g. the effect of preoperative radiotherapy became stronger as the distance from the anal verge increased. However, when patients with a positive circumferential resection margin were excluded, the relation between distance from the anal verge and the effect of radiotherapy disappeared. Quality assurance is therefore both a challenge and a necessity to account for the surgical variance and should be a condition for all future surgical trials.
Trials have an educational effect. Some of the effects of trials are seen on a national level. However, only the minority of our patients are treated within a trial. To structurally gain insight in (inter)national cancer care an audit is necessary. An audit should be seen as a quality instrument and feedback should be given to individual hospitals and surgeons (or oncologists). Currently European audits are initiated by the ESSO for colorectal cancer, breast cancer, upper GI cancer, and HPB cancer with information related to treatment and including radiology and histopathology results aiming for transparency throughout Europe for both surgical and multidisciplinary outcomes. Quality assurance remains a challenge, but generates even more opportunities to optimise the care for all our future patients.
No conflict of interest.

76 INVITED
Clinically meaningful end-points: Long term survival end-points versus early time to event based end-points

F. Pignatti[1]. [1]*European Medicines Agency (EMA), Safety and Efficacy of Medicines, London, United Kingdom*

The European Medicines Agency (EMA) has recently revised its Guideline on the evaluation of anticancer medicinal products in man (Revision 4, 2012), including guidance on choice of endpoints for confirmatory studies and methodological considerations on progression-free survival (PFS).
Generally, confirmatory (phase III) clinical efficacy trials should demonstrate that the experimental agent provides clinical benefit. In oncology, from a clinical and methodological perspective, the most persuasive outcome of a trial is the demonstration of a favourable effect on overall survival (OS), supported by secondary efficacy endpoints. Prolonged PFS or disease-free survival (DFS) is also considered to be of clinical benefit, particularly if the effect is large. The choice of primary endpoint between OS and PFS should include considerations about the relative toxicity of the experimental therapy, expected survival after progression, and availability of next-line therapies.
When comparing treatments in terms of PFS it is important to consider that treatment with an experimental agent, even if advantageous in terms of PFS, may however be associated with poorer OS (for instance, due to long term-toxicity or increased drug resistance). Thus, whenever possible, when PFS is the primary endpoint, adequate follow-up should be available for OS to provide sufficient reassurance that there is no detrimental effect. One-way cross-over to the experimental arm after progression is likely to hamper any subsequent comparisons in terms of OS and other long-term secondary endpoints. If this type of cross-over is considered unavoidable, the timing should be carefully chosen to ensure that sufficient data are available for OS and any other important secondary endpoints to meet the objectives of the trial. Similar considerations apply to timing of interim PFS analyses designed to stop the trial early for efficacy.
Where mature OS data cannot reasonably be available at the time of the primary PFS analysis, it is important to at least exclude a detrimental effect on next-line therapy (PFS2, time from randomisation to second objective disease progression, or death from any cause) or, if PFS2 is not available, end-of-next-line-treatment (time from randomisation to end or discontinuation of next-line treatment, second objective disease progression, or death from any cause). However, there is limited regulatory experience with these approaches and EMA scientific advice is recommended.
No conflict of interest.

Scientific Symposium (Sat, 28 Sep, 16:00–18:00)
Dissecting Total Therapy for Multiple Myeloma

77 INVITED

First-line treatment in elderly patients

V. Montefusco[1]. [1]*Istituto Nazionale Tumori, Department of Medical Oncology, Milan, Italy*

Currently, elderly multiple myeloma (MM) patients have several treatment options, that derive from the historical regimen of oral melphalan and prednisone (MP) in combination with a new drug, namely: thalidomide (MPT), bortezomib (MPV), and lenalidomide (MPR). In all cases the new regimens have shown a statistically significant superiority respect to MP in phase III trials. The first combination to be described was MPT (Palumbo et al. Lancet 2006). Since then, several versions of this regimen have been reported. The most effective MPT was described in the IFM 99–06 trial. In this study patients received 12 courses of therapy without maintenance. MP median time of progression-free survival (PFS) was 18 months, compared to 27 months for MPT. Similarly, MP median time of overall survival (OS) was 33 months, compared to 52 months for MPT. Outcome after retreatment was not different in either groups, suggesting a low risk of induction of chemoresistance. The second combination to be tested was MPV in the VISTA trial. Patients were randomized to receive 9 courses of either MP or MPV. The first 4 MPV cycles were delivered with an intensified dose of bortezomib. Median time to progression was 17 months in the MP, and 24 months in the MPV group. Three-year OS was 54% in the MP, and 68% in the MPV group. The rate of serious adverse events was higher in the MPV group (46% vs. 36%), in particular 14% of bortezomib-treated patients developed grade 3–4 peripheral neuropathy. Interestingly, MPV was superior also in patients older than 75 years, in ISS III patients, and in case of renal failure. MPV did not increase the risk of second malignancies. The most recent combination is MPR. In the MM-015 trial MP was compared to MPR, and to MPR with lenalidomide maintenance (MPR-R). After 9 cycles the outcome was quite similar, however, with a median follow-up of 30 months, patients who received lenalidomide maintenance had a significant advantage. PFS was 13 months for MP, 14 months for MPR, and 31 months for MPR-R. However, to now, this PFS differences did not translate into an OS advantage. Clinical benefits of MPR-R were limited to patients 65 to 75 years of age. On the other side, toxicity was more pronounced for MPR and MPR-R, and 3-year rate of second primary malignancies was 3% with MP, 7% with MPR, and 7% with MPR-R. In conclusion, elderly patients have now several treatment options, with the real chance of transforming MM into a chronic disease.
No conflict of interest.

78 INVITED

First-line treatment in young patients

J. San Miguel[1]. [1]*Hospital Universitario de Salamanca. IBSAL IBMCC (USAL-CSIC), Servicio de Hematologia, Salamanca, Spain*

Current treatment of newly diagnosed transplant candidate patients usually includes 3–6 cycles of induction therapy, consolidation with ASCT and the possibility of maintenance therapy.
1. Induction: Triple drug combinations based on Thalidomide (T) (TAD or TCD) induces 80% responses although the CR usually is <15%; by contrast the TD combination is suboptimal. Regarding Lenalidomide (Len), in combination with dex the majority of patients (>85%) respond, but probably a minimum of 4–6 cycles would be required to achieve >10% CRs. With Bortezomib (Bz) based regimens, particularly triplets such as BzAD, BzCD or even better BzTD or BzLenD the RR is around 90% with up to 30%CR. Moreover, several randomized trials have shown that triplets based on bortezomib (BzAD, BzTD) are not only superior to VAD in terms of response rate but does also induce longer progression free survival (PFS). Thalidomide or bortezomib combinations did not affect stem cell collection, while for lenalidomide it is recommended to harvest stem cells after no more than 3–4 cycles.
2. Autologous Stem Cell Transplant: Several randomized trials have shown that high dose therapy after induction with novel agents results in an upgrade of the CR rate and prolonged PFS suggesting that induction with novel agents and ASCT are complementary rather than alternative treatment approaches. Nevertheless randomized trials comparing early versus late transplant are underway. Regarding tandem ASCT, its use has significantly decreased in favour of consolidation or maintenance therapies, however in two large trials based either on BzTD or BzAD induction, the use of tandem transplant appears to be of benefit for patients with high-risk cytogenetics.
3. Consolidation and Maintenance: The use of 2–3 cycles of consolidation therapy (BzTD or BzLenD) after ASCT is associated with further improvement in depth of responses, including molecular responses. As far as maintenance is concerned, interferon +/− corticosteroids have shown a prolongation in PFS and OS of approximately 6 months, but due to the poor tolerability have been abandoned in most centers. Six randomized trials based on T or TD have shown a significant prolongation in PFS, but in only 3 of them this translated into an OS prolongation. Moreover the benefit was modest (approximately 6 months) and this together with the toxicity and possibility of inducing more resistant relapses is an important concern. Two randomized trials have reported a highly significant benefit for lenalidomide maintenance in terms of PFS (42 vs 24 months in the placebo arm) but only in one there is so far benefit in OS. The initial concern about a higher incidence of second primary malignancies has decreased with longer follow-up, but close follow-up is still needed, and although maintenance therapy cannot be recommended yet as an standard of care, it is becoming an attractive possibility.
4. Allogeneic Transplant: Six randomized trials have compared the use upfront of double ASCT versus single ASCT followed by allo-RIC; only in two of them the allo approach was superior in terms of PFS and OS. Moreover, unfortunately, a high proportion of patients develop extramedullary relapses without bone marrow involvement indicating that, although the disease may be under control in the bone marrow milieu, extramedullary spread may occur. These transplants should be performed by experienced groups and within clinical trials.

Defining and maintaining response

Abstract not received.

80 INVITED

New drugs

M. Dimopoulos[1]. [1]*Medical School Athens University, Department of Clinical Therpeutics, Athens, Greece*

Patients with multiple myeloma (MM) who have received “novel” agents (thalidomide-, lenalidomide- and/or bortezomib-based regimens) and their disease has relapsed or has become refractory to these treatments present a particular challenge. These patients can be treated with the novel proteasome inhibitor, carfilzomib or with the novel immunomodulatory drug (IMiD), pomalidomide or they can be encouraged to participate in clinical trials of novel experimental agents.
Carfilzomib has been approved by FDA in July 2012 based on the results of a phase IIb trial. This study included 266 MM patients who had been exposed to both bortezomib and an IMiD and who were relapsed and refractory to their most recent line of therapy. Carfilzomib was administered on days 1, 2, 8, 9, 15, and 16 of 28-day cycles (20 mg/m^2 in cycle 1; 27 mg/m^2 in cycles 2–12). The response rate was 23.7%. The median time-to-response was <2 months and the response duration was 7.8 months. The median TTP was 3.9 months, and the OS was 15.6 months. Carfilzomib showed very low rates of peripheral neuropathy.
Pomalidomide was approved by FDA In February 2013 for the same MM population based on the results of a phase III study in relapsed or relapsed and refractory MM patients who had failed to both bortezomib- and lenalidomide-based regimens and were refractory to last tretment: 302 received pomalidomide at a dose of 4 mg/day for 21 days in a 28-day cycle with low dose dexamethasone and 153 patients received high dose dexamethasone. The objective response rate was 21% in Pom/Dex arm vs. 3% in high-dose Dex. Median PFS and OS were 4.0 and 12.7 months, respectively for Pom+Dex vs. 1.9 ($p < 0.001$) and 8.1 months ($p = 0.028$), respectively for high-dose Dex arm.
The most promising novel agent that is under investigation is daratumumab. Daratumumab is an anti-CD38 monoclonal antibody and has been given as monotherapy in relapsed or refractory patients to at least two different prior lines of therapy who were ineligible for ASCT. To-date there is limited reported data: 4/9 patients who received $\geqslant$4 mg/kg achieved a PR. No DLTs were reported in the 2, 4, 8 and 16 mg/kg cohorts, while the most common adverse events reported were infusion related events.
Elotuzumab is a monoclonal antibody against CS1 and is combined with lenalidomide and low dose Dex in phase III studies. This combination has produced very encouraging results in phase II study in relapse/refractory MM: ORR 92% and median PFS of 27 months.

Scientific Symposium (Sat, 28 Sep, 16:00−18:00) **Cancer Screening – Redefining the Modality of Screening**

81 INVITED

Cervical cancer screening in light of HPV testing and immunisations

E. Franco[1]. [1]*McGill University, Montreal, Canada*

Since 2006, when the first human papillomavirus (HPV) vaccine was approved, there has been much progress on the prevention of diseases associated with HPV infection, particularly cervical cancer. A decade earlier, the first clinically validated HPV assay was approved as an adjunct test in cervical cancer screening. As the two cervical cancer prevention fronts, i.e., primary via vaccination and secondary via screening, progressed more or less in parallel they have begun to intersect in recent years, as it has become clear that effective deployment of these strategies requires integration of resources and planning. However, acceptance of these technologies has not been without obstacles. Although the evidence for the superior value of HPV testing in cervical cancer screening had become unequivocal, up until recently consensus guidelines tended to indicate uncertainty as to the degree and strength of evidence for this test's efficacy. This state of affairs changed in March 2012 with the simultaneous publication of the guidelines from the US Preventive Services Task Force and from the joint society consortium that involved the American Cancer Society, the American Society for Colposcopy and Cervical Pathology, and the American Society of Clinical Pathology. These guidelines placed greater emphasis on HPV testing in primary screening and discouraged unnecessary screening at younger ages and overly frequent screening. While co-testing is still favored by the new guidelines, other high-resource countries began to pilot or even to implement programmatically the strategy of HPV testing as the sole primary screening test, reserving Pap cytology for the triage of women who are HPV positive. The author will review the historical milestones of how HPV-based strategies have moved to center stage in cervical cancer prevention and discuss the research directions in the area, particularly with respect to how screening is to be performed in vaccinated women.

Conflict of interest: *Other substantive relationships: Occasional consultant to companies involved with HPV vaccines (GSK and Merck), cervical cancer screening (Cytyc, Ikonisys), and HPV diagnostics (Roche, Qiagen, BD, Gen-Probe)*

82 INVITED

New opportunities and challenges in colorectal cancer screening − FIT vs FOBT vs sigmoidoscopy

N. Segnan[1]. [1]*CPO − Piemonte, Department of Cancer Screening and Unit of Cancer Epidemiology, Turin, Italy*

There is a general consensus that screening for colorectal cancer reduces mortality from and incidence of the disease. However, the debate about which routine screening strategy should be adopted is everlasting. Sundry technologies for colorectal cancer screening (CRC) are currently available: Faecal Occult Blood Test (FOBT), Faecal Immunochemical Test (FIT), Flexible Sigmoidoscopy (FS), Total Colonoscopy (TC), CT Colonagraphy (CTC), Capsule Endoscopy, DNA Test and other biomarkers.

Different colorectal cancer screening strategies can be compared through several non mutually exclusive criteria: cancer prevention and mortality reduction, stage distribution of screening detected cancer, distal vs proximal incidence and mortality rates of colon cancer, screening interval, cost, side effects, preparation, participation, Number Needed to Screen, Number Needed to Invite.

The focus of this intervention is on FIT, FOBT, and FS.

Guaiac test to detect faecal occult blood showed to be less accurate than immunochemical tests. According to a trial performed by the Erasmus University in Rotterdam, FIT slightly outperforms gFOBT with a lower level of reported discomfort and overall burden. The ultimate of a screening programme with a given method is strongly determined by participation rates and detection rates. An RCT performed in Italy found similar participation rates for sigmoidoscopy and FOBT, whereas the detection rate for advanced neoplasia was three times higher following screening by sigmoidoscopy than by FOBT. The Erasmus University study found that adherence to sigmoidoscopy (32%) was lower than for FOBT (50%) and FIT (62%).

However European FS trials (SCORE, UK Flexible Sigmoidoscopy Trial) showed that, after 10−11 years of follow up, the reduction of incidence of colon cancer in not yet declining. Ten years cumulative detection rates and ten years cumulative participation rates should be estimated for comparing the impact of FS and FIT in cancer screening.

All these technologies show advantages and disadvantages when used in colorectal cancer screening. Choice depends on the concrete possibility, in a given context, to set an organized screening programme, that must be sustainable (in economic and human resources) and cost-effective. Anyhow an expectation to prevent 100% of cases, whatever the chosen strategy is, cannot be realistic.

83 INVITED

Should all men receive PSA screening?

J. Cuzick[1]. [1]*Cancer Research UK, Centre for Epidemiology Mathematics and Statistics Queen Mary University of London Wolfson Institute of Preventive Medicine, London, United Kingdom*

Two major trials have addressed the issue of PSA screening for prostate cancer. The European ERSPC trial found a highly significant 21% reduction in prostate cancer in men invited for screening and at 29% reduction in those who actually were screened, while the US based PLCO trial found no effect. The difference can largely be explained by the trial design − in that screening in the European trial was very uncommon in controls, but almost routine in the US study, so that it was in reality a trial of organised vs opportunistic screening. However over-diagnosis is a major issue and in the European trial 37 cancers would need to be diagnosed and treated to prevent one death after 11 years of follow up, and the morbidity associated with these diagnoses has been clearly documented. A major research priority remains to clearly separate low risk cancers with minimal risk of mortality, which can be safely watched, from more aggressive ones in need of immediate radical treatment. A range of options for achieving this goal will be examined. Until this need is met, population based screening should not be recommended and the decision for PSA based screening should remain an individual choice based on risk factors, symptoms and other personal factors.

84 INVITED

UK Breast cancer screening

D. Cameron[1]. [1]*Edinburgh Cancer Research Centre, Edinburgh, United Kingdom*

This talk will outline the basis of the UK breast cancer screening programmes, and the approach of the 2012 Marmot review to establish the benefits and harms of breast cancer screening.

The Marmot review concluded that randomised trials still gave the best estimates of mortality benefits and overdiagnosis, even though much has changed since then in terms of screening techniques, diagnostic pathways, and treatments. In the context of the UK screening programme that review concluded that around 1300 premature deaths from breast cancer were prevented, but this came at the "cost" of overdiagnosis, with some 4000 breast cancers each year being overdiagnosed, and therefore "overtreated".

The discussion will touch on how this could be addressed in terms of future research.

No conflict of interest.

85 INVITED

The cost-effectiveness of cancer screening

H. De Koning[1]. [1]*Erasmus MC, Dept. of Public Health, Rotterdam, Netherlands*

Population-based cancer screening is a major effort to try and reduce morbidity and mortality from the disease. The European code against cancer presently stipulates screening for 3 types of cancer sites: cervical cancer screening by a Pap smear for women aged 30 and over, breast cancer by mammography screening for women aged 50 and over, and colorectal cancer screening for persons 50 and over by FOBT. Many countries' public health policies endorse these guidelines, but differences may exist in screening interval, ages invited and tests applied.

Randomised controlled trials or clear-cut geographical differences in the past have formed the evidence-base on benefits, but these basically apply to one specific design. Modelling is often needed to estimate long-term benefits, harms, cost and savings, and to guide policies. Mostly, cancer screening programmes require additional funds, but this may lead to substantial benefits and even some savings.

At present debate exists whether new more effective treatments may be so effective, that benefits seen in the population as a whole may be contributed to treatment rather than screening (and early treatment). Sometimes screening is considered to be expensive given the annual number of screens needed.

However, new screening techniques may lead to alterations and more effective screening programs. It may also lead to new screening programs, e.g., for prostate cancer screening and lung cancer screening, or screening in high risk groups.
In this presentation, effects and cost of cancer screening are presented, including the debate on breast cancer screening versus treatment, and prospects for new screening programs are being addressed.

Scientific Symposium (Sat, 28 Sep, 16:00−18:00)
Imaging to Support Drug Development

86 INVITED

Use of advanced imaging in drug development: An industry perspective

B. Fine[1]. [1]*Genentech, Research & Early Development, South San Francisco CA, USA*

In clinical drug development, particularly in oncology, long timelines and high failure rates remain critical challenges. These challenges may be addressed, at least in part, by the information provided by advanced imaging approaches that reflect biological processes relevant to cancer and its treatment. While using these approaches to improve endpoints in registrational clinical trials is a longer-term possibility, in the shorter term, advanced imaging approaches are already providing information that could improve the accuracy and efficiency of decision-making early in clinical development. A number of novel imaging techniques are now well positioned to inform these decisions. Examples include positron emission tomography (PET) using ^{18}F-deoxyglucose (FDG-PET), ^{18}F-fluorothymidine (FLT-PET) or radiolabeled antibodies (immunoPET) and magnetic resonance imaging techniques using dynamic contrast enhancement (DCE-MRI) or for vessel size imaging (VSI). A review of these examples highlights the importance of clearly defining expectations at the outset for how the imaging data will be used in development decision-making. With this clear definition of expectations other key consideration then follow that facilitate well designed and executed clinical imaging studies, including: (1) appropriate use and interpretation of preclinical models, (2) appropriately matching the imaging technique to the mechanism of action of an investigational treatment and (3) appropriately rigorous standardization of clinical image acquisition and analysis to ensure consistent and reliable information from imaging, particularly in multicenter trials. As the number of well designed and executed studies using advanced imaging increases over the coming years, the impact of advanced imaging on improving decision-making in clinical drug development will likely become increasingly apparent.
Conflict of interest: *Ownership: Roche. Other substantive relationships: Employee, Genentech*

87 INVITED

Minimising lymphoma treatment using PET

M. Hutchings[1]. [1]*Finsen Centre, Copenhagen, Denmark*

Most malignant lymphomas can be cured with available treatment regimens. However, the high cure rates are accompanied by a serious risk of long-term treatment-related complications, including second malignancies, infertility, and cardiopulmonary disease. It is widely acknowledged that even within the refined existing histological entities and risk groups, some patients need more intensive therapy to achieve cure, while many patients are prone to some degree of overtreatment even with existing regimens. In order to balance efficacy of treatment with the risk of late effects, a patient-tailored approach requires that treatment be adapted to the individual patient's risk profile and treatment response.
Selection of treatment for lymphoma is based on clinical staging, on well-established clinical prognostic factors, and on the age and general state of the patient. A number of biologic markers and cytokines have prognostic abilities, but they have yet no proven therapeutic value for the patients.
PET/CT has emerged as the most accurate tool for staging, treatment monitoring and response evaluation in Hodgkin lymphoma and aggressive non-Hodgkin lymphoma. While accurate staging and restaging are very important for the choice of therapy in lymphoma, we are only beginning to understand how to use PET/CT to improve our patients' outcomes. More precise determination of disease extent may result in more precise pre-treatment risk stratification, and is also essential to the minimal and highly individualised radiotherapy volumes of the present era.
A number of trials currently investigate the use of PET/CT for early response-adapted therapy, with therapeutic stratification based on interim PET/CT results. Some trials use early PET/CT to select patients for less intensive or abbreviated chemotherapy in patients with a favourable prognosis based on a negative scan, or to select early-stage patients where radiotherapy can be omitted without a loss of efficacy. Other trials use a positive early PET/CT to select less optimally responding patients who might benefit from a change to a more intensive strategy. Post-treatment PET/CT is a cornerstone of the most recent revisions of the international response criteria for malignant lymphoma, and enables selection of advanced stage Hodgkin lymphoma patients without need for consolidation radiotherapy. PET/CT also looks promising for selection of individualised, response-adapted therapy in relapsed and refractory disease.
No conflict of interest.

89 INVITED

Molecular imaging using radiolabeled drugs

E. Smit[1], A. Van der Veldt[2], A. Lammertsma[3]. [1]*VU University Medical Center, Amsterdam, Netherlands;* [2]*VU University Medical Center, Internal Medicine, Amsterdam, Netherlands;* [3]*VU University Medical Center, Radiology & Nuclear Medicine, Amsterdam, Netherlands*

Background: Anticancer drugs can be labeled with positron emitters to study in vivo pharmacokinetics. The development of radiolabeled anticancer drugs will be illustrated by validation studies of carbon-11 labeled docetaxel ([^{11}C]docetaxel) in lung cancer patients.
Methods and Results: Biodistribution and actual human radiation dosimetry of [^{11}C]docetaxel was determined in 7 patients with solid tumors (van der Veldt et al., 2010). The effective dose of [^{11}C]docetaxel was 4.7 $\mu Sv \cdot MBq^{-1}$, comparable to the estimated effective dose in rats. [^{11}C]docetaxel showed low uptake in human lungs., and therefore could be a useful tracer for tumors in the thoracic region.
Tumor kinetics of [^{11}C]docetaxel were irreversible and could be quantified using Patlak graphical analysis. In tumors, the net rate of influx (Ki) of [^{11}C]docetaxel was variable and strongly related to tumor perfusion,. Also, dexamethasone pretreatment significantly lowered 11C-Docetaxel uptake in human tumors.
The microdosing concept was subsequently validated. (van der Veldt et al., 2013). Docetaxel naive lung cancer patients underwent two [^{11}C]docetaxel PET scans, one after a bolus injection of a tracer dose [^{11}C]docetaxel and another during a combined infusion of [^{11}C]docetaxel and docetaxel ($75\ mg \cdot m^{-2}$). The accumulated amount of docetaxel in tumors was <1% of the total infused dose of docetaxel.
The effects of the anti-angiogenic drug bevacizumab on tumor perfusion and [^{11}C]docetaxel uptake in lung tumors were investigated in non-small cell lung cancer (NSCLC) patients. It is assumed that anti-angiogenic drugs transiently normalize tumor vasculature and contributes to improved delivery of chemotherapy (Jain, 2001). Within five hours, bevacizumab reduced both perfusion and [^{11}C]docetaxel uptake in NSCLC. These effects persisted after four days and were not associated with significant changes in heterogeneity of [^{11}C]docetaxel uptake in tumors (van der Veldt et al., 2012).
Conclusion: PET using radiolabeled anticancer drugs enables assessment of accumulation of drugs in human tumors and may facilitate rational treatment choices that are tailored to improve drug delivery to tumors.

Special Lecture (Sun, 29 Sep, 08:00−08:45)
Vasculogenesis: A new Target to Improve the Radiotherapy of Solid Tumors

90 INVITED

Vasculogenesis: A new target to improve the radiotherapy of solid tumors

M. Brown[1]. [1]*Stanford University Medical Center, Department of Radiation Oncology, Stanford, USA*

Radiotherapy, and other cytotoxic agents, kills both the tumor cells and the stromal cells of the tumor including the endothelial cells of the tumor vasculature. Thus, for the tumor to recur from surviving cancer cells, the vasculature must be restored following therapy. A variety of studies have shown that tumor blood vessels can derive from two sources: From angiogenesis, the sprouting of endothelial cells from nearby blood vessels, and from vasculogenesis, the formation of blood vessels by circulating cells. For most tumors following therapy angiogenesis is the most important process for the formation of these vessels. However, in the case of radiation, and with some anti-angiogenic or anti-vascular therapies, angiogenesis is abrogated (in the case of irradiation by the killing of the endothelial cells) thereby forcing the tumor to use vasculogenesis to restore the vasculature.

We have tested the hypothesis that the radiation response of tumors can be increased by blocking vasculogenesis using two human tumors (FaDu head and neck tumors and the U251 glioblastoma) transplanted into nude mice as well as an autochthonous tumor developing in the brains of rats treated while *in utero* with a single injection of the carcinogen ethylnitrosourea (ENU). We show that an essential contributor to vasculogenesis in irradiated tumors are CD11b+ myelomonocytic cells expressing MMP-9. These are recruited to the irradiated tumors by stromal cell-derived factor-1 (SDF-1, or CXCL12) induced by increased levels of HIF-1 in the irradiated tumors. Importantly, a variety of ways of blocking this process (neutralizing antibodies to CD11b, inhibition of the interaction of SDF-1 with CXCR4 and with CXCR7, antibodies against CXCR4, and inhibition of HIF-1) render tumors less able, or unable, to recur following irradiation. This is particularly the case with the rat autochthonous brain tumors. The SDF-1 inhibitor NOX-A12, while having no affect alone, dramatically improves the survival time of rats given whole brain irradiation.

However, though these CD11b myelomonocytes are essential for vasculogenesis, they are not sufficient, and we show using a dual color parabiosis system that circulating endothelial progenitor cells (EPCs) (defined as CD117+, VEGFR2+, and CD45−) migrate into the tumor after irradiation to restore the vasculature. We also show that blocking vasculogenesis does not increase the radiation damage to normal skin. In fact there is evidence both from our studies and those of others that this can be radioprotective of normal tissues.

Thus blocking circulating normal cells (monocytes/macrophages and EPCs) that can reconstitute the tumor vasculature after irradiation can have a major positive impact on the response of solid tumors to irradiation and potentially represents a new paradigm for the treatment of such tumors.

No conflict of interest.

Scientific Symposium (Sun, 29 Sep, 09:00−11:00)
Palliative Care in 2014

91 INVITED

Physicians and nurses experiences with continuous palliative sedation

S.J. Swart[1], J.A.C. Rietjens[1], C. Van Zuylen[2], R.S.G.M. Perez[3], J.J.M. Van Delden[4], A. Van der Heide[1]. [1]*Erasmus MC, Department of Public Health, Rotterdam, Netherlands;* [2]*Erasmus MC, Department of Medical Oncology, Rotterdam, Netherlands;* [3]*VU Medical Center, Department of Anesthesiology, Amsterdam, Netherlands;* [4]*Utrecht University Hospital, Health Sciences and Primary Care, Utrecht, Netherlands*

Background: Palliative sedation, a medical intervention aimed at relieving intractable suffering at the end of life by inducing decreased awareness of symptoms, has become a substantial practice in Dutch end of life care. In 2001, continuous deep sedation was used in 5.6% of dying patients. Since then, this figure rose from 8.2% in 2005 to 12.3% in 2010. In 2005 the Royal Dutch Medical Association launched a national guideline.

Material and Methods: Quantitative questionnaire and additional qualitative interview, inquiring about the last patient for whom Continuous Palliative Sedation until death (CPS) had been used. We studied CPS-practices of physicians and nurses in general practice, nursing homes and hospitals after introduction of the national guideline.

Results: We found that next to dyspnoea, pain and delirium, physical exhaustion and existential suffering were reported as refractory symptoms being decisive for starting CPS. Nurses more often than physicians indicated that patients were anxious prior to the start of continuous sedation and they more often mentioned pain as the decisive indication for starting CPS. Nurses less often felt pressure from patients or relatives to start CPS. A qualitative analysis regarding the considerations concerning the indication for CPS revealed that CPS is not only provided in situations in which *one* symptom was decisive. CPS may also be used to address a 'refractory state' resulting from an accumulation of physical and non-physical symptoms. Furthermore, physicians followed two different approaches towards the depth of CPS. Physicians either aim at deep sedation right from the start, or they start with mild sedation and only deepen it gradually if needed. We found that these approaches are influenced by preferences of patients and relatives, e.g. patients' and relatives' fear of awaking from sedation may affect the dosage of sedatives administered.

Conclusion: Different experiences of physicians and nurses with CPS in clinical practice may be a reflection of their different roles. Whereas in guidelines, proportional sedation is typically understood as sedation in which the dose of sedatives is individually titrated to the relief of distress caused by refractory symptoms, our study shows that in practice proportionality seems to be understood as a multidimensional notion to which preferences of patients and relatives also contribute.

No conflict of interest.

92 INVITED

Define future palliative care − should it form part of rehabilitation?

P. Larkin[1]. [1]*University College Dublin, Health Sciences Centre BelfieldSchool of Nursing Midwifery and Health Systems, Dublin, Ireland*

The place of rehabilitation in cancer and survivorship as an initiative to promote quality of life is well established. With people surviving longer with their disease and a strategic shift in the understanding and practice of palliative care, there has also been increasing evidence that rehabilitation has a place in the vernacular of contemporary palliative care. A core message in relation to palliative care rehabilitation is that it should meet patient goals, be provided by a multidisciplinary team and be cognisant of the core issues of independence and functional mobility.

In this presentation, the place of rehabilitation as a defined outcome of palliative care will be discussed. The evidence-base for palliative care rehabilitation will be presented as well as the challenges that the development of such initiatives poses for clinical practice. A consideration of the changing dynamic of palliative care will be offered and how the construct of rehabilitation may need further refinement to meet the needs of the population of patients who may require palliative care in the future.

No conflict of interest.

93 INVITED

Xerostomia in palliative care: The "orphan" symptom

A. Charalambous[1]. [1]*Cyprus University of Technology, Nursing Department School of Health Sciences, Limassol, Cyprus*

Background: Xerostomia is the subjective sensation of dryness of the mouth caused or not by function lowering of salivary glands, with decrease of saliva quality or quantity.

The prevalence of xerostomia has been variously reported as ranging from 60% to 80% in patients with advanced cancer and patients at the end-of-life. The aim of this presentation is to illuminate the impact of xerostomia on the patients' lives and present the available strategies for its comprehensive management.

Material and Methods: A comprehensive review of the relevant literature through electronic databases (Cochrane, MEDLINE, EMBASE) with selective keywords.

Results: Xerostomia is a persistent and severe symptom that is difficult to manage and it is associated with a significant degree of morbidity in patients with advanced cancer. It can have a transient or permanent effect and can lead to several complications in the oral and esophageal regions. These include dental caries, mouth infections, taste alterations, bad breath, swallowing difficulties along with alternation in speech formation and voice function. Patients report that xerostomia can negatively affect their daily living exacerbating their suffering. The available pharmaceutical agents have limited contribution to the relief of dry mouth and are often accompanied with severe side effects (i.e. pilocarpine). The evidence for the effectiveness of other agents (i.e. sugar-free chewing gum) used to treat xerostomia is poor and often conflicting.

Conclusions: Xerostomia although a non-life threatening symptom it can have a profound effect on the patient's life. Xerostomia is mainly considered as a symptom with effect on the physical body however this review has revealed social as well as psychological effects on the lives of the patients and their families. There is no strong evidence from this review that any topical therapy is effective for relieving xerostomia.
No conflict of interest.

94 INVITED

Competence for nurses in palliative care in Denmark

M. Bentzen[1]. [1]*Sankt Lukas Hospice, Hellerup, Denmark*

Background: Surveys carried out by the Danish Knowledge Center for Palliative Care (PAVI) confirm a large variation in education standards in palliative care and medicine in nursing competences across Denmark.
Objective: To ensure that palliative patients have equal access to high quality care the Danish Multi-Disciplinary Cancer Group for Palliative Care (DMCG-PAL) prepared standardised recommendation for Nurses in Palliative Care − at an Undergraduate and Postgraduate Level in order to provide opportunities for nurses to obtain and develop a standardised set of skills in palliative care.
Design and Setting: The standardised curriculum of required skills was created, based on a range of national and international palliative care training curricula. The CanMEDS-7-roles Framework has been adapted to the nursing profession. The required skills have been separated into 4 domains: empirical, ethical, personal and psychosocial. The learning outcomes (knowledge, skills and attitudes) were specified in three levels in order to show the progression from undergraduate to postgraduate level of nursing training. The suggested standardised curriculum has been circulated amongst clinical and educational professional groups in Denmark.
Main outcome measures: The standardised curriculum provides a framework for current and future training of nurses in palliative care and creates a foundation for development and evaluation of professionals skills.
Results: 'National recommendations of Competencies for nurses in Palliative Care' was compiled and published in december 2012 with financial support from the Danish Nursing Organisation.
Conclusion: Nursing training in Denmark has been offered a standardised curriculum of required competences in palliative care.
Acknowledgements: The authors are grateful to the the Danish Multi-Disciplinary Cancer Group for Palliative Care and Danish Nursing organisation for their financial support og this project.
No conflict of interest.

Society Session (Sun, 29 Sep, 09:00−11:00)
European Society of Breast Cancer Specialists (EUSOMA) − Ensuring Quality in Breast Care

95 INVITED

The requirements of a specialist breast center: EUSOMA updated recommendations

L. Marotti[1], A. Ponti[2], A.R.M. Wilson[3]. [1]*EUSOMA − European Society of Breast Cancer Specialists, Executive Director, Florence, Italy;* [2]*EUSOMA − European Society of Breast Cancer Specialists, Executive Committee Member, Florence, Italy;* [3]*EUSOMA − European Society of Breast Cancer Specialists, Executive Committee President, Florence, Italy*

Background: The European Society of Breast Cancer Specialists (EUSOMA) is a multidisciplinary society particularly dedicated to the harmonisation of breast cancer care in Europe according to the highest available standards with a multidisciplinary approach and a rigorous quality control.
In 2000 EUSOMA published the recommendations on "The requirements of a specialist breast unit". The document followed what requested by the EBCC1 consensus statement, that all women have access to fully equipped multidisciplinary breast clinics.
The document has been accepted and recognised as a benchmark for the set up of a breast unit.
Material and Methods: EUSOMA has decided to up-date and revise its paper, following the advances in diagnosis and treatment and evidence based changes in practice occurred in the recent years and the experience deriving from voluntary certification process. It has been updated by consensus between a multidisciplinary expert group.
The paper defines the organisational model for a Breast Centre (BC), the minimum standards for the resources, expertise and data audit required to ensure high quality care.
Results: The basic criteria to be considered for the set up of a BC are being an integrated breast centre, dealing with a sufficient number of cases to allow effective working and continuing expertise/care, dedicated specialists working with a multidisciplinary approach, providing all services throughout the patients pathway in the centre, data collection and audit.
It is important that the BC guarantees the concept of continuity of care also in patients with advanced/metastatic disease offering treatments according to multidisciplinary competencies and ensuring a high quality palliative care service.
The BC must ensure to the patients all the support and expertise that may be needed not only through expertise of the BC team members but also consulting all those other experts that may be necessary on a case to case basis, referring the patient to the specific health care giver depending on the problem.
The role of breast care nurses guarantees the support to the patients during their whole pathway from diagnosis to follow up to offer practical advice, emotional support, further explanation with regard to treatment plan and information on side effects, etc.
Conclusions: The constant monitoring of the quality is essential in patient care, through auditing the unit's performance with internal and external audit aiming at improving organization, performance and outcomes.
No conflict of interest.

96 INVITED

Auditing quality of care in a Breast Center

Abstract not received.

97 INVITED

Quality indicators in breast cancer: The EUSOMA database experience

A. Ponti[1], M. Tomatis[1], L. Marotti[2]. [1]*CPO-Piemonte, EUSOMA Data Centre, Torino, Italy;* [2]*EUSOMA, Firenze, Italy*

Background: The European Society of Breast Cancer Specialists (EUSOMA) aims to promote multidisciplinary research and collaboration between scientists and professionals interested in the management of breast cancer. The goal is to improve the quality of breast cancer diagnosis and treatment across the EU, interacting with the appropriate local, national and international authorities as well as fostering training programs.
Material and Methods: With regard to Quality Control EUSOMA published a consensus document identifying quality indicators (QIs) in breast cancer care ranging from diagnosis to local and adjuvant treatment and follow up. To monitor the breast units' performance, EUSOMA has developed eusomaDB, i.e. a central data warehouse of prospectively collected information which includes individual records of primary breast cancer cases diagnosed and treated by those certified European breast units which have provided data according to the society requirements.
Results: eusomaDB is accessible on the web to all registered users. It was started in 2006 and includes about 65,000 cases, diagnosed between 2000 and 2013, entered by the nearly 50 breast units from 7 European countries (Germany, Switzerland, Belgium, The Netherlands, Austria, Spain and Italy) and transferred from 16 different databases. The data record is represented by 108 variables, including patient and tumour characteristics, information about preoperative work-up, multidisciplinary management and follow-up. Records hold no personal identifiers. Data transfer from each unit is performed yearly through an online application and represents a requirement to obtain and to continue to hold certification.
The web system offers analysis functions, including the calculation of 20 EUSOMA QIs. Most QIs show improvement overtime. Besides quality assurance and certification, eusomaDB is used for audit and research. All breast units contributing information into the database convene yearly in a meeting which is finalised to improve the completeness and quality of the data and to discuss research proposals.
Conclusions: Two papers on mastectomy trends have been published using data from the eusomaDB. Current research projects include breast cancer management by age, appropriateness of use of the sentinel lymph node technique, histopathology and biological characterisation of micro-invasive cancer, and the influence of certification in improving quality of breast cancer care.
No conflict of interest.

98 INVITED

European performance on EUSOMA quality indicators

Abstract not received.

99 INVITED

A parallel European objective: Guidelines for quality assurance in Breast Cancer Care and a voluntary accreditation scheme for Breast Cancer Services

D. Lerda[1], S. Deandrea[1], C. Freeman[1], J. Lopez-Alcalde[1], S. Martin[1], C. Nicholl[1], A. Uluturk[1]. [1]*European Commission Joint Research Centre, Institute for Health and Consumer Protection, Ispra (VA), Italy*

A European Parliament resolution (10/04/2008), reiterated by European Council conclusions, called on the European Commission (EC) to "*support the development of European accreditation/certification programmes in cancer screening, diagnosis and treatment based on European quality-assurance guidelines, which could also serve as an example for other areas of health care*". The EC responded by dedicating resources to the development of an EU quality assurance (QA) scheme for breast cancer services and to the updating of the European Guidelines for Quality Assurance in Breast Cancer Screening and Diagnosis. Throughout 2012, the EC's Joint Research Centre (JRC) conducted bilateral meetings with stakeholders involved earlier in similar projects. It also investigated and compared existing QA schemes in Europe, and organised two European surveys, one on the situation of breast cancer services and one on use of the European QA Guidelines. Two workshops were organised at the beginning of 2013, one for experts and one for countries' delegates, with the purpose of reaching consensus on the overall concept of the scheme and of its reference documents, e.g. the new edition of the European QA Guidelines. As regards the inputs for the project and definition of boundary conditions:

– QA scheme needs to be modular and flexible in order to adapt to all organisational settings;
– linking of recommendations to evidence and an easier utilisation and maintenance (e.g. via an improved structure of guidelines and use of target languages) are needed for the guidelines;
– a fit-for-purpose proposal for the European QA scheme should avoid duplication of effort and guarantee that every aspect of quality and safety is covered;
– the feed-back from participants into the two workshops focused on the urgency for updating the European QA Guidelines and on the need for respecting guidelines and schemes already in place at national level.

The Commission will proceed with a consensus-seeking process for identifying the optimal way forward for this important EU initiative. Whereas the JRC will coordinate and steer the project, all stakeholders will be involved and consulted at all stages.
The project will be based on the need for harmonising benchmarking for breast cancer care across Europe; this means linking evidence-based guidelines based those QA requirements which are considered essential due to their high impact on population-based outcomes without neglecting quality-of-life aspects.
No conflict of interest.

Society Session (Sun, 29 Sep, 09:00−11:00)
European Society for Therapeutic Radiology and Oncology (ESTRO)

100 INVITED

Radiotherapy in rectal cancer − What have we learnt?

B. Glimelius[1]. [1]*Akademiska Sjukhuset, Dept of Radiology Oncology and Radiation Science, Uppsala, Sweden*

Background: In patients with resectable rectal carcinoma, radiotherapy (RT) has been used with surgery to decrease local recurrence rates, improve survival, increase sphincter preservation and, most recently, preserve the organ.
Methods: A systematic approach to the literature was used.
Results: Preoperative (preop) RT at moderate doses decreases local failure rates by 50−70% whether combined with surgery not optimized or optimized to achieve lateral clearance. Postoperative RT at higher doses is less efficient, even if combined with chemotherapy (CRT). The preop RT can be given with low morbidity, provided the treatment technique is optimised; if not, unacceptable adverse effects have been seen. Since RT adds morbidity, it must be given when the absolute gains are sufficiently large to counterbalance the negative consequences.
Although the balance between positive and negative effects, including financial costs, from RT with optimized surgery is not precisely known, we have learnt to discuss in multidisciplinary team meetings in risk groups, very early, early, intermediate or locally advanced, the "good, bad and ugly concept". There is a gain from preop RT also in early tumours operated by the best surgeons, but it is likely too small (from 3−4% down to 1−2%) considering the late toxicity. In intermediate tumours, where the risk of local failure even after excellent surgery is higher (8−15%), preop RT is motivated since it decreases the risk to 3−7%. In locally advanced tumours (cT3 mrf+ or cT4), chemotherapy adds to the efficacy of RT (decreases local failure rates from 25−30% to 10−15%), and is recommended even if it increases acute and late toxicity. 5x5 Gy is as efficient as 45−50 Gy with chemotherapy, less toxic and more convenient and cost-effective in intermediate rectal cancers.
Survival is only slightly improved after preop (C)RT. Preop (C)RT does not increase anal sphincter preservation, but may in responsive tumours allow a 'wait-and-see' policy (organ preservation). Although this undoubtedly happens in some patients, the negative impact on those who do not respond so well is not discussed.
Conclusions: The locoregional problem in rectal cancer has been solved, albeit not universally. Quality assurance and control programmes are fundamental for success. Novel ways to integrate the different therapy modalities must be explored also to improve survival.
No conflict of interest.

101 INVITED

The science, art and joy of teaching medicine: Reflection on a 25-year personal journey

R. Chhem[1]. [1]*International Atomic Energy Agency (IAEA), Division of Human Health, Vienna, Austria*

In theory, most academic physicians are required to provide clinical services, to teach and to conduct research. The respective amount of time spent working in each of these three areas varies widely. For most physicians, the clinical workload is the major duty. Additionally, productive research activities determine a physician's career progression because research are valued so highly in academic settings. Research performance provides physicians with academic prestige. In contrast, teaching − a less glamorous activity − is undervalued by institutions, and poorly supported in part because its outcomes are difficult to measure.
While physicians claim to practice medicine based on evidence, few realize that teaching also needs to be based on evidence in order to provide diverse students with the best conditions for learning to support the achievement of educational goals.
Based on these premises, I would like to share with the audience my reflections on my transformation from a young teacher of diagnostic radiology into a global promoter for effective medical education that uses scientific methods in all stages of teaching − from the design to implementation and evaluation of curriculum. Is teaching a science or an art? To quote one educationalist: "Good teaching cannot be reduced to a technique. Good teaching comes from the identity and integrity of the teacher" (Palmer P.J.) in his book entitled *The courage to teach: Exploring the inner landscape of a teacher's life*. It is in this spirit that I would like to tell the story of my life as a teacher, and to share with the audience the science and art of teaching medicine and the joy it brings to me.
No conflict of interest.

102 INVITED

Multimodality imaging in head and neck cancer

R. Hermans[1]. [1]*UZ Leuven, Department of Radiology, Leuven, Belgium*

CT and MRI are well established methods in the initial diagnostic evaluation of head and neck malignancy, and are also widely used for treatment monitoring and follow-up. MRI is the preferred method for imaging certain tumour sites, such as the nasopharynx, skull base and sinonasal cavities. However, the characterisation of neck lymph nodes remains a difficult issue with anatomy-based imaging methods. High sensitivities and specificities were reported using diffusion-weighted MRI (DWI), better than what is obtainable by CT or conventional MRI. This increased accuracy is mainly due to improved detection of subcentimetric nodal metastases.
Differentiation of treatment induced tissue changes, especially after (chemo) radiotherapy, and persistent or recurrent cancer, is another topic in which DWI may be helpful. Also, studies investigating the role of DWI as prognostic tool during, and very early after treatment, are ongoing. Preliminary results are encouraging, and if confirmed, tailoring treatment according to the very early individual response, as seen on DWI, may become feasible.
For several of these possible applications of DWI in head and neck cancer, currently FDG-PET is being used or advocated. However, FDG is not an entirely specific cancer tracer, and false positive finding are not uncommon. The spatial resolution of PET is relatively low, potentially leading to false negative results. DWI is an interesting alternative, as correlation with anatomical MR images acquired during the same study is possible, allowing precise anatomical localisation of the observed abnormalities. DWI also appears to better discriminate between neoplastic disease and inflammatory changes than PET.

FDG-PET is indicated in case of a clinically unknown cancer, if CT or MRI fail to reveal the primary tumor. Also, FDG-PET can be used to search for distant disease.
No conflict of interest.

103 INVITED
Advances in the adjuvant management of rectal cancer

B. Minsky[1]. [1]*MD Anderson Cancer Center, Houston Texas, USA*

Chemoradiation is the standard treatment for locally advanced, clinically resectable (T3 and/or N+) rectal cancer. When 5-FU is used concurrently with radiation, continuous infusion is the conventional regimen. Two randomized trials confirmed that capecitabine based chemoradiation regimens are equivalent.
Adjuvant preoperative therapy for rectal cancer is delivered by two fractionation schedules: short course radiation and long course chemoradiation. There are 2 randomized trials of short course radiation vs. chemoradiation. Overall, the TROG data suggest a small local control advantage for long course chemoradiation, especially for distal tumors.
Four randomized trials examined the role of adding oxaliplatin to 5-FU or capecitabine based preoperative chemoradiation. Three reported higher acute toxicity and no significant benefit in the pCR rate. The German trial reported the opposite results. The ACCORD 12 trial revealed no improvement with the addition of oxaliplatin in 3-year local control or survival. Targeted biological agents are being added to preoperative chemoradiation regimens. In the adjuvant setting, preliminary results from the EXPERT-C phase II trial (50.4 Gy/CAPOX/Cetuximab) suggest a survival benefit in patients whose tumors were KRAS wild type vs. mutant. Early trials using preoperative chemoradiation with CAPOX + bevacizumab revealed pCR rates of 18−24%. Unfortunately, more recent trials report increased acute toxicity and have been closed early.
Given the improvements in systemic chemotherapy there may be an opportunity to use preoperative radiation more selectively. This approach remains investigational and is being prospective tested in the phase II/III Alliance N1048 trial.
There are four series which advocate the watch and wait approach following preoperative chemoradiation. This approach remains investigational.
The Spanish GCR-3 randomized phase II trial compared neoadjuvant chemotherapy followed by chemoradiation with conventional preoperative chemoradiation followed by surgery and postoperative chemotherapy. The neoadjuvant chemotherapy approach is now the template for all new US NCI rectal trials.
The therapy of rectal cancer continues to evolve. Both diagnostic and therapeutic advances are challenging historical approaches and have opened new directions for the future and are areas of clinical investigation.
No conflict of interest.

104 INVITED
Optimal multidisciplinary treatment of the cancer patient with a focus on surgery/radiation oncology

Abstract not received.

Scientific Symposium (Sun, 29 Sep, 09:00−11:00)
Care of Special Lymphomas − Challenges in the Clinical Routine

107 INVITED
Waldenström's macroglobulinemia

M.A. Dimopoulos[1]. [1]*University of Athens School of Medicine, Department of Clinical Therapeutics, Athens, Greece*

Waldenström's macroglobulinemia (WM) is a rare disorder defined by infiltration of the bone marrow (BM) by lymphoplasmacytic cells which produce a monoclonal immunoglobulin M (IgM). The extent of BM infiltration (or other lymphoid organs) and the quantity and the immunohistochemical properties of the monoclonal IgM determine the spectrum of the clinical and laboratory disorders of WM. Specific criteria for initiating therapy have been proposed and an international prognostic index (ISSWM) for symptomatic patients has been developed in order to improve prognostication and clinical research.
During the last 10 years, our knowledge in the biology of WM has increased. Survival and homing of WM cells largely depends on PI3K/Akt and NF-kappaB signaling. Deregulated miRNAs and upregulated IL6 expression affect the proliferation and growth of WM cells. Cytokines (such as CCL3 and angiopoietins) and mast cells within the BM microenvironment further support WM cell survival. The most exciting recent advance was the identification of a somatic mutation in the MYD88 gene in ~90% of patients with WM, which results in increased downstream signaling through IRAK1, NF-kappaB & STAT3. Importantly, disruption of MYD88 pathway signaling induces apoptosis of WM cells. However, WM remains incurable with a median survival of 5 to 8 years.
Alkylating agents and nucleoside analogues were the backbone of therapy for several decades. Rituximab has minimal toxicity, but, as a monotherapy is associated with modest response rates and a transient increase of serum IgM ("IgM flare") in 30−80% of patients, which may exacerbate IgM-related complications. Combination of rituximab with chemotherapy (such as DRC) improved response rates but complete responses are infrequent. Combinations with more intensive chemotherapy (R-CHOP) or nucleoside analogues (FR or FCR) induce higher response rates but with significant toxicity. Bendamustine with rituximab is a promising combination with less toxicity. Bortezomib, a proteasome inhibitor, can rapidly reduce IgM levels, and has synergistic clinical activity in combination with rituximab and/or steroids. Other monoclonal antibodies, such as alemtuzumab (anti-CD52) and ofatumumab (anti-CD20) are also under clinical investigation. Everolimus (mTORC inhibitor) and perifosine (Akt inhibitor) have shown encouraging results. Ibrutinib, a BTK inhibitor, induced significant response rates in pretreated patients with WM and has been granted a breakthrough therapy designation by the FDA.
No conflict of interest.

108 INVITED
MALT lymphoma

Abstract not received.

109 INVITED
Primary CNS lymphoma

A.J.M. Ferreri[1]. [1]*San Raffaele Scientific Institute, Department of Onco-Hematology, Milan, Italy*

The use of high-dose methotrexate (HD-MTX)-based chemotherapy, followed or not by whole-brain radiotherapy, is the commonest therapeutic approach for primary central nervous system lymphomas (PCNSL). The current therapeutic knowledge in this field comes from single-arm phase-II trials, meta-analyses of published series, large retrospective, multicentre series, and three randomized trials. Numerous methodological pitfalls were highlighted in both prospective and retrospective series, further hampering interpretation of results. Importantly, the first worldwide randomized trial with completed accrual was recently reported [1]. This trial demonstrated that, in patients $\leqslant$75 years old with PCNSL, the addition of HD-cytarabine to HD-MTX results in consistently better outcome and acceptable toxicity over HD-MTX alone. MTX+cytarabine is an active combination that may be considered as the control arm for future randomized trials since it is supported by the best level of evidence available in the field of PCNSL [2]. Despite this benefit, current results in PCNSL patients remain unsatisfactory. Accordingly to the worldwide used therapeutic strategies for aggressive lymphomas, it is unthinkable to treat PCNSL exclusively with antimetabolites and the assessment of other drugs active against other phases of the tumour cell cycle should be considered for future trials. Some alkylating agents (i.e., temozolomide, ifosfamide, thiotepa, nitrosoureas) are interesting candidates since they are able to cross the blood–brain barrier, exhibit anti-lymphoma activity, are active against phase-G0 cells, and increase cytotoxicity of antimetabolites. Rituximab could be another candidate, especially considering its safe profile. Its combination with HD-MTX-based chemotherapy is feasible, but several doubts on its capability to cross the blood–brain barrier exist. High-dose chemotherapy supported by ASCT has produced encouraging results in PCNSL. However, this strategy seems feasible in young and fit patients, which excludes one third of PCNSL patients. Interestingly, some authors recently suggested that this strategy could replace consolidation radiotherapy, which deserves to be assessed in a future randomized trial. It is clear that a more effective international multidisciplinary collaboration is needed in the fight against PCNSL. Evaluation of single agents in phase II trials on patients with failed PCNSL, and definition and assessment of treatment-related neurotoxicity in prospective trials should be strongly encouraged.
No conflict of interest.

110 INVITED
Treatment of post-transplantation lymphoproliferative disorders

R. Trappe[1]. [1]*UKSH Campus Kiel, Kiel, Germany*

Post-transplantation lymphoproliferative disorders (PTLD) are the second most frequent malignancies after solid organ transplantation and cover a wide spectrum ranging from polyclonal early lesions to monomorphic lymphoma. Available treatment modalities include immunosuppression

reduction, immunotherapy with anti-B cell monoclonal antibodies, chemotherapy, antiviral therapy, cytotoxic T-cell therapy as well as surgery and irradiation. The prospective trial of immunosuppression reduction (IR) showed an overall response rate (ORR) of 6% while the combined ORR for all first-line rituximab monotherapy trials is 55% (95% CI: 45−65%) with a median OS of 2.4 years. Allogeneic EBV-specific T-cells resulted in 64% ORR and a median OS >2 years in EBV-associated PTLD. The PTLD-1 trial, which is the largest prospective trial in PTLD so far, evaluated sequential treatment with rituximab and CHOP in patients unresponsive to IR and has produced better response rates and overall survival than any other prospective trial so far (ORR: 90%, median OS: 6.2 years). As sequential treatment with rituximab followed by CHOP is superior to rituximab monotherapy plus chemotherapy at relapse, it should be applied first-line to all patients not responding to immunosuppression reduction. Outside clinical trials, we currently regard sequential therapy with rituximab and CHOP chemotherapy as standard evidence-based treatment for CD20-positive PTLD. Based on the result of the PTLD-1 trial showing that the response to rituximab at interim staging predicts OS in sequential treatment, risk stratification according to the response to rituximab currently is evaluated by the European PTLD Network. In risk stratified sequential treatment patients achieving a complete remission after rituximab monotherapy (low risk) continue with four 3-weekly courses of rituximab monotherapy while patients in PR, SD or PD at interim staging (high risk) are followed by four cycles of R-CHOP-21 (PTLD-1/3 trial). Interim results will be presented and demonstrate similar efficacy, but less toxicity. While CD20-positive PTLD accounts for only around 75% of PTLD cases, we will also summarize our approach to other PTLD subtypes like plasmacytoma-like PTLD and plasmablastic PTLD, and to primary-CNS PTLD based on the available retrospective data and our experience.

Society Session (Sun, 29 Sep, 09:00−11:00)
European Association of Nuclear Medicine (EANM) − Diagnostic Imaging and Therapy in Prostate Cancer

111 INVITED

Prostate cancer: State of the art and future perspective in diagnosis and therapy

I.J. De Jong[1]. [1]*University of Groningen University Medical Center Groningen, Department of Urology, Groningen, Netherlands*

Prostate cancer treatment schemes can be distinguished by 4 clinical stages: 1. Primary tumor, 2. PSA recurrent disease after first line local treatment, 3. Metastatic hormone naive and 4. Castrate Resistant disease. In diagnosis and treatment of primary tumors the balance of (early) diagnosis and treatment outcome is negative. Currently screening with PSA is not recommended by many guidelines and societies. Although recent improvements in imaging using mpMRI and MRI guided or MRI Ultrasound fused biopsy techniques have improved radiological and histological detection rates of Gleason 4 and 5 disease, any advantage of early treatment over standard clinical care has to been proven. Treatment of localized prostate cancer is highly driven by technology. Outcomes of local treatment using radical surgery, brachytherapy and external beam radiotherapy are clinically equivalent when comparing risk groups. Active surveillance increases as first line treatment in low risk prostate cancer given the low 10 years disease specific mortality rates of 1−2%. In locally advanced disease (T3) the standard of care is radiotherapy plus adjuvant androgen deprivation treatment for 2−3 years based on multiple randomized clinical trials.

In PSA recurrent disease after radical prostatectomy early salvage radiotherapy is standard of care. Randomized trials like Radicals (MRC, UK) are still ongoing to study the optimal timing and the role of adjuvant hormonal treatment in salvage radiotherapy. In PSA recurrent disease after radiotherapy, local salvage treatments like prostatectomy, cryoablation, HIFU, laser and brachytherapy are used but with limited long term follow up and all with moderate to severe toxicity. In future more focal treatment would be possible using image guided ablation reducing toxicity.

In metastatic hormone naive prostate cancer the corner stone of treatment is androgen deprivation treatment. However, in non symptomatic man the start of treatment can be delayed, reducing the morbidity and loss of quality of life without any effect on disease specific mortality. Improvements in reduction of toxicity by using intermitted treatment schemes were reported from several randomized trials but efficacy could not be proven in all cohorts of metastatic prostate cancer.

In the final stage of CRPC the increase in active drugs has never been so high as in the last decade. With docetaxel as standard first line chemotherapy, new drugs like abiraterone, cabazitaxel, enzalutamide and sipuleucel-t have been registered form CRPC in the last years. It is clear that within the coming years more new compound will de available and so he need for personalized treatment is there. Having in vivo information about changes in the tumor characteristics during treatment using bioimaging would be one of the rate limiting steps. At present targeted imaging of for instance the androgen receptor is studied as an early response tool.

No conflict of interest.

112 INVITED

Nuclear imaging in urology: From anatomic and functional to molecular imaging

S. Fanti[1], C. Nanni[2], P. Castellucci[2], R. Schiavina[3], G. Martorana[3]. [1]*Università di Bologna, Dipartimento Clinico di Scienze Radiologiche ed Istocitopatologiche, Bologna, Italy;* [2]*Università di Bologna, Nuclear Medicine, Bologna, Italy;* [3]*Università di Bologna, Urology, Bologna, Italy*

In recent years molecular imaging is acquiring importance for the evaluation of cancer patients, being complementary to conventional imaging methods as CT, MR and US. Among molecular imaging procedures, PET is the most diffuse and rapidly growing, and at present it is routinely used in patients affected by a large variety of malignant neoplastic diseases, as well as in other diseases. The usefulness of PET relies on its capability of investigating molecular processes by means of specific radiotracers, with the most employed being 18F-FDG. Despite FDG scans represent more than 90% of all PET scans, other positron emitter tracers are available and other tracers have been developed to study other metabolic pathways.

In the field of Urology, Choline PET/CT has been successfully used for studying prostate cancer, using either 11C-Choline or 18F-Choline. Choline PET has been successfully used mainly with the aim of identifying prostate cancer recurrence; however Choline PET/CT has also been suggested for diagnosis, staging and therapy planning in prostate cancer. The usefulness of Choline PET is based on its capability of localizing focal areas of increased metabolism as result of presence of malignancy; such information are often more accurate than those provided by conventional anatomic imaging. Also Choline PET/CT enables to non invasively study the whole body, and a number of investigations are currently evaluating the clinical role of Choline PET.

The real frontier research in this field is the development of other tracers, aimed to identify the tracers best suited for evaluating a specific functional pathway, thus acting like metabolic probes. Many other radiotracers have already been tested in humans, and are currently under study to evaluate the diagnostic accuracy. Among these radiopharmaceuticals there are metabolic tracers, such as syntetic aminoacid (FACBC); receptor tracers such as GRP receptors (BOM) and hormonal receptors (FDHT); and PSMA specific tracers. It is clear that the future of PET holds great promises of further growth, and will likely continue to increase its impact on clinical and experimental medical science.

No conflict of interest.

113 INVITED

Role of bone scan in prostatic cancer in the era of choline PET

F. Giammarile[1], A. Wahart[2]. [1]*Centre Hospitalier Lyon Sud, Faculté Charles Mérieux Lyon Sud EA 3738 − Université Claude Bernard Lyon 1, Pierre Benite, France;* [2]*CHU St Etienne, Centre LUMEN, Lyon, France*

Introduction: In Western Europe and North America, prostate cancer is the most common tumour in men. The incidence of bone metastatic involvement depends on tumour stage and histology. In advanced disease, bone involvement occurs in 65−75% of patients and reflect prognosis [1]. The initial localisation of metastases in the skeleton has a relatively better prognosis in comparison with visceral metastases. The early detection of bone and bone marrow metastases allows a more adapted therapeutic management and a subsequent reduction in morbidity.

Nuclear bone imaging is performed with radiopharmaceuticals which uptake is directly related to blood flow and osteoblastic activity. The most widely used is 99mTechnetium-hydroxymethylene diphosphonate (Tc-HMDP). Image acquisition requires gamma camera for 2D whole body bone scan (WBBS) or partial 3D Single Photon Emission Computed Tomography (SPECT) imaging, which is generally fused with multislice CT (SPECT-CT). A more recent option is 18F-Fluoride (FNa) and Positon Emission Tomograph (PET) bound with multislice CT to obtain whole body 3D fusion imaging (PET-CT).

Bone metastases arising from prostate cancer may also be detected by PET-CT using 18F-Fluoro-Choline (FCH), a lipid component analogue of cell membrane. This radiopharmaceutical is accumulated, by choline metabolism alteration, in several cancer tissues and is manly interesting in non-aggressive forms of cancer [2].

Results: *Bone scan vs 18FNa*: Both FNa and 99mTc-HMDP are able to show the osteoblastic reaction in sclerotic lesions, present in 85% of prostate bone metastases. In case of mixed lesions, bone peripheral reaction seems more evident in FNa imaging. Indeed, PET-CT has a better spatial resolution than SPECT-CT, therefore a better detection and analysis of small lesion. Obviously, CT images add sensitivity (in case of pure lytic lesion with no osteoblastic reaction) and specificity (in case of equivocal bone uptake) to functional imaging.
For these reasons, FNa PET/CT is more sensitive and more specific than WBBS or bone scan SPECT-CT in prostate bone metastases detection.
Nuclear bone imaging vs 18F-Choline: It is important to notice that the radiopharmaceuticals didn't show the same bone involvement. FCH is a direct image of prostate metastasis (eventually localized on bone marrow), while both Tc-HMDP and FNa show only osteoblastic reaction. A very dense sclerotic lesion (easily depicted on CT) or a metastasis depressed after treatment may show no FCH uptake, due to a low cellularity, but still a high bone uptake. Similarly, FNa and Tc-HMDP may show false positive results in case of benign bone pathologies [2].
Overall, bone seeking radiopharmaceuticals methods may result more sensitive but are less specific than FCH imaging in prostate bone metastases detection.
Conclusion: 18F-Choline PET-CT utilization as alternative or complement to nuclear bone imaging in detection of prostate bone metastases should still be defined.
No conflict of interest.

Society Session (Sun, 29 Sep, 09:00−11:00)
European School of Oncology (ESO) − The Importance of Management Skills in Running Oncology Services

114 INVITED

Organizing cancer services: Hierarchies, markets or networks? A personal review

E. Ferlie[1]. [1]*King's College London, London, United Kingdom*

Cancer services represent a major subsystem of the health care system in terms of resource levels, the number of people affected and political visibility. Yet while narratives of health system reform are often visible at a macro level, their implications for cancer services may be opaque. So how should cancer services be best organized?
This paper offers a social science perspective, specifically from the analysis of health care organizations. It is a personal review which draws on some literature on health care organizations and applies it to the domain of cancer services (e.g. managed cancer networks in the UK).
Hierarchies, markets and networks are introduced as three different ways of organizing health care. Their implication for the organization of cancer services are worked through, with brief examples given. Strengths and weaknesses of each mode are identified, and the question of possible hybrids raised.
No conflict of interest.

115 INVITED

Leadership and management skills for oncologists in the complexity of the European health systems

F. Lega[1]. [1]*Bocconi School of Business, Milan, Italy*

In this session we'll address four issues of paramount importance for oncologists in leadership positions or willing to assume leadership roles.
What is leadership? Why is an essentially ambiguous concept? Here we look at whether it is possible to pin down what leadership really is. Especially when we refer to medical leadership.
Can we develop leaders who are not self-serving? This session focuses on how leaders are developed. We ask whether it is possible to develop servant leaders who are able to put others first.
Do the characteristics of leaders make a difference? In this part we examine how personal and demographic characteristics might influence leaders' decision-making in healthcare settings, and we also look at what motivates leaders.
Why are leaders reluctant to lead? Here we explore the increasingly recognised phenomena of reluctant leadership. We examine why in healthcare there exists both a reluctance to take on leadership roles, and a reluctance to be led.
No conflict of interest.

116 INVITED

Development of management skills from an oncologist's perspective

I. Duran[1]. [1]*Hospital Universitario Virgen del Rocío, Sevilla, Spain*

Background: The increasing emphasis on patient-centered care requires the integration of disease-management abilities with "people-oriented" skills, including communication and management. Hospital-specific management practices are strongly related to a hospital's quality of patient care and productivity outcomes (Management in Healthcare Report, 2010). However, when surveyed, only 20% of oncologists felt sufficiently well trained in management skills (Ramirez AJ. Br J Cancer. 1995). Therefore, development of these abilities is an unmet need in medical oncology.
Material and Methods: The available literature on this topic was reviewed to illustrate the relevance of management skills in running an oncology unit. The current knowledge of this topic among oncologists was explored. Additionally, the different strategies presently available to improve the development of management skills were researched and analyzed.
Results: Management skills (including technical, human and conceptual) are critical and should be emphasized to a greater extent in medical oncology training programs. There is a significant lack of knowledge about this topic in the medical oncology community. Ad-hoc courses are currently being developed and conducted in different academic institutions within Europe and the United States. Medical oncology trainees and staff should be exposed to these skills and acquire a baseline knowledge and understanding.
Conclusions: The new scenario in health care requires an active participation of the physicians in hospital-specific management practices. The advancement of academic programs to train doctors in this particular field remains critical and should be emphasized by European Academic Institutions.
No conflict of interest.

117 INVITED

Practical aspects in managing daily interaction between the institute (general management priorities) and the medical department objectives and priorities

D. De Valeriola[1]. [1]*Institut Jules Bordet-Centre des Tumeurs de l'Université Libre de Bruxelles, General Medical Direction, Brussels, Belgium*

Managing daily interactions between the head office and the medical departments of a comprehensive cancer center is a complex task due to the diversity of professionals involved, the increasing requirement for care coordination among all health care providers to ensure an efficient multidisciplinary approach, the need of a good integration of research, innovation and education into care, the positive impact of a rapid transfer of lab discoveries to the bedside.
It is also somewhat difficult to ensure that the goals of a medical department in research, care and education will converge and that the available ressources of the institution will be used to realize in a good balance the objectives of these 3 main missions.
Maintaining a good equilibrium between, on one hand, the self-fulfillment of the professionals, the freedom necessary at the medical department level to progress in adequacy with the medical and scientific advances and to improve creativity in research and, on the other hand, the respect of equity and esteem between employees but also the important constraints related to financial, legal and regulatory aspects, is a daily challenge.
One of the key issue is certainly to ensure that all the employees know, understand and are involved in the vision and the mission of the organisation of the institution and are able to work together on ensuring that this vision and mission is communicated and implemented.
Communication and evaluation of the performance of the processes are important tools to use.
Tirelessly, re-centering the goals of all the professionals onto the patient and relatives's needs is certainly the key of success.
The presentation will tackle some practical tools that may be used to improve the convergence between the priorities of the institution and the, potentially different, objectives of the medical departments.
No conflict of interest.

Society Session (Sun, 29 Sep, 09:00−11:00)
European Society of Oncology Pharmacy (ESOP)

118 INVITED

Patient adherence to oral anticancer drugs

A. Eberl[1]. [1]*Institute of Oncology Ljubljana, Pharmacy, Ljubljana, Slovenia*

Background: Patient adherence to oral therapy is an emerging issue in cancer treatment. Non-adherence to anticancer drugs is a growing concern because of the increasing number of novel oral targeted therapies. Suboptimal adherence to a regimen may lead to ineffective outcomes of treatment, drug resistance, altered response to the therapy or result in disease progression or constitute a potential risk of toxicity and waste of resources.
Furthermore, high rates of non-adherence to oral anticancer drugs have been reported in some publications. Methods for measuring adherence, which differ greatly in published literature, include self-reporting, pill counts, microelectronic monitoring systems (MEMS), prescription database analysis, and the assessment of serum or urine drug levels.
Objectives: Since measurements of patient medication adherence and use of interventions to improve adherence are rare in routine clinical practice, the aim is to investigate cancer patients' attitude, adherence and practices with their oral anticancer agents.
Methods: A systematic literature review was conducted to gain insight into determinants and associated factors of non-adherence in patients taking oral anticancer therapy. Data regarding all the cancer patients treated with oral anticancer agents will be collected from national prescription database and analyzed retrospectively. Patients will be asked to participate in the survey during their visits to the pharmacists or physicians to obtain their oral anticancer medication.
Expected results: Non-adherence and non-persistence to oral anticancer drug therapy are complex phenomena. Since a large number of patients will be taken into account, we will be able to provide information on adherence to anticancer agents at our institute. Monitoring adherence to oral cancer therapies is not a recent approach, but presents an increasing challenge as additional oral therapies enter the marketplace. Oncology pharmacists are uniquely positioned to promote patient adherence to oral cancer therapies by ensuring that patients understand the goals of treatment and identifying or resolving underlying barriers to adherence.
No conflict of interest.

119 INVITED

Drug interactions in cancer treatment: Identify them before they do

L. Knez[1], T. Cufer[2]. [1]*University Clinic Golnik, Pharmacy, Golnik, Slovenia;* [2]*University Clinic Golnik, Oncology Department, Golnik, Slovenia*

Background: Cancer patients are prescribed numerous medications, including anticancer drugs, drugs for supportive care and comorbidities. Anticancer drugs are considered high risk drugs and drug interactions may have important implications for patient safety. Potential drug interactions should be detected early in order to prevent their manifestation. The presented study evaluates the management of drug interactions with anticancer drug therapy in a routine clinical practice.
Materials and Methods: The study was designed as a retrospective study and reviewed drug interactions in patients where anticancer drug therapy was initiated between the years 2010 and 2013 at the University Clinic Golnik. As part of routine clinical practice, before the initiation of a new anticancer drug, all included patients were visited by a pharmacist, who obtained a comprehensive drug history and searched for potential drug interactions. Drug interactions judged to be clinically important were discussed with the treating physician. As part of the study, patients' medical records were reviewed and drug interactions were reassessed using three different databases. The clinical importance of detected interventions was rated by an expert panel of pharmacists and oncologists.
Results: Our study included over 500 patients, most of which were treated for lung cancer. As the data are still being analysed, their collection revealed that some clinically important drug interactions were easily avoidable by changing patient's chronic therapy whereas this was not possible in other instances. For example, often, therapy with the tyrosine kinase inhibitor (TKI) erlotinib or gefitinib was planned in a patient prescribed with a proton pump inhibitor (PPI): the concurrent treatment may reduce TKI bioavailability and impair TKI treatment outcomes. Luckily, in most cases, PPIs treatment could be stopped to avoid the interaction. On the other side, sometimes, the interacting drug in patient's chronic therapy, e.g. amiodarone, could not be stopped, and a non-interacting anticancer drug, e.g. gemcitabine, had to be chosen over an interacting one, e.g. vinorelbine, as the interaction may lead to increased exposure to vinorelbine and toxicities.
Conclusions: Pharmacist-led review of drug interactions when starting a new anticancer drug may help prevent potentially dangerous drug interactions.
No conflict of interest.

120 INVITED

Medication reconciliation process in oncology patients

A.R. Rubio Salvador[1], J.I. Chacón López-Muñiz[2], J.M. Martínez Sesmero[1], P.A. Bonal López[3], F.J. Rodríguez García[4], C. Cornejo Castro[2], M.A. Cruz Mora[2], P. Moya Gómez[1]. [1]*Hospital Virgen de la Salud, Pharmacy, Toledo, Spain;* [2]*Hospital Virgen de la Salud, Oncology, Toledo, Spain;* [3]*Hospital Virgen de la Salud, Informatics, Toledo, Spain;* [4]*Toledosoft, Informatics, Toledo, Spain*

Background: A common element among the wide variety of onco-haematological malignancies diagnoses is the management of the complex information related to these patients, in which, due to the characteristics of the disease and the drugs used to treat it (most of them with a narrow therapeutic index) it is necessary to closely monitor the clinical and pharmacotherapeutic history in order to control drug interactions, toxicities and side effects, which may compromise the therapeutic success if not handled properly.
In our environment the information generated in the care of these patients in this setting is managed by two different computerized physician order entry system (CPOE) depending on where the patient is being attended:

a. In the hospital, the CPOE is ONCOBASS®. It has been in operation for 6 years, and includes the design, preparation and administration of all chemotherapy courses prescribed by oncologists/haematologists.
b. In the Primary Care setting, the CPOE is TURRIANO®, where the Primary Care physicians register all drugs prescribed to treat any pathological condition in cancer patients (related or not with their main process).

The main objective of this project is to implement a communication tool between the two CPOE: ONCOBASS® and TURRIANO® in order to coordinate all relevant drug information of oncology patients in different health system levels through a medication reconciliation process inside a complete Medication Prevention Error Program.
Material and Methods: We pretend to extend and integrate the pharmacotherapy management of these patients into the Primary Care system, allowing oncologists/haematologists to get access to online data about any drug prescribed by General Practitioners (GP). This online information includes alarms about interactions and incompatibilities between the drugs prescribed by the specialist and those used by the GP. For this objective, a multidisciplinary team has been created to define the tools necessary to communicate with TURRIANO® to implement them and to follow up the project:

- doctors (oncologists, haematologists) are responsible for selecting clinical data relevant to share with GP in order to control medications prescribed for managing adverse effects of chemotherapy drugs.
- pharmacists are responsible for selecting target drugs to be followed up to avoid relevant interactions and for medication reconciliation.
- nurses are responsible for registering any over-the-counter medication taken by patients that are not registered in any of both electronic system.
- Informatics expert to develop the informatics tools necessary for integration of both systems.

Conclusions: With this project we expect to implement a Complete Medication Reconciliation Process across the continuum of care in cancer patients attended in our area within a general Medication Error Prevention standard of care.
We hope to present preliminary results of the project during the European Cancer Congress 2013.
No conflict of interest.

121 INVITED

Pharmacokinetic reasoning − Pemetrexed distribution into third space fluid

P.G. Hartvig Honoré[1], A. Mellemgaard[2], M.A. Olesen[1], S. Samuelsen[1]. [1]*Department of Drug Design and Pharmacology, University of Copenhagen, Copenhagen, Denmark;* [2]*Department of Oncology, Herlev Hospital, Copenhagen, Denmark*

Dosing of drugs is an art and a science. Scientific based dosing is based on pharmacokinetics and knowledge on the positive and negative effects of the drug. The evaluation of dose strength, dose interval and eventually dosing length is based on measurement of drug concentration over time in the blood, the body or in the urine. The relation of drug concentration over time is expressed by simple mathematical expressions as well as the effect magnitude over time or related to drug concentration. The different relations

are expressed in a series of technical terms such as bio-availability, volume of distribution, elimination rate, ED_{50} and clearance assuming that the processes of pharmacokinetics and pharmacodynamics are linear and non-saturated.
The technical terms form a language for expert pharmacokineticists to talk and understand pharmacokinetics and to use for dose suggestions. For others in the beginning they have a high degree of abstraction. The relation to normal physiology and to pathophysiology as well as drug induced changes is difficult to see and to use. Therefore it is essential to point out that pharmacokinetics has its base in physiology and quantitative drug characteristics.
This is a knowledge base that has been termed Pharmacokinetic reasoning (Holford and Karlsson, 2007). The concept of Pharmacokinetic reasoning is stated as follows: *From pharmacokinetic parameters and the relation to the pharmacodynamics understand the physiology for drug disposition in other terms and to get understanding on its mechanism of action and an integration of PK-PD into biological meaning giving basis for execution of trials and for safety sciences.*
Pharmacokinetic reasoning opens up a mechanism-based pharmaco-kinetic-pharmacodynamic domain making possible the elucidation of normal physiology or patophysiology; understanding the site of action of the drug; understanding the mechanism of action of the drug and to separate physiologic changes from the effect of the drug.
Methotrexate is a cytotoxic drug with relative good hydrophylic properties. In high dose significant amounts are distributed to third space fluids like pleura that is withdrawn from following doses of methotrexate in patients wih NSCLC. There have been questions whether the same procedure was neccessary for the analogue drug pemetrexed used for similar indications. Pharmacokinetic reasoning made the conclusion that this probably was not demanded which had to be followed by a clinical pharmacokinetic study in a group of NSCLC patients where samples from pleura were taken once from each but at variable time. The pleura concentrations were low.
No conflict of interest.

Keynote Lecture (Sun, 29 Sep, 11:30−12:15)
Mouse Hospital and the Co-Clinical Trial Project

122 INVITED

The mouse hospital and the co-clinical trial project

P. Pandolfi[1]. [1]*Beth Israel Deaconess Medical Center, Medicine/CLS 401, Boston, USA*

Tremendous advances in technology have allowed us to gain powerful insights into the molecular and genetic drivers of cancer. The rate at which this knowledge has been translated into effective therapeutics, however, has often been pitifully slow. To facilitate this process, we have launched a new platform and initiative, both nationally and internationally, that we refer to as “The Co-Clinical Project”. Its major goal is to accelerate the stratification of patients based on molecular and genetic criteria, and the identification of mechanisms of acquired resistance to specific treatments towards the development of novel therapies that overcome such resistances. This is achieved through integrated analyses of data obtained from preclinical trials performed in the “Mouse Hospital” in genetically engineered mouse models (GEMMs) of human cancer, as well as mouse models orthotopically transplanted with primary human cancers, and run in parallel and synchronicity with experimental clinical trials as well as existing standard-of-care treatments in human patients ongoing in the “Human Hospital” (hence the term “Co-Clinical”).
No conflict of interest.

Special Session (Sun, 29 Sep, 13:15−14:15)
Management of Bladder Cancer

123 INVITED

Surgical status of lymphadenectomy

A. Stenzl[1]. [1]*University of Tuebingen, Department for Urology, Tübingen, Germany*

The role of lymphadenectomy for staging and possibly for a perioperative therapeutic consequence in addition to surgical treatment of the bladder tumour itself has been under discussion for several decades. In the largest series with a long term follow-up exceeding 10 years (e.g. Stein et al, J Clin Oncol. 19: 666, 2001, Monoharan et al, BJU Int. 104:1227, 2009) a disease specific survival of up to 30% at ten years in surgically treated bladder cancer patients with positive nodes has been demonstrated.
From an anatomical standpoint we differentiate between limited, standard, extended, and superextended lymphadenectomy, depending on the cranial limits (obturator fossa, iliac bifurcation, aortic bifurcation, branching of the inferior mesenteric artery, resp.). To date there are indications but no prove that cranial extension of the lymphadenectomy per se may improve survival (Stenzl et al, Eur Urol. 2011 Jun;59:1009).
There are currently 2 ongoing randomized phase III trials which try to answer whether extended lymphadenectomy improves survival compared to standard lymphadenectomy (German AUO trial, US SWOG1011 trial). Results will be available in 2015 and 2020, resp.
The minimum number of removed lymph nodes between 10−20 has been used as a surrogate marker for the quality and extension of lymphadenectomy in bladder cancer treatment (May et al, Ann Surg Oncol. 2011 Jul;18(7):2018). However, the dissection template as well as the way the nodes are worked up in pathology are equally if not more important. Furthermore patients constitution will also lead to different numbers of nodes within the same template.
Recent studies have shown that serum markers such as C-reactive protein (CRP) in combination with T-stage, lymph node density and resection margin (à TNR-C score) may have some prognostic value and may lead thus to a more extensive lymphadenectomy (Gakis et al, BJU Int. 2011 Dec; 108(11): 1800).
No conflict of interest.

124 INVITED

Is organ preservation for muscle invasive bladder cancer viable?

N.D. James[1]. [1]*University of Birmingham, School of Cancer Sciences, Birmingham, United Kingdom*

Prevailing orthodoxy is that cystectomy is the gold standard for invasive bladder cancer. This view is not underpinned by any randomized trials comparing different primary modes of therapy but rather by indirect comparisons of large surgical and radiotherapy series. Scrutiny of these results actually suggests very similar long term survival rates and population-based studies do not appear to show any survival differences linked to mode of treatment. Furthermore, most large surgical series have median ages in the mid-sixties, well below the (rising) disease population median, suggesting the results may well not be applicable to many or even most patients with invasive bladder cancer. Salvage cystectomy remains an option for local radiotherapy failure and appears to carry similar prognosis. Recent publications using synchronous chemo-radiation both from the USA and UK show excellent rates of bladder preservation and good long-term functional outcomes with little or no risk of treatment related death. As bladder cancer is a smoking related disease with a peak age of incidence in the mid-70s, adherence to the dogma that surgery is the treatment of choice needs re-evaluation when safe, lower morbidity alternatives are available. In particular, in older age groups, risks associated with surgery rise, especially in the presence of co-morbidities such as obesity, diabetes, respiratory and cardiovascular problems which may be associated with long term smoking and inactivity. Data from trials such as BC2001 and BCON show that chemo-radiation remains safe even in patients in their 80s. The role of bladder preservation as a primary therapy, especially for older patients rather than as a niche alternative to surgery in younger patients needs urgent re-evaluation by the uro-oncology community.
No conflict of interest.

125 INVITED

Biomarkers for neoadjuvant chemotherapy in bladder cancer

J. Bellmunt[1]. [1]*Dana Farber Cancer Institute and IMIM Barcelona, Medical Oncology, Boston MA., USA*

Neoadjuvant chemotherapy followed by cystectomy improves survival compared to surgery alone. To prevent overtreatment is of outmost importance to define molecular predictors of response for patient selection. We present the currently available data outlining a variety of potential markers to aid for a personalized decision making process. Apart from p53, other markers of cell cycle regulation and apoptosis as p21WAF1/CIP1 (p21) gene, Bcl-2, mdm-2 and pRB have also been related to survival. The clinical relevance of EGFR and HER2 expression has also been investigated with no success. Regarding Ki67, overexpressing tumors may potentially benefit from neoadjuvant therapy and conversely overexpression of VEGF and bFGF have been linked to resistance to cisplatin-induced apoptosis. The role of multidrug resistance gene 1 (MDR1) and ERCC1 support that enhanced DNA repair in the tumor decreases the benefit of platinum-based treatment. A 20 gene expression model has shown to predict lymph node involvement, helping on decision making. A gene expression profiling has been proposed as predictive for response to neoadjuvant chemotherapy.
Conclusion: Predictive markers will eventually aid in the selection of patients that most likely benefit from preoperative treatment. In the coming

Table (abstract 125).

Biomarker	Predictive value	Biomarker status good outcome	Results	Ref.
p53	Controversial	Non overexpression	Related with higher RR to Neoadjuvant MVAC Related to better DFS and OS to RT-Cisplatin	[2]
		Not related with higher RR to Neoadjuvant MVAC Not related to better OS to RT-Cisplatin	[1], [3]	
p21 and p53	Prognostic value	Non overexpression	Related to better DFS or OS to RT-Cisplatin	[2]
pRB	No	Non overexpression	Not related to better DFS or OS to RT-Cisplatin	[2]
Bcl2	Yes, not validated	Non overexpression	Related with better OS in cisplatin and radiotherapy treated patients	[4]
Mdm-2	No	Non overexpression	Not related with pathologic downstaging after neoadjuvant MVAC	[5]
Ki67	No	Overexpression	Trend to better PFS and OS after neoadjuvant MVAC	[6]
XAF-1	Yes, not validated	High mRNA expression	Related with higher RR and PFS after neoadjuvant GC	[7]
VEGF	Prognostic value	Low expression	Related with better DFS after neoadjuvant MVAC	[8], [9]
Her2	Yes, not validated	Non overepression	Related with higher CRR after RT-Cisplatin	[10]
BCRA1	Yes, not validated	Low mRNA expression	Related with higher RR after neoadjuvant Cisplatin regimen	[25]
ERCC-1	Yes, not validated (RT-Cisplatin)	Low expression	Related with higher RR after RT-Cisplatin regimen Not related with higher RR after neoadjuvant Cisplatin regimen	[11], [12], [13]
14-gene expression	Yes, Validated	Positive score	Related with higher RR after MVAC	[14], [16]
20-gene expression	Prognostic value, Validated	Cuttoff high/low risk	Related with risk of nodal involvement in neoadjuvat treated patients	[15]

years a panel of markers will become available to achieve the predicted goal. (See table summary.)

Special Session (Sun, 29 Sep, 13:15−14:15)
Aspirin − A Wonder Drug in the Fight Against Cancer?

126 INVITED
Aspirin and GI cancer incidence

Abstract not received.

127 INVITED
Aspirin and cancers other than gastrointestinal ones

C. Bosetti[1], V. Rosato[1], C. La Vecchia[1]. [1]*IRCCS-Istituto di Ricerche Farmacologiche Mario Negri, Epidemiology, Milano, Italy*

Background: The role of aspirin on neoplasms other than colorectal and upper digestive tract ones is still unclear. As for gastrointestinal cancers, aspirin may have a chemopreventive effect on other neoplasms by inhibiting cyclooxygenase (COX)-2, which has been reported to be abnormally expressed in many cancer cell lines and has been implicated in the process of carcinogenesis, tumor growth, apoptosis, and angiogenesis. Additional mechanisms of the anticarcinogenic effect of aspirin include the induction of apoptosis through COX-independent pathways, the inhibition of NF$\kappa\beta$ factor, and the upregulation of tumor suppression genes.
Material and Methods: We reviewed epidemiological data on aspirin and the risk of lung, breast, and prostate cancer, and provided an up-to-date quantification of the associations using a meta-analytic approach.
Results: At least 20 epidemiological studies on approximately 16,000 cases reported that aspirin is associated with a modest overall reduction (around 10%) of lung cancer risk. The inverse association, however, seems restricted to case-control studies. Moreover, there is evidence of some publication bias, with several small studies reporting the strongest inverse associations. A modest reduced risk has also been found for breast cancer in over 30 studies on approximately 54,000 cases, with consistent results in case-control and cohort studies. However, some heterogeneity in risk estimates and evidence of publication bias is observed. Moreover, there is no indication of dose and duration-risk relationships. At least 24 studies on more than 37,000 cases indicate that prostate cancer risk is reduced by 10% in aspirin users, with similar risk reductions in case-control and cohort studies, and for less aggressive versus more aggressive cancers. However, as for breast cancer there is no evidence of a relation with frequency, dose, or duration of use. Detection bias is possible since men and women taking aspirin regularly may have had more frequent medical contacts and consequently prostate-specific antigen measurements or mammographies, thus increasing their probability of being diagnosed with prostate or breast cancer.
Conclusions: Regular aspirin use appears to be inversely, but modestly, related to breast and prostate cancer risk. Inference for causality and public health implications are, however, still unclear given the heterogeneity of results, possible bias, and the lack of dose and duration-risk relationships.
No conflict of interest.

128 INVITED
Aspirin in cancer prognosis and pharmacogenetics

C. Ulrich[1]. [1]*German Cancer Research Center, Division of Preventive Oncology, Heidelberg, Germany*

Inflammation has long been recognized as an important contributor to risk of colorectal and other cancers. Although the exact mechanisms that contribute to this process are still unclear, inflammation enables carcinogenesis by contributing to cell proliferation and survival, angiogenesis, and genetic mutations. Use of non-steroidal anti-inflammatory drugs (NSAIDs) is effective in decreasing risk of colorectal and other cancers − in particular, recent studies exemplify that already a low dose of ASS has major potential in the chemoprevention of cancer. In addition, NSAID use appears to improve cancer prognosis. However, there are side effects, such as gastrointestinal upsets and bleeding. This limits the ability to use these agents in cancer prevention among healthy individuals. Interestingly, we have shown that inherited variation in genes that affect NSAID metabolism or efficacy can alter their potential as preventive agents and thus alter each person's individual risk-benefit balance.
NSAID pharmacogenetics can play a role at the level of drug metabolism and excretion, as well as at the level of prostaglandin synthesis. That pathway is the primary target of aspirin/ other NSAIDs and effects are mediated by the inhibition of prostaglandin H synthases (also termed COX1 and COX2). We have shown that polymorphisms in NSAID metabolism or prostaglandin synthesis can be important factors determining the efficacy of NSAIDs in cancer prevention, and are likely also determinants of toxicity. Utilizing NSAID pharmacogenetics is a key tool for tailoring the intervention towards individuals most likely to benefit at the lowest possible risk. This knowledge will provide the foundation for a strategy of personalized cancer prevention.
No conflict of interest.

Special Session (Sun, 29 Sep, 13:15−14:15)
Management of Toxicities Related to Chemotherapy and Targeted Therapy

129 INVITED

Pharmacological principles in relation to toxicity

A. Bergman[1]. [1]*Antoni van Leeuwenhoek Ziekenhuis, Medical Oncology, Amsterdam, Netherlands*

Pharmacology, the science of drug actions, studies the pharmacokinetics and pharmacodynamics of therapeutic agents. Pharmacokinetic parameters are the absorbance, metabolism, distribution and excretion of drugs, while pharmacodynamic studies concentrate on the interaction between the drug and its target cells and tissues and the body's response to that interaction. The maximum tolerated dose (MTD) is the highest dose of a drug that can be administered to a patient without unacceptable toxicity. This MTD is established in early clinical trials, which are designed to step wise increase the dose of a new drug until the dose limiting toxicity is reached (Phase 1 trial). The therapeutic activity of the drug at the MTD is studied in subsequent clinical trials (Phase 2 and 3). The therapeutic index (TI) of a drug is a ratio of the therapeutic efficacy and the severity of toxicities. Since anticancer drugs are toxic and have limited activity, the TI for these drugs is generally low. Therefore, registration and treatment of side effects is an important aspect of the work of an oncology care professional. Toxicity of anticancer drugs can often be explained by their mode of action, metabolism and their distribution over fatty and aqueous tissues in the body. Toxicity of drugs with a specific drug target, such as tyrosine kinase inhibitors and monoclonal antibodies, can be related to the functions of their target. Changes in pharmacokinetic or pharmacodynamic parameters might alter the TI. For example, ascites or pleural effusion will disturb clearance of methotrexate, which might result in unpredictable and prolonged toxicity. Impaired kidney functions will decrease elimination and results in increased toxicity of drugs cleared by the kidney (e.g.: Carboplatinum), impaired liver functions might result in decreased activity of drugs that require enzymatic conversion in the liver from a prodrug into an active drug (e.g.: capecitabine), while increased toxicity can be expected from drugs that are eliminated by the liver (e.g.: taxanes). Also genetic defects might result in increased toxicity of specific drugs. Dihydropyrimidine dehydrogenase (DPD) and UGT1A1 are essential for capecitabine/5-Fluorouracil and irinotecan elimination, respectively. Genetic deficiency of these enzymes is related to increased toxicity. In conclusion, pharmacokinetic and pharmacodynamic properties of anticancer drugs should always be considered prior to prescription.
No conflict of interest.

130 INVITED

Caring for patients with cardiotoxicity

S. Atay[1]. [1]*Hacettepe University, Oncology Hospital, Ankara, Turkey*

Cardiotoxicity is one of the most significant adverse effects of cancer treatment, and is responsible for considerable morbidity and mortality. The most frequent clinical manifestation of cardiotoxicity is asymptomatic or symptomatic left ventricular dysfunction. It may be induced not only by conventional cancer therapy, like anthracyclines, but also new antitumoral targeted therapy such as trastuzumab.
Incidence: From 5% to 65% of treated cases, and has been noted in 3−5% of patients when trastuzumab was administered as a single agent and in up to 64% of patients receiving the drug in combination with anthracyclines.
Risk factors: Most frequently associated with cardiotoxicity are anthracyclines, taxanes, alkylating agents and trastuzumab. The most important risk factor is cumulative dose of doxorubicin. In contrast to anthracyclines, trastuzumab toxicity does not appear to be dose related. Risk factors for developing trastuzumab cardiotoxicity are not clear. Age, obesity and hypertension are known risk factors for cardiac dysfunction.
Prevention strategies: Cardioprotective strategies protocols should be developed for patients undergoing treatment. Although cardiotoxic effects of cancer treatment occur infrequently, early detection and toxicity requires cardiac monitoring. Unfortunately, no proven strategies are available. The American Heart Association recommended close monitoring of cardiac function during anthracycline treatment but does not specify how often or by which means.
Many factors can increase the risk of cardiac toxicity in patients receiving cancer therapy, and nurses should be aware of them. Rigorous assessment of patients before treatment and careful monitoring during and after treatment can help to minimize risk and identify early signs of cardiac dysfunction. Nurses can help to minimize these risk factors by educating patients about the importance of quitting smoking, increasing physical activity, and limiting alcohol intake.
Nurses also can minimize the risk of cardiac toxicity by understanding the types and doses of chemotherapy or targeted therapy that patients have received previously, and whether patients have received radiation therapy to the chest. Knowledge about patients' previous exposure to chemotherapy could help nurses alleviate potential risks associated with treatment administered in the metastatic setting.
Management: No specific evidence-based guidelines exist for the management of chemotherapy-induced cardiac dysfunction. The Heart Failure Society of America's practice guidelines state that before treatment, interventions should be employed to control the following cardiovascular risk factors: body weight, hypertension, hyperglycemia, smoking, and alcohol consumption. Clinical studies have demonstrated the benefit of ACE inhibitors and beta blockers in patients with chemotherapy induced cardiac dysfunction.

131 INVITED

Caring for patients with skin toxicity

P. Dielenseger[1]. [1]*AFIC, Institut de Cancérologie Gustave Roussy, Villejuif, France*

Cancer becomes a chronic disease with long term treatments associated with new and long terms toxicities.
Cancer professionals discovered new skin toxicities related to targeted therapies. New symptoms with new physiopathology . . . what challenges for nursing in cancer care!
Skin toxicity is one of the common ones, with wide consequences: symptoms by themselves, their management, but also issues about body image and social interactions. We are not focused on prevention for the moment, but this should be an aim.
We will discuss and share about these challenges, and propositions in nursing care.
No conflict of interest.

Special Session (Sun, 29 Sep, 13:15−14:15)
Matching p-values to Clinical Needs: Statistical Significance vs Clinical Relevance

132 INVITED

Payers perspective

K. De Nys[1]. [1]*University Hospitals of Leuven, Head Clinical Trial Center Chairman Belgian Federal Commissie voor Tegemoetkoming Geneesmiddelen/Commission de Remboursement des Médicaments (CTG/CRM), Leuven, Belgium*

Payers are facing challenging times. Not only the economic crisis but also the aging population, suffering from various chronic diseases, and the high prices of new drugs increase the pressure on drug reimbursement systems. Moreover and especially in the oncology area, launch volumes are expected to increase when considering the current pipeline[1]. With the sustainability of health care systems at stake, most parties involved realize that a change of mentality, not only in drug development plans, but also in the pricing and reimbursement policies imposes. From a payers perspective, some suggestions can be made.
At the registration level, adding values such as clinical relevance to the classical registration parameters could be considered, as relatively little attention seems to have been paid to the availability of (good) alternative treatment options until recently[2]. In order to better define the best Standard of Care, academic head-to-head trials comparing available treatments, objective registers or trials challenging the optimal dose or duration of treatment offer an important added value to the registration trials, and should therefore be promoted. In the set-up of such trials, participation of the reimbursement systems, defining the current gaps and the research questions, is absolutely necessary.
Reimbursement systems need guidelines, which should be − at least partly − based on the results of these academic studies. The scope of those guidelines can be international especially in the field of the mentioned scientific assessments, but since reimbursement decisions are taken on the national level, national guidelines adapted to the local situation can be helpful. Organizations editing these guidelines should be as independent as possible and free of

133 INVITED

Matching p-values to clinical needs: Practitioner's perspective

A. Sobrero[1], A. Pastorino[1], P. Bruzzi[1]. [1]*IRCCS San Martino IST, Department of Medical Oncology, Genova, Italy*

Background: The size of clinical trials in advanced solid tumors has become larger and larger in the last decade. As a consequence, statistical significance is achieved with smaller and smaller absolute and relative treatment effects. The relevance of statistically significant differences has increasingly been challenged whenever the treatment effect is small. There is thus the need to identify the minimum clinically worthwhile effect (MCWE) to pursue in randomized clinical trials. There are 3 major dimensions to characterize the MCWE: the endpoints used, the way to measure them and the threshold values to define the MCWE. In general, depending on the prognosis and the setting of the disease, there is agreement on the fact that OS or PFS are the endpoints to be used in advanced solid cancers.
Methods: Therefore we have concentrated our analysis on the identification of the parameters to be used and on the definition of their threshold levels for MCWE. Starting from 4 premises (1 the incremental nature of cancer treatment advances; 2 the prognostic heterogeneity of the conditions investigated in clinical trials; 3 the search for a compromise between what is relevant and what is feasible; 4 the need to express the benefit in a language understandable by patients), we have identified two conditions satisfying the MCWE in conceptually different ways: small benefit for many (SMALL) and large benefit for few (LARGE). SMALL may be measured both in terms of HR and median gain, whereas LARGE may be more appropriately measured by proportional and or absolute increase in 1, 2, 3 year OS.
Results and Conclusions: We have thus postulated threshold values for MCWE as a function of toxicity and prognosis for each of these 4 parameters and challenged these postulated values with the actual results of 50 trials on 39,426 patients in 13 cancer types on 19 new drugs. This model allows to preliminarily conclude that a) SMALL is more frequently achieved than LARGE, b) the threshold values for MCWE are more frequently obtained for HR than in terms easily understandable by patients (absolute median gains and absolute % increase of OS at 1, 2, 3 years), and c) the chances of obtaining MCWE by these parameters are similar in conditions of poorer or better prognosis (more or less than 12 months).
No conflict of interest.

Patient perspective

Abstract not received.

Special Session (Sun, 29 Sep, 13:15−14:15) **How Should Complex Treatments in Radiation Therapy be Monitored to Guarantee Quality?**

135 INVITED

In vivo dosimetry

L. McDermott[1]. [1]*University Medical Center Utrecht, Radiation Department, Utrecht, Netherlands*

Patients should receive "treatment (that) is individualised for the specific patient's cancer, taking account of the patient's personal circumstances", according to ESTRO's Vision for 2020. This should go for quality assurance (QA) too. In vivo dosimetry is a patient specific QA procedure, and the only way to ensure the treatment went as intended. For this discussion, we define in vivo dosimetry as a measure of the dose delivered inside the patient during treatment time. The location of the dose in question is important, and not the location of the detector. Compared to pre-treatment dose verification, in vivo can be too late to prevent an erroneous treatment. On the other side, errors can (as reported) occur during treatment that are a missed in pre-treatment checks.
Whether errors that occur are systematic (repeated for many patients/fractions) or unique to one instance, treatment providers want to know when they happen − to assess consequences and prevent re-occurrance. Complete in vivo dosimetry is a measure of the sum of any errors that occurred in the entire chain of planning, data transfer, functioning of the linac, patient set-up and patient displacement. Some like to grade these sources of error in terms of high and low level etc, but in the end, the only interesting information is the similarity between the intended and actual dose. The question is then: is it worth measuring the dose in vivo, if the rest of the treatment chain is in good working order? The answer depends on whether the in vivo dose *can* be measured accurately, quickly, at all points of interest and for all simple or complicated treatments. The past decade has proven this to be not only possible, but has provided years of successful clinical experience that says 'yes it can'. A department can know and respond to errors instantly, as well as collect data indicating how well they are treating large patient groups over long periods.
The problems are not academic but pragmatic − mainly being the lack of any commercially developed solutions. It is not a high enough priority for vendors, who claim the demand from customers has not been sufficiently high. This discussion will address the issue of whether the focus of QA should simply lie with equipment, without the bother of patient-specific in vivo dosimetry. Or perhaps in vivo dosimetry can really guarantee high quality for all current and future RT treatments, and is indeed a worthwhile investment.
No conflict of interest.

136 INVITED

A comprehensive QA programme of treatment unit and treatment planning systems would make pre-treatment verifications redundant

D. Verellen[1], M. De Ridder[1]. [1]*UZ Brussel, Oncologisch Centrum, Brussels, Belgium*

Modern radiation oncology is a well-established, cost-effective and essential component in the curative and palliative treatment of malignancy. The challenge of individualized treatment optimization continuously drives research and technology, yet we should be careful not to get trapped in the "Cargo Cult Science" as described by Richard Feynman. In an attempt of avoiding a blind gallop towards increasingly more precise means of tumour localization and delivery this perspective on challenges in quality will contemplate 3 topics: (a) Due to the cutting edge technology, one might argue that radiation oncology, long considered to be a physical intervention, is now more accurately conceptualized as a biologic intervention with profound effects at the cellular and molecular level. The big challenge is to bring this into daily clinical routine in a safe an consistent way. (b) As systems become more automated and complex the potentials for failure become less intuitively obvious and we need more process-oriented rather than device oriented Quality Assurance to ensure patient safety. Moreover, it suffices no longer to prove we can irradiate phantoms with high precision, patients demand prove of the true delivered dose in their particular case. Again, this implies comprehensive Quality Assurance programs. (c) Scientific and technological progress comes at a significant cost, and many concerns exist regarding the value of that progress. Within these difficult economic times, health care politicians face the difficult challenge to create a furtive soil (e.g. supporting adequate reimbursement) allowing progress through efficacy and driven by outcomes. There is also a danger in that too much focus on sophisticated expensive technology may create a double layer health care system where not all patients have access to the best of care. Ideally, efforts in development should also aim at harmonizing the quality of care throughout Europe and the rest of the world. One might argue that a large part of the financial resources goes to treatments that show limited benefit for the patient and we need new financing mechanisms such as Coverage with Evidence Development. The latter, again, will need feedback from appropriate Quality Assurance programs.
No conflict of interest.

Special Session (Sun, 29 Sep, 13:15−14:15) **Centralisation of Complex Cancer Surgery: Do Outcomes Improve?**

137 INVITED

UK perspective

Abstract not received.

138 INVITED

Swedish perspective

P. Naredi[1]. [1]*Sahlgrenska University Hospital, Department of Surgery Institute of Surgical Sciences Sahlgrenska Academy, Göteborg, Sweden*

In Sweden all complex cancer surgery is provided by hospitals in the public health care system. These are governed by county or regional politicians and at national governmental level only supervision and recommendations can be given. Over the last decade the trend has been towards voluntary centralisation of complex cancer surgery. During the same period traditional outcome measures as postoperative morbidity and mortality and long-term survival have improved for most cancer diagnosis. Whether centralisation of complex cancer surgery has a major role in the improvement is debatable.

For many cancer diagnosis we have national population-based quality registries and historically these were initiated by professionals and managed by regional oncology centers. The data generated have been used by national networking groups to discuss what needed to be done to improve cancer care and to design clinical trials. While there is clear evidence that targeted quality indicators have been improved by these measures there is less evidence that centralisation to date has been of similar importance.
Smaller units have to large extent stopped doing complex cancer surgery. For some diagnosis like pancreatic and esophageal cancer the centralisation is at regional level while e.g. rectal or gastric cancer also is commonly performed at county hospital level. The national cancer plan and collaboration between six Regional cancer centres has initiated projects with the intention to centralise complex cancer surgery to high volume centres. Key arguments are not mainly focused at the improvement of the surgical procedure but more handling postoperative complications and fascilitating an optimal multidisciplinary diagnostic and treatment process for the patient.
No conflict of interest.

Epigenetics in Cancer

140 INVITED
Epigenetic therapies in haematologic and solid malignancies

Abstract not received.

141 INVITED
Reprogramming the cancer phenotype by epigenetic drugs

J. Issa[1]. [1]*Fels Institute Temple University, Philadelphia, USA*

The epigenome is reset during embryogenesis and matures around the end of development. Large scale genomic studies have now shown considerable proliferation dependent epigenome changes in aging cells and in cancer cells (DNA methylation instability, chromatin instability). Epigenetic instability creates gene expression variation that serves as an enabler of Darwinian evolution at the tissue level, leading to disease formation (e.g. cancer), but also to selectable phenotypes such as drug resistance. Consequently, epigenetic reprogramming has been investigated for prevention and treatment of cancer. In hematologic malignancies, reprogramming by DNA methylation inhibitors has gained acceptance as effective therapy for myeloid leukemias, and drugs for other epigenetic targets are rapidly proceeding towards clinical trials. The hypomethylating drugs azacitidine and decitabine induce clinically meaningful remissions or improvements in 30−60% of patients with leukemias and prolong survival compared to standard approaches including chemotherapy. Both drugs are approved in the for the treatment of advanced and/or symptomatic MDS and AML. Histone deacetylase inhibitors belong to another class of epigenetic modifying agents which also has clinical activity in MDS and AML, though primarily when used in combination with hypomethylators. Clinical observations (delayed responses that are optimal at low doses) and laboratory studies (correlations between sustained hypomethylation, gene activation and response) both suggest that responses are mediated by epigenetic mechanisms. Current studies are investigating more potent DNA hypomethylators such as SGI-110, combination epigenetic therapy, translation of the hematologic malignancies experience to solid tumors, incorporation of epigenetic drugs with standard cytotoxics and a search for drugs that reprogram the epigenome through alternate mechanisms.
Conflict of interest: *Advisory board: Astex, Janssen. Corporate-sponsored research: Astex*

142 INVITED
How to overcome resistance to HDAC inhibitors?

S.E. Bates[1], A.R. Chakraborty[1], A. Basseville[1], V.L. Luchenko[1], R. Frye[1], Z. Zhan[1], R.L. Piekarz[2], R.W. Robey[1]. [1]*National Cancer Institute, Center for Cancer Research, Bethesda, USA;* [2]*National Cancer Institute, Cancer Therapy Evaluation Program, Bethesda, USA*

Histone deacetylase inhibitors (HDIs) have demonstrated activity in cutaneous and peripheral T-cell lymphomas and two have received regulatory approval for these indications in the United States. Histone deacetylases are found in both the cytoplasm and nucleus and are involved in the regulation of multiple cellular processes, most notably the deacetylation of nucleosomal histone proteins, which results in transcriptional silencing. Three families of HDAC enzymes have been described, with the HDIs exhibiting differences in potency of inhibition. Romidepsin and entinostat are potent inhibitors of class I HDACs, while vorinostat, belinostat, and panobinostat are inhibitors of both class I and II HDACs. In the clinic, T-cell lymphoma responses to romidepsin and vorinostat are observed in about a third of patients treated. Responses can be durable but the median time to disease progression is under a year − defining both intrinsic and acquired resistance in T-cell lymphoma. HDI resistance is also widely observed in solid tumors, despite widely documented activity in *in vitro* studies. Mechanisms of resistance have not been clearly delineated but are likely multi-factorial. With the HDAC enzymes as molecular targets, HDIs can be considered targeted therapies, but they differ from other classes of targeted therapy in that the HDAC targets to date have not been shown to be mutated or to be isolated oncogenic drivers in cancer. Accordingly, resistance mechanisms observed with the tyrosine kinase inhibitors (TKIs), such as target resistance mutations or bypass signaling, have not been described. To date, resistance mechanisms reported in various laboratory models include persistent activation of the STAT signaling pathway (with clinical data as well for vorinostat), activation of NF-kB and increased Bcl-2, reduced expression of pro-apoptotic Bim, activated MAPK signaling and in the case of romidepsin overexpression of the drug efflux transporter P-glycoprotein. Our laboratory data demonstrate that downregulation of Bim via activation of MEK is important in T-cell lymphoma resistance to romidepsin. Preliminary results in clinical samples show a wide variation in Bim levels and correlations with outcome are ongoing. Various reports, and data from our group in CTCL and other models, have shown that cells can be sensitized to HDAC inhibition via concurrent treatment with MEK inhibitors, PI3K inhibitors, CHK1/2 inhibitors, and knockdown or inhibition of anti-apoptotic proteins such as Bcl-2. Thus, it appears a key mechanism of HDI resistance is an increase in pro-survival signaling coupled with failed activation of apoptosis − highlighting potential strategies for development of combination therapy in the clinic.

Special Session (Sun, 29 Sep, 13:15−14:15)
Tumour Response Assessment

143 INVITED
Anatomic and functional imaging

D.M. Koh[1]. [1]*Royal Marsden Hospital, Dept. of Diagnostic Radiology, Sutton, United Kingdom*

Anatomic imaging using computed tomography (CT) and magnetic resonance imaging (MRI) remains the cornerstone for tumour response assessment in clinical practice. The Response Criteria In Solid Tumours (RECIST) version 1.1 is widely adopted in clinical trials, although bidimensional tumour size measurement criteria (e.g World Health Organization Criteria; MacDonald Criteria) are sometimes utilized. The assumption that effective therapy results in tumour shrinkage underpins the use of anatomic imaging for tumour response assessment; this observation being true for a range of effective treatment.
However, there are increasing examples of drug that can result in patient benefit without reducing tumour dimensions. This poses a real challenge for evaluating the therapeutic efficacy of such drugs that are already licensed for clinical use; and even more pertinently, raises questions as to how best to measure the therapeutic efficacy of many new drugs in the development pipeline, whose actions are targeted towards specific cellular or metabolic pathways, which may not result in profound cell death and thus tumour size regression. Furthermore, there are “blind spots” in the existing tumour response assessment criteria (e.g. there are still no validated response criteria for bone disease).
Functional imaging CT, MRI and molecular imaging are seen as techniques that can improve tumour response assessment. These techniques reflect changes in specific aspects of the tumour pathophysiology and allow quantitative measurement to be made. There are a range of functional imaging techniques, which enables us to probe, reflect and quantify tumour vascularity, cellularity, metabolism, hypoxia and internal heterogeneity. The parameters derived have been shown to change (often early) in response to drugs that modulate these tumour properties.
However, as many of these techniques are complex to perform, translating functional imaging measurements into robust multi-centre techniques has been challenging. Nevertheless, multicentre studies employing some

of these techniques (e.g. dynamic contrast enhanced MRI; diffusion-weighted MRI) have shown good to moderate measurement reproducibility and acceptable inter-scanner variance. With technological convergence between imaging platforms, it is likely that these techniques will be realized in future clinical practice.
No conflict of interest.

144 INVITED
Data warehouse and uncertainties in response measurements

S. Litière[1], J. Bogaerts[1], L. Seymour[2], E. De Vries[3]. [1]*EORTC Headquarters, Statistical Department, Brussels, Belgium;* [2]*NCIC Clinical Trials Group, Investigational New Drug Program & Audit and Monitoring Group, Kingston, Canada;* [3]*University Medical Center Groningen, Department of Medical Oncology, Groningen, Netherlands*

To evaluate response and/or progression based on RECIST in clinical trials, detailed information is collected on the extent of disease at the start of the study and how disease evolves on treatment. Therefore clinical trial data based on RECIST-like criteria contain a wealth of longitudinal information on objectively measured tumor lesions. Previous analyses have shown that the contribution of tumor growth based on objective tumor measurements may not add much to the predictive capacity of a model for overall survival which already includes factors for tumor shrinkage and progression of non-target disease (Litière et al. J Clin Oncol 30, 2012 (suppl; abstr 10602)). One possible explanation may be the variability associated with these tumor measurements. Different sources could be identified, including measurement error, differing behavior of lesions within a patient as a response to treatment, heterogeneity between patients' measurement profiles, ... The data warehouse used for RECIST 1.1, including 16 randomized clinical trials across various tumor types (breast, colorectal, lung cancer), is a unique source to investigate this variability. Therefore, we will report on some of these results and how they may affect ongoing efforts to improve RECIST.
No conflict of interest.

145 INVITED
Imaging and beyond: What is needed in drug development?

L. Seymour[1]. [1]*Cancer Centre of Southeastern Ontario, Kingston − Ontario, Canada*

The development of cancer therapeutics is dogged by high late-stage failures, resulting in enormous costs, wasted resources, and lost opportunities. Although late-stage failures are the most costly, failures even in phase I are significant, as the selection of that agent may result in another potentially effective drug being abandoned. Failures, while expected, need to be identified at the earliest possible phase; robust methods, including imaging, are needed to improve decision making. Critical is the 'pharmacological audit trail' demonstrating: expression of the relevant target (e.g. her-2), evidence of drug penetration, effect on the target and the pathway, biologic effect and anticancer effect both pre-clinically and in humans.
Reliable processes are needed to ensure optimal decision making, including candidate selection, no-go decisions on proceeding to later development, and importantly, but often undervalued, the selection of an optimal tolerable dose and schedule. Adaptive trial designs have been proposed using efficacy, toxicity and pharmacokinetics, but have been hard to conduct because of the difficulty of evaluating response early. In later phases of development, surrogates of clinically meaningful anti-cancer effects that do not require long, large and costly trials, with overall survival endpoints often complicated by the use of salvage therapies, are highly desirable. These methods would ideally be usable in small trials and be reliable with good predictive value.
Imaging techniques can be harnessed in many of these areas and can be used to molecularly characterize tumours, evaluate metabolism, perfusion, hypoxia, cell proliferation, characterize pharmacokinetics and pharmacodynamics, drug distribution and kinetics, interaction of the drug with the target, as well as follow treatment effects.
Although progress is being made, further improvements are needed including in availability, cost, speed, validation and consistency. In addition, even in clinical practice, existing techniques and methods may be difficult to reliably interpret such as the evaluation of bone metastases, immunotherapeutics, and in certain tumour types such as prostate and pancreatic cancer, brain and hematologic malignancies, and mesothelioma, among others.
Pooled databases, even from negative trials, are needed to robustly evaluate imaging techniques. Data sharing initiatives such as the RECIST warehouse are imperative.
No conflict of interest.

Special Session (Sun, 29 Sep, 13:15−14:15)
How to be a Happy Oncologist

146 INVITED
Quality of life of young oncologists

P. Blanchard[1]. [1]*Institut Gustave Roussy, Villejuif, France*

Numerous multi-institutional studies have shown that medical students have a lower mental quality of life than similarly aged individuals in the general population and that burnout is highly prevalent in this population, reaching 76% in a study among residents in a US internal Medicine program. A meta-analysis of observational studies as shown that depression and anxiety rates were high among US and Canadian medical students, with levels of overall psychological distress consistently higher than in the general population and age-matched peers by the later years of training, the rate being even higher when considering only female students. Besides burnout has a detrimental effect on the physician's quality of life, is associated with an increased risk of suicidal ideation and has been linked to poorer quality of care, increased medical errors and lawsuits, decreased empathy, job withdrawal and absenteeism. Factors usually associated with burnout are insufficient personal or vacation time, a sense of failure, unrealistic expectations of patients, cognitive or ethical dissonance, repeated losses and grieving or problems concerning managed care.
However the prevalence and causes of burnout and low quality of life have rarely been studied specifically in an oncology resident population. In a recent French nationwide cross-sectional study among oncology residents (hematology, medical oncology, radiation oncology), burnout prevalence was 44% and was not significantly different between the three specialties. Burnout was higher among residents who did not feel adequately rewarded for their work. Burnout was associated with a lower perception of one's general health status and the desire to quit Medicine or to change specialty. The aims of this talk are to quickly introduce the concepts of burnout and quality of life, and then to focus on studies evaluating these items among oncology physicians (surgeons, medical oncologists and radiation oncologists) and when available oncology residents. Factors associated with burnout will be analyzed in order to discuss areas for future improvement.
No conflict of interest.

147 INVITED
Why choose oncology? How to identify goals/aims/barriers towards professional fulfilment for young oncologists

P. Dubsky[1]. [1]*Medical University of Vienna, Surgery, Wien, Austria*

Oncology has a potential for both professional fulfillment and total personal burn-out.
What are some of the factors leading to "happiness"? and at the same time- What can go wrong?
"Happiness" is a highly subjective feeling- and this presentation will remain unabashedly so. Motifs behind becoming and staying an oncologist will be presented. Medical education, job training, academic training and mentorship are important factors to stay healthy and happy. Science and research are no longer first steps in an early career. Both private and public settings to practice oncology can be rewarding- both can also be highly frustrating. Oncology is a rare profession that enables you to experience and help others at a time of existential need. At the same time getting paid for a job that is much more than a profession is important for sustained practice.
No conflict of interest.

148 INVITED
Managing burnout in oncology − special focus on young oncologists

L. Fallowfield[1]. [1]*University of Sussex, Brighton East Sussex, United Kingdom*

Medicine is a well-respected, well- paid and rewarding job but mental health problems are common, suicide has been reported as twice as high as in the general population. Alcoholism and deaths from cirrhotic liver disease is greater than in many other professional groups and divorce rates are also high. Burnout − a syndrome of emotional exhaustion, depersonalization and reduced professional accomplishment has been shown in many studies of oncologists in the US and Europe. Examining the reasons for these alarming findings is important, not only to protect young oncologists from experiencing a similar fate, but also for the well-being of their patients, their professional colleagues and their own personal relationships. Good stress and challenges leave individuals fulfilled with a sense of achievement that is validating for oneself and for others. Bad chronic and prolonged stress

is physically and emotionally debilitating and damaging for all. In this talk some top tips and suggestions will be given that will hopefully help towards making your career one that leaves you burnished not burned out!

New Insights into Biology of Brain Tumours

149 INVITED

Histones and paediatric high-grade gliomas

Abstract not received.

150 INVITED

Recent insights into the biology of low-grade gliomas

D.T.W. Jones[1]. [1]*German Cancer Research Center, Division of Pediatric Neurooncology (B062), Heidelberg, Germany*

Background: Low-grade gliomas (LGGs) together account for around a third of all brain tumors in children. This catch-all term, however, masks a significant amount of underlying histological and biological heterogeneity, with many morphologically-defined entities that can show substantial overlap in their microscopic appearance and genetic alterations. It is also now clear that many of these entities are either unique to childhood, or are clearly distinct from their adult counterpart. The pace of progress in LGG research, however, has previously been hampered by delayed application of the latest methodologies in contrast to malignant entities such as medulloblastoma, and also by a paucity of cellular or *in vivo* models. Fortunately, both of these limitations are now beginning to be addressed.
Summary: This presentation aims to provide an overview of the most important findings from several recent genomics and functional biology studies focused on LGG. For example, whole-genome sequencing and high-resolution copy-number profiling have revealed novel alterations in *FGFR1* and *NTRK2* in pilocytic astrocytomas (Zhang J *et al*. Nat Genet 2013; Jones DTW *et al*. Nat Genet 2013), as well as structural rearrangements of *MYB*/*MYBL1* in other LGGs (Zhang J *et al*. Nat Genet 2013; Ramkissoon LA *et al*. PNAS 2013). Important functional investigations have also shed light on possible mechanisms of resistance to BRAF inhibitors in tumors harboring *BRAF* fusion genes (Sievert AJ *et al*. PNAS 2013), or elucidated cell type-specific responses to oncogenic stimuli and cooperating pathways in a new mouse model of LGG (Kaul A *et al*., Genes Dev 2012).
These studies and others from several international groups have provided very welcome new insights into the pathogenic diversity of LGG. They have also opened novel avenues for further research into mechanisms of tumorigenesis involving *BRAF* as well as new targets, providing reasons for cautious optimism about the translational prospects for these results in the not too distant future.
No conflict of interest.

151 INVITED

Biomarkers in ependymoma

J. Grill[1], F. Andreiuolo[1], M.C. Le Deley[1], R. Grundy[2], J.P. Kilday[2], M.C. Maasimino[3], P. Modena[4], S. Pfister[5], H. Witt[5], T. Pietsch[6]. [1]*Institut Gustave Roussy, Pediatric and Adolescent Oncology, Villejuif, France;* [2]*Nottingham University, Pediatric and Adolescent Oncology, Nottingham, United Kingdom;* [3]*Istituto Tumori, Pediatric Oncology, Milano, Italy;* [4]*National Cancer Instiute, Centro di Riferimento, Aviano, Italy;* [5]*DKFZ, Molecular Genetics, Heidelberg, Germany;* [6]*Neuropathologie Referenz Centrum, Pathology, Bonn, Germany*

Ependymoma is the third most common malignant brain tumor in children. They exist also in aldults but spatial distribution, genomic alterations and gene expression profiles are different. Ependymomas consist in different categories of glial neoplasms with specific biological characteristics. Their behaviour is associated with clinical characteristics such as age and location. Recent microarray studies have been able to identify subclasses of ependymomas. These classifications are either based on chromosomal imbalances or gene expression profiling; none however has managed to integrate the complex genetic changes simultaneously. The grouping and the number of subclasses vary between studies and consensus has still to be reached before they can be implemented in routine. Conversely, only limited amount of data has been generated with respect to specific biological drivers in these tumors. Notch pathway, including some of its effectors such as tenascin-C or activators such as YAP1, has been shown to be altered by different studies and could be one of these. *EPHB2* has been associated with a given subclass of supratentorial ependymomas. Despite the limitation of our knowledge about ependymoma oncogenesis, several prognostic markers have been identified. A European endeavour, called BIOMECA, is underway to test and validate existing and new biomarkers within the framework of the new SIOPE ependymoma cooperative trial. Amongst these biomarkers, gain of 1q25 has been confirmed as a poor prognostic markers in large studies with homogeneously treated patients populations included in prospective trials. Tenascin-C expression on IHC appears to be as well a marker of poor prognosis, especially in young children. The assessment of these biomarkers need thereafter to be standardized with robust procedures that can be widely applied in Europe. More biomarkers are needed to describe properly the biological landscape of this tumor type in order to guide therapies and to develop targeted approaches.
No conflict of interest.

Scientific Symposium (Sun, 29 Sep, 15:00−17:00)
Technical and Biological Developments in Breast Radiotherapy

152 INVITED

Impact of radiotherapy on loco-regional control

I. Kunkler[1]. [1]*Western General Hospital, Clinical Oncology, Edinburgh, United Kingdom*

The Oxford overview established that postoperative radiotherapy (RT) improves loco-regional control and survival in early breast cancer both after mastectomy and breast conserving surgery (BCS). After BCS adjuvant RT roughly halves the risk of first recurrence. For patients at low risk of local recurrence, it is still uncertain whether there is a subset from whom RT may be safely omitted. Selection based on molecular subtype might provide a more reliable way of identifying benefit from RT. There is limited literature on such correlations. To date molecular classification cannot reliably differentiate those at higher or lower risk of local recurrence after RT. After mastectomy in the DBCG 82b and 82c trials (Kyndi et al, 2008) adjuvant RT significantly reduces LRR in luminal hormone receptor (HR) positive/HER2 negative tumours (3% RT+, 32% RT-), HR positive, HER2 positive (3% RT+, 48% RT-) and triple negative cancer (15% RT+, 32% RT-). No reduction in LRR was seen from PMRT in HER negative, HER2 positive patients, perhaps reflecting the impact of Trastuzumab on local control. Analysis of TRANS SUPREMO in the BIG 2−04 MRC/EORTC SUPREMO trial should provide prospective data on molecular subtypes and risk of LRR +/− RT. The role of axillary RT in patients with a positive sentinel node biopsy (SNB) remains controversial. Interpretation of the ACOSOG Z11 trial which showed no statistically significant difference in regional recurrence or DFS from axillary dissection vs no additional treatment is difficult due to the lack of adequate RT QA and failure to meet its target accrual. There is limited literature on the role of loco-regional radiotherapy in the context of neoadjuvant systemic therapy. Potentially the response to neoadjuvant chemotherapy measured at definitive surgery as residual tumour burden might individualise the need for locoregional therapy to the breast/chest wall and axilla (Smith, 2012). The role of axillary RT in this setting is under study in the recently launched NSABP-RTOG 9353 trial. The Alliance Cooperative Group trial is comparing axillary clearance and axillary RT in patients with residual nodal disease on SNB after neoadjuvant chemotherapy in T1−3, NI patients.
No conflict of interest.

153 INVITED

Image-guided radiation therapy

P. Poortmans[1], M. Essers[1], S. Osman[1], S. Hol[1]. [1]*Dr. Bernard Verbeeten Instituut, Radiotherapy, Tilburg, Netherlands*

Background: Radiation therapy (RT) has demonstrated clear clinical benefits for all patients treated with breast conserving therapy (BCT) and for patients with risk factors after radical mastectomy. However, part of this gain can be lost by non breast related mortality, especially due to increased late cardiovascular damage. Especially with locoregional RT, it can be difficult to avoid cardiac dose exposure. Therefore, efforts to reduce the dose to organs at risk are of high clinical relevance. One of these is reducing the margin from clinical to planning target volume (CTV-PTV), needed to compensate for set-up and movement uncertainty.
Material and Methods: We systematically investigated and compared the set-up accuracy, breath-hold stability and reproducibility of our image-guidance procedure for left-sided breast cancer patients treated with 3D-CRT in voluntary moderate deep inspiration breath hold (vmDIBH). Set-up data from 20 patients were used. Before each treatment fraction, patients

were positioned using skin tattoos. Subsequently, a set of anterior-posterior (AP) and left-right (LR) megavolt images were acquired in vmDIBH. Bony structures and soft tissues were matched followed by set-up corrections using shifts to the treatment couch. For verification purposes we made a set of images of the mediolateral (ML) and lateromedial (LM) tangential fields in vmDIBH just before delivery of each of the tangential fields. Breath-hold reproducibility during each treatment fraction was determined from the difference in the thorax-wall position between ML and LM fields delivery in each fraction. Finally, images of the ML and LM treatment fields were acquired in "cine acquisition mode". The difference between the maximum and minimum thorax-wall position within one field is used as an indication of the vmDIBH stability. Geometrical variability values were expressed in terms of group mean (μ), systematic (Σ), and random (σ) errors. Using a standard margin formula, we estimated the required CTV-PTV margin to account for geometrical uncertainties.
Results: The largest measured residual set-up errors (μ, Σ, σ) after on-line set-up correction were in the AP direction (μ = 1.8 mm, Σ = 1.4 mm, σ = 1.9 mm). The required margins to account for these errors were 4.1 mm and 3.3 mm in the AP and LR directions, respectively. The intra-beam thorax-wall position variability was 0.8 ± 0.5 mm. The breath-hold reproducibility (population averaged $\pm$ SD) was 0.3 ± 0.9 mm.
Conclusions: Using on-line daily setup correction, the measured residual setup uncertainties combined with the intra-beam thorax-wall position variability and the breath-hold reproducibility justifies a total CTV-PTV margin of 5 mm. In clinical practice, we now use daily on-line setup correction using AP and LR setup images, combined with a ML verification image once a week.
No conflict of interest.

154 INVITED
The long and short of radiation fractionation

J. Yarnold[1]. [1]*The Institute of Cancer Research, Section of Radiotherapy and Imaging, London, United Kingdom*

There is level I evidence that breast cancer is, on average, as sensitive to fraction size as the dose-limiting normal tissues, a conclusion based on 10-year follow up of 7,000 patients entered in randomised clinical trials. Subgroups based on patient age, breast size, tumour grade, receptor status, node status, surgery, lymphatic radiotherapy and systemic therapies can only be fully represented in overviews involving tens of thousands of patients, but the analyses conducted on current data sets are reassuring. Where the heart is concerned, there is no lower dose threshold for major cardiac events, so the priority is to protect the heart whatever fractionation is used. Whichever values of α/β are assumed to describe the fractionation sensitivity of brachial plexus, 40 Gy in 15 fractions delivers a dose intensity lower than 50 Gy in 25 fractions. Current 15-fraction schedules are standard of care for local-regional radiotherapy in the UK, but 15- or 16-fraction regimens are unlikely to represent the lower limit for whole or partial breast external beam radiotherapy. Based on first analysis of the UK FAST trial comparing two 5-fraction schedules of whole breast radiotherapy delivered over 5 weeks against 25-fractions of 2.0 Gy, the current UK phase 3 FAST Forward trial (n = 4000) tests two 5-fraction regimens of local-regional radiotherapy delivered in 1 week against a control regimen of 40 Gy in 15 fractions. Hypofractionation trials provide the evidence base for synchronous boost techniques delivered using intensity modulated radiotherapy, approaches that are also under evaluation in current randomised trials.
No conflict of interest.

155 INVITED
Intra-operative radiotherapy A (ELIOT)

R. Orecchia[1]. [1]*Istituto Europeo di Oncologia, Dept. of Radiotherapy, Milan, Italy*

Electron Intra Operative Radiation Therapy (ELIOT) has been extensively tested in Milan since 1999. After a pilot trial, a randomized study has been carried out from 2000 to 2007. Aims of the study was to compare patients submitted to a 21 Gy single-fraction treatment targeted at the tumour bed only, given at the time of the quadrantectomy, versus standard post-operative WBI after the same BCS. Eligible patients were women with early invasive ductal or lobular breast cancer with a maximum diameter up to 25 mm if they were aged between 48 and 75 years old and suitable for BCS. The study protocol was approved by the institutional ethical committee and a written informed consent was obtained from eligible patients. The primary endpoint was the incidence of local relapse, including ipsilateral breast cancer. Secondary endpoints included overall survival, incidence of axillary or distant metastasis, contralateral breast cancer, and other primary cancers. A total of 1305 breast cancer patients were randomized before surgery in the study (654 in the WBI arm and 651 in the ELIOT arm). Due to ineligibility, 119 patients were excluded and a total of 1186 patients were available for analysis (601 and 585 in the 2 arms). The analysis is based on effective treatment received and not an intention-to-treat. The two treatment groups were perfectly comparable at baseline. All the events are reported at the 5-year follow-up. An excess of "true local relapses" (WBI = 5/ELIOT = 23), "ipsilateral breast cancer" (0/14, respectively) and "axillary/regional lymphonode metastases" (2/9, respectively) in the ELIOT group were observed. An excess of controlateral breast cancer, but without significant statistical difference, was observed in the conventional arm, 1.7% versus 0.8%. If we consider the cumulative incidence of new cancers not related to the recurrence in index quadrant (ipsilateral and contralateral second cancer) we observed a rate of 1.7 in the WBI arm, and 2.9 in the ELIOT arm. We found a low rate of local relapse in women with small tumor ($\leqslant$1 cm), grade 1 tumor and luminal A tumor. Among 200 patients with small ($\leqslant$1 cm) luminal A breast cancer we observed only one local relapse in the WBI group versus 2 in the ELIOT group (log-rank p = 0.55). Among 986 patients with either large (>1 cm) or non luminal A breast cancer we observed 4 local relapses in the WBI group versus 35 in the ELIOT group (log-rank p < 0.0001). In order to assess some subgroups of patients to be selected for ELIOT treatment without statistical differences with the conventional arm, we stratified the patients according to the ASTRO criteria. We had 129 patients in the "suitable" group, 270 in the "cautionary", and 184 in the "unsuitable" group. In the low risk group no statistical differences have been observed between the two arms. No differences were observed in death rate and overall survival. The actuarial 10-year overall survival rates were 92.0 and 89.8, respectively (P = 0.69). This study contributes to identify properly selected patients for PBI.
No conflict of interest.

156 INVITED
Intra-operative radiotherapy B (TARGIT)

Abstract not received.

Scientific Symposium (Sun, 29 Sep, 14:45−16:45)
Joint ECCO/ASCO Session − Improvements and Outcomes in Breast Cancer Care

157 INVITED
EUSOMA

R. Audisio[1], L. Marotti[2], A. Ponti[3]. [1]*St. Helens Hospital, University of Liverpool, Prescot, United Kingdom;* [2]*EUSOMA, Florence, Italy;* [3]*EUSOMA, Turin, Italy*

EUSOMA, The European Society of Breast Cancer Specialists, is a multidisciplinary society of experts dedicated to breast cancer care.
The Society aims to promote scientific research and increase contacts between scientists and health professionals interested in the management of breast cancer. Eventually, the final target is to harmonise, at the highest achievable level, the quality of breast cancer diagnosis and treatment across the EU, interacting with the appropriate local, national and international authorities as well as fostering training programs for young health professionals.
To achieve these goals EUSOMA publishes peer-reviewed recommendations on the different aspect in breast cancer care and promotes voluntary certification of specialist breast units.
The First European Breast Cancer Conference (EBCC) demanded that all women in the EU have access to fully equipped, multi-professional breast services, and that a quality assurance program has to became mandatory; EUSOMA published a position paper on "The requirements of a specialist breast unit" which has been widely accepted and recognised as a benchmark to set up dedicated breast teams.
The requirements underlying the set up of breast units are summarised as a) being a single integrated unit, b) dealing with a sufficient number of cases such to allow effective working and continuing expertise/care by c) dedicated breast specialists in all the required disciplines working within a multidisciplinary approach, providing care and support throughout the patient's journey, from early diagnosis, local and adjuvant treatment and patient support, to the management of advanced disease and palliative care, data collection and audit.
With regard to Quality Control EUSOMA published a paper identifying quality indicators (QIs) in breast cancer care from diagnosis to local and adjuvant treatment and follow up.
To monitor the breast units' performance with respect to the QIs, EUSOMA has developed a database, i.e. a central data warehouse of prospectively collected information which includes individual records of primary breast cancer cases diagnosed and treated by those certified European breast units which have provided data according to the society requirements.

The database is accessible on the web to all registered users; started in 2006 it includes about 65.000 cases, entered by the nearly 50 breast units from 7 European countries. It collects 108 variables for each individual patient, including patient and tumour characteristics, information on preoperative workup, multidisciplinary management and follow-up data. The web system offers analysis functions, including the calculation of the 20 EUSOMA QIs. Besides quality assurance and certification, the EUSOMA database is used for audit and research. All breast units contributing information into the EUSOMA data base convene yearly in a meeting which is finalised to improve the completeness and quality of the data and to discuss research proposals.
No conflict of interest.

158 INVITED

EURECCA Breast: European Breast Audit

G. Liefers[1], On behalf of the EURECCA Breast group. [1]*Leiden University Medical Centrum, Surgery, Leiden, Netherlands*

Comparing patterns of care for breast cancer internationally: an overview and future perspectives for EURECCA − EUropean REgistration of Cancer CAre.
In the past few years, several observational studies have been published addressing variations in patterns of care for breast cancer between countries. Studying several different patient populations; all researchers came to the same conclusion: despite national and international treatment guidelines, wide variations in patterns of care are observed between different European countries, but also on a global scale. However, the few studies that analyzed patient outcome in relation to different treatment approaches did not show an effect of different patterns of care on survival of breast cancer patients, in particular among the elderly. Consequently, it is questionable if different patterns of care have a major impact on breast cancer specific outcomes, and probably in the future we can add other, patient specific, outcome measures to survival or breast cancer specific outcomes. The aim of the EURECCA Breast project is to audit breast cancer care in Europe, to define best practice for breast cancer patients using large observational studies.
In this presentation, the first analyses of the EURECCA-breast group will be shared. For this purpose we collected already existing retrospective data from several European countries to assess differences in patterns of care, impact on survival, differences in quality of databases and gaps in the existing data.
No conflict of interest.

159 INVITED

ASCO's CancerLinQ and breast cancer outcomes

A.P. Abernethy[1]. [1]*Duke University Medical Center Center for Lear, Durham, USA*

The proliferation of scientific results and novel treatments is a growing challenge for oncology professionals as we enter the era of highly personalized cancer care. Patients are increasingly presenting cancers narrowly defined by molecular characteristics, often making the best course of treatment unclear. Oncologists need real-time decision support to help them provide the most effective treatments tailored to a patients' unique biology and tumors. Further, we need data systems that capture adequate information to monitor clinical impact, providing summaries of the relationship between treatments and outcomes including treatment response, toxicity, survival and quality of life. Big data, bioinformatics, clinical informatics, electronic health records, patient reported outcomes, data warehouses, machine learning, mobile health solutions, and precision analytics are health information technology tools that support personalized cancer care through discovery and healthcare optimization; leveraged thoughtfully, they are also fundamental tools for clinical decision support at the point of care. When data are interoperable and can flow across these systems, then they become available in real-time in support of the clinical task; data can be banked and reused to support discovery of personalized interventions, monitoring of quality of personalized care provided, and comparative effectiveness research. Thus, a (rapid) learning health system evolves − where clinical care and research are better approximated through data and information flow. This is the vision of ASCO's CancerLinQ™ − a knowledge-generating computer network that will unlock and analyze cancer care data from every possible source and feed up-to-the-minute conclusions and guidance back to physicians and patients, ultimately generating a learning health system for cancer. CancerLinQ incorporates a growing number of open-source applications; features include real-time data collection from electronic health records and other sources; clinical decision support; and data mining and visualization. A breast cancer-specific prototype has been developed linking information about clinical care, analytics to determine outcomes, and real-time decision support.
No conflict of interest.

160 INVITED

CancerLinQ: A practitioner's perspective

C. Penley[1]. [1]*Tennessee Oncology Centennial Medical Center, Nashville TN, USA*

CancerLinQ: A Community Oncology Perspective.
In late summer 2012, the American Society of Clinical Oncology (ASCO) announced the development of a prototype of a rapid learning system for oncology called CancerLinQ. The project proposed to assimilate and aggregate de-identified breast cancer data regarding patients receiving care in multiple settings, with the intent of analyzing the data and learning from it, and ultimately improving the quality of care delivered. Many practices were invited to participate in the development of the prototype. The prototype set out to accomplish 5 key goals:
1. Identify technology and other challenges to building they system
2. Demonstrate ability to aggregate data from any source in any format and make it available for multiple reporting systems
3. Demonstrate ability to provide real time quality measurement and reporting
4. Demonstrate ability to provide real time Clinical Decision Support
5. Demonstrate a willingness for oncologists to share data for quality improvement purposes.

Tennessee Oncology (TO) is a large community oncology practice located in middle and eastern Tennessee, in the Southeastern United States. TO is composed of fifty five hematologists and oncologists who work in multiple communities in this region. TO has a robust internal quality improvement program, and participates in (and is certified by) ASCO's Quality Oncology Practice Initiative (QOPI). The practice has an internal information technology department, and uses a commercially available electronic health record. When invited to participate in the development of the CancerLinQ prototype, TO leadership readily accepted.
In collaboration with information technology staff at ASCO, an automated data query was developed and tested. Ultimately, TO contributed de-identified data regarding more than 12,000 individual breast cancer patients. The speaker will discuss the importance of CancerLinQ from the perspective of a community oncologist, and will describe the logistics of participation.

Scientific Symposium (Sun, 29 Sep, 14:45−16:45)
New Challenges in Metastatic Renal Cancer Cells: Identifying What is Worth Pursuing

161 INVITED

Identifying biomarkers in RCC

T. Eisen[1]. [1]*Addenbrooke's Hospital, Cambridge, United Kingdom*

At the time of writing, the only validated prognostic biomarkers are simple clinical measures such as performance status, LDH, calcium level, neutrophil level and so forth.
Anti-angiogenic treatments work at least temporarily in the majority of patients with clear-cell renal cell carcinoma. Even today, we have relatively few data relating to non-clear cell carcinoma efficacy, let alone biomarkers in that setting. Attempts to predict the impact of tyrosine kinase inhibitors have been made using imaging techniques, including DC-MRI and Doppler ultrasound, and genetic biomarkers usually using a candidate approach of VEGF or VEGF receptor SNPs. Similarly, mutations in pTEN and other pI3K signalling pathway molecules have been investigated to try to select for mTOR benefit. None of these are ready for routine practice. More recently, pharmacokinetic approaches looking at drug level concentrations have shown significant promise. Unfortunately PK approaches are relatively unattractive to drug companies who fear that it will complicate the treatment paradigm and make their product less attractive.
T-cell checkpoint modulators have well-defined mechanisms of action, which can be probed to search for predictive biomarkers. Interestingly, one such biomarker, the expression of PDL1, appears to be both a poor prognostic factor and a positive predictive factor. These observations are based on small scale data and must be viewed with considerable caution at present.
What biomarkers might be useful in the more distant future? Renal cell cancer is a tumour type where a successful adjuvant therapy could have a major role to play, given the epidemiology of the disease. Unfortunately, adjuvant trials take an extremely long time to conduct, limiting the rate of progress and the interest in this form of therapy. A biomarker which could act as a molecular surrogate of progressive disease might accelerate progress in these trials significantly. I will mention ctDNA work we are

conducting in Cambridge and our plans to incorporate this work in adjuvant therapy designs.
No conflict of interest.

162 INVITED
Immune therapy in renal cancer: Not such an ugly duckling?

P. Mulders[1]. [1]*Radboud University Medical Centre Nijmegen, Department of Urology, Nijmegen, Netherlands*

Kidney cancer is a disease that can be cured by only surgery. When metastasized the prognosis is poor. The introduction of new targetted has improved survival with a medium duration of 2 years. However with these new agents cure can not be obtained, and toxicities are class specific and considerable. Improvements have also be obtained with a better selection of patients. The improvements were already obtained during the immunotherapy era, with increased knowlegde of prognostic factors. Also the tendency towards more specific immunotherpy has gained its effect with less toxicities. Especially in the time that many new agents are introduced there is an interest in agents that can cure metastatic renal cell carcinoma with less toxicity. The challenge is in the best timing an sequence of agents, including immunotherapeutic approached. These items will be discussed.
No conflict of interest.

163 INVITED
The mechanism of resistance to targeted therapy

T. Powles[1]. [1]*Barts Cancer Institute, London Cancer, London, United Kingdom*

The introduction of VEFG targeted therapy and mTOR inhibitors have significantly improved the outcomes of patients with metastatic clear cell renal cancer (mRCC). Unfortunately resistance develops, limiting the use of these agents to finite periods of time. This onset of this resistance is unpredictable for both classes of agents. There is molecular and functional imaging data to suggest dynamic changes occur with therapy, which may part explain the difficulies is unlocking the key to resistance in mRCC.
The majority of research in this area has been with the VEGF targeted therapies, such as sunitinib. A small proportion of patients obtain no clinical benefit with these agents, which is known as inherent resistance. The molecular mechanism associated with inherent resistance is inconclusive. The remaining patients initially achieve clinical benefit with sunitinib, followed by treatment failure after approximately 1 year. The molecular mechanism underlying this acquired resistance is also unknown, but is likely to be multifactorial. While it is apparent that adequate VEGF targeting is important in maintaining response, VEGF independent factors such as FGF-2 or MET may also contribute to treatment failure. Further research in this area is required. The mechanisms of resistance to mTOR inhibitors are even less explored. Mutation to the PI3K pathway is under investigation, but results are awaited.
There are a number of logistic and scientific factors hampering progress in this area. These include a lack of adequately collected tissue and a scarcity of sequential tissue, which may be required to indentify the mechanisms of acquired resistance. Other factors such as tumor heterogeneity increase the complexity of this field further. Overall the current data is only able to speculate rather than map out clear pathways of resistance and further work is required.

164 INVITED
The role of novel and established imaging modalities in predicting outcomes in clear cell renal cancer

L.S. Fournier[1], S. Oudard[2], C.A. Cuénod[1]. [1]*Université Paris-Descartes INSERM, Radiology, Paris, France;* [2]*Université Paris-Descartes INSERM, Oncology, Paris, France*

Oncologists need fast and reliable tools for evaluating efficacy when treating a patient. New challenges for imaging treatment response are emerging as patients with renal cell carcinoma (RCC) receive targeted therapies stabilizing rather than curing them, or repeated focal therapies inducing changes in lesion morphology but not size.
Current imaging methods of response assessment in RCC will be reviewed, with focus on the prediction of patient outcome, for which no biomarker has been validated to date.
Morphological methods can be based solely on size such as RECIST (Response Evaluation Criteria In Solid Tumours), which is the most often used by convention, though never validated in this setting. Other size-based criteria have been proposed, using a new threshold for response set at −10%, chosen based on prediction of outcome. Other criteria use both size and attenuation to evaluate treatment efficacy, such as Choi, modified Choi [4], SACT (size and attenuation CT), and MASS (morphology, attenuation, size and structure). Contradictory results have been obtained using these, and it remains to be determined in which setting they could be of use.
The potential to predict outcome of functional imaging techniques will also be discussed, focusing on evidence obtained to date. Dynamic contrast-enhanced (DCE) techniques, whether using CT, MRI or ultrasound, are very promising, since they quantify tumor microvessels, and seem the most logical to detect the effect of anti-angiogenic therapies. The level of evidence for each of these will be reviewed, as well as the advantages and disadvantages of each technique. Finally, new radiotracer approaches for positron emission tomography will be reviewed, including (18)F-fluoromisonidazole quantifying hypoxia, and the future potential for the new (124)I-girentuximab antibody which seems specific for clear cell renal carcinoma.

Scientific Symposium (Sun, 29 Sep, 14:45−16:45) **Exploiting Defective DNA Damage Response Pathways in Tumours**

165 INVITED
Combining radiation therapy with DNA damage response inhibitors

A.J. Chalmers[1], R. Carruthers[1], S. Ahmed[1]. [1]*University of Glasgow, Institute of Cancer Sciences, Glasgow, United Kingdom*

In the context of radical radiotherapy treatments, radiosensitive normal tissues adjacent to tumours frequently prevent the delivery of a curative dose. Attempts to increase tumour responses by combining radiation with sensitising agents have generally been thwarted by similar sensitising effects upon normal tissues. To improve clinical outcomes, radiosensitisers must be tumour specific.
Radiation kills tumour cells primarily by damaging DNA. Many of the proteins and pathways that protect cells by recognising, signalling and repairing this damage have been characterised, and this knowledge has revealed potential targets for radiosensitising drugs. Furthermore, inherent differences between the DNA damage responses of tumour cells and non-malignant cells raise the exciting prospect of achieving tumour-specific potentiation of radiation therapy by pharmacological inhibition of key DNA damage response proteins.
Poly(ADP-ribose) polymerase (PARP) is a DNA damage sensing protein that plays an important role in the base excision repair (BER) pathway. Highly potent and specific inhibitors of PARP have been developed, and early clinical trials have shown that these agents are extremely well tolerated. PARP inhibitors exert modest radiosensitising effects in cellular systems but show therapeutic potential because these effect are observed only in cells that are actively dividing. Most tumours treated by radiation exhibit rapid cellular proliferation rates, in contrast to a number of critical normal tissues such as brain and spinal cord. Hence PARP inhibitors may act as tumour specific radiosensitisers in selected cancer types, and a number of clinical trials are now underway with the aim of verifying this hypothesis.
Cell cycle checkpoints are frequently defective in cancer, with the majority of malignant cells failing to activate the G1-S checkpoint in response to DNA damage. In simple terms, this increases the relative importance of intra-S and G2-M checkpoint responses in protecting malignant cells from the cytotoxic effects of DNA damaging agents such as ionising radiation. Chk1 plays a key role in mediating these protective responses, and pre-clinical studies have shown that inhibition of Chk1 has enormous potential as a tumour-specific route to radiosensitisation.
Other DNA damage response proteins have been investigated as potential targets and it is likely that a range of novel radiosensitising drugs will enter the clinic in the near future. Patient selection and clinical trial design will be key to realising the potential benefits of this exciting approach. By minimising radiation doses to normal tissues, it is hoped that intensity modulated and image guided radiotherapy techniques will facilitate the use of safe and effective radiation/drug combinations in the treatment of cancer patients.

166 INVITED
New DNA repair targets in cancer treatment

T. Helleday[1]. [1]*Karolinska Institutet, Department of Medical Biochemistry and Biophysics, Stockholm, Sweden*

Mutations in DNA repair are sometimes found in cancer, such as mutations in mismatch repair or *BRCA1* or *BRCA2* genes. We previously

demonstrated that PARP inhibitors can selectively kill BRCA2 defective tumours through synthetic lethality.
Here, I describe efforts into translating the synthetic lethal approach into treatment of cancer in the clinic and the challenges. The overall conclusion is that the synthetic lethal approach offers significant advantages, but no real cancer cures and suffer from similar resistance problems as many other targeted therapies.
The earliest anti-cancer treatments identified, ionzing radiation, nitrogen mustard analogues and nucleosides, all share a common mechanism of action, i.e., causing DNA damage to kill cancer cells. Such DNA damaging treatments sometimes offers complete cancer cures, which are rarely seen by more modern anti-cancer treatments that do not cause DNA damage.
Here, I exemplify how DNA repair inhibitors to a novel DNA repair target, MTH1, can be used in a different context, to overload the high level of DNA damage that is present in cancer. This treatment leads to increased overall DNA damage load in cancer and has a potential to be superior to targeting the cancer genotype. This strategy may offer a treatment for a broad spectrum of cancers, regardless of cancer genotype. This exemplifies a novel concept for targeting the cancer phenotype.
No conflict of interest.

167 INVITED

Targeting oncogene-induced replicative stress for cancer therapy

Ó. Fernández-Capetillo[1]. [1]*Spanish National Cancer Research Centre (CNIO), Genomic Instability Group, Madrid, Spain*

Our laboratory has focused much of its research in trying to understand how cells respond to “replicative stress” (RS), a type of DNA damage which arises unavoidably every time that a cell replicates its DNA, and which is mainly prevented by a RS-Response (RSR) coordinated by ATR and Chk1 kinases.
Given that certain oncogenes can generate substantial amounts of RS, we hypothesized that cells carrying these oncogenes might be “addicted” to a proficient RSR. To explore these ideas, we have generated several cellular, animal and chemical tools for the study of ATR function in mammals. These incluce (1) a cell system in which ATR can be selectively activated at will; (2) mice with a reduced or increased RSR, and (3) chemical inhibitors of ATR. Our early works suggested that ATR inhibitors would indeed be particularly deleterious for tumors with high levels of RS, such as those induced by the Myc oncogene. Our ideas and new results in this area will be presented.
No conflict of interest.

168 INVITED

High throughput screening for genetic determinants of radiosensitivity

W.G. McKenna[1], G.S. Tiwana[1], R. Prevo[1], B. Budwal[1], D. Ebner[2], A. Howarth[2], K.Y. Chu[1], L. Durrant[1], G.S. Higgins[1]. [1]*University of Oxford, Gray Institute for Radiation Oncology and Biology, Oxford, United Kingdom;* [2]*University of Oxford, Target Discovery Institute, Oxford, United Kingdom*

The therapeutic window of radiotherapy could be improved if tumour cells could be selectively rendered more sensitive to radiation. Such a strategy depends upon exploiting tumour specific targets, many of which remain to be identified.
The colony forming assay (CFA) is the ‘gold standard’ method for assessing intrinsic radiosensitivity *in vitro*. We have developed a technique to perform high-throughput CFAs in 96 well plates and have recently completed a siRNA screen of approximately 10,000 genes, of which the 793 gene ‘kinase’ section of the library has been examined in detail.
HeLa cells were reverse transfected with 20nM siRNA (Dharmacon ONTARGET*plus*) in 96 well plates. Seventy-two hours post-transfection, cells were lifted and plated into two sets of quadruplicate repeats. One set of repeats was irradiated at 7 Gy using 6MV photons on a Varian Linear Accelerator, and the other set left unirradiated. Plates were incubated for 7−9 days, stained with crystal violet, and the number of colonies counted. For each gene the fraction of cells that survived 7 Gy irradiation was normalised to the survival of non-targeting (NT) siRNA transfected wells on the corresponding plate. A Z-score was calculated using the median of NT wells across all plates.
The kinase screen was performed on two separate occasions and a ranked-product analysis used to identify the top hits from both runs. On the basis of the top candidate genes identified by the primary kinase screen, an 80 gene siRNA library was produced. This secondary library was then screened on three occasions.
This work identified several genes such as ATM, ATR, DNA-PK and CHEK1, which are known to play key roles in tumour cell radiosensitivity. In addition, we identified a number of novel genes whose depletion induced HeLa radiosensitisation in 6-well plate CFAs. These experiments were repeated with separate siRNA (Ambion) to ensure these findings were not the result of off-target effects. Depletion of these genes appeared to cause radiosensitisation in several other tumour cell lines as well.
We are currently investigating the effects of several of these genes in greater detail. Ongoing work will clarify the effects of gene knockdown on radio- and chemosensitivity in several tumour and normal tissue lines. The mechanism by which this knockdown causes these effects is also being examined.
No conflict of interest.

Scientific Symposium (Sun, 29 Sep, 14:45−16:45)
Outcome Measures in Clinical Trial Design?

169 INVITED

What defines a validated biological biomarker? A pharmacodynamics measurement or a patient-reported or -related outcome?

J. Verweij[1]. [1]*Erasmus University Medical Center, Department of Medical Oncology, Rotterdam, Netherlands*

The development of novel agents for cancer is heavily dependent on so-called biomarkers. There are many definitions of biomarkers, but in essence they describe a biological effect that reflects the effect of an agent on the human body. The ultimate biomarker in cancer is survival. However, in the favored scenario this is a long-term outcome marker, and particularly in the early stages of drug development cannot rely on long-term outcome measures since it would take too long to the next step of development. Therefor in early clinical trials other markers are used to describe short-term outcomes. Only a few of those can be considered as evidence-based as far as the intention to appropriately reflect longer-term outcomes.
The validation mentioned in the title points to the need to provide evidence as best as we can, of the relationship between the early effect marker and survival, in order to be able to adequately rely on the marker in essential decisions to continue or discontinue drug development in early stages.
Extensive clinical research has provided relevant data on the use of biomarkers such as progression free survival, and on anatomical size change (for instance assessed by RECIST) to reflect a drug effect on tumors. All of these have been tested in large data sets, and can be used in a uniform way all over the world. The more recently used markers reflecting several parameters of pharmacokinetic and/or pharmacodynamic effects are frequently based on well-considered assumptions rather than on evidence of outcome. A nice example is the use of molecular imaging. This is certainly a potential future way forward to assess drug effect and try to predict long-term outcome, but the examples of false-positives are many. A more detailed overview will be provided.
Another way of trying to assess drug effects is to use patient reported outcomes. To some extent safety issues but also Quality of LIfe assessment can be considered as such. While safety has been helpful in identifying doses for further studies or halting drug development in specific cases, these outcomes have not been able to predict more long-term outcomes and a successful further drug development.The challenge we are facing is to limit failures in use of biomarkers while, at the same time, identifying and applying meaningful markers of effect in early stages of development. Recommendations for early clinical trials will be discussed.
No conflict of interest.

170 INVITED

What is the best measure for patient benefit?

E. Eisenhauer[1]. [1]*Queen’s University, Kingston ON, Canada*

Results from well conducted clinical trials form the evidence base for the practice of cancer medicine. As interventions from trials are moved into practice it is important to consider whether the endpoints of trials measure those outcomes that are important to patients in their decisions about treatment. Research into patient choices of treatment and the information needed to make decisions may provide guidance to investigators on the selection of appropriate endpoints for clinical trials.
In a curative or adjuvant setting, patient preference studies evaluate benefit in terms of overall survival (OS) or probability of cure. Very small gains may be acceptable to patients even when treatment leads to substantial toxicity. Thus the appropriate endpoints for curative intent trials are OS or valid surrogates for OS such as disease free or relapse free survival.
In the non-curative setting, studies of patient preferences have considered information on increments in OS, toxicity, symptom benefit (SB) and/or quality of life (QoL). These studies presume that quality and/or quantity of life are the most relevant endpoints for patients in decision making. However, the last few years have seen an increase in the number of randomized controlled trials (RCTs) of new agents in metastatic solid

tumors that utilize progression free survival (PFS) or rates of non-progression (so-called “clinical benefit rates”) as primary efficacy endpoints. Some trials showing an improvement in PFS, without any corresponding OS increase, have led to approval of new drugs and/or changes in standard of care. The justification of investigators for the choice of PFS as a primary endpoint is varied and has included arguments such as: a) Progression is observed earlier than OS, b) PFS may be a valid surrogate for OS, c) Post-progression therapy may obscure OS gains rendering OS an unreliable measure of treatment effect, and, of particular importance to this presentation, d) that delays in progression are meaningful since they are likely associated with QoL improvement or SB. This assignment of meaning to PFS in terms of its surrogacy for improved SB or QoL is concerning since the definitions of progression used in clinical trials are arbitrary and were created with the intent to guide decisions about biological activity of new drugs in early trials, rather than policy decisions on patient care in metastatic disease. There is little research on whether patients understand the meaning of improved PFS, whether it is associated with SB or QoL improvement, and whether PFS improvement *without* SB or OS prolongation would be viewed as beneficial by patients. Thus research on the SB of PFS gains in a variety of tumour types, as well as patient views on the value of this endpoint is needed.
No conflict of interest.

171 INVITED
Technical pitfalls of measuring biological biomarkers

Abstract not received.

172 INVITED
Impact of biomarkers on the value of crossover designs in cancer clinical trials

J. Doroshow[1]. [1]*National Cancer Institute, Division of cancer treatment and diagnosis, Bethesda, USA*

The application of a crossover design in randomized cancer clinical trials has frequently been deplored because of the potentially confounding impact of the crossover treatment on the value of overall survival as a primary study endpoint. However, the use of overall survival as the primary endpoint in the era of molecularly targeted cancer therapeutic agents has become increasingly less attractive for patient populations that may be selected for an individual therapy based on the presence in tumor of well-defined biochemical characteristics. Since the effectiveness of targeted agents, as opposed to traditional cytotoxic drugs, may be equivalent in the first- or second line-therapy setting, ethical as well as scientific considerations for the use of such agents may mandate crossover designs to facilitate accrual or to answer specific molecular questions regarding the efficacy of the treatment in predefined patient populations. In studies where drug selection is driven by the presence in the tumor of a particular mutational spectrum, treatment may be specified for not one but a series of therapeutic agents administered in sequence. Progression-free survival would then be measured after each “crossover” at the time of progression; in this case prior therapies may be expected to have only a modest impact on the utility of the each subsequent agent that has been “matched” to the target based on a different molecular characteristic. Furthermore, if the efficacy of the drug in the particular molecular setting is of sufficient magnitude (whether it involves disease stabilization or an objective response), use of a PFS endpoint will be a sufficient measure of efficacy to move the agent toward regulatory approval whether or not a crossover design is employed. As competence in matching specific therapies to selected patient populations improves, the utility of non-survival trial endpoints will steadily be refined, alleviating concerns about crossover designs that were more pertinent in the era of non-specific cytotoxic treatments.

175 INVITED
Minimal metastatic pancreatic cancer: Is it a surgical disease? The value of synchronous resection

T. Hackert[1], M. Büchler[1]. [1]*University of Heidelberg, Abteilung fur Allgemeine Vizerale und Unfallchirurgie, Heidelberg, Germany*

Pancreatic cancer (PDAC) as the fourth leading cause of cancer-related mortality in the Western countries is found to be irresectable by the time of diagnosis in app. 80−85% of all patients due to locally advanced tumors or metastatic disease. Although improved surgical techniques and neoadjuvant treatment have pushed the borders of resectability in locally advanced tumors during the last decade, there is little evidence on the value of surgical therapy in metastastic disease. The largest series available in the literature report on 22 and 29 PDAC patients that underwent metastases resection either syn- or metachronously. Localization of the metastases (liver, peritoneum, interaortocaval lymph nodes) does not seem to have on influence on surgical morbidity and mortality, in both studies these parameters were similar to standard PDAC resections. Regarding oncological outcome, results show one-year survival rates of 40−60% with median survival times between 8 and 27 months. This seems to be superior in patients with lymph node metastases when compared to outcome in peritoneal or liver metastases resection. However, still liver resection of solitary metastases seems to be beneficial for the patients compared to palliative treatment as median survival can be prolonged from 6 to 12 months in this situation. A metaanalysis published in 2008 with an overall number of 103 patients included the above mentioned studies as well as other publications − mainly case reports and small case series - and led to the conclusion that no general recommendation can be given on the basis of the existing data. As the level of evidence has not substantially increased in the meantime, synchronous resection of minimally metastatic disease in PDAC cannot be recommended as an evidence-based approach. It should be attempted in the setting of accidental intraoperative finding of a solitary metastatic lesion, that can be resected without increasing morbidity. In the metachronous setting, indication for a resection is a highly individual decision for selected patients. However, both approaches may provide benefit for the patient and prolong survival, although adequately powered studies on this topic are still lacking.
No conflict of interest.

176 INVITED
Is local control an issue?

K. Haustermans[1]. [1]*Radiation Oncology University Hospitals Leuven, Department of Oncology KU Leuven, Leuven, Belgium*

Pancreatic ductal adenocarcinoma is one of the most aggressive cancers, and complete surgical resection is a requirement for a potential cure. However, only approximately 20 % of the patients are operable at the time of diagnosis. The majority of patients are diagnosed with advanced-stage disease, either metastatic (50%) or locally advanced (30%) cancer. Although palliative chemotherapy is the standard of care for patients with metastatic disease, management of locally advanced or minimal metastatic adenocarcinoma is more controversial. Several treatment options, including extended surgical resection, preoperative chemoradiation with subsequent resection, as well as palliative radiotherapy should be considered. Techniques of stereotactic body radiotherapy (SBRT) with movement compensation strategies have shown low rates of adverse effects with good local control in patients with locally advanced pancreatic cancer. However, there is little evidence available to support treatment options. As valid predictive biomarkers for stratification of therapy are not available today, future trials need to define the role of the different treatment options. Also, more effective systemic agents are needed to maximize radiation sensitisation and to treat upfront microscopic extra-pancreatic disease.
No conflict of interest.

Society Session (Sun, 29 Sep, 14:45−16:45) **European Society of Gynaecological Oncology (ESGO)**

177 INVITED
Role of centralisation in outcome of gynecological cancer treatment and organisation of cancer services

N. Reed[1]. [1]*Beatson West of Scotland Cancer Centre, Glasgow Scotland, United Kingdom*

The management of cancers has seen a very significant change in the course of the past 20 years. Arguably one of the most important

developments of the past 20 years has been the development of multidisciplinary management of cancers and the establishment of tumour boards or multidisciplinary team meetings (MDTs) as the standard of care. Previously tumour boards tended to be selectively deployed in some of the specialist cancer centres but these have been rolled out and are now in many countries deployed for the management of all cancers. This overcomes the problems of clinicians working in isolation or maverick clinicians not working to nationally accepted standards of care.
The development of National guidelines by Ministries of Health, professional bodies and scientific societies and organisations has complemented this approach to care. In Gynaecological cancers, cervix and vulval cancers have tended to be managed centrally but for endometrial and ovarian cancers there has been slower adoption of centralised surgical care. radiotherapy services have traditionally been centralised. The delivery of chemotherapy has been more flexible and maybe provided by medical, clinical or gynaecological oncologists according to local prctices. There has been increasing confirmation from a variety of tumour types to show that the use of multidisciplinary meetings improves the quality of care. This includes the involvement of specialist imaging experts who will review the images prior to decisions being made on surgery, the use of specialist histopathologists who reduce the likelihood of misdiagnosis and of course the opportunity for specialist gynaecological surgeons and radiation and medical oncologists to discuss the optimal treatment for each individual case.
There is increasing evidence that the issues of sub-specialisation and greater experience will improve outcome. Evidence to show that the use of tumour boards/NDTs has actually improved outcome is quite difficult but in Scotland (UK) the setting up of managed clinical networks, a vital component of which was the establishment of tumour boards, has indeed shown increased survival and outcome. Part of this may be due to improved staging and accuracy which may lead to an element of stage migration. Nevertheless it does mean that patients have a better chance of being offered the right care. Good examples of this are illustrated in the management of ovarian cancer where the use of the risk of malignancy index and the tumour board discussion will ensure that the patient gets the optimal surgical approach. Patients can now be selected for referral to the specialist gynae-oncology units to undergo more aggressive surgery which has a greater chance of leading to optimal (maximal) debulking. Patients and their families should now feel more confident that their case is being managed in the optimal way. For rare and uncommon cancers there is a stronger feeling that centralised care together with shared management with local clinicians offers a practical way of managing rarer cancers.
No conflict of interest.

178 INVITED

Lifestyle risk factors and prevention of gynaecological cancer

A.J. Nordin[1]. [1]*Queen Elizabeth The Queen Mother Hospital, East Kent Gynaecological Oncology Centre, Margate Kent, United Kingdom*

Whilst we continue to progress the diagnosis & treatment of gynaecological malignancies, there is far greater potential for reducing the mortality through of cancer prevention strategies. Interventions such as screening & vaccination programmes are making a substantial impact, but we have largely ignored the potential for lifestyle modification to lower the risk of gynaecological cancers.
Obesity now contributes as greatly as smoking to cancer-related deaths worldwide. It is estimated that 36,000 cancer cases could be prevented annually by halving the rate of obesity & overweight people in Europe. The risk of endometrial cancer (OR 4.5−6.2), ovarian cancer (OR 1.4), post-menopausal breast cancer (OR 1.3) & adenocarcinoma of the cervix (OR 2.1) are increased with obesity. Most classifications indicate a BMI >25 as overweight, >30 as obesity, and >40 as morbid obesity. In the UKGOSOC audit of 2948 consecutive gynae oncology surgeries, 38% of women had BMI >30 and 9% had BMI >40. The obesity pandemic is responsible for an increasing incidence of endometrial cancer in the developed world. In the UK, the incidence of endometrial cancer has risen from 13.8/100,000 women in 1997 to 19.3 in 2010.
Endometrial cancer risk relates to adult obesity & perimenopausal weight gain, and weight reduction may decrease the risk. Additionally, physical activity protects against ovarian, endometrial and postmenopausal breast cancer, independent of BMI. Diets featuring fruit, vegetables & antioxidants reduce risk whereas high animal fat & energy intakes increase risk. A high glycaemic load diet increases ovarian cancer risk, independent of BMI.
Alcohol intake increases the risk of breast cancer (accounting for 4% of cases) & mucinous ovarian cancer. The increased risk of cervical cancer (OR 2.9) & vaginal cancer (OR 4.6) may reflect associated lifestyle factors (eg promiscuity, smoking, combined oral contraception use).
Exposure to and persistent infection by oncogenic HPV (particularly HPV 16 & 18) is the major risk factor for cervix and vaginal cancer, and 1 in 3 cancers of the vulva. Risk factors include the number of sexual partners, frequency of vaginal intercourse, behaviour of sexual partners, age at first intercourse, multiparity, Chlamydia infection & divorce. Smoking increases the risk of squamous cell carcinoma (OR 2.2). Tobacco carcinogens in high concentrations in cervical mucous promote HPV infection and predispose to carcinogenesis. Smoking also increases the risk of ovarian cancer, particularly mucinous tumours.
Reproductive and contraception behaviours influence the risk of gynaecological malignancies. The combined oral contraceptive has a substantial and long-lasting reduction in the risk of ovarian and endometrial cancer, but may marginally increase the risk of breast cancer during use. Long-term HRT increases breast cancer risk by a similar magnitude to that of a late menopause. Childbearing protects against ovarian, endometrial and breast cancer but increases the risk of cervical cancer.
No conflict of interest.

179 INVITED

Cancer in pregnancy

F. Amant[1]. [1]*University Hospital Gasthuisberg, Gynaecologic Oncology, Leuven, Belgium*

Pregnancy associated cancer is defined as cancer diagnosed during pregnancy or within one year after delivery. Invasive primary breast cancer (BCP) is the most common encountered cancer during pregnancy (Amant et al., 2012a).
BCP typically presents as a painless lump palpated by the woman. Breast ultrasonography is safe and differentiates solid and cystic breast masses. The standard examination to obtain a histological diagnosis is a core biopsy under local anaesthesia which can be performed safely during pregnancy. Overall, staging examinations should be performed as far as they alter clinical management and magnetic resonance imaging in combination with sonography.
In general, surgery can be performed safely during any stage of pregnancy. Both mastectomy and breast conserving surgery with axillary or sentinel lymph node dissection can be carried out safely during pregnancy and should follow the same guidelines as for non-pregnant women. Pelvic surgery, either open or laparoscopic, is possible and safe in expert hands during pregnancy.
Standard regimens of chemotherapy can be administered from 14 weeks gestational age onwards. Treatment with trastuzumab in HER2-positive tumours in pregnant women cannot currently be recommended. For hematologic and gynecologic cancers, standard treatment including paclitaxel-carboplatin, ABVD and CHOP are also possible. Despite the dilution of chemotherapy during pregnancy, the data do not show a worse outcome in pregnant women who receive chemotherapy. Therefore, we advocate the same dosages of chemotherapy based on the actual weight and height during pregnancy.
Although there are no guidelines for obstetricians to monitor pregnant patients treated for breast cancer, some recommendations have been suggested (Amant et al., 2012a). It is advisable to perform the prenatal care of women in a high-risk obstetric unit. The timing of delivery should be balanced according to the oncological treatment schedule and the maturation of the foetus. As in non cancer patients, term delivery (>37 weeks) should be aimed for (Van Calsteren et al, 2010; Loibl et al, 2012). Early labour induction results in prematurity and low birth weight that have been identified as contributing factors in the cognitive and emotional development of children (Lohaugen et al., 2010; Tamaru et al., 2011). The mode of delivery should be determined based on obstetrical indications. Only for cervical and vulvar cancer, a caesarean section is advocated.
Based on recent data it appears that fetal exposure to chemotherapy is not associated with increased morbidity at the level of the central nervous system, cardiac, and auditory functions, as well as general health and growth. Importantly, prematurity was frequently encountered, and was associated with impairment in cognitive development (Amant et al., 2012b). Therefore, we believe that perinatologists should be part of the interdisciplinary discussion and that iatrogenic preterm delivery should be avoided as much as possible.
No conflict of interest.

180 INVITED

Psycho-oncology in gynaecological cancer

V. Kesic[1]. [1]*Clinical Center of Serbia, Department of Obstetrics and Gynecology, Belgrade, Serbia*

Treatment of cancer is sometimes prolonged and difficult, however in large number of cases it is also highly successful. Extensive screening programs and early diagnosis of the malignant diseases have contributed to even better survival owing to which, several million of people worldwide are cured or live with the malignant diseases for years.
Gynecological cancer is particularly delicate type of the disease, influencing not only physical capacities, psychological and social life of women, but also

her future reproductive capacities. Therefore, psychological aspect of care of patients with gynecologic cancer is particularly important. It is estimated that one fourth of the patients diagnosed with malignant diseases are also experiencing some form of psychological disorder. Recognition and help in cases of anxiety and depression, which are naturally developing in patients affected with malignant diseases are important parts of treatment aimed at improvement of their quality of life.
Psycho-oncology is a new sub-specialty concerned with psychological responses of patients and their family members to cancer, as well as the factors that may influence the disease. It is dealing with understanding and treatment of psychosocial, emotional, spiritual, existential and practical aspects of the malignant diseases, as well as the aspects related to quality of life during all stages of the disease and survival. The primary objective of the psycho-oncology is to offer an integral approach to all cancer patients. This is an approach focused on the individual as a whole, which addresses a range of highly diverse needs.
Collaboration of different specialities, such as surgery, gynecology, medical oncology, radiotherapy, psychiatry, psychology, palliative management, rehabilitation medicine, epidemiology, immunology, ethics and research is essential in achieving the optimal care for gynecologic cancer patient.
Complete information on all the aspects of the disease, both medical and psycho.sexual may significantly contribute to prevention or alleviation of the psychological problems in the affected women and their family members. Assistance to patients in accepting treatment necessitates absolute sincerity, the most accurate medical information and detailed advice. Effective communication, which includes active listening, expression of empathy, detection and responding to emotional signs and sensitivity toward the experience of the patient affected with a malignant disease lead to improvement of psychological adjustment, compliance with the treatment plan and satisfaction with care. Compliance with certain treatment option and careful monitoring are basic requirements for successful treatment.

Combination therapy: Is more better?

A.K. Larsen[1], V. Poindessous[1], D. Ouaret[1], A. Bouygues[1], M. Ayadi[1], P. Mésange[1]. [1]*Saint-Antoine Research Center INSERM U938 and Université Pierre & Marie Curie, Cancer Biology & Therapeutics, Paris 12, France*

The development of novel anticancer agents targeting oncogenic signaling pathways represents a major conceptual break-through. However, in many cases the clinical outcome has been less than expected, in part due to the existence of downstream mutations, unsuspected feed-back loops and signaling pathway cross-talk. As a result, much effort is currently focused on targeting of several signaling pathways at the same time or, alternatively, on targeting different steps of the same signaling pathway. Targeted agents have often been added directly to established cytotoxic agents without dose adjustment, sometimes resulting in excessive toxic side effects. One reason for this is that exposure to classical DNA-targeted agents triggers a range of signaling cascades associated with cell cycle control, DNA repair and cellular survival which may interfere with the targeted agents. In this presentation we will discuss the mechanistic basis for combining selected targeted agents with emphasis on EGFR and VEGF(R) pathway cross-talk.

183 INVITED
Role of genomic sequencing in therapeutic decision making with tyrosine kinase inhibitors

E. Voest[1]. [1]*University Medical Center Utrecht, Medical Oncology, Utrecht, Netherlands*

Detailed information on the genetic make up of tumors holds the promise to better select patients for specific treatments. Examples such as trastuzumab for Her2 amplifications in breast cancer and imatinib for BCR-ABL translocations in leukemia have clearly demonstrated the validity of the concept. Further proof came from pivotal studies with drugs such as vemurafenib and crizotinib targeting V600E mutations in melanoma en ALK-EML4 translocations in lung cancer. Unfortunately, the common denominator in these studies is that the spectacular treatment successes are temporary because of the emergence of resistance to these drugs.
With the advances in sequencing technologies it is now possible to generate detailed information on the genomic aberrations in a tumor. Single gene analysis (e.g. BRAF, KRAS) will be replaced by whole exome or even whole genome in the foreseen future. This more complete genetic overview of a tumor allows analysis at the level of pathways rather than at the level of single genes. For example, we could not find a correlation between chemotherapy outcome and specific actionable mutations in the PI3K gene in breast cancer patients. In contrast, there was a strong correlation with response to chemotherapy when mutations in the PI3K pathway used.
These findings shed light on the use of various genetic abnormalities. Oncogene addiction makes tumors vulnerable to a specific targeted treatment, testing for these genes will define the population of patients most likely to respond. However, some forms of oncogene addiction may also depend on the tissue background. Melanoma patients with BRAF mutations respond far better than patients with colorectal cancer with the same BRAF mutation.
Tumor heterogeneity is an important dimension of tumor growth and during treatment clonal outgrowth of resistant populations is likely to occur. (Ultra)Deep sequencing may identify these clones in an early stage and allow an anticipatory treatment approach. Dynamic changes as a result of treatment may activate certain survival pathways to compensate for the The current dogma is that it will be easier to find a predictive genetic profile for drugs with a specific mechanism of action (such as vemurafenib) than for broad spectrum kinase inhibitors (such as sunitinib). However, given the correlation between response to chemotherapy and the PI3K pathways this may be a misconception and these studies should therefore be performed.
In summary, we are entering an era in which large scale genetic testing of tumor and germ line DNA will become part of our regular diagnostic work up of cancer patients. The sequencing itself will not be a major bottle neck. High quality interpretation of the data by bioinformaticians will be key in a successful implementation of DNA guided decision making. However, to define and refine these genetic profiles we need high quality drug-based databases in which clinical outcome is linked with genetic data. For that collaboration is essential.
No conflict of interest.

184 INVITED
The concept of basket trials

J. Baselga[1]. [1]*Memorial Sloan Kettering Cancer Center, Department of Oncology, New York, USA*

Results from the world-wide sequencing effort have revealed a number of specific genomic mutations or molecular alterations are both infrequent in a given tumor type while may be shared by more than one tumor type. In order to methodically characterize whether they are therapeutically actionable in a context dependent fashion we have launched a series of "basket" studies with tyrosine kinase inhibitors. This new type of genotype-focus studies is particularly useful when the cancer type and the mutations are rare. Ideally, these studies enrolled 10−15 subjects per tumor type and also include a miscellaneous category for patients with rare types of cancer in which the mutation of interest was not previously known to exist.
We have launched a number of basket trials including in patients BRAF V600E, PI3KCA, erbB2 mutations, and FGFR family amplifications or other activating alterations. We will present data with the logistical aspects of such trials as well as emerging results from some of these trials.
No conflict of interest information specified.

185 INVITED
Clinical development of TKIs: Learning from our mistakes

S. Sleijfer[1]. [1]*Erasmus University Medical Center, Department of Medical Oncology, Rotterdam, Netherlands*

In recent years several novel targeted kinase inhibitors (TKIs) have rapidly been introduced into the oncology practice following successful studies. In contrast, many other TKIs failed, sometimes already at an early clinical trial stage, others only after completion of large and expensive phase III studies. From both successful and unsuccessful drug development tracks, important lessons for designing new studies can be learned.
Most of the successful TKIs concerned drugs that directly target and inhibit the product of a mutated gene driving a certain subgroup of malignancies. As the mechanism of action of these drugs was known, and therefore the patient population in which these TKIs were likely to exhibit anti-tumor activity could be identified, these TKIs were tested in specifically selected patient groups from start of their clinical development. Successful couples of such drugs and diseases include imatinib in GIST, vemurafenib

in *BRAF*V600E mutated melanoma, and crizotinib in non-small cell lung carcinoma (NSCLC) harboring an *EML-ALK* fusion gene.
An important feature of drugs that ultimately failed or were only approved after a cumbersome and expensive road to registration is that the mechanism of action was unknown prior to starting clinical trials. As a result, predictive profiles were not established, patients likely to respond could not be identified beforehand, and clinical studies were performed in unselected patient populations. Recent examples are IGF-1R antagonists and mTOR inhibitors.
Most important lesson from these studies is the need to reveal the exact mechanism of action of the compound under study and to identify predictive markers before initiating large clinical trials. If unknown, it is questionable whether such drugs should enter a drug development track at all given the valuable resources needed for such trials and the enormous number of alternative drugs that need further testing. If a compound is taken forward into a drug development track despite the fact that no predictive profiles are known, some adaptive designs are possible. In such circumstances, collection of biomaterial is essential to reveal predictive profiles in retrospect such as was done with EGFR-TKIs in NSCLC.
In summary, identification of predictive profiles and robust assays to select the appropriate patient group is essential before starting novel anti-tumor drugs.
No conflict of interest.

Society Session (Sun, 29 Sep, 14:45−16:45)
European Association of Neuro-Oncology (EANO)

186 INVITED
IDH1 and 2 mutations in gliomas from biology to treatment

M. Sanson[1], V. Gleize[1], L. Connen de Kerillis[1], A.L. Di Stefano[1], M. Labussière[1]. [1]*CHU Pitié Salpetrière, Neurology, Paris, France*

IDH1 gene encodes the cytoplasmic isoform of isocitrate dehydrogenase, and is mutated at Arg132 (mostly Arg132His) in 40% of gliomas (5−8% of primary glioblastoma, vs 75% of grade II and 50% of grade III gliomas). Mutations of the analogous amino acid residue (Arg172) of the mitochondrial isoform *IDH2* are less frequent. *IDH1*/*IDH2* mutated tumors have a better outcome, whatever grade considered. Whether *IDH1*/*IDH2* mutation can predict response to treatment in gliomas needs to be further investigated.
The mutation causes the loss of the isocitrate dehydrogenase function and the gain of an α-ketoglutarate reductase function leading to the cellular accumulation of D-2-hydroxyglutarate (D-2HG) that represents a diagnostic marker (this change is almost specific for gliomas) and prognostic (mutated gliomas have longer survival) of interest. Interestingly, D-2HG can be detected using proton magnetic resonance spectroscopy.
The accumulation of D-2HG, which acts mostly as an inhibitor of alpha-ketoglutarate dependent dioxygenase, results in a wide range of cellular changes including profound modulation of epigenome, with CpG island hypermethylation and histone methylation, and inhibition of terminal differentiation. Strikingly *IDH1*/*IDH2* mutations is a constant feature in 1p19q codeleted gliomas, and suggest a critical role in oligodendrogliomagenesis (in association with *hTERT* and *CIC* mutation) that need to be elucidated.
The mutated neoenzyme is an attractive target for futures therapies: specific inhibitors for IDH1 and IDH2 have been shown to reverse the epigenetic changes induced by the mutation, and to inhibit the growth of the mutated, but not wild type tumors on xenograft models, opening new perspective for glioma treatments.
No conflict of interest.

187 INVITED
Neuroimaging after antiangiogenic agents: What have we learnt?

W. Wick[1]. [1]*University of Heidelberg, Abteilung NeuroonkologieNeurologische Klinikund Nationales Tumorzentrum, Heidelberg, Germany*

High response rates (RR) in two uncontrolled phase II studies were the basis for approval of the vascular endothelial growth factor (VEGF) antibody bevacizumab (BEV) for patients with recurrent glioblastoma in the USA. The acceptance of RR as a denominator for clinical relevance poses increasing weight on magnetic resonance imaging (MRI) as surrogate marker for treatment efficacy. As the accepted mode of action of anti-VEGF/VEGF receptor (VEGFR) compounds includes stabilization of the blood–brain-barrier, it may well be that some responses are in fact due to a decrease contrast enhancement and edema without real antitumor effect. In addition to this phenomenon of pseudoresponse induced by BEV and other agents, there is a lot of discussion on the radiochemotherapy-associated MRI-effect called pseudoprogression. Pseudoprogression is increasing enhancement in the T1-wheighted MRI in the irradiation volume, mainly with no or little clinical symptoms and a resolution over time without changing management. It may prevent to call the correct time point of progression and also changing management in patients that may not be really progressive.
Two further challenges for modern neuroimaging are: the assessment of non-enhancing T2/FLAIR abnormalities, which may reflect invasive tumor and contribute to (neurocognitive) morbidity. Secondly, imaging should be developed to help delineating patients getting benefit from antiglioma therapies, including but not limited to BEV.
A series of well-designed, though retrospective translational imaging studies and new phase III data assist in answering or at least following on these questions. These data suggest that RR cannot be taken as a surrogate for progression-free (PFS) or even overall survival (OS). Further, the data suggest that the application of strict imaging algorithms, but also BEV are reducing the number of pseudoprogressing patients. Further, T2/FLAIR progression remains complicated to quantify, though specific properties of BEV to induce diffuse infiltrative tumors are not demonstrated by case-control series nor the data of the AVAglio trial.
Clearly, the biggest challenge is the provision of imaging parameters helping to predefine patients with likely benefit from a given treatment, specifically antiangiogenic therapy. The development of MRI imaging as a marker for treatment decisions would be a major step ahead in neurooncology.

188 INVITED
Amino acid PET for gliomas

U. Roelcke[1]. [1]*Cantonal Hospital Aarau, Neurology Neurooncology, Aarau, Switzerland*

The signal of amino acid PET which visualizes gliomas is governed by radiotracer influx across the blood–brain barrier (BBB). In tumors with intact BBB (low-grade gliomas) facilitated transport accounts for tracer uptake which is mediated by the L-amino acid transporter 1 (LAT-1). In tumors with BBB breakdown (malignant gliomas) also passive diffusion contributes to tracer uptake which results in 'BBB images' resembling the pattern of contrast enhancement on MRI. In tumors with intact BBB the PET signal is composed by the density and activity of LAT-1, and by the density of capillaries which exhibit LAT-1. Therefore amino acid PET in these tumors can be considered a technique to explore microvessel density.
^{11}C-methyl-methionine (MET) and ^{18}F-fluoro-ethyl-tyrosine (FET) are the most common used amino acids for clinical PET examinations. The intratumoral accumulation of MET/FET can be quantified as the ratio of tumor-to-brain uptake. Uptake ratios for MET range in between 1.0−2.4 for low-grade gliomas, and 2.0−3.8 for malignant gliomas. Of note MET uptake is also increased in the infiltration area of malignant gliomas. According to the specificity of PET images in tumors without BBB breakdown MET/FET are well suited to characterize lesions which do not enhance contrast medium on MRI. Apart from information on tumor grade and prognosis, MET/FET PET can be applied to characterize lesions suspective for low-grade glioma if they are not amenable to resection. In this setting the metabolically most active region should be selected for diagnostic biopsy as this region most likely represents the correct tumor grade. In addition MET/FET can be used for early response assessment in low-grade gliomas during chemotherapy. Metabolic (PET) may precede anatomical (MRI) responses by several months. This allows to individually tailor therapy of these tumors. MET/FET has been also applied to differentiate true progression of malignant gliomas from pseudoprogression and radiation necrosis. However, due to BBB breakdown in these conditions the interpretation of PET images remains a matter of debate.
As a perspective amino acid PET may be used to investigate the behaviour of tumor compartments which do not enhance contrast medium on MRI, e.g. during anti-angiogenic therapy of malignant gliomas. Combined with MRI measures of cellularity (diffusion restriction) amino acid PET should enhance our knowledge on response and resistance to anti-angiogenic agents.
No conflict of interest.

189 INVITED
Chemotherapy induced neuropathies − new frontiers

W. Grisold[1], A. Grisold[2]. [1]*Department of Neurology, KFJ Hospital, Vienna, Austria;* [2]*LBI for Neurooncology, KFJ Hospital, Vienna, Austria*

Modern cancer therapy often involves treatment with chemotherapy. Several drugs as platinum compounds, taxanes, vinka alkaloids, epithelons,

thalidomide and bortezomib cause predominately sensory neuropathies, which are often dose dependent. In addition to the common pattern of cumulative toxicity, also in oxaliplatin and taxanes also acute effects occur, coasting is a featture of platinum drugs and increasingly long term effects in long time survivors are gaining importance.
The mechanisms of the individual drugs toxicity vary and damage to dorsal root ganglions, axons and small fibers has been identified. In addition in acute toxicity damage of ion channels at the neuromuscular transmission site occur. At present prophylactic treatment for CIPN, except suppression of acute oxaliplatin toxicity has not been successful.
CIPN may be overlooked or can be underestimated in clinical setting. The diagnosis is based on toxicity scales, electrophysiology and increasingly patient based assessment of well being and quality of life.
Although the pattern and cumulative toxicity causing CIPN has been identified for most drugs, clinical experience teaches, that patients are subject to individual different susceptibility. Some factors as preexisting neuropathy, pretreatment with other toxic drugs, and drug combinations, sequences of different lines of chemotherapy have been identified, but other factors as possible genetic dispositions are subject to research, as well in acute as in cumulative neurotoxicity.
The term late toxicity defines persistence of neuropathic syndromes far beyond the termination of cancer therapy for several years. The increasing number of long term survivors has revealed that not all CIPNs are reversible. Reports have been published on platinum compounds, taxanes, vinka alkalods and other drugs or combinations. The symptoms can be persistence of neuropathy, neuropathic pain syndromes. unpleasant sensations, Raynaude's syndrome and muscle cramps.
Strategies for the identification of persons at risk for CIPN, preventive strategies, and more effective symptomatic treatment will be needed to lower the burden of disease.
No conflict of interest.

Scientific Symposium (Sun, 29 Sep, 14:45−16:45)
End of Life Care

190 INVITED

What makes the last few months of treatment so expensive?

T.J. Smith[1], B.E. Hillner[2], R.J. Kelly[1], J.B. Cassel[3]. *[1]Sidney Kimmel Comprehensive Cancer Center of Johns Hopkins, Oncology, Baltimore, USA; [2]Virginia Commonwealth University, Medicine, Richmond, USA; [3]Virginia Commonwealth University, Massey Cancer Center, Richmond, USA*

Background: We celebrate that more people are reaching the age of peak cancer incidence and surviving cancer, but must determine how to pay for cancer care as well as other chronic and expensive conditions. The last months of life are becoming increasing more expensive due to more resource use including chemotherapy, supportive care, and diagnostic testing near the end of life; more frequent and resource-heavy hospitalizations with more intensive care unit use; increasing patient and societal expectations; failure to elicit choices about advance care planning; poor communication and planning for death; and inability of most health systems and practitioners to monitor and change their performance.
Material and Methods: Literature review and policy analysis.
Results: The cost of cancer treatment is expected to rise at least 2 % annually in most countries and could be substantially more. Some programs that have shown benefit in maintaining the general quality of care while restraining costs include the following: 1. Evidence-based pathways such as those used by U. S. Oncology; 2. Elicitation of advance directives with better planning for the last months of life, including death, to avoid the hospital; 3. Cost control by limitation of prices (NICE; Veterans Administration Medical Centers); 4. Integration of palliative care earlier, with transition to hospice when appropriate; 5. Regionalization and specialization of services, such as specialty pharmacies for expensive oral drugs; 6. Better communication about medically appropriate treatments with decision aids; 7. Better communication in the community including traditional (Gunderson, Wisconsin) and "cloud" solutions (NHS Coordinate my Care); and 8. Better information about actual patterns of care with real-time feedback to practitioners. There is no simple single solution. All alternatives involve changing patterns of care and expectations, and all alternatives involve someone not getting therapy that might be perceived to be useful.
Conclusions: Cancer care is increasingly complex and costly, as are most chronic diseases. Bending the cost curve downwards while maintaining quality will demand more efficient care, reducing care that is expensive but of little "value", putting downward pressure on prices, and monitoring practice in real-time.
No conflict of interest.

191 INVITED

To treat or not to treat at end of life

S. Kaasa[1], M.R. Grønberg[1]. *[1]Norwegian University of Science and Technology, European Palliative Research Centre (PRC), Trondheim, Norway*

To treat in this context is understood as tumor directed treatment, i.e. chemo- and/or radiotherapy. Symptomatic treatment for pain, dyspnea, anxiety, depression etc. should be offered patients throughout the "cancer journey" − from primary diagnosis until end-of-life care − along with palliative care in general.
Tumor directed treatment is basically offered to the patients with the aims to cure, to prolong life, to prevent and/or treat symptoms. If such treatment is offered to patients having short life expectancy aiming at preventing or relieving symptoms, and maybe marginally prolonging life, the patients' burden needs to be carefully evaluated against the treatment benefit.
Studies have demonstrated that 15−45% of the cancer patients received chemotherapy the last 30 days of life − this proportion appears to increase − while 8−19% received radiotherapy the last 30 days of life. It may be argued that chemotherapy and radiotherapy offered to patients at this stage of the disease is futile; maybe with exception for one fraction radiotherapy for painful bone metastasis.
It is documented in clinical studies that a palliative care program offered to the patients early in their disease trajectory as well as information about palliative care may lead to reduced use of chemotherapy, less anxiety and improved survival at end-of-life. Studies also show that patients prefer to die at home; however, extensive use of tumor directed treatment may result in less patients dying at home.
There is a need for increased awareness of indications and timing of offering tumor directed treatment to palliative care cancer patients.
No conflict of interest.

192 INVITED

Psychological and social factors in palliative care

G. Rodin[1]. *[1]Princess Margaret Hospital, Toronto − Ontario, Canada*

Psychological and social factors are important outcomes in palliative care, although research in this domain was limited by significant methodological and practical obstacles, including the lack of relevant and validated outcome measures. Further, most psychosocial research in palliative care was conducted near the end of life, even though symptom burden and psychological distress is considerable much earlier in the course of advanced and terminal disease. The creation and validation of measures that assess relevant psychosocial outcomes in palliative care has significantly increased the rigour of clinical studies in this field. These measures have been critical to evaluate the impact of novel psychosocial interventions that have been developed for this population. The preliminary findings from clinical trials of such interventions suggests that they have the potential to diminish psychological distress and to protect psychological well-being prior to and near the end of life. Although many challenges remain in the conduct of psychosocial research in patients with advanced disease, an evidence base to guide psychosocial interventions in palliative care has now emerged.
No conflict of interest.

193 INVITED

Symptom control at the end of life: What about palliative sedation?

A. Caraceni[1]. *[1]National Cancer Institute, Palliative Care, Milan, Italy*

Palliative sedation (PS) is now considered a normal medical procedure and a required therapeutic intervention at the end of life, in selected cases. The experience on palliative sedation is now well established and numerous case series were published which clarified its indications, clinical characteristics and risks. The widest experience in the use of palliative sedation regards the control of untreatable symptoms in the terminal phases of cancer among which the most prevalent are dyspnoea and delirium. Other less frequent conditions, requiring sedation in the terminal phase of cancer, are hemorrhage and vomiting due to GI obstruction; pain alone is hardly ever an indication to PS. When PS is indicated because of the onset of untreatable symptoms, which are the immediate consequence of life threatening conditions, its prompt use can be a priority to allow a confortable death. In these cases PS is usually a time limited procedure, seldom lasting more than 24−48 hours and often less before death. In case of terminal delirium the timing of sedation tends to be longer. More rarely psychological distress or unbearable psychological suffering can be addressed by sedation but these cases require very careful assessment and pose more complex ethical problems. Available guidelines can be used to frame the clinical and ethical principles informing this practice,

including pharmacological protocols and clinical monitoring. The European Association for Palliative Care recommends that sedation is considered for symptoms that are judged untreatable notwithstanding the provision of appropriate specialized palliative care interventions. Usually specialized palliative care input should be sought to appropriately perform PS. Patient and family comunication and team approach are also required. Data from controlled trials and prospective case series shows that palliative sedation, in expert hands, bears low risk of complications and that patients undergoing PS do not have a shorter survival than patients who do not need PS at the end of life.
PS aims at the control of symptoms and not at hastening death; this distinction in the intention qualifies PS as a medical procedure together with the clinical outcome that is a reduced level of consciousness, pharmacological therapy and monitoring requirements and their careful documentation. PS is now an integral part of the armamentarium of palliative care discipline and the lack of appropriate use when indicated should be viewed as an insufficient level of care if not malpractice.

Next generation sequencing: Lessons from an ICGC project

S. Tavaré[1]. [1]*University of Cambridge, Cancer Research UK Cambridge Institute, Cambridge, United Kingdom*

The Cancer Genome Atlas (TCGA) and the International Cancer Genome Consortium (ICGC) have among their aims the elucidation of the genomic, transcriptional and epigenetic architecture of cancers, and next-generation sequencing provides one approach to this. In this talk I will describe some of the bioinformatic, computational and statistical issues that arise in such projects. I will touch upon the identification of somatic aberrations, inference about clonal substructure, and tumour heterogeneity. Data from our ICGC Esophageal Adenocarcinoma project will be used to illustrate the methods.
No conflict of interest.

195 INVITED

Novel technologies for deep genome sequencing − target enrichment

C. Mein[1]. [1]*Barts and The London, John Vane Science Centre Genome Centre, London, United Kingdom*

Next Generation Sequencing has the power to exhaustively profile and monitor the transcriptome, methylome or genome of any biological system, including the evolution of tumour progression. Targeted deep resequencing of key components of the genome can help provide enough depth to identify low copy number clones and follow their evolution. The Fluidigm Access Array system enables high throughput PCR amplification of up to 480 target regions, or around 60 target genes based on median exon count. Coupling this with Illumina MiSeq Next Generation Sequencing enables sequencing of up to 300 patients to 100X coverage. We review our first year's experience with this approach on both human and non-human samples. We discuss the advantages and disadvantages in light of our experience with other sequence enrichment strategies, e.g Sure Select and Haloplex.
No conflict of interest.

Deep sequencing is now rapidly being applied within many biomedical domains, presenting challenges at many levels to harvest the analytical precision and genome scale depth inherent in the technology. The large-scale generic mapping of genomic features at many levels in the chromosomal organization enables novel computational approaches. The emerging charting of the three-dimensional organization of the DNA in the nucleus provides even further unprecedented opportunities to understand not least complex diseases such as cancer, provided available analytical strategies of sufficient vigor and flexibility.
The Genomic HyperBrowser framework (http://hyperbrowser.uio.no/) will be presented as one realization of a statistical genomics system to meet the challenge. It embodies rich and flexible statistical testing on a genome-wide scale, permitting rapid solutions in both interactive tabular formats and visualizations, for a multitude of biological examinations.
Methods for analysis of genomic information in a three-dimensional setting have also been developed within the same framework, again providing robust procedures for a number of 3D related questions.
We leverage such solutions in the quest to ascribe importance to the multitude of changes to DNA and chromatin as observed in cancer, not least in the context of personalized medicine.

European Association for Cancer Research (EACR) − microRNAs in Cancer

198 INVITED

Long noncoding RNAs required for p53 tumor suppressor activity

R. Agami[1]. [1]*The Netherlands Cancer Institute, Department of Oncology, Amsterdam, Netherlands*

p53 is a transcription factor and tumor suppressor that is very frequently mutated in cancer. Chromatin binding profiles reveal specific interactions of p53 with promoter regions of nearby genes, within genes, but also with remote regions located more than 50 kbps away from any known gene. Interestingly, many of these remote regions possess evolutionary highly conserved p53-binding sites and all known hallmarks of enhancer regions, as well as binding of RNAPII. While p53 binding to promoter regions locally activates expression of one gene, its binding in the context of enhancers may affect several distant genes in tissue dependent manners. Interestingly, several of these p53-enhancer domains produce, in a p53-dependent manner, a unique type of non-coding RNAs termed enhancer RNAs (eRNAs). We show that p53-dependent eRNA production is required for efficient transcriptional enhancement of interacting target genes and induction of a p53-dependent cell-cycle arrest.
No conflict of interest.

199 INVITED

MicroRNAs, EMT and cancer stem cells

T. Brabletz[1]. [1]*Universitätsklinikum Freiburg, Freiburg, Germany*

We have shown, that in particular tumor cells at the invasive front of common adenocarcinomas undergo an epithelial–mesenchymal transition (EMT) and aberrantly express EMT-associated transcriptional repressors, like ZEB1. The amount of such cells strongly correlates with metastasis formation and poor clinical outcome. Strikingly, metastases show again a re-differentiated phenotype, indicating a mesenchymal-epithelial re-transition (MET) and a support a regulatory role of the tumor environment for malignant tumor progression.
We described that the EMT-activator ZEB1 is a crucial promoter of metastasis and demonstrated that ZEB1 inhibits expression of cell polarity factors and the microRNA-200 family, whose members are strong inducers of epithelial differentiation. These results indicate that ZEB1 triggers a microRNA-mediated feedback-loop, which stabilizes EMT and promotes dissemination of cancer cells. Moreover we detected that in addition ZEB1 is necessary for the tumor initiating capacity of pancreatic, breast and colorectal cancer cells. ZEB1 inhibits expression of miR-200c, miR-203 and miR-183, which cooperate to suppress expression of stem cell factors, as demonstrated for the polycomb repressor Bmi1.
We propose that ZEB1 links EMT-activation and stemness-maintenance by suppressing stemness-inhibiting microRNAs and thereby is a promoter of mobile, migrating cancer stem cells. Notably, these cells also acquired a drug-resistance phenotype. Thus, targeting the ZEB1 − miR-200 feedback loop might be a promising treatment option for fatal tumors, such as pancreatic cancer.

200 INVITED

Role of oxidative stress in tumor development and response to treatment

F. Mechta-Grigoriou[1]. [1]*Institut Curie, Paris, France*

The discovery of free radicals -highly unstable molecules present at low levels in our body- has greatly modified our view of certain biological processes. Free radicals are constantly produced in the body by metabolism and cellular respiration; but this physiological production is controlled by efficient “antioxidant” defence systems. Under certain circumstances, imbalance arises, either because of antioxidant deficiency or overproduction of radicals. The excess of derivatives of oxygen (or ROS, reactive oxygen species) becomes toxic for major components of the cell: this reaction is called oxidative stress. We have investigated the role of chronic oxidative stress on tumor development. We have shown that persistent accumulation of ROS (still faint enought for being compatible with cell survival) promotes tumor development. Indeed, accumulation of ROS stabilizes HIF under normoxic conditions and further increases tumor angiogenesis (Gerald D. et al., Cell, 2004). HIF has also been defined as a key regulator of glucose metabolism by regulating insulin secretion (Laurent G. et al., Cell Metabolism, 2008). Interestingly, chronic oxidative stress also deeply modifies other components of the stromal compartment, such as fibroblasts. Indeed, ROS accumulation converts fibroblasts into myofibroblasts and promotes dissemination of metastatic cells into lymph nodes in HER2 breast cancers (Toullec, A., EMBO Molecular Medicine, 2010). Finally, we recently defined a miRNA-dependent stressrelated signature, which has a predictive value for survival of patients suffering from high grade ovarian cancers. miR-141 and miR-200a target p38α and modulate the oxidative stress response. Enhanced expression of these miRNAs mimics p38α deficiency and increases tumor growth in mouse models, but it also improves the response to chemotherapeutic agents. High-grade human ovarian adenocarcinomas that accumulate miR-200a have low concentrations of p38α and an associated oxidative stress signature. The miR200a-dependent stress signature correlates with improved survival of patients in response to treatment. Therefore, the role of miR-200a in stress could be a predictive marker for clinical outcome in ovarian cancer. In addition, although oxidative stress promotes tumor growth, it also sensitizes tumors to treatment, which could account for the limited success of antioxidants in clinical trials (Mateescu, B. et al., Nature Medicine, 2011; Batista, IJBCB, 2013).

No conflict of interest.

201 INVITED

Identification of microRNA functions in cancer using high-throughput screens

A.H. Lund[1]. [1]*University of Copenhagen, Biotech Research and Innovation Centre, Copenhagen, Denmark*

MicroRNAs are important regulators of gene expression in normal development and disease. With the number of human microRNAs approaching 2000 a major quest is to incorporate these into cellular pathways. Whereas a multitude of studies have demonstrated deregulated microRNA expression in human cancers, establishing causal roles for microRNAs in cancer development and maintenance is lagging behind.
High-throughput functional screening for microRNAs affecting cancer-related cellular functions is an efficient first step to identify key microRNAs in a particular pathway. The p53 tumour suppressor acts as a negative regulator of cell proliferation in response to stress and represents the most commonly lost and mutated gene in human cancers. To identify microRNAs affecting the p53 tumour suppressor pathway a library of 500 microRNA precursors were screened. The screen data will be presented focussing on the identification of a potent inhibitor of the MDM2 ubiquitin ligase responsible for functional inhibition of p53.

No conflict of interest.

Scientific Symposium (Sun, 29 Sep, 14:45−16:45) **Treatment of Rhabdomyosarcoma in Children and Adolescents Across the Atlantic: Time for Increasing Joint Initiatives?**

202 INVITED

Reducing radiation therapy for children with rhabdomyosarcoma: Results of the European strategy

O. Oberlin[1]. [1]*Institut Gustave Roussy, Pediatrics, Villejuif, France*

Outcomes of patients with localized RMS although not yet satisfactory, are sufficiently good enough to justify a focus not just on cure but also on the consequences of cure. This focus is reinforced by the proportion of children who are very young and for whom the consequences of local treatment is a particular concern. It is of paramount importance to identify which subset of patients can be spare aspects of treatment which may cause important long-term sequelae.
Since the 80s, the links between the North American and European Soft Tissue Sarcoma groups offered the possibilities of meta-analysis of outcomes for groups of patients treated in different settings.
In 1997, the cooperative groups took as the topic the outcome of children with orbital RMS. Long known to have a favourable outcome, there was concern that the systematic use of radiation therapy, at this site, in young children, created a high risk of important late sequelae Data showed that a subset of patients with orbital RMS could be cured without systematic local therapy, although there was a high relapse rate in those who did not receive radiation therapy as part of primary treatment. The possibility of salvage for some of those who relapsed resulted in overall survival rates being no different whether patients received radiation therapy during primary treatment or not. However, the total burden of treatment (i.e., primary therapy and treatment given for relapse) needs to be taken into account when assessing the implications for late sequelae for all patients.
Similar analyses were performed in other relatively favourable sites of disease including bladder/prostate or vagina/ uterus RMS and produced similar conclusions: delayed selective RT was not disadvantageous in relation to overall survival.
However, the application of a similar strategy for parameningeal RMS was not successful and accounted for the less good overall results of some European studies compared with those undertaken by the North American group.
The challenge of how to spare the sequelae of radiation therapy remains an important issue and work still needs to be done to try and further refine the selection of patients who may have less treatment. Apart from conventional measures of prognosis including site, size, stage, age, pathological subtype and rapidity of chemotherapy response, we hope that in future studies markers of tumour’s biology might help to select these tumours.

No conflict of interest.

203 INVITED

Progress in the treatment of rhabdomyosarcoma: Results of the North American strategy

D. Hawkins[1]. [1]*Seattle Children’s Hospital, Hematology-Oncology, Seattle, USA*

Background: The Children’s Oncology Group (COG) continues the legacy of the Intergroup Rhabdomyosarcoma Study Group to improve the outcome for rhabdomyosarcoma (RMS) using risk stratified clinical trials based upon the expected failure-free survival (FFS).
Materials and Methods: Recent COG RMS trials included ARST0331 for low-risk RMS (defined as embryonal histology, non-metastatic disease, and either favorable site ***or*** unfavorable site with completed resection prior to chemotherapy), ARST0531 for intermediate-risk RMS (defined as embryonal histology, non-metastatic disease, unfavorable site, and unresected ***or*** alveolar RMS without metastatic disease), ARST0431 and ARST08P1 for high risk RMS (defined as any RMS with metastatic disease), and ARST0921 for recurrent RMS.
Results: ARST0331 used a modest cyclophosphamide dose (4.8 g/m^2), with 22 week of therapy for subset 1 (mostly orbital and paratesticular RMS) and 46 weeks of therapy for subset 2 (mostly unresected tumors at favorable sites). For subset 1, the 2 year FFS was excellent (88%); for subset 2, the 2 year FFS was worse than anticipated (68%). ARST0531 was a randomized addition of irinotecan to standard chemotherapy. Secondary aims included evaluation of early radiotherapy, functional response imaging with positron emission tomography (PET), and assessment of *FOXO1* translocations in alveolar RMS. ARST0531 completed enrollment in December 2012 with results pending. ARST0431 used a very intensive seven agent chemotherapy combination for metastatic patients. Compared to historic results, the outcome for patients with embryonal RMS appeared to be improved (3 year FFS: 60%), while there was no improvement for alveolar RMS (3 year FFS: 21%). ARST08P1 uses the same intensive backbone as ARST0431 with the addition of cixutumumab (given weekly) or temozolomide (given with concurrently with irinotecan). ARST0921 uses a vinorelbine/cyclophosphamide backbone with the addition of either bevacizumab or temsirolimus in a selection design to identify the agent of greater interest for future development. Both ATSR08P1 and ARST0921 will reach their accrual goals soon.
Conclusions: The COG RMS risk stratification requires modification to account for changes in outcome for selected low-risk and metastatic embryonal RMS and molecular features. Planned changes include PET as an early surrogate for outcome and incorporation of molecularly targeted agents into frontline therapy.

No conflict of interest.

204 INVITED

Treatment of relapsed rhabdomyosarcoma − Experience of the CWS Study Group

E. Koscielniak[1], T. Dantonello[2], B. Kazanowska[3], R. Ladenstein[4], G. Ljungman[5], F. Niggli[6], I. Leuschner[7], A. Schuck[8], T. Klingebiel[9]. *[1]Olgahospital Klinikum Stuttgart, Ped. Oncology/Haematology, Stuttgart, Germany; [2]Olgahospital Klinikum Stuttgart, Ped. Oncology/ Haematology, Stuttgart, Germany; [3]Wroclaw Medical University, Ped. Oncology/ Haematology, Wroclaw, Poland; [4]St. Anna Kinderspital, Ped. Oncology/ Haematology, Vienna, Austria; [5]University of Uppsala, Ped. Oncology, Uppsala, Sweden; [6]University of Zürich, Ped. Oncology, Zürich, Switzerland; [7]University of Kiel, Ped.Pathology, Kiel, Germany; [8]Radiation Oncology, Radiation Oncology, Ingolstadt, Germany; [9]University of Frankfurt, Ped. Oncology/Haematology, Frankfurt (Main), Germany*

Despite improved prognosis in patients with RMS, about 30% percent of patients with primary localised tumours who achieved complete remission (CR) relapsed, mainly locoregional (50−60%) and/or metastatic. The relapse rate (RR) did not differ substantially between the consecutive CWS-Studies and was similar to the RR reported by other RMS-Study groups (SIOP-MMT, STS Committee of COG, AIEOP-ICG) showing that no major progress has been achieved in treating patients after recurrence in the last 20 years. The relapse behaviour depends on the histological subtype (alveolar vs. embryonal) and primary tumour site. Alveolar RMS (RMA) relapsed more frequently: 48% of primary non-metastatic RMA relapsed after achievement of CR, majority of them experienced systemic relapse. The most frequent site of systemic relapses (in all RMS) were thorax (ca. 50%) and abdomen (ca.30%). 70−80% of the recurrences occurred $\leqslant$2 years after diagnosis and only 1% later than 4 yrs after diagnosis. Post − relapse overall survival (OS) was 20−30% but varied greatly depending on histology, type of relapse (locoregional vs. combined or metastatic) and time of occurring. Patients with embryonal RMS (RME), local, late (>12 months after diagnosis) recurrence and a still existing option for irradiation (RT) have a survival chance of about 50%. Similarly patients with a relapse to the lung as a solely metastatic site have an OS of ca. 50%. In contrast patients with RMA and metastatic relapse have a very poor prognosis (OS <5%). However, even in this poor prognostic group, survival in the subgroup of individuals with circumscribed recurrences and an option for local therapy was significantly better (ca.50%). Early relapse (<6 months after diagnosis) was associated always with poor prognosis (4 yrs OS of 19% and 4% in RME and RMA respectively). Age, histology, tumour size and site, post-surgical stage and omission of RT were identified in the multivariate analysis as factors associated with an increased relapse risk. Tumour site, an option for RT, time to relapse and type of relapse, were identified as independent factors predicting survival after relapse. Alkylating agents and anthracyclines should be used in patients who did not receive these agents in the first-line therapy. Additionally topoisomerase inhibitors (VP-16, topotecan, irinotecan), cisplatin, carboplatin, vinorelbine are used in relapse treatment. The use of high-dose chemotherapy has not been shown to improve prognosis. Advances in molecular characterization of RMS have identified new therapeutic targets which are being tested in phase I−II studies. The characterization of subgroups with distinctive pattern and risk of relapse can be used to develop risk-adapted, tumour-directed guidance for detection of recurrent disease in RMS and identification of patients for experimental therapeutic approaches.

No conflict of interest.

205 INVITED

Biology-driven strategy for new drug development in rhabdomyosarcoma

J. Chisholm[1]. *[1]Royal Marsden NHS Foundation Trust, Children and Young People's Unit, London, United Kingdom*

Despite significant improvements in outcome for children and young people with rhabdomyosarcoma (RMS), outcomes remain suboptimal in certain groups, particularly high risk localized disease, metastatic and relapsed disease. In addition to continued improvements in local therapy (surgery and radiotherapy) there exists a need to improve systemic therapy for these groups of RMS. Cytotoxic chemotherapeutic agents remain the gold standard of systemic therapy, with studies in Europe and North America now underway to begin to evaluate the addition of targeted therapies.

Many potential targets have been identified in rhabdomyosarcoma. These include: ALK; MET; FGFRs; HSP90; IGF1R; PDGFR; VEGFR; PI3KCA/mTOR; SPRY1; PTEN; Raf1; Src; G2M kinases; PLK1; NOTCH. In translocation positive alveolar RMS, the PAX3-FOXO1 or PAX7-FOXO1 fusion gene drives a number of downstream effects, although as yet the fusion gene cannot be targeted directly. The biological differences between translocation-positive alveolar RMS and embryonal RMS/translocation-negative alveolar RMS must be recognised in future therapeutic strategies and clinical trials.

Prioritization of known druggable targets with potential therapeutic benefit in RMS is important to aid selection of the most promising agents or combinations of agents for in vitro and in vivo studies with a view to early phase clinical trials in children. In reality, prioritization is complex. Moreover, the number of relevant targeted agents with phase I paediatric data currently available for clinical trials in RMS remains limited.

The European paediatric Soft tissue Sarcoma Group and the Innovative Therapies for Children with Cancer network are collaborating together to introduce targeted agents in RMS. The role of bevacizumab in combination with standard chemotherapy is being evaluated in newly diagnosed metastatic RMS and other soft tissue sarcomas in a randomized phase II study. In the relapse setting a randomized phase II study of vincristine and irinotecan with or without temozolomide seeks to define the chemotherapy backbone to which targeted therapies will be added in future studies.

In the future, more flexible trial designs incorporating predictive and pharmacodynamic biomarkers may facilitate more rapid introduction of new drugs in the phase II setting, give a faster indication of their likely effectiveness and allowing the most promising new drugs to be taken forward in the phase III setting. In addition, transatlantic cooperation in trial design will enable early identification and introduction of those targeted therapies that are of most benefit to RMS patients.

Conflict of interest: *Ownership: F Hoffman La Roche. Advisory board: Steering committee for BERNIE trial, a randomised phase II study of chemotherapy with or without bevacizumab in newly diagnosed rhabdomyosarcoma and non rhabdomyosarcoma soft tissue sarcoma*

Special Session (Sun, 29 Sep, 17:00−18:00)
Concurrent Chemo-Radiotherapy Prediction of Outcome and Toxicity

206 INVITED

Predicting survival outcome for stage III lung cancer

C. Oberije[1]. *[1]MAASTRO Clinic GROW, Radiation Oncology, Maastricht, Netherlands*

Although the TNM staging system gives the same survival prognosis for all patients with stage III lung cancer, these patients form a very heterogeneous group, which leads to large differences in survival outcome. These differences can, to some extent, be explained by basic patient, tumor and treatment characteristics.

A short overview will be given of prediction models that have been developed, the factors that have been incorporated and the performance of the models. It will be shown that these models already outperform the prediction of doctors. In addition, the possible impact of new variables, derived from genetic or imaging information, will be discussed. Finally, the importance of collecting and sharing cohort data for modeling will be explained.

No conflict of interest.

207 INVITED

Predicting oesophageal and lung toxicity

J. Belderbos[1], C. Chen[1], M. Kwint[1], W. Uyterlinde[2], J. Nijkamp[1], M. Van den Heuvel[2], M. Van Herk[1], J. Sonke[1]. *[1]The Netherlands Cancer Institute, Radiotherapy, Amsterdam, Netherlands; [2]The Netherlands Cancer Institute, Thoracic Oncology, Amsterdam, Netherlands*

Background: The improved survival in locally advanced non-small cell lung cancer (NSCLC) patients treated with concurrent chemo-radiation (CCRT) comes at a price of increased oesophagus toxicity. Estimation of the probability to develop oesophageal toxicity or lung toxicity after CCRT is crucial. This allows for individual prescription of (adequate) tumour doses based on normal tissue complication probabilities. Several theoretical models have been developed to estimate the risk of radiation pneumonitis based on the planned dose distributions. These models simplify dose-volume histograms to a single parameter like the mean lung dose (MLD) or the volume of lung receiving more than a threshold dose (V_x). For conventional fractionated radiotherapy, both the MLD and the V_{13-20} are used for the prediction of RP. For acute oesophagus toxicity (AET) several dose-volume parameters were reported but for late oesophagus toxicity (LET) like stenosis and fistula, models are lacking.

Material and Methods: The dose-effect relation of AET (185 patients) and LET (171 patients) and dose-volume parameters of the esophagus after Intensity Modulated Radiotherapy up to 66 Gy in 24 fractions and concurrent daily cisplatin for NSCLC patients were investigated. To that

end, the dose distribution were first converted to Normalized Total Doses (NTD) to account for fractionation effects with an α/β-ratio of 10 Gy (AET) or 3 Gy (LET). Clinical parameters, onset and recovery times were analyzed as well.
Results: Radiation pneumonitis grade $\geqslant$3 was scored in 7% of the patients. A total of 22% patients developed AET toxicity and 6% developed grade $\geqslant$3 LET. For prediction of grade $\geqslant$3 AET the equivalent uniform dose (EUD) with n = 0.13 (high dose) was found to be the best predictor. Patients with un-recovered AET had a significantly ($p < 0.001$) higher risk of developing severe LET, compared to patients without or with a recovered AET. Higher grade of AET was also associated with a lower recovery rate. The median time to AET grade 3 was 30 days, with a median duration of 80 days. Prediction of LET $\geqslant$ grade 3 was done using $EUD_{n = 0.03}$, where all severe LET patients had an oesophageal EUD >70 Gy.
Conclusions: In routine clinical practice it is possible to estimate the probability and severity of lung toxicity as well as the occurrence of AET for each individual patient. Both the maximum grade and the recovery rate of AET were significantly associated with severe LET. In clinical practice, oesophageal $EUD_{n = 0.03}$<70 Gy could be a dose constraint to prevent severe LET.
No conflict of interest.

208 INVITED

Resectability after concurrent chemoradiotherapy (CCRT)

P. Van Schil[1]. [1]*Antwerp University Hospital, Departement Thorax- en Vaatheelkunde, Antwerp, Belgium*

Due to a variable degree of fibrosis that occurs after chemoradiation surgical resection may become technically challenging, especially after high-dose concurrent chemoradiation. A distinction has to be made between induction chemoradiotherapy followed by surgical resection and so-called salvage surgery after previous full-dose chemoradiation.
For locally advanced stage IIIA-B non-small cell lung cancer (NSCLC) chemoradiation has become standard treatment but in selected patients induction therapy may be followed by surgical treatment when a downstaging is obtained and a complete resection seems feasible. However, a higher morbidity and mortality have to be anticipated, especially when a pneumonectomy has to be performed. In the Intergroup 0139 trial patients with proven stage IIIA-N2 NSCLC were randomized between full-dose chemoradiotherapy and induction chemoradiation followed by surgery. In the surgical arm mortality after lobectomy was 1% in contrast to 25% after pneumonectomy. In a recent review induction chemoradiation was not found to be superior to induction chemotherapy alone in stage IIIA NSCLC. Superior sulcus or apical chest tumours respond very well to induction chemoradiation and good long-term survival results have been reported. Most severe complications after induction chemoradiation include empyema and bronchopleural fistula which are difficult to treat with still a very high mortality rate and often a prolonged hospitalisation time in surviving patients.
Locoregional recurrence of NSCLC may occur months or years after full-dose chemoradiation given with curative intent. In selected patients salvage surgery is sometimes the only remaining therapeutic option, especially when an infected cavity is present. At the present time only a few reports have appeared in literature but it is obvious that surgical resection in these cases represents a real challenge to thoracic surgeons with an increased morbidity and mortality rate. Such cases should be discussed individually at a multidisciplinary team to determine optimal treatment. These patients should be operated in high-volume institutions with adequate experience, also in postoperative care. As high-dose radiotherapy in combination with chemotherapy is more frequently utilized, thoracic surgeons will increasingly be confronted with salvage surgery in often desperate cases and should be prepared to deal with this new category of patients representing new challenges, as well intraoperatively as postoperatively.
No conflict of interest.

Special Session (Sun, 29 Sep, 17:00–18:00)
New Clinical Opportunities in Targeted Therapies

209 INVITED

Combination modality treatment for brain metastases

G.V. Long[1]. [1]*Melanoma Institute Australia and The University of Sydney, Medical Oncology, Sydney, Australia*

Brain metastases are difficult to manage and carry a poor prognosis regardless of the solid tumour from which they arise. They are frequent in melanoma, a cancer for which there was no systemic therapy that prolonged overall survival until recently. Immunotherapy and targeted therapy (e.g. BRAF inhibitors) prolong survival in patients with metastatic melanoma, and have shown activity in brain metastases. Using melanoma as an example, the approach to the management of brain metastases using systemic and local therapies will be discussed, with a focus on the shift in the treatment paradigm due to highly active systemic therapies. Understanding the patterns of response and relapse to systemic therapies in brain metastases is critical for the planning of treatment with local therapies such as surgery and stereotactic radiosurgery. For example, the BRAF inhibitor dabrafenib reduces the size of brain metastases in most patients with V600 BRAF-mutant melanoma, with a disease control rate of over 80% in the brain. However, relapse is not necessarily in the brain, and although the median duration of response in the brain is over 20 weeks, some patients continue to respond for over a year. Anticipating the duration of response and the type of relapse is important for optimal management and use of local therapies. Most importantly, inclusion of patients with active brain metastases in early-phase drug trials is a priority, and remains a barrier to better outcomes for patients with brain metastases.
Conflict of interest: *Advisory board: GSK, Roche, Novartis, BMS*

210 INVITED

Combination treatment for irresectable melanoma masses

O. Nieweg[1]. [1]*The Netherlands Cancer Institute, Skin and Melanoma Center/Surgery, Amsterdam, Netherlands*

Unresectable melanoma masses are rare, but if they occur they are usually lymph node metastases in the axilla or in the pelvis. Unresectable in-transit metastases are more frequent but their number rather than their size typically prevents resection. Regional drug therapy is the traditional approach if such lesions are situated on a limb. Regional perfusion results in a complete response in some 55% of the patients and a partial response in another 35%. A partial response is usually sufficient to allow excision of the remaining lesions.
An underrated approach is the combination of intravenous dacarbazine and topical dinitrochlorobenzene, an allergenic substance. The complete response rate with this regimen is 25%.
The armamentarium of surgeons is quickly expanding. Electrochemotherapy combines high-intensity electric pulses over the mass with intravenous or intralesional cytotoxic drugs. The electroporation improves drug delivery into the tumor cells. A systematic literature review showed a complete response rate of 57% and a partial response rate of 81%.
Diphencyprone is a topical immunogenic drug with a complete response rate of 14% and partial response rate of 8% in patients with intradermal metastases. The immune-stimulatory imiquimod cream combined with the depigmenting agent monobenzone is another promising approach for dermal metastases and resulted in five partial responses in eight patients at our institution. These treatments can be combined with laser ablation. Rose Bengal (PV-10) works for subcutaneous lesions with a complete response rate of 24% and a partial response rate of 13%.
Oncovex is a vaccine made of an oncolytic Herpes virus. It is administered in the tumor mass where it encodes GM-CSF, which stimulates the immune system. In a phase II trial, 16 percent of patients achieved a complete response and 10 percent achieved a partial response.
The recently approved drug Vemurafenib with its swift response offers an interesting option in patients with the V600E BRAF mutation and quickly growing non-resectable masses. Half of the patients respond, although responses are not durable and rarely complete. However, the speed of the response may offer a time window for resection before the metastasis becomes resistant and starts to grow again. This appears to be good option in patients with inoperable lymph node metastases.
In conclusion, melanomologists have an increasing number of options for combination treatment of unresectable melanoma masses. At this point, there is not a standard regimen.
No conflict of interest.

Special Session (Sun, 29 Sep, 17:00–18:00)
Hope Across Cancer Care

211 INVITED

Portraying hope – a study among woman newly diagnosed with gynecological cancer

K. Hammer[1]. [1]*University of Faroe Islands, Faculty of Natural and Health Sciences – Dept. of Nursing, Tórshavn, Faroe Island*

Aim: The aim of the thesis *Portraying hope among women with newly diagnosed gynaecological cancer* is to examine hope experienced the day the woman get diagnosed with cancer. Hope is also closely linked

to hopelessness, and the day you get a cancer diagnose can be a day of emotional chaos and a feeling that one has lost control over life. The feeling of hopelessness can easily appear. However, precisely because hope is a part of life, hope is present, in one form or another.
Background: Helping a patient to find hope in illness and suffering is one of the cornerstones of humanistic-oriented nursing where also dignity, respect, integrity and caring are overarching values. Knowledge of how patients themselves feel hope at the time of diagnosis will enhance the nursing knowledge base and will increase understanding and opportunities for clinical nurses. Cancer is a common and often life-threatening disease and also the word cancer have a stigmatizing meaning. Gynaecological cancer is one of the most frequent cancers among women.
Methods: This qualitative study was carrying out at a surgical unit at a Danish University Hospital, in order to provide a comprehensive understanding of hope. The data collection is based both on interviews and drawings. Fifteen women, all diagnosed with gynaecological cancer, were interviewed the same day they received their diagnosis. Semi-structured interviews were chosen in order to investigate the informants lived experiences of hope. Data was analyzed using a phenomenological and a visual approach.
Results: In this thesis hope as collected in a synthesis showing three sides, an internal, an external and a commotional force are belonging together, and where hopelessness is seen as a dark shadow in a circumference of the triangle shaped design. The findings discovered of the close relationship between hope and hopelessness supports the need for nurses and other health care to supports patients find hope starting from time of diagnosis.
Perspective and Implication: New in this study is to use interviews and drawings in combination and that hoped stimulated by external force loaded from the nature. Drawings and conversations about the drawings gave a deeper understanding of the phenomenon of "experience of hope." This study, which creates new knowledge about patients' experiences of hope in general and describes hope in newly diagnosed gynaecological cancer, are importance for clinical nursing practices. The results may create a platform for discussion between nurses and compared with their own experiences. Perhaps crayons and drawing paper could be included as standard in clinical nursing practices when interview with patients about hope or other existential topics are actual. A combination of interview and drawing could have a therapeutic and explanatory of those involved. Hope could give life force − whether the patient has newly diagnosed or otherwise in need of support and nursing care.
No conflict of interest.

212 INVITED
Nurses' perspective of hope in cancer care

E. Benzein[1]. [1]*Linnaeus University, Kalmar, Sweden*

Background: Nurses who meet patients with cancer in palliative care have a great challenge to create possibilities to facilitate the experience of hope in patients and their families. Nurses need to be aware of the phenomenon *per se* and each patient's potential for experiencing hope. A most important start is that the nurses themselves become aware of their own perceptions of hope related to their patients. Research show however that nurses' experiences are not always in line with the patients' experiences.
Material and Methods: Individual interviews with nurses in oncology care was performed in a previous study (n = 9) and some additional interviews is ongoing. Nurses are asked to narrate their reflections on hope as a phenomenon and their experiences of patients who they consider have had hope and those who had not. Interviews are analyzed by a hermeneutic approach.
Results: The results from the previous study showed that nurses view hope as an inner strengths and energy in their patients. Hope for patients could also be to achieve and experience significant events, often including relatives and friends. The nurses argued it was from relatives and friends the patients got the most important support to experience hope. Being in the home milieu was also a way to support hope. Further, many patients put their faith in various treatments and if nurses support the patients' decisions it is also a source of hope for the patients. The nurses thought that nursing actions could both foster and reduce hope in their patients.
The analysis of additional interviews is ongoing and will be presented at the conference together with a comparison of the experience of hope from the patients' perspective.
Conclusion: Nurses can be important persons for patients with cancer and their families in order to experience hope. By being aware of one's own perceptions of hope nurses can open up space to invite patients and families to narrate their experiences and needs in order to experience hope. The nurse-patient/family relationship should be characterized by a partnership in which hope can be created in a collaborative way.
No conflict of interest.

213 INVITED
When hope is all that is left: Hope and end of life care for cancer patients

H.W.M. Van Laarhoven[1]. [1]*Academic Medical Center, Department of Medical Oncology, Amsterdam, Netherlands*

Hope can be a valuable asset in coping with terminal disease. However, fostering hope in the context of end of life care may be complicated. How can there be hope if life is coming to an end? Hope has been defined as 'a confident yet uncertain expectation of achieving a future good which, to the hoping person, is realistically possible and personally significant'. This definition highlights three important characteristics of hope. It refers to personal significance, a future perspective, and combines confidence with uncertainty. In this presentation we will discuss the relevance of these characteristics for end of life cancer care.
Although the concept hope relates to personal significance, it does not state *what* is personally significant. Hope may refer to hope for cure or prolongation of life, but also to a broader perspective of living life to the fullest.
Hearing that the disease is incurable destroys one's future perspective in a split second. To maintain hope, some kind of future perspective is needed, however short the time ahead may be. The HP's main task is to restore this perspective by discussing different themes, giving patients a new perspective which allows them to live full lives until the end. Such a focus on the future, rather than the past, may be related to reduced levels of distress, even in the last phase of life.
The characteristic of hope combining confidence with uncertainty does not preclude honesty of HPs. In fact, the majority of patients and their caregivers report that they want the HP to be honest when discussing prognosis and end-of-life issues. However, patients may differ in their view what constitutes a honest approach. They may request full disclosure, including statistical information about their life expectancy, while others prefer to remain partly ignorant and receive general information only. In general, highly explicit information combined with the reassurance that patients will receive continued support from their HP in the course of progressive disease, decreases patients' uncertainty and anxiety, while increasing self-efficacy and satisfaction.
No conflict of interest.

Special Session (Sun, 29 Sep, 17:00−18:00)
Is There a Role for Surgery in the Management of HCC?

214 INVITED
Value of liver function tests and volumetry

P. Pessaux[1], L. Soler[1], T. Piardi[1], D. Mutter[1], J. Marescaux[1]. [1]*Nouvel Hôpital Civil, Service de Chirurgie Hépato-biliaire et Pancréatique, Strasbourg, France*

The hepatic functional reserve may be evaluated by the association of the measurement of the volume of the future remnant liver and the assessment of the preoperative liver function. The importance of assessing liver function has been further increased because several aggressive preoperative therapies could alter the liver function and so decrease the postoperative outcomes.
Imaging reconstruction techniques in three dimensions is mandatory to evaluate the total volume of the tumors and the volume of non-tumoral liver. Although the normal liver tolerates removal of up to 60−70% of its volume, the extent to which the liver parenchyma may be resected in patients with Chemotherapy-associated steatohepatitis has not yet been clearly defined. The 3D-CT has been shown to be the most adequate procedure for measurement of liver volumes. When the volume of the future remnant liver seems to be insufficient, portal embolization or two-stage hepatectomy has been recommended in order to improve the safety of the procedure.
Standard liver biochemistry tests have not been shown to be of any predictive value. Other methods have included measurement of uptake of organic anions (such as bromsulphtalein, rose Bengal and indocyanine green (ICG)), the arterial ketone body ratio, redox tolerance test, aminopyralene breath test and the amino acid clearance test. These tests measure different aspect of hepatic function and may not correlate with one another. The ICG clearance test appears to be the best discriminating investigation. Hepatectomy involving resection of up to 60% of the parenchyma can be justified in patients with normal liver function and with ICG retention at 15 minutes value <20%. Minor hepatectomies can be accomplished even if ICG retention at 15 minutes reaches 23 to 25%.

Nuclear imaging with variety of agents has existed for years. Synthetic asialoglycoprotein, galactosyl-neo-glycoalbumin was complexed to 99m-Tc to study hepatocyte binding via asialoglycoprotein receptor. In addition, imaging provided volumetric/anatomic information, as well as a functional assessment.
No conflict of interest.

Scientific Symposium (Mon, 30 Sep, 09:00−11:00) Metastatic Breast Cancer: From Biology to Therapeutic Strategies

217 INVITED
Dealing with tumour heterogeneity: The exception or the rule?

M. Piccart[1], D. Zardavas[1]. [1]*Institut Jules Bordet, Bruxelles, Belgium*

Breast cancer is a heterogeneous disease, with its diversified clinical and histological aspects having been recognized since a long time. Gene expression profiling analysis studies deepened our understanding of this intertumoural heterogeneity, with different molecular subtypes of breast cancer identified among different patients. Recently, our conceptual view of cancer has been shifted to an ecological perspective, according to which breast cancer progression proceeds in a Darwinian-like branched evolution manner. Powerful next generation sequencing and other high-throughput molecular analysis techniques enable us to interrogate the complex intratumoural heterogeneity of breast cancer, with cancer cells within one tumor of any given patient displaying heterogeneity in a number of their molecular features. This refers to both spatial and temporal heterogeneity, as tumor cells of different topologies or different phases of the life cycle of breast cancer have been shown to display different molecular and phenotypic profiles. Importantly, evidence supports the existence of both genetic and non-genetic heterogeneity, with the existence of subclonal cancer cell populations exhibiting distinct landscapes of genetic and epigenetic aberrations. In the metastatic setting intratumoural heterogeneity is a significant impediment to precision medicine, since to the present day we have been basing our therapeutic strategy upon analysis of the primary tumour. However, as already shown by conventional pathology assessments, discordance in biomarkers dictating the clinical management of breast cancer patients can occur between primary and metastatic tumor lesions. Lastly, data supports that molecularly targeted agents pose a selective evolutionary pressure against breast cancer cells, inducing treatment resistance through the emergence of intratumoural heterogeneity. These aspects render the issue of tumor sampling extremely important, since the genetic and non-genetic landscape of molecular changes in the metastatic lesions should guide treatment decisions. To this end, molecular analysis of plasma-derived biomarkers holds a great promise. Additionally, “warm” autopsy studies can help us reconstruct the evolutionary tree of breast cancer disease. Having entered the era of individualized cancer medicine, the dissection of this tumour heterogeneity is of paramount importance, and this is why the Breast International Group (BIG) is launching an ambitious longitudinal study that will consist in target sequencing (n = 400 genes)of 1000 metastatic lesions together with their respective primaries with clinical follow-up (the “PRISM” project).

218 INVITED
How to best assess response: New imaging techniques

E. De Vries[1], F. Bensch[1], A.H. Brouwers[2], C.P. Schroder[1]. [1]*University Medical Center Groningen, Department of Medical Oncology, Groningen, Netherlands;* [2]*University Medical Center Groningen, Department of Nuclear Medicine and Molecular Imaging, Groningen, Netherlands*

Currently, treatment response monitoring in metastatic breast cancer is based on measurement of changes in anatomical sizes. This is in clinical trials with primary endpoint of objective response done according to Response Evaluation Criteria in Solid Tumors (RECIST) and is generally performed every other cycle. This approach provides no insight in changes of molecular characteristics, and assessment of response takes at least weeks before information is obtained. Moreover, bone metastases, being the most common site of distant metastases in breast cancer, are not measurable by RECIST. In the era of targeted medicine, knowledge of specific tumor characteristics becomes more important. A potential way to assess this is by means of molecular imaging. Techniques for molecular imaging include magnetic resonance imaging (MRI), optical imaging, and radionuclide imaging with single photon emission computed tomography (SPECT) or positron emission tomography (PET).
Currently, most know-how is available about PET. Molecular imaging by PET can visualize general tumor processes, such as glucose metabolism with ^{18}F-fluorodeoxyglucose (^{18}F-FDG) and DNA synthesis with ^{18}F-Fluorodeoxythymidine (^{18}F-FLT). In addition, an increasing number of more specific targets, such as hormone receptors, growth factor receptors and growth factors can be evaluated. Moreover, PET imaging provides a whole body image, also allowing assessment of heterogeneity between and within lesions.
Optical imaging can be performed to provide real-time visualization of small lesions during surgery, which may aid intra-operative staging and image-guided surgery. We are currently performing a feasibility fluorescence imaging study with the NIFR 800CW-bevacizumab tracer in primary breast cancer. If successful, optical imaging with for example a handheld probe might also be able to support evaluation of drug effects.
Molecular imaging may thus be of value for personalized treatment by providing insight in the expression of drug targets and by intra-operative tumor visualization. Additionally, molecular changes may be observed soon after therapy initiation, which may serve as early predictor of response. In order to define clinical utility of these techniques, including burden for the patient and evaluation of costs, results from (ongoing) clinical trials are required.
Conflict of interest: *Advisory board: Genentech, Roche. Corporate-sponsored research: to the UMCG, Novartis, Genentech, Roche*

219 INVITED
How to best assess response: Blood-based tests

J.Y. Pierga[1], R. Lebofsky[2], F.C. Bidard[1]. [1]*Institut Curie, Department of Medical Oncology, Paris, France;* [2]*Institut Curie, Circulating Biomarkers Lab SIRIC, Paris, France*

Serum markers as carcinoembryonic antigen (CEA) and cancer antigen 15.3 (CA 15−3) have been developed in metastatic breast cancer (MBC) patients as tools for non-invasive assessment of the tumour burden. Quantitative variations are used to assess treatment efficiency. However, the specificity and sensitivity of serum tumour are considered as low and no clear consensus exists on what threshold and/or variation are clinically significant. Additionally, it is not uncommon for a phenomenon of flare of tumour markers to occur in the first 6 weeks of an efficacious therapy. According to ESMO recommendations, a change in tumour markers alone should not be used as the only determinant for treatment decisions. Since a study by Cristofanilli et al. in 2004, the enumeration of circulating tumour cells (CTC) has emerged as a promising biomarker. Although there are numerous methods to detect CTC in the research setting, the CellSearch System is the only test that has repeatedly demonstrated its clinical validity (i.e. association with outcome) in breast cancer. Moreover, we have recently confirmed in a level of evidence 1 study that changes in CTC count after one cycle of chemotherapy were associated with progression-free survival and demonstrated that CTCs, but not serum markers, have an independent prognostic value in multivariate analysis. Current prospective large interventional studies have been specifically designed to demonstrate that CTC enumeration/ characterization may improve the management of MBC patients: STIC CTC METABREAST (France) and Endocrine Therapy Index (USA) assess the CTC-guided hormone therapy vs chemotherapy decision in M1 patients; SWOG0500 (USA) and CirCe01 (France) assess the CTC count changes during treatment in MBC patients. These trials are expected to be the pivotal trials for CTC implementation in the routine management of MBC patients. A third blood-based marker is particularly promising, and is currently under investigation: circulating tumour DNA

(ctDNA). These specific DNA fragments can be detected in the plasma, in general after the genetic alterations harboured by the primary tumour and/or its metastases have been characterized. Several highly sensitive techniques, such as BEAMing, PAP, or digital PCR have been used for the purposes of finding a single ctDNA molecule within a large volume of plasma sample. Recent pioneering study has shown that ctDNA detection is associated with tumour burden. Demonstration that the method can be used to take better care of patients with MBC in a cost-effective manner awaits further studies. Next generation sequencing analysis of ctDNA in plasma could also complement current invasive biopsy approaches to identify mutations associated with acquired drug resistance in advanced disease.

220 INVITED

Personalised drug discovery: An academic experience

F. Andre[1], M. Arnedos[1], S. Delaloge[1], H. Bonnefoi[2], T. Bachelot[3], J.C. Soria[4]. *[1]Institut Gustave Roussy, Department of Medical Oncology, Paris, France; [2]institut Bergonie, Department of Medical Oncology, Bordeaux, France; [3]centre Leon Berard, Department of Medical Oncology, Lyon, France; [4]institut Gustave Roussy, Department of Medical Oncology, Villejuif, France*

Background: Breast cancer includes a large number of rare genomic segments defined by genomic alteration on targetable genes. The use of multiplex genomic technologies have been proposed in order to optimally drive patients to clinical trials testing targeted therapies. Based on this background, we have developed molecular screening programs that aim at genotyping breast cancer and treat them accordingly.
Patients and methods: The current presentation will update participants on two molecular screening programs: SAFIR01 and MOSCATO, with an emphasis on breast cancer patients. These two programs use array CGH and sequencing (sanger and next generation sequencing) to identify a targetable genomic alteration.
Results: SAFIR01 was a multicentric trial performed in 18 centers that included 423 patients. 48 patients have been treated with a targeted therapy matched on genomic alteration, with evidence on antitumor activity in 28% of them. MOSCATO is a monocentric trial that aims at including 600 patients. Update results will be presented about this trial.
Perspectives: Several additional molecular screening programs are being developed including PRISM program from BIG, PROFILER from Centre Leon Berard. These molecular screening trials aim at identifying rare genomic alterations that are associated with drug sensitivity. The molecular screening programs feed large database that will be used to develop algorithm for individual drug response. The mid-term perspective will be to evaluate, in the context of randomized trials, whether the use of these algorithms improve outcome.

Scientific Symposium (Mon, 30 Sep, 09:00−11:00) **Personalised Treatment in Colorectal Cancer**

221 INVITED

Are predictive/prognostic biomarkers/platforms ready to be placed in adjuvant treatments?

A. Roth[1]. *[1]University Hospital, Oncosurgery, Geneva 14, Switzerland*

Recent improvements in the knowledge of the molecular biology of colon cancer have provided us with new tools, which might enhance our ability to assess the prognosis and the risk of relapse of curatively resected colon cancer. These would allow us to better select patients in the need of adjuvant therapy and avoid over-treatment of tumors with good prognosis. However, despite of the large amount of exciting positive results obtained with molecular markers (mutations,changes in expression or ploidy alterations etc) and with the development of sophisticated signatures based on extensive genomic profiling, many of these potential tools lack formal validation to allow us to apply them safely in daily practice. In the present paper we will detail the present status of this innovative field with special emphasis on the traps we could encounter in case of insufficient validation of the molecular markers/signatures used.

222 INVITED

Selecting for maintenance or stop-and-go strategy in metastatic colorectal cancer

A. De Gramont[1]. *[1]Hôpital Saint Antoine, Service d'Oncologie Médicale, Paris, France*

Survival in metastatic colorectal cancer is improving. Several recent trials have shown a median survival in excess of two years with some patients still alive after 5 years. Continuing first-line toxic chemotherapy for such a long period negatively impacts the quality of life. Furthermore, some drugs, like oxaliplatin, have a cumulative toxicity which occurs before tumor progression. Stopping oxaliplatin after 6 cycles of FOLFOX reduces the neurotoxicity and allows reintroducing later the drug which remains particularly active in case of a long interval between the two periods of treatment. These facts provide a rationale to develop alternative strategies such as oxaliplatin stop and go with maintenance therapy after a few cycles of combination chemotherapy or even a complete stop in chemotherapy followed by reintroduction of oxaliplatin in sensitive patients who did not develop neurotoxicity. Recent trials have given data to support this strategy and have studied maintenance therapy with fluoropyrimidines alone or in combination with bevacizumab, bevacizumab alone or bevacizumab with erlotinib.
Without any patient selection, fluoropyrimidines plus bevacizumab is the most active and recommended maintenance therapy. Fluoropyrimidines alone, 5-fluorouracil or capecitabine, or bevacizumab alone also appear beneficial over a complete stop in therapy. Bevacizumab plus erlotinib is superior to bevacizumab alone regardless of the KRAS status. However, based on retrospective data, a subset of patients with MCRC may benefit from stopping chemotherapy: patients with normal platelet count at baseline and/or patients with normal CEA level after 3 months of oxaliplatin-based chemotherapy. New studies are ongoing or needed to further improve maintenance therapy: maintenance or stop and go after irinotecan-based chemotherapy, capecitabine or erlotinib in combination with bevacizumab, new combinations of chemotherapy such as S1 or TAS 102 and targeted therapies such as regorafenib or others.

Selecting for anti-EGFR inhibitors in CRC: KRAS and beyond?

Abstract not received.

224 INVITED

Do we have a light for predictive biomarkers with angiogenesis inhibitors or are we still lost in translation?

D. Lambrechts[1]. *[1]University of Leuven, Vesalius Research Center, Leuven, Belgium*

Angiogenesis inhibitors have been established over the past decade as valuable tools to inhibit tumor growth and improve tumor response to chemotherapy. In advanced colorectal cancer, these include the humanized monoclonal antibody against VEGF, bevacizumab, the more recently developed soluble VEGF receptor fusion protein, aflibercept, as well as the multikinase inhibitor of VEGF-receptors and other pro-angiogenic molecules, regorafenib. Although these molecules have changed clinical practice, some patients do not respond or gradually develop resistance, resulting in rather modest gains in terms of overall survival. A major challenge is to develop robust biomarkers that can guide selection of patients for whom bevacizumab therapy is most beneficial. During my presentation, I will highlight recent progress in finding such markers, including the first results from randomized phase III clinical trials evaluating the efficacy of bevacizumab in combination with comprehensive biomarker analyses. In particular, these studies suggest that circulating levels of short vascular endothelial growth factor A (VEGF-A) isoforms, expression of neuropilin-1 and VEGF receptor 1 in tumors or plasma, and genetic variants in VEGFA or its receptors are strong biomarker candidates. The current challenge is to expand this first set of markers and to validate it and implement it into clinical practice. In breast cancer, a first prospective biomarker study known as MERiDiAN, which will treat patients stratified for circulating levels of short VEGF-A isoforms with bevacizumab and paclitaxel, is ongoing and will hopefully provide us with new directions on how to treat patients more efficiently.

Treatment Planning of Lung Cancer Using Innovative Therapy

225 INVITED

Latest developments in imaging

C. Fink[1]. [1]*AKH Celle, Abteilung Radiologie, Celle, Germany*

Imaging plays a major role in the entire spectrum of diagnosis and treatment of lung cancer ranging from tumor detection to post-treatment follow-up and surveillance.
This presentation will give an overview over the current perspectives of modern imaging for the purpose of image-guided therapy of lung cancer. This includes image guided radiotherapy, as well as imaging in the context of innovative targeted medical therapy. The presentation will especially focus on new imaging techniques (PET-CT, functional CT, functional MRI) allowing functional tumor characterization and improved patient selection.
No conflict of interest.

226 INVITED

Drug uptake − monitoring and prediction

S. Burgers[1]. [1]*The Netherlands Cancer Institute, Department of Thoracic Oncology, Amsterdam, Netherlands*

The most commonly used and most reliable methods to predict responses of NSCLC to EGFR-tyrosine kinase inhibitors are screens for activating EGFR mutations. Monitoring of TKI- plasma levels is hardly incorporated in daily clinical care. In contrast to the dosing of chemotherapeutics, dosing of small molecules is not adapted to body surface or other individual traits of the patient. And surprisingly, the fixed dose for these drugs seems appropriate for most patients. Nevertheless, monitoring plasma levels of, for instance, erlotinib and its active metabolite *O*-desmethyl erlotinib might be appropriate when tumors do not respond despite the presence of activating mutations, when unexpected side effects arise, or when alternative dosing schedules are used like the weekly high-dose erlotinib schedules used for central nervous system metastases or to overcome acquired resistance mechanisms. Preliminary studies using radiolabeled erlotinib seem to show a correlation between drug uptake and its clinical efficacy.
TKI's induce drastic initial responses in sensitive tumors. However, almost all patients develop drug resistance within a year. Molecular heterogeneity of cancers that appear similar when examined through conventional diagnostics requires new predictive markers to foretell responses to specific therapies. Techniques like patient derived xenografts and short term *ex vivo* tumor cell cultures are used to explore the sensitivity of individual tumors for multiple anti-cancer agents, and have resulted in exciting and promising data. Whether the *ex vivo* techniques represent the *in vivo* tumor characteristics remains to be established, preferentially by translation of the data to the clinic.
No conflict of interest.

227 INVITED

Radiomics: A new paradigm in the analysis of medical imaging data − The example of lung cancer

P. Lambin[1]. [1]*Maastricht University Medical Centre, Maastricht, Netherlands*

"Radiomics" refers to the extraction and analysis of advanced quantitative imaging features in high throughput from medical images, including computed tomography (CT), positron emission tomography (PET) and magnetic resonance imaging (MRI) (Lambin *et al*. EJC 2012; ww.radiomics.org). Importantly, these features are designed to be extracted from standard-of-care images, leading to a very large potential subject pool. Radiomic data are in a mineable form that can be used to build descriptive and predictive models. The core hypothesis of radiomics is that these models, which can include biological or medical data, can provide valuable diagnostic, prognostic or predictive information. Also, relating image features to phenotypes or gene-protein signatures is being investigated. The radiomics enterprise can be divided into four processes, each with its own challenges that need to be overcome: (1) image acquisition and reconstruction, (2) image segmentation and rendering, (3) feature extraction and qualification, (4) bioinformatic analyses. Each step, especially involving large datasets, poses unique challenges. The focus of this presentation will be on the predictive value of CT & FDG-PET radiomics features of non-small cell lung cancer and head and neck cancer, complemented by preclinical tumour data. Finally we will describe the current and potential applications of radiomics to other problems in oncology.

Scientific Symposium (Mon, 30 Sep, 09:00−11:00)

Joint ECCO/JSCO Session: Extended Lymph Adenectomy in GI Cancer

228 INVITED

European view gastric cancer

H. Hartgrink[1]. [1]*Leiden University Medical Centrum, Surgery, Leiden, Netherlands*

The extent of lymphadenectomy is under discussion since Billroth performed the first gastrectomy in 1881. Since then a lot of studies have been performed to find out to what extent a lymph node dissection should be performed. Theoretically, removal of a wider range of lymph nodes by extended lymph node dissection increases the chances for cure. Such resection, however, may be irrelevant if there are no lymph nodes affected or if the cancer has developed into a systemic disease, or if it increases morbidity and mortality substantially.
D2 dissections became standard in the 90's of the last century in East Asian countries. Western countries, however, found that D2 dissections lead to a higher mortality, which offset a possible survival advantage. More recent evaluations, however, show that there is an advantage for D2 dissections even in Western patients. More extended dissections in Japan (i.e. D4) did not further improve survival.
In order to reduce the post-operative mortality, D2 dissections in Europe do not include pancreatico-splenectomy anymore, unless there is direct invasion into these organs. Furthermore registration and centralisation should lead to a further decrease in post-operative morbidity and mortality. Data bases of several European countries are now being combined in the Eurecca upper GI project in order compare protocols, evaluate current treatment and to define future treatment protocols.
Finally more individual techniques of lymph node removal like Image Guided Surgery are explored to optimize the extent of lymph node dissection.

230 INVITED

Optimal nodal dissection for curable advanced gastric cancer

M. Sasako[1], S. Kikuchi[1], M. Takemura[1], T. Oshima[1], N. Kaibe[1], H. Yamashita[1], H. Niwa[1], M. Takii[1]. [1]*Hyogo College of Medicine, Surgery Division, Nishinomiya, Japan*

There are several evidences to support superiority of D2 dissection for curable advanced gastric cancer, although two major European trials failed to prove the benefit in their primary endpoints.
1. Lymphadenectomy for gastric cancer is quite different from that of colonic surgery. In the latter, mesentery can be taken out en-bloc by just ligating and cutting the first trunk of mesentery. In the former exceptionally, the organ has two mesenteries (dorsal and ventral) and the dorsal mesentery incorporate the pancreas body and tail. This means D2 level nodal dissection is special type of dissection, preserving all second branches of the mesentery. In many cases, even in this anatomical disadvantage, complete dissection from the root of first trunk (i.e., celiac artery) and its braches resulted in better survival than D1 dissection.
2. Dutch and MRC D1 versus D2 study were surgical RCTs which have been carried out before each participant learned the technique and post-operative care to a plateau level. Immediate high mortality offsets the benefit of D2 surgery, which was eventually shown after 15 years follow-up by significantly better disease specific survival rate and significantly better local control. High mortality in these studies was attributed to limited experience to cure post-operative surgical complications throughout the study period due to extremely low hospital volume. This was suggested strongly by much lower hospital mortality in Italian study where they carried out a feasibility study of 200 cases among only 8 hospitals and participant had more cases and experience to avoid treatment related death after surgery.
3. A Taiwanese RCT proved the benefit of D2 dissection over D1. Due to high hospital and surgeons' volume, their hospital mortality was zero. This study is the only one which could show statistically significant improved OS after D2 than D1.
4. In the past, many of Western surgeons claimed that gastric cancer with nodal metastasis is already a systemic disease and therefore incurable even by providing a good local control. INT0116 study compared R0 surgery alone versus post-operative chemoradiation treatment, for first,

clearly demonstrated the benefit of good local control for curable gastric cancer.
It is already known that hospital mortality after D2 surgery for gastric cancer can be reduced as low as 3% by good training and having relatively high volume even in Western patients.
Now, not only in Asia but also in the West, both in Europe and USA, D2 is recommended as standard surgery for potentially curable gastric cancer.

231 INVITED

Lateral lymph node dissection for rectal cancer − A Japanese perspective

T. Watanabe[1], T. Akiyoshi[2], K. Sugihara[3]. *[1]The University of Tokyo, Division of Surgery, Tokyo, Japan; [2]Cancer Institute Hospital, Division of Surgery, Tokyo, Japan; [3]Tokyo Medical and Dental University, Division of Surgery, Tokyo, Japan*

In Japan, lateral lymph node dissection has been widely performed to reduce local recurrence after surgery for low rectal cancer. However, in many countries, lateral lymph node metastasis is considered as a systemic disease and lateral lymph node dissection is not performed as a standard therapy. Therefore, we examined whether lateral lymph node metastases are metastatic disease or part of regional lymph node metastases that are amenable to curative resection. We extracted data of all patients with stage I−III low rectal cancer who underwent curative resection from 1978 to 1998 from the Multi-institutional Registry of Large Bowel Cancer in Japan. We compared overall survival (OS) and cancer-specific survival (CSS) between patients with only mesorectal lymph node metastasis (mesorectal-Node group) and lateral lymph node metastasis localized to or extending beyond the internal iliac area (internal-LN group or external-LN group). Among 11,567 patients, lateral lymph node dissection was performed in 5,789 (50%). Mesorectal-Node, internal-LN, and external-LN metastases were present in 3,905 (34%), 411 (3.6%), and 244 (2.1%) patients, respectively. Next, we subdivided the mesorectal-Node group according to the classification by the American Joint Committee on Cancer. Both in 5-year OS and CSS, there were not significant differences between the N2a and internal-LN groups (OS: 45% vs. 45%, *P* =. 9585; CSS: 51% vs. 49%, *P* =. 5742). Furthermore, there were not significant differences between the N2b and external-LPLN groups either (OS: 32% vs. 29%, *P* =. 3342; CSS: 37% vs. 34%, *P* =. 4347). When we compared 5-year OS and CSS between the external-LPLN group and the stage IV patients who underwent curative resection, external-LPLN group showed significantly better 5-year OS and CSS than stage IV patients (OS: 29% vs. 24%, *P* =. 0240; CSS: 34% vs. 27%, *P* =. 0117). These results suggest that lateral lymph node metastasis is not a systemic disease and can be considered as regional lymph node metastasis in low rectal cancer. However, metastasis extending beyond the internal iliac area is associated with poorer survival. From a technical point of view, open surgery is the standard procedure to perform lateral lymph node dissection. In Japan, there are institutions where lateral lymph node dissection is performed laparoscopically. However, it is still not clear whether laparoscopic procedure can achieve the same quality as compared to open surgery in lateral lymph node dissection. On the other hand, recent studies have shown that robotic surgery with enhanced dexterity and stable camera platform may provide a powerful additional tool for optimal management of rectal cancers. We performed rectal cancer surgery in 35 cases including 10 cases with lateral lymph node dissection. In our experience, robotic approach seems to allow better ergonomics and more refined dissection during lateral lymph node dissection. However, further studies are needed to confirm the usefulness of robotic approach both from oncological and functional aspects.
No conflict of interest.

Scientific Symposium (Mon, 30 Sep, 09:00−11:00) **Potential Novel Targets in Gynaecological Cancer**

232 INVITED

Novel membrane receptor inhibitors

A. Leary[1]. *[1]Institute Gustave Roussy, Villejuif, France*

Early trials of membrane receptor inhibitors, such as gefitinib, erlotinib, lapatinib or trastuzumab in unselected patients (pts) with cervical, ovarian or endometrial cancer were negative. However advances in the profiling of gynaecological cancers and new inhibitors targeting c-Met, FGFR, HER3, IGF1R, or the folate receptor offer new hope. Data from the TCGA have made it quite clear that ovarian (OC) and endometrial cancers (EC) are heterogeneous diseases. When considered individually, genomic alterations are rare. However amplifications (A+) and mutations (M+) in membrane receptors are described and associated with specific histological subtypes: HER2 M+ are found in 9% of low grade serous OC while HER2 A+ in 20% of clear cell OC or high grade serous EC. HER3 A+ and EGFR M+ are described in 4−9% of high grade serous OC, c-Met A+ in 20% of clear cell OC, FGFR2 M+ in 15% of endometrioid EC and FGFR-1/3 A+ in a subset of high grade serous EC, while IGF1R is amplified in 5% of high grade serous OC and EC. These data may provide the rationale for an adaptive trial matching pts to inhibitors according to specific genomic alteration. Finally the folate receptor (FR) is ubiquitously expressed in OC and EC and antibodies targeting FR are in phase II/III development. However a number of questions remain unanswered. Early negative trials used receptor inhibitors alone in unselected pts. Response may require an association with chemotherapy. If pt selection is required, what is the appropriate biomarker: receptor protein, mRNA, mutation or amplification? The only response to gefitinib in OC was associated with an EGFR M+, however trastuzumab had no activity in HER2 A+ EC; trials of FGFR inhibitors in FGFR2 M+ EC are ongoing. In addition, ligands may be relevant; preclinical studies suggest that autocrine receptor activation predicts sensitivity to HER inhibition. Dimerization inhibitors have the potential to disrupt more HER-mediated pathways, unfortunately phase II studies of pertuzumab in unselected pts with OC have been disappointing. However a trial of pertuzumab selecting pts on the basis of tumor HER3 mRNA levels as a surrogate for receptor activation is ongoing. Finally, unless the receptor is a true oncogenic driver (such as EGFR M+ in lung cancer), inhibiting the target alone may not translate into tumor shrinkage. However drug-antibody conjugates may be worth investigating in patients selected for receptor overexpression as a means of selective chemotherapy delivery. For example, a phase III trial of the antibody against FR, farletuzumab, in OC was negative, however a phase II trial of EC145, an FR antibody-drug conjugate showed a significant PFS benefit in FR expressing OC. An update on these and other novel membrane receptor inhibitors in gynaecological cancers will be presented.
No conflict of interest.

233 INVITED

Novel agents in overcoming drug resistance

A. Reyners[1], B. Poppema[1], S. De Jong[1], H. Hollema[2], H.W. Nijman[3], E.G.E. De Vries[1]. *[1]University Medical Center Groningen, Medical Oncology, Groningen, Netherlands; [2]University Medical Center Groningen, Pathology, Groningen, Netherlands; [3]University Medical Center Groningen, Gynaecological Oncology, Groningen, Netherlands*

Standard treatment of advanced epithelial ovarian cancer (FIGO stage IIB-IV) consists of surgery and 6 cycles platinum-based chemotherapy. Despite tumor responses of ~80% to this frontline therapy, recurrences are common and result in a 5-year overall survival (OS) rate of ~35%. The addition of other chemotherapeutic drugs and/or targeted therapy to the frontline regimen as well as dose dense or maintenance therapy failed to show therapeutic superiority.
Patients that initially responded well to platinum-based chemotherapy can be re-treated with a platinum-based regimen if the treatment naive interval was $\geqslant$6 months. Prolongation of the platinum-free interval by other drugs has been advocated to allow reintroduction of a platinum-based regimen and thereby increase OS. Data of 2 phase III studies that compare a platinum-based to a non-platinum-based regimen (liposomal doxorubicin and/or trabectedin) in patients with recurrent disease 6−12 months after platinum-based therapy, are awaited to proof this hypothesis. No effective treatment has been established for platinum-refractory disease.
Eventually, most patients will develop platinum-resistant disease and then only ~15% response rate can be achieved with various chemotherapy regimens. Therefore, novel agents are warranted to overcome drug resistance. Combining standard chemotherapy in first or second line with the VEGF-A antibody bevacizumab, prolongs progression-free survival with 4 months without affecting OS.
Recently, more insight has been obtained in the various ovarian cancer subtypes. PARP inhibition resulted in up to 40% responses in patients with BRCA1/2 mutation associated ovarian cancers in phase II studies. The most prevalent histological subtype, the high grade serous, is genomic unstable and associated with various mutations and/or molecular aberrations, whereas only a limited number of driver oncogenes are apparent. This makes the emerging fields of immunotherapy, treatment with antibody drug conjugates and drugs interfering with cell cycle kinases of major interest. Low-grade serous cancer is different, the mitogen-activated protein (MAP) kinase pathway is frequently activated and MEK inhibition showed efficacy. Moreover in about a third of the clear cell and endometroid ovarian cancers the PI3K pathway is activated and therefore a potential drug target.

E-health is empowered health

L. Engelen[1]. [1]*Radboud University Nijmegen Medical Center, REshape & Innovation Center, Nijmegen, Netherlands*

The “e” of e-health is very popular nowadays. Mostly pointed as electronic health the real value in my perspective is the empowering value of real e-health. For that over the past years I have been renaming e-health in to empowering health.
The lecture will reflect on the current and future developments that will be brought through (exponential) growing technological possibilities. (Monitoring of) health will be consumerized over the next 5−10 years, where devices, applications and services will be developed that will turn the way we will deliver health(care) ‘a bit’ upside down.
Personal Health Records, activity trackers, blood pressure meters, EKG-sleeves, and other (FDA approved) devices that can track 9 vitals signs all priced under $200 will be hitting the market; are we in healthcare ready for that, whether or not the speed of these developments may vary, as the impact will as well, it is going to affect our work. Are we willing to accept that the livespan of inventions might be half the one that we are used to. Accept in terms of actively collaborate to find the true value of this. How do we cope with this in education, training, CME?
That and more, also from the work I am doing at Singularity University, FutureMed Silicon Valley.
No conflict of interest.

237 INVITED

Patients’ experiences in dealing with technology

J. Pelouchova[1]. [1]*Leukemia Patient Advocates Foundation, Prague, Czech Republic*

While the 21st Century represents a decade of targeted therapies in oncology, the focus on e-health is emphasised on the field of patients’ use of technology. The increasing demand for information on cancer is connected to improving treatment outcomes, legislative changes enabling cancer patients to access their medical records and the constant rise of internet connectivity amongs all generations.
These factors contribute to a general need for information concerned with disease related facts, treatment options, navigation to experts in the respective cancer diagnostic area and crucial possibilities regarding medical innovations such as enrollment in clinical trials. Internet as the prime medium of information distribution needs to be used as a reliable source of knowledge as opposed to floods of unsorted and dubious material.
This presentation aims to address vital possibilities and options that can be offered via means of technology to help patients seeking expertise, advice and support and, impacts on the patient-doctor relationship.
Main issues are the navigation of patients towards support groups, online patient discussion forums connecting patients by sharing experiences and methods of patient education. Electronic tools and materials represent a cost-effective information flow with a wide outreach, i.e. educative videos, online surveys or mobile applications for patients and, have proven successful for patients (examples of patient led projects).
No conflict of interest.

238 INVITED

Nurses’ experiences in dealing with technology

R. Fraser[1]. [1]*Patient Order Sets, Research and Development, Toronto, Canada*

Nurses work across the healthcare system in many ways − interacting with patients in acute and community care, as well as working in public health, health administration and as researchers. Nurses’ wide range of involvement with clients and caregivers across the care continuum means they frequently interact with traditional and emerging technologies in healthcare. Healthcare 2.0 technologies offer platforms with entirely new potential that previous technology, time and geography prevented. Therefore, it is critical for nurses to learn the appropriate skills to leverage the expanding possibilities and mitigate risks created by digital tools and social media.
New technology enables new possibilities and can have unintended consequences. As new uses for technologies are explored within healthcare, equal consideration must be made for the potential harm. Nurses must be aware of both the benefits and risk when engaging with digital tools. New opportunities must be balanced with clients’ preferences and their right to access and control their information. As health professionals navigate these challenges, lessons have emerged which need to be shared.
When risk is considered and mitigated, nurses can explore and experiment with new technologies to advance healthcare and the health of patients. Understanding both perspectives will enable nurses to develop new ways to support collaboration, expand research, enhance knowledge translation, and accelerate quality improvement in healthcare. Healthcare 2.0 can surface previously hidden work and connect groups with shared interests. A selection of examples will be used to illustrate ways healthcare providers are working to advance healthcare delivery and patient outcomes.
The objectives of this presentation are to highlight the opportunities of healthcare 2.0, explore the risks, and suggest ways to plan and measure online initiatives. Case studies and examples will be used to illustrate the nurses’ experience with technology.

Scientific Symposium (Mon, 30 Sep, 09:00−11:00) **Therapeutic Procedures in Liver Metastases: Conventional and Future**

239 INVITED

Therapeutic procedures in liver metastases: SBRT for which patients?

L. Dawson[1]. [1]*University of Toronto, Princess Margaret Hospital, Toronto, Canada*

Background: Resection of liver metastases from colorectal carcinoma (CRC) is associated with 5 year survival rates from 30 to 40%, with the possibility for cure, even in the absence of systemic therapy. This demonstration of a local therapy improving outcomes for ‘oligo-metastatic’ CRC is well accepted. Long term survivors have also been reported following resection of liver metastases from sarcoma, renal cell carcinoma, breast cancer and melanoma. Clinical experience in stereotactic body radiation therapy (SBRT) for CRC and non-CRC liver metastases is rapidly increasing.
Material and Methods: SBRT is an attractive option for patients with liver metastases, due to increased convenience, as well as pre-clinical data demonstrating dose-per-fraction effects (e.g. endothelial and immune effects), with a threshold of approximately 8 Gy. SBRT has been used most often to treat liver metastases <6 cm in maximum diameter, with a range in doses from 30 to 60 Gy in 1 to 6 fractions.
Results: In general, survival rates following SBRT for liver metastases have been better than that expected with systemic therapy alone, and toxicity is uncommon as long as enough uninvolved liver can be spared from radiation therapy (e.g. >700 cc receiving 15 Gy in 3 fractions). The median survival of patients treated with SBRT ranges from 17.6 to 37 months, with the best outcomes seen in more recent series. Local control at one year ranges from 67% to 100%. Median survival from a phase I/II study of 107 patients with bulky metastases (median volume 75 cc) treated with 6 fraction SBRT (median dose 42 Gy) at PMH, Toronto was 18.1 months. Presence of extra-hepatic disease was associated with worse survival. Prognostic factors for improved local control included breast primary site, dose and tumor volume. Some patients with CRC or breast cancer liver metastases have had no progression, with no further therapies at 5 or more years post SBRT. In a pooled analysis of CRC metastases SBRT, dose was the only significant prognostic factor for local control, and extra-hepatic disease and local recurrence were associated with impaired survival. A dose of 48−51 Gy in 3 fractions was estimated to be associated with a one year local control rate of 90%. As outcomes are best following higher dose SBRT, the most suitable patients for SBRT include those with 3 or fewer metastases, <3 cm in maximal diameter, more than 1 cm from luminal gastrointestinal organs. However, long term local control is also possible in patients with 3−5 metastases, >3 cm in maximal diameter. Breast cancer metastases appear more sensitive than CRC metastases.

Conclusions: SBRT is a promising treatment for patients with focal 'oligo' liver metastases. More research is required regarding SBRT specific mechanisms of actions, as well as optimal patient selection.

240 INVITED

Gastrointestinal malignancies − noncolorectal cancer: RFA for which patients?

A. Veltri[1], I. Garetto[1], M.A. Satolli[1], C. Gazzera[2], M. Busso[3], F. Solitro[3]. *[1]University of Torino, Department of Oncology, Torino, Italy; [2]University of Torino, Città della Salute e della Scienza, Torino, Italy; [3]University of Torino, A.O.U. San Luigi Gonzaga, Orbassano (TO), Italy*

Background: While RFA has accepted indications for HCC and has demonstrated some usefulness for metastatic colorectal cancer (CRC), there are few studies on hepatic metastases (METS) from non-colorectal (NCRC) gastrointestinal malignancies (GIM).
Material and Methods: We performed a retrospective analysis on 75 patients (46 male; age 30−81 y, av. 64) with 140 METS from NCRC GIM, treated at our institution between 1998 and 2013. They were sub-classified by primary histological types, due to a potentially very different biological behavior. 51 METS were from neuroendocrine tumors (NET), 45 from pancreatic and biliary cancer (PBC), 29 from gastro-esophageal cancer (GEC), and 15 from GIST. The mean tumor size was 25 mm (6−65 mm). 129 treatments were percutaneous, 11 intraoperative.
Adverse events (AE), technique effectiveness (TE) and clinical usefulness were statistically analyzed.
Results: AE rate was 7% (10/140; only 4 major, 3%); a lower mean size seemed to be protective against AE (35 vs. 24 mm, $p = 0.0092$).
During the follow-up (1–134 months, av. 25) a maintained complete ablation (CA) was obtained in 70% of METS (98/140), while 30% showed viable tissue either residual at first follow-up imaging or recurrent after a CA had initially achieved (local tumor progression). Predictors for TE have been diameter $\leqslant$25 mm ($p = 0.0015$; mean diameter of CA vs. non CA, 21 vs. 31 mm, $p < 0.0001$) and the intraoperative approach ($p = 0.0334$).
4 patients were lost at follow-up; 32 patients died, mainly for a systemic progression of the disease. By histological subtypes, 3 and 5-yr overall survival (OS) rates were 100% and 57% for NET, both 28% for PBC, 24% and 8% for GEC, 83% (3-yr only) for GIST. Despite a bad overall prognosis, single vs. multiple METS resulted predicting better 3-yr survival in the GEC group (39 vs. 11%, $p = 0.015$).
Conclusions: Based on our results and literature, RFA of METS is feasible and safe. However, so far RFA should be considered less useful for NCRC as compared with CRC, except for NET, in which loco-regional therapies can both reducing symptoms and prolonging survival. Currently, there is no evidence robust enough to demonstrate which patients could benefit from RFA. Therefore, a patient selection based on a multidisciplinary approach should be recommended, including RFA in a multimodal therapy. In fact, it could be an adjunctive tool in treating METS from NET and GIST and may be used in conjunction with systemic therapy to manage limited PBC and GEC metastatic disease.

241 INVITED

Radioembolization: For which patients?

A. Hendlisz[1], A. Deleporte[1], P. Flamen[2]. *[1]Institut Jules Bordet, Digestive Oncology, Brussels, Belgium; [2]Institut Jules Bordet, Nuclear Medicine, Brussels, Belgium*

^{90}Yttrium-loaded microspheres, used for radioembolization, are registered in the European Union as medical devices, indicated for treatment of liver neoplasms.
This definition is vague and allows many different interpretations.
Radioembolization is a locoregional treatment that has to be compared to other local techniques such as surgery, radiofrequency ablation, stereotactic radiotherapy, chemoembolization, etc.
Radioembolization takes advantage of the anatomical particularity of dual liver blood flow by delivering the therapeutic devices via the hepatic artery, which predominantly brings its blood flow to the liver tumors as opposed to the portal vein irrigating mainly the liver parenchyma.
Radioembolization requires usually a pre-therapeutic simulation with ^{99}Technecium-labelled albumin macro aggregates (99mTc-labeled MAA). This test is commonly used to assess the presence of a hepatopulmonary shunt, precluding the use of radioembolization if superior to 20%. It allows also the prediction of the therapeutic effects by assessing the concordance between lesions mapped out by the baseline imaging (CTScan, magnetic resonance imaging, FDG-PET, . . .) and the lesions showing an uptake of microspheres, visualized by 99mTc-labeled MAA.
As commonly discussed for every loco-regional treatment, the decision-making process of radioembolization should undergo 3 major steps:
1. A multidisciplinary discussion on the medical indication, taking into account the tumoral histology, the general and liver status of the patient, the curative or palliative therapeutic intention, put in perspective with available data in the medical literature.
2. A technical discussion, essentially held between the interventional radiologists and the nuclear medicine specialists, where the liver artery anatomy, existing shunts (pulmonary or others) and the uptake of 99mTc-labeled MAA in the liver lesions are reviewed in order to define the feasibility, the potential toxicity and the foreseen oncological outcome for the patient. This should take place after the simulation.
3. A general discussion in a multidisciplinary setting to discuss and confirm the indication and the treatment before its effective administration.

As a consequence, almost 50% of the patients proposed in our hospital for this therapy are denied radioembolization because of poor indication, excessive toxicity or therapeutic futility. The aim of this talk will be to identify the principles underlying yttrium-90 microsphere therapy for hepatic malignancy, review theoretical indications and help clinicians understand the potential and challenges of this innovative technique.
No conflict of interest.

242 INVITED

HIFU for which patients?

G. Ter Haar[1]. *[1]ICR − Centre for Cancer Therapeutics, Division of Radiotherapy and Imaging, Sutton Surrey, United Kingdom*

High intensity focused ultrasound (HIFU) is a technique which allows selective destruction of tissue at depth by thermal ablation, whilst sparing overlying and surrounding tissues. For most current applications it is delivered using an extracorporeal source. A relatively recent technique, it has been used most extensively for the treatment of uterine fibroids, and (using a trans-rectal route) for the treatment of prostate cancer.
There are limited clinical trials for the application of HIFU to the treatment of primary liver cancer, but to date its use for liver metastases is limited, and reports of its efficacy are largely anecdotal.
HIFU can be delivered entirely non-invasively, and so is suitable for patients who cannot withstand hepatic surgery. In order to reduce organ movement, a light anaesthetic is usually administered, thus allowing control of respiratory motion. Few side effects have been reported, the most serious being minor skin burns that resolve rapidly, without the need for further treatment. Tumours can be targeted trans-costally, although this may restrict the depth at which ablation is achievable, and care must be taken that the energy deposition at the rib surface does not lead to excessive tissue heating. It is important to use an acoustic window at the skin surface that does not include any scar tissue as its high acoustic energy absorption may result in a skin burn.
HIFU has the potential to ablate tumours under real time imaging guidance, and is well tolerated by patients. When appropriately delivered, only tissue in the focal region is exposed, and so repeat treatments can be carried out, in the same, or adjacent targets.
There is a real need for well designed prospective trials of the use of HIFU for the treatment of liver metastases, either on its own, or in conjunction with adjuvant therapies, in order that its true potential can be properly assessed.

Translational biomarkers in immunotherapy

M. Maetens[1], D. Fumagalli[1], C. Sotiriou[1]. *[1]Institut Jules Bordet, Breast Cancer Translational Research Laboratory, Brussels, Belgium*

In the past decade, cancer immunology has emerged as a fundamental aspect of oncology and immunotherapy has become a reality for cancer patients. While immunotherapies are routinely used against tumor types such as melanoma and renal cell carcinoma, increasing evidence suggests that certain subtypes of Breast Cancer (BC) may also be vulnerable to immune approaches. Our group showed that an immune response module, the STAT1 module, was predictive of a better prognosis in TN and HER2+ BC patients, and other investigators showed in the same setting that the overexpression of immune related genes was able to identify subgroups of patients with a better prognosis.
Specific cytotoxic agents were found to induce "immunogenic" cell death that can facilitate host immune tumor elimination and produce better clinical outcomes.

In a neoadjuvant clinical trial (Trial of Principle (TOP) study) in which patients with ER− BCs were treated with anthracycline monotherapy, we showed that high immune module scores were associated with sensitivity to anthracyclines. Similarly, in a recent meta-analysis of 996 patients treated with neoadjuvant chemotherapy (CT), we showed that an immune module, consisting mainly of TH1/interferon response, predicted pathologic complete response (pCR) in all BC subtypes adding prediction to standard clinico-pathologic parameters. The IS seems also pivotal in determining the response to monoclonal antibodies such as trastuzumab, and some evidence indicates a possible role in the response to endocrine treatment. In a recent study, Denkert et al. showed that the percentage of tumor-infiltrating lymphocytes (TILs) was a significant independent parameter for pCR in BC patients treated with anthracycline/taxane neoadjuvant CT. Several subsequent studies showed that besides being a predictive biomarker of CT and trastuzumab efficacy in TN and HER2+ BC, respectively, baseline TILs levels seem to be associated with better survival. Further prospective studies are needed to validate these findings and to better characterize the population of TILs in breast tumors.
The observed correlation of clinical prognosis with PD-L1 expression in multiple cancers suggests that the PD-1/PD-L1 pathway might play a critical role in tumor immune evasion and should be considered as an attractive target for therapeutic intervention. Indeed, recent trials with agents inhibiting programmed cell death-1 (PD-1) or its ligand PD-L1 showed durable tumor regression and stabilization of disease in patients with advanced cancer, providing new hope for the treatment of BC patients.

244 INVITED

Engaging in adaptive tumour response in cancer

M. Postow[1]. [1]*Memorial Sloan-Kettering Cancer Center, New York, USA*

Immunotherapeutic strategies that modulate the adaptive immune system to enhance antitumor immunity have demonstrated remarkable recent clinical success. Specifically, targeting the normally negative T cell regulators, cytotoxic T-lymphocyte antigen 4 (CTLA-4) and programmed death-1 receptor (PD-1) with monoclonal antibodies has led to improvements in overall survival and durable tumor responses, respectively. We and others are studying ways to further improve the number of patients who benefit from these treatments by combining these antibodies with conventional cancer treatments and performing biomarker studies to identify patients most likely to benefit. This talk will focus on the preclinical rationale and our ongoing clinical investigations of CTLA-4 blockade in combination with PD-1 blockade, radiotherapy, targeted therapy, and vaccines. We will also discuss our current work investigating the absolute lymphocyte count and the immunosuppressive cell population, myeloid derived suppressor cells, as potential biomarkers for CTLA-4 blocking antibodies and tumor cell membrane expression of PD-L1 as a potential biomarker for antibodies blocking PD-1 and/or PD-L1.
Conflict of interest: *Advisory board: Non-paid advisory board participation for Bristol-Myers Squibb. Corporate-sponsored research: Recipient of research funding from Bristol-Myers Squibb*

245 INVITED

Targeting immune regulator circuits in cancer: New mechanistic insights

S. Quezada[1]. [1]*University College London, UCL Cancer Institute Department of Haematology, London, United Kingdom*

The continual interaction of the immune system with a developing tumor is thought to result in the establishment of a dynamic state of equilibrium. This equilibrium depends on the balance between subsets of effector and regulatory lymphocytes. Whereas the overall mechanisms underpinning this balance remain unknown, we have learned that regulatory T lymphocytes have a great tendency to infiltrate and accumulate in tumors, meanwhile effector T cells fail to efficiently do so. Furthermore, different subtypes of regulatory cells and inhibitory molecules such as CTLA-4 tightly control the few effector T lymphocytes that manage to infiltrate the tumor. The outcome of this balance is critical to survival, and while in a few cases the equilibrium resolves in the elimination of the tumor by the immune system, in many other cases the tumor manages to escape immune control. Remarkably, antibodies against CTLA-4, a key immune modulatory receptor expressed on T cells, efficiently modify this balance, driving effector T cell expansion and increasing the ratio of Teff/Treg within the tumor. Whilst the high Teff/Treg ratio in the tumor directly correlates with tumor destruction in mice and humans, the mechanisms underpinning this phenomena remain unknown. By focusing in the study of effector and regulatory tumor-reactive CD4+ T cells my group is interested in the mechanism underpinning the activity of different immune-modulatory antibodies within the tumor microenvironment, and the potential positive and negative impact that the tumor microenvironment may have in the recruitment, survival and function of different T cell subsets.

246 INVITED

Immunology from bench to bedside

G. Curigliano[1], C. Criscitiello[1], A. Esposito[1], L. Fumagalli[1], L. Gelao[1], M. Locatelli[1], I. Minchella[1], A. Goldhirsch[1]. [1]*European Institute of Oncology, Early Drug Development Division, Milan, Italy*

The basic concept of immunotherapy in cancer is to enable the immune system to identify neoplastic cells and to either prevent carcinogenesis and/or reject transformed cells with a potential for malignant tumour growth. Denkert et al showed that the percentage of tumor-infiltrating lymphocytes (TILs) defined on a hematoxylin-eosin slide was a significant independent parameter for pCR in breast cancer (BC) patients treated with anthracycline/taxane neoadjuvant chemotherapy (CT). Several subsequent studies showed that besides being a predictive biomarker of CT and trastuzumab efficacy in triple negative and HER2+ BC, respectively, baseline TILs levels seem to be associated with better survival in the same two BC subtypes. More prospective studies are needed to validate these findings and to better characterize the population of TILs. Available data suggests that TILs are mainly represented by non-active T cells that can become active after CT induction, but the role of B cells, natural killer (NK), NKT and TReg cells is still unclear. This is of particular relevance now that therapeutic strategies targeting the immune system are emerging. Recently, molecules inhibiting programmed cell death-1 (PD-1) or its ligand PD-L1, which inhibit antitumor immune response, were shown to induce durable tumor regression and stabilization of disease in patients with advanced cancer and give new hope for the treatment of BC patients. A major limitation of the various approaches to turning on an immune response to cancer is that the immune system exerts a major effort to avoid immune over-activation, which could harm healthy tissues. Cancer takes advantage of this ability to hide from the immune system by exploiting a series of immune escape mechanisms that were developed to avoid autoimmunity (mechanisms of tolerance). Among these mechanisms are the hijacking of immune-cell–intrinsic checkpoints that are induced on T-cell activation. Blockade of one of these checkpoints, cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4) or the programmed death 1 (PD-1) receptor, provided the first evidence of activity of an immune-modulation approach in the treatment of a solid tumor. The future frontier in the treatment of cancer requires identification of potential targets in order to personalize therapies. The immune system remembers what it targets, so once the system is correctly activated, it may mediate a durable tumor response.

Next generation sequencing: Basic principles and applications in the biomarker arena

Abstract not received.

248 INVITED

Massively parallel sequencing analysis of clinical samples: Challenges and opportunities

M. Berger[1]. [1]*Memorial Sloan Kettering Cancer Center, New York NY, USA*

Massively parallel sequencing technology has the potential to transform cancer diagnosis and treatment through the identification of driver genetic alterations that may be suppressed by targeted therapies. Through retrospective analysis of clinical specimens, one can discover genomic biomarkers that correlate with outcomes and therapeutic response. Profiling multiple tumors from individual patients can reveal factors that influence tumor progression and drug resistance. Finally, prospective sequencing of clinical specimens can complement traditional radiology and histology based imaging in the routine diagnosis and treatment of cancer patients.

For increasingly lower costs, one can interrogate all clinically relevant genes for mutations, copy number alterations, and structural rearrangements, with high detection sensitivity in heterogeneous tissue. Advances in exon capture, molecular barcoding, and profiling of formalin-fixed paraffin embedded (FFPE) specimens have further established the clinical potential of next generation sequencing. However, challenges remain in the application of these techniques to the analysis of clinical tumor samples. In addition to the technical challenge of analyzing ever-decreasing amounts of FFPE tissue, one must overcome the biological challenges of aneuploidy and heterogeneity inherent to the genetics of cancer.
In this talk, I will discuss different strategies for sequencing clinical samples, including different sequencing platforms, capture methods, and breadth of testing (i.e. targeted versus comprehensive approaches). I will describe examples in which our group has performed massively parallel sequencing on clinically annotated tumor specimens to identify genomic biomarkers predictive of drug response and resistance. Finally, I will describe additional challenges in the application of these techniques involving bioinformatics, scalability, clinical interpretation, reporting, regulatory compliance, reimbursement, and ethics.
No conflict of interest.

249 INVITED

Massively parallel sequencing for predictors of therapy

M. Ellis[1]. [1]*Washington University in St Louis, Division of OncologyCampus, St Louis, USA*

Next generation sequencing is beginning to suggest new therapeutic approaches that might be more effective for the treatment of breast cancer (Cancer Discovery 2013: 3; 27−34), the most notable of which are HER2 mutations in HER2 non-over-expressed tumors which are the target of an ongoing neuratinib trial (Cancer Discovery 2013: 3; 224 227). Other areas of focus for discovery sequencing in advanced clinical trials include the CDK4/CyclinD pathway and the PI3K pathway. However there are currently no clinically validated predictive biomarkers for the use of CDK4 inhibitors, rapalogs or other PI3 kinase inhibitors so that these agents are being used in a relatively indiscriminate way. The efforts to define predictors based on sequencing DNA is clearly limited by the focus on analysis of paraffin-embedded formalin-fixed primary breast tissue and the retrospective nature of the analysis. It is clear that biopsies of advanced disease before the initiation of treatment and higher quality material would be ideal, but there are ongoing concerns about the feasibility of obtaining this material which is magnified when research questions require serial sampling before and after treatment to study resistance. There is also a more fundamental biological problem. Instead of the one gene one drug paradigm pathway exemplified by our HER2 mutation and neuratinib study, CDK 4/6 inhibitors and PI3 kinase inhibitors target complex multi-gene mutational spectra and we have yet to secure algorithms that can put multiple genes in a pathway into a common predictor.
The use of patient-derived xenografts (PDX) is an alternative system to develop predictors of response based on genome sequencing. PDX models are readily obtainable from HER2− and ER− disease at any stage of presentation, but for ER+ HER2− disease, most models are derived from advanced disease patients. Whole genome sequencing was used to demonstrate that a PDX was excellent genomic replica of the originating basal-like breast cancer (Nature 2010 464:999–1005) and we now have extensive experience of multiple whole genome comparisons between originating tumor/PDX pairs.
We are now initiating a series of “xenograft phase 2 trials” with CDK4/6 inhibitors, PI3 kinase agents and MDM2 inhibitors that are not only designed to study drug efficacy but to develop a more secure diagnostic paradigm for the use of these novel targeted agents through DNA, RNA and protein sequencing approaches. The relatively large yield of tissue in this system facilitates the use of next gene mass spectrometric analysis of phosphoproteomes. This is a logical compliment to DNA and RNA sequencing in our search for predictive markers because perturbations in signaling flux induced by somatic mutations and drugs execute the phenotypes we are interested in.
No conflict of interest.

250 INVITED

The impact of massively parallel sequencing on the classification and prediction of haematological malignancies

T. Haferlach[1]. [1]*MLL Münchner Leukämielabor GmbH, München, Germany*

The diagnosis, characterisation, classification and prognostication of haematological malignancies are changing gears. The description of the diseases are on the way from a phenotype to a molecular genotype. This is paved due to increasing knowledge of the cytogenetic background but even much more due to rapidly emerging molecular techniques. Thus, so called Next Generation Sequencing techniques had revolutionized the field in haematology during the last five years and led to fascinating and important examples first by gene expression profiling nearly ten years ago but finally due to massively parallel sequencing based on amplicon or panel testing, whole exome sequencing or even whole genome sequencing.
Due to this new application not only many new genes have been found to be of importance for the underlying biology of the respective leukemias and lymphomas. But in addition new prognostic markers and even new targets have been defined. This is true for several genes that are involved in DNA methylation, chromatin modification, for cohesin complex genes and also theses of the spliceosome. The landscape of several diseases such as AML and MDS has been highlighted by combination of several techniques, in detail also based on these next generation sequencing approaches. It will be our challenge now to place these new techniques and results on the background of techniques such as morphology, immunophenotyping, cytogenetics, FISH and standard molecular approaches. The final scenario of the diagnosis, classification and prognostication of haematological malignancies will for sure be a mixtum compositum of all these approaches but will be mainly driven by the understanding of the genome of the respective diseases.
Conflict of interest: *Ownership: MLL Munich Leukemia Laboratory. Corporate-sponsored research: Novartis, ROCHE*

Scientific Symposium (Mon, 30 Sep, 09:00−11:00)
Empowering Survivors of Childhood and Adolescent Cancer

251 INVITED

What is the issue? The survivor's view point

A. Brownsdon[1]. [1]*University College London Hospitals, Oncology, London, United Kingdom*

There is a gap in services for survivors of childhood and adolescent cancer particularly for those over 25 years old.
The main gaps in service provision for adult cancer survivors are around education, employment and psychological support. In addition adult and children's services in the UK are funded and managed differently. This can make it hard for survivors to access appropriate care and support especially when transitioning between services.
The specific needs of adult cancer survivors are also different to those of children and adolescents. For example, as adults, survivors of childhood cancer can face societal expectations of independence and an ability to maintain self-sufficiency which cannot always be met. In addition, many adult survivors will be trying to access higher education or employment with the added burden of a cancer history and some may also have families of their own to support.
Adult cancer survivors have repeatedly expressed their need to address issues such as those outlined above. It is important that they feel empowered to make informed decisions about their health and lives in general and that they are supported in making these choices.
Survivors of childhood and adolescent cancer want to receive reliable, personalised information and follow-up care from specialists with expertise about late effects occurring in adult life. Survivors also want to be able to access specialist health services without a GP referral.
In addition, adult survivors would like advice and support regarding access to education and employment as well as information on issues such as life and travel insurance. Survivors have also expressed a need for access to support groups and networks in order to meet others in a similar position and to share experiences.
The National Cancer Survivorship Initiative (NCSI), a part of the National Cancer Reform Strategy for England has helped to recognise some of the needs of adult childhood cancer survivors. This includes the development of models of long-term follow-up care which promote self-management, effective transition between services and service re-entry without referral as well as treatment summaries for survivors. As a result of the NCSI work some of the needs of survivors are being recognised and there are now more specialist long-term follow-up and late effects nurses in more treatment centres than previously.
Despite these changes, there is still a long way to go in terms of addressing the issues faced by adult survivors of childhood cancer. Services need to be developed so that adult survivors can feel empowered to self-manage and make informed, supported decisions about their health in order to lead lives that are as normal and independent as possible.
No conflict of interest.

252 INVITED

Genetic predisposition to late complications after cancer treatment − what do we know?

T. Langer[1], S. Radtke[1], J. Meitert[1], O. Zolk[2]. [1]*University Hospital for Children & Adolescents, Ped. Oncology, Erlangen, Germany;* [2]*Institute for Experim. and Clinical Pharmacology and Toxicology, Pharmacogenetics, Erlangen, Germany*

Modern therapy optimizing protocols raise the survival rates of children with cancer. These patients are exposed to the risk of late effects of their treatment. Adverse effect of the cytostaticum cisplatin is the irreversible hearing impairment of the inner ear. The risk of ototoxicity is associated with polymorphism in candidate genes, i.e. megalin, glutathion-S-transferase, *COMT* and *TPMT*. These results have to be conformed by larger study cohorts with more statistical power. Furthermore methotrexate is an example for a drug with many adverse effects. Based on data from the ALL-BMF 2000 study cohort we showed that the polymorphism c.521C>T in SLCO1B1 is highly significant associated with the MTX-clearance. In a multiple regression model, MTX AUC0−48 h increased by 26% (P=6.8x10−8) per *SLCO1B1* rs4149056 C allele. MTX AUC0−48 h was a significant predictor of overall toxic adverse events during MTX courses (R2=0.043, P=2.9x10−5), whereas the *TYMS* rs34743033 tandem repeat polymorphism was predictive of stomatitis (R2=0.018, P = 0.009), a frequent side effect of high-dose MTX. Multiple Cox regression analysis revealed an association of minimal residual disease (hazard ratio 7.3; P=3.2x10−4) and *MTHFR* rs1801131 (hazard ratio 3.1; P = 0.015) with event-free survival in the ALL-BFM 2000 study population. Studies on pharmacogenetics may identify genetic markers to avoid acute or chronic late effects in future.

No conflict of interest.

253 INVITED

Non-visible subtle long-term complications to treatment − what are they, how do we find them and what do we do?

H.J. Van der Pal[1], L.C.M. Kremer[2]. [1]*AMC, Medical Oncology/Pediatric Oncology, Amsterdam, Netherlands;* [2]*AMC, Pediatric Oncology, Amsterdam, Netherlands*

Major advances in medical and supportive care have contributed to a growing population of childhood cancer survivors (CCS). With 5-year overall survival approaching 80%, most children diagnosed with cancer today are expected to become long-term survivors.

Unfortunately, successful cancer treatment can cause treatment-related health problems, the so-called late adverse effects or chronic health conditions which can emerge even decades after treatment.

Previous studies have soon that approximately 3 out of 4 survivors will experience one or more late effects, which are severe or life-threatening in 25%. Adverse late effects are divers and include the full spectrum of potential health problems. Late effects such as; second malignancies, cardiovascular disease, endocrine disorders, and cognitive and psychosocial problems, often affect quality of life. Asymptomatic late effects precede most symptomatic late effects. By identifying these asymptomatic late effects, treatment can be started early and can possible prevent deterioration or development of a symptomatic late effect. In light of this, long-term risk-based follow-up care of CCS is advocated to facilitate early detection of late effects and timely initiation of interventions to optimize life-long health of survivors.

It is very important to realize that screening for asymptomatic events should only be done based on guidelines. These guidelines should focus on five key issues: (1) Who needs surveillance? (2) At what age or time from exposure should surveillance be initiated? (3) At what frequency should surveillance be performed? (4) What surveillance modality should be used? (5) What effective treatments are available if health problems are identified? Only if possible treatment for asymptomatic late effects could be effective to prevent further deterioration, screening should be recommended. For example serial monitoring of cardiac function in CCS treated with anthracyclines to identify asymptomatic cardiac dysfunction is recommended based on the evidence that early treatment with ACE-inhibitors can prevent deterioration of cardiac function. Furthermore it is essential to weigh the benefits of screening for asymptomatic disease against the harms of finding an asymptomatic but possibly incurable disease.

Since the 1980s pediatric oncology centers have developed programs specifically for CCS. However, relatively few programs are able to provide follow-up into the adult age range.

No conflict of interest.

254 INVITED

Health Passport for risk adapted follow-up: A joint project of the ENCCA and PanCareSurFup EU consortia

R. Haupt[1], M. Ortali[2], S. Caruso[1], F. Bagnasco[1], C. Dellacasa[2], S. Karner[3], L. Kremer[4], A. Kienesberger[3], R. Skinner[5], L. Hjorth[6]. [1]*Giannina Gaslini Children's Hosp., Epidemiology and Biostatistics, Genoa, Italy;* [2]*Consorzio Interuniversitario CINECA, Health Care, Bologna, Italy;* [3]*International Confederation of Childhood Cancer Parents Organizations (ICCCPO), Survivors, Nieuwegein, Netherlands;* [4]*Emma Children's Hospital/Academic Medical Center, Pediatric Oncology, Amsterdam, Netherlands;* [5]*Great North Children's Hospital Royal Victoria Infirmary, Paediatric and Adolescent Haematology and Oncology, Newcastle Upn Tyne, United Kingdom;* [6]*Skåne University Hospital, Pediatric Haematology and Oncology, Lund, Sweden*

Background: Between 300,000 and 500,000 childhood cancer survivors (CCS) are now living in Europe and most of them have reached or are entering adulthood. Cancer or its treatment put survivors at increased risk of developing chronic health conditions that may affect their quality of life. It is important that each CCS is given a document summarizing cancer history and providing recommendations on targeted follow-up based on treatment exposure. This document should be discussed with the family doctor or any other health provider and should empower survivors of taking care of their own health.

Materials and Methods: Within the EU funded European Network for research on Cancer in Children and Adolescents (ENCCA), paediatric oncologists, cancer survivors, and IT experts set up a working group aiming to develop an electronic data base for treatment summary reports available on a secure website or in a document on paper, translated in several European languages. Cancer-specific and treatment data can be downloaded from clinical trials data bases through standard format files or can be imported by the pediatric oncologist or survivors. Recommendations for surveillance, based on the best available evidence, are formulated after extensive literature review and consensus meetings within the EU funded project: PanCareSurFup in collaboration with the International Late Effects of Childhood Cancer Guideline Harmonization Group. Four categories for the strength of recommendations will be used: (1) strong; (2) moderate; (3) weak recommendation "to do"; and (4) a recommendation not to do. The passport provides tailored follow-up to each CCS in order to optimize age-appropriate healthcare.

Results: The Survivorship passport prototype is available and provides information relevant to each individual patient. Data transfer from some clinical trials data bases has shown to be feasible; when needed scientific nomenclature has been "automatically" translated in lay language and changes can be made if needed. Guidelines have already been developed for breast cancer and cardiomyopathy surveillance. Guidelines for gonadal toxicity are in progress and other topics are planned for the next years.

Conclusions: Providing treatment summary and standardized patient-specific follow-up guidelines to every patient at the end of cancer treatment should be considered as a key component that will foster the delivery of high-quality patient care and awareness throughout adulthood.

No conflict of interest.

Keynote Lecture (Mon, 30 Sep, 11:30−12:15)
Improved Cure Through Personalised Radiation Oncology − Basis and Perspectives

255 INVITED

Improved cure through personalised radiation oncology − basis and perspectives

M. Baumann[1]. [1]*Universitätsklinikum Carl Gustav Carus, Klinik und Poliklinik Strahlentherapie, Dresden, Germany*

Radiotherapy has a proven curative potential in many cancer types, due to its high efficacy to inactivate cancer stem cells in the primary tumor and regional metastases as well as its increasing ability to spare normal tissues. Already today radiation treatment planning and delivery is fully individualized based on anatomical imaging, precise space-resoluted radiation dose models, tumor control probability- vs. normal tissue complication-models and clinical parameters. Most of these advances in personalized radiation oncology can be attributed to the revolutionary progress in high-precision radiation delivery and planning technology during the past decades. These have been rapidly translated into clinical practice and allowed the development of novel more efficient clinical strategies. Further rapid technological advances are anticipated for the coming years both in hardware and software development. These

advances will further promote personalized radiation oncology, however this process in the future will be significantly spurred by integrating biological information on the specific tumor and on surrounding normal tissues in the treatment strategy of patients. Because of spatially resoluted information, biological imaging is of particular relevance for advancing biology-driven individualization of radiation oncology, but other predictive and prognostic markers also demonstrate high potential in preclinical and clinical studies. This holds true for stratified selection of the best total dose, dose-distribution and fractionation parameters but also for the combination of radiation with specific drugs. An important feature specific for personalized radiation oncology is that already broad biological stratification of patients in two or few groups can very substantially enhance individualization as this information adds a power-function to the fully anatomically-personalized dose-distributions achieved today. This lecture will review preclinical and clinical examples, including data on bioimaging, demonstrating how systematic integration of technological advances with biological information may improve cure rates through personalized radiation oncology.
MB receives support by the Bundesministerium für Bildung und Forschung (BMBF, BMBF-ZIK program 01KS9602).

Special Session (Mon, 30 Sep, 13:15−14:15)
Improving Therapy for Locally Advanced Cervical Cancer

256 INVITED

Image-guided adaptive brachytherapy

P. Petric[1]. [1]*National Center for Cancer Care and Research, Department of Radiotherapy, Doha, Qatar*

Advantages of 4D image guided adaptive brachytherapy (IGABT) over conventional BT include application and dose-planning individualization, dose volume histogram analysis and improved clinical outcome.
Assessment of initial tumor, its regression during treatment and size/topography at IGABT enables individualized refinement of application technique and development of new standard applicators. Image guidance of application can be accomplished pre- or intra-operatively. Common preoperative strategy consists of integration of initial imaging and findings at BT; additional imaging just before the application facilitates insertion. Intraoperative US-guided uterine tandem placement helps preventing uterine perforation and US-guided needle insertion is a feasible method to achieve optimal interstitial implant. Common approach to intraoperative MRI or CT guidance consists of application interruptions to acquire verification images. Open MRI and modified closed-system techniques enable real-time guidance. Optimal BT implant geometry facilitates achievement of planning aims during dose optimization.
IGABT is based on clinical and imaging interpretation of initial tumor spread and residual pathological tissues during treatment. Using optimisation of dwell-times and positions of ^{192}Ir stepping sources, IGABT enables dose escalation to the target volume while respecting OAR tolerance. Small inconsistencies in delineation of these regions may translate to large uncertainties of the optimized dose distribution, challenging the gain of IGABT and complicating interpretation of studies. Adequate training and respecting the recommendations are required to minimize variations. One of the sources of uncertainties is the choice of imaging modality. MRI demonstrates excellent soft tissue contrast and is the modality of choice. However, due to its limited availability, CT- and US-based techniques are gaining increasing attention. Further research is needed to validate their potential in cervix IGABT.
In parallel to monoinstitutional reports, the upcoming results of the EMBRACE (intErnational study on MRI-guided Brachytherapy in locally advanced CErvix cancer) and retro-EMBRACE studies provide evidence for effectiveness of IGABT and improve our understanding of dose-response relationships. For patients with recurrent cervix cancer following radiotherapy, reirradiation is one of the only therapeutic options. IGABT may increase the chance of uncomplicated cure in these patients.
No conflict of interest.

257 INVITED

Optimal management of nodal disease

A. Taylor[1]. [1]*Royal Marsden Hospital, Department of Radiotherapy, London, United Kingdom*

The presence of lymph node metastases is one of the most important prognostic factors for locally advanced cervical cancer. Whereas central pelvic disease can receive a very high dose from brachytherapy, the external beam radiotherapy dose delivered to nodes is limited by normal tissue tolerance. Inadequate treatment to this region can result in pelvic sidewall relapse which is rarely salvaged successfully.
In addition to the prognostic significance, identification of the anatomical location of nodal disease can determine the extent of radiation fields. Standard cross-sectional imaging with CT and MRI using size criteria has low sensitivity and specificity for detecting metastases. CT-PET is the imaging modality of choice for evaluating lymph nodes at diagnosis and for follow up. There remains debate about the role of diagnostic para-aortic lymphadenectomy.
Different approaches have been advocated for improving control of nodal disease although there have been few prospective studies to establish optimal management. Surgical debulking of bulky metastatic nodes is often undertaken prior to radical chemoradiation. Several case series have reported equivalent local control and survival in the resected group compared to a node negative cohort, but at the cost of increased morbidity. Inferior outcomes with poor pelvic control and increased distant relapse are reported for patients with unresectable nodes.
Conventional external beam radiotherapy treatment delivers 45−55 Gy to the pelvis and para-aortic nodes. With advanced radiotherapy techniques it is now feasible to deliver higher doses concomitantly to involved nodal regions. There are limited data on the optimal dose required for control of enlarged nodes and these will be reviewed. Distant failure remains high even with improved pelvic control and more effective systemic therapies are therefore also required.
No conflict of interest.

258 INVITED

Rationale and trials of adjuvant and neoadjuvant therapy with chemoradiation

D. O'Donnell[1]. [1]*St James's Hospital, Haematology Oncology Day Care Centre, Dublin, Ireland*

Chemoradiation remains the standard treatment for locally advanced cervical cancer but a substantial proportion of women relapse after that. Most who relapse die of their cancer or its complications, so there is an urgent need to improve the cure rate after first-line therapy. This talk will describe previous and ongoing trials of therapies added to standard chemoradiation and discuss potential future approaches.
Conflict of interest: *Other substantive relationships: Member of Trial Management Group of INTERLACE trial (academic trial just started of neoadjuvant chemotherapy before chemoradiation for cervical cancer*

Special Session (Mon, 30 Sep, 13:15−14:15)
Survivorship and Follow up

259 INVITED

Meaningfulness of physical activity and exercise in cancer rehabilitation − a meta-synthesis of qualitative research

J. Midtgaard[1]. [1]*Copenhagen University Hospital (Rigshospitalet), Department of Health Care Research (UCSF), Copenhagen, Denmark*

Background: Evidence for the health benefits of physical activity and exercise for cancer survivors is accumulating. However, the meaningfulness of physical activity from the perspective of the patient has not yet been established. Meta-synthesis has evolved as a rigorous method for integrating findings from multiple qualitative studies to produce a new interpretation of findings that is more substantive than those resulting from individual investigations. The aim of this meta-synthesis was to aggregate, interpret and synthesize findings from qualitative studies that included cancer survivors' experiences of physical activity and exercise training.
Material and Methods: Four electronic databases were searched systematically for articles published up to May 2013, using keywords and mesh headings. Reference lists of included articles were screened for eligible papers. The meta-synthesis approach was based on the guidelines by Sandelowski and Barroso (Qual Health Res 2003).
Results: 61 papers were critically appraised and 17 papers were identified for inclusion. Most studies included patients with breast cancer and/or patients undergoing treatment or who had recently completed treatment. Three main categories were identified across the studies: (1) Resurrection of continuity (including the subthemes: structure, hope, and goal-setting), (2) Preservation of normality (including the subthemes: social participation and positive distraction), and (3) Reclaiming the body (including the subthemes: enhanced energy and performance, autonomy, and illness resistance). Together, these categories indicate that the meaningfulness of physical activity and exercise for cancer survivors is related to the development of personal strategies including keeping a routine, which may help the individual to feel in control and to sustain or restore confidence in their body and uphold a positive outlook towards the future.

Conclusions: The findings of this meta-synthesis suggest that cancer survivors experience physical activity and exercise as a means to fulfill their mental, social and physical well-being independent of disease status. In addition to the current evidence on the efficacy of exercise training in cancer survivorship, it is incumbent upon clinicians and policy-makers to acknowledge and promote the meaningfulness of physical activity and exercise, and to use this knowledge to provide new solutions to current problems related to recruitment, adherence and implementation.
No conflict of interest.

260 INVITED

Using technology in supportive cancer care

S. Kaasa[1], S.X. Raj[2], A.K. Knudsen[3]. *[1]Norwegian University of Science and Technology and St. Olavs Hospital Trondheim University Hospital Trondheim Norway, European Palliative Research Centre (PRC), Trondheim, Norway; [2]Norwegian University of Science and Technology and Trondheim University Hospital St. Olavs Hospital, European Palliative Research Centre (PRC) and Cancer Clinic Trondheim University Hospital, Trondheim, Norway; [3]Norwegian University of Science and Technology and Trondheim University Hospital St. Olavs Hospital, European Palliative Research Centre (PRC) and The Regional Centre of Excellence, Norway*

Patients in any stage of cancer are suffering from several symptoms. According to studies, subjective symptoms reported by the patients (patients reported outcomes − PRO) are under-reported and under (insufficiently)-recognized during consultations and in patients' records.
Pain, fatigue, dyspnea, constipation, loss of appetite, depression and anxiety are among the most common symptoms. In a meta-analysis on prevalence of cancer pain, 33% reported pain after curative treatment and 64% of the patients with metastatic disease. Even when effective treatment exists for pain and depression as many as 50% of the cancer patients are undertreated for these symptoms.
Inadequate assessment, lack of standardized assessment tools, poor communication and challenges of implementing evidence-based guidelines into clinical practice have been identified as barriers to improving symptom treatment.
There is a need for a tool that combines symptom assessments and classification, evidence- based guidelines and decision making support. These tools should be computerized since this will allow individualized and dynamic symptom assessment, thus improving the efficiency of consultations. Additionally, it may facilitate the long-term follow-up of patients and incorporate the results into patient's electronic medical records. Eir, a computerized decision support system, is under development and testing for implementation in routine clinical practice. This software is primarily based upon PRO's, international evidence-based guidelines and an interactive decision support system. The overall aim by applying the software into clinical practice is to enhance the patient-centered communication and treatment by facilitating an optimal exchange of information between the patients and the health care providers.
No conflict of interest.

261 INVITED

Health-related choices in survivors

G. Pravettoni[1]. *[1]European Institute of Oncology, Director Psychology Unit, Milano, Italy*

Nowadays the majority of cancer patients receive highly effective treatments that result in long-term, disease-free survivorship. Often, however, in the post-treatment phase cancer patients are left with subtle and sometimes more overt sequelae because of the cancer treatments that can affect their quality of life and their life-related decisions. Although a substantial proportion of cancer survivors spontaneously initiate positive behavioral changes, many do not adhere to follow-up or screening behaviours, and to recommendations in regards to diet, physical activities and smoking behavior therefore. It becomes crucial to promote health-related behaviours, in order to reduce the probability of relapses and comorbidities.
On the other hand, beside life-style changes there is the need to promote the reintegration of cancer survivors at the workplace. Going back to work is important, not only for financial reasons, but also to facilitate the adaptive process to the illness, that, in turn, facilitate an improvement of the survivor's psychological and psycho-social conditions. However, while survivorship following cancer diagnosis is increasing in prevalence, looking for a new job or reentering the job market can be a challenging experience. Several factors may adversely affect employment over the long term. Because of treatment consequences and for a mere psychological reaction to the illness, physical limitations, fatigue, emotional problems, difficulties with concentration and memory, awkward or negative interactions with coworkers, and changing personal priorities make difficult for cancer survivors to maintain or look for a job. Employment discrimination is also an ongoing concern, despite laws or agreements for strategic cooperation to promote and develop values of equality, opportunity and non-discrimination in the workplace toward individuals with a history of cancer.
There is the need, given these premises, to find efficient strategies to foster health promotion and a sensitization campaign for job reintegration among both cancer survivors, organizational management and society, in order to facilitate and improve cancer survivors empowerment and well-being.

Special Session (Mon, 30 Sep, 13:15−14:15)
Controversies in Gallbladder Cancer

262 INVITED

When should we worry about gallbladder polyps?

Abstract not received.

263 INVITED

Management of Stage T1B gallbladder cancer discovered after laparoscopic cholecystectomy

Y. Fong[1]. *[1]MSKCC, Department of Surgery, New York, USA*

T 1b lesion is one which invades the muscularis propria but does not involve the perimuscular connective tissue. There is controversy as to the extent of additional surgery needed if a T1b lesion is found at pathologic analysis after laparoscopic cholecystectomy. Published reports have a wide spectrum of recommendations that range from no additional surgery to reports recommending routine additional radical surgery. In fact, the 2009 NCCN guidelines recommend additional hepatic resection and lymphadenectomy for T1b lesion.
In this lecture, we will discuss the published data to date. We will also review the options for preoperative staging, surgical therapy, and long-term follow-up. Overall, we wish to present the spectrum of acceptable care for this stage of disease, as well as present sensible guidelines for treatment of any individual patient.
No conflict of interest.

264 INVITED

Management of Stage 3 gallbladder cancer

T. Gruenberger[1]. *[1]Medical University of Vienna, Dpt. General Surgery, Vienna, Austria*

Introduction: Gallbladder cancer represents the most aggressive form of biliary tract cancer (BTC). In most instances it's either diagnosed incidentally during cholecystectomy or at an advanced stage where potential curative approaches are not possible any more. Stage III disease is defined as locally advanced but still amenable for surgical resection; it's either an extension out of the gallbladder wall into adjacent organs and/or spread to regional lymph nodes. The review will summarize current understanding and treatment options for stage III disease.
Methods: Literature search including western and eastern experience will be performed and summarized and accompanied with personal practice.
Results: Surgical resection of stage III gallbladder cancer requires expertise both in hepato-biliary and vascular procedures and deserves therefore best outcomes both short and long-term in high volume centres with a specialized team for such operations. Recommended extend of resection comprises liver resection including a margin of normal liver tissue, the resection of adjacent organs (large bowel, duodenum), eventually the bile duct(s) if involved and the regional lymph nodes (down to the coeliac axis and behind the pancreatic head). Vascular resections and reconstruction is seldom curative as lymphatic spread extends to the para-aortic region. Reported 5 years overall survival figures for stage III disease range from 0−44%, where the benefit of surgical removal is only demonstrated in part of the publications. However the value of adjuvant therapies and its composition on outcome has not sufficiently been studied. Interestingly recent data do suggest that patient's fitness and ability to tolerate systemic therapy enables a similar outcome of gallbladder cancer patients compared to other types of BTC.
Conclusion: Advanced gallbladder cancer requires multidisciplinary approach to overcome dismal prognosis.
No conflict of interest.

Special Session (Mon, 30 Sep, 13:15−14:15)
MRI and Radiation Therapy in Prostate Cancer: Optimisation of Targeting and Delivery

265 INVITED

MRI-guided brachytherapy

R. Alonzi[1]. [1]*Mount Vernon Hospital, Marie Curie Research Wing, Middlesex, United Kingdom*

It is possible to evaluate prostate cancer with a combination of MR techniques. These include anatomical T_2-weighted sequences with the addition of diffusion, spectroscopy, intrinsic susceptibility-weighted and/or dynamic contrast-enhanced sequences. This multi-parametric approach improves our ability to locate tumour regions within the gland and to estimate the associated tumour aggressiveness and the risk of progression. These sequences produce a range of quantitative biomarkers that assess a host of physiological and biochemical tumour characteristics. These include clonogen density, oxygenation, blood flow, vascular permeability, interstitial fluid pressure and a range of metabolic parameters. Integration of this information into the radiotherapy planning process offers a range of possibilities.
High dose gradients created during the brachytherapy process result in extremely high degrees of conformity to the planning target. The degree of flexibility in source placement and loading facilitates 'dose-painting' with the opportunity to maximise the dose to the highest risk prostate regions and to moderate or reduce the dose to areas that are unlikely to contain any clinically significant tumour. This in turn may improve the therapeutic ratio for prostate radiotherapy by maintaining or even improving tumour control whilst reducing normal tissue toxicity.
In the salvage setting, following localised relapse after external beam radiotherapy, conventional imaging is rarely capable of locating the region of recurrence. Multi-parametric imaging has a higher detection rate and can guide focal salvage brachytherapy. Furthermore, if primary focal therapy is contemplated then it will be imperative to use the optimum multi-modality imaging series, including multi-parametric MRI, to direct the therapy.
This special session lecture will outline the various MRI techniques and discuss the imaging biomarkers derived from each. The methods of integrating the imaging data into the brachytherapy planning process will be outlined together with a discussion of sources of error. MRI-guided brachytherapy dose-painting in the primary and salvage settings will be shown with clinical examples.
No conflict of interest.

266 INVITED

MRI-guided external beam radiotherapy of prostate cancer

U. Van der Heide[1]. [1]*Netherlands Cancer Institute, Radiation Oncology, Amsterdam, Netherlands*

In radiotherapy, prostate cancer is usually treated by delivering a homogeneous dose to the total gland. Technical inabilities in dose delivery and limited access to imaging prevented a more sophisticated approach: differentiating the dose between the tumor and the rest of the prostate. With improvements in both areas, such treatment options are now being explored.
The use of multi-parametric MRI is highly successful in the localization of prostate cancer. Dynamic Contrast-Enhanced (DCE-) MRI shows the passage of contrast agent in tissue and reflects micro-vessel density and permeability. Diffusion-Weighted Imaging (DWI) is sensitive to the random motion of water in the tissue and reflects tissue cellularity.
A limiting factor in the use of multi-parametric MRI for prostate diagnosis and staging is the interpretation of the images. Here a high level of expertise is required. This is even more so for the delineation in radiotherapy, which is labor intensive and prone to observer variability.
This level of uncertainty may be problematic for treatment modalities such as surgery, cryotherapy, high-intensity focused ultrasound and photodynamic therapy. Here essentially a binary decision is made about what (part of the prostate) to treat and what to spare. Radiotherapy has the capacity to differentiate the dose level locally within a single treatment, based on the varying probability of tumor burden. This differential capacity of radiotherapy avoids therefore a binary decision of what to treat and provides an elegant method to deal with uncertainty in the interpretation of multi-parametric MRI. Using logistical models, areas can be defined with a high positive predictive value for the presence of tumor. This constitutes the gross tumor volume (GTV). Similarly, areas can be defined with a high negative predictive value. This constitutes the low-risk clinical target volume (CTV) where no macroscopic tumor is expected, but presence of microscopic disease is anticipated. The remaining part constitutes the high-risk CTV and reflects the part of the prostate for which the tumor presence is uncertain. With external beam radiotherapy dose differentiation between these target volumes is feasible and this allows for the testing of various dose ranges in randomized clinical trials. For intermediate and high-risk patients, this concept is currently tested in the FLAME trial, a multi-center phase III study of dose escalation to the MRI-visible tumor from 77 to 95 Gy.
No conflict of interest.

Special Session (Mon, 30 Sep, 13:15−14:15)
Medical Treatment of GIST

267 INVITED

How to order the many different medical treatments

Abstract not received.

268 INVITED

Adjuvant treatment: To whom, how much and for how long?

H. Joensuu[1]. [1]*Helsinki University Central Hospital, Department of Oncology, Helsinki, Finland*

Adjuvant imatinib administered at the dose of 400 mg/day improved substantially recurrence-free survival of patients with operable GIST in 2 large randomized trials (ACOSOG Z9001 and SSGXVIII/AIO). One of the trials (SSGXVIII/AIO) found that 3 years of adjuvant imatinib improves overall survival as compared with 1 year of imatinib in a population of GIST patients with a high estimated risk for recurrence after surgery, but this observation was based on a limited number of survival events. Based on these data, adjuvant imatinib is recommended for 3 years after surgery to patients who have a substantial risk for GIST recurrence.
Since most patients with local GIST are cured by surgery (approximately 60%), the risk of GIST recurrence should be estimated before starting adjuvant imatinib to identify those patients who are likely cured by surgery alone. Several validated risk stratification schemes are available, including the NIH consensus classification, the modified NIH classification, the AFIP scheme, 2 nomograms and prognostic heat maps. These tools are based on a few standard prognostic factors (tumor size, site, rupture and mitotic count). Prognostic gene expression arrays and comparative genomic hybridization arrays have yielded promising results in small series.
Mutation analysis of *KIT* and *PDGFRA* genes must be carried out from the tumor tissue to further exclude patients who are unlikely to benefit from adjuvant imatinib. Mutations at the *PDGFRA* locus 842 (usually D842V) are relatively common (up to 10% of GISTs) and confer resistance to imatinib. Many patients whose tumor is wild-type with respect of *KIT* and *PDGFRA* are also unlikely to benefit from adjuvant imatinib, including patients with neurofibromatosis 1-associated GIST. Data from advanced GIST suggest that patients with *KIT* exon 9 mutated GIST benefit from higher than the 400 mg daily imatinib dose, but such doses have not been tested in the adjuvant setting.
Longer than 3-year adjuvant regimens have not yet been rigorously evaluated, and the benefits and harms of such regimens remain unknown. Since many GISTs (20−35%) recur during the first 2 years that follow discontinuation of adjuvant imatinib, frequent imaging at 3- to 4-month intervals with CT or MRI during this time period may be beneficial to achieve early detection of recurrence and re-starting of imatinib when the tumor bulk is still small.
Conflict of interest: *Corporate-sponsored research: Novartis*

269 INVITED

How can molecular biology guide future research?

J. Martin-Broto[1], J.A. Lopez-Guerrero[2]. [1]*Son Espases University Hospital, Sarcoma and Melanoma UnitDepartment of Oncology, Palma de Mallorca, Spain;* [2]*IVO Hospital, Laboratory of Molecular Biology, Valencia, Spain*

Gastrointestinal stromal tumors (GISTs), with already registered 3 targeted compounds, represent a molecular targeted therapy model within solid tumors. Most GISTs share a similar genetic profile including *KIT* or *platelet-derived growth factor receptor-alpha* (*PDGFRA*) gain-of-function mutations. Most of GISTs harbour a *KIT* (60−85% of cases) or *PDGFRA* (5%-10%) mutations and approximately 10−15% of GISTs lack of detectable mutations in either receptor, considering these cases such as GIST *wild type* (wt) and indicating that other molecular pathways are also important in the development of GIST.
Molecular biology is leading research in GIST in three different ways:

- Etiopathogenic: Wild type GIST is currently a special interest area of research. Several authors are investigating other pathogenic mechanisms in this context of wt. *IGF1R* is differentially upregulated in wt GIST especially in pediatric population. One well characterized subset

of wt GIST is constituted by epithelioid gastric phenotype, syndromal (Carney triad i.e), with frequent lymph node involvement, multicentric presentation and offering primary resistance to Imatinib with an indolent metastatic evolution. These cases are typically SDH-deficient detected by immunostaining and commonly harbouring SDH mutations.

- Prognostic relevance: Several authors have pointed out the significant poor relapse free survival (RFS) of patients with deletions involving codons 557 and/or 558 when compared with either patient with mutations in exon 11. In addition, investigators have demonstrated that such mutations constitute a time-dependent variable, having their prognostic relevance for RFS within the first 3−4 years after surgery. This fact could contribute to identify a subset of GIST patients with higher and earlier risk of relapse irrespective of clinical prognostic factors. Other studies performing tissue microarrays and microRNA arrays have found some components of Wnt pathway as prognostic relevant for RFS in localized GIST.
- Predictive biomarkers: Meta-analyses compiling two large phase III trials comparing, in metastatic disease, 400 mg vs 800 mg of Imatinib reinforced the previously reported findings that GIST genotype constitutes an independent prognostic factor for time to progression and overall survival. Patients with exon 11 mutations presented better outcome than wt or exon 9 mutations. However for sunitinib the correlation was different: those wt or exon 9 mutated cases had better TTP (19 mounts) than exon 11 mutated (5 months). Unfortunately, the scenario after the emergence of imatinib resistance is highly complex. Polyclonal acquired resistance or genomic amplification could be responsible of secondary resistance. Microenvironment represents an interesting area that translational research should focus on especially after the successful outcome of regorafenib as third line in GIST.

No conflict of interest.

Abstract not received.

271 INVITED

Bridging tumor genomics to patient outcomes through a Large Scale Patient Derived Xenograft (PDX) Platform: Non-Small Cell Lung Cancer (NSCLC) Pilot Studies

D.R. Gandara[1], T. Li[1], P.N. Lara[1], D.T. Cooke[2], R. Gandour-Edwards[3], K. Yoneda[4], N. Goodwin[5], P.C. Mack[1]. *[1]University of California Davis, Internal Medicine HemOnc, Sacramento, USA; [2]University of California Davis, Surgery − Cardiothoracic, Sacramento, USA; [3]University of California, Pathology, Sacramento, USA; [4]University of California Davis, Pulmonary, Sacramento, USA; [5]The Jackson Laboratory West, Sacramento, USA*

Background: Previously described preclinical models have proven suboptimal for directing clinical application of new anti-cancer therapies. Here we detail an integrated research platform engaging core resources at JAX-WEST and the clinical research and genomics facilities at UCDCCC. Pilot studies using this platform are focusing on non-small cell lung cancer (NSCLC) due to molecular targets of interest, such as epidermal growth factor receptor (EGFR), heterogeneity in NSCLC tumor biology and the complexity of related cancer signaling pathways.
Methods: Clinically and demographically annotated cancer patients (pt) seen at UCDCCC and collaborating facilities undergo tumor biopsies of various types which are implanted into JAX Nod Scid Gamma (NSG) mice to develop PDXs. Pt tumors and subsequent PDXs are assessed by histomorphology, clinically applicable molecular biomarkers, gene expression arrays and genome-wide technologies (NGS). NSCLC PDXs are grouped as panels EGFR mutant (MT), KRAS MT ALK+. PDX panels of interest undergo multi-regimen drug testing for differential efficacy, together with pre- and post-therapy NGS and timed tumor pharmacodynamics (PD), to determine mechanisms of primary and acquired resistance in individual PDX models and how to overcome them.
Results: As of June 1, 2013 over 1,000 cancer pt tumors have been xenotransplanted into NSG mice (~160 from NSCLC), including successful PDX formation from small FNA/cell pellets and transportability of specimens by overnight shipping for implantation. NSCLC PDXs show excellent histomorphologic, gene expression and mutational fidelity to host pt tumors, including mutation status for KRAS, EGFR and gene expression levels. Pilot studies in a panel of EGFR MT PDXs with TKI-acquired resistance demonstrate differential drug activity which mimics that of the host pt to the same therapy, and tumor PD at baseline and timed intervals post-therapy provide the basis for subgrouping resistance mechanisms.
Conclusion: This UCDCCC-JAX collaboration has established a large resource applicable to multi-drug testing and tumor PD in a wide range of clinically and genomically characterized tumors, including PDX panels for representative oncogene-driven NSCLCs. An EGFR-directed pilot project supports the feasibility of systematically integrating data derived from these models in order to optimize drug development and treatment strategies to address drug resistance mechanisms. This approach to PDX development and testing will be prospectively integrated into a developing multi-institution clinical trial of the Southwest Oncology Group, designed to advance understanding of differences in inter- and intra-patient tumor biology and hasten the transition to personalized cancer therapy.

Symptom management for cancer patients via mobile phones

Y. Wengström[1], A. Langius Eklöf[1], K. Sundberg[1], K. Blomberg[1]. *[1]Karolinska Institutet, Department of Neurobiology Care Science and Society Nursing, Huddinge, Sweden*

Background: In the front line in cancer care is to systematically integrate patient reported outcomes (PRO) in clinical practice. The development of this research program is based on The Participatory Care Model, and builds on how patients can be integrated in their care. The aim is to evaluate the effects of an interactive e-health solution for assessment of symptom burden, generating instant self-care advice and instant access to health care professionals.
Methods: The hypothesis is that the intervention promotes safe and participatory care and thereby improves clinical management and health care costs. The experimental multicenter studies incorporate a mixed-method approach. Ongoing studies include patients with pancreatic and prostate cancer using the mobile phone application in comparison to control groups in standard care.
Outcomes are collected before and after treatment by questionnaires concerning capacity to understand, communicate health needs and promote healthy behaviors (health literacy), symptom burden and management and quality of life and from records and registers about disease progress and health care costs. Interviews concern participatory and meaningful care. Studies are ongoing for patients with prostate and pancreatic cancer and elderly populations living at home or in care homes.
Results: By using technology patients are able to communicate symptoms and receive instant support while cared for on an outpatient basis and at the same time feel reassured that their condition is monitored by health care professionals facilitating safe and participatory care.
No conflict of interest.

Special Session (Mon, 30 Sep, 13:15−14:15)
Improving Hands-on Education for Young Oncologists

275 INVITED

Training surgical oncologists in Europe

P. Naredi[1]. *[1]Sahlgrenska University Hospital, Department of Surgery Institute of Surgical Sciences Sahlgrenska Academy, Göteborg, Sweden*

Until recently the surgeon often was considered a person who could take on any case and operate if that was decided. A trend in most european countries is that surgeons have some basic training but then we all split into different sub-specialities. Most of these sub-specialities are organ-based

and in very few countries do we have a sub-speciality named surgical oncology. Still we have an EBSQ examination in surgical oncology and ESSO is living well and healthy running more courses than ever and with a updated core curriculum. The core curriculum reflects the direction of a modern training program to become a surgical oncologist.
New demands on cancer care have changed the working environment for the surgical oncologist and she/he must master certain skills. Among these are diagnostic work-up and communication with the patient and relatives. Earlier this often could be done at the ward during a longer hospital stay. Now most diagnostic procedures are done ambulatory and the communication done at the out-patient ward. A second distinct change is decision-making which earlier was done by the surgeons themselves and now often is made by a multidisciplinary tumour board. In this situation the surgeon must be capable to present the case, assess alternative treatments and lead the board to the best decision. A traditional core activity, the surgical procedure is affected by demands of increased experience and optimal performance by the surgeon and at the same time working regulations and many conflicting tasks give little time for the young surgical oncologist in the operating theatre.
The solution to overcome these demands is to a large extent hands-on training with increased supervised training in patient care, tumour board leadership and basic surgical skills training in simulation and then operating with experienced tutors as assistants.
No conflict of interest.

276 INVITED

Training medical oncologists in Europe

J. Smyth[1]. [1]*University of Edinburgh, Edinburgh, United Kingdom*

Medical oncologists need to be trained in both the science and the art of cancer medicine. The science is the easy bit! The greater challenge is to learn how to communicate appropriate explanations of the aetiology, prognosis, and management of a particular cancer to an individual patient. The ever-increasing knowledge base upon which we depend for recommending specific management plans means that there is more and more information that we would like to discuss with individual patients. The more choices there are, the greater the responsibility for giving explanations that are understandable by patients. One of the great challenges for trainees in medical oncology is to learn how to apportion time most appropriately for the giving of information and listening to patients to verify their comprehension. Patient information leaflets and standard protocols are helpful but nothing replaces the personalised consultation to reassure a highly anxious patient at first presentation, a disappointed patient at relapse, or a patient entering the terminal stages of their illness. This presentation will focus on training aspects of communication − appropriate to the different phases of the illness, emphasising how to optimise precious consultation time and to choose the best environment in which to hold these very challenging conversations.
No conflict of interest.

277 INVITED

Training radiation oncologists in Europe

R. Pötter[1], M. Schmid[1]. [1]*Medical University of Vienna, Department of Radiation Oncology, Vienna, Austria*

Training and education of young radiation oncologists in Europe is structured by national radiation oncology societies, national laws and regulations which have led to a great heterogeneity in its practical performance throughout Europe. In order to introduce a minimum joint European standard, in 1991, a "minimum curriculum for the theoretical education in radiation oncology in Europe" was presented by the European Society of Radiotherapy and Oncology (ESTRO), which was endorsed by 22 national radiation oncology societies. This first European curriculum played a major role in harmonizing education and in establishing comparable standards for training in radiation oncology across a considerable number of countries in Europe. In 2004, a second core curriculum edition was published meeting the increasing needs according to the dynamic developments in radiation oncology. Recently, the ESTRO core curricula for clinicians (3rd edition), medical physicist (2nd edition) and RTTs (3rd edition) were updated. The major novelty of the latest editions was the shift from a focus on knowledge and skills (1991, 2004) towards competency based education and training (2012). Beside knowledge and skills, attitude − "to be able to perform a professional act adequately in a given situation" − has become a major goal in education and training now. The following seven competencies were defined in agreement with international preceding developments in this field (CANMED): "medical expertise", "communication", "collaboration", "knowledge/science", "health advocacy/social actions", "management/organisation" and "professionalism".
Furthermore, the integration of radiation oncology has been emphasized as an integral part of the multidisciplinary management of cancer patients including responsibilities of radiation oncologists for diagnosis, treatment decision, performance and evaluation, follow up and supportive care of cancer patients. Recent developments in the field of concomitant radio-chemotherapy and radio-immunotherapy e.g. require specific new knowledge with regard to application and handling of systemic agents, treatment-specific effects and side effects − including their interaction with radiation - and tailored supportive measures. Advances in radiotherapy technology with modern imaging integrated into treatment planning process and performance of complex radiotherapy techniques such as intensity modulated radiotherapy (IMRT), image guided (adaptive) radiotherapy (IGRT) and stereotactic radiotherapy (SBRT) require increasing attention in the training and education process. This includes in particular the ability of (adaptive) tumor and target volume definition, organ at risk selection and delineation, treatment plan evaluation with dose-volume histogram analysis − all within the frame of the overall oncological treatment aims.
The transition to competency based education and training is supported by ongoing developments in the ESTRO School with an increasing number of competency orientated didactic elements within the growing number of "on-site" teaching courses and teaching sessions during congresses focussing on active learning by problem solving, interactive teaching elements, small group tutorials and workshops. In addition, web based and e-learning educational tools and activities were recently introduced into the ESTRO School (e.g. FALCON − web based learning platform for contouring; EAGLE − e-learning teaching courses) in order to further facilitate access to education and training in radiation oncology in Europe and worldwide.
No conflict of interest.

Special Session (Mon, 30 Sep, 13:15−14:15)
EONS−ESO Joint Session − Cancer Surgery and Nursing

278 INVITED

Oncoplastic surgery

M. Cardoso[1]. [1]*Champalimaud Cancer Center, Breast Unit, Lisbon, Portugal*

Breast cancer surgery has evolved in the last 50 years from the radical mastectomy concept to progressive conservation of the gland, which has shown to be an equally effective oncological treatment when combined with radiotherapy.
However, aesthetic results from breast conserving surgery are in 10−30% of cases considered fair or even poor. Increasing sophistication and need for improved global outcomes and patients demand of a better aesthetic outcome has led to the development of oncoplastic surgery. This involves simultaneous excision of the tumour and reconstruction of the defect applying techniques used frequently in cosmetic breast surgery.
Classically the term oncoplastic surgery has been applied to reconstruction in breast conserving surgery but lately mastectomy and immediate breast reconstruction have been progressively included in the designation.
Regarding breast conserving surgery there are two main techniques for oncoplastic surgery: volume displacement and volume replacement. The choice of these depends on the volume of the respected tumour and the total breast size ratio.
The main current indication for oncoplastic surgery is surgeon's preference and capacity to execute the mentioned techniques. There is no doubt that accurate preoperative evaluation of both the tumour and patient characteristics are crucial steps.
If mastectomy is necessary, the whole range of appropriate techniques for breast reconstruction should be offered either immediately if appropriate, or after all adjuvant therapy has been given. Studies have shown that the majority of patients having a mastectomy would like a breast reconstruction if possible. Women choose immediate breast reconstruction because it helps them face the physical and emotional impact of the loss of a breast. With immediate breast reconstruction, a second operation and general anaesthetic can be avoided.
Oncoplastic surgery is becoming progressively available in centers dedicated to breast cancer treatment all over the world. However the monitoring of oncological and aesthetic results has not been walking hand in hand with the dissemination of these new techniques.
A better outcome for patients with oncoplastic surgery is expected but we must support our findings and further progression with the publication of results, ideally, from clinical trials.
No conflict of interest.

279 INVITED

Nurses' role in robotic surgery

D. Lichosik[1]. [1]*European Institute of Oncology, General Surgery − OT, Milan, Italy*

Introduction: Throughout the history of nursing, the discoveries and system of belief of yesterday have served as a platform for the innovations of today. That is especially true for minimally invasive surgery (MIS) approach, exactly indeed perioperative practitioners have been challenged to stay abreast of technology in a field that is a constantly changing landscape of new techniques and improved instruments and equipment.
The "laparoscopic revolution" of the 1980s propelled and encouraged the changes towards a less invasive approaches and new techniques, such as modern robotic-assisted surgery. Science and technology are advancing at an incredible pace and a critical analysis of these new developments become a duty in the perioperative nursing. Nurses, as a member of Robotic Surgical team must represented very good level of professional knowledge, and be an expert in robotic technology, playing a key role in data collection, analyzing trends and outcomes, and identifying safety issues.
The professional nursing staff has an important responsibility to work following best-practice rules, and to analyze periodically roles and habits. This could be an effective instrument in order to improve every-day practice. A team training that involves all members of the robotic surgical team learning together, is the main key to ensuring patient advocacy and safe care. Creation and application of guide lines and specific protocols is giving positive results in daily practice as well.
Conclusions: The role of robotics nurse specialist is both challenging and exciting because the technology is so new and the role is open to interpretation and definition − needs of job description. Daily practice showed us the needs of continues education, especially regarding e nursing skills, creation and revision of guide lines and specific protocols.
No conflict of interest.

280 INVITED

Surgical oncology (several tumor types) in the elderly

R. Audisio[1]. [1]*St. Helens Hospital, University of Liverpool, Prescot, United Kingdom*

Historically, surgery was the only treatment for cancer however, over the last 50 years a better understanding of the disease has led to a multidisciplinary approach, where every single component of the team interacts in order to optimize treatment outcomes, compliance, quality of life and cost effectiveness.
Despite these important improvements, surgery remains the most widely practiced treatment modality with curative intent in the treatment of solid tumours.
"No surgery − no cure" remains a valid aphorism but "no high quality surgery without nursing" is not less important, particularly when dealing with older cancer patients. Here is why: several clinicians and oncologists claim that there is no need of a dedicated team to deal with older cancer patients; the assumption is that we are all perfectly comfortable in treating senior patients who throng our clinic and take out most of our practice.
The epidemiology is self-explanatory: 2/3 cancers affect older people. Breast, colorectal, lung, liver cancers may all affect young individuals but the probability of this is hugely increased with the patient's age.
Most importantly, as the world population is globally ageing (not only in the most economically advanced countries), we will soon be facing a time bomb, an emergency we should well be prepared to deal with.
The most important point is accepting the diversity of the older individual: as one in two geriatric individuals suffers from cognitive impairment, incontinence, need help for feeding and lack of mobility, with one in four is showing signs of delusion, depression, if not of delirium or aggressiveness, it is crucially important that medical professionals understand these differences and their impact; treatment targets are to be modified, compliance is different, consenting is to be adjusted. Social and familiar support needs to be taken into account when offering active treatment, or simply arranging for imaging or follow-up visits.
The diversity of the elderly individual is thus functional as well as intellectual; these domains will both have to be taken into account when designing a treatment plan. If not, the patient will simply not comply with the prescription, fail to attend, develop serious side effects to confirm how poorly designed the therapeutic strategy was.
To assist on this, numerous scoring systems have been designed to define frailty. Ageing results in decline of several physiological systems, giving rise to vulnerability to changes in health states in response to minor stressors. Frailty is a state of increased vulnerability to poor resolution of homeostasis after a stressor event occurs, increasing the risk of adverse outcomes, including falls, delirium and disability. Frailty is not-uniformly distributed suggesting that a) it is not inevitably associated to ageing and b) frailty can (and should) be identified and actively treated. Regrettably, there has been no consensus of the assessment tool to be used, and this has inappropriately generated some confusion. A significant amount of research has focused on this during the last two decades, when oncologists have joined forces with geriatricians. Comprehensive Geriatric Assessment tools have been tested in the oncological setting and proven useful in predicting complications related to cancer treatment, length of hospital stay and related costs. A full Comprehensive Geriatric Assessment is time-consuming and difficult to use in our busy clinics; most importantly, only a small proportion of patients (18−20%) would benefit of this assessment, as they might not require any intervention. On this background, quick tools have been developed to screen for frailty; such instruments only take a few minutes to administer and they have proven very effective: GFI, VES-13 and fTRST are some of these useful instruments which assist the decision-making process in everyday's clinical practice. However achieved, an indication of the patient's fitness is absolutely mandatory when attempting to predict outcomes, individualizing treatment, consenting patients, designing trials and comparing series and results. However defined, there will be more and more frailty assessment at the GP's practice as well as at admission into hospital.
Modern onco-geriatric literature is loaded with attempts to frame cancer patients with a various tools and associate their outcomes to frailty. The role of onco-geriatric nurses here is particularly relevant: some universities have already set up courses for professionals with an interest in this specific field. Here is a window of opportunity for nurses who might consider a switch toward the end of their training. A degree in Onco-Geriatric, for nurses who have completed their oncology training, is a brilliant career opportunity. Nurses are better set to provide expert and tailored care in two parallel fields.
No conflict of interest.

Special Session (Mon, 30 Sep, 13:15−14:15)
Shared Challenges of Small Group Trials

281 INVITED

Principles of adaptive designs and application

A. Faldum[1], H. Müller[2]. [1]*Westfälische Wilhelms Universitat Münster, Institute of Biostatistics and Clinical Research, Münster, Germany;* [2]*Klinikum Oldenburg gGmbH, Klinik für Allgemeine Kinderheilkunde Hämatologie/Onkologie, Oldenburg, Germany*

In clinical trials a periodical check of safety and efficacy data is often needed. For organizational reasons it is rarely desirable to stop a trial during such an interim analysis. Therefore, new study patients are included in the trial while the interim analysis is ongoing. Disregarding the additional information provided by these interim patients would be unsatisfactory, especially for an office of regulatory affairs. Consequently, the rules for flexible decisions must be adjusted to the recruitment of interim patients.
The KRANIOPHARYNGEOM 2007 trial is the first randomised trial in children and adolescents with craniopharyngeoma. An interim analysis is planned to draw conclusions on efficacy, futility, and safety in time. Primary objective of the trial is the comparison of the quality of life between patients with early and late irradiation after incomplete tumour resection. The quality of life is assessed three years after randomisation. Therefore, patients who are enrolled less than three years cannot be evaluated in the interim analysis. If one of the irradiation time points proves to be superior those interim patients have to be evaluated additionally.
In the context of this prospective randomised adaptive trial, different strategies are discussed to consider the analysis of interim patients. The impact of the proposed modifications on power, sample size, and trial duration is demonstrated. With an adequate consideration of interim patients the maximum sample size can be reduced considerably by 50%. The importance of interim analyses increases with the duration of the trial. The strategy for considering interim patients plays an important role for the credibility of the confirmatory analysis. It is essential to incorporate the decision rules in the analysis plan and adjust the adaptive design to the particular situation in time.
No conflict of interest.

282 INVITED

Multi-arm multi-stage studies for speeding the process of new drug evaluation

M. Parmar[1]. [1]*MRC Clinical Trials Unit, London, United Kingdom*

Background: Despite both the increase in basic biologic knowledge and the fact that many new agents have reached various stages of development during the last 10 years, the number of new treatments that have been shown to improve outcomes for patients has not increased as expected.

Methods: We propose the multi-arm, multi-stage trial design as a way to evaluate many treatments at once making treatment evaluation faster and more efficient than current standard trial designs. The design uses intermediate outcomes to conduct lack of activity analyses, to stop randomisation of further patients to research arms which are unlikely to be effective.
Conclusions: By using intermediate outcomes and testing a number of new agents (and combinations) simultaneously, the new design requires fewer patients, and provides a way of improving outcomes for patients more rapidly. Two trials using this methodology are presented.
No conflict of interest.

283 INVITED

Bayesian designs for early phase clinical trials

P. Thall[1]. [1]*MD Anderson Cancer Center, Department of Biostatistics, Houston, USA*

Scientific evaluation of new drugs, devices, or medical procedures is difficult both technically and ethically. This is especially problematic in early phase trials, where little is known, safety is a paramount issue, and sample sizes are small. Bayesian sequentially adaptive methods are particularly well suited for design and conduct of such trials. In this talk, I first will discuss and illustrate some basic principles of Bayesian statistics and sequentially adaptive "learn as you go" clinical trials. Recently developed Bayesian designs based on elicited joint utilities of multiple outcomes then will be presented, with two illustrative dose-finding trials. The first is an oncology trial that uses utilities of two ordinal outcome variables, toxicity severity and number of efficacy events, to optimize palliative radiotherapy dose in children with brain stem gliomas. The second is a multi-institution trial to optimize pre-intubation sedative dose in pre-term infants with respiratory distress syndrome undergoing the Intubation-Surfactant-Extubation procedure. In this trial, sedative doses are chosen for successive cohorts of infants based on the joint utilities of three clinical outcome variables. Computer simulations that establish numerical design properties will be presented for each trial.
No conflict of interest.

Scientific Symposium (Mon, 30 Sep, 15:00−17:00) **Molecular Classification of CRC: Ready for Prime Time?**

284 INVITED

Pitfalls of and opportunities for molecular characterisation in CRC

P. Quirke[1]. [1]*University of Leeds, Department of Histopathology, Leeds, United Kingdom*

The importance of molecular characterisation of CRC has been robustly demonstrated over the last few years. The finding that Ras mutations predict response to anti epidermal growth factor receptor antibodies has rapidly brought molecular testing into routine practice. Many more will emerge in the future.
Molecular data may contribute to prognosis as well as predicting response to targeted therapy. Before being adopted as a prognosticator a molecular test should be demonstrated to be reproducible, 'effective' i.e to achieve a clinically valuable result, to be properly validated in appropriate series and to be superior to all current methods.
Predictive markers need to ensure they identify appropriate patients who may respond to the drug of interest and not exclude individuals who may respond. They may also be prognostic and therefore this element needs to be evaluated and thus randomised trials are the most appropriate setting for such testing.
Robustly evaluated markers of prognosis are available for loss of the mismatch repair proteins (MMR) and these can be combined with B-Raf testing to help identify HNPCC cases and sporadic deficient MMR cases for prognosis. Other claimed prognostic markers such as mRNA profiling have some way to go before being accepted into routine clinical practice. Braf mutations appear to identify a poor prognosis group of stage IV cancers.
Predictive markers are very valuable but need validation. Unfortunately at present we have a limited number of predictive markers. There are currently no markers for the targeted therapies of Bevacizumab, Regorafenib or Aflibercept. The group who respond to anti-EGFr antibodies is being narrowed as one manufacturer now includes NRas mutations as a contraindication and no doubt as further evidence emerges this will be narrowed again. A number of new markers are under investigation but they need validation in clinical trial material from more than one trial. Thought also needs to be given to the identification of molecular lesions that may be relatively uncommon in colorectal cancer but to which there are effective targeted agents that have been proven to work in other cancers. Her-2 amplification occurs in 2.6% of our stage IV cancers but this small group might benefit from anti-Her2 antibody therapy. International trials covering these rare targets need to be developed.
The molecular characterization of CRC's is worthwhile and will contribute to improving outcomes in colorectal cancer.
Conflict of interest: *Ownership: None. Advisory board: None. Board of directors: None. Corporate-sponsored research: Genomic health Oncotype Dx research funded. Amgen Piccolo trial support for research testing. Affymetrix testing of oncoscan chips.*

285 INVITED

Precision medicine for colorectal cancers

A. Bardelli[1]. [1]*University of Torino − IRCC, Department of Oncology, Torino, Italy*

The EGFR-targeted monoclonal antibodies cetuximab and panitumumab paved the way to the individualized treatment of metastatic colorectal cancer (mCRC). In the last 5 years it has become evident that mCRCs respond differently to EGFR-targeted agents and that the tumor-specific response has a genetic basis. After the initial response, secondary resistance invariably ensues, thereby limiting the clinical benefit of anti-EGFR therapies. Understanding the molecular bases of secondary resistance to cetuximab and panitumumab is required to design additional therapeutic options. We found that molecular alterations in KRAS and MET are causally associated with the onset of acquired resistance to anti-EGFR blockade in colorectal cancers. We optimized a diagnostic platform to identify resistance-associated genetic alterations in the blood of patients (liquid biopsy) months before radiographic documentation of disease progression. Preclinical models of relapse including cell lines and patient-derived xenografts (*xenopatients*) allowed us to assess new lines of therapy. Overall our results provide the rationale for delaying or reversing resistance to anti EGFR therapies in mCRCs and support the initiation of innovative − molecularly driven- clinical trials.
No conflict of interest.

286 INVITED

Finding genetic dependencies in BRAF and KRAS mutant tumors

R. Bernards[1]. [1]*The Netherlands Cancer Institute, Division of Molecular CarcinogenesisCenter for Biomedical Genetic and Cancer Genomics Center, Amsterdam, Netherlands*

Cancer remains difficult to treat, even with the new generation of targeted cancer drugs. By far the most formidable obstacle is the rapid emergence of therapy resistance. Indeed, many of the new cancer drugs elicit powerful initial responses, leading to dramatic effects on "progression free survival", but far less long-term benefit is seen in terms of overall survival.
Combination therapies can help fight therapy resistance, but with an arsenal of over 1000 cancer drugs in clinical development, the number of possible combinations seems nearly endless. In my laboratory we employ functional genetic screens to find powerful combinations of cancer drugs by exploiting the concept of "synthetic lethality". Using RNA interference-based genetic screens with collections of shRNAs that target drugable gene families, we search for genes whose inactivation is particularly synergistic with clinically-relevant cancer drugs. Such screens can identify drug combinations that are far more powerful than the sum of the two single agents. We aim to understand the molecular rationale for the observed synergy between two cancer drugs. Once we have insight into the molecular mechanism, we aim to bring such rationally-designed combinations to the cancer clinic as soon as possible through our clinical collaborations in our comprehensive cancer center.
As a second approach, we use genome wide loss-of-function genetic screens in cancer cells that are sensitive to the drug-of-interest to search for genes whose down-regulation confers resistance to the drug-of-interest. Such genetic screens can identify novel mechanisms of drug resistance. This in turn may suggest strategies that help prevent drug resistance.
Examples of genetic screens that help optimize the treatment of KRAS and BRAF mutant cancers will be presented.
No conflict of interest.

287 INVITED

Relevance of non K-RAS mutations for new drug selection

Abstract not received.

Society Session (Mon, 30 Sep, 14:45−16:45)
European Society for Medical Oncology (ESMO)

288 INVITED

The development of targeted therapies in the genomic era: What is the expected impact on breast cancer?

F. Andre[1]. [1]*Institut Gustave Roussy, Department of Medical Oncology, Paris, France*

Molecular characterisation of breast cancer has shown that this disease includes a very large numbers of sub-entities. This concept of disease fragmentation according to the presence of oncogenic drivers is challenging the conventional way of developing drugs in the breast cancer field.
First, the disease fragmentation makes mandatory to re-organize the organisation of cooperative groups into large consortium. Indeed, a single cooperative group is no longer able to develop a drug when a genomic segment accounts for less than 10% of breast cancer.
Second, since most of the breast cancer patients are treated outside the comprehensive cancer centers, there is a need to perform molecular screening in peripheral centers, and then attract patients with a genomic alteration to the centers of drug development.
These two changes could allow making feasible drug development in rare genomic segments. Nevertheless, these rare genomic segments defined by single genomic alteration will then be sub-fragmented into further segmentation. This further level of complexity will make extremely difficult the development of targeted therapy in a biomarker-defined stratum of patients. From this point, we will have to change the way clinical research is being done. One possible solution to overcome the problem of paucity in rare genomic segments is the development of clinical trials that will test whether the use of a genomic algorithm improves outcome in breast cancer patients. In this model, several drugs are being tested in the same experimental arm, each of them matched to specific genomic alteration. This new model of clinical trials could allow including all breast cancer patients in the same trial.
Finally, these genomic algorithms should integrate genomics of other pathways than oncogen-de addiction including DNA repair system, immunology system and metabolism, in order to propose a personalized medicine based not only on kinase inhibition.
No conflict of interest.

289 INVITED

Molecular screening and patient selection for phase I/II trials

P. Bedard[1]. [1]*Princess Margaret Hospital, Division of Medical Oncology and Hematology, Toronto, Canada*

The traditional model of drug development in oncology involves phase I testing to establish the maximum tolerated dose and phase II testing to evaluate activity in tumour-type specific cohorts. With an increasing repertoire of available targeted cancer drugs and potential therapeutic combinations, drug development has evolved to include molecular enrichment of early phase clinical trials. This involves early proof-of-concept testing of new cancer drugs in patients whose tumours harbour sensitizing genomic alterations. Many large academic centres and co-operative clinical research groups have recently launched molecular screening programs to identify patients with “druggable” mutations who can be matched to genotype-directed early phase clinical trials. There are a variety of molecular screening approaches that have been used, including single gene testing; genotyping panels that cover recurrent oncogenic hotspot mutations; genome-wide testing for copy number alterations; and targeted next generation DNA sequencing of cancer relevant genes. The key considerations for molecular screening, such as use of archival tumour tissue or fresh biopsy of a metastatic lesion; testing in a clinical or research laboratory; turnaround time for the reporting of results; the interpretation of clinical actionability; the identification of incidental findings in heritable cancer susceptibility genes with germline testing; and access to a investigational targeted therapies will be discussed.
Conflict of interest: *Advisory board: Sanofi, Novartis, Roche. Corporate-sponsored research: GlaxoSmithKline, Sanofi, Novartis, BristolMyersSquibb, Roche, Genentech, Servier*

290 INVITED

Increased fragmentation of solid tumors: Implications for patient care

J. De Grève[1]. [1]*Oncologisch Centrum UZ Brussel, Medical Oncology, Brussels, Belgium*

Fragmentation of solid tumors is the gateway to personalized medicine. Fragmentation relies on clinical, pathological criteria and molecular criteria. Clinical/pathological criteria mostly provide prognostic information and are more subjective. The molecular criteria are more objective and predictive. The earliest model is HER2 in breast cancer and the most sophisticated lung adenocarcinoma.
Today, the clinical oncologist deals with individual driver mutations and single agent targeted therapies (with or without chemo); the cancer researcher has an integrative approach: pan-genomic interrogation at gene and RNA level, proteomics and functional pathway analysis. That analysis will lead to an even more sophisticated fragmentation of cancers and ever-smaller patient cohorts with shared characteristics. Not all of the possible combination therapies will be testable in the clinic. Therefore interest has emerged in panels of xenografts with representative genomic profiles (avatar mice) in which to test drug combinations before bringing them to the clinic.
Currently genomic testing uses validated companion diagnostics. Limitations are the incomplete sensitivity and expense of commercial diagnostic kits and amount of biopsy material available. In lung cancer, ten percent of biopsies are insufficient for a definitive exclusion of an EGFR mutation and most biopsies will allow only a couple of assays (e.g. EGFR and Alk). On the other hand there will be a couple dozen of genes and resistance mutations to be examined to select the appropriate treatment.
For all of these reasons we need comprehensive methods for mutation screening: defined cancer gene panels that correspond to drugs that are in development or registered.
For each patient a molecular diagnostic report is to be tied to the initial pathological report and accompany the patient as a “molecular passport”. If the ensuing fragmentation does not immediately benefit the treatment of a particular patient, it might allow so in the near future without having to resort to last minute diagnostic efforts in a progressive disease context.
Oncologists need molecular based guidelines that link molecular profiles with therapeutic options.
The limitations of tissue quantities and quality as well as the future need to monitor for resistance mutations and the reluctance of patients for undergoing re-biopsies or the technical impossibility asks for additional approaches such as circulating tumor cells (CTC’s).
Currently the interval between initial demonstration of high efficacy and marketing of new drugs can is too long. The development of drugs that fit into the fragmentation model should accelerate for early access to patients in medical need and simplified for reducing development cost. Additional measures need to be taken in order to keep this affordable.
For rare mutations we need mutation-driven studies in which patients with a particular mutation (whichever cancer type) can access a corresponding drug. Significant efficacy (RR) in a small cohort of patients should then suffice for registration and broad access.
The advantage of the fragmentation of cancers is that treatments have become more efficient and less toxic. This fragmentation is only beginning to govern patient care and no doubt will amplify and lead to steady progress in outcome for all cancer types.
No conflict of interest.

Scientific Symposium (Mon, 30 Sep, 14:45−16:45)
Do Resistance Mechanisms Require Combination Treatment in Immunomodulated and Targeted Therapies?

291 INVITED

New strategies for immunotherapies

S. Quezada[1]. [1]*University College London, UCL Cancer Institute Department of Haematology, London, United Kingdom*

Mobilising and reprograming the immune response with immune modulatory antibodies has emerged as a promising anti-cancer strategy, capable of producing significant and durable responses as demonstrated in recent high-profile immunotherapy trials targeting the immune-modulatory receptors PD-1 and CTLA-4.
Nonetheless, despite the success of therapies aiming to redirect or enhance T cell responses against tumours (*e.g.* vaccination, adoptive T cell transfer and immunomodulatory antibodies), complete responses remain limited to a fraction of treated patients, and there is an urgent need to explore the mechanisms underlying response and resistance in order to improve the efficacy of these novel therapeutics.
By focusing in the study of effector and regulatory tumour-reactive $CD4^+$ T cells my group is interested in the mechanism underpinning the activity of different immune-modulatory antibodies, and the potential positive and negative impact that the tumour microenvironment may have in the recruitment, survival and function of different T cell subsets. We will discuss data on the critical role played by tumour-reactive $CD4^+$ T cells in tumour progression and elimination as well as new therapies

capable of neutralising the immune-suppressive nature of the tumour microenvironment, and promoting potent rejection of fully established cancers.
No conflict of interest.

292 INVITED
Resistance mechanisms to BRAF targeted agents

K. Flaherty[1]. [1]*Massachusetts General Hospital Cancer Center, Boston, USA*

For half of the advanced melanoma population, selective BRAF inhibitor therapy has transformed the natural history of disease and provided a platform for developing molecularly targeted therapy combinations. The clinical utility of vemurafenib, FDA approved BRAF inhibitor, has been validated by another potent and selective agent, dabrafenib. However, two clinical limitations of BRAF inhibitor therapy frame the problem for the melanoma field: *de novo* and acquired resistance. Insights into the mechanisms underlying both of these phenomena have set the stage for clinical investigation of several novel BRAF inhibitor based combination therapies. Foremost among them is the combination of a MEK inhibitor with BRAF inhibitor. Preliminary clinical evidence suggests that this combination may supplant single agent BRAF inhibitor therapy near future as the standard approach for metastatic patients. Yet resistance remains a challenge and strategies to target non-MAP kinase pathway dependent mechanisms are needed.
Optimal schedule of administration has not yet been explored clinically and represents an opportunity to maximize the impact of already available agents. Opportunities to further exploit the profound dependence that BRAF mutant tumors have on the MAP kinase pathway are evident with emerging preclinical data with HSP90 and ERK inhibitors. Intercepting pathways that are activated as a consequence of BRAF inhibitor therapy, such as up regulation of BCL2A1 and ERBB3, represent tractable strategies for improving on the early impact of therapy. And, blocking compensatory pathways not impacted by BRAF inhibitor therapy such as the PI3K pathway (in some cases) and growth factor receptor activation derived from the tumor microenvironment provide further opportunities for improving on a backbone of optimal MAP kinase pathway inhibition. As this broad array of novel therapeutic strategies are investigated clinically, an immediate need arises for the development of predictive biomarkers that allow for the novel combinations to be deployed in as personalized a fashion as BRAF inhibitor therapy was itself.
Conflict of interest: *Advisory board: Roche/Genentech, GlaxoSmithKline, Novartis*

293 INVITED
Resistance mechanisms to immunotherapy

A. Ribas[1]. [1]*University of California Los Angeles, Medicine, Los Angeles, USA*

As immunotherapy approaches for cancer become more widely used and have higher response rates, it is important to understand how some tumors may escape its control. There are two main types of immunotherapy for cancer with significant activity, therapies that stimulate T cells in vivo, and adoptive cell transfer (ACT) transfer therapy where T cells are expanded ex vivo and reinfused to patients.
A hallmark of tumor immunotherapy has been the extremely long duration of the tumor responses noted with a variety of agents, including vaccines, cytokines and immune modulating antibodies. As such, the issue of resistance to these immunotherapies is mainly innate resistance, where many patients do not respond to therapy and the ones who respond unfrequently develop acquired resistance. Multiple immune self-regulating mechanisms limit such immune responses to cancer antigens. It has become clear that an important one is adaptive resistance by expressing PD-L1 when tumor cells are infiltrated by T cells producing interferons. Blocking PD-1/PD-L1 interactions with specific antibodies results in unprecedented high response rates for this mode of immunotherapy, with most of the responses being durable.
ACT with tumor-infiltrating lymphocytes (TIL) or T cell receptor (TCR) engineered lymphocytes results in a higher frequency of initial tumor responses. Resistance can be innate, when tumor cells do not respond to the infusion of a large pool of tumor-specific activated lymphocytes, but it can also be acquired resistance with progression after an initial tumor response. In the ACT setting, acquired resistance is common. This can be due to a decreased functionality of T cells after ACT, where T cells initially have high antitumor activity but they then lose it over time, or because the cancer adapted to the therapy. Acquired resistance due to tumor adaptation was thought to be due to the outgrowth of subclones that do not express a certain tumour antigen and therefore survive ACT using engineered T cells specific for that antigen, or as a result of some or all cells in a tumour lacking key proteins in the cellular pathway by which antigens are 'presented' to T cells. However, such processes are uncommon in the tumor biopsies studied by many groups. Recently, Tuetling and colleagues proposed a mechanism of acquired resistance to ACT immunotherapy where the antitumor T cells produce cytokines (i.e. TNF-alpha) that are used by the cancer cells to de-differentiate and lead to escape from immune recognition. Demonstration that this process happens in humans may lead to improved ACT-based therapies for cancer.

294 INVITED
Resistance to combination therapies

F. Hodi[1]. [1]*Dana-Farber Cancer Institute, Boston MA, USA*

Success with targeted and immune therapies for the treatment of melanoma has provided a new basis to approach clinical development. The potential for combinatorial approaches to improve patient outcomes has never been so promising. CTLA-4 blockade with ipilimumab as a single agent or in combination with dacarbazine chemotherapy can improve survival in patients with metastatic melanoma. Vemurafenib has demonstrated a survival advantage in patients whose tumors harbor a BRAF V600E mutation. Potential resistant mechanisms to immune checkpoint blockade as well as known resistant mechanisms to selective BRAF inhibition will be discussed. In addition, PD-1 blockade as well as BRAFi/MEKi combinations have already showed additional promise for progress against resistant mechanisms. Challenges will be discussed how to provide synergistic benefits to patients without significant increases in side effects. Potential combinatorial approaches include targeted therapies with immune checkpoint blockade, anti-angiogenic therapies, and combined immune therapy reagents. Based on preclinical and early clinical experiences, the possible combinations of checkpoint blockade with cytokine, targeted therapy, and anti-angiogenic agents will be discussed. Understanding mechanisms of resistance to these novel therapeutic approaches and potential means to counteract these will shed insight into future best approaches to patient care.

Scientific Symposium (Mon, 30 Sep, 14:45−16:45)
The Elderly Cancer Patient

295 INVITED
Adherence in elderly patients: The importance of adequate and continuous dosing

L. Noens[1]. [1]*University Hospital Ghent, Department of Haematology, Ghent, Belgium*

The number of oral anti-cancer drugs is rising constantly. However the issue of poor adherence to these medications still is not acknowledged. Its importance in failed treatments or underestimated effectiveness makes it mandatory to create awareness and to develop pragmatic strategies to enhance medication adherence. The striking example of the impact of suboptimal adherence to the Bcr-Abl inhibitors in CML illustrates the need for understanding the best approaches to adherence-enhancing interventions. The observations can be extrapolated to any longterm oral treatment for chronic conditions.Therefore adherence should be assessed routinely, and specifically in oral cancer therapies. The development of methodologies improving adherence has gained attention in recent years. The literature reveals a variety of non-adherence determinants. Focusing on predictors of non-adherence, listed from most frequent: adverse events, side effects, disease and treatment duration, the patient-physician relationship and disease related education. Patient characteristics are age, gender, disease severity, comorbidities and health believes and expectations. Treatment related factors are dosing schedule and co-medication. The findings on the relationship between adherence and age are contradictory across studies. Given the rate of comorbidities and therefore the extented list of medications, older patients carry a higher risk of becoming a poor adherer with dire consequences. In the prospective CML trial, age and living alone were among the risk factors, indicating the importance of social support and daily assistance. Regimen complexity is also a barrier to adherence, with additionally other constrains such as food or storing conditions. Another very important issue is "drug forgiveness" i.e. the non-adherence margin that should be defined for all oral cancer therapies. From a follow-on analysis of the CML-trial, we demonstrated the need for optimal adherence: no margin for non-adherence in CML! The poor adherence risk also depends on the hospital

discharge management of patients with an extended list of medications. Certainly for older people, special attention has to be focused on their proper medication management, ideally prior to discharge and with the aid of relatives, but also by implementing helpful devices and last but not least home-care provision. Unfortunately, for measuring adherence there is no gold standard method available. Every method has its drawbacks. Although an improved awareness on barriers to adherence is slowly emerging, most of the strategies for improvement are still under development. Methods that may be effective for long-term adherence are centered around more frequent interaction with the patient. The advantages of oral treatment for many conditions, including cancer, mandate that all members of the care team use effective strategies and tools to encourage proper adherence, specifically in older patients.

Polypharmacy in the elderly patient

F. Van den Berkmortel[1]. [1]*Atrium Medical Center, Heerlen, Netherlands*

The connection between aging and cancer is significant, with more than 60% of all cancers occurring among those over 65 years of age. Persons over the age of 65 represent approximately 15% of the population, but account for more than a third of all prescription drugs taken and an even higher percentage of nonprescription drugs. Except for concomitant use of 5 or more drugs, polypharmacy also includes the use of unnecessary/potentially inappropriate medication, underuse and non-prescribed medication (herbal/complementary agents). An average use of 5−9 drugs was reported in old cancer patients. In elderly cancer patients use of preventative and complementary medication was reported in 30−80%. Approximately 5−10% of hospital admissions of elderly patients are related to adverse drug reactions. An exponential increase in the incidence of adverse drug reactions is observed with the addition of each drug to an existing regimen. In ambulatory cancer patients about 30% was exposed to potentially interacting pairs of drug. Complementary medication such as St. John's wort, ginseng and garlic imposes a higher risk for drug interaction in patients using chemotherapy. Drug compliance decreases in proportion to the number of drugs prescribed, meaning that anti-cancer and symptom control medication may not be taken because of the burden of other medication, leading to poor disease control, increased healthcare costs, and increased mortality. Several tools either using specific lists such as Beers criteria, Screening Tool of Older Persons' Prescriptions (STOPP) and Screening Tool to Alert doctors to Right Treatment (START) or using general guidelines such as the Medication Appropriateness Index (MAI) have been developed to guide optimal treatment. In intervention studies a reduction in the number of medications and/or use of potentially inappropriate medications was reported although reduction in mortality or hospital admission is less clear. A multidisciplinary approach is needed to address the issue of polypharmacy in the older cancer patient. In the presentation the challenges of polypharmacy in elderly cancer patients will be discussed.
No conflict of interest.

297 INVITED

The geriatric navigator/assessment

B.A. Esbensen[1]. [1]*Copenhagen University Hospital Glostrup, Department of Nursing and Health Science, Glostrup, Denmark*

Background: During the last decades, several studies have described substantial variation in changes in functional ability. Quality of Life (QoL) among elderly people is highly affected by dependency in Activities in Daily Living (ADL) following reduced functional ability. The aim of this presentation is to focus on overall results from a mixed method study aiming to explore dependency in elderly persons newly diagnosed with cancer and to focus on Comprehensive Geriatric Assessment (CGA) as a tool in clinical practice.
Method: In total, 101 elderly (aged 65+) newly diagnosed with cancer were included in the quantitative part of the study (median age 74.74 (IQR 8.75); N = 74 Women); whereas 16 elderly participated in the qualitative part (median age 73.90 (IQR 5.19); N = 12 women). Issues about quality of life and dependency were covered in a questionnaire. Open-ended interviews were the tool to getting closer to the experience of being dependent in old age.
Results: In total, 72.3% were independent in all Instrumental-ADL functions, and 17.8% were independent in regard to Personal-ADL. Factors significantly associated with low quality of life were e.g. 'need more help in daily living', 'dependency in ADL' and 'getting help from adult children'. '*Dependence on health care*' was an essential consequence of getting cancer in old age, and implied a change in social identity − from being an ordinary person to becoming a patient. *'Everyday life controlled by bodily limitations'* meant that bodily complaints limited everyday life. Fatigue restricted daily living, led to dependency and was a reminder of both growing old and of illness.
Conclusion and further perspective: Combining different approaches was seen as complementary, and by integrating different methods a more complete picture was achieved about elderly persons with cancer. The results highlight that dependency affects the elderly negatively and that appropriate intervention strategies aiming to identify a person's resources is recommended.
Attention to ADL capacity in the elderly seems vital to identifying those who experience limitations. When considering cancer in the elderly, other problems are also prevalent, and a narrow perspective on the cancer may be detrimental to the older person.
CGA is suitable to identify vulnerable individuals in order to optimize adjusted care. CGA has proved to be a sound procedure to recognize the heterogeneity of the elderly population and focus their care plans accordingly. Such assessment leads to a deeper understanding of how dependence influences to a more accurate intervention. Combining different approaches was seen as complementary, and by integrating different methods a more complete picture was achieved about elderly persons with cancer.

Circulating tumour cells as a liquid biopsy in breast cancer: Are we there yet?

M. Ignatiadis[1]. [1]*Institut Jules Bordet, Medical Oncology, Brussels, Belgium*

Recent next generation sequencing (NGS) studies have shown that breast cancer (BC) is characterized by a considerable inter- and intra-tumoral heterogeneity and that this heterogeneity is one of the drivers of tumor evolution. The detection and characterization of Circulating Tumor Cells (CTCs) in the peripheral blood of patients with BC is expected to provide an opportunity for real-time evaluation of tumor evolution, monitoring treatment response and understanding treatment resistance. There have been several challenges associated with the study of CTCs as a "liquid biopsy". First, around two thirds of metastatic BC patients and a considerably lower proportion of early BC patients have detectable CTCs with widely used technologies. Secondly, even in patients with detectable CTCs, these cells are often rare events in peripheral blood and therefore downstream applications depend on the use of limited material. As a consequence, for comprehensive genomic analysis of these cells, DNA amplification is required and this may introduce several biases that need to be carefully corrected. Recent advances hold the promise to address these challenges. The most widely used technologies for CTC detection depend on the use of antibodies against Epithelial Cell Adhesion Molecule (EpCAM), a protein expressed by epithelial tumor cells but not blood cells. Several lines of evidence suggest that technologies relying on EpCAM do not adequately capture CTCs with an Epithelial–mesenchymal transition (EMT) phenotype, a biologically aggressive and potentially relevant subpopulation. The optimization of existing technologies including microfluidics together with enrichment approaches that rely on multiple markers or on the physical properties of CTCs (e.g. filter technologies) can address this problem. All these technologies need to undergo appropriate analytical and clinical validation. Ultimately, clinical utility needs to be demonstrated. Currently, there is only one technology for CTC detection (CellSearch, Veridex) that has been cleared by the Food and Drug Administration (FDA) as an aid in monitoring metastatic breast, colorectal and prostate cancer patients. Several ongoing trials are evaluating the role of CTC detection using CellSearch in treatment decision making. However beyond enumeration, there are already examples of CTC phenotypic and molecular characterization (e.g. androgen signaling in prostate cancer, epidermal growth factor mutations in lung cancer and the ratio of mesenchymal to epithelial CTCs in BC) to monitor treatment response/resistance in clinical studies. In early BC, a pioneering phase 2 study including 75 patient with HER2-negative early BC showed that trastuzumab can eliminate Cytokeratin-19 mRNA-positive CTCs and reduce clinical relapses. The molecular analysis of CTCs could complement analysis of primary/metastatic tumor and together with circulating DNA might ultimately lead closer to precision cancer medicine.

299 INVITED

Circulating tumour DNA sequencing: From targeted mutations to whole genome resolution

Y. Lo[1]. [1]*Chinese University of Hong Kong, Hong Kong SAR, China*

Background: Tumour DNA has been found in the plasma of cancer patients. We have explored the use of techniques capable of detecting targets at single DNA molecule resolution for analysing plasma DNA in cancer patients.
Material and Methods: Patients with lung cancer and hepatocellular carcinoma (HCC) were recruited from the Prince of Wales Hospital in Hong Kong. Digital PCR was used to detect epidermal growth factor receptor (EGFR) mutations in lung cancer patients. Shotgun massively parallel sequencing (MPS) was used to analyse plasma DNA from the HCC patients' plasma.
Results: Digital PCR allowed the sensitive, specific and quantitative detection of EGFR mutations in the plasma of lung cancer patients. Such detection demonstrated a good correlation with the clinical course. MPS analysis of plasma DNA from HCC patients allowed genomewide copy number aberrations and single nucleotide variations of the tumour genomes to be detected from the patients' plasma. MPS also allowed the fractional circulating tumoral DNA concentration for each patient to be measured.
Conclusion: Digital PCR and MPS are powerful methods for the detection of tumour-derived DNA in the plasma of cancer patients.
Conflict of interest: *Ownership: Sequenom. Other substantive relationships: Patent filing*

300 INVITED

Noninvasive monitoring of cancer dynamics using circulating tumour DNA

N. Rosenfeld[1]. [1]*University of Cambridge, Cancer Research UK Cambridge Institute, Cambridge, United Kingdom*

Improved methods for detection of residual disease, quantification of tumour burden, and molecular characterization, will help management of cancer care. Presence of circulating tumour DNA fragments in patient plasma has long been recognised, however only recently have technologies matured that allow these entities to be effectively studied and exploited as diagnostic tools. Different analysis methods can work together, allowing noninvasive assessment of both levels and genetic characteristics of circulating tumour DNA (ctDNA). Analysis of mutation patterns in ctDNA can help select suitable therapies, and can help identify novel resistance mechanisms in patient cohorts or the emergence of resistance in individual patients. Accumulating evidence suggests that levels of ctDNA are an informative prognostic factor in advanced epithelial cancers, and that changes in the levels of ctDNA correlate with disease progression and response to treatment. Because this analysis relies on readily accessible blood samples, those can be collected serially over clinical follow-up, providing a window into tumour dynamics. Our studies in cohorts of patients with advanced metastatic cancers show that in many patients, serial analysis of ctDNA provides the earliest indication of disease progression or response. For earlier cancers, only limited quantitative data on ctDNA levels is at present available. Potential applications of ctDNA as a diagnostic aid span a wide range of clinical scenarios, but further studies are needed to establish the clinical utility, limitations, and performance characteristics. As methods become more accessible, these are likely to emerge in the coming years.

Radiomics: Promoting evidence through image features from radiographic images

H.J. Aerts[1]. [1]*Dana-Farber Brigham and Women's Cancer Center Harvard Medical School, Radiation Oncology & Radiology, Boston, USA*

Individualized medicine requires techniques that enable visualization, quantification and time series of disease processes in a non-invasive way in individual patients. Medical imaging is intuitively very suitable for this purpose. Over the past decades, medical imaging has progressed in four distinct ways allowing quantitative imaging: innovations in medical devices (hardware), innovations in imaging agents, standardization in imaging protocols, and innovations in imaging analysis. By these we have witnessed medical imaging in clinical oncology evolving from a primarily diagnostic tool to a theragnostic tool by a multitude of techniques involved in the treatment and characterization of tumors and normal organs and tissues. "Radiomics", the extraction and analysis of large amounts of advanced features from medical images, addresses this subject. The central hypothesis of radiomics is that these radiomic features are related with the underlying tumor phenotypes and gene-expression profiles, thereby potentially providing valuable diagnostic, prognostic or predictive information. However, there are distinct processes involved in radiomics, each with its own challenges. The first step involves the acquisition of high quality and standardized imaging, for diagnostic or planning purposes. From this image, the macroscopic tumor is defined, either with an automated segmentation method or alternatively by an experienced radiologist or radiation oncologist. Quantitative imaging features are subsequently extracted from the previously defined tumor region. These features involve descriptors of intensity distribution, spatial relationships between the various intensity levels, texture heterogeneity patterns, descriptors of shape and of the relations of the tumor with the surrounding tissues (i.e. attachment to the pleural wall in lung, differentiation). The extracted image traits are then subjected to a bioinformatics analysis using machine learning techniques for feature selection and model building. The most informative features are identified based on their independence from other traits, reproducibility and prominence in the data. The most promising features are assessed with outcome, for example survival time or gene-expression. In this presentation I will give a detailed description of the radiomics workflow and show recent results from our groups and collaborators.

303 INVITED

Promoting evidence through correlation of radiology information to genomic data: The Radiogenomic Consortium

C. West[1]. [1]*University of Manchester, School of Medicine, Manchester, United Kingdom*

Radiotherapy patients show individual variation in toxicity, which can impair quality-of-life and is dose-limiting. Modern radiotherapy techniques improve outcomes but future gains require biological optimisation − information on patient radiosensitivity being particularly useful. Radiosensitivity is a complex, polygenic, heritable trait. Rare homozygote mutations in some genes (e.g. *ATM*) have large effects but most of the variation in radiosensitivity is attributed to large numbers of common genetic variants (mostly single nucleotide polymorphisms − SNPs) each conferring small, but together clinically exploitable, effects. As effect sizes for common variants are small, large databases are required to identify the genetic variants involved. A Radiogenomics Consortium was established in 2009 to facilitate large cooperative studies. The consortium has >150 members and from ~80 institutions in ~18 countries. Two published cooperative studies involved meta-analysis of SNP data for *TGFB1* and *TNF* in >2,000 patients and highlight the ability to pool radiotherapy databases across centres and countries to link genotype with toxicity. Common variants are identified in genome wide association studies (GWAS) with no prior assumption of the genes involved. The area of work is challenging because of the amount of data that must be collected: prospective assessment of toxicity (including pre-treatment); information on dose and other treatments; data on modifiers and confounders of the relationship between genotype and toxicity such as age, smoking history, co-morbidities. The Radiogenomics Consortium is carrying out a meta-analysis of four GWAS from prostate cancer cohorts recruited in the UK, Spain, Canada and USA ($n \approx 1{,}600$). Unpublished data show validation of several loci at genome-wide-appropriate levels of significance and that there are many more loci, which will achieve statistical significance given larger sample sizes. The meta-analysis shows the feasibility and potential of large-scale national and international cooperation to correlate radiotherapy and genomic data.

MDM2 and CDK4 as a therapeutic target in sarcomas

J. Blay[1], A. Le Cesne[2], P. Cassier[3], I. Ray-Coquard[3]. [1]*Centre Régional Léon Berard, MedecineINSERM U590, Lyon, France;* [2]*Institut G. Roussy, Medecine, Villejuif, France;* [3]*Centre Régional Léon Berard, MedecineINSERM U590, Lyon, France*

MDM2 amplification occurs across many tumor types but is particularly common in sarcomas. It is observed in a subset of liposarcoma (LPS), intimal sarcoma, surface osteosarcoma. LPS is the most frequent histological type of soft tissue sarcoma and well-differentiated (WD) and dedifferentiated (DD) LPSs are the most frequent subtypes (incidence ~1/100000/year). WD/DD LPS has a simple genomic profile characterized by a molecular and diagnostic hallmark: the amplification of the 12q14−15 segment, including MDM2 and most often (80%) CDK4. Molecular diagnosis can be obtained by FISH, and overexpression detected by IHC is an important part of the diagnostic tools. In advanced/unresectable disease, cytotoxic agents provide limited response rates (~10%) and resulting in short median progression free survival (PFS) (2 to 6 months). For these tumors innovative approaches introduced early in advanced phase might be proposed. The administration of Nutlin 3a, RG7112, in WD/DD LPS has been reported to enable the reactivation of p53 in vivo in cancer patients, with the induction of apoptosis, cell cycle arrest, increase of circulating MIC-1 as a potent biomarker. Antitumor activity was observed in some of these patients. Very interestingly, antitumor activity was observed in one patient with an associated p53 mutation. Other agents affecting MDM2/p53 protein interaction are currently being investigated. CDK4 inhibitor PD0332991 has also recently been explored in patients with advanced *CDK4*-amplified well-differentiated or dedifferentiated liposarcoma, with detectable antitumor activity. The development of these agents as single agent, combinations, in sarcomas with or without MDM2 amplification and p53 alteration will be discussed.

307 INVITED

Targeted treatment of Ewing sarcomas: Current status

A.B. Hassan[1]. [1]*University of Oxford, Sir William Dunn School of Pathology and Oxford University Hospitals Trust, Oxford, United Kingdom*

Ewing sarcoma, although rare, is an excellent paradigm of high grade malignancy in the diagnostic, prognostic and clinical setting. The presentation of disease varies, with bone sites predominating over soft tissue, and younger patients (peak incidence age 15) commoner than older patients. Following core biopsy, it requires both specialist histopathology diagnosis of round blue cell tumour with associated immunocytochemistry antibody markers, and confirmation of the t(11:22) translocation, usually with fluorescent in situ hybridisation. Once diagnosed and staged, treatment currently comprises systemic multi-agent dose intense chemotherapy that includes etoposide, followed by local disease control with surgical resection, reconstruction and radiation therapy. Variations to the conventional treatment are currently minimised because of treatment protocols such as the EuroEwing 99/2008/2012 trials.
Despite standardisation of the molecular basis, clinical diagnosis and management, there are a wide range of clinical outcomes and complications of treatement. A few patients are refractory to standard treatment, some relapse locally, and of those, many also relapse systemically with decreased overall survival. There are a number of poorly understood questions that underpin any prospect of effective targeted and personalised therapy for Ewing sarcoma. These include: the identification of the molecular abnormalities at diagnosis beyond the diagnostic translocation, what is the clonal variation and heterogeniety of response to chemotherapy at the genomic level, i.e. are there common variants that account for recurrent disease, whether there are new aquired mutations or chromosomal abnormalities depending on the treatment and whether comprehensive genomic abnormalities can be identified and are actionable with clinical impact.
Some of these key mechanistic issues will be discussed and the resulting options with respect to targeted therapy options also presented. The overwhelming data points to the poorly appreciated heterogeneity of Ewing sarcoma, in terms of somatic genetics and treatment responses when targeted therapies have been attempted. This will require a more personalised approach to genomic and next generation sequencing technology and so a more informed basis to treatment decisions and combinations. This data will ultimately require us to move away from toxic systemic chemotherapy studies currently underway to more challenging molecular stratified small sample number trials, but with marked improvements in outcome. Identifying at risk patient subgroups with both molecular and clincial criteria, but that are enriched for benefit to selective targeted agents, are the required next steps.

309 INVITED

Development of biosimilars

H. Schellekens[1]. [1]*Utrecht University, Departments of Pharmaceutical and Innovation Sciences, Utrecht, Netherlands*

Legislation allowing the approval of competitor versions of biopharmaceuticals, so-called biosimilars, has been in place in the European Union (EU) since 2004. For the marketing authorization of a biosimilar the European Medicine Agency (EMA) expects a full quality dossier and in addition, comparative analytical, pre-clinical and clinical studies demonstrating comparable quality, safety and efficacy to a product authorized in the EU. At present 13 biosimilar products have been authorized in the EU, epoetins, filgrastims and human growth hormones. These products are comparatively simple molecules, homologues of human proteins with a physiological function and are used clinically mainly as supportive or supplemental therapy.
As the patents of some of the top selling and expensive monoclonal antibodies (MABs) used in cancer therapy are about to expire, there is a lot of interest in developing biosimilar versions of these products. Compared to currently approved biosimilars, MABs are much larger and complicated products. A European guideline for biosimilar MABs was relatively recently released. However, the development of biosimilar monoclonal antibodies will not be as simple as the first generation of biosimilars. Unlike the existing biosimilars, monoclonal antibodies have multiple biological functions, are used for functions that are normally not performed by antibodies and also are very specifically directed to intervene locally in the disease process that are complicated and not very well known.
The concepts that have been used to show clinical similarity and extrapolation of indication will very difficult and even in many cases impossible to apply in the development of biosimilar monoclonal antibodies. The regulatory approach to this new class of biosimilars should be reconsidered, before affordable alternatives for the expensive anticancer monoclonal antibodies can be developed.
Conflict of interest: *Corporate-sponsored research: Research concerning quality of biologic products in the third world sponsored by Sandoz*

310 INVITED

Chemotherapy drug shortages in Europe: A call to action

G. Wiedemann[1], K. Meier[2], A. Astier[3], W. Ludwig[4]. [1]*European Society of Oncology Pharmacy, Medical Oncology, Ravensburg, Germany;* [2]*European Society of Oncology Pharmacy, Pharmacy, Soltau, Germany;* [3]*European Society of Oncology Pharmacy, Pharmacy, Paris, France;* [4]*Drug Commission of the German Medical Association, Medical Oncology, Berlin, Germany*

The increasing worldwide demand for essential oncology drugs coincides unluckily with short supply of raw materials, production problems (as contamination of materials, aging production plants, deficiencies in good manufacturing practice), reduced productive capacity because of limited profit margins for generic drugs and administrative over-regulation, resulting in gray markets, stockpiling, price gouging and drug shortages. In the long run, this could promote an increasing use of costly, not sufficiently established innovative treatments instead of well-tried generic drugs.
Identifying drug shortages: To prevent drug shortages in Europe, action has to be taken according to the early notification program of the US Food and Drug Administration (FDA). This includes establishing a register of essential cytotoxic drugs, predictive analytical methods to detect potential drug shortages and identifying the patients most likely to be adversely affected by them.
Preventing drug shortages: This includes:
- Identifying clinically working criteria for being "medically necessary" (a drug that is used to treat or prevent cancer for which there is no alternative drug available).
- Establishing a program to support manufacturers and pharmacies to produce essential generic cytotoxic drugs.
- Alerting manufacturers of predicted or observed increases in demand for critical drugs.
- Identifying alternative manufacturers for critical drugs when more than one manufacturer exists.
- Installing a website that is updated daily with information on current shortages, including all sources of each drug and how long the shortage is expected to continue (according to the websites maintained by the American Society of Health System Pharmacists [ASHP] and the FDA).

Actions that have been proposed by the European Society for Oncology Pharmacy (ESOP) and by the Drug Commission of the German Medical Association will be addressed in this talk.
No conflict of interest.

311 INVITED

Stability of biological anticancer drugs in practical situations

A. Astier[1]. [1]*CHU Henri-Mondor − APHP, Department of Pharmacy and UMR CNRS 7054, Créteil cedex, France*

Background: It is of paramount importance for hospital pharmacists to have well-documented data about the real stability of an opened drug formulation, after reconstitution of a lyophilised product or after dilution in various vehicles. Indeed, it is critical for pharmacists to be sure that their handling techniques and current practices of transportation or storage are not deleterious for the final administered drug (FAD), i.e. a drug diluted in a specific vehicle at its final concentration in the administering device (bag or syringe). Clearly, these real-life practices must be validated by studies independent of the manufacturer to insure the safety of the FAD to the patient. Unfortunately, only limited industry-independent studies on the stability of mAbs in practical situations were available.
Materials and Methods: We have studied the stability of several monoclonal antibodies (cetuximab, trastuzumab, rituximab and bevacizumab) and an enzyme (L-asparaginase), submitted to thermal and/or mechanical which can occur in practical situations. To assess a complete stability profile (chemical, physical and biological), we used several complementary (orthogonal) methods following the recommendations of the ESOP European consensus.
Results: We demonstrated that diluted rituximab and trastuzumab can be kept at 4ºC for 6 months and also at room temperature for months without any degradation, especially in terms of aggregation which is the main marker of instability. This excellent thermal stability was also demonstrated for bevacizumab and cetuximab. It is interesting to note that the corresponding manufacturers indicate only a stability of 24 hrs. L-asparaginase is stable until seven days after reconstitution (8 hrs for the manufacturer). However, their stability under mechanical stresses is more complex, depending mostly on the presence of air/liquid interfaces. Indeed, we demonstrated that the role of hydrophobic air interfaces is critical during the use of pneumatic-network transportation. If bags were emptied of air, the use of pneumatic- network transportation is not deleterious.
Conclusion: The tested biologicals in their FAD are remarkably more stable than indicated by the manufacturers. For mechanical stresses that can appear during handling and transportation, the presence of air/liquid interfaces should be avoided. Stability studies in real-life situation permit to extend the stability limits of very costly biologicals and would be extremely helpful both for practical and financial reasons.
No conflict of interest.

312 INVITED

Ensuring prescription and delivery accuracy for cytotoxics

K. Meier[1]. [1]*Heidekreis Klinikum GmbH, Department Hospital and Clinical Pharmacy, Soltau, Germany*

Introduction: Antineoplastic chemotherapy describes a group of hazardous drugs commonly used in the treatment of cancer. Potential risks are not only recognised for patients, but extend to pharmacists and other healthcare workers. Guidelines for safe handling are well established in the traditional settings of hospitals and ambulatory clinics for the IV chemotherapy. In tumour therapy, documentation, quality management and standardisation of interdisciplinary processes are increasingly gaining importance in form of therapy protocols and guidelines for clinical treatment.
Method: Non-adherence, application errors and interactions due to insufficient education of the patient can compromise therapeutic success. An adequate, quality assured, multi-professional care is therefore urgently required for oncology patients receiving oral chemotherapy. A programme is set up in Germany to teach 20,000 community and hospital pharmacist in the next year in supporting patients the best in taking oral cytotoxic drugs. This initiative aims to reach the following goals for oncology patients:
1. On-site optimisation of oral chemotherapy and improvement of pharmaceutical care for oncology patients.
2. Cost-effective and reliable care for cancer patients due to professional collaboration of local physicians, pharmacists and other healthcare professionals at the right time.
3. Recognising and solving drug-related problems related to oral chemotherapy.
4. Enhancing the quality of life of oncology patients through a coordinated management of side effects and interactions during and after therapy.
5. Providing new insight as a contribution to health services research and to encourage drug safety.

Results: Not only the way to win the societies of doctors and community pharmacists but also to engage the industry to jump over their own marketing shadow. Finally the support of the agency for data privacy protection is giving all other interested parties the chance to become part of it.
Conclusion: The increasing role of oral cytotoxic drugs and the growing demand of its good use can finally only insured by well trained pharmacists. The campaign which is starting in Germany by 250 teaching meetings is followed in Austria, Estonia and Slovenia in order to demonstrate the good outcome in a few years.

314 INVITED

Integrating germline cancer gene testing into routine cancer care

N. Rahman[1]. [1]*Institute of Cancer Research, Section of Cancer Genetics, Sutton, United Kingdom*

Genetic testing of cancer predisposition genes is one of the major activities of Clinical Genetics. Currently, nearly 100 genes associated with predisposition to cancer are known, but in most countries testing is very restricted with respect to the number of genes and the number of people tested. The value of genetic testing in individuals with cancer is underappreciated; it provides important information with respect to the cause and optimal treatment of the current cancer, and the risk and optimal management of future cancer. Moreover, testing cancer patients followed by cascade testing of mutation carriers is an effective and efficient way of identifying unaffected mutation carriers in whom screening and risk-reducing strategies can be deployed. The Mainstreaming Cancer Genetics (MCG) Programme is a UK national cross-disciplinary initiative to develop the NGS assays, analytical and interpretive pipelines, clinical infrastructure, training, ethical and evaluation processes required.

In collaboration with Illumina we have developed a NGS panel targeting 97 cancer predisposition genes with >1500 probes (called the TruSight cancer panel) and have completed detailed evaluation of performance, sensitivity and specificity under different levels of multiplexing, coverage and throughput. We are using bespoke analytical pipelines developed for high-throughput clinical diagnostic data analysis (called GAMA) and clinical interpretation (called CIGMA). We are implementing a new mixed-model of cancer gene testing whereby consent for medical testing (i.e. in cancer patients) is undertaken by oncologists, with only the mutation carriers seen by geneticists. Predictive testing (i.e. in unaffected individuals) will continue to be undertaken in genetics. We have developed protocols and e-learning modules to deliver the required training for oncologists. We hope this model will allow throughput of testing to greatly increase, whilst retaining input and support from Genetics, where it is required. We are piloting the new model in ovarian and breast cancer patients. A key first aspiration of the MCG programme is to make genetic testing available to all ovarian cancer patients, 15% of whom have a germline cancer predisposition gene mutation. www.mcgprogramme.com

Expression profiling in breast cancer: Ready for clinical use?

M. Maetens[1], C. Sotiriou[1]. [1]*Institut Jules Bordet, Breast Cancer Translational Research Laboratory, Brussels, Belgium*

For more than a decade now, microarrays have been the methodology of reference for the study of gene expression profiling (GP). In the breast cancer (BC) field, this technology has been implemented in the attempt to dissect the biological complexity of the disease and define its clinical course.

Several studies have demonstrated that BC consists of different diseases with specific molecular profiles and clinical behaviors that can help selecting patients for enrollment in clinical trials and orienting therapeutic approaches. Microarrays have also been used to identify gene expression signatures (GS) with a prognostic and/or predictive value. After a wave of “first generation signatures” mostly based on the ability of proliferation to discriminate which patients can be spared aggressive treatments, signatures of “second generation” have explored the prognostic value of gene related to immune response and stromal compartment. Multigene classifiers have also been developed to predict response to either generic or specific endocrino- or chemotherapies. Despite the reliability of microarray technology has been demonstrated, the clinical implementation of GS is still limited mostly in relation to the uncertainty of their added value compared to standard clinical-pathological factors. While the results of three large randomized trials will help establishing the clinical role of some of the GS tested, the advent of next generation sequencing (NGS) technologies, in particular RNA sequencing (RNA-seq), appears to enrich the discovery spectrum compared to other GP technologies. These discoveries will surely have an impact on the management of BC in the future. To date however, their integration in the clinical setting is still premature.

While subtyping of BC and treatment decisions still largely rely on classical clinical and pathological parameters, efforts should be invested in overcoming the hurdles that prevent the integration of high throughput technologies into daily clinical practice.

316 INVITED

Genetic analysis in advanced cancer patients: What test for which patient? Matching patient, biomarker and drug

J. Rodon[1], R. Dienstmann[2], J. Tabernero[1]. [1]*Vall D’Hebrón University Hospital, Medical Oncology, Barcelona, Spain;* [2]*Massachusetts General Hospital Cancer Center, Molecular Pathology, Boston, USA*

Uncovering the genetic changes of cancer through genomic profiling in the clinical setting could provide insights into the management of a patient. Different platforms have been used in different clinical settings or moments of the disease for diverse clinical decisions. Nowadays, genomic technologies such as next generation sequencing platforms are able to analyze point mutations, copy number alterations, translocation mapping, and exon/allele specific transcriptome profiling in a reasonable timeframe. In Early Drug Development, some of these technologies are quickly being implemented for selecting patients that may benefit from an experimental drug. Therefore, phase I trials are being transformed in an arena where biomarkers, technology and experimental drugs are being tested.

The implementation and future routine use of technologies such as large-scale genome sequencing, will not only unravel the biology of each tumor but transform the way we test novel agents.

No conflict of interest.

317 INVITED

Impact of genetic analyses on patients − what to tell our patients?

M. Abramowicz[1]. [1]*Université Libre De Bruxelles, Brussels, Belgium*

Technical advances in massively parallel sequencing (MPS) of DNA will soon change clinical practice. The biological interpretation of genetic findings however limits clinical applications.

MPS of *tumor DNA* allows for better molecular pathology, and drug sensitivity of cancer cells. MPS of *patient DNA* (germline mutations) allows for individual profiling of specific cancer risks. Currently, this approach is clinically validated only for high penetrance mutations, i.e. mutations causing a Mendelian or near-Mendelian, hereditary cancer syndrome, e.g. hereditary breast and ovarian cancer, and Lynch syndrome, which represent about 5% of breast cancer and of colon cancer respectively. The decision to test for an inherited mutation is not straightforward and depends on the personal and family history. Among the many variants identified in cohorts of patients with a inherited cancer syndrome, a sizeable proportion are currently of unknown clinical significance (VUCS). Patients must be informed before testing of the limitations of the test, of potential impact in relatives, and on medical options in genetic risk carriers. For example, while evidence shows that risk-reducing oophoro-annexectomy is superior to surveillance of ovaries in *BRCA1* mutation carrying women, evidence is much scanter for prophyllactic mastectomy, at least in terms of mutation-associated mortality.

Testing for low penetrance mutations currently has little clinical utility as compared to the clinical history-based evaluation of the risk and empirical follow-up. This is however likely to change in the future, adding significant complexity to risk assessment and strategic decision making.

Incidental findings are those discovered by coincidence while investigating other symptoms. An example is the serendipitous discovery, in a fetus investigated for malformations, of a chromosomal microdeletion encompassing the *MLH1* gene causing Lynch syndrome, with expected consequences for the future adult, and for some of his relatives. Likewise, finding a germ-line change while investigating tumor DNA may have further consequences for the patient, and family relatives.

Implementing MPS in clinical practice will require thorough information of the patients, which in turns calls for education of both patients and medical teams.

No conflict of interest.

Lifestyle, Exercise and Vitamins

318 INVITED

Fit or fat? Energy balance in cancer risk and prognosis

C. Ulrich[1], K. Steindorf[1], J. Wiskemann[2]. [1]*German Cancer Research Center, Preventive Oncology, Heidelberg, Germany;* [2]*German Cancer Research Center, Medical and Preventive Oncology, Heidelberg, Germany*

Energy balance and its underpinnings, physical activity, dietary intake, and obesity, are known to play a role in the primary prevention of cancer. Low levels of physical activity and overweight or obesity have been associated with multiple cancer types, particularly of the colorectum and postmenopausal breast (for physical activity) or the colorectum, postmenopausal breast, liver and esophagus (for obesity). A number of biologic mechanisms have been discerned, including effects on systemic inflammation, immune function, insulin-like growth factors, insulin resistance, steroid hormones, vitamin D levels, and antioxidant defenses and DNA repair. Finally, weight-loss results directly in gene-expression changes in the adipose tissue.

In addition, energy balance can also affect the the well-being and prognosis of cancer patients. Among cancer patients, initial clinical studies illustrate benefits of exercise training on quality of life or fatigue as well as fitness levels, strength and cachexia. Epidemiologic studies also suggest a positive influence of physical activity on prognosis, particularly for colorectal cancer patients. However, many questions remain regarding causality of the associations, interrelationships between exercise and body weight, and the most appropriate type and timing of exercise training of cancer patients.

No conflict of interest.

319 INVITED

Interplay between the cancer genome and epigenome: opportunities in elucidating mechanisms of carcinogenesis and cancer prevention

Z. Herceg[1]. [1]*IARC, Mechanisms of Carcinogenesis Section Epigenetics Group, Lyon, France*

The evolution of common human cancers involves the gradual accumulation of genetic and epigenetic cancer-promoting changes with different mechanisms assuming primary roles during different stages of cancer development. Recent international sequencing efforts have revealed comprehensive genomic landscapes of common human cancers and the Human Epigenome Project will not only yield an unparalleled view of the "normal" epigenome in different tissues but also identify epigenome variations against which environmental exposure can be assessed. The remarkable advances in our knowledge of carcinogenesis and the cancer genome can now guide the development of new strategies for therapy. These advances are also expected to accelerate the revival of cancer prevention research. I will discuss opportunities and challenges in identifying functionally important "*driver*" events and environmental factors associated with these changes as well as how comprehensive portraits of the cancer genome and epigenome and mechanistic advances in identifying "driver" genes and pathways may provide an evidence base for the next generation of cancer prevention efforts.
No conflict of interest.

Diet and cancer

Abstract not received.

321 INVITED

Are there any vitamins we can recommend?

J.L. Jahn[1], S.A. Kenfield[2], M.J. Stampfer[3]. [1]*Brigham and Women's Hospital, Channing Division of Network Medicine, Boston, USA;* [2]*University of California at San Francisco, Department of Urology, San Francisco, USA;* [3]*Harvard School of Public Health, Departments of Nutrition and Epidemiology, Boston, USA*

Introduction: The World Health Organization and U.S. guidelines neither recommend nor warn against taking a daily vitamin supplement. However, 49% of Americans report using a dietary supplement. We evaluated the evidence in support or against vitamin supplements for cancer prevention.
Material and Methods: We reviewed nutritional surveys comparing actual versus recommended levels for various vitamins, and observational studies, randomized trials, and meta-analyses for vitamin supplements in relation to cancer.
Results: Surveys indicate that many individuals have vitamin intake or blood levels below the recommended standard, particularly for vitamin D. Confounding factors and reverse causation (high risk or more health conscious individuals may take more supplements) make observational studies difficult to interpret. For cancer prevention, only long-term trials are useful. So, although a recent meta-analysis of 21 randomized trials reported no significant effect of multivitamins, only 4 trials extended beyond 7 years. Any potential effect (beneficial or harmful) depends critically on the underlying nutritional status. Thus, the marked reduction in gastric cancer in the Linxian General Population Nutrition Intervention Trial may not be generalizable to populations with better nutrition. Perhaps the most compelling evidence derives from the trial among 14,641 (presumably well-nourished) U.S. male physicians, which found a significant 8% reduction in total cancer incidence (and a non-significant 12% reduction in cancer mortality) over a median follow-up of 11.2 years.
Substantial basic science and observational evidence suggests that adequate vitamin D status may be important for cancer prevention. One randomized trial of 1100 IU vitamin D_3 in 1179 women showed a strong protective effect against total cancer incidence with 4 years of intervention. Two other trials tested too low (400 IU) or unphysiologic (100,000 IU/3 months) dosages. A major trial is now assessing the efficacy of 2000 IU/day.
Conclusions: Given the safety, low cost, and magnitude of potential benefit, it seems reasonable for most individuals to take a multivitamin supplement and perhaps extra vitamin D. However, the evidence appears insufficient for a major public health policy intervention, and supplements rank low in importance to health compared with other modifiable activities such as smoking cessation, physical activity, and maintaining a healthy diet and weight.

Scientific Symposium (Mon, 30 Sep, 14:45–16:45)
Chip Technologies

322 INVITED

The impact of chip technology on cancer medicine

M. Fey[1]. [1]*Inselspital Bern, Dept of Medical Oncology, Bern, Switzerland*

The molecular pathology of cancer is governed by step-wise accumulation of somatic mutations in genes or regulatory DNA sequences with important tasks in the life of a normal cell. Pathways involved are those directing programmed cell death, proliferation, cellular differentiation, and perhaps autophagy.
Techniques such as cytogenetics or later FISH are suitable to light up those alterations which imply structural aberrations of chromosomes or chromosomal material. In their early days molecular genetic tests often looked into a single locus per test, e.g. a PCR assay. It has long become clear that these techniques, valuable as they are, overlook the complex orchestrated "ensemble" of molecular alterations that are present in a given cancer case.
The chip technology, and new generation DNA sequencing have overcome these limitations and have brought new light as well as new problems into the field. Initially microchips or -arrays were used to discover comprehensive gene expression profiles (GEP) in a cancer. Next these patterns were compared to normal counterpart tissues oft he given cancer or other cancer cases. Depending on the reference material used, distinct cancer profiles or signatures come up which encompass important pathways, as well as many irrelevant or minor alterations. Nowadays complete sequence information of particular cancers has become available with astounding myriads of sequence alterations detectable, particularly in solid tumours. For example, in a lung cancer case one gene mutation or acquired sequence variation was found per 3 cigarettes that the patient had smoked until diagnosis. Not all findings are relevant, however. To separate genetic wheat from molecular chaff is in no way trivial, as molecular alterations in cancer are hierarchically organised, with few driver mutations at the top and many molecular epiphenomena at lower ranks. Efforts to identify driver mutations are important as these may offer the best chance to discover new targets for therapy. Treatment of ELM-ALK positive lung adenocarcinoma with crizotinib is a good example.
In breast cancer, established targets, such as the hormone receptors or HER2 were discovered prior to the aera of modern molecular genetics. Gene expression profiling has helped to define several types (or perhaps entities) of breast cancer, i.e. luminal A or B type breast cancers, or triple-negative cancers. Often these subtype diagnoses are now made in routine pathology reports, merely based on immunohistochemistry patterns. Whilst some of these combined markers may indeed come close to identifying cancers harbouring one or the other GEP, the correlation between immunohistochemistry findings and GEP data is not strict. Furthermore, and perhaps more importantly, it remains to be seen which specific therapies will work particularly well in one breast cancer subtype (i.e. luminal A), and perhaps less in another one. Trials to pinpoint such predictive markers and the effect of specific treatments are underway, but most of them are not mature at present. Increasingly, commercial assays testing gene signatures in cancer biopsies are offered to predict benefit or perhaps harm from one chemotherapy or another. There seems to be a lot of enthusiasm in the oncological community to use these tests (e.g. oncotype dx) in practice. However, they must be viewed with caution at present, as the trial data necessary to assess test value (i.e. prospective randomised trials suitable to prove the predictive power of a given marker) are not yet mature. Also new driver mutations are eagerly awaited in breast cancer, similar to non-small cell lung cancer which has become a paradigm disease for the rapid discovery of new molecular therapies.

323 INVITED

Direct profiling of cancer biomarkers using novel chip technology

S. Kelley[1]. [1]*University of Toronto, Department of Biochemistry, Toronto, Canada*

Robust, practical platforms that detect low levels of biomolecules (<1000 copies) are urgently needed to advance medical care by diagnosing and predicting the progression of cancer and other disease states. Electrochemical methods providing low cost and direct biomarker read-out have attracted a great deal of attention for this application, but have, to date, failed to provide clinically-relevant sensitivity. We exploit controlled nanostructuring of electrode surfaces to promote surface accessibility and enhance capture rate and efficiency to solve this long-standing problem, and showed that the nanoscale morphologies of electrode surfaces control their sensitivities (*Nature Nanotechnol.,* 2009). In addition, we have worked towards integrating nanomaterials-based electrodes into a chip-based

platform to facilitate multiplexed analysis in a robust, practical format. Recently, we have developed an assay that is able to detect nucleic acids, proteins and small molecules, with universally high sensitivity levels (*Nature Chemistry*, 2012). Our efforts to use these components to detect biomarkers in tumors and circulating tumor cells will be featured in this lecture.
No conflict of interest.

324 INVITED
Lab-on-chip tracing circulating tumour cells

L. Lagae[1], C.X. Liu[1], D. Latta[2], O. Henry[3], C. O'Sullivan[3], T. Roeser[4], J. Lundeberg[5], L. Kvastad[5], I. Riley[6], E. Borgen[7]. *[1]Imec vzw, Life Science Technologies, Leuven, Belgium; [2]IMM, Mainz, Germany; [3]URV, Chemical Engineering, Tarragona, Spain; [4]Thinxxs, Zweibrücken, Germany; [5]KTH, Science for Life Laboratory, Stockholm, Sweden; [6]Labman Automation, North Yorkshire, United Kingdom; [7]Oslo University Hospital, Pathology, Oslo, Norway*

Circulating tumor cells (CTC) are currently believed to be the primary pathway for cancer metastasis. The isolation and cellular/genetic analysis of CTCs is important not only for clinical prognosis but also for personalized therapy. The extremely low CTC amount (<1 CTC/mL blood) demands identification and isolation of individual viable CTCs, as well as multi-gene analysis for single CTCs. The vision of the EU funded MIRACLE project is to develop the first automated system that can isolate viable circulating tumor cells (CTC's) from blood with high purity and perform multigene-analysis for individual CTCs. We employed a two-step CTC isolation process: immunomagnetic CTC isolation followed by single cell electrical impedance spectroscopy (EIS). The integrated circuit based EIS, in particular, identifies CTCs based on their lower electrical impedance in comparison to normal cells. After CTC isolation, we perform multi-gene amplification & detection on single cell level, based on multiplex ligation dependent probe amplification (MLPA). Integrating both the cell isolation and the gene amplification-detection modules in a single system, we aim at an automated miniaturized system for CTC detection and analysis. The high specificity, sensitivity & flexibility of CTC analysis will allow accurate early prognosis for metastasis and will foster fundamental studies on metastasis at single cell level. This talk will summarize the progress and main results obtained in the currently ongoing MIRACLE project.

B-RAF as a druggable target in paediatric malignancies

Abstract not received.

327 INVITED
Targeting the sonic hedgehog pathway in paediatric malignancies

B. Geoerger[1]. *[1]Institut Gustave Roussy, Department of Pediatrics and "Pharmacology and new treatments in cancer", Villejuif, France*

Aberrant Hedgehog (Hh) signaling is involved in tumorigenesis through promotion of cell proliferation, survival, and differentiation in numerous human cancers, including medulloblastomas (MB), basal cell carcinoma (BCC), and rhabdomyosarcoma. Hh signaling in cancer may occur through a cancer cell-autonomous role, paracrine signaling involving tumor and stromal interactions, or autocrine signaling via cancer stem cells. Pathway activation through mutations in *PTCH1* or *SuFu* (loss of function), or *Smo* (gain of function) leads to ligand independent, constitutive signaling through Gli and its transcription factors. Such mutations have been identified in approximately 20% to 30% of sporadic MBs. A direct example of the linkage between constitutive activation of the pathway and tumorigenesis is Gorlin syndrome, an autosomal dominant disease, caused by mutation in PTCH (chromosome 9q22.3). Gorlin patients have an increased tendency to develop BCC, MB, rhabdomyosarcoma, and ovarian neoplasia. Other pediatric malignancies such as neuroblastoma, rhabdomyosarcoma, hepatoblastoma, and glioma are found with increased expression of HH pathway proteins (Shh, PTCH1 and Gli1) suggesting that Hh signaling may play a role in the pathogenesis of these tumors too.
Inhibition of the HH pathway was first found for the steroidal jeveratrum alkaloid cyclopamine isolated from the corn lily that causes fatal birth, holoprosencephaly and cyclopia. Cyclopamine, Smoothened (Smo) knockdown with Smo small hairpin ribonucleic acid, or recently developed Smo small molecule inhibitors promoted G1 cell cycle arrest and prevented growth of glioma and osteosarcoma *in vitro* and *in vivo*. Oral administration of Smo inhibitors caused more than 90% tumor regression in genetically defined *in vivo* MB xenograft models characterized by heterozygous deletion of *PTCH*. Pharmacodynamic studies showed nearly complete and sustained inhibition *Gli1* mRNA expression in tumor samples. The proof-of-concept for the clinical utility of this class of agents has been established in patients with metastatic or locally advanced BCC. A clinical phase 1 trial of the SMO inhibitor LDE225 showed promising efficacy in children with HH-activated MB and a phase 3 pivotal trial is currently underway. However in view of the role of the Hh signaling in the normal growth and development of tissues, the use of SMO inhibitors in children needs to be carefully assessed in order to manage the potential adverse effects, in particular, on bone growth plates, developing teeth, and the immature reproductive system.
The inhibition of HH pathway is one of the encouraging examples for how detailed knowledge of molecular and genetic abnormalities may pave the way to more efficiently target specific pathways leading to a personalized treatment with beneficial on patient outcome.
Conflict of interest: *Advisory board: Novartis*

328 INVITED
Targeting the mTOR/AKT/PI3K pathway in paediatric malignancies

A. Pearson[1]. *[1]Institute of Cancer Research/Royal Marsden Hospital, Sutton, United Kingdom*

mTOR / PI3K/AKT pathway in paediatric malignancy: The mammalian target of rapamycin (mTOR)/phosphoinositide-3-kinase (PI3K)/AKT signalling pathway is deregulated in many poor prognosis childhood malignancies, through:

1. Increased levels of MYCN oncoprotein − Amplification of the *MYCN* oncogene and increased MYCN protein levels occurs in poor prognosis paediatric tumours, neuroblastoma, medulloblastoma and rhabdomyosarcoma. Intracellular MYCN protein levels are maintained by proteasomal degradation mediated by E3 ubiquitin ligases whose interaction with MYCN is controlled by phosphorylation of serine and threonine residues, which is in turn is regulated by the mTOR / PI3K/AKT pathway. Therefore, pathway inhibitors can destablise MYCN protein.
2. Aberrant activation of the PI3K pathway as demonstrated by high levels of AKT phosphorylation. This has been shown in poor prognosis neuroblastoma, medulloblastoma, high grade glioma and rhabdomyosarcoma. In this situation combined inhibition of the PI3K and RAS/RAF pathway may be valuable.
3. Aberrant activation of TORC1 and/or TORC2 with high levels of S6 and 4EBP1 phosphorylation.
4. Intrinsic PI3K pathway activating mutations (PI3KCA [medulloblastoma, high grade glioma] AKT) or deletions (PTEN [high grade glioma]) − although these generally occur less frequently in paediatric than in adult cancers.

Inhibitors − Different classes of agents inhibit the pathway:

- mTOR inhibitors: rapalogues: everolimus, temsirolimus, deforolimus and ridaforolimus;
- TORC 1 and 2 inhibitors (one of their major benefits is the lack of feedback): AZ2014 and OSI027;
- PI3K inhibitors: GDC0941, BKM, BYL;
- Combined PI3K and mTOR inhibitors: BEZ 235, GDC980;
- AKT inhibitors: MK-2206, perifosine

Consensus in neuroblastoma: At a recent Innovative Therapies for Children with Cancer European Consortium (ITCC), European Network for Cancer Research in Children and Adolescents (ENCCA), International Society Paediatric Oncology Europe Neuroblastoma Group (SIOPEN) symposium to prioritise targets for neuroblastoma (the Neuroblastoma Drug Development Strategy meeting, NDDS) the target TORC1/2 was given top priority for clinical development for neuroblastoma. mTOR inhibitors were ranked high, however AKT and PI3K inhibitors were given low priority.
Clinical studies: Despite the strong rationale for targeting this pathway clinical studies to date have been completed only with rapamycin derivatives − phase I (oral and intravenous ridaforolimus, temsirolimus, everolimus) and II studies (temsirolimus). Paediatric combination trials of rapalogues with IGF-1R monoclonal antibodies and other therapies are ongoing as are studies of AKT inhibitors (MK-2206 and perifosine).
Conclusion: Paediatric early clinical trials of TORC 1 and 2 and PI3K/mTOR inhibitors are eagerly awaited as are combinations with MEK inhibitors.
No conflict of interest.

329 INVITED

Disialoganglioside GD2 directed immunotherapy of neuroblastoma

H. Lode[1], N. Siebert[1]. [1]*Klinik und Poliklinik fuer Kinder, Greifswald, Germany*

Background: Targeting of GD_2 emerges as an important option for the treatment of neuroblastoma.
Here, we report preclinical and clinical advances in passive and subsequent active immunotherapeutic approaches to this challenging problem.
Material and Methods: Clinical passive immunotherapy results using ch14.18/CHO in combination with IL2 relate to an ongoing Phase I/II clinical trial in relapsed and refractory disease. Active immunizations against GD_2 were studied in a GD_2 expressing syngeneic animal model and in a few patients in the compassionate use setting.
Results: Passive immunotherapy with ch14.18/CHO in combination with IL2 shows activity related to effective immunomodulation indicated by an increase in NK-cells, effective antibody levels and neuroblastoma specific ADCC and CDC. An improved pain toxicity profile was observed using a long term infusion schedule folowed by objective clinical responses in treated patients.
Active immunotherapy was studied using mimotopes of ganglioside GD_2, since GD_2 itself is a weak and T-cell independent antigen. Peptide and protein vaccines were effective against neuroblastoma in a preclinical neuroblastoma mouse model. Patients immunized with a GD_2 mimotope developed a long lasting GD_2 specific humoral immune response.
Conclusions: Passive immunotherapy with anti-GD_2 antibody ch14.18/CHO shows activity in relapsed/refractory disease and active immunization with GD_2 mimotopes may be a future concept to further consolidate such responses achieved with ch14.18/CHO.

Tailoring neoadjuvant radio-chemo-therapy treatment for organ preservation

Abstract not received.

332 INVITED

The oncological and functional risks of the organ preservation experimental treatment approach

C. Coco Martins[1]. [1]*Centro Hospitalar Torres Vedras, Lisbon, Portugal*

We increasingly face conservative surgery for rectal cancer and even the so called 'wait and see' approach, as far as 10–20% patients can reach a complete pathological response at the time of surgery. But what can we say to our patients about risks? Standard surgery with mesorectal excision gives a <2% local recurrence with a post operative death rate of 2–8% (may reach 30% at 6 months in those over 85), but low AR has some deterioration in bowel function and in low cancer a permanent stoma may be required. Also a long-term impact on urinary and sexual function is possible. Distant metastasis rate seem to be identical in the standard and conservative approach. It is difficult to evaluate conservative approach because a not clear standardization of surgery for low rectal cancer. Rullier et al tried to clarify, and they found identical results for recurrence (5–9%), disease free survival (70%) at 5 y for coloanal anastomosis and intersphinteric resection. Other series have found local recurrence higher than with standard approach and functional results may be worse and, in some situations, salvage therapy is compromised or has more complications. In this context, functional outcomes are very important but most studies are incomplete in measuring bowel function in the context of conservative approach. In 2005 Temple et al made a survey of 122/184 patient after sphinter preserving surgery and found a 96.9% of incomplete evacuation, 94.4% clustering, 93.2% food affecting frequency, 91.8% gas incontinence and proposed a systematic evaluation with a specific questionnaire. In which concerns 'Wait and see' approach for complete clinical responders, it was first advocated by Habr Gama for tumors up to 7 cm, with a low locoregional failure of 4.6%, 5 y overall survival 96%, 72% for disease free survival; one fifth of patients failed in the first year; a Dutch trial had identical results but others had worse recurrence rates; in other series 25% of patients could not be salvaged even with APR; 30% have subsequent metastatic disease what seems equal for 'wait and see' and operated patients. In a recent review Glynne Jones considers that all the evaluated 'wait and see' studies are heterogeneous in staging, inclusion criteria, design and follow up after chemoradiation and that there is the suggestion that patients who progress while under observation fare worse than those resected. He proposes long-term observational studies with more uniform inclusion criteria. We are now facing a moment where we may be more aggressive in early cancer and neoadjuvant treatment to be more conservative in the subsequent treatment but we need a better stratification of patients, better evaluation of results and more clear prognostic markers.
No conflict of interest.

Special Session (Mon, 30 Sep, 17:00–18:00)
New Treatment for Complex Basal Cell Carcinoma

333 INVITED

New treatment opportunity for non-resectable BCC

N. Basset-Seguin[1]. [1]*Hôpital Saint Louis, Department for Dermatology, Paris, France*

Background: The discovery of the implication of the patch sonic hedgehog pathway in the pathogenesis of basal cell carcinoma (BCC) has brought new therapeutical strategies for the treatment of non resectable (La BCC)or metastatic BCC (mBCC). While most BCC are curable by surgery, some tumors are very aggressive, relapse frequently and are no longer accessible to radiotherapy or conventional surgery due to either high morbidity of the surgical procedure (eye exenteration, amputation of the nose or the ear), or the extension of the surgery, or the recurrence of basal-cell carcinoma after two or more surgical procedures and an expectation that curative resection would be unlikely. Additionally some rare cases of BCC can metastasize (mBCC) and have a very poor prognosis. Molecular and genetic studies have shown that almost all basal-cell carcinomas contain genetic alterations in the hedgehog signaling pathway (driver mutations), resulting in aberrant pathway activation and uncontrolled proliferation of basal cells. Most commonly, these alterations cause loss of function of patched homologue 1 (PTCH1), which normally acts to inhibit the signaling activity of smoothened homologue (SMO), a seven-transmembrane protein. Vismodegib is the first of the class of smo inhibitors that has been shown to have anti tumoral efficacy for advanced BCC.
Material and Methods: A review of phase I and II studies using Vismodegib in advanced BCC is presented.
Results: A phase 1 study of vismodegib involving 33 patients with advanced basal-cell carcinoma showed a 58% confirmed response rate and a median duration of response of 12.8 months. A phase 2 Erivance study enrolling 33 mBCC and 63 La BCC has shown an initial evaluation of overall response rate (ORR) by independent review of 30% for mBCC and 43%for La BCC. This efficacy is maintained over time. Major and most frequent side effects are muscle spasms, alopecia, dysgyueusia, weight decrease, fatigue and nausea. The ongoing phase II multicentric study Stevie aims at recruiting above 800 patients. The primary endpoint of the study is safety and the initial report (150 patients with > months follow up)has shown that among the 138 patients with LaBCC and the 12 patients with mBCC 75% were still on the drug while about 25% in each group had stopped the drug. Reasons for arrest were mostly sides effects or patients desire or death (N = 7, but none of them were thought related to the drug). The efficacy observed in the Stevie study is comparable to that observed in the Erivance study. Tumor relapse after stopping the drug seems to be variable according to investigator experiences.
Conclusion: Vismodegib is a very exciting new treatment option for aggressive BCC. Long term use is limited by some side effects but new therapeutical regimens might improve the tolerability.

Can Drug Approval Keep Pace With Translational Research in Cancer?

335 INVITED

Can drug approval keep pace with translational research in cancer?

B. Chabner[1]. [1]*Massachusetts General Hospital, Department of Medicine, Boston MA, USA*

The past decade has witnessed a remarkable acceleration in cancer drug discovery, beginning with the landmark studies of bcr-abl inhibitors, and their subsequent approval for chronic myeloid leukemia, and herceptin for Her2 amplified breast cancer. The first of these targeted agents, imatinib, showed that a nearly 100% response could be achieved with a targeted small molecule in a disease uniformly characterized by a molecular lesion. Studies of the second agent, herceptin, illustrated the value of patient selection (those with Her 2 amplified tumors) in enriching a relatively modest response rate. Re-inforcment of the principle of patient selection to enrich response rates and guide drug use came from studies of gastro-intestinal stromal tumors and EGFR mutations in non-small cell lung cancer. This work has set the stage for a radical shift in cancer drug approval. With a strong targeted agent and appropriate patient selection, it is now possible to define a highly responsive patient subset in otherwise chemotherapy-resistant patients, leading to early and convincing evidence for drug benefit in expanded cohorts in Phase I trials. No longer does it make sense to require the painful process of randomized Phase III trials to gain drug approval. What has evolved is the notion that with a properly targeted agent and with an available assay for the presence of the mutated or amplified target, it is possible to demonstrate the unique benefit of a new drug in Phase I. Ongoing studies of second generation EML-4/ALK inhibitors in non-small cell lung cancer, such as the Novartis LDK 378 compound, may provide the first example of a drug approvable based on a Phase I trial. Strategies to expedite future studies, including collaborative networks among major cancer centers in Phase I, expanded gene sequencing facilities, and oncology training programs that emphasize the interplay of tumor genomics and drug development, will be discussed. The need for a national plan for tumor genotyping, as part of this effort, will also be emphasized.

MOBILE (Mapping of Oxygen By Imaging Lipids relaxation Enhancement) – New approach to imaging hypoxia by MR

F. Colliez[1], B.F. Jordan[1], J. Magat[1], T. Duprez[2], B. Gallez[1]. [1]*Université Catholique de Louvain, Biomedical Magnetic Resonance Research Group, Brussels, Belgium;* [2]*Université Catholique de Louvain, Radiology Department, Brussels, Belgium*

Quantitative follow-up of changes in tumor oxygenation can find relevant applications in radiation therapy planning as well as with regard to anti-angiogenic and anti-vascular treatments optimization. Because of its paramagnetic properties, oxygen may act as an endogenous MRI contrast agent by changing proton relaxation rates. Variations in T_1 and T_2* are potentially valuable MRI tools to monitor changes in tumor oxygenation: T2* is sensitive to the relative Hb/HbO2 ratio in vessels, while T_1 change is sensitive to dissolved oxygen in tissues. Changes in tumor oxygen concentrations have been shown to produce changes in relaxation time T_1 of water, but this technique still lacks a good sensitivity. To increase the sensitivity, we developed an innovative MRI technique that exploits the higher solubility property of oxygen in lipids than in water. This MRI pulse sequence, called *MOBILE* for Mapping of Oxygen By Imaging Lipids relaxation Enhancement, sensitively monitor tissue oxygen levels by selectively measuring the T_1 of lipid protons.

To assess the sensitivity and the quantitative properties of *MOBILE*, measurements of Lipid R_1 (=1/T1) were compared to absolute values of pO_2 obtained by Electron Paramagnetic Resonance (EPR) oximetry. This was achieved in two mammary tumor models (MDA-MB-231 and NT2), in response to a hyperoxic breathing challenge (carbogen breathing) and to a hypoxic challenge (administration of the vascular disrupting agent combretastatin CA4). We found a direct correlation between Lipid R_1 and pO_2 values, with Lipid R_1 being about 3 to 4 times more sensitive than R_1 measured in water.

We are also currently working on the clinical translation of the method. The *MOBILE* sequence was implemented on a 3 Tesla clinical scanner and was successfully applied in the brain of healthy human volunteers exposed to an oxygen breathing challenge (n = 11), in stroke patients (n = 9), in brain tumors (n = 6), and in head and neck tumors (n = 7).

In conclusion, *MOBILE* arises as a promising non-invasive and sensitive tool for diagnosis and therapeutic guidance in cancer treatments involving hypoxia.

No conflict of interest.

337 INVITED

Preclinical and clinical optical imaging

G. Van Dam[1]. [1]*Groningen University Hospital, Department of Surgery, Groningen, Netherlands*

In recent years, significant progress has been made in both optical imaging systems and fluorescent contrast agents for clinical applications. NIRF imaging with a free-floating imaging device mounted on the ceiling of the operating theatre or on a microscope articulating arm during surgery for cancer will enable visualization of tumor delineation, locoregional metastases, remnant disease as well as e.g. tumor-containing lymph nodes. Hereby, the surgeon can both detect (diagnostic) and excise (therapeutic) malignant tissue and possible residual disease at the same time. The use of NIRF optical imaging has a range of advantages. Most prominent among these is the fact that it is very safe technology, simple to operate, fast, high resolution (as low as 10 μm), relatively inexpensive and makes use of non-ionizing radiation. Based on the above, it is clear that intra-operative imaging is on the verge of entering standard clinical practice for surgery. Not only the imaging system but also the availability of clinical grade tumor-targeted probes is of the utmost importance for a succesful introduction into clinical practice. This talk will give an overview of the current concepts and future perspectives of intraoperative fluorescence image-guided surgery using non-targeted and targeted optical contrast agents for the first-time ever used in patients with ovarian cancer and the anticipated developments within the next 5 years. It will become clear that Europe will play a major role in bringing this technology into the clinic and the necessity of standardization of methodology when applied in multicenter studies.

No conflict of interest.

338 INVITED

PET/MR imaging

A.J. Beer[1], M. Eiber[2], M. Schwaiger[1]. [1]*Technische Universität München, Department of Nuclear Medicine, Munich, Germany;* [2]*Technische Universität München, Department of Radiology, Munich, Germany*

The introduction of whole-body PET/MR scanners combining magnetic resonance (MR) imaging and positron emission tomography (PET) in one system 3 years ago raises great expectations especially in the field of oncological imaging. In this talk a short overview of the different systems and general technical background for PET/MR is given. The focus will be on the current and future use of whole-body PET/MR in oncology for clinical indications as well as for more research oriented applications.

For routine clinical applications in oncology, basically all indications lend themselves for PET/MR where on the one hand we know that MR is superior to CT and where on the other hand we know that PET might give additional information. In these cases there is the logistical advantage of a one-stop-shop examination and also the advantage of very exact image fusion which might provide synergistic effects. Examples are head-and-neck-cancer imaging and imaging of pathologies in the pelvis like ovarian- and cervical cancer or prostate cancer imaging. Concerning research oriented applications, there is great promise in using all the functional, physiological and biological information that both PET and MRI can provide to get more insight in tumour biology and tumour heterogeneity than was possible before with only one modality. This concept of multimodality multiparametric imaging of tumour biology might be beneficial e. g. for biopsy planning, prognostic stratification of patients during primary staging and for early response evaluation during therapy.

Finally one potential benefit of PET/MR is that it not only brings technology together but that it also has the chance to bring people together. That means that to exploit all the potential advantages of PET/MR, physicists, physicians, technicians, clinicians and basic scientists have to come together and join their expertise to make optimal use of these exciting new technique for the maximum benefit for our patients.

Special Session (Mon, 30 Sep, 17:00−18:00)
Current and Future Approaches for Recurrent Glioblastoma

339 INVITED

Does surgery at relapse impact survival?

J. Tonn[1]. [1]*Klinikum der Universität München-Großhadern, Dept. of Neurosurgery, München, Germany*

Up to now, no treatment standard exists for recurrent glioblastoma. There is even no consensus reached about the value of re-operation. However, patients in whom another operation might be of additional benefit can be identified by means of clinical and imaging parameters.
First, early post-op imaging after the initial surgery according to the RANO criteria helps to visualize tumor remnants and thus, in future, to separate tumor progression from real recurrency.
Second, pseudo-progression or any unspecific contrast enhancement should be excluded by either short-term repetition of MRI or additional PET using aminoacid tracer like 18-FET or 11-C-Met.
Third, a simple scoring system rating size of the lesion, clinical status of the patient and location of the tumor in less or more than 2 eloquent regions helps to assess the potential benefit of a re-operation.
Frequent follow up including clinical assessment and MRI imaging helps to detect recurrent tumor early when the tumor mass is still small and asymptomatic − good preconditions for re-operation.
As the molecular markers like mutation of the IDH-1 gene, LOH 1p/19q and the methylation of the *MGMT* promoter do not change in recurrent glioma, there is no need for re-operation just to determine the molecular status of the recurrent tumor tissue. However, if any doubt exists about either the dignity of the lesion or its histology, tissue sampling is mandatory. This can also be done as a stereotactic serial biopsy whenever the patient is not likely to benefit from extensive cytoreductive re-operation.
Conflict of interest: *Advisory board: Roche, MerckSerono*

340 INVITED

Recurrent glioblastoma: Role of focal therapy in an infiltrative disease

B.G. Baumert[1]. [1]*MediClin Robert-Janker Clinic & University of Bonn Med Ctr Cooperation Unit Neurooncology, Bonn, Germany;* [2]*Radiation Oncology (MAASTRO) GROW Maastricht University Medical, Netherlands*

Patients with a glioblastoma have an increasing survival after initial standard treatment with combined radiochemotherapy with temozolomide and have a good performance status which makes most of them eligible for retreatment. However, to date re-irradiation has not been investigated in randomized controlled trials.
Results from retrospective and cohort studies report survival rates for high grade glioma of 5−14 months with a median of 9−11 months. This broad range depends primarily on the tumour grade: low grade glioma recur less and usually later than high grade glioma. These differences in overall survival emphasize the need to take into account prognostic factors such as primary histology, age, performance status, re-resection and corticosteroid use. Also the time interval since first radiation is a prognostic factor based on initial histology: previous histology of low grade glioma results in a longer interval to develop a recurrence as well as longer survival. Different prognostic scores are being developed to identify patients for re-irradiation or retreatment like the recursive pattern analysis for recurrent glioblastoma. Preliminary single institution data based on a matched pair analysis found a difference in overall survival between patients with a primary GBM with or without re-irradiation (own data). Whether a retreatment with combined chemoradiotherapy and temozolomide transfers a survival advantage is unclear. According to results reported in the literature a clinical response with improvement or stabilization of symptoms can be reached in about 60−70% of the patients after re-irradiation.
The majority (ca 80%) of glioma recur locally within 4 cm from the original site, thus often within the previous radiation field or at the margin of the primary radiation border. Re-irradiation is therefore usually given in the same area as primary radiotherapy and cerebral radiation necrosis is a potential risk for toxicity. This risk depends on the total radiation dose of both radiotherapy treatments and the time interval between first and second treatment as well as the tumour volume. Radiation-induced cerebral necrosis was found to occur at cumulative doses from both treatments above 100 Gy. Studies using a conventional fractionation scheme and/or a restricted radiation volume report a low toxicity rate of 10%. If the total cumulative dose is beyond 100 Gy and a defined time interval between both treatments is taken into account, occurrence of cerebral necrosis is low. A higher cumulative dose can be considered when the treatment volume is kept small (e.g. stereotactic radiotherapy). In the Maastricht group of re-irradiated patients the rate of radiation necrosis was 6% (based on MR imaging). However, during further follow-up tumour progression on MRI was observed at the same location where radiation necrosis was suspected earlier.
First research of recurrence pattern after reirradiation found that the cumulative recurrence pattern is predominantly distant especially if patients are surviving longer, whereas first recurrences are observed predominantly local.
In conclusion, it can be said that for a subgroup of patients selected by prognostic factors, taking into account radiotherapy dose prescription and timing, re-irradiation is effective, has impact on survival and can improve clinical symptoms with low toxicity.
No conflict of interest.

341 INVITED

What is the best option for recurrent glioblastoma in 2013 and 2023?

A. Brandes[1]. [1]*Bellaria Maggiore Hospital, Medical Oncology, Bologna, Italy*

Despite efforts and novel options in the treatment of recurrent glioblastoma, this disease remains almost incurable, with a limited survival expectancy. The upcoming strategy of inhibiting tumor angiogenesis has generated different treatment modalities, which have been transferred into clinical practice in recent years, and found in the inhibition of VEGF with bevacizumab (Avastin) the best clinical results. Our understanding of angiogenesis inhibition in glioma therapy is continually evolving. After the first two key noncomparative phase II studies, the BRAIN study and the NCI 06-C-0064E study, that found a significant improvement in efficacy with bevacizumab compared with historical data, other randomized trials have been performed showing a role of this drug in combination with chemotherapy, survival rates at 9 months of about 60%.
Moreover, the continuation of bevacizumab beyond progression in patients who received this monoclonal antibody in combination with radiotherapy and temozolomide, is under investigations, since this approach has been showed to increase survival in colorectal carcinoma, thus showing that the future backbone of some cancer types will be based on the block of angiogenic pathways during the entire natural history of these diseases.
A novel study, M028347, is a randomised, placebo-controlled, phase III trial, which aims to evaluate whether bevacizumab plus standard-of-care therapy improves overall survival in patients with glioblastoma who have progressed after first-line bevacizumab plus standard radiotherapy and temozolomide. However, despite these efforts, disease recurs and further options are limited.
Thus, as in other cancer types, basic research is moving to find driver mutations able to impact the fate of glioblastoma cells. Several putative alterations have been found, such as FGF mutation/amplification, or PI3KCA mutations, as well as MET alterations.
In conclusion, improvements in cancer survival observed over recent years appear to be the sum of incremental gains achieved with the introduction of novel treatments alongside other advances in patient care. In the next 10 years we expect to continue this incremental improvement in survival, as well as identification of specific treatments for subgroups of glioblastoma patients characterized by specific genetic signatures.
No conflict of interest.

Abstract not received.

343 INVITED

Androgen-receptor: A two-edge sword?

W.D. Tilley[1], T.E. Hickey[1]. [1]*The University of Adelaide, Dame Roma Mitchell Cancer Research Laboratories, Adelaide, Australia*

The androgen receptor (AR) is a key oncogenic driver and therapeutic target in prostate cancer, with recent studies of advanced disease revealing diverse adaptive mechanisms to sustain AR signalling under therapeutic conditions that aim to silence the receptor. On the horizon are new targeting

strategies aimed to outsmart known adaptive mechanisms, particularly in terms of targeting regions of the receptor that lie outside of the ligand binding domain. While these new strategies hold great promise for more effective AR inhibition, historical experience of employing androgen deprivation therapy raises a key question: will more effective AR silencing lead to more durable disease regression and significantly extend life for men with metastatic prostate cancer or will it reveal yet unknown treatment-induced adaptations that allow the disease to persist? These advances in knowledge of AR signalling and its targeting are now also being actively employed in the field of breast cancer with clinical trials already begun or commencing to examine the efficacy of AR target therapies for the treatment of metastatic disease. As a large majority of primary and secondary breast cancers display immunoreactivity for the AR, it represents a prevalent therapeutic target. However, unlike normal and malignant prostate tissues, AR signalling is not essential for breast development and appears to have dichotomous roles in breast cancer, with ascribed tumour suppressive or oncogenic capacities. On the one hand, AR signalling exerts an anti-estrogenic, growth inhibitory influence in normal breast tissue and in estrogen receptor (ERa) positive luminal breast cancers. On the other hand, evidence has been accumulating to support the concept that AR exerts an oncogenic influence in ERa negative breast cancers with a molecular apocrine phenotype and may play a role in the development of treatment resistance to anti-estrogen therapies currently in clinical use for ERa positive disease. Due to the inherent heterogeneity of breast cancer and the potential for AR signalling to exert tumour suppressive or oncogenic effects on different cell types within breast tissues, understanding the molecular mechanisms whereby AR signalling can elicit distinct gene expression programs and opposing proliferative responses in different breast cancer contexts is critical to the effective deployment of AR targeting therapies for treatment of women with breast cancer.
No conflict of interest.

344 INVITED

Micro-environment and bone metastases

R. Coleman[1]. [1]*Weston Park Hospital, Department of Clinical OncologyCancer Research CentreAcademic Unit of Clinical Oncology, Sheffield, United Kingdom*

Bone metastases result from the complex interactions between cancer cells in the bone marrow microenvironment, haematopoietic stem cells (HSC) and normal bone cells. Disseminated tumour cells (DTC) home to the HSC niches adjacent to Nestin+ cells in the perivascular space of small bone marrow arterioles at the bone surface and/or the lining osteoblasts. There, they can remain quiescent and in a dormant state for years prior to subsequent activation, the development of micro-metastatic foci and either stimulation of osteoclast function resulting in the development of a bone metastasis or onward dissemination to other metastatic sites. Thus, while the phenotype of the primary tumour and the ability of tumour cells to undergo epithelial mesenchymal transition (EMT) may influence the capacity of DTC to home to bone in the first place, it is the adaption of DTC to the bone microenvironment and the interactions with the many cell types within the bone marrow that probably determine whether a DTC is able to progress to a life-threatening metastasis, not only in bone but also at other sites. Bone-targeted treatments such as bisphosphonates (BPs) and denosumab (Dmab) have profound effects on the cellular interactions within the bone marrow micro-environment. Extensive preclinical research led to the hypothesis that BPs and Dmab might influence the course of the disease and led to the design of adjuvant studies in breast cancer and castrate resistant prostate cancer (CRPC).
Prostate cancer has the propensity to metastasize almost exclusively to bone and provides an ideal clinical setting for the evaluation of bone-targeted treatments. In a study in CRPC with unfavourable PSA kinetics, denosumab significantly increased bone metastasis-free survival by a median of 4.2 months over placebo (HR = 0.85; 95% CI 0.73–0.98, P = 0.028), and delayed time to symptomatic first bone metastases.
In women with early breast cancer, improvements in both disease free (DFS) and overall survival have been demonstrated in several large randomised adjuvant trials. The evidence for this is particularly strong with zoledronic acid but appears to be confined to patients with low levels of reproductive hormones including premenopausal women receiving ovarian suppression therapy and those who have passed through menopause at the time of diagnosis. In this group of patients, study level meta-analysis has shown an 18% improvement in DFS (hazard ratio [HR]=0.82; 95% CI 0.74–0.92, 2P=<0.001) with reductions in relapse rates not only in bone but also at extra-skeletal and loco-regional sites. Conversely, in premenopausal women, an increase in visceral and loco-regional relapse was seen that outweighs any reductions in bone metastases with marked heterogeneity of treatment effect according to menopausal status. The EBCTCG is currently performing a formal meta-analysis of the world-wide evidence and, if confirmed, these findings are likely to change clinical practice for postmenopausal women with breast cancer.

345 INVITED

A critical role for snail-regulated EMT in PI3K and MAPK pathway co-activation-induced prostate cancer progression and metastasis

H. Wu[1], M. Ruscetti[1], N. Kobayashi[1]. [1]*UCLA, Molecular Biology Institute, Los Angeles, USA*

The PI3K and RAS/MAPK pathways are co-activated in a high number of metastatic human prostate lesions, but the mechanisms of their collaboration are poorly understood. We show here that PI3K and RAS/MAPK pathway co-activation sensitizes the prostatic epithelium to TGF-b stimulation and leads to the upregulation of *Snail,* a key epithelial to mesenchymal transition (EMT) transcription factor. Downregulation of *Snail*, either by genetic deletion or co-inhibition of the PI3K and RAS/MAPK pathways in a metastatic prostate cancer model delays EMT-associated cancer progression and prevents distant macrometastasis. Mechanistically, cancer cells with EMT features are hypersensitive to SNAIL loss-induced and p53-dependent apoptosis. Our findings identify the critical role of SNAIL in the PI3K and RAS/MAPK co-activation-induced EMT program and prostate cancer metastasis *in vivo.*

Society Session (Tue, 1 Oct, 09:00−11:00)
European Association of Urology (EAU)

346 INVITED

Post-chemotherapy RPLND for testis cancer

S. Horenblas[1]. [1]*The Netherlands Cancer Institute, Urologische Oncologie, Amsterdam, Netherlands*

While surgical resection of residual masses after induction chemotherapy of non seminomatous germ cell tumors (NSGCT) is considered standard approach, questions and controversies remain. There is hardly any controversy in the management of the patient typically presented to the urologist with negative markers after chemotherapy with a large mass in the retroperitoneum. Results of surgery have been excellent with a low risk of recurrence. Template surgery has evolved based on mapping studies of the lymphatic landing zones. These studies were mostly done in low stage tumors and extrapolated to postchemotherapy surgery. However there is no consensus on the extent of surgery. While some advocate a full formal retroperitoneal lymph node dissection, removing all lymphatic tissue in the retroperitoneum, we and others advocate the removal of the lesion only. A limited removal has been helpful in decreasing the morbidity. Since the unraveling of the anatomy of autonomic nerves, nerve sparing surgery is considered standard procedure in low stage NSGCT. In certain patients this can also be achieved in a complete postchemotherapy RPLND. However, restricting the extent of the surgery has been beneficial especially to the maintenance of antegrade ejaculation without jeopardizing oncological results.
Most experts in the field agree there is no indication for surgery in patients with masses <1 cm, despite evidence in the literature that up to 30% of masses with a diameter<1 cm can contain viable tumor or mature teratoma. We and others continue to observe these patients as long term follow up has shown extremely low recurrence figures, far below the figures found in the past.
Recent figures have shown a shift in pathology of the resected specimen. Traditionally fibrosis/necrosis was found in 40%, mature teratoma in another 40% and viable germ cell tumor in 20%. Probably due to more effective chemotherapy and stage migration, figures have shifted to fibrosis in 50% and viable tumor in only 10%.
All agree there is no true benefit in removing dead tissue. Despite all efforts to use risk factors in order to better stratify patients for surgery and omitting surgery in patients with a high probability of necrosis/fibrosis in the mass, the best prediction models have a 20% false negative rate. So far these prediction models have had a limited place at best in the selection of patients.
Future imaging modalities could change daily practice as it has been the case with PET-CT scan in seminoma patients. As mature teratoma cannot be distinguished from necrosis/fibrosis, PET-CT scan has been not very helpful in NSGCT.
The biology of mature teratoma is unpredictable with growth (“growing teratoma syndrome”) and malignant transformation, resulting in chemotherapy resistant adenocarcinoma and sarcoma. Surgery is the only effective

treatment of mature teratoma and should therefore strive for complete removal.
Completeness of resection is an independent and consistent factor of clinical outcome.
While surgery has been advocated in NSGCT for small residual masses, this had not been the case in seminoma. Shrinkage of the mass has been observed in a majority of patients, restricting surgery to masses >3 cm.
PET-CT scan has been helpful in identifying patients with viable tumor.
Postchemotherapy RPLND is a technically demanding surgery. It is reasonable to restrict this type of surgery to dedicated centers where the procedure is performed by experienced surgeons.
No conflict of interest.

347 INVITED

New medical treatment options in prostate cancer

M. Wirth[1]. [1]*Universitätsklinikum Carl Gustav Carus, Department of Urology, Dresden, Germany*

A survival benefit for patients treated with Abiraterone and Cabazitaxel after failure of first line docetaxel treatment in CRPC has been proven in phase III studies. The final analysis of the Cougar 301 study confirmed again this survival benefit for patients treated with abiraterone.
Therapy with abiraterone before docetaxel chemotherapy was investigated in a further phase III study (COU-AA-302). This study included asymptomatic or mildly symptomatic patients with CRPC and showed a benefit in the primary endpoint progression free survival in favour of patients treated with abiraterone compared to placebo. Also a clear trend towards improvement of overall survival, although not significant, was seen in patients treated with this substance. This study led to the approval of abiraterone for asymptomatic and mildly symptomatic patients with CRPC not pretreated with docetaxel by the FDA and the EMA.
In a phase III trial the effect of Enzalutamide in patients with progressive disease after chemotherapy with docetaxel was investigated. In this study enzalutamide increased overall survival compared to placebo from 13.6 months to 18.4 months (HR 0.63, $p < 0.001$). For other secondary endpoints (PSA-response, response in soft tissue metastases, time to first skeletal event) also a benefit was achieved with enzalutamide. Therefore Enzalutamide was approved for the treatment of progressive CRPC after docetaxel therapy by the FDA and approval of the EMA is expected soon.
An alpha-emitting radionuclide (radium-223 dichloride-"Alpharadin") was tested in CRPC-patients with bone metastases. Patients included in the trial were progressive after docetaxel or unfit for docetaxel. Alpharadine led to a survival benefit of 14 months in comparison to 11.2 months (Placebo and best supportive care). Alpharadin has recently been approved by the FDA and approval in Europe is also expected soon.
In conclusion there are several new medical treatment options for patients with advanced and metastatic prostate cancer.
No conflict of interest.

348 INVITED

Sequencing surgery and drugs in renal cell cancer

P. Mulders[1]. [1]*Radboud University Medical Centre Nijmegen, Department of Urology, Nijmegen, Netherlands*

Kidney cancer treatment has changed substantially during the last decade. The targetted therapies have been implemented in the algoritms of treatment of metastatic renal cell carcinoma. This has led to an improvement in survival over the immunotherapy era a decade ago. Several agents can be used in first and second line for the treatment of this disease, approved for mainly progression free survival benefit. Moreover different toxicity profiles, although class specific, are apparent and should be implemented in treatment decisions. Mode of action is important for the best sequence decision, although cross reactivity may exist and will have its impact.
The discussion on the best sequence also includes the timing of surgery in combination with targetted agents. Pro and cons of nephrectomy will be discussed.
The role of targetted agents in the neoadjuvant and adjuvant is still unclear. Trials are ongoing to select out the best treatment sequence.It is clear that manh treatment options are available and results of pivotal trials should be implemented to improve the survival of renal cell carcinoma and decrease toxicities.

349 INVITED

Update on the management of muscle invasive bladder cancer

H. Van Poppel[1]. [1]*University Hospitals KU Leuven, Urology, Leuven, Belgium*

Background: Radical cystectomy is considered the gold standard for treating muscle invasive bladder cancer. Despite progress in diagnosis and treatment a considerable number of patients die from metastatic disease.
Materials and Methods: A number of items were looked after in recent publications.
Results: *Timely indication for cystectomy*: Timely indication of cystectomy and performance of surgery for BCG resistant T1GIII and for muscle invasive bladder cancer is clearly an important prognostic factor. Delaying the surgery is associated with a significant decrease in survival probability.
Adequate extent of surgery: Radical cystectomy in males refers to cystoprostatectomy with or without urethrectomy. In female patients it involves an anterior exenteration with resection of the internal genitalia, resection of the anterior vaginal wall and cystourethrectomy unless the urethra is used for bladder replacement. In both sexes, an extended lymphadenectomy needs to be performed since a number of patients with limited nodal disease can be cured. While the exact template is not yet clearly defined most experts include external and internal iliac vessels, obturator fossa and common iliac vessels up to the ureteral crossing.
Combination with systemic chemotherapy: The EAU Guidelines 2010 state that neoadjuvant cisplatin containing combination chemotherapy should be considered in muscle invasive bladder cancer, irrespective of the definitive treatment. In contrast, it remains clear that neoadjuvant chemotherapy is not recommended in older patients with poor performance status or in patients with impaired renal function.
Cystectomy in experienced centers: Mortality and morbidity following cystectomy is strongly related to the number of cystectomies performed by the center per year. This is clearly a factor that patients (and insurance companies) should consider. Urological surgeons must be aware of their own figures and critically analyze whether a sufficient number of procedures is performed to maintain surgical skill.
What type of urinary diversion? While bladder substitution procedures will be proposed in younger patients in which the urethra can be preserved, it is obvious that the majority of patients in most centers still undergo a cutaneous Bricker diversion. Comparative studies by the Cochrane collaboration has not come to a specific recommendation for the diversion type. Cutaneous continent diversions are more difficult and more complicated.
Conclusion: Radical cystectomy, once indicated, should not be postponed. An extended lymph node dissection is an integral part of the procedure. Neoadjuvant chemotherapy should be discussed with healthy younger patients with large T2 or T3 bladder cancer. Urinary diversion should be chosen following the patients preference and the surgeons expertise.
No conflict of interest.

Metabolism and Cancer

350 INVITED

Targeting treatment-related hypermetabolism in cancer

C. Schmitt[1]. [1]*Charité Campus Virchow, Department of Haematology and Oncology, Berlin, Germany*

Cellular senescence, a DNA damage-initiated terminal cell-cycle block, is an important component of chemotherapeutic drug action. The Eμ-*myc* transgenic mouse was previously established as an excellent model to explore the role of candidate genes and candidate programs (such as apoptosis) in aggressive B-cell lymphomas in response to chemotherapy. We previously demonstrated the essential role of the histone H3 lysine 9 methyltransferase Suv39 h1 in oncogene-induced senescence; here we characterize biological features and clinical impact of Suv39 h1-dependent TIS in Eμ-*myc* transgenic mice.
Tumor-bearing mice entered TIS in their lymphomas and achieved a much better long-term treatment outcome when compared to mice harboring TIS-incapable Suv39 h1-deficient lymphomas. While TIS lymphomas presented with a sharp decline in ^{18}F-fluoro-deoxythymidine positron emission tomography (PET) activity (scanning DNA synthesis as a functionality of dividing cells), they − unexpectedly − exhibited even enhanced ^{18}F-fluoro-deoxyglucose PET signal intensities (scanning glucose metabolism). *In vitro*, TIS lymphomas showed increased glucose uptake, a higher glycolytic rate and higher ATP levels. Mechanistically, due to the overwhelming production of senescence-associated secretory proteins, senescent cells displayed massive proteotoxic stress (endoplasmic reticulum stress and

the unfolded protein response), which they buffered by strongly enhanced and energy-consuming autophagy to clear the toxic proteins. In turn, TIS lymphomas − as well as a large variety of senescent human cancer cell lines and primary tumor samples − underwent cell death when exposed to autophagy or glycolysis inhibitors. Importantly, this sequential treatment also produced lymphoma regression and improved long-term outcome *in vivo*. Hence, metabolic targeting can be employed to effectively eliminate senescent cells, which are potentially harmful because they secrete proinflammatory cytokines and may eventually resume proliferation, thereby giving rise to a relapse. These findings represent a proof-of-principle how to utilize a cancer-specific condition (not a single molecular lesion) in a conceptually novel anticancer strategy that produces little harm to normal tissues.
No conflict of interest.

351 INVITED
HIFs, hypoxia, and tumor progression

C. Simon[1]. [1]*University of Pennsylvania, Philadelphia, USA*

Solid tumors exhibit heterogeneous microenvironments, often characterized by limiting concentrations of oxygen (O_2), glucose, and other nutrients. How oncogenic mutations alter stress response pathways, metabolism, and cell survival in the face of these challenges is incompletely understood. Here, we report that constitutive mTORC1 activity renders hypoxic cells dependent on exogenous desaturated lipids, as levels of de novo synthesized unsaturated fatty acids are reduced under low O_2. Specifically, we demonstrate that hypoxic $Tsc2^{-/-}$ cells deprived of serum lipids exhibit a magnified UPR response, but fail to appropriately expand their ER, leading to IRE1-dependent cell death that can be reversed by the addition of unsaturated lipids. UPR activation and apoptosis were also detected in Tsc2-deficient kidney tumors. Importantly, we observe this phenotype in multiple human cancer lines and suggest that cells committed to unregulated growth within ischemic tumor microenvironments are unable to balance lipid and protein synthesis due to a critical limitation in desaturated lipids.
No conflict of interest.

352 INVITED
Targeting the PI3K pathway in cancer

P. Workman[1]. [1]*The Institute of Cancer Research, UK Centre for Cancer Therapeutics, Sutton, United Kingdom*

The PI3 kinase pathway is frequently hijacked in cancer, for example by mutation of *RAS* and the *PIK3CA* gene encoding PI3 kinase p110a, loss of PTEN and increased activity of receptor tyrosine kinases. Numerous PI3 kinase inhibitors are now progressing through clinical trials (Shuttleworth SJ, Silva FA, Cecil AR, Tomassi CD, Hill TJ, Raynaud FI, Clarke PA, Workman P. Curr Med Chem. 2011;18:2686–714). I will provide an update on the mechanism of action of PI3 kinase inhibitors, including GDC-0941 which we discovered in collaboration with Piramed and Genentech. Key issues include isoform selectivity, the selection of pharmacodynamic and predictive biomarkers and the elucidation of potential resistance mechanisms (Clarke PA, Workman P. J Clin Oncol. 2012;30:331−3). I will place PI3 kinase inhibitors in the overall context of the selection of new drug targets in the genomic era and the development of drug combinations to overcome tumour heterogeneity, clonal selection and drug resistance. I will describe a new mechanism of action for protein kinase inhibitors involving chaperone deprivation (Polier S, Samant RS, Clarke PA, Workman P, Prodromou C, Pearl LH. Nat Chem Biol. 2013; 9:307−12).

353 INVITED
Metabolism in cellular senescence and therapy

D.S. Peeper[1]. [1]*Netherlands Cancer Institute, Division of Molecular Oncology, Amsterdam, Netherlands*

In response to various stress signals, such as the unscheduled activation of oncogenes, cells can activate tumor suppressor networks to avert the hazard of malignant transformation. A large body of evidence indicates that oncogene-induced senescence (OIS) acts as such a break, withdrawing cells from the proliferative pool virtually irreversibly, thus acting as a vital pathophysiologic mechanism protecting against cancer. In spite of the established role of OIS in preventing tumorigenic expansion both in animal models and humans, we have only begun to define the underlying mechanism and identify the key players. For example, while deregulation of metabolism is intimately linked to the proliferative capacity of cells, and despite of the wide belief that senescent cells remain metabolically active, little has been investigated in detail about the role of cellular metabolism in OIS.
By metabolic flux profiling and functional perturbations we find that the mitochondrial gatekeeper Pyruvate Dehydrogenase (PDH) is a crucial mediator of senescence induced by $BRAF^{V600E}$, which is encoded by a common oncogene in melanoma and other cancers. OIS is accompanied by suppression of the PDH-inhibitory enzyme pyruvate dehydrogenase kinase 1 (PDK1) and induction of the PDH-activating enzyme pyruvate dehydrogenase phosphatase 2 (PDP2). The resulting concerted activation of PDH enhances metabolic flux of pyruvate into the tricarboxylic acid (TCA) cycle, causing increased respiration. Restored PDK1 expression abrogates OIS, thereby licensing $BRAF^{V600E}$-driven melanoma development. Conversely, PDK1 depletion causes regression of established melanomas and eradicates subpopulations resistant to targeted BRAF inhibition. These results reveal a mechanistic relationship between OIS and a key metabolic signaling axis, which may be exploited therapeutically.

Scientific Symposium (Tue, 1 Oct, 09:00−11:00) **Innovative Molecular Imaging Strategies for Radiotherapy Individualisation**

354 INVITED
What reliable knowledge can molecular imaging offer nowadays to radiation oncologists?

W. Oyen[1]. [1]*Radboud University Medical Centre, Department of Nuclear Medicine, Nijmegen, Netherlands*

In the past decade molecular imaging with positron emission tomography (PET) has become increasingly important in clinical oncology. A wide variety of radiopharmaceuticals for PET is available to delineate and characterize tumors. The most extensively used radiopharmaceutical used is the glucose analogue F-18-fluorodeoxyglucose (FDG), depecting the metabolic activity of tumors. The introduction of integrated PET/CT was a major step forward, especially for the adequate evaluation of anatomically complex areas. Nowadays, FDG-PET is almost exclusively performed on integrated PET/CT scanners.
Besides the obvious contribution of FDG-PET/CT to more adequate staging of patients with a wide variety of cancer types, there are a number of indications that specifically aid radiation oncologists to improve patient management, treatment and follow-up. In this presentation the potential and pitfalls of FDG-PET/CT for tumor characterization and delineation, early therapy response assessment and prediction, treatment adaptation and detection of recurrent disease are discussed.
No conflict of interest.

355 INVITED
Cetuximab Zirconium, a new generation of functional imaging

F. Hoebers[1], H. Aerts[1], J. Van Loon[1], G. Van Dongen[2], P. Lambin[1]. [1]*MAASTRO-clinic, Radiotherapy Department, Maastricht, Netherlands;* [2]*VU University Medical Centre, Department of Nuclear Medicine and PET Research, Amsterdam, Netherlands*

Personalized medicine which aims at offering a patient the treatment that best suits the characteristics of the tumor of the individual patient, has been applied using genomic-based approaches by molecular tumor profiling and characterization. These analyses are often based only on biopsy specimens, thereby neglecting intra-tumor heterogeneity. In addition to genomic studies, efforts have been made to characterize tumors based on protein expression (receptor) profiles. However, regarding the Epidermal Growth Factor Receptor (EGFR), no association has been reported between receptor status and response to its blocking antibody cetuximab (Bonner, 2010). We hypothesized that the effect of cetuximab is also exhibited by other factors than receptor status alone, including e.g. vascular perfusion and interstitial pressure.
Non-invasive imaging offers the potential to study a tumor and to address its full spatial and temporal heterogeneity. This lecture will focus on the development and application of ^{89}Zr-cetuximab for the in vivo imaging of cetuximab uptake.
As the biologic half-life of cetuximab in the blood is 65−95 hours, a positron emitter with a long half-life is needed to visualize its uptake. For this purpose, cetuximab has been successfully labeled with ^{89}Zr (half-life 78 hours) in preclinical animal models and PET with ^{89}Zr-labeled cetuximab

was performed on tumor-bearing nude mice, using cell lines with varying EGFR expression levels (Aerts, 2009). Uptake of labeled cetuximab was demonstrated only in the EGFR-positive tumors. However, the level of EGFR expression did not correlate with ^{89}Zr-cetuximab uptake, confirming our hypothesis.
The first in human phase 1 study using ^{89}Zr-cetuximab has now recently been completed and showed a heterogeneous uptake pattern of cetuximab with no additional toxicity beyond the expected skin rash associated with cetuximab therapy. Currently, the multicenter international randomized phase II ARTFORCE trial (NCT01504815) is open for accrual, in which patients with locally advanced Head and Neck Cancer will undergo ^{89}Zr-cetuximab PET-scanning before chemoradiation. One of the primary endpoints is the correlation of the ^{89}Zr-cetuximab uptake and treatment-specific outcome.
No conflict of interest.

356 INVITED
Hypoxia-PET and its predictive value in HNSCC

Abstract not received.

357 INVITED
Amino acid PET

A. Grosu[1]. [1]*University of Freiburg, Department of Radiation Oncology, Freiburg, Germany*

The higher sensitivity and specificity of amino acids (AA)-PET in the diagnosis of gliomas in comparison to CT and MRI was demonstrated in many clinical trials. Summarizing the data of the literature we found between 1983 and 2008 45 trials including 1721 patients, which investigated the role of MET-PET in diagnosis of gliomas. Eleven studies including 706 patients were based on PET/MRI/CT stereotactical biopsies. Between 2000 and 2008 12 trials including 361 patients evaluated the role of FET-PET in the diagnosis of brain gliomas. In 3 studies evaluating 126 patients the results were based on PET/MRI/CT stereotactic biopsies. All these studies have shown that the sensitivity and specificity of MET-PET and FET-PET for malignant gliomas is significantly higher (85−95%) in comparison to MRI, which has a high sensitivity but a lower specificity.
Following topics will be discussed:
1. Amino-acids PET (AA-PET) for tumor detection and differentiation between tumor and treatment-related-changes in brain gliomas. The sensitivity and specificity of L-(Methyl-^{11}C) methionine (MET-PET) and ^{18}F- O-(2) fluoroethyl-L-tyrosine (FET-PET) for tumor tissue will be discussed.
2. Comparison between different AA tracers in diagnosis of brain gliomas and metastases.
3. Integration of AA-PET in treatment planning of brain tumors: radiation therapy, surgery, chemotherapy.
4. AA-PET and Bevacizumab.
5. Other tumor entities in which the integration of PET could give additional information about tumor extension and biology: meningiomas, glomus tumors, brain metastases

Scientific Symposium (Tue, 1 Oct, 09:00−11:00)
How to Put Evidence into Daily Nursing Practice

358 INVITED
Introduction: The Euro-PEP Project

A. Margulies[1]. [1]*Zurich, Switzerland*

Identifying a clinical care problem poses little difficulty to staff nurses, but the process of defining and identifying the clinical problem, and implementing those ideas through a change in practice can be more difficult. If guidelines do not exist for particular symptoms or supportive care issues, much time and effort has to be invested to find the evidence. Do nurses have the time in their daily practice or are they given the time from their supervisors or management?
The original inspiration for the Euro-PEP project came from the Oncology Nursing Society, U.S.A. The Euro PEP project has been developed in partnership with them and funded by EONS and the European Commission as part of the European Action Against Cancer.
The documentation provides a concise summary of the evidence, a synthesis of patient assessments, a summary of evidence based interventions, and expert opinions to help guide you in the interpretation of European standards along with the references and source material.
Evidence based practice is propagated in many oncology settings. One finds guidelines from various societies, institutions and countries, however one size does not fit all. Often the guideline has to be adapted to the individual work setting, and the Euro PEPs gives the guidance to do this. The material has been reviewed through a rigorous process by some of the leading experts and practitioners in the field.
In this session, five Euro-PEPs will be presented, each demonstrating how they can be implemented as well as showing the necessity to filter inappropriate care measures while initiating practice change. Using such information can only result in improvement of cancer care and patient safety.
No conflict of interest.

359 INVITED
Lymphoedema − prevention and treatment in daily practice

M. Sneddon[1]. [1]*University of Glasgow, Glasgow, United Kingdom*

Lymphedema is the accumulation of lymph fluid causing persistent swelling of the affected body part due to obstruction of the flow of fluid in the lymphatic system. In the oncology setting, the most common causes of lymphedema are radiation therapy and lymph node dissection. Lymphedema can occur in one or more extremities and can involve the corresponding quadrant of the trunk. Lymphedema arises in 15−28% of women treated for breast cancer. Lower extremity lymphedema occurs in up to 80% of those who had lymph node dissection in the groin or those who have compression of pelvic or inguinal lymph nodes. It can also affect the head and neck, breast, genitalia and lower limbs, depending upon surgeries and radiation therapy performed. Understanding which patients are most at risk facilitates early recognition and intervention which will improve outcomes of treatment, facilitate self management and improve quality of life.
Research based evidence for various lymphoedema prevention and treatment interventions is variable in quantity and quality but increasing research activity suggests that some emergent therapies may have much to offer. The content of the Euro PEP will be presented and key aspects of the current evidence base highlighted with discussion of how it can be used to guide clinical practice in relation to reducing risk of lymphedema, reducing complications and severity of lymphedema, supporting self management and ensuring patients have access to appropriate treatment interventions.
No conflict of interest.

360 INVITED
Peripheral neuropathy: Dealing with a difficult side effect

A. Margulies[1]. [1]*Zurich, Switzerland*

Patients report tingling, numbness, numbness, difficulty in walking. Approximately one third of patients who receive neurotoxic agents such as taxanes, platinums, vinca alkaloids, or bortezomib can develop painful neuropathy that significantly interferes with their daily activities and consequently quality of life.
Oncology nurses can play an important role in not only in the assessment of this side effect, but also with the management. The medical treatment is limited, but with initial assessment and follow-up, managing pain, maintaining safety, and maximizing physical function goals can be achieved.
The Euro-PEP “Peripheral Neuropathy” includes evidence based information to guide nurses and the healthcare team to make better management decisions. This session will discuss clinically feasible management approaches that might relieve or lessen the symptoms of a chemotherapy induced peripheral neuropathy.
No conflict of interest.

361 INVITED
Dyspnoea − an oncological challenge

A. Daibes[1]. [1]*Institut Jules Bordet, Medical Department, Brussels, Belgium*

Dyspnea is a subjective experience of breathing discomfort and one of the most frequent, refractory and distressing symptoms for patients with cancer especially in advanced stages.
It often coexists with fatigue, depression and anxiety.
It is estimated to occur in 15−55% of cancer patients at diagnosis and up to 18−79% during the last week of life, depending on the site of tumour.
It is not always possible to identify the cause(s) of dyspnea. Even if identified, it is difficult to treat these causes, mainly in patients with advanced cancer.
Currently, there is no internationally agreed upon roadmap to guide treatment for dyspnea. Changing the Caregivers’ mentalities seems to be one obstacle towards achieving this.

No single tool measures all the dimensions of dyspnea. Asking patients how short of breath they feel, by using a numeric rating scale, is the most accurate measure of dyspnea severity.
The EONS Putting Evidence into Practice (PEP) project, which resulted in the Euro PEPs, has provided a summary of evidence for cancer related symptoms. This study will present and discuss the measures included in the Euro PEPs concerning dyspnea.
Immediate-release oral and parenteral opioids are recommended for practice in relieving shortness of breath in cancer patients. This is the only evidence-based practice recommendation to alleviate dyspnea.
No conflict of interest.

362 INVITED
Pain management

Abstract not received.

363 INVITED
Radiation skin reactions

L. Sharp[1]. [1]*Karolinska University Hospital, Department of Oncology, Stockholm, Sweden*

The majority of patients undergoing radiotherapy (RT) experience acute radiation skin reactions, to some degree. Most patients have mild reactions (erythema) but 30−40 % also experience more severe reactions, such as dry and/or moist desquamations. The severe reactions often result in pain, itching, discomfort and sleeping problems. The management of radiation skin reactions vary a great deal between departments and local remedies with non-evaluated skin care products are not unusual. There is an increasing number of published studies on prevention and management of radiation skin reactions. The Euro-PEP's present an overview of the current evidence base and have been adapted to European conditions.
In this presentation, the content of the Euro PEP for radiation skin reactions will be presented and discussed with focus on how to improve clinical practice. What products could be used safely and which should be avoided? Strategies for skin care, the importance of systematic assessments and assessment tools will also be discussed as well as risk factors and information/education to patients.
No conflict of interest.

Scientific Symposium (Tue, 1 Oct, 09:00−11:00) **Geriatric Assessment and Their Clinical Applications**

364 INVITED
Definition of aging and functional decline

S.R. Kristjansson[1]. [1]*Diakonhjemmet Hospital, Department of Medicine, Oslo, Norway*

Background: The aim of this presentation is to define aging and describe the importance of assessing functional decline in older cancer patients.
Material and Methods: Literature search in databases and textbooks to identify review articles and chapters discussing aging, frailty and functional decline in older cancer patients.
Results: Aging is a gradual biological event, and there is no universally accepted age cut-off for defining older cancer patients. However, most studies define older patients arbitrary as aged 65 and above or 70 years and above. In general, all age-related changes in humans lead to reduced function. However, with increasing chronological age, the heterogeneity between individuals becomes larger. Thus, cancer patients' vulnerability towards side effects of treatment and remaining life expectancy is better explained by frailty or biological age than by chronological age alone. As reduced organ function associated with aging often leads to functional decline, one of the main treatment goals in older cancer patients is to optimize functional status. Curiously, few studies on older cancer patients include information about pre-treatment functional status, and functional decline following treatment is not a common endpoint. This is especially evident in studies of cancer surgery. As well as being an important treatment goal, functional status is a powerful predictor of negative outcomes as well as survival. Functional status is also a hallmark of the concept of frailty. It seems that the most important predictive information of functional status is obtained by objective measurements of physical performance such as gait speed or timed up-and-go. Such measurements should be included in a pre-treatment assessment of older cancer patients, and functional trajectories should be assessed during the treatment course.
Conclusion: Aging is associated with loss of function, but the heterogeneity between individuals is high, and chronological age alone is insufficient for treatment decisions. Functional status needs to be assessed before treatment, preferably by physical performance measures, in order to manage and prevent functional decline during and after treatment. Furthermore, functional status predicts negative treatment outcomes and survival.
No conflict of interest.

365 INVITED
Comorbidities

U. Wedding[1]. [1]*Friedrich Schiller Universität, Klinik für Innere Medizin II (Hämato-Onkologie), Jena, Germany*

Incidence and prevalence of co-morbidities are increasing with advanced age. Whereas co-morbidities are of major importance in clinical decision making they are hardly included in clinical trials. Co-morbidity is defined as one or more additional disease in the presence of an index disease. In this case the index disease in cancer. Multi-morbidity is defined as the sum of all morbidities/diseases. A number of validated tools are available to a structured assessment of co-morbidities. The presence of co-morbidity is associated with increased vulnerability to cancer treatment of poorer prognosis regarding survival. The most widely used scores are the Charlson-Comorbidity-Score and the Cumulative Illness Rating Score. Functional decline and presence of co-morbidity are associated however not strongly. It is therefore important to assess both functional status and co-morbidity. Future research should focus on the different impact of various co-morbidities on the vulnerability/toxicity of cancer treatment and on the prognostic importance. The longer the prognosis of a cancer diagnosis, the more effective the treatment, the more co-morbidities determine the major cause of death.
No conflict of interest.

366 INVITED
Importance of nutrition in geriatric oncology

P. Soubeyran[1]. [1]*Institut Bergonié, Bordeaux, France*

With the increasing of life expectancy, the number of elderly with cancer is rising quite rapidly. Older patients with cancer will experience more toxicity from treatment because of multiple comorbidities, concomitant medications and multiple geriatric problems including malnutrition. To avoid complications, better evaluation of patients is needed. It may lead to treatment dose reduction or even geriatric intervention on the altered dimension.
It is already demonstrated that nutritional status is a major prognostic factor in cancer patients. This is true also in the elderly with cancer but many questions remain to be answered.
The first topic is the evaluation of nutrition which can be performed through monitoring of albumin level or weight follow-up but also by the more specific MNA (MiniNutritional Assessment) tool. This questionnaire has already demonstrated its value to predict early death and chemotherapy-related toxicity. However, mainly because it is time-consuming, few older patients benefit from it. This is why screening procedures have been developed among which the G8 questionnaire, a tool derived from MNA.
Another major question to solve is the value of nutritional intervention. While it is well known and performed in cancer patients, its value to improve outcome in the elderly with cancer is not demonstrated. One randomized phase III trial, focused on patients at risk of malnutrition, has been completed recently. Results are pending.
Overall, nutrition is certainly a major topic to work on in the elderly with cancer and answers to these questions may help oncologists find clues to improve outcome.
No conflict of interest.

367 INVITED
Is frailty assessment effective?

H. Wildiers[1]. [1]*Wildiers, Department of General Medical Onciology − Multidisciplinary Breast Centre, Leuven, Belgium*

Frailty is often conceptualized as a state of late life decline and vulnerability characterized by weakness and decreased physiologic reserve. Frailty is associated with reduced resistance to stressors, and increased vulnerability/ risk for future poor clinical outcomes, such as falls, disability, adverse drug reactions, institutionalization, or death. Cross sectional studies suggest that about 4% of persons older than 65 years are frail, increasing up to 26% after age 85. Frailty is a dynamic process and is often associated with multimorbidity and disability. But frailty is certainly not identical to multimorbidity and disability which can precede or follow the occurrence of frailty. Frailty is a unifying notion in the care of elderly patients that directs attention away from organ-specific diagnoses towards a more holistic viewpoint of the patient.

Dysregulation in multiple physiologic systems, especially stress response systems including the immune and endocrine system, is a key feature of frailty and contributes to sarcopenia (age-related loss of skeletal muscle strength), a key physiologic component of frailty. Efforts are being done to develop 'biomarkers' of frailty (e.g. pro-inflammatory cytokines) that can be reproducibly measured in different settings, and that can predict outcome in addition to clinical evaluation.
Despite general agreement on the necessity and usefulness of the concept of frailty, there is still a lack of consensus definition and standardized assessment tool. Operational definitions like the frailty definition of Fried mainly rely on the musculoskeletal component of the frailty syndrome (sarcopenia). The most commonly used measurements for frailty screening are physical function, gait speed, and muscle strength. Besides the well validated but difficult to implement Cardiovascular Health Study index from Fried, other tools have been proposed such as the study of osteoporotic fractures index (SOF) which is much easier to measure in clinical practice, the Short Physical Performance battery (SPPB), or short single item functional tests like the timed-up-and go test of hand grip strength test.
Importantly, interventions have been proposed that are not (yet) focused on frailty per se, but rather on components of frailty, and can be reasonably applied to patients with frailty, such as exercise and nutrition interventions. The development of comprehensive geriatric assessment (CGA) in oncology is a major step forward in the care of older cancer patients. Recent studies confirm that CGA is sensitive to the reliable detection of degrees of frailty, and could be the gold standard to detect frailty. Nevertheless, functional tests measuring muscle strength have received (too) little attention in geriatric oncology settings so far. International efforts are required to establish uniform definitions and measurement tools for frailty and muscle strength in older cancer patients, which can be integrated in clinical care and research.
No conflict of interest.

Scientific Symposium (Tue, 1 Oct, 09:00−11:00) **Diagnosis and Treatment of Oncological Emergencies**

368 INVITED

Malignant bowel obstruction: The surgeons' perspective

W. Bemelman[1]. [1]*Academic Medical Center, Department of Surgery, Amsterdam, Netherlands*

Patients presenting with emergent left sided colonic obstruction vary with respect to stage of the colonic cancer (metastasized or not) and operative risk. Several strategies can be adopted.
With curative intention:
– Immediate resection of the obstructing tumor: The disadvantage of acute resection is that the frail patient might die of this invasive approach, the stoma rate is high and the oncologic quality might not be optimal in the emergency setting. The advantage is that the obstruction and the tumor is treated right away.
– Delayed resection after initial decompression either via colonic stent placement or a decompressive stoma: This bridge to definite surgery is used to optimize the patient, to stage the patient properly and to operate the patient by the most appropiate surgical team in the elective setting.

Stent placement before elective surgery, also known as a bridge to surgery, had been shown to decrease mortality, morbidity, and number of colostomies in uncontrolled studies. Prospective studies show less favorable results. Transverse colostomy via a threphine method is minimally invasive and associated with low morbidity and mortality rates. It is the surgical bridge to elective resection. The literature on diverting colostomy for obstructing left-sided colon cancer is scarce. This minimal invasive surgical intervention probably guarantees a more optimal decompression than stenting and avoids oncological risk of (micro) perforation.
With palliative intention: Conservative management avoiding resection is indicated in the patients in the metastasized setting or in the very frail who have a too high operative risk. The obstruction is treated by palliative stenting or a decompressive stoma done via a minilaparotomy.
There is a large controversy with respect to the use of the colorectal stent as bridge to surgery. In France and the Netherlands, the stent is underused due to the disappointing results of national trials conducted in these countries. In other countries, there is a great enthusiasm with respect to stenting.
Apart from conflicting short term results of colorectal stenting, data are accumulating with respect to the oncologic risk of stenting as bridge to surgery. Increased local recurrence and a shorter disease free survival are reported particularly in the patients having had an overt or silent stent perforation.
There is no evidence what is the most optimal strategy in patients with left sided colonic obstruction. Fit patients who can be treated with curative intent, are probably best managed with immediate surgical resection avoiding the risk of stent perforation which compromises long term oncologic outcome.
No conflict of interest information specified.

369 INVITED

Conservative treatment of malignant bowel obstruction

D. Currow[1]. [1]*Flinders University, Palliative and Supportive Services, Adelaide, Australia*

Malignant bowel obstruction is a frequently encountered cause of morbidity and mortality in people with cancer. High rates of this are seen with ovarian and primary peritoneal cancers. Causes include intra-luminal and intra-peritoneal lesions.
Two key elements in evaluating bowel obstruction are:
a. whether there is clinical evidence of a single level bowel obstruction or of multiple levels; and
b. the person's overall well being.

The person with established cachexia (not simply weight loss secondary to anorexia or starvation) is unlikely to tolerate even minimally invasive procedures and arguably, the catabolic insult may hasten his/her death.
Single level obstruction, whether as the initial presentation of cancer, at recurrence or related to surgical complications such as adhesions, is almost always best palliated by surgery, expect very late in the disease trajectory. At that time, the use of self-expanding metal stents, argon plasma coagulators or laser are options for single-level colonic lesions.
From recent epidemiological data from the SEER data base, multi-level obstruction secondary to cancer should be considered a pre-terminal event and is rarely amenable to meaningful palliation with surgery. The aim of therapy is reduce the symptoms of vomiting, nausea and pain, each of which can be effectively palliated.
Potential medical therapies include the use of dexamethasone, H_2 antagonists and somatostatin analogues such as octreotide. The latter two are primarily designed to reduce the volume of gastric secretions. A recent phase III study failed to demonstrate any benefit of octreotide over placebo, with octreotide apparently causing much more colicky abdominal pain.
The role of nasogastric tubes beyond initial decompression is limited, and any parenteral hydration should be approached with care. Palliative procedures may include a venting gastrostomy in a highly selected sub-group of patients.
No conflict of interest.

370 INVITED

Management of hemoptysis

J. Lehto[1]. [1]*Tampere University Hospital and Hyvinkää Hospital, Department of Palliative Medicine and Department of Respiratory Medicine, Tampere and Hyvinkää, Finland*

Hemoptysis is defined as coughing up blood from the respiratory tract. About 30 % of all the cases are due to malignancy, while hemoptysis occurs in 10−30 % of the patients with lung cancer. Hemoptysis is usually mild (<200 ml/24 h) rather than a real emergency, but massive hemoptysis capable of causing respiratory distress may occur in about 5 % of the cases. Although in most cases the blood is originated from the tumor growth, other etiologies do occur also with cancer patients (e.g. respiratory infection, pulmonary embolism, bronchiectasis, and side effects of oncologic therapy). Optimal therapy depends on the etiology and severity of hemoptysis as well as performance status and prognosis of the patient.
General management includes correction of coagulopathies, antibiotics for respiratory infection, cough suppressants and a trial with tranexamic acid (500–1000 mg thrice a day). In the case of massive hemoptysis the primary goal is to prevent asphyxia by oxygen, positioning the patient on the bleeding side down, and, if definitive therapy is available, endotracheal or unilateral intubation.
Radiotherapy is the treatment of choice for non-massive cancer related hemoptysis with response rates ranging from 70 to 90%. The alleviation of hemoptysis is equal with short course and low dose radiotherapy (e.g. 8−10 Gy in 1 fraction or 16−17 Gy in 2 fractions) when compared to higher doses. Higher doses and multiple fractions are, however, associated to a slightly better survival in patients with good performance status (about 5 % in 1 year), but with a cost of more acute toxicity. Endobronchial brachytherapy is also highly effective and may be used in selected cases, but it has no proven efficacy over external beam radiation therapy (EBMT). Therefore, EBMT is recommended as first line modality for hemoptysis.
Bronchoscopy is used as a diagnostic procedure and to remove blood from tracheobronchial tree. In addition, several techniques are available to control the bleeding (argon plasma coagulation, electrocautery, laser and

tamponade with balloon), but no studies exist on the superiority of these procedures.
Bronchial artery embolization is very effective in the management of severe hemoptysis, but only few studies have included patients with malignancy. Nevertheless, response rates up to 89% have been reported also in cancer patients.
Surgery is definitive therapy for bleeding local tumor, but it is not generally an option for patients with hemoptysis and advanced cancer due to high mortality and morbidity especially in emergency setting.
In the last weeks of life hemoptysis is reported in 9 % of lung cancer patients. Conservative management including radiotherapy is offered to patients in palliative care, while invasive procedures are usually futile. Massive hemoptysis at the end of life is a rare but possible phenomenon, which usually requires rapid sedation of the patient together with support for the caregivers and family.
No conflict of interest.

371 INVITED
Spinal cord compression

D. Rades[1]. [1]*University Hospital of Schleswig-Holstein, Radiation Oncology, Luebeck, Germany*

MSCC occurs in 5−10% of cancer patients during the course of their disease. Radiotherapy (RT) alone is the most common treatment. For patients with a poor survival prognosis, short-course RT (8−20 Gy in $\leqslant$1 week) is preferable to longer-course RT (30−40 Gy in 2−4 weeks) to reduce the burden of treatment for these often debilitated patients. Short-course RT results in similar functional outcome as longer-course programs. However, longer-course RT leads to better re-calcification and local control of MSCC. Since relevant re-calcification can only be expected several months following RT and since the probability to develop a local recurrence of MSCC increases with survival time, patients with a favourable survival prognosis appear better treated with longer-course RT. The survival of patients with MSCC can be estimated with the help of prognostic scores.
Highly selected patients with an extraordinarily favourable survival prognosis may be also considered for high-precision RT such as radiosurgery (RS) and stereotactic body radiotherapy (SBRT) in order to better spare the surrounding normal tissues. Another group of patients who may benefit from SBRT are those with MSCC from a less radiosensitive tumour. However, the tolerance doses of both spinal cord and vertebral bone must be considered when using RS and SBRT. The maximum dose to the spinal cord should not exceed 13 Gy in 1 fraction or 21 Gy in 3 fractions, and the maximum dose to the vertebral body should not exceed 15.5 Gy in 1 fraction or 25.5 Gy in 3 fractions. However, sufficient long-term data are currently lacking.
Upfront decompressive surgery with direct stabilization in addition to RT is recommended for selected patients with a good performance status, a favourable survival prognosis, involvement of only one spinal segment, and MSCC from a solid tumour. Also patients with a less radiosensitive tumour appear to benefit from additional surgery.
If an in-field recurrence of MSCC occurs, re-RT appears safe if the cumulative biologically effective dose (BED) is $\leqslant$120 Gy_2. If longer-course RT has been initially given, the cumulative BED may exceed 120 Gy_2. These patients should be treated with decompressive surgery if possible and indicated. Otherwise, high-precision RT should be considered.
Currently, the recommendations for the treatment of MSCC are based mostly on non-randomized studies. More randomized trials are required to better define the best (individual) treatment for this oncologic emergency.

Scientific Symposium (Tue, 1 Oct, 09:00−11:00) **Molecular Profiling in Neuro-Oncology**

372 INVITED
Glioblastomas

W. Wick[1]. [1]*University of Heidelberg, Abteilung NeuroonkologieNeurologische Klinikund Nationales Tumorzentrum, Heidelberg, Germany*

The World Health Organization (WHO) Classification of Tumors of the Nervous System classifies and grades tumors by histological criteria. This classification associates the presumed histogenetic origin and WHO grades I to IV to the expected clinical course. It has fundamental clinical relevance since its diagnostic classification determines whether the individual patient will be managed after surgery by watchful waiting or decide for further treatment, commonly radiotherapy, chemotherapy or both. Since the analysis of outcomes with nitrosoureas in the late nineties, there is knowledge about *O6-Methyl-Guanine-Methyl-Transferase* being decisive for benefit from alkylating chemotherapy. This was formally addressed and operationalized by the EORTC 26981/NCIC CE.3 trial, in which patients with a tumor haboring a methylated (inactive) *MGMT* promoter did considerably better than those without this methylation, most of all in the temozolomide-containing treatment arm.
Recent practice-changing academic clinical trials have defined a role for routine assessment of *MGMT* promoter methylation in glioblastoma of the elderly. Moreover, high-throughput analyses have led to the identification of new mutational targets in gliomas, notably isocitrate dehydrogenase (IDH) and histone H3, and allowed to subclassify gliomas into distinct molecular subgroups defined by age, localization, and outcome, although not yet benefit from therapeutic interventions. Large scale genome-wide epigenetic screens revealed distinct subgroups of patients, basically on grounds of IDH, two distinct histone H3 mutations, the mesenchymal signature and expression of receptor-tyrosine kinase-related genes. In clinical trials or daily practice, so far only *MGMT* has a role as an eligibility criterion and a decisive biomarker for elderly patients' treatment. Apart from further prognostic marker/signatures, it was only the RTOG-0825 trial comparing standard of care $\pm$ bevacizumab that now suggests a predictive role for a nine-gene classifier for bevacizumab treatment.
In the future, validation of existing markers needs to be done, new targeted treatment developments should inherit a biomarker program, as a unsupervised approach to deduct targets from large-scale approaches would be desirable.
Conflict of interest: *Advisory board: Roche, MSD. Corporate-sponsored research: Boehringer Ingelheim, MSD, Apogenix, Eli Lilly*

373 INVITED
Anaplastic gliomas

M. Van den Bent[1]. [1]*Erasmus University Medical Center, Neuro-Oncology, Rotterdam, Netherlands*

In anaplastic glioma, three clinically relevant molecular markers have now been identified: combined 1p/19q loss, IDH1/2 mutations and MGMT promoter methylation. To complicate this, these markers are correlated: 1p/19q co-deleted tumors as a rule have IDH mutations, and IDH mutations are related to CpG Island hyperMethylation (CIMP) of which MGMT promoter methylation is a part. IDH mutations aear to be an early eventin gliomagenesis, and the current understanding is that most tumors with an astrocytic phenotype will have TP53 mutations, and tumors with an oligodendroglial phenotype have the 1p/19q co-deletion. Glioblastoma with IDH mutations tend to have a more favorable outcome than gradeIII gliomas without IDH mutations. Several studies have shown the more favorable outcome of 1p/19q co-deleted tumors; but also, grade III tumors with an IDH mutation have a better prognosis than IDHwt tumors. Recent trials have shown that 1p/19q loss is a predictive marker for benefit to adjuvant PCV chemotherapy, but the current evidence suggest that other markers may allow a better identification of patients benefitting to adjuvant chemotherapy.
MGMT promoter methylation is in glioblastoma related to more benefit to concurrent temozolomide. Surprisingly, in studies in grade III glioma MGMT promoter methylation was found to be of prognostic siginficance, even in radiotherapy treated patients. This may be related to the simultaneous presence of IDH mutations and CIMP, but more recent studies suggest that examination of MGMT promoter methylation using a genome wide array may in fact be predictive for benefit to adjuvant chemotherapy. Thus, some of the differences found between studies on the clinical impact of MGMT promoter methylation studies may actually be related to differences in the used techniques, which assess different regions of the CpG islands in the MGMT promoter region.
Recently, several new mutations have been identified (CIC and FUBP in 1p/19q co-deleted tumors, mutations in the ATRX gene in other IDH mutated tumors). It has been suggested these may further guide the molecular classification of glioma, but this requires validation. From a clinical perspective, the most attractive markers are those that predict benefit to a specific treatment.
To conclude, 1p/19q has diagnostic, prognostic and therapeutic implications. IDH identifies a subgroup of grade II/III diffuse glioma, with CIMP and MGMT promoter methylation. The role these latter markers have in therapeutic decisions is still unclear, but may eventually come down to MGMT promoter methylation. And the presence of that marker is not limited to 1p/19 co-deleted, IDH mutated or CIMP positive tumors, but may occur as a single event. Further research in independent (randomized) clinical studies is required to increase our understanding of the role these markers can play in clinical decision making.

374 INVITED

Brain metastases

R. Soffietti[1]. [1]*University of Torino, Neuroscience, Torino, Italy*

The huge amount of information on new molecular compounds and the advances in understanding the molecular pathways that mediate brain colonization have led to an increase of interest in preclinical and clinical investigations in the field of brain metastases. Targeted therapies can be employed either on established brain metastases or in a prevention setting. Targeting angiogenesis is an attractive approach. Up to date, large clinical trial datasets have shown that antiangiogenic agents do not increase the risk of bleeding into the brain. Bevacizumab (an anti-VEGF agent) is undergoing investigation in clinical trials on brain metastases from NSCLC, breast cancer and melanoma. Sunitinib, a multitarget small molecule tyrosine kinase inhibitor, is a promising agent in brain metastases from renal cell cancer. The EGFR inhibitors gefitinib and erlotinib have a definite activity in brain metastases from NSCLC with activating EGFR mutations. Regarding HER2 positive breast cancer patients with established brain metastases, lapatinib (small molecule tyrosine kinase inhibitor) seems particularly active in association with capecitabine. Lapatinib alone is attractive in the prevention setting. Brain metastases from melanoma with BRAF V600E mutations respond a specific inhibitor, such as vemurafenib. The immunomodulator ipilimumab is also active on brain metastases from melanoma.

No conflict of interest.

375 INVITED

Medulloblastoma: Next-generation diagnostics entering the clinical stage

S.M. Pfister[1]. [1]*DKFZ − German Cancer Research Center, Division of Pediatric Neurooncology, Heidelberg, Germany*

It is well established now, that the morphological diagnosis “medulloblastoma” is in fact a mixture of several distinct biological entities. In a consensus process between the leading medulloblastoma groups worldwide, these subgroups have been termed WNT, SHH, group 3 and group 4 in an attempt to unify terminology. Recent advances in genome and epigenome sequencing have revealed fundamental new insights in recurrently mutated genes and pathways both somatic and in the germline, many of these in a subgroup-specific manner. Interestingly, novel genetic patterns have been identified in subsets of tumors including tetraploidy as an early event in group 3 and 4 tumors, which is potentially a durggable hit, and chromosome shattering in Li-Fraumeni associated MBs. Furthermore, the genetic landscape of SHH-driven medulloblastoma has been deciphered, which is of central importance for clinical trials targeting the SHH pathway at teh level of Smoothened.

Im summary, this talk will focus on genomic and epigenetic hits in medulloblastoma that confer important information for the clinics and highlights ways of translating these findings to the benefit of our patients.

No conflict of interest.

Scientific Symposium (Tue, 1 Oct, 09:00−11:00)
The Future of Paediatric Oncology in Europe

376 INVITED

Re-enforcing integration of research and care in childhood and adolescent cancer: A new role for clinical epidemiology in outcomes research?

K. Pritchard-Jones[1]. [1]*University College London, Institute of Child Health, London, United Kingdom*

In high-income countries, survival from childhood cancer has reached 80% through a continuous focus on the integration of clinical research into front-line care for nearly all children affected by malignant disease (1). The early successes of international, collaborative clinical trials led to the recognition that such trials were the basis for rapid improvements in survival and should be viewed as best practice (2). However, amongst children with the most excellent survival rates, approaching 90%, (e.g. localised low and intermediate risk Wilms tumour, localised embryonal rhabdomyosarcoma at favourable anatomical sites, extra-cranial germ cell tumours, approximately one third of childhood acute lymphoblastic leukaemia and some lymphomas), continuation of a full portfolio of clinical trials is becoming unaffordable both in terms of financial resources and competing priorities for academic investigator time, when there remain hard to treat sub-groups. Hence, new approaches are needed to continue high quality prospective clinical research. These must capture detailed clinical information on patients treated on standard protocols, allow biological sampling with appropriate consent, monitor outcomes including relapse and generate large cohorts of patients to improve risk stratification through a biology-driven approach and adequately study long-term side effects.

The European Network for Cancer research in Children and Adolescents (ENCCA) has dedicated a specific workpackage to developing mechanisms to conduct prospective clinical studies that do not fall within the definition of a clinical trial testing an investigational medicinal product (IMP). At present, this is focusing on working with existing cancer registration processes at a national level to define what data could be collected routinely and to test the feasibility and resource implications of collecting an enhanced dataset that could be used to continuously monitor the success rates of front line therapy. This will build on the long standing collaboration between cancer registries in the ACCIS and EUROCARE projects, and is being co-ordinated by Dr Steliorova-Foucher at IARC, Lyon.

In parallel, the European paediatric renal tumours study group (SIOP-RTSG) is setting up a prospective registration study with consent, that introduces rapid radiology review and consent for Omics testing as a prelude to more biomarker driven personalized risk stratification for good risk tumours and earlier signposting of patients with very high risk tumours to appropriate targeted therapy trials. This has already highlighted the differences in consent processes for parents to give permission for genomic testing of their child’s tumour and also how this complies with data protection legislation across the EU.

Progress (and barriers to progress) in both of these areas will be discussed.

No conflict of interest.

377 INVITED

Risk adapted therapies for personalising medicine for children and adolescents with cancer

M. Schrappe[1]. [1]*University Medical Center Schleswig-Holstein, Pediatrics, Kiel, Germany*

Systematic recruitment of children and adolescents with leukemia and cancer into clinical trials is one of the largest achievements in oncology and pediatrics. This unique process established profound knowledge on clinical and biological prognostic parameters in all entities of cancer in childhood and adolescence. The clinical trials in Pediatric Oncology comprising combination therapies of all kinds have significantly reduced the risk of disease recurrence but also that of acute and late side effects. One can simply state that in 2013 more children are cured but in most entities with less or different therapy than 20 years ago.

Identification of risk groups has been the main focus of the past years. In childhood leukemia, some distinct unfavourable subgroups were identified in which treatment success is less frequent while others have been shown to benefit from novel strategies. In acute lymphoblastic leukemia, high tumor load (WBC), lack of response, age under one year, or beyond 10 years (more pronounced beyond 15 years), and (rare) cytogenetic subtypes such as translocations t(9;22), or t(4;11), or the presence of *IKZF1* may characterize a significant proportion of children and adolescents with high risk (HR-) ALL. This example may also serve to demonstrate a dilemma which is reflected by the fact that the majority of relapses may occur among so-called intermediate risk patients. Thus, quite frequently, specific characteristics to identify the patient at risk to relapse have been missing. Recently, genetic signatures in various tumors were described which may further characterize high relapse risk patients. Careful response assessment preferably by detection of minimal residual disease (MRD) has become mandatory in leukemia to identify patients at risk to relapse but also those who can be spared intensive therapy. MRD monitoring may also contribute to determine the activityof novel therapies, such as functionally targeted or immunotherapeutic strategies, or it may be used to monitor the efficacy of allogeneic hematopoetic stem cell transplantation. In solid tumors, monitoring of treatment response by MRD detection may be difficult, therefore, the imaging techniques and specific biomarkers play the more important role to assess the efficacy of novel therapies. Eventually, more specific and molecularly targeted therapies may enter clinical practice if the toxicity is acceptable, in particular with regard to specific pediatric aspects, such as growth, organ functions, and mental development.

Light-activated multimodal nanoparticles

M.P. Melancon[1], R.J. Stafford[2], C. Li[3]. [1]*University of Texas MD Anderon Cancer Center, Diagnostic Radiology, Houston Texas, USA;* [2]*University of Texas MD Anderon Cancer Center, Imaging Physics, Houston Texas, USA;* [3]*University of Texas MD Anderon Cancer Center, Cancer Imaging Systems, Houston Texas, USA*

Multifunctional nanoparticles (NPs) that interact with light provide a unique opportunity for applications in image-guided therapy. These NPs have a strong and tunable surface plasmon resonance absorption in the near-infrared (NIR) region, which can also carry diagnostic and therapeutic agents. These novel nanostructures home in on solid tumors either via passive targeting mechanism or active targeting facilitated by ligands bound on their surfaces. Once they reach their target tissue, their activity can then be turned on using NIR laser for photothermal ablation therapy (PTA). However, PTA is only effective on a very confined region and is also unlikely to kill all tumor cells when used alone. NPs can also efficiently trigger the release of drugs and activate RNA interference. A multimodal approach, which permits simultaneous PTA therapy, chemotherapy, and therapeutic RNA interference, has the potential to completely eradicate residual diseased cells. In this presentation, an up-to-date review of the synthesis and characterization, functionalization, and in vitro and in vivo evaluation of NIR light activatable multifunctional gold-based nanostructures used for imaging and therapy will be provided. Emphasis will be given on our research on hollow gold nanospheres and magnetic core–shell gold nanoshells.

No conflict of interest.

381 INVITED

Radiosensitisation by gold nanoparticles at megavoltage radiation energies

F.J. Currell[1]. [1]*Queen's University, School of Maths and Physics, Belfast, United Kingdom*

Background: Radiation enhancement by targeted nanoparticles containing a heavy atom species (e.g. gold) has great potential to improve cancer therapy. Based on readily available physical parameters, predictions can be made in terms of the physical dose enhancement. These predictions indicate that treatment of a number of cancers that could benefit from this approach. However, *in vitro* dose enhancements, particularly at megavolt energies, have been observed to be far larger than those arising from these simple physical predictions. The purpose of this study was to reconcile this discrepancy.

Material: Radiation track structure calculations were made concerning the irradiation of gold nanoparticles under various conditions. Drawing on concepts of local dose effects drawn from the heavy ion therapy community these simulations were processed to provide a prediction of the cell killing. Also a number of radiochemistry experiments were conducted whereby nanoparticle-doped aqueous samples were irradiated with the production of the hydroxyl radical being assayed.

Results: The predictions display excellent agreement with measurements, showing the importance of considering the nanoscale effects of radiation in the presence of heavy-atom nanoparticles. The measurements of the hydroxyl radical production show very large enhancements when gold is added. The enhancement is too large to be explained by the localised electron emission mechanism used to explain the cell killing.

Conclusion: Both the simulations and the experimental measurements suggest the targeted use of heavy atom nanoparticles in conjunction with radiotherapy should be applicable to a wider range of cancers. Whilst these are positive indicators for the clinical application of such nanoparticles, basic questions still remain pertinent to the wider field of applying nanotechnology to cancer. The measurements suggest radiation chemistry ideas will need to be reviewed significantly to account for the situation when nanoparticles are present in the system − this then has impact on the whole field of cancer nanotechnology since it is unthinkable that clinical practice will abandon the diagnostic use of X-rays. As well as making the case for heavy atom nanoparticle therapy, this talk will outline the emerging need for basic data, modelling and measurements as nanotechnology becomes more broadly applied to cancer therapy.

No conflict of interest.

382 INVITED

Effectiveness of electrochemotherapy in brain tumours

J. Gehl[1]. [1]*Copenhagen University Hospital, Department of Oncology, Herlev, Denmark*

Brief electric pulses that exceed the electric capacitance of the cell membrane may be used to transiently cause cell permeabilisation (electroporation), enabling direct access to the cell cytosol. The cytotoxicity of e.g. bleomycin may be enhanced several hundred fold in the area subjected to electric pulses (electrochemotherapy). The dramatic increase in cytotoxicity allows treatment of all cancer histologies, and electrochemotherapy is now routinely used for cutaneous metastases from e.g. breast cancer and malignant melanoma with very high local response rates. Electrochemotherapy is currently being pursued for tumors in internal organs, and here we summarize development of an expandable electrode device, as well as preclinical studies and a phase I clinical trial.

First, a novel electrode device able to go through a single insertion point (e.g. burr hole) and deploy electrodes at the location of the tumor, was designed and produced, along with a 'mini-model' for use in experimental rat brain tumor studies.

Preclinical data (Agerholm-Larsen et al, Cancer Research 2011) showed that electrochemotherapy highly efficiently could eliminate rat brain tumors and that side effects were very modest in this experimental model. This first study using intracranial injection of bleomycin followed by electroporation was succeeded by a study using iv bleomycin, and the results here showed similarly impressive responses, and with more favorable effect on normal tissue evaluated by histology (Agerholm-Larsen et al, abstract 2069, Journal Clinical Oncology 2012).

Magnetic resonance imaging (MRI) on a rat brain model (Mahmood et al, J. Membrane Biology 2011) showed that apparent diffusion coefficient (ADC) was very useful in elucidating the treatment area due to changes in diffusion after permeabilisation.

Finally, a clinical study for patients with brain metastases from any histology, where whole brain irradiation and all other relevant treatments had failed, was initiated (clincaltrials.gov NCT01322100). The first patient has been treated, indicating that electrochemotherapyin the brain using the designed electrode device was feasible and safe. After localisation of the target lesion, the patient was anesthetised and in an interventional CT-scanner, a burr hole was made after which the electrode device was inserted to the correct point and the electrodes expanded. Bleomycin (15.000 IU/m^2) was infused iv, and electric pulses were administered over a few minutes, after which the device was folded back and retracted. The patient suffered progression of systemic disease which shortened follow-up, but MRI at 5 weeks indicated progression of untreated metastases whilst the treated metastasis was reduced in size.

In conclusion, a novel electrode device for electrochemotherapy in the brain was designed and preclinical data as well as very early clinical data are promising. This electrode device could potentially be used for primary brain cancers as well as other soft tissue tumors.

Conflict of interest: *Other substantive relationships: Julie Gehl is an inventor of patents related to the electrode device.*

383 INVITED

Multicomponent nanoparticles for enhanced delivery of chemotherapy

S. Jain[1]. [1]*Centre for Cancer Research and Cell Biology Queen's University Belfast, Cancer Centre, Belfast, Ireland*

Nanotechnologies have tremendous potential to improve cancer treatment. The efficacy of systemic anti-cancer therapy is often limited by normal tissue toxicity leading to sub-therapeutic intratumoural drug concentrations. The development of drug nano-conjugates has enabled more targeted delivery of systemic therapies, with several agents improving patient survival in well-conducted Phase III clinical trials. Beyond simple conjugates, many multifunctional nanoparticles have been developed which have been shown to overcome aspects of traditional drug resistance including targeting, cellular entry, nuclear entry, tumour hypoxia and drug efflux. Preclinical and clinical examples will be discussed. In the era of stratified cancer medicine, drug libraries are being developed based on standard core preparations. Similarly, it is clear that the clinical utilisation of many multifunctional nanoparticles is limited by consistency and reproducibility of manufacture and batch-to-batch variability which can dramatically alter drug function. Some of these limitations will be addressed in this overview.

The Pathology of Lung Cancer and its Clinical Implications

387 INVITED

Lung Adenocarcinoma − from pathology to therapeutic implications − Pathologist viewpoint

W. Travis[1]. [1]*Memorial Sloan Kettering Cancer Center, Department of Pathology, New York, USA*

The new IASLC/ATS/ERS Lung Adenocarcinoma classification provides for the first time, standardized terminology for lung cancer diagnosis in small biopsies and cytology (Table 1), as this was not primarily addressed by previous WHO classifications.

Table 1.

2004 WHO Classification including updated IASLC/ATS/ERS terminology	Morphology/Stains	IASLC/ATS/ERS Terminology
ADENOCARCINOMA Mixed subtype Acinar Papillary Solid Micropapillary	Morphologic adenocarcinoma patterns clearly present	Adenocarcinoma (describe identifiable patterns present)
Lepidic (nonmucinous)		Adenocarcinoma with lepidic pattern (if pure, add note: an invasive component cannot be excluded)
Lepidic (mucinous)		Invasive mucinous adenocarcinoma (describe patterns present; use term mucinous adenocarcinoma with lepidic pattern if pure lepidic pattern − see text)
No 2004 WHO counterpart − most will be solid adenocarcinomas	Morphologic adenocarcinoma patterns not present (supported by special stains, i.e. +TTF-1)	Non-small cell carcinoma, favor adenocarcinoma
SQUAMOUS CELL CARCINOMA	Morphologic squamous cell patterns clearly present	Squamous cell carcinoma
No 2004 WHO counterpart	Morphologic squamous cell patterns not present (supported by stains i.e. +p40)	Non-small cell carcinoma, favor squamous cell carcinoma
LARGE CELL CARCINOMA	No clear adenocarcinoma, squamous or neuroendocrine morphology or staining pattern	Non-small cell carcinoma, not otherwise specified NSCLC-NOS

Until recently there have been no therapeutic implications to further classify NSCLC, so little attention has been given to the distinction of adenocarcinoma and squamous cell carcinoma in small tissue samples. This situation has changed dramatically in recent years with the discovery of several therapeutic options that are only available to patients with adenocarcinoma or NSCLC-not otherwise specified (NOS), rather than squamous cell carcinoma. This includes recommendation for use of special stains as an aid to diagnosis, particularly in the setting of poorly differentiated tumors that do not show clear differentiation by routine light microscopy. A limited diagnostic workup is recommended to preserve as much tissue for molecular testing as possible. Most tumors can be classified using a single adenocarcinoma marker (e.g. TTF-1 or mucin) and a single squamous marker (e.g. p40 or p63) NOS carcinomas that stain with adenocarcinoma markers are classified as *NSCLC, favor adenocarcinoma* and tumors that stain only with squamous markers are classified as *NSCLC, favor squamous cell carcinoma*. Carcinomas lacking clear differentiation by morphology and special stains are classified as *NSCLC, NOS*. The need for every institution to develop a multidisciplinary tissue management strategy to obtain these small specimens and process them, not only for diagnosis but also for molecular testing and evaluation of markers of resistance to therapy, is emphasized.
No conflict of interest.

388 INVITED

Adenocarcinoma − from pathology to therapeutic implications − clinician's viewpoint

D. Camidge[1]. [1]*University of Colorado Cancer Center, Medical Oncology Developmental Therapeutics, Aurora Colorado, USA*

Approximately 60% of adenocarcinomas of the lung harbor a dominant driver oncogene based on recent large US and European sequencing initiatives. Most but not all of these abnormalities appear mutually exclusive. Notable clinical successes utilizing specific small molecule inhibitors in defined molecular subgroups of adenocarcinoma include a range of EGFR tyrosine kinase inhibitors (TKIs) in EGFR mutant disease, crizotinib in ALK rearranged and ROS1 rearranged disease and, most recently, BRAF inhibitors in V600E mutant disease and RET inhibitors in those with RET rearrnagements. Early data suggest MET gene amplifcation may also be an actionable primary abnormality although as gene copy number is a continuous variable the challenge will lie in determining the relevant cutpoint for determining appropriate predictive potential. Because most dominant drivers occur early in carcinogenesis, heterogeneity is unlikely to be a factor in determing which initial lesion to biopsy. Several other rare abnormalities continue to be described although simple sequence abnormalities may, ultimately, not reveal drivers in all cases and the mechanism driving 'pan-negative' cancers continues to be explored. The clincial significance of 'double mutants', similarly, continues to be explored. Following successful targeted treatment, acquired resistance generates additional clincially relevant diversity which is now also starting to be addressed for EGFR and ALK in clincial trial successes.
No conflict of interest information specified.

389 INVITED

Squamous cell carcinoma − from pathology to therapeutic implications − pathologist's viewpoint

E. Brambilla[1]. [1]*Institut Albert Bonniot, Groupe de Recherche sur le Cancer du Poumon, La Tronche Cedex, France*

Squamous cell carcinoma (SCC) accounts for a approximately 20 % of all lung cancers in the United States and 30 % in Europe. The frequency of peripheral lung involvement has increased as compared to central squamous cell carcinoma. Morphologically, squamous differentiation is identified by inter-cellular bridging, squamous pearl formation and individual cell keratinisation. The intensity of these features characterizes well differentiated squamous cell carcinoma, versus poorly differentiated tumors that lack clear squamous morphology, are more difficult to differentiate from large cell carcinoma or from non cell lung carcinoma on small biopsies, deserving the molecular marker P63 and/or P40, and negativity of TTF1 for a tumor to be classified as SCC. In addition to well and poorly differentiated squamous cell carcinoma, basaloid carcinoma represent a third class recently identified as a specific molecular entity among SCC on gene expression profiling (E. Brambilla, *submitted 2013)*. Expression cluster of basaloid carcinoma retrieve the more dismal prognostic among squamous cell carcinoma cases from worldwide data sets. Recently significant knowledge of genomics of SCC has been provided by comprehensive analysis of genetic alteration as part of the cancer gene genome atlas (TGA)which transformed the landscape of genomic and epigenomic alterations. Among specific genetic alterations discovered as driver oncogenes targetable by specific therapies, FGFR1 amplification to 25 % of SCC even smokers restricted to those cases exposed to tobacco carcinogens (upper and lower airways) exclusively, DDR2 mutation accounting for 3 % of SCC targetable by dasatinib; PIK3 amplication (PIK3CA inhibitors). The PIK3CA is amplified in 20−30 % of SCC. In addition, frequent mutation has been discovered on CDKN2/P16 gene, PTEN, PIK3CA, KEAP1 and MLL2, as well as significant copy number alterations including amplifications on SOX2 and deletion of CDKN2/P16. Many of the somatic alterations identified in SCC were drivers of pathway important for initiation and tumor progression.
Therapeutic targets are ready for DDR2 mutation (dasatinib) and FRGR1 amplification (FGFR1 TKI) with anticipated approval for a target for PIK3CA.

All together about 50 % of squamous cell carcinoma are potentially targetable with specific therapies.
No conflict of interest.

390 INVITED

Squamous cell carcinoma − from pathology to therapeutic implications − clinician's viewpoint

J. Soria[1]. [1]*Institut Gustave Roussy, Medical Oncology/Lung Unit, Villejuif, France*

NSCLC is segmented on the basis of modern molecular portraits that allow the identification of new molecular subtypes.
Squamous-cell carcinoma (SCC) of the lung is the second most frequent histology in non-small cell lung cancer. Advances in the understanding of the biology of SCC have also been made and this may pave the road to develop targeted therapies.
Fibroblast growth factor receptor 1 (FGFR1) is a transmembrane tyrosine kinase receptor that plays a role in normal physiological functions and there is evidence of deregulated signals in the pathogenesis of many different cancer types including in lung SCC.
The discoidin domain receptor 2 (DDR2) is a tyrosine kinase that binds collagen as its endogenous ligand and following its activation it interacts with Src and Shc, and can be rarely mutated in SCC of the lung (1 to 2%).
The deletion of exon 2−7 of EGFR is known as variant III mutation of EGFR which is more frequent in SCC of the lung (5%). Amplifications of EGFR are common in SCC but it has not been addressed yet if they confer sensitivity to treatment with EGFR kinase inhibitors or antibodies. Mutations in ERBB2 gene are rare (1%) in SCC.
PIK3CA copy number gains are more frequent in SCC (33.1%) than in adenocarcinoma (6.2%). In lung SCC PTEN mutations are described in 10% of samples, being more frequent than in adenocarcinoma (2%). At genomic level PTEN loss is seen in 8−20% both for SCC and adenocarcinoma.
Somatic activating B-RAF mutations in melanoma are highly prevalent (~60%), and usually involve a single substitution (V600E. In SCC of the lung the mutation prevalence is of 2%.
PDL1 expression is reported to be in the range of 50% in NSCLC and notably SCC of the lung. PDL1 appears as potential predictor of the efficacy of new immune checkpoint modulators.
The table below provides a summary of specific alterations, their frequencies and their potential corresponding molecular targeted interventions.

Molecular alteration	Frequency in adenocarcinoma	Frequency in squamous cell carcinoma	Potential drugs
EGFR mutation	10−40%	2−5%	Gefitinib Erlotinib Afatinib PF-00299804
EML4-ALK translocation	5−7%	Rare	Crizotinib New ALK-inhibitors HSP90 inhibitors
HER2 mutation or amplification	2% 6%	Rare 2%	Trastuzumab Lapatinib PF-00299804 Afatinib
PI3K mutation or amplification	5% <10%	5% <10%	GDC-0941 XL-147 XL-765 PX-866 BEZ-235 BKM120 PF-05212384

Special Session (Tue, 1 Oct, 11:30−12:30) **Castration Resistant Prostate Cancer: New Therapies**

391 INVITED

Molecular pathways of castration resistance in prostate cancer

J. Schalken[1]. [1]*Radboud University Nijmegen Medical Centre, Urology Research Laboratory, Nijmegen, Netherlands*

The role of the androgen receptor in advanced prostate cancer has regained considerable attention in the past decade. The true importance of some (very) old observations is now generally acknowledged.
These observations are that in endocrine therapy resistant PrCa. − still significant levels of DHT can be measured, and that − at this stage of the disease cancer cells express high evels of nuclear Androgen Receptor. We, therefore, now refer to this stage as Castration Resistant Prostate Cancer. Despite castrate levels of circulating testosterone, the AR in cancer cells is active.
Various mechanism can lead to the adaption to low levels of circulating androgens. Mutations (therapy induced) leading to constitutively active and/or promiscuous AR occur, albeit in a low frequency,in CRPCs(<10%). The most common mechanism of adaptation is by over expressing the AR and/or by AR gene amplification (50−85%). Recently, also splice variants leading to a constitutively active AR, have been reported. Another mechanism, illustrating the versatility of cancer cells is by increasing intra-tumoral steroidigenesis. The recently approved endocrine therapies are targeting these adaptive changes, by interfering with CYP17 associated steroidigenesis (abiraterone acatetate) and by a strong antagonist of androgen receptor signaling (enzalutamide). These interventions, may be more effective in earlier stage disease, however, only appropriately designed clinical trials can test this hypothesis.
We have to anticipate to a mechanism of cancer progression where a cell type is involved that drives the adaptive changes, yet for its survival isn't dependent on the AR. The new endocrine therapies, would then more clearly 'unmask'/reveal this putative (cancer initiating) cell population. The cellular basis of progression under endocrine therapy and the molecular understanding of this cell type, should provide the a model for new targets for therapy.
Conflict of interest: *Advisory board: Astellas, Medivation, Jansen Cilag, Takeda*

392 INVITED

Androgen receptor (AR) and AR-signaling directed therapies in the age of precision medicine

H. Scher[1]. [1]*Memorial Sloan-Kettering Cancer Center, Department of Medicine Sidney Kimmel Center for Prostate and Urologic Cancers Genitourinary Oncology Service, New York NY, USA*

Background: Precision medicine enables the selection of treatments to which patients are most likely to benefit, reducing the chance of exposing individual patients to ineffective, potentially toxic, and costly treatments. Molecular profiling and laboratory studies have shown reactivation of AR and AR signaling to be a key driver of castration resistant prostate cancer (CRPC) growth and survival, informed the successful development of the androgen biosynthesis inhibitor abiraterone acetate (AA), the androgen receptor (AR) signaling inhibitor enzalutamide and newer AR-directed therapies. Not all patients respond, suggesting the presence of predictive biomarkers of sensitivity.
Material and Methods: A key focus now is to understand and target mechanisms associated with both intrinsic and acquired resistance to these agents. Proposed mechanisms include reciprocal feedback between the PI3K/PTEN and AR signaling pathways, AR splice variants, mutations in the ligand binding domain, and activation of glucocorticoid receptor signaling.
Results: Trials targeting the AR and the PI3K/PTEN signaling axes, alone or in combination are ongoing in which analysis of tumor material from patients is planned. Limitations to implementation of a precision medicine paradigm include the lack of analytically and clinically validated assays for the predictive biomarkers proposed, and the availability of tumor material at the time treatment is considered. Disease heterogeneity is another major limitation.
Conclusions: A variety of blood and tissue based biomarkers are under development through a multidisciplinary assay validation program to address the unmet need for integral biomarkers to guide treatment

selection. Co-development of integral biomarker assays is a practical strategy for investigating the next generation of promising AR-directed therapies.
No conflict of interest.

393 INVITED

Non-androgen receptor (AR) targeted approaches for managing castration-resistant prostate cancer (CRPC)

M. Smith[1]. [1]*Massachusetts General Hospital, Harvard Medical School, Boston MA, USA*

The treatment landscape for metastatic CRPC has been transformed by the development of both AR targeted and non-AR targeted therapies. Abiraterone acetate and enzalutamide increase progression-free and overall survival in metastatic CRPC. While the efficacy and safety of these AR-targeted therapies are favorable, not all patients benefit from treatment. Many patients with CRPC do not respond to new AR-targeted therapies and most responding patients develop overlapping resistance. Accordingly, non-AR targeted therapies will continue to have an important role in the management of metastatic CRPC. Cabazitaxel improves progression-free and overall survival for patients with disease progression after docetaxel; an ongoing randomized controlled trial will evaluate the comparative effectiveness of these agents as first line chemotherapy. For patients who are not candidates for chemotherapy or experience disease-progression after docetaxel, radium-223 improves overall survival and delays onset of skeletal-related events. Several investigational drugs have novel mechanism(s) of action. Cabozantinib, for example, is an orally bioavailable tyrosine kinase inhibitor with activity against MET and VEGFR2. In phase 2 clinical trials, cabozantinib was associated with high rates of bone scan improvement, decreases in measurable disease, and reductions in bone biomarkers and circulating tumor cells. Two ongoing randomized controlled trials (COMET-1 and COMET-2) will evaluate the effects of cabozantinib on overall survival and cancer-related pain for patients with metastatic CRPC and disease progression despite docetaxel and abiraterone acetate (and/or enzalutamide).

Special Session (Tue, 1 Oct, 11:30−12:30)
Autophagy in Cancer and Cancer Therapy

394 INVITED

Signalling pathways controlling autophagy and its crosstalk with apoptosis

A. Kimchi[1], I.K. Koren[1], A.D. Rubinstein[1], Y. Ber[1], R. Shiloh[1]. [1]*Weizmann Institute of Science, Faculty of Biochemistry, Department of Molecular Genetics, Rehovot, Israel*

Autophagy, a catabolic process responsible for the degradation of cytosolic components, is induced when nutrient supplies are limited, as well as in response to other stress conditions. While in various stress conditions this process contributes to continuous cell survival, under some circumstances it induces cell death, either by 'self eating' of the vital components of a cell or by triggering apoptosis. We focus on the discovery of novel signaling pathways which negatively or positively regulate the autophagic flux and on the identification of new points of interface between autophagy an apoptosis. We found that DAP1, a conserved proline rich adaptor protein, which is a direct substrate of mTOR, acts as an inhibitor the autophagic flux. mTOR phosphorylates DAP1 on two critical serine residues which inactivate its function. Thus, mTORC1 inhibition activates simultaneously autophagy and a specific brake which limits the intensity of autophagic activity to prevent harmful effects when over activated. Additionally, a few novel positive pathways accelerating the autophagic flux have been identified in our lab. These pathways are initiated by members of the DAPK family of calcium-regulated Ser/Thr kinases, including DAPK1 and DAPK2. In parallel, points of interface between autophagy and apoptosis were recently discovered in our lab by applying unbiased siRNA screens. We identified the essential autophagy protein Atg12 as a positive mediator of mitochondrial apoptosis, and showed that Atg12 directly regulates the apoptotic pathway by binding and inactivating the pro-survival Bcl-2 family members. The binding requires a BH3-like motif in Atg12. The interaction between Atg12 and Bcl-2 family members may thus constitute an important point of convergence between autophagy and apoptosis in response to specific signals.
No conflict of interest.

395 INVITED

The importance of autophagy in cancer

K. Ryan[1]. [1]*The Beatson Institute for Cancer Research, Tumour Cell Death Laboratory, Glasgow, United Kingdom*

For over 50 years, preservation of genomic integrity has been considered a cornerstone in the body's defence against cancer. It must be remembered, however, that a DNA mutation will only have an impact if it encodes for a damaged species within the cell. As such, damaged proteins or organelles constitute non-heritable 'mutations' if they are not removed and if these proteins lie in critical cellular pathways, then these cells will have a higher propensity for aberrant function. Therefore in addition to genomic integrity, protein and organelle integrity are also critically important for protecting us against various forms of human disease including cancer.
Autophagy is a cellular trafficking process that serves to degrade cellular constituents in lysosomes. It is major mechanism for the degradation of long-lived proteins and protein aggregates and it is the only process for degrading organelles. As a result, it is a major catabolic process within the cell which acts to preserve cellular homeostasis and integrity. It has recently become clear the autophagy plays an important role in tumour development and may also be an important target for cancer therapy. It seems, however, that autophagy has dual roles in cancer. On the one hand, it is clear that autophagy can keep cells alive and in the context of the cancer cell, this aspect of autophagy can be considered oncogenic. Conversely, several reports have also shown that autophagy can contribute to tumour suppression. Although several clinical trials are underway to target autophagy therapeutically, it seems critical to understand in which cancers and at what stage, autophagy in oncogenic versus tumour suppressive if we are to consider targeting this pathway effectively.
We have been studying the role of autophagy in the context of various aspects of tumour development both in vitro and in vivo. We will present our findings and discuss how they fit with published studies to convey what we currently understand about how this fundamental process contributes to tumour development and how it could be an avenue for the development of novel chemotherapeutic drugs.
Work in our laboratory is supported by Cancer Research UK and The Association for International Cancer Research.
No conflict of interest.

396 INVITED

Fundamental mechanisms in autophagy

S. Tooze[1], H. Dooley[1], H. Jefferies[1], J. Joachim[1], C. Lamb[1], F. McAlpine[1], M. Razi[1], M. Wirth[1]. [1]*Cancer Research UK, London Research Institute, London, United Kingdom*

Background: Autophagy is a highly conserved cell survival pathway that is essential for cell health and homeostasis. Autophagy is a membrane-mediated lysosomal degradation process that can be acutely induced by withdrawal of amino-acids, and more chronically by withdrawal of glucose, growth factors or stressful environmental conditions. Induction by amino-acid starvation has been fundamental in the identification of the 35 or more autophagy-related (Atg) genes first in yeast, and more recently in mammals.
Material and Methods: We use 2 hours amino-acid withdrawal to induce autophagy, followed by morphological and biochemical approaches to study protein localization and protein-protein interactions in a variety of cells.
Results: We are interested in how the autophagosome forms, and study a set of these Atg proteins and regulators required for formation. In particular, we are studying the PI3P effector WIPI2, and the transmembrane protein Atg9, both of which make important contributions at early stages of the pathway by sensing lipids and delivering vesicles. Furthermore, we have identified a RabGAP and associated effectors that mediate ULK1-dependent transport from the recycling endosome to the early autophagosome, also contributing to the early stage expansion of the autophagosome. Starvation-induced autophagy is negatively regulated by mTORC1. ULK1 and ULK2 (mammalian Atg1 homologues) are found in association with mTORC1 in fed cells and negatively regulated by active mTORC1. Activation of the ULK1/2 complex by inhibition of mTORC1 initiates the formation of phagophores, autophagsosome precursor membrane structures. At, or on, these membranes ULK1/2, its complex members FIP200, Atg13 and Atg101, and at least seven other Atg proteins assemble and together mediate the formation of the double membrane autophagosomes on ER-associated membranes. The class III PI 3-kinase complex is also required for initiation, producing an autophagy-specific pool of PI 3 phosphate (PI3P) which is recognized by the effector WIPI2. Using ULK1/2 double knock out MEF cell lines we have found that both amino acid withdrawal-induced PI3P production, and autophagosome formation requires both ULK1 and ULK2. However, while glucose-withdrawal induced autophagy required both ULK1 and ULK2 it

did not require PI 3P production on the phagophore as detected by WIPI1 and WIPI2 puncta formation.
Conclusions: Our current data and the pathways leading to the regulation and formation of autophagy will be discussed.
No conflict of interest.

Special Session (Tue, 1 Oct, 11:30−12:30) **Stem Cell Therapy for Preventing Salivary Gland Toxicity**

397 INVITED

Kit+ progenitor cells regenerate the branching architecture of salivary glands

I. Lombaert[1], S. Abrams[1], M. Hoffman[1]. [1]*National Institutes of Health, Nidcr, Bethesda, USA*

Irradiation damage to salivary glands during cancer treatment often leads to a permanent loss of saliva production. Regeneration of irradiated submandibular glands (SMGs) in mice can occur after transplantation of SMG epithelial Kit+ progenitors. However, the mechanism by which Kit+ progenitors regenerate the tissue is not well understood. Using fetal SMG development, we show that signals from the mesenchyme stimulate both Fgfr2b and Kit signaling to expand the Kit+ progenitors. These progenitors in turn produce neurotrophic factors that promote neuronal innervation, which influences a separate population of K5+ epithelial progenitors that form ductal structures. Ultimately, reiterative rounds of this multicellular communication establish the branching architecture of the developing organ, and a similar molecular mechanism maintains adult tissue homeostasis. This model of organogenesis provides a template for regenerative medicine and may also have implications for targeting receptor kinases of SMG cancer stem cells.
No conflict of interest.

398 INVITED

Stem cell therapy for prevention of radiation-induced salivary gland toxicity

R. Coppes[1]. [1]*University Medical Center Groningen, Department of Cell Biology, Groningen, Netherlands*

Hyposalivation and its consequence xerostomia are sequelae of salivary gland (SG) functional ablation, commonly caused by radiotherapy (RT) treatment for head and neck cancers. 40% of the patients treated for head and neck cancer suffer from oral dryness leading to impaired speech, chewing, taste and swallowing, higher susceptibility for infections, and caries. These sequelea severely affect the patients' wellbeing and quality of life. A lack of viable stem cells able to maintain glandular homeostasis underlies age and radiotherapy induced SG dysfunction. Therefore, stem cell therapy could ameliorate xerostomia. Indeed, recently we showed that transplantation of mouse stem cells can rescue murine SG from radiation damage. Currently, we are translating our findings in mice to the human situation. Using human submandibular and parotid biopsies material we are able to culture human primary salispheres (hS) from which single cells could be obtained that were able to self-renew for $\geqslant$5 passages *in vitro*. Moreover, single hS cell derived salispheres could be stimulated to develop into an organoid with cells differentiating in ductal and acinar lineages as indicated by the expression of cytokeratins (Cyt^{+}) and aquaporin-5 ($AQP5^{+}$), respectively. These results indicate that in vitro we can obtain cells that are able to self-renew and differentiate into salivary gland lineages, two prerequisites of tissue stem cells. When xeno-transplanted into a mouse model of radiation-induced hyposalivation, hS cells proliferate extensively and were found to differentiate into human salivary gland structures within the mouse. Moreover, human proteins were detected into the saliva collected from the mice.
We believe hS cell transplantation represents a logical, long-term option for the management of RT-induced xerostomia. We are currently working on the translation of our hS knowledge towards GMP standards, optimization of our cell delivery technique, and the ultimate realization of an hS cell therapy for xerostomia.
No conflict of interest.

399 INVITED

Parotid deformation during IMRT correlates with clinical and dosimetry information

G. Sanguineti[1], C. Fiorino[2]. [1]*Ospedale Sacrocuore, Department of Radiotherapy, Verona, Italy;* [2]*Ospedale San Raffaele, Department of Physics, Milano, Italy*

The rapid spread of integrated delivery and image-guidance systems in combination with accurate morphological and functional imaging techniques opened the possibility of adapting the treatment to take into account modifications occurring during the course of radiotherapy. Another issue of paramount importance concerns how organ deformation during radiotherapy may predict acute and subacute/late toxicity. The detection of anomalous deformation may be a signal of a potentially high risk of toxicity; consequently, early detection could permit the selective adaptation of the treatment in order to reduce the risk of toxicity or, if adaptation is not feasible, to better/timely manage the toxicities and the supportive therapies. Within our group we have investigated the role of both deformation and density variation of parotids as surrogates of long term functional changes. Regarding the former, elastic registration was applied in quantitatively estimating entity and direction of deformation occurring during treatment; in a preliminary study, elastic matching was validated for the parotid glands. In this study, the entity of deformation (in terms of compression of expansion of each single voxel) was expressed by the Jacobian (Jac) of the deformation field, and the Jac was used to quantify inter-fraction anatomical changes. The Jac analysis showed correlation between the low-dose bath (around 10−15 Gy) and a larger fraction of voxels subject to large compression. In a follow up study on 84 pts, the Jac mean value (Jac_mean) was found to be correlated to pretreatment dosimetric parameters, particularly V10 and V40.
Regarding parotid density changes, we assessed the predictive power of parotid gland early variations on final deformations at the end of therapy and, possibly, on peak xerostomia during IMRT for head-neck cancer by considering 92 parotids. For 24 patients prospectively collected toxicity data (CTCAE v3.0) during treatment were analyzed. Kinetics of the changes during treatment were described by the daily rate of density ($r\Delta\rho$) and volume ($r\Delta vol$) variation and the mean Jac (Jmean). A larger $r\Delta\rho$ was observed at the beginning of the treatment, compared to the end ($p = 0.0001$). Both early $r\Delta\rho$ and $r\Delta vol$ predicted for mean acute xerostomia$\geqslant$median population value (1.57;p-value=0.01,logistic regression). Therefore, a larger longitudinally assessed score of acute xerostomia is well predicted by larger $r\Delta\rho$ and $r\Delta vol$ in the first two weeks of treatment.
No conflict of interest.

Special Session (Tue, 1 Oct, 11:30−12:30) **Retroperitoneal Sarcomas**

400 INVITED

Surgical aspects of retroperitoneal sarcomas

S. Bonvalot[1]. [1]*Institut Gustave Roussy, Dept of Surgery, Villejuif, France*

Retroperitoneal sarcomas expose to a high risk of local recurrence compared to limbs. Their extra compartmental expansion, adjacency to vital structures, and significant size at diagnosis challenging one bloc surgery, represent the main reasons. In low and intermediate grades, death is mainly related to local recurrences that eventually become non resectable. Concerning primaries; two teams initiated compartmental resection (CR) in order to limit the areas of close margins, by assimilation to other soft tissue sarcomas. Their studies provided a local benefit, reporting greater than 75 % local control at 5 years. CR has been accepted by many other teams, especially in Europe. However, it is difficult to demonstrate an impact on overall survival, knowing that patients who have had a simple resection for a low grade may have been operated several times and that high grade sarcomas expose to visceral metastasis. This is one of the reasons why there is still a debate about best indications of CR.
Best indications of CR are represented by potentially curative situations. This includes primary tumors (especially when a previous piecemeal resection was performed: it exposes to peritoneal seeding), unifocal sarcomas (6), and those with the lower metastatic risk. However, many WD/DD liposarcomas seem to be multifocal, while they're a single tumor, made by several different components. This apparent multifocality may be the result of a non-compartmental surgical approach, which does not visualize the contiguous areas. Decision making is finally balanced according to expected morbidity of accumulated resections and patient's co morbidities. Morbidity is around 10%, comparable to other high risk visceral surgery. Experience of the surgeon is also another prognostic factor and CR should be performed in referential centers (2).

Many retrospective studies suggest a benefit of adding radiation therapy, even with CR (8). The pre-operative radiotherapy timing appears to display less toxicity. There is currently a randomized study of EORTC (protocol 62092–22092, ClinicalTrials.gov Identifier: NCT 01344018) to evaluate the benefit of pre operative radiotherapy (28 daily fractions of 1.8 Gy (5 fractions per week) for a total dose of 50.4 Gy). Of course, limits of preoperative radiotherapy are tumor size (too large fields are not possible) and growth kinetic. Patients must be both resectable and suitable for radiotherapy. Chemo sensitive sarcomas (such as rhabdomyosarcomas, PNET or other small round blue cells sarcomas) and visceral sarcomas should not be included in this trial.
There are currently too much redundant literature and too many hasty conclusions drawn from retrospective studies, sometimes limited, and we can emphasize the importance of prospective and controlled studies or registry.
No conflict of interest.

401 INVITED

The role of radiotherapy in retroperitoneal sarcoma

R. Haas[1]. [1]*The Netherlands Cancer Institute, Radiotherapy, Amsterdam, Netherlands*

Retroperitoneal sarcomas (RPS) are rare. They comprises about 15% of all soft tissue sarcomas. RPS are diagnosed at a median size of 15−18 cm, because they remain asymptomatic for a relatively long period. The majority (70%) of RPS is either a liposarcomas or a leiomyosarcomas and predominantly of high grade histology.
The chance to obtain negative margins in these large tumors is small. In a substantial proportion of cases the surgeon has to leave macroscopic tumor behind (R2 resections). This results into a local failure rate of 52−60% at 5 years. Predictive factors for local recurrence are grade, margin status, the fact whether patients have been operated upon in reference centers and whether or not radiotherapy (XRT) has been applied.
The cause of death in patients with extremity sarcomas (ESTS) is most often metastatic disease. In contrast, most RPS patients die due to local failures. In order to obtain the highest probability of abdominal control complete resection with gross negative margins and aggressive en bloc resection of the primary disease is now considered standard of surgical care.
What is the role of XRT in RPS and are aspects from XRT in ESTS applicable to RPS? In contrast to ESTS it is almost impossible to perform postoperative XRT due the high complication rates of the small intestines, kidneys and liver. Possibly the best timing of XRT is preoperative. In the presentation XRT trials and studies focused on RPS are discussed.
No conflict of interest.

402 INVITED

The role of chemotherapy

M. Montemurro[1]. [1]*University Hospital Zurich (USZ), Oncology, Zürich, Switzerland*

A third of all retroperitoneal tumors are sarcomas, and 10−15% of all sarcomas are located in the retroperitoneum, with liposarcoma (70%) and leiomyosarcoma (15%) being the two most frequent histologies.
Surgery is the mainstay of treatment for retroperitoneal sarcomas. Location and extent of the disease pose significant challenges, but an aggressive surgical approach improves survival. Radiotherapy is often part of the treatment plan to achieve better local control, as recurrences are frequent and cause significant morbidity and mortality.
Chemotherapy has been used in the metastatic and adjuvant, and more recently in a preoperative setting.
While it has been recognised that the role and effect of any treatment depends on the histological or molecular sarcoma subtype, matching a disease subtype with an effective drug is complicated by the lack of (trial) data. Furthermore, the identification of oncogenic targets or pathways has just started.
For unresectable retroperitoneal leiomyosarcomas or liposarcomas the role of trabectedin has been established in the past years, but only recent reports suggest that a preoperative use might be of benefit in selected patients.
Reviewed will be potential oncogenic targets, and the role of chemotherapy and molecular agents in retroperitoneal sarcoma.
No conflict of interest.

Special Session (Tue, 1 Oct, 11:30−12:30)
Advanced Practitioner Roles in Cancer Care: Where Next?

403 INVITED

Developing appropriate education programmes in advanced nursing practice: The Irish experience

E. Furlong[1], J. Drennan[1], K. Wedgeworth[1], C. Naughton[1], M. Kemple[1], R. Smith[1]. [1]*University College Dublin, UCD Health Sciences, Dublin, Ireland*

Background: Advanced practice in nursing and midwifery has developed internationally and nationally. In Ireland the Commission on Nursing recognised that promotional opportunities should be open to nurses and midwives wishing to remain in clinical practice and accordingly recommended a clinical career pathway leading from registration to clinical specialisation and to advanced practice (Government of Ireland 1998). In 1999 the establishment of the National Council for the Professional Development of Nursing and Midwifery enabled nurses to be approved and accredited as Advanced Nurse Practitioners (ANP). A framework for Advanced Practice was developed with criteria to become an ANP and the attainment of Core Competencies.
In 2010 the Department of Health in Ireland transferred the area of Advanced Practice to the Nursing and Midwifery Board of Ireland and Advanced Practice became a registration qualification.
What do ANPs in Ireland do? ANPs are experienced nurses who are educated to a Master's Degree or above, are at least 7 years post-registration and have a minimum of 5 years working in their speciality area of practice, such as cancer care, palliative care, diabetes. These ANPs promote wellness, offer healthcare interventions and advocate healthy lifestyle choices for patients/clients, their families and carers in a wide variety of settings in collaboration with other healthcare professionals, according to agreed scope of practice guidelines. They utilise advanced clinical nursing knowledge and critical thinking skills to independently provide optimum patient/client care through caseload management of acute and/or chronic illness, such as cancer care.
Evaluation of ANP Programme in UCD: In 2001 University College Dublin (UCD) commenced an Advanced Practice education programme. Preparation and education for Faculty was undertaken in University of Pennsylvania, Philadelphia, USA. Eleven years later this programme was evaluated by a research team in UCD. Two questionnaires were used to evaluate the education programme undertaken by nurses and midwives to prepare them for advanced nursing practice. The first, entitled the *Outcomes Evaluation Questionnaire* (OEQ), evaluated course participants' abilities and understanding of advanced practice as a consequence of the preparation programme. The second, the *Course Evaluation Questionnaire* (PCEQ), evaluated course participants' perceptions of the quality of their preparation programme. This presentation will conclude with preliminary results from a national survey of nurses who undertook their Advanced Practice education at University College Dublin, Ireland.
No conflict of interest.

404 INVITED

The role of advanced nursing practice in teenage and young adult cancer care

S. Smith[1]. [1]*Teenage Cancer Trust, London, United Kingdom*

Background: It is now over twenty five years since the first Teenage Cancer Trust Unit opened in London. Teenage and Young Adult (TYA) cancer care has gained recognition as a specialty within its own right and the UK are seen as worldwide leaders in TYA cancer care. Development of TYA nursing expertise has largely been organic through the experience of specialist nurses working in this field. TYA "expert" nurses have evolved over time and range from Clinical Nurse Specialists, Lead Nurses and Nurse Consultants. These nurses have led developments in TYA cancer care in the UK and Internationally.
Material: The best standard of care for TYA patients is undoubtedly provided by staff who have been specifically trained to care for them. The UK has developed TYA cancer care for twenty years and has captured their expertise in delivering age-appropriate, multidisciplinary and nursing care within A Blueprint of Care (2012). Alongside the development of TYA cancer nursing and services the UK has developed multidisciplinary education programs for staff working in this field through both pre and post graduate education.
Results: We are now in a position to define and describe TYA cancer care nursing from foundation level to expert and advanced practice. The UK is in the process of formally capturing and describing the knowledge, skills, competences and education requirements for nurses working in this specialty through a project and publication supported by the Royal College

of Nursing. This will enable TYA specialist nursing care in the future to be delivered by a competent and knowledgeable nursing workforce.
Conclusions: TYA cancer nursing expertise is largely confined to a small number of nurses in the UK and even fewer internationally. However, TYA cancer care is rapidly evolving internationally and it is crucial that care is delivered by a skilled and appropriately trained workforce of which nursing skills and competencies are the cornerstone for specialist age appropriate care delivery. The UK are in an ideal position to share practice and collaborate with international colleagues who are now developing specialist nursing care for this patient group. Defining TYA Cancer Nursing competencies will provide a framework for both the UK and International colleagues to educate and develop a knowledgeable nursing workforce and embed the philosophy and principals of age appropriate care for TYA's with cancer.
No conflict of interest.

405 INVITED
Advantages of nurse-led follow up

E. Van Muilekom[1]. [1]*Netherlands Cancer Institute- Antoni van Leeuwenhoek Hospital, Amsterdam, Netherlands*

The cancer incidence in Europe is increasing, caused by factors as the aging population. As a result of this more people will need treatment and follow up in a curative or palliative setting.
Due to the fact that cancertreatment is often very successful, the group cancer survivors will also increases and conventional follow-up will have a major impact on outpatient services. So new strategies for follow up are needed.
Follow up normally contains inventigating possible recurrence, support for treatment related side effects (immidiate or late) and psychosocial support. The European commission has estimated a shortage of physicians in 2020 of 13%, what results in a challenge to cover the increasing demand for specilized care and physician led follow up. We have to face this and reorganize our care. Nurse-led follow up is a promising alternative.
Although the evidence is limited, there is already more then enough experience in breast-, lung- and prostate cancer, that nurse led follow up is a part of daily routine in a lot of countries and institutions. A few randomised controlled trials can be identified were no statistically significant differences in survival, recurrence or psychological morbidity were found in nurse led follow up. Some studies even showed a better quality of live measures.
Although the level over basic nursing education differs in European countries, more and more nurses have the ability to follow specilized oncology training as a bachelor or master program. In a lot of European countries well trained specialized oncology nurses and/or clinical nurse specialists/nurse practitioners take over originaly physicians tasks in patients follow up. For nurses this is also a possibility to develop themselves an extent their responsabilities and specialized role.
An other aspect is the increasing health care costs, wich gives us the responsibility to organize the care as cost effective as possible. Nursing-led follow is less expensive without a decrease of quality and is therefore a good and save way of organizing care. Also alternative follow-up strategies have to be considered, for example telephone follow up.
The available studies and experiences from the field show that patients appeared satisfied with nurse-led follow-up. Patient-initiated or telephone follow-up could be practical alternatives to conventional care. However, more well-conducted research is needed before equivalence to physician-led follow-up can be assured in terms of survival, recurrence, patient well-being and cost-effectiveness.
No conflict of interest.

Special Session (Tue, 1 Oct, 11:30−12:30)
Outcome Issues for the Older Patient

406 INVITED
Which outcomes for older cancer patients

M. Janssen-Heijnen[1]. [1]*VieCuri Medical Centre, Clinical Epidemiology, Venlo, Netherlands*

Background: Presently, almost 30% of newly diagnosed cancer patients are aged 75 years or older. Treatment of older cancer patients is challenging, since it is often complicated by comorbidity, poor performance status, or social or psychological factors. Elderly patients are often excluded from clinical trials and therefore evidence is scarce about predictors for the risks and benefits of treatment. Although mortality reduction is important for patients of all ages, additional endpoints, such as toxicity and completion of planned treatment, and the ability to live independently and with a high quality of life, may be equally (or more) important for older patients.
Material and Methods: An overview of current literature concerning important outcomes for elderly cancer patients as well as evidence for predictors of outcome.
Results: Survival time, response and toxicity are often included as endpoints in clinical trials, but quality of life and geriatric assessment scores such as independency are seldom included. It is unknown whether outcomes from clinical trials are valid for everyday clinical practice, because elderly and those with serious comorbidity or poor performance status are often excluded.
Population-based observational studies have shown that despite high toxicity rates in elderly and poor treatment completion rates, those who received standard treatment had a significantly better survival. Unfortunately, results on predictors for outcome of treatment in observational studies cannot be fully adjusted for the fact that the fittest patients are selected for (aggressive) treatment.
There is an urgent need to identify patient characteristics that are predictive for the relevant outcomes in elderly. Some prediction models for toxicity of chemotherapy, postoperative mortality or hospital stay have been developed. However, the geriatric predictors that were identified differ significantly between the models and outcome measures.
Conclusions: Elderly cancer patients experience competing events which interfere with the disease-specific outcome of interest. It is important to avoid discomfort (loss of functionality or autonomy, deterioration of quality of life, time spent in the hospital). This means that, besides traditional outcomes as survival time, it is important to include other outcomes as preservation of independency and quality of life in older-specific clinical trials.
No conflict of interest.

407 INVITED
New targeted outcomes for colorectal cancer in older patients

G. Liefers[1], on behalf of the Geriatric Oncology Group. [1]*Leiden University Medical Centrum, Surgery, Leiden, Netherlands*

Elderly colorectal cancer patients have worse prognosis than younger patients. Age-related survival differences may be cancer or treatment related, but also due to death from other causes. Elderly colorectal cancer patients who survive the first year have the same cancer-related survival as younger patients. Therefore, decreased survival is mainly due to differences in early mortality. The 30-day mortality rate highly underestimates the risk of dying in the first year after surgery, with excess 1-year mortality rates varying from 15 to 30%. This excess mortality is especially prominent in patients with comorbidities, higher stages of disease, emergency surgery, and postoperative surgical complications. Treatment of elderly colorectal cancer patients should focus on perioperative care and the first postoperative year. In this presentation we will discuss the differences between young and older patients with regard to outcome and highlight the potential design of studies to improve treatment of this vulnerable and growing group of patients.
No conflict of interest.

Special Session (Tue, 1 Oct, 11:30−12:30)
Repainting and Tracking in Ion Beam Therapy

408 INVITED
Motion mitigation using scanned beams with moving targets

A. Knopf[1]. [1]*PSI − Paul Scherrer Institut, Center for Proton Therapy, Villigen, Switzerland*

Currently newly built particle therapy centers are mostly equipped with scanning beams, since they provide highly conformal dose distributions when treating static targets. However, scanned beams face significant challenges when applied to moving targets. To mitigate motion effects, different approaches have been suggested.
In this talk, we would like to concentrate on a motion mitigation technique that exploits the characteristics of scanning, namely rescanning. The idea of rescanning is to statistically average out dose heterogeneities by repeatedly delivering the planned dose to the target with an accordingly reduced number of particles per scan. For a successful application of rescanning it is therefore essential to choose the right "flavor" of rescanning.
Before going into different rescanning flavors one should be reminded that scanning itself can be performed in many different ways. Lateral as well as depth (energy) beam adjustments can be undertaken in a discrete or continuous manner. Furthermore, the dose grid points within the target can be visited in different orders. Also it has been suggested to vary the beam spot size during one scan, using small sizes at the boarder of the volume to closely conform the dose to the target and large sizes in the center of the volume to minimize dose inhomogeneities due to misspositioned spots.

In addition, rescanning can be performed in a layered or a volumetric way. In the layered approach, N rescans are applied to an iso-energy-layer before a change in depth is done. In the volumetric approach each dose grid point of the entire volume will be visited once, before the next rescan is started. Finally, also different flavors of beam weighting can be chosen. Such as scaled, where each spot weight is divided by the number of rescans and alternatively iso-layered, where the weight per spot visit is kept below an upper limit.
Each specific way of scanning and each flavor of rescanning has its own characteristic delivery-time-line which is machine specific. In this presentation, we will show examples to emphasize that for a successful application of rescanning it is important to choose a way of scanning and a flavor of rescanning appropriate for your specific facility and adapted to the characteristics of each specific patient.
Finally, we will introduce the “slow tracking” approach which in our opinion is currently the most practical way to treat moving targets with scanned beams. In this approach, each treatment fraction would be delivered during several breath-holds, within which the tumour position would be verified and the beam parameters would be adjusted to compensate for inter-breath-hold positioning changes. Ultimately this procedure could be combined with rescanning to smooth out any interplay effects resulting from residual motions during the breath-holds.
No conflict of interest.

409 INVITED

Motion mitigation in scanned carbon beam therapy

C. Bert[1]. [1]*University Clinic Erlangen, Radiation Oncology, Erlangen, Germany*

Scanned ion beams interfere with intra-fractional organ motion potentially leading to underdosage of the clinical target volume (CTV). Several techniques are proposed to overcome that challenge, including beam tracking, gating, rescanning and potentially 4D optimized treatment plans. The talk focuses on latest developments in motion mitigation with a scanned carbon beam with an emphasis on beam tracking and 4D optimization.
Beam tracking aims at compensating intra-fractional target motion by adapting the scanned pencil beam during treatment delivery. 4D treatment planning data, i.e. compensation vectors that are based on information from 4D computed tomography (4DCT) + deformable registration, and a precise motion monitoring system are essential. In addition, a dedicated delivery system is needed. For beam tracking, 4D treatment planning is already based on 4DCT data but does not include the temporal domain in the plan optimization. Dedicated routines were developed that use target motion as an additional degree of freedom within the optimization process. In addition, these data can be used for precise internal target volume (ITV) definition.
Based on experimental and simulation data acquired at GSI in cooperation with several partner institutes the current status of the above mentioned techniques will be presented. Beam tracking is at the verge to a clinically applied method. Experiments with complex phantoms showed the feasibility of the complete technical workflow. Bottleneck will be 4DCT validity which can be overcome by treatment plan (adaptation) briefly before treatment delivery. 4D treatment plan optimization is feasible. Data of in-silico studies with 9 NSCLC patient showed feasibility. Also 4D optimized plans need a refined treatment delivery control. The GSI systems has been updated accordingly and first results show that treatment plan application is possible with acceptable delivery times.
In conclusion, beam tracking and 4D optimized treatment plans are feasible candidate techniques to enhance the possibilities of treatments for intra-fractionally moving tumors with scanned ion beams. Especially 4D optimization requires more research prior translation to clinical use can start.

Distinct chromatin binding patterns for estrogen receptor and histone marks classify aromatase inhibitor resistant breast cancer

M. Jansen[1], T. Knijnenburg[2], E. Reijm[3], I. Simon[4], R. Kerkhoven[5], X. Alexi[6], L. Wessels[2], S. Linn[6], P. Berns[3], W. Zwart[6]. *[1]Erasmus MC University Medical Center Rotterdam, Medical Oncology, Rotterdam, Netherlands; [2]Netherlands Cancer Institute, Molecular Carcinogenesis, Amsterdam, Netherlands; [3]Erasmus MC University Medical Center, Medical Oncology, Rotterdam, Netherlands; [4]Agendia, Amsterdam, Netherlands; [5]Netherlands Cancer Institute, Central Genomic Facility, Amsterdam, Netherlands; [6]Netherlands Cancer Institute, Molecular Pathology, Amsterdam, Netherlands*

Background: Estrogen receptor-positive breast cancer patients receive endocrine treatment, however, resistance is common. To date, few tumor tissue specimens have been evaluated for their global binding patterns of the estrogen receptor to DNA in patients. The goal of this study is to identify chromatin binding events of the estrogen receptor and epigenetic histone marks that associate with endocrine therapy resistance.
Methods: Using chromatin immunoprecipitation followed by high-throughput sequencing (ChIP-seq), we analyzed primary tumor specimens from breast cancer patients with metastatic disease treated with first-line aromatase inhibitors, and mapped the genome-wide chromatin binding patterns of the estrogen receptor alpha (ERa) and epigenetic histone 3 modifications H3K4me3 and H3K27me3 for activation and suppression of gene expression, respectively.
Results: Differential binding patterns of all three markers were found between patients with a good and poor outcome after aromatase inhibitors, where altered ERa binding patterns were not accompanied by changes of epigenetic marks. Integrating these findings with array-based gene expression and progression-free survival data enabled us to identify distinct gene expression profiles linked to these altered binding events of ERa and H3K27m3 that associate with outcome upon aromatase inhibitors (ERa (HR = 5.02, 95% CI: 2.41–10.5; $p < 0.001$) and H3K27me3 (HR = 2.25, 95% CI: 1.19–4.24; $p = 0.013$)). Both ERa and H3K27me3 ChIP-seq based expression profiles remained significant in an independent cohort of specimens and in multivariate analyses with known clinical markers but did not correlate with progression-free survival upon first-line tamoxifen, illustrating a treatment-selective classification.
Conclusion: We applied a novel approach in primary tumor tissue specimens by integrating ChIP-seq with mRNA expression profiling. Above findings indicate that poor outcome after aromatase inhibitor therapy is accompanied by distinct ERa and H3K27me3 binding patterns. These altered binding patterns result in differential gene expression profiles that associate with outcome after aromatase inhibitors but not after tamoxifen in independent sets of specimens.

The stem cell-associated transcription factor TCF3 promotes breast tumor initiation and growth

M. Slyper[1], A. Shahar[1], A. Bar-Ziv[1], R.Z. Granit[1], I. Ben-Porath[1]. *[1]Institute for Medical Research-Israel-Canada Hadassah School of Medicine The Hebrew University of Jerusalem, Department of Developmental Biology and Cancer Research, Jerusalem, Israel*

Background: Regulatory factors controlling stem cell identity and self-renewal are often active in aggressive cancers and are thought to promote their growth and progression. TCF3 is a member of the TCF/LEF transcription factor family that is pivotal in regulating epidermal and embryonic stem cell identity. We found that TCF3 is highly expressed in poorly differentiated human breast cancers, preferentially of the basal-like subtype. This suggested that TCF3 is involved in the regulation of the breast cancer cell differentiation state and tumorigenicity.
Methods: We set out to characterize the role of Tcf3 in breast cancer and in normal mammary stem cells. We silenced or overexpressed TCF3 in breast cancer cells as well as in the normal mouse mammary gland, relying on a combination of shRNA and transgenic tools.
Results: Silencing of TCF3 in basal-like breast cancer cell lines disrupted cell proliferation and morphology, and TCF3-silenced cancer cells formed smaller and less invasive tumors. We found that TCF3 enhances cancer stem cell-associated traits, including mammosphere formation and the $CD44^{high}/CD24^{low}$ marker profile. Importantly, tumor initiating capacity upon implantation in mouse mammary glands was dramatically reduced in TCF3-silenced cells, indicating that TCF3 is required both for the initiation and the growth of breast cancers. TCF3 is known to suppress Wnt target genes and self-renewal in ES cells; in contrast, we found that in breast cancer cells TCF3 binds and activates a subset of Wnt target genes while suppressing a distinct set of Wnt targets. Moreover, upon stimulation with Wnt3A, cells silenced for TCF3 showed reduced mammosphere formation ability compared to treated controls, suggesting that TCF3 can act also as a positive regulator of the Wnt signaling. Tcf3-silenced mouse mammary epithelial cells formed fewer mammospheres and showed reduced tissue reconstitution ability, while transgenic Tcf3 overexpression disrupted mammary ductal growth, revealing that Tcf3 is necessary for normal mammary stem cell function.
Conclusions: Our results identify TCF3 as a key regulator of breast cancer growth and initiation, and a novel link between stem cells and cancer.

Moving beyond in vitro models: Addressing the challenges of pooled RNAi screens in xenografts

P. Diehl[1], D. Tedesco[1], K.R. Bonneau[1], M. Makhanov[1], P. Sun[2], A. Chenchik[1]. *[1]Cellecta Inc., Mountain View CA, USA; [2]The Scripps Research Institute, La Jolla CA, USA*

To date, several groups have successfully run genome-wide *in vitro* RNAi screening using pooled libraries expressing a complex diversity of shRNA molecules. Integral to obtaining reliable and robust results with this technique has been the use of quantitative next generation sequencing to accurately assay hairpin representation levels in the endpoint populations of cells transduced with an shRNA library. However, there are significant challenges in adapting the current pooled RNAi screening approaches to more sophisticated cell model systems, such as *ex-vivo* xenograft models. Our studies tracking the fates of thousands of individually barcoded implanted cells found that xenograft growth is characterized by a small subset of cancer cell sub-clones that ultimately produce the bulk of the resulting tumor mass. This phenomenon significantly impacts the ability to reliably detect shRNA-induced growth inhibition in these systems. To address this problem, we have developed a novel approach to constructing pooled shRNA libraries that enables effective viability screening in systems in which external parameters strongly influence cell growth rates, such as xenograft tumors. We will present preliminary data using this approach, as well as data from more conventional *in vitro* 'drop-out' lethality screens, to identify genes essential for cell proliferation. The results demonstrate that complex pooled shRNA libraries offer an efficient and flexible tool for both *in vitro* and *in vivo* screens aimed at discovering potential cancer therapy targets.

Genome-wide identification of stromal metastasis regulators in breast cancer mouse models (Winner of ECCO/EJC Young Investigator's Award)

T.R. Geiger[1], L. Bai[1], Y. Hu[2], R.C. Walker[1], J.D. Webster[1], D.M. Gatti[3], R.M. Simpson[1], G.A. Churchill[3], F. Pardo Manuel de Villena[4], K.W. Hunter[1]. *[1]National Cancer Institute, Laboratory of Cancer Biology and Genetics, Bethesda MD, USA; [2]National Cancer Institute, Laboratory of Population Genetics, Bethesda MD, USA; [3]The Jackson Laboratory, Bar Harbor ME, USA; [4]University of North Carolina, Department of Genetics, Chapel Hill NC, USA*

Background: Metastasis is the leading cause of death in breast cancer patients and its molecular mechanisms remain largely elusive. In addition to the many genes that have been identified in cancer cells to regulate metastasis in a tumor cell-autonomous way, it has become increasingly recognized that the host stroma including vasculature, immune cells, and extracellular matrix plays a critical role as well. Unfortunately, to date no experimental systems exist that allow for the unbiased identification of stromal metastasis regulators on a genome-wide scale.
Methods: We have set up a genetic approach to map variants in host genes associated with metastasis. To this end, we orthotopically injected a genetically diverse mouse population with a metastatic mouse mammary carcinoma cell line and quantified lung metastasis. We then searched for associations of metastasis and other phenotypes with allelic variants in a genome-wide Quantative Trait Loci (QTL) analysis. As a genetic panel, we used the Diversity Outbred (DO) heterogeneous stock, recently developed by the Jackson Laboratory. These mice have a highly mosaic genetic background from eight different strains.
Results: To avoid immune rejection of the implanted breast cancer cells, we injected 150 F1 female progenies from a DO $\times$ FVB cross with FVB-derived Mvt-1 mammary carcinoma cells. 13 mice did not develop tumors, suggesting the presence of tumor-suppressive stromal factors at the

primary site. Genotyping with the 77,8k MEGA-MUGA BeadChip SNP array and generating haplotype structures using Haploview and PHASE software revealed 148 QTLs associated with stromal tumor suppression at a false discovery rate (FDR) <0.05. The other 137 tumor bearing mice were analyzed for metastasis and presented between 0 and 147 macroscopic tumor nodules on the surface of the lungs, uncovering 15 statistically significant QTLs. 14 mice displayed also tumor cell dissemination to kidneys, associated with another 3 QTLs. Several drug-amenable candidate genes could be identified within the mapped loci (interval sizes 1.7kb − 497.3kb).
Conclusions: Our approach represents a novel model system that screens for host-specific regulators of metastasis in an unbiased manner. We demonstrate that with the state-of-the-art genetic tools available, QTL mapping is feasible to identify candidate stromal metastasis regulators that can be further validated as prognostic markers and novel therapeutic targets for metastatic breast cancer.

Integrative analysis of genomic and transcriptomic data reveals the presence of a novel molecular class of biomarkers shared by all cancer entities

M. Beleut[1], M. Baudis[2], M. Thürk[3], R. Goetz[3], M. Egorov[3], M. Wiesenfeldt[3], A. Knuth[4], P. Schraml[5], H. Moch[5], K. Henco[1]. *[1]PAREQ, Zürich-Schlieren, Switzerland; [2]University of Zürich, Institute of Molecular Life Sciences, Zürich, Switzerland; [3]Qlaym GmbH, Düsseldorf/Göttingen, Germany; [4]University Hospital Zürich, Department of Oncology, Zürich, Switzerland; [5]University Hospital Zürich, Institute of Surgical Pathology, Zürich, Switzerland*

Recent approaches to the classification of human tumour types have mainly been based on clinical, pathological, as well as molecular parameters. By contrast, gene expression patterns reflecting the sum of genetic aberrations in individual tumours have not been fully explored. We hypothesized that similar sets of common, tumour-specific properties exist which are independent of any histologic, clinical or single molecular parameters. In an attempt to uncover such prominent and common molecular features, we developed a novel, unbiased and integrative approach.
We first analysed matched pairs of normal and tumour DNA of 45 renal cell carcinoma (RCC) patients, unbiased from current clinico-pathological, genetic and biological valuations, using SNP microarrays. Based on the hypothesis that genomic alterations impact on the expression of a broad array of genes, we integrated these results into a novel workflow by combining data from *in silico* data mining tools, gene expression and tissue microarrays (TMA). Finally, we used our Artificial Intelligence platform (Q-USD™) to screen for systematics identified in RCC and potential novel ones in 12 additional human tumour types encompassing more than 3000 individual samples.
We have identified five possible global constellations of genetic relationships within the tumours that we call the 'Cancer States.' These Cancer States split the entire patient cohort into up to five homologous molecular subgroups, which appear independent of any currently used pheno- or genotypic classification. Translating these results into applied tumour pathology, we demonstrate that Cancer States represent a novel view for classifying human cancer. Ongoing clinical investigations suggest Cancer States as independent predictors of overall patient survival in RCC. Tamoxifen treated breast cancer patients with Cancer State A were found to have a better prognosis compared to patients with all other Cancer States. Thus, Cancer State A clearly identifies a distinct responder subpopulation among the entire cohort of treated patients.
In summary, Cancer States are reflecting global-mRNA-represented systematics as recurrent features in human cancer. We suggest that the sum of individual molecular alterations in a given tumour represents an intrinsic roadmap to establish one out of the five Cancer States.

Tumor associated copy number changes identified by whole-genome sequencing in the circulation of patients with prostate cancer

E. Heitzer[1], P. Ulz[2], J. Belic[2], S. Gutschi[3], F. Quehenberger[4], M. Auer[2], H. Augustin[3], G. Hoefler[5], J.B. Geigl[2], M.R. Speicher[2]. *[1]Medical University of Graz, Graz, Austria; [2]Institue of Human Genetics, Medical University of Graz, Graz, Austria; [3]Department of Urology, Medical University of Graz, Graz, Austria; [4]Institute for Medical Informatics, Medical University of Graz, Graz, Austria; [5]Institute of Pathology, Medical University of Graz, Graz, Austria*

Background: Patients with prostate cancer may present with metastatic or recurrent disease despite initial curative treatment. The propensity of metastatic prostate cancer to spread to the bone has limited repeated sampling of tumor deposits. Hence, considerably less is understood about this lethal metastatic disease, as it is not commonly studied. Here we explored whole-genome sequencing of plasma DNA to scan the tumor genomes of these patients noninvasively.
Methods: We wanted to make whole-genome analysis from plasma DNA amenable to clinical routine applications and developed an approach based on a benchtop high-throughput platform, i.e. Illuminas MiSeq instrument. We performed whole-genome sequencing from plasma at a shallow sequencing depth to establish a genome-wide copy number profile of the tumor at low costs within 2 days. In parallel, we sequenced a panel of 55 high-interest genes and 38 introns with frequent fusion breakpoints such as the *TMPRSS2-ERG* fusion with high coverage. After intensive testing of our approach with samples from 25 individuals without cancer we analyzed 13 plasma samples derived from 5 patients with castration resistant (CRPC) and 4 patients with castration sensitive prostate cancer (CSPC).
Results: The genome-wide profiling in the plasma of our patients revealed multiple copy number aberrations including those previously reported in prostate tumors, such as losses in 8p and gains in 8q. High-level copy number gains in the *AR* locus were observed in patients with CRPC but not with CSPC disease. We identified the *TMPRSS2-ERG* rearrangement associated 3-Mbp deletion on chromosome 21 and found corresponding fusion plasma fragments in these cases. In an index case multiregional sequencing of the primary tumor identified different copy number changes in each sector, suggesting multifocal disease. Our plasma analyses of this index case, performed 13 years after resection of the primary tumor, revealed novel chromosomal rearrangements, which were stable in serial plasma analyses over a 9 months period, which is consistent with the presence of one metastatic clone.
Conclusions: The genomic landscape of prostate cancer can be established by non-invasive means from plasma DNA. Our approach provides specific genomic signatures within 2 days which may therefore serve as 'liquid biopsy'.

Temporal dynamics of the unfolded protein response and chemoresistance in hepatocellular carcinoma

Y. Vandewynckel[1], I. Colle[1], D. Laukens[2], B. Lambrecht[3], B. Descamps[4], C. Vanhove[4], H. Van Vlierberghe[1]. *[1]University Hospital Ghent, Hepatology, Ghent, Belgium; [2]University Hospital Ghent, Gastroenterology, Ghent, Belgium; [3]Flemish Institute of Biotechnology (VIB), Pneumology, Ghent, Belgium; [4]University of Ghent, INFINITY Lab for Small Animal Imaging, Ghent, Belgium*

Background: Hepatocellular carcinoma (HCC) ranks as the fifth most common cancer worldwide. HCC is a chemoresistant tumour. Systemic therapy with cytotoxic drugs yields low response rates. Medications influencing the chemosensitivity profile are therefore needed. The unfolded protein response (UPR) is implicated in the pathophysiology of several diseases including cancer and endoplasmic reticulum (ER) stress could be a cause of the chemoresistance in HCC. To investigate these phenomena in HCC, we examined the presence and time-dependent alterations of ER stress and multidrug resistance (MDR) in a mouse model of HCC in order to have an in vivo method for the evaluation of UPR manipulation strategies as future cancer therapy.
Material and Methods: The in vivo study design was a diethylnitrosamine (DEN)-induced mouse model for HCC. Mice (6 groups of n = 14) where sacrificed after 20, 25 and 30 weeks of DEN or saline administration. The activation pattern of the UPR and the expression of MDR-related efflux pumps were determined by qRT-PCR, Western blot, ELISA and immunohistochemistry. The histology of the HCC nodules was examined by H/E, Sirius red, F4/80 and reticulin staining. Small animal imaging by dynamic-contrast-enhanced MRI and choline PET was performed.
Results: After 25 weeks of DEN, this model showed MR/PET-positive hepatocarcinogenesis occurring in a background of inflammation and fibrosis. The major MDR-related efflux pumps including mdr1, mrp1, mrp4 and brcp were significantly upregulated in the HCC nodules from 25 weeks. The master regulator of the UPR, bip, was significantly induced on 25 and even more on 30 weeks. Downstream targets of the perk branch (phosphorylated eif2a part: atf4, chop, gadd34 and nrf2 part: gclc, gsta1 and −2) were significantly upregulated after 25 weeks and continued to rise until 30 weeks. Unexpectedly, we could not show an increase in xbp1 splicing, spliced xbp1 targets or ire1a phosphorylation in the HCC nodules compared to the normal liver tissue. Only after 30 weeks, the atf6 pathway and the downstream targets showed significant induction.

Conclusions: Here, we provide the first evidence of the presence and the time-dependent alterations of MDR-related efflux pumps and a specific activation pattern of the UPR in the HCC nodules of a DEN-induced mouse model.
Consequently, this model can be used to manipulate the fine-tuning of the UPR in hepatocarcinogenesis and the related MDR development.

Constitutive activation of RANK in the mammary gland disrupts luminal and basal cell fate leading to tumorigenesis

P. Pellegrini[1], A. Cordero[1], M.I. Gallego[2], W.C. Dougall[3], P. Muñoz[1], M.A. Pujana[4], E. Gonzalez-Suarez[1]. [1]*Bellvitge Biomedical Research Institute, Cancer Epigenetics and Biology Program, L'Hospitalet de LLobregat, Spain;* [2]*Instituto de Salud Carlos III, Department of Cell and Developmental Biology, Madrid, Spain;* [3]*Amgen Inc, Therapeutic Innovation Unit, Seattle, USA;* [4]*Catalan Institute of Oncology, Translational Research Laboratory, Barcelona, Spain*

Introduction: RANK pathway controls mammary gland development in mice but its role in mammary stem cell fate remains undefined. The aim of the study is to investigate the role of RANK pathway in mammary morphogenesis and tumorigenesis.
Methods: MMTV-RANK transgenic mice were used in this study. Normal glands and tumors were characterized by expression analysis of keratins and key markers of mammary differentiation. Mammary epithelial populations were analyzed by surface marker expression in flow cytometry. Mammary stem cells and progenitor cells were quantified by mammary repopulating assays and colony forming assays respectively.
Results: We show that constitutive RANK signaling expands luminal and basal mammary compartments including mammary stem and luminal progenitor cell pools and interferes with the generation of CD61+ and Sca1+ luminal cells and Elf5 expression. Impaired mammary cell commitment upon RANK overexpression leads to the accumulation of progenitors such as K14+K8+ bipotent cells and the formation of heterogeneous tumors containing hyperplastic basal, luminal and progenitor cells. RANK expression increases in wild-type mammary epithelia with age and parity, and spontaneous preneoplastic lesions express RANK and accumulate K14+K8+ cells. In human breast tumors, high RANK expression levels are also associated with altered mammary differentiation.
Conclusions: These results suggest that increased RANK signaling interferes with mammary cell commitment, contributing to breast carcinogenesis.
No conflict of interest.

508 POSTER

Traditional chinese medicine BDL301 inhibits stat3 signaling pathway and angiogenesis in colorectal cancer cells in vitro and in vivo

L. Chu[1], Q. Xu[1], J.M. Fang[1], C.Y. Li[1], H. Han[1], H.X. Zhao[1], X. Zhang[1], Z.Q. Liu[1], Y.J. Chen[1]. [1]*Tenth People's Hospital Tongji University, Department of Medical Oncology, Shanghai, China*

Background: Signal transducer and activator of transcription 3 (Stat3) and p-Stat3 are overexpressed compared with normal intestinal epithelial tissue in invasive colorectal adenocarcinoma, and they are closely related with tumor proliferation, lymph node metastasis, the depth and degree of tumor invasion in the colorectal cancer. Traditional Chinese medicine BDL301 has significant anti-inflammatory effect. The development of colorectal cancer and chronic inflammation are closely related. We therefore hypothesize that BDL301 might inhibit Stat3 Signaling pathway in colorectal cancer cells mediated by the down regulation of inflammatory pathway.
Material and Methods: Specificity of the BDL301 was demonstrated by High-Performance Liquid Chromatography (HPLC). CT26 and HCT116 were used in this study and treated by BDL301 in Vitro. Stat3, p-Stat3, P65, p-P65, COX2 were assessed by Western Blot, proliferation inhibition was tested by CCK8 (Cell Counting Kit-8) experiments. Cell cycle inhibition was investigated by Flow Cytometry. In Vivo studies were done in the Mouse CT26 Tumor Model. Stat3, p-Stat3, P65, p-P65, CD31, VEGF, SHP1, SHP2, IL-6 were investigated in the control and BDL301 treatment groups by Hematoxylin and eosin (H&E), Immunohistochemistry and Western Blot.
Results: Main components of BDL301 were quantified compared with biological reference preparation (BRP) by Agilent 1200 HPLC System. In Vitro, p-Stat3, p-P65, COX2 were down regulated and proliferation of CT26 cells was inhibited by BDL301, while Stat3, P65 has no significant decrease. In Vivo, p-Stat3, CD31, VEGF, IL-6 were investigated to be lower-expressive in the treatment group than the control, accordingly, SHP1, SHP2 were higher. The implantation tumors Weight and Volume of the Mouse CT26 Tumor Models in treatment group were significantly lower. Moreover, angiogenesis was observed to be obviously inhibited in treatment group whose implantation tumors have more apoptosis and necrosis by H&E staining.
Conclusions: We have demonstrated that BDL301 had a significant inhibition of Stat3 Signaling Pathway and angiogenesis in colorectal cancer cells in Vitro and in Vivo. Down regulation of p-P65, COX2 and IL-6 may be taking an important and active effect in the process that should deserve further (pre)clinical evaluation.

509 POSTER

Study of nephrotoxic effects of vincristine treatment in mice

S. Hejazi[1]. [1]*Tabriz Branch Islamic Azad University Tabriz Iran, Department of Anatomy, Tabriz, Iran*

Background: Vinca alkaloid drugs such as vincristine and vinblastine are known to disrupt microtubule functions of the cell, especially in the mitotic spindle apparatus leading to arrest of cellular mitotic division in metaphase and apoptosis. Hyperuricaemia may occur in some patients receiving vincristine, especially those with non-Hodgkin's lymphomas or leukaemia. According this adverse reaction we evaluated nephrotoxic effect on mice kidney tissue.
Material and Methods: This study was done on 40 adult male mice. Mice were divided randomly into 2 groups (control and treatment). The treatment group received vincristine as I.P in 3 weeks (single dose in each week). In the end mice were scarified and kidney were gathered and fixed to staining with H&E and Masson's Trichorome. Data were analyzed by T-test and SPSS software. There was also a meaningful relation in the statistical analyses of comparing treatment and control group parameters ($p < 0.05$).
Results: According the observations, this drug, Vincristine, induced necrotic effect on proximal convoluted tubules. Epithelial cells of tubules, were seen with hyper chromatin nucleus and hyper eosinophilated cytoplasm and destructions of Brush borders observed too. Furthermore hyaline droplets were observed in collecting ducts. Additionally membranous glomerulopathy and proliferative glomerulonephritis were seen.
Conclusions: The dangers of prescribing these anticancer agents to patients with impaired liver function are always emphasised but hepatotoxicity of these drugs is often overlooked. Entero-hepatic circulation and subsequent elimination may also account for its prolonged elimination. Approximately 8% of the injected dose was excreted in the urine as unchanged vincristine. It was revealed that nephrotoxic effect of the vincristine was obvious as in renal tissue particularly. The existence of proteinuria after vincristine administration is the major consequences of drug induced glomerulopathy. In the end we recommended the massive water taking and co-administration of urocozoric agent for decreasing of nephrotoxic side effects of vincristine.
No conflict of interest.

510 POSTER

Improving discrimination in the grading of rat mammary tumours using low-dimensional mapping of histopathological observations, and advanced modeling techniques

A. Calado Lopes[1], T. Cova[2], A. Pais[2], J. Pereira[2], B. Colaço[3], A. Cabrita[4]. [1]*University School of Vasco da Gama, Veterinary, Coimbra, Portugal;* [2]*Faculty of Sciences and Technology, Chemistry Department, Coimbra, Portugal;* [3]*ECAV, Zootechny, Vila Real, Portugal;* [4]*Faculty of Medicina University of Coimbra, Experimental Pathology, Coimbra, Portugal*

The Nottingham Grading System defines three groups for invasive tumors, apart from their global heterogeneity, histogenesis and morphology. On tumors with no clear evidence of invasion, increasing concerns related with the comparison between animal models and humans support a deep interest on enhanced histopathology and its improvement by numerical analysis. In this context, is suggested that principal component analysis (PCA) can be central to find new relations, groups and trends using multiple ranged biological parameters. For each animal model, PCA builds up a low-dimensional map that reflects tumoural heterogeneity. This is useful for making a parallelism between pre-clinical and clinical studies. Statistical estimates based on conditional probability and ordinary least squares and logistic regression allow to relate tumor grade, histological patterns and histological parameters.
48 virgin female Sprague Dawley rats were orally induced with a single dose (65 mg/kg) of 7,12-dimethylbenz(a)-anthracene (DMBA) at 50 days of age. At 27 weeks of experiment and a full necropsy and histological evaluation were performed over multiple ranged microscopic parameters of traditional pathology. Statistical, multivariate analysis was carried out resorting to R (version 2.15.3).
A total of 148 mammary tumors were developed in 75% of rats. In the global set 93% of tumoural lesions are invasive carcinomas. Most of invasive tumors are of low and intermediate grade and 12% are high grade tumors.

All non-invasive tumors (benign and in-situ carcinomas) are of grade I. The number of histological patterns present on a tumor tends to correlate with more malignant features. When tumors were grouped according to the number of histological patterns, most of single pattern tumors were of low grade, two and three pattern tumors were almost equally distributed on low and moderate grade. Four and five pattern tumors were high graded. Cribriform pattern is correlated with grading, *i.e*, tumors having a higher predominance of cribriform pattern are likely to be more malignant. Microcalcifications are present in 12% of tumoural lesions and does not relate with tumoural grade. In contrast, necrosis and haemorrhage intensity relate with more malignant tumors, being the latter in a moderate level. The absence of necrosis is associated with low grade tumors. All high grade tumors have inflammatory infiltrating cells usually lymphocytes and eosinophils, but the intensity of these cell populations as well as secretion does not correlate with malignancy grading.
A characterization of mammary tumors based on the proposed analysis reveals new insights behind the pathology. Malignancy discrimination within a specific grade relies on pertinent parameters related with tumour grading and provide a detailed kaleidoscope map of tumour heterogeneity very useful for mammary comparative oncology and mammary tumour model comparison.
No conflict of interest.

511 POSTER

'Ex vivo' culture of human micro-tumors in unfertilised avian eggs

S. Crawford[1], P. Mrowiec[1], K. Floyd[1]. [1]*Southern Connecticut State University, Biology, New Haven Connecticut, USA*

Background: The quest for more relevant pre-clinical models for testing cancer drug efficacy is a primary focus of cancer research. Current *in vitro* protocols are poor representations of the cancer microenvironment inside the body. The focus of this research study was to evaluate a novel pre-clinical model involving the culture of tumor cells in unfertilised avian eggs. The choice of this experimental system is based on the hypothesis that the avian egg may represent a pre-clinical model of intermediate complexity between the *in vitro* system and the *in vivo* setting that combines essential elements of the *in vivo* system with the simplicity of a highly accessible, stable and quantifiable *'ex vivo'* system to assess tumor biology and drug sensitivity. Fertilised avian eggs inoculated with human tumor cells have been used to assess tumor neo-angiogenesis of the chorioallantoic membrane; to date, there are no reported studies of tumor cells cultured in *unfertilised* avian eggs.
Materials and Methods: Unfertilised avian eggs were inoculated with tumor cells from glioblastoma and juvenile osteosarcoma cell lines in the following procedure: a 1−2 cm opening in the egg shell and membrane was made by small punctured hole on top of the egg. Egg white (albumen) was removed with a syringe and different amounts of media were replaced. Trypsinised tumor cells or tumor spheroids from suspension culture were inoculated into the albumin portion of the egg. Eggs were covered with sterile gauze pads and placed into the incubator where they were incubated at 37ºC with a atmospheric saturation of 5−10% CO_2 from 4 days to 2 weeks. To assay tumor growth, 1 ml of incubated albumin contents were removed with a syringe and placed onto a monolayer culture plate containing standard culture media. After 24 hours the egg contents were observed. Tumor attachment to culture dish substrate and the trypan blue exclusion assay were used as indicators of viability.
Results: Live cell photo microscopy studies showed that both cell lines were capable of proliferation and micro-tumor formation in the albumin component of unfertilised avian eggs when at least 15−20% of the egg albumen was replaced by complete culture medium (RPMI 1640 or DMEM) supplemented with 10% serum. When cells inoculated into avian eggs were transferred to liquid culture, cells were able to reattach and form small cell masses indicative of micro-tumor formation.
Conclusion: This research has shown that two tumor cell lines of diverse tissue type can be successfully cultured in unfertilised avian eggs. This may be the first series of experiments to show the possible use of this system to support the growth of tumor cells. Future studies will attempt to quantify the growth parameters, biological properties and treatment sensitivity of tumor cell lines cultivate in this novel '*ex vivo*'system.

512 POSTER

Effect of zinc supplementation on the expression of metallothionein and p53 in mus musculus with induced metastatic breast cancer

J. Gumulec[1], M. Sztalmachova[1], H. Polanska[1], M. Raudenska[1], V. Adam[2], R. Kizek[2], M. Masarik[1]. [1]*Masaryk University Faculty of Medicine, Department of Pathological Physiology, Brno, Czech Republic;* [2]*Mendel University, Department of Chemistry and Biochemistry, Brno, Czech Republic*

Background: Zinc is considered an important regulator of apoptosis, cell cycle and oxidative stress and thus is interesting from the perspective of tumour development. The aim of this study was to evaluate the effect of zinc supplementation on metallothionein 1 and 2, metal-regulatory transcription factor 1 (MTF-1) and p53 gene expression on an animal model with induced advanced breast cancer.
Material and Methods: 40 Balb/c female mice were equally distributed to 2×2 groups according to tumor presence (tumour/control) and zinc supplementation (supplemented/not supplemented). 4T1 metastatic breast cancer cell line was used to induce neoplatic process and total 0.15 mg/g zinc sulphate divided in 4 doses was applied to mice. After 1 month, animals were inducted to anaesthesia, the weight and size of tumor was measured and following organs were isolated: primary tumour, brain, liver, lung, spleen, kidney, blood. RNA was isolated and qRT-PCR was performed with b-actin as housekeeping gene. Following TaqMan probes were used: Mm 00485274_m1 Mtf1; Mm 01731290_g1 Trp53; Mm 00496660_g1 Mt1; Mm 04207591_g1 Mt2. Factorial ANOVA with Bonferroni post-hoc test were used for statistical analysis. Animal experiments were approved by Ethic commission Faculty of Medicine, Masaryk University, Brno, CZ.
Results: The tumour size of zinc-treated animals was 40% smaller ($p = 0.04$) in the end of experiment. Significant differences in the gene expression were observed between organs; while significantly highest levels were observed in liver and kidney, significantly lowest levels were determined in primary tumor, lung and spleen. Brain showed significantly elevated expression of MTF-1 and MT2 only. In mice with tumours, hepatic MT-2 and −1 expression increased 22-fold and 3-fold when exposed to Zn treatment ($p < 0.05$). Animals without Zn supplementation did not show similar trend. In kidney, level of MT1 and 2 was significantly lower in cancer mice. When zinc-treated, MT level increased up to the level as in healthy controls. In other tissues there are no such characteristics changes in MT expression.
Conclusions: Zinc supplementation significantly reduces the progression of breast cancer, most likely through metallothionein-mediated pathways. Liver and kidney are tissues with highest zinc turnover, with MT level being decreased in cancer cases and restored up to control level, when treated with zinc.

Evidence for a direct relationship between the metabolic profile of tumor cells and their response to ionizing irradiation

V. Bol[1], A. Bol[1], C. Bouzin[2], D. Labar[1], J. Lee[1], G. Janssens[1], P.E. Porporato[2], P. Sonveaux[2], O. Feron[2], V. Grégoire[1]. [1]*University Catholique de Louvain, IREC-MIRO (Molecular Imaging Radiotherapy and Oncology), Brussels, Belgium;* [2]*University Catholique de Louvain, IREC-FATH (Pôle de Pharmacologie et Thérapeutique), Brussels, Belgium*

Background and Aim: The Warburg phenotype identified decades ago describes tumor cells with increased glycolysis and decreased mitochondrial respiration even in the presence of oxygen. This particular metabolism also termed 'aerobic glycolysis' reflects an adaptation of tumor cells to proliferation in a heterogeneous tumor microenvironment. Although metabolic alterations in cancer cells are common features, their impact on the response to radiotherapy is not yet fully elucidated.
Material and Methods: We produced Warburg-phenotype tumor cells with impaired mitochondrial respiration (MD) and after characterization of their metabolism we injected subcutaneaously the cells for tumor xenograft. Mice were then imaged with a small-animal PET system for tumor in vivo characterization before irradiation (16 Gy). Tumor regrowth delay was recorded until mean diameter reached 16 mm. We then determined radiosensitivity in vitro by clonogenic survival, analysis of cell cycle distribution, G2/M checkpoint and gamma-H2Ax assay kinetics.
Results: We first confirmed that MD cells were exclusively glycolytic while WT cells exhibited mitochondrial respiration. We then used these cells for assessing the response of WT and MD tumors to a single dose of radiation and showed that the in vivo tumor growth delay of the MD group was increased, indicating therefore an increased radiosensitivity compared to WT. However, in vitro radiation showed that the ability of both

cell lines to repair radiation-induced DNA damage was similar in terms of clonogenic survival and gamma-H2AX clearance, suggesting that the increased radiosensitivity of MD tumors could at least partially be explained by the impaired oxygen consumption of these cells. Therefore, we tested this hypothesis by using different cell lines irradiated in a closed system and obtained a significant positive correlation between survival fraction and respiratory rate.
Conclusion: Our study highlights the impact of the metabolic profile of a tumor on its response to irradiation. In addition, our study provides a rationale for combining antimetabolic therapeutic strategies to radiotherapy in particular if such therapies focus on decreasing the oxygen consumption of tumor cells.

Cancer cells switch between glycolytic and nonglycolytic phenotype

X. Hu[1], J. Xie[1], H. Wu[1], C. Dai[1], Q. Pan[1], Z. Ding[1], D. Hu[1], Y. Luo[1].
[1]*The 2nd Affiliated Hospital of Zhejiang University School of Medicine, Cancer Institute, Hangzhou, China*

Background: Cancer cells typically exhibit the Warburg effect, i.e., aerobic glycolysis that converts between 80 to 90% incoming glucose to lactate as a metabolic waste. However, because of the poor circulation, glucose concentrations in many solid tumors are very low, e.g., the glucose concentrations in non-necrotic regions of colon and stomach cancer are only ~0.1 and ~0.4 mM, respectively. Conceivably, cancer cells in these tumors cannot afford to constantly waste the very limited source of glucose, which supplies not only energy but also building blocks for biosynthesis. We propose that cancer cell can switch between Warburg and nonglycolytic phenotype (economic utilization of glucose), and that lactic acidosis, a common tumor environmental factor, is responsible for the phenotype switch.
Material and Methods: Cancer cells were incubated in the presence or absence of lactic acidosis (lactate: 0−25 mM, pH:6.7−7.4). The following parameters were measured: the rates of glycolysis, lactate generation, and OXPHOS (oxidative phosphorylation); cell growth; intracellular ATP, ADP, AMP; intracellular mass action ratio ([pyruvate][NADH]/[lactate][NAD]); the effects of pH on the kinetics of glycolytic enzymes.
Results: Without lactic acidosis, cancer cells showed typical Warburg effect, which led to accumulation of lactate and proton, creating a lactic acidosis environment, which then led to a decrease of intracellular pH and an increase of intracellular lactate. While acidic pH inhibited glycolytic enzymes and significantly reduced glycolysis, high lactate concentration led to the mass action ratio ([pyruvate][NADH]/[lactate][NAD] approach to the equilibrium constant of this reaction. As a result, cancer cells did not produce or only produce minimal amount of lactate, instead, cancer cells diverted glucose to OXPHOS and biosynthesis. We further demonstrated that lactic acidosis permitted cancer cells proliferate under moderate glucose deprivation that otherwise was unsupportive for cell survival let alone cell growth, and that eradicating the acidosis component of lactic acidosis by elevating intratumoral pH significantly inhibited tumor growth and promoted tumor necrosis in a mouse breast cancer model.
Conclusion: Cancer cells show dualism of glucose metabolism: typical Warburg and nonglycolytic phenotype in the absence or presence of lactic acidosis. The nonglycolytic phenotype is potentially crucial for cancer cell survival and growth in vivo, as it allows cancer cells to use economically the limited supply of glucose in many solid tumors. This metabolic dualism may allow cancer cells to sustain/obtain growth advantage by adapting to dynamic microenvironments with temporal/spatial fluctuations of glucose, lactate and proton levels.

Chronic intermittent hypoxia triggers adaptive changes that promote protection against cell death

J. Matschke[1], H. Riffkin[1], R. Handrick[2], L. Klein-Hitpass[1], V. Jendrossek[1].
[1]*University Hospital Essen, Institute of Cell Biology, Essen, Germany;*
[2]*University of Applied Sciences, Institute for Pharmaceutical Biotechnology, Biberach, Germany*

Introduction: Hypoxia is a common feature of human solid tumors and is considered as one main biological factor driving malignant progression and promoting tumor cell resistance to chemotherapy and radiotherapy. We showed in previous work that chronic intermittent hypoxia drives the evolution of hypoxia-tolerant lung cancer cells that display increased resistance to stimuli of the intrinsic apoptosis pathway. Aim of the present study was to gain further insight into the molecular changes responsible for hypoxia tolerance and to understand the molecular mechanisms that link hypoxic selection to apoptosis resistance.
Methods: Human lung adenocarcinoma cells (NCI H460) were subjected to up to 25 cycles of severe hypoxia (48 h <0.1% O_2) and reoxygenation (120 h 21% O_2). We analyzed tumor cell growth and sensitivity to dihydroartemisinin [DHA] and ionizing radiation. Moreover, we compared gene expression profiles of hypoxia-selected and control cells under resting and stress conditions by microarray analysis. Cell function was determined by measuring apoptosis (SubG1 population), cell death (Propidium iodide [PI] exclusion), mitochondrial potential (Tetramethylrhodamine, ethyl ester [TMRE]), and reactive oxygen species (Dihydroethidium [DHE]).
Results: The hypoxia-selected cells were characterized by decreased sensitivity to radiation-induced apoptosis. Moreover, the hypoxia-selected cells displayed increased resistance to the reactive oxygen donor DHA when treatment was performed under hypoxic conditions. Death resistance was associated with deregulated expression of genes involved in defense against oxidative stress, metabolic regulation, and mitochondrial function under resting conditions and with differential responses to hypoxia or reoxygenation stress.
Conclusions: We speculate that the adaptive changes observed in our hypoxia tolerant tumor cells act in concert to attenuate oxidative damage thereby decreasing sensitivity to cell death in response to (oxidative) stress.

Pten loss increases pd-l1 protein expression and affects the correlation between PD-l1 expression and clinical parameters in colorectal cancer

H. Liu[1], M. Song[1], D. Chen[2], B. Lu[1], L. Huang[1], C. Wang[1], J. Zhang[1], X. Wu[2], L. Wang[2], J. Wang[2]. [1]*Sun Yat-sen University, Institute of Gastroenterology and the Sixth Affiliated Hospital Institute of Human Virology Key Laboratory of Tropical Disease Control (Sun Yat-sen University) Ministry of Education, Guangzhou, China;* [2]*Sun Yat-sen University, Institute of Gastroenterology and the Sixth Affiliated Hospital, Guangzhou, China*

Background: Programmed death ligand-1 (PD-L1) has been identified as a factor associated with poor prognosis in a range of cancers, and was reported to be mainly induced by phosphatase and tensin homolog (PTEN) loss in gliomas. However, the clinical effect of PD-L1 and its regulation by PTEN has not yet been determined in colorectal cancer (CRC). In the present study, we verified the regulation of PTEN on PD-L1 and further determined the effect of PTEN on the correlation between PD-L1 expression and clinical parameters in CRC.
Material and Methods: RNA interference approach was used to down-regulate PTEN expression in SW480, SW620 and HCT116 cells. Tissue microarray immunohistochemistry was used to detect PD-L1 and PTEN in 404 CRC patient samples. The relationship between the expression levels of PD-L1/PTEN and clinical parameters was analyzed. We also investigated the clinical significance of PD-L1 in a subset of 39 patients with PTEN complete loss to explore whether the effect of PD-L1 in CRC is dependent on PTEN expression.
Results: It was showed that PD-L1 protein, but not mRNA, was significantly increased in cells transfected with siRNA-PTEN compared with the negative control. Moreover, the capacity of PTEN to regulate PD-L1 expression was not obviously affected by IFN-γ, the main inducer of PD-L1. Overexpression of PD-L1 was significantly correlated with distant metastasis ($P<0.001$), TNM stage ($P<0.01$), metastatic progression ($P<0.01$) and PTEN expression ($P<0.001$). Univariate analysis revealed that patients with high PD-L1 expression had a poor overall survival ($P<0.001$). However, multivariate analysis did not support PD-L1 as an independent prognostic factor ($P = 0.548$). Univariate ($P<0.001$) and multivariate survival ($P<0.001$) analysis of 310 located CRC patients revealed that high level of PD-L1 expression was associated with increased risks of metastatic progression. Furthermore, the clinical effect of PD-L1 on CRC was not statistically significance in a subset of 39 patients with no PTEN expression (distant metastasis: $P = 0.102$; TNM stage: $P = 0.634$; overall survival: $P = 0.482$).
Conclusions: PD-L1 can be used to identify CRC patients with high risk of metastasis and poor prognosis. This clinical manifestation may be partly associated with PTEN expression.
No conflict of interest.

Relationship between rest metabolic rate and nutritional, inflammatory status and cancer stage: A prospective observational study in cancer patients

C. Vazeille[1], J.P. Durand[1], N. Neveux[2], A. Cessot[1], P. Boudou-Rouquette[1], I. Gataa[1], S. Bellanger[1], L. Cynober[2], F. Goldwasser[1]. [1]*Cochin Teaching Hospital AP-HP Université Paris Descartes, Oncology, Paris, France;* [2]*Cochin Teaching Hospital AP-HP Université Paris Descartes, Biochemistry, Paris, France*

Background: In cancer patients (pts), evaluating the rest metabolic rate (RMR) could help to improve early nutritional support. However, it remains poorly documented. This study aimed to investigate the correlation between RMR and pts characteristics.
Material and Methods: This observational prospective unicenter study included chemotherapy-naive cancer pts. Before treatment initiation they underwent indirect calorimetry. We recorded the following data: WHO performance status (PS), weight loss, number of metastatic sites, serum albumin and transthyretin levels, C-reactive protein (CRP), ferritin, α-1 glycoprotein acid (α-1 GPA). A Spearman's test was performed to determine correlation between RMR and these parameters.
Results: 140 consecutive pts were included. Median age was 64 years (20−94), 40% were females. Main primary tumors were: genito-urinary (28%), gastro-intestinal (25%) and lung (18%) cancers. 59% of the pts were metastatic, 35% were PS $\geqslant$2. Median percentage of weight loss was 3.0% kg (−33.9–19.0). Mean RMR was 1711.6 kcal/d (922–2605). Mean RMR was significantly higher in metastatic pts: 1775.0 versus 1628.4kcal/d ($p = 0.012$; unpaired t-test). Significant positive correlations were found between RMR and number of metastatic sites ($r = 0.170$, $p = 0.044$), percentage of weight loss ($r = 0.172$, 95% CI [0.006;0.329], $p = 0.04$), inflammatory serum markers: CRP ($r = 0.311$, 95% CI [0.149;0.457], $p < 0.001$), ferritin ($r = 0.239$, 95% CI [0.072;0.396], $p = 0.006$) and α-1 GPA ($r = 0.223$, 95% CI [0.024;0.404], $p = 0.0292$), as assessed by Spearman's coefficient. There were no relationship between RMR and PS, serum albumin and transthyretin levels.
Conclusion: Inflammation and metastatic stage are determining factors of higher energy expenditure in cancer pts. Early nutritional guidance should be provided according to the cancer stage and the inflammatory status.

518 POSTER

Glucose induced wnt signalling in cancer

A. Chocarro-Calvo[1], J.M. García-Martínez[1], A. De la Vieja[2], C. García-Jiménez[1]. [1]*Universidad Rey Juan Carlos, Department of Biochemistry Physiology and Human Genetics, Alcorcon (Madrid), Spain;* [2]*Instituto de Salud Carlos III, Chronic Disease Research Unit, Majadahonda (Madrid), Spain*

Background: Nuclear accumulation of β-catenin, a widely recognized marker of poor cancer prognosis, drives cancer cell proliferation and senescence bypass. High levels of sugar in plasma, as present in diabetes increase cancer risk enhance the cancer-associated Wnt signalling pathway and promote nuclear accumulation of b-catenin, but whether other dietary components or metabolic intermediates impact on cancer associated signalling pathways is not known.
Material and Methods: Mouse and human intestinal tumour cells were used to study the influence of metabolic intermediates on cancer-associated pathways. Endogenous gene expression was analysed by RT/PCR and chromatin immunoprecipitation. Mechanistic studies were done using a range of mutants from transduction intermediaries. Fractionated extracts, immunofluorescence and immunocytochemistry were used to assess translocation of essential Wnt components.
Results: Here we show that distinct inhibitors of glucose metabolism block the enhancement of Wnt signalling induced by glucose at different levels, including nuclear translocation or transcriptional activity of β-catenin.
Conclusions: Certain metabolic intermediates or suppressors of glucose metabolism block signalling through the cancer-associated Wnt/β-catenin pathway and may provide new compounds and targets for cancer prevention and anti-cancer therapies.
No conflict of interest.

Cholangiocarcinoma diagnosis and therapy: in vitro studies contribution

A.F. Brito[1], M. Ribeiro[2], A.M. Abrantes[1], J. Casalta-Lopes[1], J.G. Tralhão[3], M.F. Botelho[1]. [1]*Biophysics Unit − IBILI, Faculty of Medicine of University of Coimbra, Coimbra, Portugal;* [2]*Life Sciences Department, Faculty of Science and Technology of University of Coimbra, Coimbra, Portugal;* [3]*Surgical Department − Surgery A, Coimbra University Hospitals, Coimbra, Portugal*

Background: Cholangiocarcinoma (CC) is the second most frequent primary liver tumor. Surgery is currently the only curative therapy. In most cases the CC diagnosis occurs late and patients are conducted to other therapies such as chemotherapy. However, in majority of the cases chemotherapy is palliative. More recently, new drugs for targeted therapies have been developed, including sorafenib, a tyrosine kinases inhibitor. In the diagnosis of malignant lesions some improvements have also been observed, including the development of new radiopharmaceuticals to use in PET, such as ^{18}F-Fluorocholine. Thus, the objectives of this experimental work were to evaluate the effect of various conventional chemotherapy agents and also sorafenib on cell proliferation of a human CC cell line, and also study the ^{18}F-FDG and ^{18}F-Fluorocholine uptake profiles by the same cell line.
Material and Methods: An human CC cell line, TFK1, was used. Cells were incubated with increasing concentrations of cisplatin, doxorubicin, etoposide, 5-fluorouracil (5-FU) and sorafenib during 24, 48, 72 and 96 hours. After, the effect on cell proliferation was evaluated using the MTT assay, in order to calculate the half maximal inhibitory concentration (IC_{50}). Uptake studies using ^{18}F-FDG and ^{18}F-Fluorocholine were performed.
Results: For all the drugs tested, the effect on cell proliferation was time and concentration dependent. The drug with less potential for cell proliferation inhibition was etoposide, with a IC_{50} after 24 hours of incubation of 407μM and after 96 hours of incubation of 14μM. Sorafenib was the drug that showed the best results for shorter incubation times (IC_{50}(24 h)=23μM), being also the drug with which it has obtained the best fit to the kinetic function, which corresponds to a better pharmacokinetic effect. The radiopharmaceutical with higher uptake by the cell line used was ^{18}F-Fluorocholine.
Conclusion: In general, the CC cell line shown to be highly resistant to the drugs used, what is concordant with the disappointing results that chemotherapy usually presents in patients with CC. However, the results obtained with sorafenib were much better that those achieved with other drugs, indicating that tyrosine kinase inhibitors may be a therapeutic option for CC. On the other hand, ^{18}F-Fluorocholine uptake was higher than ^{18}F-FDG uptake, demonstrated that cell proliferation indicator may be more useful for CC diagnosis than the metabolic activity indicator.
No conflict of interest.

Role of AML-1a/RUNX1 in TRPV2-mediated transcriptional regulation of glioblastoma stem cell (GSC) proliferation and differentiation

M.B. Morelli[1], M. Santoni[2], C. Amantini[1], V. Farfariello[1], S. Liberati[1], L. Ricci-Vitiani[3], R. De Maria[3], S. Cascinu[2], G. Santoni[1], M. Nabissi[1]. [1]*University of Camerino, Experimental Medicine, Camerino (MC), Italy;* [2]*Polytechnic University of Marche, Department of Clinic Oncology, Ancona, Italy;* [3]*Istituto Superiore di Sanità, Department of Hematology Oncology and Molecular Medicine, Roma, Italy*

Background: Astrocyte differentiation occurs through the regulation of a variety of transcription factors. Among these, AML1/RUNX1 has been suggested to play a pivotal role not only in definitive hematopoiesis or in embryonic stem cells but also in the development of stem/neural progenitor cells. Microglia, the resident macrophages of the SNC, are associated with the pathogenesis of many stem cell-derived brain tumours. Ontogenetically they derive from primitive myeloid progenitors, and represent a distinct haematopoietic population in the mononuclear phagocyte system. In this regard, we have recently reported that TRPV2 channel promotes both in vitro and in vivo Glioblastoma Stem Cell-Like (GSC) differentiation and inhibits their proliferation (Morelli MB et al., Int J Cancer 2012). However no findings on transcriptional regulation of TRPV channels during astroglial differentiation of GSCs have been provided so far. AML1/RUNX1 coordinates the proliferation and differentiation of olfactory neuron stem/neural progenitor cells, but to date its involvement on GSC progression has not been elucidated. Aim of this study was to elucidate the role of AML-1a in the regulation of TRPV2 expression during GSCs differentiation.
Materials and Methods: Chromatin immunoprecipitation assay was used to detect the binding of AML-1a with TRPV2 promoter. Short-interfering

RNA was performed to silence AML-1a in GSCs during differentiation and Real Time PCR was performed to verify AML-1a silencing. Western blot analysis and bromodeoxyuridine incorporation assays were used to detect protein expression and cell proliferation respectively.
Results: We demonstrated that AML-1a is efficiently recruited onto TRPV2 target gene promoters following GSC differentiation, indicating that AML-1a is involved in TRPV2-mediated transcriptional regulation during GSC differentiation (Morelli MB et al. Int J Cancer 2012). Indeed, forced down-regulation of AML-1a by gene silencing inhibits transcriptional activity of TRPV2 in response to differentiation and reduces differentiation marker expression level (e.g. GFAP). Moreover, we observed that knockdown of AML-1a increases GSC proliferation.
Conclusions: Taken together, our data suggest that AML-1a is required for the stimulation of TRPV2 in response to GSC differentiation and also provide novel insight into understanding the molecular mechanisms behind TRPV2 transcriptional regulation.

521 POSTER

Strategies targeting fusion machinery of bone marrow derived macrophage may ameliorate intestinal fibrosis after radiation

H. Ch'ang[1], Y. Chang[1], L. Lin[1]. [1]*National Health Research Institutes, National Institute of Cancer Research, Tainan City, Taiwan*

Background: Bone marrow (BM) cells could repopulate damaged tissue and contribute to repair in non-hematopoietic tissues. Our previous observations demonstrated that the mitigating effect to intestine after acute radiation damage was achieved through paracrine mediators released by BM cells. Maximal appearance of BM cells, however, occurred long after intestine mucosa recovered from radiation damage. Recent studies revealed cell fusion between BM and somatic cells were enhanced by chronic inflammation. There was a significant role of BM cells in triggering fibrotic responses and contributing to liver and renal fibrosis. We would like to explore the association between cell fusion and intestine fibrosis after radiation.
Material and Methods: Using gender-mismatched BMT and BMT from GFP mice donors, we quantified the fusion phenomenon within intestine of mice after irradiation. By using pravastatin, an HMG Co-A reductase inhibitor, to diminish intestine fibrosis after WBI, we evaluated the proliferation and fusion phenomenon as well as fusion signaling proteins (macrophage fusion receptor (MFR) and CD47) and fibrosis markers (CCN2, fibronectin, collagen). Using immunohistochemical study and isolated CD11b(+) BM cells for BMT, we evaluated the major BM derived cells contributing to the fusion phenomenon. Clodronate liposome was used to deplete macrophage/myelomonocytic cells in mice as BMT donors. Anti-cell fusion strategies including MMP9 inhibitor, Rac 1 inhibitor and MFR RNA silencing were used to suppress fibrotic protein expression of co-culture between intestine stromal and BM cells.
Results: BM cells fused with intestine stromal cells after BMT to mice after WBI. The maximal fusion phenomenon occurred before significant level of fibrosis appeared within intestine of mice after WBI+BMT. Pravastatin suppressed intestine fibrosis and fusion phenomenon of mice. The cell fusion protein expression and the proliferation index within fused cells were also decreased by prvastatin. BM derived macrophage/myelomonocytic cells contributed majorly to the fusion phenomenon. Treatment with MMP9 inhibitor, Rac 1 inhibitor or MFRsiRNA during co-culture between BM and intestine stromal cells suppressed fibrosis protein expression. Intestine mucosa lysates from mice receiving clodronate liposome after WBI and BMT revealed decreased cell fusion and fibrosis in histology as well as in biochemical examination.
Conclusions: Fusion between BM and intestine stromal cells is associated with chronic intestine fibrosis after radiation. The fusion phenomenon can be diminished by anti-fibrosis agent. Intestine fibrosis may be ameliorated by depleting macrophage/myelomonocytic cells as well as strategies against fusion machinery.

RANK induces epithelial–mesenchymal transition and stemness in human mammary epithelial cells and promotes tumorigenesis and metastasis

M. Palafox[1], I. Ferrer[1], P. Pellegrini[1], S. Hernandez-Ortega[1], F. Climent[2], M.T. Soler[2], M. Tometsko[3], D. Branstetter[3], W.C. Dougall[3], E. González-Suárez[1]. [1]*Institut d'Investigacio Biomedica de Bellvitge, Cancer Epigenetics and Biology Program, L'Hospitalet de Llobregat Bar, Spain;* [2]*University Hospital of Bellvitge, Pathology, L'Hospitalet de Llobregat Bar, Spain;* [3]*Amgen Inc, Hematology/Oncology Research, Seattle, USA*

Background: Paracrine signaling through RANK pathway mediates the expansion of mammary epithelia that occurs during pregnancy and activation of RANK pathway promotes mammary tumorigenesis in mice. The objective of this study is to analyze the effect of RANK overexpression in human mammary epithelial cells.
Materials and Methods: Human RANK was overexpressed by lentiviral infection in non-transformed human mammary cells and tumoral BRCA1 deficient cells. Then, we analyzed the role of RANK in:
– Stemness: we analyzed stem cells markers by flow citometry, stem cells transcription factors by QRT-PCR and functionality by mammary reconstitution assays.
– Epithelial–mesenchimal transition (EMT): we measured the levels of epithelial/mesenchimal markers by QRT-PCR and immunofluorescence, EMT transcription factors by QRT-PCR and migration capacity by Wound-Healing.
– Tumorogenesis: we performed in vitro assays like 3D cultures and foci assays, and in vivo assays by injection of these cells in immunodeficient mice.
– Clinical samples: we analyzed RANK and RANKL mRNA expression levels by QRT-PCR in human adenocarcinomas considering their pathological characteristics.
Results: Overexpression of RANK induces the expression of breast cancer stem and basal/stem cell markers in tumoral and normal human mammary cells. High levels of RANK in untransformed MCF10A cells induce changes associated with both stemness and transformation including mammary gland reconstitution, epithelial–mesenchymal transition, increased migration and anchorage independent growth. In addition, spheroids of RANK-overexpressing MCF10A cells displayed disrupted acinar formation, impaired growth arrest and polarization, and luminal filling. RANK overexpression in tumor cells with non functional BRCA1, enhances invasiveness in acinar cultures and increases tumorigenesis and metastasis in immunodeficient mice. High levels of RANK were found in human primary breast adenocarcinomas that lack expression of the hormone receptors, estrogen and progesterone, and in tumors with high pathological grade and proliferation index; high RANK/RANKL expression was significantly associated with metastatic tumors.
Conclusions: RANK promotes tumor initiation, progression and metastasis in human mammary epithelial cells by increasing the population of CD44+CD24− cells, inducing stemness and epithelial mesenchymal transition. These results suggest that RANK expression in primary breast cancer associates with poor prognosis.
No conflict of interest.

523 POSTER

The effect of salinomycin and analogs on breast cancer stem cells

X. Huang[1], B. Borgström[2], D. Strand[2], L. Persson[3], C. Hegardt[4], S. Oredsson[1]. [1]*Functional Zoology, Department of Biology, Lund, Sweden;* [2]*Centre for Analysis and Synthesis, Department of Chemistry, Lund, Sweden;* [3]*Biomedical Centre, Department of Experimental Medical Sciences, Lund, Sweden;* [4]*Division of Oncology, Department of Clinical Sciences, Lund, Sweden*

Background: Agents that selectively target cancer stem cells (CSC), either by selective inhibition or by induction of a phenotypical change, have attracted considerable attention recently as a new venue to minimize recurrence and/or metastasis of cancer. A study by Gupta *et al*. details that out of a library comprising over 16000 compounds, the naturally occurring ionophore antibiotic salinomycin was the most selective in reducing the relative proportion of cells with the CD44+/CD24− phenotype associated with CSC properties. We have synthesized a unique library of presently 30 structurally distinct synthetic analogs of salinomycin. The potency and selectivity against CSCs have been evaluated in JIMT-1 breast cancer cells.
Materials and Methods: Potency was evaluated as the inhibitory concentration 50 (IC50) deduced from dose response curves obtained using an MTT 96-well assay. Selectivity was studied by investigating the effect of treatment with the compounds on the putative CSC CD44+/CD24− cell population by flow cytometry. Selectivity was also investigated by determining the colony forming efficiency (CFE) in a serum free soft agar assay.
Results: Chemical modification of salinomycin resulted in analogs with higher or lower IC50 than salinomycin. The IC50 of salinomycin was 0.59 μM and 0.16 μM for the analog with the highest potency. At a 0.05 μM concentration, salinomycin did not affect the CSC population. On the other hand, some of the analogs reduced the CD44+/CD24− population by almost 80% and the CFE was around 50% of control.
Conclusions: Chemical modification of salinomycin results in analogs with higher potency *i.e*. lower IC50 and increased selectivity to CSCs at a low dose.
No conflict of interest.

524 POSTER

Evidence of an association of mRNA expression of inhibitors of DNA binding 1 and 2 with advanced tumour stage and adverse clinical outcome in human breast cancer

U. Wazir[1], W.G. Jiang[2], A.K. Sharma[3], R.F. Newbold[4], K. Mokbel[1].
[1]Princess Grace Hospital London UK, The London Breast Institute, London, United Kingdom; [2]Cardiff University School of Medicine Cardiff University Cardiff Wales UK, Metastasis and Angiogenesis Research Group University Department of Surgery, Cardiff, United Kingdom; [3]St George's Hospital, Breast and Endocrine Surgery, London, United Kingdom; [4]Brunel University Uxbridge London UK, Brunel Institute of Cancer Genetics and Pharmacogenomics Faculty of Life Sciences, London, United Kingdom

Background: Inhibitors of DNA binding (ID) are known to have a role in embryogenesis, cancer stem cell renewal, and oncogenesis. In this study, we studied the role of ID1 and ID2 in breast cancer, by assessing associations of mRNA expression with clinicopathological parameters.
Materials and Methods: Breast cancer tissues (n = 152) and adjacent normal tissues (n = 31) underwent reverse transcription and quantitative polymerase chain reaction (qPCR). Transcript levels were correlated with clinicopathological data.
Results: *ID1* mRNA expression was found to be increased in breast cancer samples. Its expression was significantly associated with adverse clinical outcomes. This was highly significant when comparing patients who had no recurrences over a decade of follow-up with those with disease-related mortality ($p = 0.0169$), and when comparing patients who were disease-free with all other patients ($p = 0.0033$).
The Kaplan–Meier plot analysis demonstrated that patients with higher *ID1* mRNA expression had reduced disease-free ($p = 0.001$) and overall ($p = 0.02$) survival.
ID2 expression was also found to be directly associated with breast cancer. *ID2* expression was significantly increased with higher NPI scores (NPI 2 *vs*. 3; $p = 0.0062$).
Mean and median *ID2* copy numbers were also significantly increased with advanced disease. This attained highest significance when comparing patients who were disease-free during follow-up with those with disease related mortality ($p = 0.0004$).
A similar, albeit insignificant, association was seen between *ID2* expression, tumour grade and TNM stage.
This was further illustrated by the Kaplan–Meier plot analysis, in which higher *ID2* mRNA expression was associated with worse disease-free ($p = 0.01$) and overall ($p = 0.005$) survival.
Conclusion: Our findings are suggestive of a role for ID1 and ID2 in human breast cancer as possible prognostic markers and therapeutic targets meriting further validating investigations, including immunohistochemistry and mechanistic studies.
No conflict of interest.

525 POSTER

Cancer stem cells in lung cancer: The resident evil!

C.F.D. Rodrigues[1], M.F. Botelho[2], A. Paiva[3], M.C. Alpoim[4]. *[1]Centro de Neurociências e Biologia Celular, University of Coimbra, Coimbra, Portugal; [2]Centro de Investigação em Meio Ambiente Genética e Oncologia, Faculty of Medicine University of Coimbra, Coimbra, Portugal; [3]Centro de Histocompatibilidade do Centro, Faculty of Medicine University of Coimbra, Coimbra, Portugal; [4]Departamento de Ciências da Vida, Faculty of Sciences and Technology University of Coimbra, Coimbra, Portugal*

Background: Cancer is a major public health problem affecting millions of new individuals each year. Recent research emphasized the major role of cancer stem cells (CSCs) in the metastatic disease, the main cause of cancer patients' mortality. CSCs drive tumorigenesis and differentiation, contributing to tumors' heterogeneity and to their therapy resistance and eventually relapse. Albeit targeted therapies have been developed, CSCs can reemerge by stromal-induced dedifferentiation through mechanisms still unclear.
Materials andMethods: Various cell culture techniques allowed the establishment of 4 cell lines out of the non-malignant human bronchial epithelial system BEAS-2B. Cells' characterization involved cytogenetic and flow cytometry tools, metabolic studies with [^{18}F]fluoro-2-deoxyglucose(^{18}FDG) and nuclear magnetic resonance (NMR) spectroscopy, real time PCR and immunocitochemistry. Sphere-formation assay was used to isolate CSC-sand co-cultures and cytokine multiplex arrays to disclose dedifferentiation.
Results: BEAS-2B was malignantly transformed into the RenG2 using low density culture in the presence of hexavalent chromium [Cr(VI)]. Under the same conditions, though inthe absence of Cr(VI), Cont1 was also produced. Two derivative cell lines (DRenG2 and DDRenG2) were attained following sub-cutaneous (*s.c.*) injection of xenograft RenG2 and DRenG2 cells, respectively. Metabolic studies using ^{18}FDG and NMR spectroscopy performed in all cell lines revealed a more glycolytic phenotype for the derivatives (DRenG2 and DDRenG2), compatible with a quiescent phenotype. CSCs' presence hypothesis was strengthened by the identification and characterization of different cellular sub-populations within each cell line, with different karyotype and real time PCR-based signatures. The sphere-formation assay revealed the presence of CSCs only in DRenG2 and DDRenG2 cell systems, suggesting that a dedifferentiation process featured the formation of CSCs during RenG2 derivation in nude mice. The involvement of mice stroma in this process was uncovered by surgical isolation of mouse stromal cells of the *s.c.* compartment and subsequent co-culture with RenG2 cells, which resulted in the emergence of aCSCs sub-population. A cytokine multiplex array analysis using the conditioned medium of the co-cultured cells revealed the paracrine orchestrators of this stromal-induced dedifferentiation process.
Conclusions: The dedifferentiation process observed in the derivation of RenG2 cell line in the mice lumbar region was driven by paracrine signalization released from mice stromal cells. These results, more than highlighting the role of stromal cells in tumor formation, classify the dedifferentiation process as essentially chemical and specie-unspecific, as human cells can respond to mice cells-released molecules.

526 POSTER

Molecular signature and functional features of cancer stem cells isolated from prostate cancer tumors

E. Castellón[1], H. Contreras[1], C. Huidobro[1], R. Valenzuela[1], V. Castillo[1], F. Cifuentes[1]. *[1]University of Chile, Faculty of Medicine, Physiology and Biophysics Program*

Background: Prostate cancer (PCa) is a leading cause of male oncologic death wideworld. Metastasis, recurrence and hormone-drug resistance are the main issues of this disease. Cancer stem cells (CSCs) have been identified in several cancers including PCa and are believed to be responsible for cancer dissemination. For this reason, CSCs are being extensively studied, mainly in cell lines models, as possible therapeutic targets. In previous report we have correlated stem markers with Gleason grade using tissue micro array and have developed a method for isolation, enrichment and culture of CSCs from tumor explants.
Materials and Methods: CSCs were isolated from PCa tumor samples through combined methods of differential cloning capacity, sphere growing induction and Magnetic-Associated Cell Sorting (MACS). Molecular markers were determined by qPCR-array, immunocitochemistry and immunofluorescence. Functional characterization was assessed by migration, drug resistance, proliferation and apoptotic assays. An orthotopic model of PCa was established in NOD/SCID immuno-compromised mice for metastasis evaluation using in vivo imaging methods. Protocols were approved by institutional Ethics Commitees.
Results: Molecular signature of CSCs from tumor explants was CD133+/CD44+/ABCG2+/Integrin$\alpha 2\beta 1$+/Oct3/4+/SOX2+/CD24−. CSCs showed increased migration capacity, decreased proliferation an apoptosis rate and high drug resistance compared with a non-stem PCa cell population. Metastatic capacity included lung, liver and kidney dissemination.
Conclusions: Enriched populations of CSCs from PCa patients show a signature with high expression of stem genes. These genes may represent appropriate diagnostic and prognostic markers as well as new therapeutic targets for PCa. Orthotopic model of human PCa in NOD/CSID mice represent a suitable model to evaluate metastasis and recurrence of PCa.

527 POSTER

The binding of translationally controlled tumour protein to HDM2 is inhibited by Nutlin-3

G. Funston[1], W. Goh[2], S. Wei[2], Q. Tng[2], C. Brown[2], L. Tong[3], C. Verma[3], D. Lane[2], F. Ghadessy[2]. *[1]University of Cambridge, School of Clinical Medicine, Cambridge, United Kingdom; [2]p53 Lab, A STAR, Singapore, Singapore; [3]Bioinformatics Institute, A STAR, Singapore, Singapore*

Background: Translationally Controlled Tumour Protein (TCTP) has a number of key functions including an anti-apoptotic role. Recently, TCTP was shown to interact with the tumour suppressor p53 and the ubiquitin ligase HDM2, inhibiting auto-ubiquitination of the latter, thereby promoting p53 degradation. Nutlin-3, a small molecule known to promote apoptosis and cell cycle arrest by blocking HDM2-p53 binding, has also been shown to inhibit TCTP's effects on HDM2. We investigated the interaction between TCTP and HDM2, mapping their reciprocal binding sites and observing the effect of Nutlin-3 on their interactions.

Material and Methods: Interactions between HDM2 and TCTP and the effects of Nutlin-3 were investigated using pull-down assays with both *in vitro* expressed and recombinant proteins. Peptides derived from putative interaction sites were also used in pull-down experiments. Cellular interactions were assessed in the HCT116 $p53^{-/-}$ and H1299 $p53^{-/-}$ cell lines by immunoprecipitation. Western blotting was used to identify interacting proteins.
Results: Using C-terminal deletion analysis, we mapped TCTP's HDM2 interaction site to within residues 80–133 corresponding to basic domain 2. C-terminal deletion analysis of HDM-2 showed that the N-terminal region alone was sufficient for interaction with TCTP, with residues 44−65 proving key. This region is also crucial in HDM2's interaction with p53. A p53 peptide, corresponding to part of the p53 transactivation domain that interacts with HDM2's N-terminal region, was shown to compete with TCTP for HDM-2 binding. Nutlin-3 produced a dose responsive inhibition of TCTP-HDM2 binding *in vitro* and abrogated endogenous TCTP-HDM2 interaction.
Conclusions: The value of modulating p53−HDM2 interactions as a target for cancer therapeutics is an area of great activity. The discovery that TCTP has a binding site on HDM2 which overlaps with that of p53 and that they compete for binding *in vitro*, adds further complexity to the p53−HDM2 interaction model. We found that Nutlin-3, currently undergoing clinical trials, competes with TCTP for binding to the p53-binding cleft in the N-terminus of HDM2. This finding should influence future studies looking at the effects of Nutlin-3 and related compounds.
No conflict of interest.

528 POSTER

Senescence sensitivity of breast cancer cells is defined by positive feedback loop between CIP2A and E2F1

A. Laine[1], H. Sihto[2], C. Côme[3], M.T. Rosenfeldt[4], A. Zwolinska[5], V.M. Kähäri[6], K.M. Ryan[4], J.C. Marine[5], H. Joensuu[7], J. Westermarck[1]. *[1]University of Turku, Turku Centre for Biotechnology and the Department of Pathology, Turku, Finland; [2]University of Helsinki, Laboratory of Molecular Oncology Molecular Cancer Biology Program, Helsinki, Finland; [3]University of Turku, Turku Centre for Biotechnology, Turku, Finland; [4]The Beatson Institute for Cancer Research, The Beatson Institute for Cancer Research, Glasgow, United Kingdom; [5]VIB-KULeuven, Laboratory for Molecular Cancer Biology Center for Human Genetics and VIB11-Center for the Biology of Disease, Leuven, Belgium; [6]University of Turku and Turku University Hospital, The Department of Dermatology and MediCity Research Laboratory, Turku, Finland; [7]Helsinki University Central Hospital and University of Helsinki, The Department of Oncology, Helsinki, Finland*

Background: Senescence induction contributes to cancer therapy responses and is crucial for p53-mediated tumor suppression. However, whether p53 inactivation actively suppresses senescence induction has been unclear. CIP2A (cancerous inhibitor of protein phosphatase 2A) is an oncoprotein that has been shown to overexpress in several human cancer types. Nevertheless, the *in vivo* relevance of CIP2A in cancer has been obscure.
Materials and Methods: In order to study the role of CIP2A in breast carcinogenesis *in vivo* CIP2A heterozygous genetrap hypomorphic mutant mice were crossed with MMTVneu mice expressing oncogenic HER2. To study the role of CIP2A in either Nutlin-3-, vinorelbine- or p21-induced senescence stable expression of CIP2A in human breast cancer cell lines was introduced with adenoviral delivery. Also, two different cohorts of human breast cancer tumor samples were immunostained for CIP2A in order to investigate the expression levels and the prognostic role for CIP2A in breast cancer.
Results: Here, we show that E2F1 overexpression, due to p53 or p21 inactivation, promotes expression of human oncoprotein CIP2A, which in turn, by inhibiting PP2A (protein phosphatase 2A) activity, increases stabilizing serine 364 phosphorylation of E2F1. Several lines of evidence show that increased activity of E2F1-CIP2A feedback renders breast cancer cells resistant to senescence induction. Importantly, mammary tumorigenesis is impaired in a CIP2A-deficient mouse model, and CIP2A-deficient tumors display markers of senescence induction. Moreover, high CIP2A expression predicts for poor prognosis in a subgroup of patients with breast cancer treated with senescence-inducing chemotherapy.
Conclusions: Together, these results implicate the E2F1-CIP2A feedback loop as a key determinant of breast cancer cell sensitivity to senescence induction. This feedback loop also constitutes a promising prosenescence target for therapy of cancers with an inactivated p53−p21 pathway.
No conflict of interest.

529 POSTER

Rapid and extensive CD40-mediated cytotoxicity in colorectal carcinoma cells by death-receptor cross-talk: Identification of a novel apoptotic pathway involving TRAIL-induced, caspase-10-mediated cell death

A. Mohamed[1], C. Dunnill[1], H. Yagita[2], A.A. Melcher[3], N.T. Georgopoulos[1]. *[1]University of Huddersfield, Chemical and Biological Science, Huddersfield, United Kingdom; [2]Juntendo University School of Medicine, Department of Immunology, Tokyo, Japan; [3]University of Leeds, Leeds Institute of Molecular Medicine, Leeds, United Kingdom*

Background: Their ability to induce apoptosis in carcinoma cells renders TNF Receptor (TNFR) superfamily members promising targets for cancer therapy. However, clinical findings have highlighted the need for a better understanding of their underlying mechanisms of action, if these molecules are to be suitable for therapy. We have previously shown that CD40, unlike classical 'death' TNFR members, such as Fas, TNFR and TRAIL-R, does not have a death domain, yet can uniquely induce apoptosis in carcinoma but not normal cells by activation of an intrinsic caspase-9/JNK-mediated apoptotic pathway. CD40 ligation by its cognate ligand in a membrane-presented form (mCD40L) has the ability induce extensive apoptosis in colorectal carcinoma (CRC) cells, however the mechanism of death is unknown.
Materials and Methods: We used CRC lines that naturally express CD40 and cells in which *de novo* CD40 expression was engineered by retroviruses. CD40 was activated by mCD40L via co-culture with growth-arrested, mCD40L-expressing third party cells. Apoptosis was quantified by fluorescence- and luminescence-based assays detecting cell membrane integrity and caspase-3/7 activation. Expression and localisation of CD40 adaptor proteins and intracellular apoptotic mediators was determined by immunoblotting and combined with cell fractionation.
Results: mCD40L caused extensive and extremely rapid apoptosis (<6 hrs) in CRC cells. This is unlike our previous findings in other carcinoma types and suggested of a novel mechanism of action. We show that early after ligation there was rapid induction of TRAF3/6 adaptors (<1.5 hrs), phosphorylation of p38 and JNK (<3 hrs) and Bax/Bak recruitment to mitochondria (<6 hrs). We found induction of intracellular TRAIL, but not FasL, which in turn drives apoptosis by activation of caspase-10, but not caspase-8. The pro-apoptotic cross-talk is not only at the receptor level but also at an intracellular pathway level, as we detected tBid formation (1.5 hrs) and functional studies showed that activation of both caspase-10 and −9 was critical in apoptosis. Pharmacological blockade of p38/JNK abrogated TRAIL induction, Bax up-regulation, caspase activation and death.
Conclusion: We show for the first time that in CRC cells CD40 triggers rapid and dramatic cytotoxicity via a novel, multi-level cross-talk mechanism which involves p38/JNK-mediated TRAIL induction that activates the caspase-10 and −9 axes to cause extensive and rapid CRC cell death.

Concomitant detection indicates differential expression of miR-21 and PDCD4 in breast lesions

B. Nielsen[1], L. Christensen[2], T. Møller[1], K. Holmstrøm[3]. *[1]Bioneer A/S, Molecular Histology, Hørsholm, Denmark; [2]Rigshospitalet, Department of Pathology BBH Team, Copenhagen, Denmark; [3]Bioneer A/S, Biomarker Group, Hørsholm, Denmark*

Background: Programmed cell death 4 (PDCD4) or neoplastic transformation inhibitor, is a protein located in the nuclei of proliferating cells. A sequence motif in the 3'UTR of the PDCD4 mRNA contains a potential microRNA (miR)-21binding site, suggesting that PDCD4 biosynthesis is regulated at the post-transcriptional level by miR-21. Several studies of cultured cells have suggested that PDCD4 is an *in vivo*target of miR-21. If this is the case, PDCD4 and miR-21 must be present in the same cell population at a transitional stage. In breast cancer, PDCD4 is predominantly expressed in the cancer cells in contrast to miR-21, which is predominantly expressed in stromal cells. This differential expression, however, may not be explained by higher miR-21 activity of the latter, since PDCD4 may not be part of the regulatory repertoire of stromal cells. MiR-21, on the other hand, can be seen in some breast cancer cells, mostly from high-gradetumors, allowing an evaluation of the differential expression of PDCD4 andmiR-21.
Material and Methods: To explore this possibility, we developed a multiplex fluorescence assay (DAPI, FITC, Cy3 and Cy5), which combines immunohistochemistry with microRNA in situ hybridization for simultaneous detection of PDCD4, miR-21 and a cell-type specific marker in tissue sections. Seven high-grade in situ carcinoma/early invasive cancers were examined.
Results: In five cases, miR-21 was predominant in stromal cells, whilemiR-21 expression in cancer cells or benign epithelial cells was sparse.

In one case, miR-21 was seen in focal clusters of cancer cells, and in another casemiR-21 was seen exclusively in cancer cells. PDCD4 immunohistochemical staining was prevalent in both malignant and benign epithelial cells, and in the case with miR-21 positive cancer cells these were negative for PDCD4. In the case with focal clusters of miR-21 positive cancer cells, a miR-21 signal was accompanied by weakly stained or PDCD4-negative cells, where as PDCD4 positive cells were often miR-21 negative. Similar differential expression patterns were observed in both benign glands and in CIS foci, though co-expression of PDCD4 and miR-21 was occasionally seen.
Conclusion: We show that multiplex assays allow confirmatory evaluation of expression of microRNAs and their target protein *in vivo*, as here exemplified by PDCD4 and miR-21.
Conflict of interest: *Other substantive relationships: BSN, TRM and KHO are full term employee at the contract research organization (CRO): Bioneer A/S, Denmark*

531 POSTER

ROS-mediated, ASK1/MKK4-dependent apoptosis induced by CD40 ligation: Development and pre-clinical testing of a novel, highly pro-apoptotic, tumour cell-specific combinatorial therapy

C. Dunnill[1], A. Mohamed[1], J. Southgate[2], N.T. Georgopoulos[1]. *[1]University of Huddersfield, Chemical and Biological Sciences, Huddersfield, United Kingdom; [2]University of York, Jack Birch Unit of Molecular Carcinogenesis, York, United Kingdom*

Background: We were the first to show that CD40 ligation by membrane ligand (mCD40L), but not soluble agonist, triggers extensive apoptosis in carcinoma cells, whilst sparing their normal epithelial counterparts. However, the need to deliver the CD40 signal by presentation of membrane-bound agonist poses important therapeutic obstacles. Our aim was to identify the signalling mechanisms that render mCD40L tumour-specific and exploit this knowledge to design novel CD40-based therapies.
Materials and Methods: We used our human uro-epithelial model to culture normal, para-malignant and tumour-derived carcinoma cell lines. CD40 was activated by mCD40L (co-culture with mCD40L expressing third party cells) or soluble agonist (recombinant CD40L or agonistic antibody). Reactive oxygen species (ROS) generation was detected using H2DCFDA and apoptosis quantified using assays detecting membrane integrity and caspase activation. Expression and localisation of intracellular apoptotic mediators was determined by immunoblotting and the functional role of identified proteins confirmed by stable shRNA-mediated knockdown.
Results: CD40 ligation by mCD40L recruited TRAF3 to trigger phosphorylation of ASK1 and MKK4-mediated JNK activation and induced Bax/Bak-driven apoptosis in tumour cells. This was dependent on up-regulation of NADPH oxidase (Nox) and rapid elevation of intracellular ROS levels, as pharmacological inhibition of both Nox and ROS abolished CD40-killing. As mCD40L but not soluble agonist elevated ROS, we tested whether pharmacological interference with the related endogenous antioxidant pathway of Thioredoxin (Trx) could render the soluble agonist pro-apoptotic. We show that Trx blockade dramatically sensitised malignant, but not normal cells, to CD40 ligation by soluble agonists and induced death to a level equivalent to that observed for mCD40L and in a tumour cell-specific fashion.
Conclusion: Unravelling for the first time the molecular nature of the CD40 signalling 'black-box' has permitted the design of a combinatorial approach involving use of soluble CD40 agonist in parallel with sub-cytotoxic doses of Trx pharmacological inhibitor. The inhibitor has conferred the non-apoptotic soluble CD40 agonist the capacity to sufficiently trigger the required pro-apoptotic 'ROS threshold' and induce apoptosis. This novel approach is tumour-specific and as highly pro-apoptotic as mCD40L, thus negating the need for complex mCD40L delivery strategies.
No conflict of interest.

532 POSTER

BP-C1, a new therapeutic compound for the treatment of cancer

F. Fares[1], N. Azzam[1], B. Fares[1], A. Kirkin[2], K. Dzhandzhugazyan[2], P. Guldberg[2], S. Larsen[3], S. Lindkær-Jensen[4]. *[1]Haifa University, Human Biology, Haifa, Israel; [2]Danish Cancer Society Research Center, Cancer Genomics Laboratory, Copenhagen, Denmark; [3]University of Oslo and Meabco A/S, Centre for Life Sciences, Oslo, Norway; [4]Imperial College of Medicineand Meabco A/S, Department of Surgery and Cancer, London, United Kingdom*

Background: Breast cancer is the most frequent malignancy in women in western countries and despite progress in the treatment options such as surgery, radiation, chemotherapy and hormonal therapy it is still the leading cause of cancer death. BP-C1 is a novel anti-cancer complex of benzene-poly-carboxylic Acids with Cis-diammineplatinum (II) developed by Meabco ltd, Denmark. The aims of the present study are to give a clinical overview and the preclinical mechanism of action data obtained so far.
Methods: The effect of BP-C1 on growth of human breast cancer cells, MCF7 and T47D, was studied. Cells were exposed to different doses of BP-C1,and cell viability, toxicity (LDH release), cell cycle, apoptosis, caspase activation and gene expression were examined. The effects on immune modulating properties were studied *in vitro* and *in vivo*. A Phase I dose escalating study in 15 metastatic breast cancer patients (Stage IV) was conducted to determine treatment routine, Maximum Tolerated (MTD) and Minimum Efficient Dose (MED) of BP-C1.
Results: BP-C1 reduced cell viability by 90%, induced apoptosis by activation of caspases 8 and 9, increased the pro-apoptotic genes and lowered levels of mRNA transcripts of some inhibitory apoptotic genes. Cytokines were significantly increased by BP-C1: IL-1beta, TNF-alpha, GM-CSF, IFN-gamma, and IL-25. IL-6 production was also found. The primary targets for the reagent are monocytes. No toxicity of BP-C1 was seen after IM administration daily during a period of 32 days. BP-C1 can safely be administrated intramuscularly daily during a period of 32 days. Based on the RECIST criteria, 7 patients were classified as responders: 1 complete response, 2 partial responses and 4 stable disease. The cumulative MTD is most probably larger than 1.12 mg/kg/Body Weight [BW] and MED estimated to 0.96 mg/kg/BW.
Seven out of 15 patients were classified as responders. The cumulative MTD is most probably larger than 1.12 mg/kg/BW and MED estimated to 0.96 mg/kg/BW.
Conclusion: BP-C1 induced apoptosis through activation of the extrinsic (death receptors) and the intrinsic (mitochondrion) apoptotic pathways. BP-C1 activated multiple immunological mechanisms of anti-tumour response. These findings have been confirmed in patients and may lead to the development of new therapeutic strategies for treatment of advanced cancers using BP-C1.
No conflict of interest.

533 POSTER

Regulation of breast cancer cell growth and migration by the steroid-converting enzyme 17-beta-HSD 1

J. Aka[1], S.X. Lin[2]. *[1]Goodman Cancer Research Centre, McGill University, Montreal QC, Canada; [2]CHUQ Research Centre, Laval University, Quebec QC, Canada*

Background: Estradiol (E2), the most potent estrogen, stimulates breast cancer cell growth, whereas the androgen dihydrotestosterone (DHT) has shown an antiproliferative effect. In breast cancer cells, E2 is principally synthesized by human 17beta-hydroxysteroid dehydrogenase type 1 (17-beta-HSD 1), a steroid-converting enzyme that also inactivates DHT. Here, the role of 17-beta-HSD 1 in the regulation of breast cancer cell proliferation and its impact on cell migration are shown.
Material and Methods: RNA interference technique was used in conjunction with a steroidal inhibitor of 17-beta-HSD 1 to establish its direct role in DHT and E2 level modulation in breast cancer cell lines T47D and MCF-7 and the regulation of cell proliferation was evaluate by MTT assay. 17-beta-HSD 1 was further stably transfected in MCF-7 and the effect of the enzyme on MCF-7 cell migration was verified by a wound-healing assay using the generated cells overexpressing 17-beta-HSD 1 and the wild type MCF-7 cells.
Results: 17-beta-HSD 1 expression is negatively correlated to DHT levels in breast cancer cell but positively correlated to E2 levels and cell proliferation. 17-beta-HSD 1 inhibition reduces DHT inactivation, increasing the antiproliferative effect by DHT in T47D cells after 8-day treatment. Thus, 17-beta-HSD 1 up-regulates BCC growth by a dual action on estradiol synthesis and DHT inactivation. Increasing 17-beta-HSD 1 expression lead to an increase by 3.6 times of the mRNA transcript and the protein expression of the metastasis suppressor gene nm23-H1 and the expression of the two enzymes are closely correlated. Intriguingly, 17-beta-HSD 1 expression is positively correlated with the migration of the breast cancer cell line MCF-7, revealing its role as a positive regulator of cell migration, contrary to nm23-H1.
Conclusions: In spite of its positive regulation of the antimetastatic gene *NM23*, 17-beta-HSD 1 increases cell migration and significantly contributes to the proliferation of some breast cancer cells. These findings strongly support the rationale for inhibiting 17-beta-HSD 1 in breast cancer therapy.
No conflict of interest.

Negative regulation of death receptors expression on cancer cells by epithelial–mesenchymal transition (EMT)

E. Curtit[1], A. Asgarova[1], D. Guenat[2], M. Jary[3], S. Kim[4], F. Fein[5], E. Dobi[3], O. Adotevi[6], Y. Godet[2], C. Borg[6]. *[1]University of Franche Comté, Unité Mixte de Recherche 1098, Besancon, France; [2]Etablissement Français du Sang de Bourgogne Franche-Comté, Unité Mixte de Recherche 1098, Besancon, France; [3]University Hospital of Besançon, Oncology, Besancon, France; [4]University Hospital of Besançon, Oncology-Clinical Investigational Center-Biotherapy-506, Besancon, France; [5]University Hospital of Besançon, Gastroenterology, Besancon, France; [6]University Hospital of Besançon, Oncology-Unité Mixte de Recherche 1098, Besancon, France*

Background: Death receptors (DR) are involved in the induction of TRAIL or Fas-mediated extrinsic apoptosis. DR agonist antibodies are currently assessed in clinical trials in pancreatic carcinoma. Tumor cells, which undergo epithelial–mesenchymal transition (EMT), acquire increased capacities of proliferation, invasion and have the ability to generate metastases. We have previously shown that Neuropilin-2 (NRP-2) promotes transforming growth factor-β1-mediated EMT and tumor cell proliferation. In the current study, we investigated the influence of NRP2-mediated EMT in immune evasion.
Methods: pCDNA3.1 plasmids were used to induce NRP2 or snail gene expression in HT29 or BxPC3 cells. Bes-PAC cell lines are tumor cells derived from patient's ascites in Besançon university hospital. All cell lines were cultured in DMEM complete medium. DR4, DR5, Fas antibodies were purchased from Diaclone-biotech. Anti-E-cadherin or Vimentin were purchased from RnDsystem.
Results: The sensitivity of pancreatic and colorectal carcinoma to DR agonist antibodies was investigated in vitro. By contrast NRP-2-negative cell lines, NRP-2^+ cancer cells were resistant to apoptosis induced by DR agonists. Then, the expression of DR on pancreatic cancer cells was investigated by western blot and flow cytometry. A negative correlation was observed between DR and NRP2 expression. The transfection of NRP2 in HT29 cell lines induced a complete loss of DR expression. Since NRP-2 mediates EMT, we decided to analyse the precise role of EMT in DR regulation. Then, EMT was induced by gene transfer of snail in epithelial cell lines (BxPC3 and Bespac07). Snail-induced EMT was also correlated to a complete loss of DR expression in these cell lines. Considering that Snail is not expressed in NRP2^+ cells, we decided to investigate the role of p53 and the NF-κB subunit RelA, two transcriptional regulators of DR expression. We first observed that EMT induces in all cell lines tested a loss of both p53 and RelA. However, the restoration of p53 and RelA expression in NRP2^+ cell lines did not restore DR expression.
Conclusion: These results show that EMT represses DR expression in a p53 and RelA independent manner. The negative regulation of death receptors DR4, DR5 and Fas by EMT can be identified as a mechanism of resistance to death receptors based therapies; this should be taken into account to better identify patients eligible for DR agonist therapies.

535 POSTER

Regulation and role of CCAAT/enhancer binding protein during differentiation of intestinal epithelial cells

A. Sade Memisoglu[1], S. Banerjee[1]. *[1]Middle East Technical University, Biological Sciences, Ankara, Turkey*

Background: The molecular mechanisms of differentiation of intestinal epithelial cells, is poorly understood and disruption of this balance may result in neoplastic transformation and malignant growth. The family of CCAAT/*E*nhancer *B*inding *P*rotein (C/EBP) transcription factors is implicated in cellular growth, differentiation, inflammation and development and control differentiation in several cell types. The involvement of these transcription factors in intestinal differentiation is not known. The aim of this study is to elucidate the transcriptional, translational and post-translational regulation of C/EBP proteins and their role during the course of intestinal epithelial differentiation.
Materials and Methods: The colorectal cancer cell line Caco-2, a well established differentiation model, was used. The expression of C/EBP genes was analyzed using publicly available microarray data. The protein levels and the phosphorylation status of translation initiation factors were checked by Western blot. The activity of C/EBP was determined by luciferase reporter and chromatin immunoprecipitation assays. Cytoplasmic calcium levels were determined fluorometrically by calcium binding with Fura-2AM.
Results: Microarray data analyses of Caco-2 differentiation have shown that C/EBPα and β expression increases during differentiation. The major regulatory mechanism for C/EBP proteins is translational in which several isoforms are produced from alternative translation initiation sites. The ratio of the two isoforms C/EBPβ1 to C/EBPβ3 was found to be decreasing in differentiated Caco-2 cells. This change could be explained by the increase in the active translation initiation factor eIF2α. The activity of C/EBP was shown to increase together with an upregulation of its target genes. The post-translational regulation was investigated by determining SERCA-3 (less affinity to calcium) levels and was shown to decrease. This lead to an increase in the cytoplasmic calcium levels which in turn may cause activation of calcium dependent calmodulin kinase II, hence increase in C/EBP activity.
Conclusions: In this study the involvement of C/EBP proteins in intestinal epithelial differentiation was investigated for the first time. We believe that the findings of this research would reveal important mechanisms underlying the intestinal differentiation-dedifferentiation processes and provide some candidate therapeutic targets for the prevention and treatment of colorectal cancer.
No conflict of interest.

536 POSTER

Modulation of genes expression as an effective tool for enhancing the antitumor effect of death ligands. Novel IFN-gamma − TRAIL/Apo2L fusion protein

B. Zerek[1], P. Rózga[1], A. Pieczykolan[1], M. Galazka[1], K. Bukato[1], S. Pawlak[1], M. Szymanik[1], A. Jaworski[1], W. Strozek[1], J. Pieczykolan[1]. *[1]Adamed Ltd, Drug Discovery, Warsaw, Poland*

Background: Interferon gamma (IFN-γ), a dimeric soluble cytokine, is an representative of type II interferons family. The molecule is secreted by NK, NKT, Th1, Tc and dendritic cells. IFN-γ ligand binds to two types of IFN-γ receptors and activates the JAK-STAT pathway.
IFN-γ anti-tumor action is mediated through the immunomodulatory function which results from the action of many different classes of IFN-stimulated genes responsible for antigen processing, leukocyte trafficking and tumor cytotoxicity. IFN-γ stimulates antibody-dependent toxicity and potentiates the process of connecting the cells with tumor cells. Additionally, IFN-γ is able to induce an anti-proliferative effects and activates caspases, thereby inducing apoptosis in many cancer cell lines. IFN-γ may cause proapoptotic Bak upregulation, cytochrome C release and Bax translocation. However, despite limited efficacy, existing therapies based on IFN-γ are not satisfying enough to be used in the treatment of cancer diseases.
What was important, in many tumor lines showing resistance to TRAIL-stimulated apoptosis, interferon gamma acted synergistically, contributing to their sensitivity to TRAIL. Additionally, one of IFN-γ effects is an intense stimulation of human monocytes to produce endogenous TRAIL protein.
We developed the novel fusion protein AD-O64.3 consists of artificial dimer of IFN-γ, recombinant variant of TRAIL fragment and sequences recognized by tumor-specific proteases (MMP's, uPa) in between.
Materials and Methods: AD-O64.3 protein was expressed in *E.coli* and purified by IEC. Obtained molecule was characterized biochemically and biophysically using CD spectroscopy, SEC-HPLC, protease cleavage and MTT cell cytotoxicity assays. The proapoptotic effect was tested with using active caspase 3 staining. For *in vivo* potential we examined the efficacy on mice xenograft models of human renal cell carcinoma (ACHN), human colon adenocarcinoma (SW620) and human hapatoma (PLC/PRF/5) cell lines.
Results: Obtained protein has well-defined secondary and quarternary structure and verified mechanism of action. The molecule showed *in vitro* specific cytotoxic effect on various cancer cell lines (IC50 below 0.1 ng/ml). New protein showed very low activity on normal cells. *In vivo* AD-O64.3 showed promising effect displaying significant tumor growth inhibition.
Conclusions: We developed very promising molecule with high pro-apoptotic activity showing synergistic effect with TRAIL/Apo2L.
No conflict of interest.

The AD-O56.9 − fusion of TRAIL/Apo2L with a membrane permeable peptide as a novel anticancer therapeutic

J. Pieczykolan[1], K. Poleszak[1], P. Rózga[1], A. Pieczykolan[1], M. Galazka[1], K. Bukato[1], M. Szymanik[1], A. Jaworski[1], S. Pawlak[1], B. Zerek[1]. *[1]Adamed Ltd, Drug Discovery, Warsaw, Poland*

Background: The tumor necrosis factor (TNF)-related apoptosis-inducing ligand (TRAIL/Apo2L) is a member of the TNF superfamily that initiate apoptosis through the activation of their death receptors. The ability of TRAIL/Apo2L to selectively induce apoptosis of tumor cells but not normal cells makes it an attractive agent for cancer therapy. However, many cancer types have developed resistance mechanisms, such as dysfunctions of proapoptotic proteins.

Here, we report the design of a novel molecule AD-O56.9, which is composed of the soluble domain of TRAIL/Apo2L fused with a cationic alfa-helical (KLAKLAK)2 peptide, that is known to induce cancer cell death by membrane disruption. Because this peptide is not efficiently internalized we fused it with a cell penetrating moiety. Additionally, the TRAIL domain and the (KLAKLAK)2 peptide are linked with a sequence motif recognized by MMPs and uPa proteases, which enables cleavage and release of the proapoptotic peptide.
Materials and Methods: MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide) cell-viability assays was used to assess AD-O56.9-mediated killing of carcinoma cells. Flow-cytometric analysis were used to evaluate the effects of AD-O56.9 on mitochondrial membrane integrity and caspase 3 activation. The expression of Bid was determined by Western Blot analysis. The tumoricidal activity of AD-O56.9 was evaluated in NOD SCID mice bearing different types of cancer xenografts.
Results: AD-O56.9 exhibited cytotoxic effect on various cancer cell lines, including TRAIL-resistant cell lines but showed no toxic effect on normal cells. In relatively sensitive cell line (NCI-H460) and TRAIL-resistant cell line (A549) AD-O56.9 caused strong depolarization of mitochondrial membrane. Importantly, administration of AD-O56.9 caused significant regression of TRAIL sensitive human pancreatic carcinoma MIA PaCa-2 and TRAIL resistant human hepatocellular carcinoma HepG2 grown as xenografts in NOD SCID mice.
Conclusions: Our novel fusion protein AD-O56.9 is able to induce apoptosis in many cancer cell lines, even TRAIL resistant and causes tumor regression in mice bearing human cancer cells.
No conflict of interest.

538 POSTER

TRAIL/Apo2L resistant cancer cells can be sensitized to TRAIL by targeted delivery of peptides derived from BH3 domain of human Bid

A. Pieczykolan[1], P. Rózga[1], S. Pawlak[1], M. Galazka[1], K. Bukato[1], W. Strozek[1]. [1]*Adamed Sp. z.o.o, Biology, Czosnow n. Warsaw, Poland*

Background: Clinical trials of recombinant human TRAIL (rhTRAIL) and its agonistic monoclonal antibody (MAb) against DR4 and DR5 have established their safety and tolerability, but their clinical utility is limited by the resistance of many cancers to TRAIL-induced apoptosis. Combinatorial therapies of TRAIL/Apo2L in conjunction with other anticancer agents such as chemo or radiotherapy amplify the activities of these agents and widen the therapeutic window by overcoming tumor resistance to apoptosis and driving cancer cells to self-destruction.
Bid, a pro-apoptotic member of the Bcl-2 family, is a mediator of mitochondrial damage induced by caspase-8. Bid induces apoptosis by binding prosurvival Bcl-2 protein and directly neutralizing its function. Bid may also promote apoptosis in a way other than inhibiting Bcl-2 proteins by oligomerization and insertion of Bax and Bak into the outer mitochondrial membrane.
To overcome TRAIL resistance, we created chimeric protein with enhanced proapoptotic and antitumor activity. AD-O57.4 is a fusion protein consisting of a short peptide derived from Bid protein linked to an amino terminus of soluble TRAIL\Apo2L domain. The linking sequence contains additional motif recognized by MMP and uPa proteases that enables cutting-off of the proapoptotic peptide in tumor environment.
Materials and Methods: Cytotoxic activity was examined using a MTT assay. Apoptotic markers and mitochondrial membrane potential change was analyzed using flow cytometry methods. Colocalization of chimeric molecules with cell surface receptors was performed by confocal microscopy. *In vivo* antitumor activity was tested in the xenograft models of human colorectal carcinomas (Colo205, HCT116 and SW620). Safety of AD-O57.4 was confirmed on primary human and cynomolgus hepatocytes.
Results: AD-O57.4 in comparison to TRAIL/Apo2L showed very high cytotoxic activity against most of the analyzed cancer cell lines and it was able to overcome TRAIL resistance in cancer cell lines *in vitro*. Analysis of caspase 3 and 9 activation and expression of Bid protein showed rapid induction of apoptosis by AD-O57.4 in comparison to TRAIL\Apo2L. AD-O57.4 induced mitochondrial depolarization both in sensitive and TRAIL-resistant cell lines. Strong antitumor activity of AD-O57.4 fusion protein was also confirmed in xenograft models. AD-O57.4 causes complete remission in Colo205 and significant regression in HCT116 and SW620 xenograft models.
Conclusion: We demonstrated that AD-O57.4 protein has broad *in vitro* cytotoxic activity against panel of cancer cell lines and *in vivo* antitumor activity in xenograft models. The use of a peptide derived from Bid protein causes a significant increase in TRAIL\Apo2L activity. Our fusion molecule connecting extrinsic and intrinsic apoptotic pathways restores susceptibility to TRAIL/Apo2L induced apoptosis.

Docosahexaenoic acid-induced reactive oxygen species correlate with apoptotic cell death through MAPK activation in human ovarian cancer cells

S. Jeong[1], K. Jing[1], S. Shin[1], S. Kim[1], J.I. Park[2], G.R. Kweon[2], S.K. Park[2], W.H. Yoon[2], B.D. Hwang[2], K. Lim[3]. [1]*Chungnam National University Medical School, Biochemistry and Infection Signalling Network Research Center, Daejeon, Korea;* [2]*Chungnam National University Medical School, Biochemistry, Daejeon, Korea;* [3]*Chungnam National University Medical School, Biochemistry and Cancer Research Institute and Infection Signalling Network Research Center, Daejeon, Korea*

Background: The role of Omega-3 polyunsaturated fatty acids (ω3-PUFAs) in cancer prevention has been demonstrated; however, the exact molecular mechanisms underlying the anticancer activity of ω3-PUFAs in ovarian cancer remain unclear. In the present study, we investigated the effect of docosahexaenoic acid (DHA), a ω3-PUFA, in ovarian cancer cells and showed its cytotoxicity against PA-1 ovarian cancer cells.
Material and Methods: The effects of DHA on cell proliferation and cell cycle were examined by MTT assay and FACS. DHA-induced apoptosis was analysed using the Annexin V staining, TUNEL assay, caspase activity assay, and western blot. Dihydroethidium and MitoSOX were used in PA-1cells for reactive oxygen species (ROS) measurement, and the effect of DHA on mitochondrial function by measuring oxygen consumption rate and tetramethylrhodamine, ethyl ester staining.
Results: DHA treatment inhibited the proliferation of PA-1 cells in a dose-dependent manner and increased caspase-3 activity, the number of AnnexinV-positive cells and TUNEL-positive cells, and the proportion of sub-G1 cells, suggesting that DHA induces apoptotic cell death in ovarian cancer cells. Western blot and immunocytochemistry assays showed that DHA significantly increased the levels of phospho-extracellular signal-regulated kinase (ERK), phospho-c-jun N-terminal kinase (JNK), and phospho-p38 in the cytosol and nucleus. Knockdown of ERK, JNK, and p38 by small interfering RNAs reduced apoptosis induced by DHA, indicating that the pro-apoptotic effect of DHA is mediated by mitogen-activated protein kinase (MAPK) activation in ovarian cancer cells. In addition, MAPK activation was associated with the production of ROS induced by DHA. The ROS scavenger N-acetyl-L-cysteine (NAC) significantly blocked the phosphorylation of ERK, JNK, and p38 triggered by DHA.
Conclusions: Together, these results indicate that DHA induces ROS production and that ROS-dependent MAPK activation plays a role in DHA-induced cell cytotoxicity in human ovarian cancer cells.

540 POSTER

Apoptosis induction and caspases activation by low voltage electric pulses

N. Matsuki[1], S. Ichiba[2]. [1]*Okayama University of Science, Okayama, Japan;* [2]*Okayama University School of Medicine, Emergency and Critical Care Medicine, Okayama, Japan*

Background: Electric fields have been widely used in a variety of biotechnical applications. Electroporation has been investigated as a novel anticancer therapy, known as electrochemotherapy. However, high-intensity electric fields may also cause undesirable side effects. On the other hand, previous studies reported that a moderate electric field avoided severe cell damage and induced apoptosis. However, few studies have examined apoptosis induced by low-voltage electric pulses (LVEPs).
Material and Methods: *Cell culture:* The B16 (mouse malignant melanoma) cells were cultured in RPMI-1640 medium containing 10% fetal bovine serum at 37ºC under 5% CO_2.
Exposure to LVEPs(Low voltage electric pulses): Cells were re-suspended in RPMI-1640 at a concentration of $2-3\times10^6$ cells/ml. The cell suspensions (400 μl) were transferred to electroporation/fusion chambers with 2-mm gaps. Relatively low-voltage, long-duration (7.5 V/mm, 100–2000 ms) square wave consecutive pulses (1−3 pulses; duty ratio = 0.5) were applied using a function generator.
Assay: A flow cytometry apoptosis detection kit (Annexin V-FITC/7-AAD) was used to identify apoptotic and necrotic cells. Caspase-3, -8 and -9 activities were measured using an activity detection kit with FITC fluorescence by a flow cytometry.
Results: *Induction of apoptosis and cell death:* Apoptosis occurred in $2.8\pm0.3\%$ of the control cells, $3.2\pm0.7\%$ of cells exposed to 100-ms triple pulses, $7.2\pm0.5\%$ of cells exposed to 500-ms triple pulses, $10.5\pm1.6\%$ of cells exposed to 1000-ms pulses, and $7.4\pm0.4\%$ of the cisplatin-treated cells.

Caspase-3, -8 and -9 activity: The relative %-fluorescence intensity of cells exposed to electric pulses increased 142.0±8.3% for caspase-3, 131.4±5.8% for caspase-8, and 141.5±9.4% for caspase-9.
Effects of pan-caspase inhibition on apoptosis: Apoptosis occurred in 2.3±0.6% of the control cells, 3.8±1.4% of the cells incubated with Z-VAD-FMK, 9.1±1.0% of the cells exposed to electric pulses, 5.2±1.3% of the cells exposed to electric pulses with Z-VAD-FMK.
Conclusions: LVEP-induced apoptosis was achieved through caspase-8 and −9 activation and subsequent caspase-3 activation (*i.e.,* both the cell death receptor and mitochondrial pathways). Moreover, long-duration LVEPs caused only mild cell damage, such that the apoptosis ratio (apoptosis/total cell death) in electric pulse-treated cells was similar to that in non-treated control cells. Therefore, LVEP treatment may be a valuable anticancer therapy. Though the mechanism of LVEP-induced apoptosis unclear, it may result from membrane dysfunction that disrupts the transport of Ca^{2+} and extracellular substances, which are potent caspase activators.

CDC 25A regulating NFAT translocation promotes TGF-β mediated cell proliferation in metastatic breast cancer cells

S. Sengupta[1], S. Jana[1], A. Bhattacharyya[1]. [1]*University of Calcutta, Zoology, Calcutta, India*

Background: Transforming growth factor-β (TGF-β), a multifunctional cytokine triggers metastasis by regulating epithelial to mesenchymal transition (EMT), a concomitantly associated phenomenon. Our main objective was to exhibit the TGF-β mediated cell proliferative mechanism where cell proliferation and EMT are maintained simultaneously.
Materials and Methods: Cell culture: MDA-MB231 and MDA-MB435s cell lines were used.
Methods: MTT and Br-dU incorporation assay, Flowcytometry, Immunofluorescence, Nuclear and Cytoplasmic extract preparation and Immunoblotting, Transfection of si RNA and RT-PCR were applied.
Results: MTT and Br-dU incorporation assay explained TGF-β mediated cell proliferation on MDA-MB231 and MDA-MB435s cells for 48 and 72 h of exposure. Upregulation of Cyclin D1, CyclinE and CDK2 and CDK4 expression both at gene and protein level reflected cell proliferation. Immunoblot results expressed the up regulation of phospho Smad2, NFAT and CDC 25A and RT-PCR results also have the resemblance with immunoblot results. Silencing of NFAT and Smad2 separately, favoured the apoptosis of cells with 48 h exposure of TGF-β. Immunofluorescence showed NFAT translocation from cytoplasm to nucleus with exposure of TGF-β for 48 h. NFAT translocation continued in presence of calcineurin pathway blocker (cyclosporine A) also. Whereas, silencing of CDC 25A expressed the inhibition of TGF-β mediated NFAT translocation and also cell proliferation. Silencing of NFAT and Smad2 separately, illustrated reduced gene expression of CDK2, CDK4 and Cyclin E for both the cases and only Smad2 silencing showed reduced gene expression of CDC 25A.
Conclusions: All of the above observations direct to summarize that TGF-β regulating CDC 25A in a Smad2 dependent way causes the translocation of NFAT. Within the nucleus, NFAT and Smad2 function cooperatively as a transcription factor and regulate the cell proliferative genes Cyclin E, CDK2 and CDK4. This study has another consequence that in absence of calcineurin pathway NFAT translocation is also possible through the CDC 25A activation.

Omega-3 polyunsaturated fatty acids induces cell death through apoptosis and autophagy in human oral cancer cells

S. Shin[1], T.W. Hong[2], K. Jing[1], S. Jeong[1], S. Kim[1], J.I. Park[2], G.R. Kweon[2], S.K. Park[2], B.D. Hwang[2], K. Lim[3]. [1]*Chungnam National University Medical School, Biochemistry and Infection Signalling Network Research Center, Daejeon, Korea;* [2]*Chungnam National University Medical School, Biochemistry, Daejeon, Korea;* [3]*Chungnam National University Medical School, Biochemistry and Cancer Research Institute and Infection Signalling Network Research Center, Daejeon, Korea*

Background and aims: In the United States, about 40,000 new cases of oral cancer are diagnosed and nearly 8,000 patients die from it each year. Omega-3 polyunsaturated fatty acids (ω3-PUFAs) have been found to have anticancer effects in a variety of cancer cell lines and animal models, but their effect in oral cancer remains unclear. This study was designed to examine the effect of ω3-PUFAs on oral cancer and the molecular mechanism of their action using in vitro and in vivo models.
Material and Methods: SCC4 and SCC9 oral cancer cell lines were treated with ω3-PUFAs, and cell viability, apoptotic parameters as well as autophagic activity were examined. Additionally, to investigate the effect of ω3-PUFAs endogenously, Fat1 stable cells of SCC9 (SCC9-fsc), which express ω3-desaturase and thus contain a higher amount of endogenous ω3-PUFAs, were generated by stably transfection and selection, and the cell growth of the SCC9-fsc was compared with Control vector expressing cells (SCC9-fcc) both in vitro and in vivo.
Results: We found that exposure SCC4 and SCC9 human oral cancer cells to docosahexaenoic acid (DHA, a kind of ω3-PUFA) resulted growth inhibition in a dose- and time-dependent manner. Meanwhile, in addition to the elevated levels of apoptotic markers such as cleaved PARP, subG1 portion and TUNEL-positive nuclei, DHA led to autophagic vesicle formation and an increase in autophagic flux, indicating the involvement of both apoptosis and autophagy in the inhibitory effects of ω3-PUFAs on oral cancer cells. Further experiments revealed that the apoptosis and autophagy induced by DHA were linked to reactive oxygen species (ROS) overproduction and inhibition of Akt/mTOR signalling molecules. Moreover, SCC9-fsc showed retarded proliferation and colony formation capacity and invasion compared to control SCC9-fcc. The tumour size and volume of SCC9-fsc implanted into nude mice were also significantly inhibited with increases in the cell death index.
Conclusions: We propose that ω3-PUFAs induce apoptosis- and autophagy-associated cell death through ROS and Akt/mTOR signalling pathway in oral cancer cells. Thus, utilisation of ω3-PUFAs may represent a promising therapeutic approach for chemoprevention and treatment of human oral cancer.

The effects of 2100 MHz UMTS signal of 3G GSM-like radiation on cell viability and nuclear morphology in hepatocellular carcinoma cells

G. Kismali[1], E. Ozgur[2], G. Guler[2], B.M. Balkan[3], T. Sel[1], N. Seyhan[2]. [1]*Ankara University, Biochemistry, Ankara, Turkey;* [2]*Gazi University, Biophysics, Ankara, Turkey;* [3]*Mehmet Akif Ersoy University, Biochemistry, Burdur, Turkey*

Background: Widespread increase of mobile telecommunication services has mainly increased the amount of radiofrequency radiation (RFR) in public and residential areas. The carrier frequencies of the 2G were 900 MHz and 1800 MHz frequency band modulated as Global System for Mobile Communication (GSM) whereas 3G frequencies are 2100 MHz frequency band with The Universal Mobile Telecommunication System (UMTS) signal modulation. Even though there is no consensus about possible carcinogenic effect of RFR exposure below present guidelines, there have been concerns that it may alter cellular functions in a way that increases the risks of cancer. Until now few in vivo and in vitro studies have been published by employing UMTS signal and the results are still inconclusive. For this purpose, we aimed to investigate whether exposure to 2100 MHz UMTS signal for cellular phones induces to alter cell viability and the nuclear morphology.
Material and Methods: Quick cell proliferation analyses were done after the HepG2 cells exposed to RFR during 1 hour and 2 and 3 hours. Nuclear morphology was investigated by DAPI staining. Furthermore, supernatant levels of Lactate dehydrogenases (LDH), Glucose (GLU) were detected as biochemical markers of cell viability.
Results: There were slight increase in the cell viability of the RFR-exposed cells in sham-exposed and control groups but these increases were not statistically significant. LDH and glucose levels were correlated with each other and there is no significant difference in RFR-exposed cells with respect to sham-exposed and control cells.
Conclusions: Although our results are consistent with previous published data; we should mention that they are not directly comparable due to the substantial difference in the employed modulation (3G vs. 2G technologies). In addition to this, it has been suggested that biological effects of RF radiation may be related not only to the frequency and the amplitude of the field, but also the type of modulation applied.

Chemotherapy for adenocarcinomas with neuroendocrine differentiation: A study in two pancreatic cancer cell lines with different somatostatin receptors expression

R. Gradiz[1], A.C. Mamede[2], A.M. Abrantes[3], J.E. Casalta-Lopes[3], A.C. Gonçalves[4], A.B. Sarmento-Ribeiro[4], M.F. Botelho[3], A. Mota-Pinto[1]. *[1]General Pathology Service, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [2]CICS − Health Sciences Research Centre, University of Beira Interior, Covilhã, Portugal; [3]Biophysics Unit − IBILI, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [4]Applied Molecular Biology and Hematology Group, Faculty of Medicine of University of Coimbra, Coimbra, Portugal*

Background: Pancreatic cancer, the fourth leading cause of cancer worldwide, is very resistant to surgery, chemotherapy and radiotherapy. Due to pancreatic cancer resistance to chemotherapy, it's important to study the single effects of chemotherapy in this type of cancer in order to improve its effects when allied with other treatment strategies.
Material and Methods: All studies were performed in two human pancreatic duct adenocarcinoma cell lines with different somatostatin receptors (SR) expression: MIA PaCa-2 (SR++) and Panc-1 (SR+). Cells were incubated with different concentrations of 5-FU or docetaxel for different times (24, 48, 72 or 96 h) and cell proliferation was evaluated through MTT assay. Through obtained dose-response curves, half maximal inhibitory concentration (IC50) for 5-FU and docetaxel was achieved. Cells were incubated with drugs IC50 and after 72 h, cell viability/death was analysed by flow cytometry using annexin V and propidium iodide.
Results: IC50 determined for each drug at each time in both cell lines were presented in table 1. After 5-FU IC50 incubation, MIA PaCa-2 and Panc-1 cell death reached 47.7% and 23.17%, respectively. Cell death in both cell lines submitted to 5-FU treatment occurred mainly by apoptosis and necrosis. Docetaxel IC50 induced 62.4% of cell death (mainly by apoptosis) in MIA PaCa-2, whereas Panc-1 cell death (33.5%) occurs either by apoptosis and necrosis.
Discussion: 5-FU and docetaxel inhibit cellular proliferation in a dose dependent-manner. Both cell lines are more sensible to docetaxel than to 5-FU. Docetaxel induces a higher percentage of cell death when compared to 5-FU. Docetaxel must be considered as a serious candidate for the treatment of adenocarcinomas with neuroendocrine differentiation.
No conflict of interest.

Gossypol: An option in cholangiocarcinoma therapy?

A.F. Brito[1], A.M. Abrantes[1], M. Ribeiro[2], J. Casalta-Lopes[1], A.C. Gonçalves[3], A.B. Sarmento-Ribeiro[3], J.G. Tralhão[4], M.F. Botelho[1]. *[1]Biophysics Unit − IBILI, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [2]Life Sciences Department, Faculty of Science and Technology of University of Coimbra, Coimbra, Portugal; [3]Applied Molecular Biology and Hematology Group, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [4]Surgical Department − Surgery A, Coimbra University Hospitals, Coimbra, Portugal*

Background: Cholangiocarcinoma (CC) is the second primary liver tumor most common with limited therapeutic options, with similar incidence and mortality rates. CC is highly resistant to chemotherapy and radiotherapy, which is due in part to resistance to apoptosis which is related to an Bcl2 over-expression. Gossypol, a natural compound extracted from the cotton plant has been shown potential to inhibit the growth of several tumor cell lines. This compound is a potent inhibitor of Bcl2 family of anti-apoptotic proteins. This study aims to test the anti-proliferative effect of gossypol in a human CC cell line, study the type of cell death induced by this compound as well as to check its effect on Bax and Bcl2 expression. We also want to evaluate the effect of gossypol on cell cycle.
Methods: The human CC cell line used was TFK1. The cells were incubated with gossypol in several concentrations. After 24, 48, 72 and 96 hours of incubation, cell proliferation was evaluated by MTT assay. The cell survival factor was evaluated using the clonogenic assay, after 12 days of incubation with gossypol. The type of cell death and the percentage of live cells were assessed by flow cytometry using double staining with Annexin-V and propidium iodide. Bax and Bcl2 expression and cell cycle was also assessed by flow cytometry.
Results: Through the results obtained by the MTT assay, it was found that gossypol inhibits cell proliferation of TFK1 cells on a time and concentration-dependent manner. The clonogenic assay revealed that this compound induces a decreased on cell survival in a concentration-dependent manner, confirming the results obtained by the MTT assay. The results obtained by flow cytometry shown that gossypol induces cell death mainly by apoptosis. These results were confirmed by Bax activation and Bcl2 inhibition and also through a delay in the pre-G1 phase on cell cycle.
Conclusions: Gossypol has an anti-proliferative effect on CC cell line TFK1. This compound can also decrease cell survival. Cell death occurs primarily by apoptosis through Bax activation and a delay in the pre-G1 phase on cell cycle (pre-apoptotic peak). It seems that this compound can reverse the resistance to apoptosis observed in this type of tumor. Thus, gossypol could help to overcome resistance to chemotherapy and radiotherapy in this type of tumor, contributing to the existence of a personalized therapy.
No conflict of interest.

NQO1 expression correlates with cholangiocarcinoma prognosis

B. Buranrat[1], S. Chau-in[2], A. Prawan[3], P. Zeekpudsa[3], A. Puapairoj[4], V. Kukongviriyapan[3]. *[1]Mahasarakham University, Faculty of Medicine, Mahasarakham Province, Thailand; [2]Khon Kaen University, Surgery Faculty of Medicine Liver Fluke and Cholangiocarcinoma Research Center, Khon Kaen, Thailand; [3]Khon Kaen University, Pharmacology Faculty of Medicine Liver Fluke and Cholangiocarcinoma Research Center, Khon Kaen, Thailand; [4]Khon Kaen University, Pathology Faculty of Medicine Liver Fluke and Cholangiocarcinoma Research Center, Khon Kaen, Thailand*

Cholangiocarcinoma (CCA) is a rare type of liver cancer with a very poor prognosis. The prevalence of CCA is markedly variable with the highest incidence in the northeast Thailand, followed by other parts of Southeast Asia and China. Currently, there is still no reliable biomarker for diagnosis or treatment. NADPH-quinone oxidoreductase 1 (NQO1) is a xenobiotic metabolising enzyme detoxifying chemical stressors and antioxidants, thereby providing cytoprotection in normal tissues. However, NQO1 is over-expressed in some cancers, suggesting roles in carcinogenesis and tumor progression. In this study, we examined NQO1 activity in surgical specimens from CCA patients and found much higher values than in the adjacent normal tissues. Immunohistochemical analysis revealed strong staining in tumour epithelial elements, whereas the non-tumour bile ducts and liver parenchyma were weakly stained. *NQO1* mRNA expression in tumour tissues was widely varied among 43 patients. A significant association was observed between high level of *NQO1* expression and short overall survival time by the Cox proportional hazard ratio of 2.40, $p < 0.05$. By histological classification, non-papillary adenocarcinoma was an independent predictor for poor prognosis with the hazard ratio of 2.79, $p < 0.05$. *NQO1* expression may serve as a prognostic biomarker for the CCA.

Scalp cooling and protection from chemotherapy-induced alopecia: Using in vitro human keratinocyte models to study the role of temperature and biological mechanisms of cooling-mediated cytoprotection

W. Al Tameemi[1], O. Hussain[1], A. Collett[1], N.T. Georgopoulos[1]. *[1]University of Huddersfield, Chemical and Biological Sciences, Huddersfield, United Kingdom*

Background: Scalp cooling is an efficient method of preventing chemotherapy-induced alopecia (CIA), with a widely reported success for

many anticancer drugs; yet some modalities do not respond well to cooling. It is essential to establish biological models that will allow the study of chemotherapy induced cytotoxicity and the effect of cooling in this context in order to a) provide biological evidence for the role of cooling and b) provide a mechanistic basis for the cell responses. This will permit the improvement of cooling-based CIA preventative strategies.
Materials and Methods: HaCaT cells, which are closely representative of normal human keratinocytes (NHKs), were used to assess cytotoxicity of commonly used chemotherapy compounds. Cells were treated with a range of doxorubicin, docetaxel and the active metabolite of cyclophosphamide, 4-hydroperoxy-cyclophosphamide. Following treatment at normal temperature and cooling conditions, cell viability was determined 48 and 72 hours post-exposure. In further optimisation experiments we tested the importance of cell density on responses. We also adapted HaCaT cells to culture conditions designed for NHKs in order to render them even more representative of normal cells (we named this newly adapted cell line HaCaTa). Using flow cytometry, immunofluorescence microscopy and immunoblotting we have investigated intracellular signalling pathways to assess the effect of cooling on cell responses.
Results: Cooling efficiently protected HaCaT cells from toxicity against most drugs tested for a wide range of concentrations, including doses representative of maximal plasma levels clinically reported. Importantly, our in vitro findings on the ability of cooling conditions to rescue from drug induced cytotoxicity are in direct agreement with clinical observations. HaCaTa cells showed phenotypic and proliferation characteristics that were more typical of NHK cells, and we will present our findings using these cells, as well as data on the role of cooling in modulating intracellular mediators (proliferation and apoptosis-related) following drug treatment.
Conclusions: Our in vitro models show clear biological relevance by reflecting clinical observations. Once fully-optimised, our reductive yet robust models will allow us to characterise the signalling pathways triggered by chemotherapy drugs in keratinocytes and how cooling influences the signalling circuitry in cells to modify cell responses.
No conflict of interest.

Studying chemotherapy-induced alopecia in vitro: Cellular models accurately mimic the cytoprotective role of cooling against chemotherapy-induced cytotoxicity

O. Hussain[1], C. Dunnill[1], W. Al Tameemi[1], P. Burke[2], A. Collett[1], N.T. Georgopoulos[1]. *[1]University of Huddersfield, Chemical and Biological Sciences, Huddersfield, United Kingdom; [2]Paxman Coolers Ltd, Research and Development Technical, Huddersfield, United Kingdom*

Background: Chemotherapy-induced alopecia (CIA) is the most common and distressing side effect of cancer chemotherapy and is associated with hair loss in an estimated 65% of females. Head cooling represents the only available treatment against CIA and advanced medical devices such as the Paxman scalp cooling system offer a promising solution. For some chemotherapeutic modalities over 90% efficiency in protecting from CIA has been reported, yet other therapeutic regimens do not respond well to cooling and CIA is not efficiently prevented. It is thus necessary to establish biological models that will allow the study of chemotherapy induced cytotoxicity and provide an understanding of the role of cooling.
Materials and Methods: Normal Human epidermal Keratinocytes (NHK), cultured in conditions that allow them to adopt a rapidly proliferating basal phenotype, were used to assess the cytotoxicity of commonly used chemotherapy compounds, such as taxanes and anthracyclines. NHK cells were exposed to a wide concentration range of docetaxel, doxorubicin and the active metabolite of cyclophosphamide, 4-hydroperoxy-cyclophosphamide (4-HC), and combinations thereof. To assess the effect of cooling on cytotoxicity cells were treated with the drugs at normal temperature and cooling conditions and cell viability was determined 72 hours after exposure. In addition, the role of cooling on drug uptake was assessed by high-performance liquid chromatography (HPLC).
Results: We show that cooling is extremely efficient at protecting NHK cells from drug-induced toxicity against all individual drugs. Notably, cooling showed maximal capacity to protect from cytotoxicity caused by drug concentrations representative of maximal plasma drug levels clinically reported. In contrast to results with individual compounds, combination of these drugs (also referred to as TAC regimen) caused cytotoxicity that was not rescued by cooling. Strikingly, our in vitro findings are in agreement with available clinical observations. Data will also be presented from our studies on the effect of cooling on cellular drug uptake.
Conclusions: We provide for the first time evidence that, despite their reductive nature, our in vitro models are robust and biologically relevant and will help us understand the role of cooling in rescuing from keratinocyte cytotoxicity. This will permit the design of scalp cooling-based protocols with improved efficiency.

Enhanced proliferation by NGF-NTRK1 signaling makes AsPC-1 cell more sensitive to 2-DG induced apoptosis

Y. Cheng[1], D.M. Diao[1], H. Zhang[1], Y.C. Song[1], D. Liu[1], C.X. Dang[1]. *[1]First Affiliated Hospital Xi'an Jiaotong University College of Medicine, Surgical Oncology, Shanxi, China*

Background: Rapid proliferating cancer cells rely on increased consumption of glucose for cell survival. Glucose analog 2-deoxy-D-glucose (2-DG) inhibits glycolysis and demonstrates anti-cancer ability against pancreatic cancers. Activation of NGF-NTRK1 signaling results in enhanced proliferation in pancreatic cancer cells, it is unknown whether inhibition of glycolysis inhibits their growth.
Methods: The cell viability of AsPC-1 and NTRK1-AsPC-1 transfected cells was analyzed by MTT assay following 2-DG treatment. LY294002 was used to inhibit PI3Kinase. Cell apoptosis was determined by detecting the cleavage of pro-caspase 3. Phosphorylation of Akt was used to monitor the activation of p38 pathway.
Result: In response to NGF, ectopic overexpression of NTRK1 in AsPC-1 cells resulted in increased cell proliferation and was not abolished by LY294002 mediated suppression of PI3Kinase. In comparison to the isogenic AsPC-1 cells,150nM 2-DG induced more apoptosis in the cells transfected with NTRK1, which was attenuated by addition of glucose. Moreover, blocking PI3K-Akt pathway by LY294002 effectively abolished the apoptosis induced by 2-DG.
Conclusion: 2-DG induced cell apoptosis is more effective in pancreatic cancer cells with a high expression of NTRK1 through PI3Kinase pathway.
No conflict of interest.

New options in primary liver tumors: The role of quercetin

A.F. Brito[1], M. Ribeiro[2], A.M. Abrantes[1], J. Casalta-Lopes[1], A.C. Gonçalves[3], A.B. Sarmento-Ribeiro[3], J.G. Tralhão[4], M.F. Botelho[1]. *[1]Biophysics Unit − IBILI, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [2]Life Sciences Department, Faculty of Science and Technology of University of Coimbra, Coimbra, Portugal; [3]Applied Molecular Biology and Hematology Group, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [4]Surgical Department − Surgery A, Coimbra University Hospitals, Coimbra, Portugal*

Background: Hepatocellular carcinoma (HCC) is the most common primary liver malignancy followed by cholangiocarcinoma (CC). The mortality is high and the therapeutic options are limited. It is urgent to find new therapeutic targets and complementary therapies. Glucose transporter-1 (GLUT-1) expression is increased in primary liver tumors (PLT's) and promotes tumorigenesis. Flavonoids, including quercetin, have shown potential as GLUT-1 function inhibition and can be useful as therapeutic weapons against these highly aggressive tumors. The aim of this study is to evaluate the potential anticancer effect of quercetin on two HCC cell lines which differ on p53 expression and one CC cell line, evaluate its effect on ^{18}F-FDG uptake and in GLUT-1 expression.
Materials and Methods: Two different HCC cell lines (HepG2 (wp53) and HuH7 (mp53)) and a CC cell line (TFK-1) were used. In order to assess the effect of quercetin, the cells were incubated in the presence of different concentrations of this compound for different periods of time, and after cell proliferation was evaluated by the MTT assay in order to calculate half maximal inhibitory concentration (IC_{50}). The type of cell death was assessed by flow cytometry using the double staining with annexin-V/propidium iodide. Bax, Bcl-2 and GLUT-1 expression was also assessed by flow cytometry. For uptake studies, ^{18}F-FDG was incubated with a cell suspension pre-incubated with quercetin and control cells. At different times, samples were collected to eppendorf tubes, centrifuged and radioactivity of pellets and supernatants was measured with a well-type gamma counter for uptake calculation.
Results: Quercetin inhibits cell proliferation in all cell lines in a time-dependent manner. This compound does not inhibit GLUT-1 expression, however is able to decrease the ^{18}F-FDG uptake in all cell lines. Flow cytometry results have shown that quercetin has a cytotoxic effect only at high concentrations. When cell death occurs, is mainly by apoptosis and this is accompanied by Bax activation.
Conclusions: This study showed that quercetin has a considerable anti-proliferative effect in all cell lines used. This compound probably modifies the function but not the expression of GLUT-1, since it inhibits ^{18}F-FDG (a glucose analogue that is transported into the cell by GLUT-1 and GLUT-3) uptake. In this context quercetin may represent a new therapeutic option in PLT's.
No conflict of interest.

551 POSTER

Hepatocellular carcinoma and chemotherapy: The role of GLUT-1 antagonists

A.F. Brito[1], M.J. Nunes[2], M. Ribeiro[2], A.M. Abrantes[1], J. Casalta-Lopes[1], J.G. Tralhão[3], M.F. Botelho[1]. *[1]Biophysics Unit − IBILI, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [2]Life Sciences Department, Faculty of Science and Technology of University of Coimbra, Coimbra, Portugal; [3]Surgical Department − Surgery A, Coimbra University Hospitals, Coimbra, Portugal*

Background: Hepatocellular carcinoma (HCC) is the third cause of cancer dead on the world. Therapeutic options are limited, and chemotherapy is in most cases mainly palliative, which is due, in part, to the resistance that HCC presents to the chemotherapy drugs. Thus urge investigate new therapeutic targets as well as new molecules for the combat to this type of tumor. The glucose transporter 1 (GLUT-1) has been suggested as a new target for this cancer. Gossypol and quercetin have been described as competitive inhibitors of GLUT-1. Thus, the objective of this experimental work was to test the combined effect of quercetin and gossypol with a drug frequently used in conventional chemotherapy, the doxorubicin.
Material and Methods: Three human HCC cell lines which differ in p53 expression: HepG2 (wp53), HuH7 (mp53) and Hep3B2.1−7 (p53 null) were used. The cells were incubated with constant concentrations of quercetin or gossypol. The concentrations of these compounds used, alone, do not inhibit more than 5% of cell proliferation. Immediately after the addition of antagonists, or after 24 hours, the cells were incubated with increasing concentrations of doxorubicin. 48 h after the addition of gossypol or quercetin, the proliferation was evaluated using the MTT assay.
Results: Taking into account the results obtained by us previously, the values of IC50 with doxorubicin are 0.68 μM for HepG2, 0.24 μM for HUH7 and 0.83 μM for Hep3B2.1−7 cell line, it was found that the IC50 decreased with the addition of gossypol or quercetin. Comparing the additive effect of the drugs used, a better effect was observed when added simultaneous than when are added with a difference of 24 hours.
Conclusion: The results obtained with the combination therapy were greater when both compounds were added simultaneously. Hep3B2.1−7 was the cell line where better results were obtained, which is a very promising result, since this cell line does not express p53, which gives a more aggressive phenotype. These results also indicate that GLUT-1 is a promising therapeutic target, once the results of the combination of GLUT-1 antagonists and doxorubicin, was much more expressive than doxorubicin alone. Thus, quercetin and gossypol enhances the effect of doxorubicin, which can be a weapon in the combat of chemotherapy resistance in HCC.
No conflict of interest.

Comparative study of antioxidant activity and antiproliferative action of rutin and its derivatives in human tumor cell lines

E.M.B. De Araujo[1], Y.E.M. Franco[1], T.G. Alberto[2], M.A. Sobreiro[2], N.P. Martinez[1], D.G. Priolli[1], J.E. De Carvalho[3], A.L.T.G. Ruiz[3], P.O. Carvalho[1]. *[1]Sao Francisco University, Postgraduate Program in Health Science, Bragança Paulista, Brazil; [2]Sao Francisco University, Iniciation Scientific Program, Bragança Paulista, Brazil; [3]UNICAMP, CPQBA, Paulinia, Brazil*

Background: Rutin (quercetin-3-O-rutinoside) is a diglycoside of quercetin which has several pharmacological functions such as antioxidative, cytoprotective, vasoprotective, antiproliferative, antithrombotic and cardioprotective activities. Bioavailability and biological properties of various flavonoids glycosides can be improved after the hydrolysis enzymatic of specific glycosyl groups. In the present study, the antiproliferative action of rutin, quercetin (aglycone form of rutin) and quercetin-3-glucoside, a monoglycosyltated derivative obtained by enzymatic hydrolyses of rutin, was evaluated in ten human tumor cell lines and correlated to their antioxidant activity.
Material and Methods: Quercetin-3-glucoside was obtained by hydrolysis of rutin performed by α-L-rhamnosidase previously heated at 70ºC for 30 min. The antioxidant capacity of compounds was investigated regarding radical scavenging activity by DPPH and xanthine oxidase inhibition activity. Antiproliferative *in vitro* activity was studied in ten human cancer cell lines, including melanoma, breast, renal, ovarian, prostate, colon, leukemia and lung cancer.
Results: Quercetin-3-glucoside and quercetin demonstrated high radical scavenging activity evaluated by DPPH assay, however quercetin-3-glucoside and rutin were weak as xanthine oxidase inhibitor. *In vitro* inhibitory activity against human tumor cell showed that quercetin-3-glucoside exerted a more powerful antiproliferative effect than quercetin and rutin on various cancer cell lines, showing higher activity for glioma, ovarian and breast adenocarcinoma.
Conclusions: The data suggest that the 3-O-glucosylation improves the quercetin antiproliferative potential, whereas the binding of a rhamnose to the aglycone greatly depresses it. The results indicate that quercetin-3-glucoside can be a promissory functional derivative obtained by rutin hydrolyses. Further *in vivo* evaluations are needed.
No conflict of interest.

553 POSTER

MEIG1, a new player in the system responsible for maintaining genome integrity

I. Marciano[1], R. Yaverboim[1], J. Don[1]. *[1]Bar-Ilan University, Ramat Gan, Israel*

Background: *Meig1* is a highly conserved gene first identified in mouse pachytene spermatocytes undergoing meiotic recombination. In these cells the MEIG1 protein enters the nucleus and forms foci along the meiotic chromosomes, reminiscent of foci obtain by proteins known to be involved in the DNA damage response. Meig1 knockout (KO) male mice are infertile. These mice exhibit significantly fragmented DNA in the few epididymal sperm cells that could be obtained, and increased apoptosis of post recombination spermatogenic cells. Given these findings we hypothesized that MEIG1 might play a role in the system responsible for maintaining genome integrity.
Materials and Methods: Immunocytochemistry of meiotic chromosomes and γH2AX signaling were used to analyze DNA integrity of post recombination chromosomes in KO versus WT spermatocytes, as well as in KO and WT MEFs exposed to etoposide treatment (50μM). Real-Time PCR was used to monitor expression of Meig1 in U2OS cells (human osteosarcoma cells) after exposure to genotoxic treatment [UV-radiation (254 nm, 50mJ/cm^2) and etoposide (50μM)]. Tumors from KO mice were analyzed histologically.
Results: Analysis of γH2AX signaling in meiotic chromosomes of late pachytene spermatocytes showed that in KO mice they were highly 'decorated' with γH2AX foci, compared to WT chromosomes. Moreover, analysis of post-recombination meiotic chromosomes revealed the existence of numerous chromosomal fragments in KO meiotic preparations whereas no such fragments could be seen in preparations from WT spermatocytes. Regarding somatic cells, KO MEFs exposed to etoposide treatment exhibited significantly slower disappearance of the γH2AX foci compare to WT MEFs, suggesting delayed or aberrant repair. In U2OS cell *Meig1* expression was significantly up-regulated soon after exposure to etoposide, whereas following UV radiation Meig1 up-regulation was delayed concomitant to the appearance of double strand breaks. Interestingly, most Meig1 KO mice (more than 30 mice to date), and about one third of the Meig1 $^{+/-}$ heterozygotes developed huge and aggressive tumors between 6−18 months of age, whereas none of the age-matched wild-type (WT) mice developed tumors. These tumors were identified as being mainly malignant adeno-carcinomas and lymphomas.
Conclusions: MEIG1 seems to be involved in maintaining chromatin integrity not only in spermatogenic cells but in somatic cells as well, rendering it as a new player in the general DNA damage response, especially the response to DSB. Meig1 has tumor suppressive properties.

PIM-2 is an essential component of the UV damage response that acts upstream to E2F-1 and ATM

S. Zirkin[1], J. Don[1]. *[1]Bar-Ilan University, Ramat Gan, Israel*

Background: PIM-2, a member of the PIM serine/threonine kinase family, is known for its pro-survival activity. Increased expression of PIM-2 was reported in several tumors, emphasizing PIM-2's involvement in human tumor formation. However, the roll of PIM-2 in the context of DNA damage has not been determinate yet. The aim of this study was to assess the potential involvement of PIM-2 in the cell's response to UV radiation and the activation of the DNA damage response.
Materials and Methods: A Tet-ON inducible system was established for expression of a HA-tagged 34kDa isoforme of PIM-2, in U2OS osteosarcoma cells. PIM-2 over-expressing cells, and control cells, were exposed to UVC radiation (254nm, 4−50mJ/cm^2), and various DNA damage mediators were monitored by real time PCR and Western Blot analysis.DNA legions (CPDs) were detected by ELISA and immunocytochemical staining. Apoptosis was determined by the anaxin/PI method or by determining the sub-G1 phase in FACS analysis. Silencing of Pim-2 or E2F1 was performed using shRNA or siRNA.
Results: U2OS cells that were exposed to UV-radiation reacted in a significant increase in endogenous PIM-2 levels. Silencing PIM-2 in U2OS cells rendered these cells much more sensitive to UV radiation whereas PIM-2 over-expressing cells showed decreased sensitivity and increased

survival following UV radiation, exhibiting increased kinetics of repair of DNA lesions compared to control cells. These protective effects of PIM-2 were mediated by increased levels of E2F-1, and activation of ATM. The protective effects of PIM-2 were much less dramatic upon silencing of E2F-1 and completely abrogated upon inhibition of ATM.
Conclusion: PIM-2 is an essential component of the UV damage response that acts upstream to E2F-1 and ATM. The increased E2F-1 levels and activation of ATM, possibly render the cells more ready for the coming UV-induced DNA damage.
No conflict of interest.

Proof of concept in breast cancer and identification of sensitivity biomarkers of a new DNA repair inhibitor (Dbait)

M. Dutreix[1], Y. Kirova[2], A. Croset[1], J.S. Sun[3]. [1]*Institut Curie, UMR-ETIC, Orsay Cedex, France;* [2]*Institut Curie Hospital, Radiotherapy, Paris Cedex, France;* [3]*DNA Therapeutics, R&D, Evry Cedex, France*

Background: Numerous therapies are available for the treatment of Breast Cancer (BC): surgery, radiation therapy, chemotherapy, hormone therapy, and most recently, targeted therapy. The limit of targeted therapy is that they are usually directed at specific targets in the body (extracellular receptors, kinases and enzymes) and therefore apply for limited number of patients. For exemple, PARP inhibitors that act as synthetic lethal with BRCA deficiency have shown promising results, but seem however less efficient in patient with active homologous recombination repair. We have recently developed a new strategy (DNA repair bait, Dbait in short) that inhibits three central repair pathways (Homologous Recombination, Non Homologous End Joining and Single Strand Break Repair). Dbait(DT01) is the 1st drug candidate of this family of DNA repair inhibitor already in a phase 1 trial in local metastatic melanoma. This study demonstrates the efficiency of Dbait in BC treatment and identify new biomarkers that predict tumor sensitivity to its administration.
Materials and Methods: Twelve BC cell lines were characterized for DNA repair gene expression and activation of the DNA damage response DDR (pH2AX and PAR detection) by western blot analysis of the proteins and classified according to their BRCA status. Clonal survival to Dbait (the DT01 in vitro variant) was analyzed 10 days after treatment. Four xenografted models derived from cell lines or patient samples were assayed for sensitivity to DT01. DT01 (5 mg) was subcutaneously administered every day for a week (5 sessions) or four days per week for three weeks (12 sessions of 2 mg). In parallel, the PARP inhibitor ABT-888 was orally administered at the dose of 25 mg/day/kg during one week to compare efficiencies. Tumor growth and survival of untreated and treated animals were monitored. Tumor biopsies were analyzed for micronuclei formation.
Results: This study provides the evidences that: i) Dbait induces death *in vitro* in BC cells independently of BRCA defect; ii) DT01 controls tumor growth and increase survival in all tested models; iii) DT01 alone cured 30% $BRCA^{-/-}$ tumors; iv) DT01 was more efficient that ABT-888 in vitro and in vivo. Micronuclei biomarkers predict the sensitivity to Dbait and are detected in many patient biopsies.
Conclusion: DT01 is a promising investigational medicinal product to treat Breast Cancer. Its association with radiotherapy is under investigation.
Conflict of interest: *Ownership: M. Dutreix and JS. Sun are co-founder of the society DNA-Therapeutics. Other substantive relationships: F. Devun is a employee of DNA-Therapeutics*

Knockdown of the caveolin-1 gene abrogates radiation-induced Akt nuclear translocation in triple negative breast cancer cells

M. Zou[1], L. Zhuang[1], S. Xia[1], S.Y. Yu[1]. [1]*Tongji Hospital, Oncology, Wuhan, China*

Background: Triple negative breast cancer (TNBC), an aggressive subtype of breast cancer, often lacks effective targeted therapy and is insensitive to chemo-or radiotherapy. We had previously detected that epidermal growth factor receptor (EGFR) nuclear translocation after ionizing radiation (XRT) was associated with radioresistance in TNBC cells and caveolin-1 was critical for this process. Akt is one of the downstream molecules of EGFR signaling cascade and Akt activation often indicates poor clinical outcome and resistance to therapy in cancer patients. Thus, we hypothesize that Akt would localize to nucleus after activated by XRT to confer radioresistance and aim to explore whether downregulate caveolin-1 could impair the radiation-induced Akt nuclear translocation in TNBC cells.
Material and Methods: Akt activation and the cytoplasmic-to-nucleus trafficking of Akt at various time points (0−2 h) following irradiation were examined in two established TNBC cell lines (Hs578t and MDA-MB-231) through western blot and confocal assay. Further, we applied small interfering RNA (siRNA) targeting caveolin-1 to downregulate its protein expression and then examined level changes of nuclear Akt. Immunofluorescence (IF) was done to observe the expression of p-DNA-PKcs (T2609) which indicates DNA repair capacity as well as γ-H2AX which is a marker of DNA damage.
Results: Our results showed that in two TNBC cell lines, radiation-treated cells exhibited an increase in nuclear Akt level while the expression of caveolin-1 in cytoplasmic and nucleus fractions did not changed. Phosphorylation of Akt on Ser-473 also increased after XRT in both cytoplasmic and nucleus, suggesting that phosphorylation at this site of Akt might be necessary for radiation-induced Akt nuclear accumulation. Downregulation of caveolin-1 by siRNA was able to block Akt nuclear import regardless of Akt phosphorylation status. Impairment of Akt localized to the nucleus further inhibited DNA repair via decreasing the expression of p-DNA-PKcs (T2609) and promoted DNA damage by enhancement of γ-H2AX foci formation to 24 h post-XRT thus eventually increased radio-sensitivity.
Conclusions: These data support the hypothesis that irradiation-induced nuclear Akt accumulation is related to radioresistance. Moreover, caveolin-1 played a prominent role in regulating Akt transportation and proved to be a promising target to exert radiosensitizing effect in TNBC cells.
No conflict of interest.

557 POSTER

Correlation between BRCA1/2 mutation and treatment side effects in breast cancer patients

J. Huszno[1], M. Budryk[2], E. Nowara[1]. [1]*Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Clinical and Experimental Oncology, Gliwice, Poland;* [2]*Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Outpatient Clinic, Gliwice, Poland*

Introduction: *BRCA1/2*are the tumor suppressor genes which are responsible for DNA damage repairs, cell cycle regulation, transcriptional control, ubiquitination and regulation of apoptosis. The presence of *BRCA* gene mutation and low expressions of BRCA proteins is associated with greater sensitivity of tumor cells to ionizing radiation and cytostatics damaging cells' DNA. This study was conducted to evaluate the influence of *BRCA1/2* mutation on toxicity of anthracycline based chemotherapy and radiotherapy.
Methods: This retrospective study was conducted on 370 patients treated with anthracycline-based chemotherapy for breast cancer in years 2006–2012. All patients were examined for the presence of *BRCA1* and *BRCA2* mutations. Medical records were reviewed to document the characteristics of each cancer and the treatments received.
Results: In analyzed group 275 (75%) received adjuvant chemotherapy and 95 (25%) neoadjuvant treatment. In 48 (13%) of patients *BRCA1/2*mutation was detected: in 44 (12%) early breast cancer and in 4 (1%) advanced breast cancer patients. Overall toxicity grade 3−4 was observed more often in non − carriers (10% vs. 17%), $p = 0.045$. Nausea and vomiting in grade 3−4 was detected only in non carriers (5%). Gastrointestinal toxicity in all grades (1−4 according to CTCAE) together also occurred more often in patients without the presence of BRCA1/2 mutations (20% vs. 7%), $p = 0.05$. In contrary, hematological side effects such as neutropenia were observed more frequently in patients withBRCA1/2 mutation (32% vs. 10%) $p = 0.0008$. No significant differences were observed between this two groups according to other side effects. Acute radiotherapy toxicity was reported in 6% patients with BRCA1/2 mutations and 9% without mutations, $p = 0.766$.
Conclusion: Anthracycline-based chemotherapy was generally well tolerated by BRCA1/2 associated breast cancer patients. The acute side effects were sporadic. BRCA1/2 mutation carriers seem to be more at risk of neutropenia and non carriers more at risk of gastrointestinal toxicity. There was no evidence of increased radiation sensitivity in BRCA patients compared with patients without mutations.
No conflict of interest.

Age-related prognostic value of global expression of histone modifications and histone modifying enzymes in colorectal cancer

A. Benard[1], I.J. Goossens-Beumer[1], A.Q. Van Hoesel[1], H. Horati[1], W. De Graaf[1], H. Putter[2], E.C.M. Zeestraten[1], G.J. Liefers[1], C.J.H. Van de Velde[1], P.J.K. Kuppen[1]. [1]*Leiden University Medical Center, Surgery, Leiden, Netherlands;* [2]*Leiden University Medical Center, Medical Statistics and Bioinformatics, Leiden, Netherlands*

Background: Epigenetic processes, including DNA methylation and histone modifications, are frequently deregulated in cancer. Histone modifications, in addition to DNA methylation, are key regulators of gene expression. In search for new biomarkers to improve the current staging system for colorectal cancer, we studied global expression of histone

modifications and their corresponding enzymes in colorectal cancer. We hypothesized that global expression of histone modifications reflect the aggressiveness of the tumor and can therefore predict clinical outcome.
Materials and Methods: Histone modifications H3K9Ac and H3K27me3 and histone modifying enzymes BMI1, EZH2 and LSD1 were immunohistochemically stained on tissue microarrays (TMA) of colorectal cancer patients (n = 249). The TMA included three tumor tissue cores per patient, and the average percentage of positive tumor cells per patient were used for survival analyses. Patients were divided into groups based on median expression of individual markers. Uni- and multivariate survival analysis was used to analyze the association between the individual markers and clinical outcome. Kaplan–Meier curves were generated in order to visualize survival differences between the expression groups.
Results: In survival analyses for all of markers reported in this study, we identified an interaction between the expression of the studied markers and age at surgery. Hazard ratios increased significantly with age at surgery. For all markers, higher expression correlated to better survival in younger patients, whereas lower expression correlated to better survival in older patients. A similar pattern was observed for recurrence free survival.
Conclusions: Based on current knowledge that global DNA methylation decreases with age, we assumed a similar decrease in expression of histone modifications and enzymes with age. In older patients, higher expression of histone modifications was considered aberrant and was therefore expected to be associated with worse prognosis, as indeed shown in this study. For younger patients, we expected and showed the opposite effect, with lower expression considered aberrant and correlating to worse prognosis. In conclusion, global expression of histone modifications can predict clinical outcome in colorectal cancer patients in an age-dependent way.
*Note: A. Benard and I.J. Goossens-Beumer contributed equally to this study.
No conflict of interest.

559 POSTER

Significance of the histone demethylase jumonji domain containing 2B in human lung carcinogenesis and the prognosis of patients with resected lung adenocarcinoma

G. Toyokawa[1], M. Takenoyama[1], K. Taguchi[2], Y. Morodomi[1], T. Takenaka[1], M. Yamaguchi[1], T. Seto[1], R. Hamamoto[3], Y. Nakamura[3], Y. Ichinose[1]. *[1]National Kyushu Cancer Center, Department of Thoracic Oncology, Fukuoka, Japan; [2]National Kyushu Cancer Center, Clinical Research Institute, Fukuoka, Japan; [3]The University of Chicago, Department of Medicine Faculty Section of Hematology/Oncology, Chicago, USA*

Background: Histone methyltransferases and demethylases are known to regulate transcription; however, the pathologic role of dysfunction of these molecules in human cancer remains to be elucidated. We herein examined the significance of jumonji domain containing 2B, JMJD2B, in the pathogenesis of lung cancer cells and clinical lung cancer patients.
Materials and Methods: The protein expression in lung cancer samples was examined using immunohistochemistry with an antibody that specifically detects JMJD2B. Cell growth and the cell cycle in lung cancer cell lines were analyzed following siRNA treatment using an MTT assay and the BrdU labeling. A microarray analysis was performed to investigate downstream genes of *JMJD2B*, while chromatin immunoprecipitation was conducted to analyze transcriptional regulation by *JMJD2B*. A total of 78 patients with resected lung adenocarcinoma were examined using immunohistochemistry, and the significance of the JMJD2B expression for the DFI and OS after surgical operation was evaluated.
Results: Immunohistochemistry revealed an elevated protein expression in the lung cancer tissues. The siRNA-mediated reduction of the expression of *JMJD2B* in the lung cancer cell lines significantly suppressed the proliferation of cancer cells, while suppression of the *JMJD2B* expression led to a decreased population of cancer cells in the S phase with a concomitant increase in the number of cells in the G1 phase. A microarray analysis conducted after the knockdown of *JMJD2B* revealed that *JMJD2B* regulates multiple pathways that contribute to carcinogenesis, including the cell-cycle pathway. Chromatin immunoprecipitation showed that, of the downstream genes, *cyclin-dependent kinase 6* (*CDK6*), which is essential for G1−S transition, is directly regulated by *JMJD2B* via demethylation of histone H3-K9 in its promoter region. The expression levels of *JMJD2B* and *CDK6* were significantly correlated with each other in the various types of cancer cell lines. Furthermore, in a total of 78 resected lung adenocarcinomas, immunopositivity for JMJD2B was observed in 50 cases, and, intriguingly, the OS of these patients after surgery was inferior to that of the patients without any JMJD2B expression.
Conclusions: In conclusion, this study revealed a novel mechanism for human lung carcinogenesis and demonstrated that JMJD2B is a feasible molecular target for anticancer therapy. Furthermore, JMJD2B may be a novel prognostic factor for resected lung adenocarcinoma.
No conflict of interest.

Functional characterization of EZH2 rs3757441 polymorphism in colorectal cancer (CRC) samples

C. Vivaldi[1], P. Faviana[2], L. Fornaro[3], E. Paolicchi[4], V. De Gregorio[1], G. Masi[1], G. Fontanini[2], R. Danesi[4], A. Falcone[1], F. Crea[5]. *[1]Medical Oncology 2 Unit, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy; [2]Pathology Unit University of Pisa, Department of Surgical Medical and Molecular Pathology and Critical Care, Pisa, Italy; [3]Medical Oncology Unit, Azienda USL2, Lucca, Italy; [4]Pharmacology Unit University of Pisa, Department of Clinical and Experimental Medicine, Pisa, Italy; [5]BCCA Cancer Research Centre, Experimental Therapeutics, Vancouver, Canada*

Background: The enhancer of zeste-homolog 2 (*EZH2*) is a cancer stem cell-related gene involved in cancer development through gene silencing by methylation of lysine 27 of histone 3 (H3K27). The *EZH2* allelic variant rs3757441 CC was shown to be associated with poor prognosis in metastatic CRC patients, but molecular and pathological characterization of the single nucleotide polymorphism (SNP) is lacking.
Material and Methods: A total of 119 formalin-fixed paraffin-embedded tissues of primary colorectal tumours were collected and used for DNA extraction, molecular and pathological analyses. *EZH2* rs3757441 SNP variants were identified by real-time PCR from colonic healthy tissue. EZH2 and H3K27 expression were evaluated by immunohystochemistry (IHC), while *KRAS* codon 12−13 and *BRAF* V600E mutational status were assessed by pyrosequencing. Statistical analysis was performed by Fisher exact test, chi-square test, T test and ANOVA.
Results: Characteristics of the specimens are summarized in Table 1. The rs3757441 CC genotype significantly correlates with both EZH2 (100 vs. 46%, p = 0.02) and H3K27 (100 vs. 38%, p = 0.01) increased expression (defined as 3+ at IHC) compared with CT and TT genotypes. We observed a significant correlation between the expression of EZH2 and H3K27 (p = 0.04), but the expression of EZH2 and H3K27 is not associated with tumour stage, site, mucinous histology or *KRAS* and *BRAF* mutational status. Poorly differentiated (grade 3) tumours display higher H3K27 expression (p = 0.05) and higher percentage of H3K27-positive cells (p = 0.06).
Conclusions: *EZH2* rs3757441 CC genotype is associated with stronger EZH2 and H3K27 immunoreactivity in primary CRC samples. Higher tumour grade shows a trend toward higher H3K27 expression and percentage of H3K27-positive cells, which may contribute to more aggressive behaviour. *EZH2* is a candidate therapeutic target in CRC and rs3757441 SNP may be a promising biomarker.
No conflict of interest.

Table 1. Characteristics of 119 specimens

Feature	n	(%)
Stage, I/II/III/IV	5/41/52/21	4/34/44/18
Grade, 2/3	76/43	64/36
Site, right colon/left colon/rectum	52/45/22	44/38/18
Mucinous histology, yes/no	37/82	31/69
KRAS, wild-type/mutant	67/52	56/44

Sensitization of TRAIL in combination with sub-toxic dose 5-FU induces apoptosis and inhibits cell proliferation in cholangiocarcinoma

T. Limpaiboon[1], R. Amornpisutt[1], R. Sriraksa[1]. *[1]CMDL Khon Kaen University, Khonkaen, Thailand*

Background: Cholangiocarcinoma (CCA) although is a rare type of primary liver cancer, the incidence and mortality rates have been reported to increase worldwide in the past decade. Surgical resection is only a potentially curative approach for the CCA patients. However, a vast majority of the CCA cases are unresectable and commonly represented in the advanced stages. Previous clinical studies have reported the relatively low responsiveness of CCA to chemotherapy with a partial response approximately 10−20%. Our recent study has shown that death receptor-induced apoptosis through TRAIL signaling is rarely silenced by epigenetic aberration in term of DNA methylation. The result suggests the advantage for optional cancer therapy using recombinant TRAIL or TRAIL receptor

agonistic monoclonal antibodies to induce cancer cell death in CCA. In the present study, we aimed to investigate the therapeutic effect of recombinant human TRAIL (rhTRAIL) in CCA cell lines (M213, M214 and KKU-100) compared with the immortal biliary cell line MMNK1.
Methods: Sulforhodamine B (SRB) assay was used to determine cell proliferation. Apoptosis was determined by assaying activities of caspases 8, 9 and 3/7. Expression of apoptotic related genes (DcR1, DcR2, DR4, DR5, and CASP8) and p53 was detected by reverse transcription polymerase chain reaction (RT-PCR).
Results: rhTRAIL is a potential agent which significantly inhibits cell proliferation and mediates apoptosis by inducing caspase activities (caspases 8, 9 and −3/7) in CCA cells. The combined treatment of 5-FU at sub-toxic dose (8 μM) and 10 ng/mL rhTRAIL was significantly inhibited cell growth in all cell lines tested compared to untreated control, 5-FU, or rhTRAIL while those combinations showed less effect on MMNK1 with cell survival >60%. mRNA of TRAIL related genes was expressed in CCA cell lines and not related to responsiveness of cells to 5-FU and/or rhTRAIL treatments.
Conclusions: The combination of rhTRAIL and 5-FU at sub-toxic concentrations could inhibit cell growth and induce apoptosis in CCA with lower cytotoxicity in immortal biliary cell.
No conflict of interest.

The relationship between microsatellite instability and diabetes mellitus in colorectal cancer patients

Y. Nakayama[1], T. Yamaguchi[1], H. Matsumoto[1], D. Nakano[1], T. Iijima[1], R. Wakaume[1], M. Miyaki[1], K. Takahashi[1]. [1]*Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Colorectal Surgery, Tokyo, Japan*

Background: Mutations in DNA mismatch repair genes result in a failure to repair errors in repetitive sequences, leading to microsatellite instability (MSI) of the tumors. MSI can occur in tumors of many organs, but it is mainly the hallmark of colorectal cancer. Colorectal cancers (CRCs) with high-frequency microsatellite instability (MSI-H) are known to show differences in their clinical and pathological features compared to microsatellite stable (MSS) cancers. In addition, previous studies revealed that type 2 diabetes mellitus (T2DM) is a risk factor of malignant tumor including colorectal cancer. In this study, we prospectively investigated the relationship between T2DM and MSI positive colorectal cancer in Japanese individuals.
Material and Methods: We consecutively selected 415 colorectal cancer patients who underwent surgical resection at the Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital from January 2008 to December 2010 after obtaining informed consent. Patients with inflammatory bowel disease, familial adenomatous polyposis or hereditary non-polyposis colon cancer (Lynch syndrome) were excluded. Microsatellite status was assessed using standard markers which are BAT25, BAT26, D2S123, D5S346, and D17S250.
Results: 22 cases (5.3%), 28 cases (6.7%) and 365 cases (88.0%) of tumors showed MSI-H, low-frequency microsatellite instability (MSI-L) and MSS, respectively. Of the 415 colorectal cancers, 90 (21.7%) were T2DM. One patient (4.5%) was T2DM of the 22 MSI-H patients, 82 (22.5%) were T2DM of the 365 MSS patients. Thus, the rate of T2DM in MSI-H patients is significantly less than that in MSS patients ($\chi 2$ test: $p = 0.497$).
Conclusion: We conclude that the rate of T2DM in MSI-H patients is significantly less than that in MSS patients.
No conflict of interest.

Endoxifen and hTra2-beta1 regulate estrogen receptor a alternative splicing pattern in breast cancer cells

C. Zheng[1], M. Hirschfeld[2], M. Jaeger[1], E. Stickeler[1]. [1]*University Medical Center Freiburg, Gynecological Hospital, Freiburg, Germany;* [2]*University Medical Center Freiburg and German Cancer Research Center Heidelberg, Gynecological Hospital, Freiburg, Germany*

Background: Endoxifen is the major metabolite of tamoxifen and acts as a selective estrogen receptor modulator (SERM) by blocking estrogen receptor alpha (ERα) transcriptional activity. Alternatively spliced ERα mRNA variants are present in normal and malignant breast tissues. These alternative ERα variants possess the potential for increased estrogen activities. Human Tra2-beta1 is a splicing factor regulating splicing processes in a sequence-specific and concentration-dependent manner. hTra2-beta1 intracellular localization may vary during cancer progression or is changed by exogenic stimuli, e.g. therapeutic drugs. Here we analyzed the potential impacts of endoxifen and hTra2-beta1 on ERα expression pattern. In addition, we examined the effect of endoxifen on hTra2-beta's alternative splicing.
Material and Methods: Three ERα-positive and one ERα-negative breast cancer cell line were subjected to parallel functional experiments. Cell lines underwent estrogen stimulation following different treatment. Cells were either kept continuously cultivated under estrogen stimulation, or treated with endoxifen. Transient knock-down of hTra2-beta1 was operated by transfection with shRNA plasmids. PCR, RT-PCR, immunocytochemistry and Western blot were applied for expression analysis on mRNA and protein level.
Results: Endoxifen induced a significant reduction of ERα protein expression in ERα positive breast cancer cells. As a feedback effect, the ERα mRNA expression levels markedly increased. Endoxifen treatment triggered a shift in ERα splicing toward the ERα Δ7 variant. hTra2-beta knock-down created a similar impact on ERα alternative splicing. In addition, a novel isoform of hTra2-beta1 occurred under endoxifen treatment. Interestingly, endoxifen also triggers an intracellular translocation of hTra2-beta1 characterized by decreased nuclear protein expression and increased accumulation in cytoplasm.
Conclusion: We hypothesize that endoxifen exerts a regulatory impact on hTra2-beta1 alternative mRNA splicing pattern and intracellular protein localization. hTra2-beta1 is most likely involved in ERα-dependent regulation of breast cancer by triggering aberrant ERα alternative splicing. The presence of different ERα mRNA and protein variants exerts different functions in controlling ERα signaling pathways. ERα Δ7 might be of auspicious clinical significance to potentially serve as a prognostic indicator for evaluation of human breast cancer endocrine therapy efficacy.

Dioxin receptor (AhR) binding to Alu elements X14S, X36S and X45S modulates the expression of stemness-relevant genes Oct4 and Nanog

F. González Rico[1], A.C. Román[1], P.M. Fernández-Salguero[1]. [1]*University of Extremadura, Biochemistry Molecular Biology and Genetics, Badajoz, Spain*

Background: Eukaryotic genomes are organized into expression domains whose activity depends on local chromatin structure. To accomplish that, functional gene clusters are defined by the binding of transcription factors to conserved regulatory sequences. Transposable elements seem to regulate gene expression by modulating genome organization and stability. Such transposons functions are likely associated to their ability to bind specific transcription factors.
Material and Methods: Ntera 2D1 cells of wild type phenotype (WT) and Ntera-2 infected via retrovirus with a short hairpin to induce the knockdown of AhR (shAhR) were used in the study. Chromatin immunoprecipitacion (ChIP) were performed to check protein bindings. We used retinoic acid (RA) treatment during 24−48 hours to promote differentiation.
Results: In the human genome, we have identified three Alu elements containing a conserved AhR binding site. These Alu(s) (hereafter X14S, X36S and X45S) are present in most stemness-relevant genes including Oct4, Nanog, Shh, Sox2 and Notch1. In the undifferentiated embryonic carcinoma Ntera 2D1 cell line, treatment with retinoic acid (RA) induces differentiation by decreasing Oct4 and Nanog expression levels. Remarkably, RA-induced differentiation promotes a parallel increase in AhR protein levels. Silencing of AhR by RNA interference (siRNA of shRNA) blocks the decrease in Oct4 and Nanog induced by RA thus maintaining an undifferentiated state. Chromatin immunoprecipitation (ChIP) experiments were performed to confirm AhR binding to the X14S, X36S and X45S Alu elements present in the promoter of such target genes. Binding of CTCF, PARP-1, Pol II and Pol III to these Alu(s) was also reported. In addition, enhancer blocking assays (EBAs) will be used to address the insulator activity of these Alu elements, and also will be confirmed in vivo in zebrafish.
Conclusions: We suggest that X14S, X36S and X45S Alu elements can represent evolutionary conserved genome-wide insulators and modulators activated by the transcription factor AhR to control developmental, oncogenic or toxicological-dependent processes.
No conflict of interest.

Dioxin receptor expression inhibits basal and transforming growth factor beta-induced epithelial-to-mesenchymal transition

E. Rico Leo[1], A. Alvarez Barrientos[2], P.M. Fernandez Salguero[1]. [1]*University of Extremadura, Biochemistry Molecular Biology and Genetic, Badajoz, Spain;* [2]*University of Extremadura, Stab, Badajoz, Spain*

Background: Recent studies have emphasized the role of the dioxin receptor (AhR) in maintaining cell morphology, adhesion and migration.

These novel AhR functions depend on the cell phenotype and while AhR expression maintains mesenchymal fibroblasts migration it inhibits keratinocytes motility. These observations prompted us to investigate whether AhR modulates the epithelial-to-mesenchymal transition (EMT).
Material and Methods: We have used primary *AhR*+/+ and *AhR*−/− keratinocytes and NMuMG cells engineered to knock-down AhR levels (sh-AhR) or to express a constitutively active receptor (CA-AhR) by retroviral transduction. To analyze the role of AhR in EMT, the following experimental procedures were performed: transient transfection and RNA interference, clonogenic and migration experiments, immunofluorescence, immunoprecipitation and immunoblotting assays as well as Real-time PCR analyses.
Results: Both *AhR*−/− keratinocytes and sh-AhR NMuMG cells had increased migration, reduced levels of epithelial markers E-cadherin and beta-catenin and increased expression of mesenchymal markers Snail, Slug/Snai2, vimentin, fibronectin and alfa- smooth muscle actin. Consistently, *AhR*+/+ and CA-AhR NMuMG cells had reduced migration and enhanced expression of epithelial markers. AhR activation by the agonist FICZ inhibited NMuMG migration whereas the antagonist alfa-naphthoflavone induced migration as did AhR knock-down. Exogenous TGF beta exacerbated the pro-migratory mesenchymal phenotype in both AhR-expressing and AhR-depleted cells, although the effects on the latter were more pronounced. Rescuing AhR expression in sh- AhR cells reduced Snail and Slug/Snai2 levels and cell migration and restored E-cadherin levels. Interference of AhR in human HaCaT cells further supported its role in EMT. Interestingly, co-immunoprecipitation and immunofluorescence assays showed that AhR associates in common protein complexes with E-cadherin and beta-catenin, suggesting the implication of AhR in cell-cell adhesion. Thus, basal or TGF beta-induced AhR down-modulation could be relevant in the acquisition of a motile
Conclusion: AhR has an intrinsic role in EMT and cross talks with TGFbeta.
No conflict of interest.

Implication of transposons in differentiation process in NTERA 2D1 cell line

A. Morales-Hernández[1], P.M. Fernández-Salguero[1], J.M. Merino[1].
[1]*Universidad de Extremadura, Bioquímica Biología Molecular y Genética, Badajoz, Spain*

Background: Transposons are mobile elements of the genome which are implicated in gene expression regulation. Cell differentiation is an important process regulated by these elements. The B1X35S is a transposon found in mouse which expression is mainly regulated by the aryl hydrocarbon receptor (AhR), having a role RNA polymerase III and PARP1. Human cells contain XS Alus, another family of transposons comparable with B1X35S. There are many genes implicated in cell differentiation that contain XS Alus.
Material and Methods: To understand the role of Alus elements in the expression of gene related with cell differentiation, we have used NTERA 2D1 cells of wild type phenotype (Wt line) and transfected with a short hairpin to induce the knockdown of AhR (Sh line).
Results: The treatment of Wt line cells with retinoic acid to differentiate NTERA cells to neuronal cells, induces an increase of the AhR level and a downregulation of Oct4 and Nanog expression, genes of undifferentiated state maintenance. On the contrary, the same treatment in Sh line cells only produces a low increase of AhR expression and a similar expression level of the undifferentiated state genes. In addition, we checked the protein levels of undifferentiated state marker Oct4 and several neuronal differentiation markers (TAU, NSE, GAP43 and βIIITubulin) and the results are in agreement with the gene expression data showing a more differentiated state in the Wt line than in the hairpin Sh line. To analyze the role of RNA polymerase III and PARP1, we measured the Nanog and Oct4 expression in the Wt line cells treated with WYE, an RNA polymerase III inhibitor through mTOR, or with 3-aminobenzamide (3AB), a PARP1 inhibitor. We observed a recovery of the expression of both genes after the decreased induced by the retinoic acid treatment. The same treatment using Sh line cells retrieves an increase of the expression of both genes with WYE treatment and a similar expression with the 3AB treatment than control non-treated cells.
Conclusion: All together, these results suggest an implication of AhR, RNA polymerase III and PARP-1 in the cell differentiation process regulating the expression of Alus elements which may be downregulating genes of undifferentiated state maintenance.
No conflict of interest.

567 POSTER

SNAIL interacts with syndecan promoters in prostate cancer cell lines

H.R. Contreras[1], V. Seguel[1], N. Farfán[1], H. Sepulveda[2], M. Gallardo[1], M. Montecino[2], E.A. Castellón[1]. [1]*Faculty of Medicine, University of Chile, Physiology and Biophysics Program. Institute of Bio;* [2]*University Andrés Bello, Laboratory of Gene Regulation, Santiago, Chile*

Background: Biopsy Studies from prostate cancer (PCa) patients show that expression pattern of syndecan 1 and 2 (SDC1 and SDC2) is associated with malignancy prognosis of biochemical recurrence. On the other hand, it has been shown an increased expression of SNAIL in biopsies from more aggressive PCa which is associated with a decreased expression of SDC. The same is observed in PCa cell lines with high tumorigenic capacity such as PC3 regarding cells with low tumorigenic potential as LNCaP. The aim of the preset work was to evaluate the specific interaction of SNAIL with gene promoter regions of SDC1 and SCD2 in PCa cell lines LNCaP and PC3.
Material and Methods: Commercial PCa cell lines of low (LNCaP, ATTC, Cat. CRL-1740) and high (PC3, ATCC, Cat. CRL-1435) tumorigenic capacities were used. Interaction of SNAIL with E-box sites of SDC1 and SDC2 promoters were assessed by chromatin immunoprecipitation (ChIP). Only E-box located −1100 bp downstream from transcription origin in both promoters were considered. To evaluate specific binding sites of promoter regions (ChIP positive) electrophoretic mobility shift assay (EMSA) were applies using fusion protein and nuclear extracts.
Results: ChIP results show interaction of SNAIL with two regions of SDC1 promoter in PC3 cells. In addition, an increase in the percentage of histone H3 input was observed in PC3 cells compared with LNCaP, suggesting an increase in chromatin compaction and the corresponding transcriptional repression of this region. No evidence for SNAIL binding to SDC2 promoter was found, suggesting no functional interaction of SNAIL with SDC promoters in none of cell lines studied. EMSA results suggest that SNAIL binding to DNA may be dependent on other factors due to no mobility retardation was found in presence of recombinant protein. When super-shift assay was performed to discriminate between two SNAIL members (SNAIL1 and SLUG) no shift difference was observed.
Conclusion: SNAIL interacts with SDC1 but not with SCD2 E-box promoter regions. SNAIL may be regulating SDC1 expression in PCa, suggesting a role in malignant progression.

Role of AhR in murine spermatogenesis through regulation of the SINE B1-X35S retrotransposon

N. Moreno Marín[1], E.M. Rico Leo[1], F.J. Gonzalez Rico[1], E.M. Barrasa Ardila[1], P.M. Fernández Salguero[1]. [1]*University of Extremadura, Biochemistry Molecular Biology and Genetics, Badajoz, Spain*

Background: The dioxin receptor (AhR) is a transcription factor highly conserved in murine genome. Recent studies have shown that AhR has an important role in cell and organ homeostasis. We have also reported that AhR cooperates with the EMT regulator factor Slug in the activation of the novel murine B1-X35S retrotransposon, which has an insulator/boundary activity able to repress gene expression. The alterations in processing of retrotransposon-derived transcripts are considered a very relevant mechanism in disease progression, particularly in cancer. In mammals, methylation is the main transposable elements (TEs) silencing mechanism. This DNA methylation is temporarily lost in male germ cells, being the piRNA pathway the main defense against transposons. Those piRNAs are produced in a dense perinuclear cloud-like region called Nuage, where they associate with MILI and MIWI (murine orthologs of PIWI proteins) to form an active piRNA-induced silencing complex.
Material and Methods: AhR wild type (WT) and AhR knockout (KO) mice were used. Mouse testis were taken at different stages of spermatogenesis in order to obtain paraffin sections for immunohistochemistry experiments. Total RNA preparation was made to perform Northern Blot assays.
Results: We have seen that mice AhR KO show a deregulation in the B1X35S/piRNAs balance. Thus, these animals displayed a higher B1X35S mRNA expression compared to wild type ones. Furthermore, we determined small RNA expression by radioactive SDS-PAGE and found that piRNAs were increased in AhR KO, and individual RNA bands that were detected by Northern Blot assays were absent in AhR WT. We have also found differences in MILI, MIWI and MVH (another Nuage component) expression levels by both qPCR and WB assays. Moreover, we observed relocation towards the more differentiated areas of the seminiferous tubules in all of three proteins in the KO phenotype earlier. Molecular beacons *in situ* and *in situ* hybridization techniques will be used to address possible co-

localization between these proteins and transcripts derived from B1X35S and piRNAs.
Conclusions: Our results suggest a higher expression level of MILI and MIWI proteins in the AhR KO phenotype, as well as an early internalization towards the light of the seminiferous tubules of MVH, MILI and MIWI. RNA analysis by radioactive SDS-PAGE revealed that piRNAs were increased in AhR KO. These mice showed slightly reduced testis size and structural differences compared to the WT ones.

Insights into the regulation of GRIM-19 expression in renal cell carcinoma

A. Dias[1], R. Batista[2], J. Lima[3], P. Soares[3], V. Máximo[3]. *[1]Institute of Molecular Pathology and Immunology of the University of Porto, Faculty of Sciences University of Lisbon, Lisbon, Portugal; [2]Institute of Molecular Pathology and Immunology of the University of Porto, Porto, Portugal; [3]Institute of Molecular Pathology and Immunology of the University of Porto, Department of Pathology and Oncology Medical Faculty University of Porto, Porto, Portugal*

Background: GRIM-19 (Gene associated with Retinoid Interferon-induced Mortality − 19) is a novel tumor suppressor gene involved in interferon-β (IFN-β) and retinoic acid (RA)-induced cell death and is also a subunit of mitochondrial respiratory chain(MRC) complex I. It has been proposed that GRIM-19 plays a critical role in the etiopathogenesis of thyroid and kidney tumors. In thyroid, mutations in GRIM-19 gene were found to be exclusively associated with mitochondrion-rich tumors of thyroid (oncocytomas), suggesting that these alterations could be the reason for mitochondria accumulation, as a compensatory mechanism. On the other hand, renal oncocytomas did not harbor GRIM-19 mutations (unpublished data). However, we found GRIM-19 loss of expression or downregulation, but no mutations, in the majority of the renal cell carcinomas (RCC) studied. The data suggest that other mechanism(s), such as GRIM-19 transcription regulation or promoter methylation, may be involved in GRIM-19 loss of expression or downregulation in RCC.
The main purpose of this study was to clarify the mechanism behind GRIM-19 loss of expression or downregulation in RCC, particularly in clear cell RCC (ccRCC), which is the most common RCC histotype and the one that shows stronger downregulation of GRIM-19.
Material and Methods: Two ccRCC derived cell lines (Caki-2 and 786-O) showing different levels of GRIM-19 protein expression were tested. GRIM-19 gene mutations were evaluated by PCR and Sequencing and GRIM-19 mRNA expression by Real-time PCR. GRIM-19 promoter methylation was evaluated by bisulfite sequencing. In order to test how promoter methylation status impacts GRIM-19 expression, we treated the two cell lines with the DNA demethylating agent, 5-aza-2′-deoxycytidine (5Aza-dC).
Results: The 786-O cell line had lower expression of GRIM-19 protein than the Caki-2 cell line. No mutations in GRIM-19 gene were found in both cell lines. GRIM-19 mRNA levels correlate with the protein expression levels. Furthermore, we evaluated GRIM-19 promoter methylation status by studying in detail the methylation profile of the CpG islands. Surprisingly, the GRIM-19 promoter in the Caki-2 cell line appears to be more methylated than in the 786-O cell line. Upon treatment with a 5Aza-dC, we found a significant decrease in the promoter methylation status of Caki-2 cell line, while the 786-O cell line did not showed significant alterations. Additionally, protein expression analysis, after 5Aza-dC treatment, did not affect GRIM-19 expression in 786-O cell line and lead to a marked reduction (approximately 50%) in GRIM-19 expression in Caki-2 cells. We further observed that the 5Aza-dC treatment resulted in an increase in STAT3 mRNA levels.
Conclusions: GRIM-19 downregulation in ccRCC cell lines is not due to gene mutations. Caki-2 and 786-O cell lines have different expression of GRIM-19 protein and also show differences concerning the methylation status of the putative GRIM-19 gene promoter region. Our results suggest that GRIM-19 expression can be regulated by changes in promoter methylation. Further analyses are necessary to prove that the binding of transcription factors to GRIM-19 promoter (e.g. STAT3) is dependent on its methylation status and play a role in the regulation of GRIM-19 protein expression.
With this study we provided, for the first time, evidence that GRIM-19 expression might be under regulation of a repressive mechanism, through the action of transcription factors.

Genome-wide investigation of FK866-induced effects in Jurkat cells

C. Zucal[1], V. D'Agostino[1], T. Tebaldi[1], S. Bruzzone[2], A. Quattrone[1], A. Nencioni[3], A. Provenzani[1]. *[1]Centre for Integrative Biology CIBIO, Trento, Italy; [2]Department of Experimental Medicine, Section of Biochemistry, Genoa, Italy; [3]Department of Internal Medicine, Genoa, Italy*

Acute lymphoblastic leukemia is a relatively uncommon form of cancer (17.3 per million in United States, of which T-ALL comprises about 25%) that usually affects infants, children and young adults. In T cell leukemia cell lines, apoptosis occurs when endogenous NAD synthesis is limited using FK866. This is a specific inhibitor of nicotinamide phosphoribosyltransferase (NAMPT), a key enzyme in the regulation of NAD biosynthesis from the natural precursor nicotinamide, that on lymphocyte activation becomes up-regulated to compensate for the increased metabolic demands.
By using Jurkat cells as a model of acute T-cell leukemia, we evaluated the effect of FK866 by AnnexinV/7AAD FACS analysis revealing a decrease in the number of cycling cells after treatment. The calculated IC_{50} at 48 hours was 5.5 nM. A significant, dose-dependent reduction of NAD-levels in treated samples confirmed the efficacy and specificity of the drug. To determine gene-expression changes caused by FK866-induced NAD depletion in leukemic T cells, we performed microarray analysis of RNA samples after sucrose gradient fractionation of Jurkat lysates (sub-polysomes, polysomes, total). Among the identified DEGs we analyzed polysomal/subpolysomal distribution in treated or untreated cells to characterize the multi-level gene-expression regulation effects of the drug. Up-regulated DEGs in the polysomal RNA from treated samples code for proteins involved in chromatin modification, nucleotide and RNA bioprocessing and metabolism.
The identified differentially expressed genes, in the early phase of cell response to FK866, and the genes accounting for a specific post-transcriptional regulation may help the identification of pathways involved in pharmacoresistance.

571 POSTER

Peculiarities of molecular chaperone Hsp60 expression in thyroid cancer

L. Kapustian[1], V. Gurtovyy[2], Y. Khozhaenko[2], V. Usenko[2], L. Sidorik[1]. *[1]Institute of Molecular Biology and Genetics NAS of Ukraine, Molecular Mechanisms of Autoimmunity, Kyiv, Ukraine; [2]Morphological Laboratory BIONTEK, Dnipropetrovsk, Ukraine*

Background: Heat shock proteins (HSPs) are the most ancient defence system of all living organisms. HSPs function as molecular chaperones in regulation of cellular homeostasis and maintenance of cell survival. They are involved in numerous diseases, including cancer, revealing changes of their expression. A wide range of tumour cells have been shown to express Hsp60 atypical levels and localisation. For example, high expression of Hsp60 on the cell surface in breast cancer was associated with poor prognosis and resistance to chemotherapy. Hsp60 expression in thyroid cancer has not been studied extensively. Understanding its role in thyroid carcinogenesis has important implications regarding tumour behaviour and potential prognostic implications. The aim of our study was to evaluate the possible changes in Hsp60 expression and localization in thyroid tissue and content of anti-Hsp60 autoantibodies in patients' sera in normal state and upon pathology.
Material and Methods: Sera of 49 patients (12 nodular hyperplasia of thyroid gland, 12 autoimmune thyroiditis, 18 follicular adenoma, 6 papillary and 1 follicular carcinoma) and 12 healthy donors were used for determination of anti-Hsp60 antibodies by ELISA. We used surgical material obtained from 50 patients with thyroid gland pathology for immunohistochemical analysis. By histology, 23 malignant tumours (21 papillary thyroid carcinoma, 1 follicular thyroid carcinoma, 1 anaplastic thyroid carcinoma), 18 benign tumours − follicular thyroid adenoma, 4 Hashimoto's thyroiditis and 5 nodular hyperplasia were diagnosed. As a control, autopsy material of 11 thyroid tissue samples without morphological signs of thyroid pathology was used.
Results: More than 50% of non-malignant pathologies and 100% of malignant tumours were characterised by increased level of anti-Hsp60 antibodies. The highest titers of anti-Hsp60 antibodies were in group of malignant tumours (by 353%). The highest frequency of elevated Hsp60 expression has been found in cancer tissues (39%). The significant difference ($p < 0.05$) of staining index for Hsp60 has been observed only for thyroid cancer group as compared with control. There was no correlation between anti-Hsp60 antibodies and Hsp60 content in thyroid gland tissue at thyroid cancer (Spirman test, $r = 0.012$, $p = 0.94$).

Conclusion: We have determined increased level of anti-Hsp60 antibodies in sera of patients with thyroid gland pathology. The highest titers of anti-Hsp60 antibodies have been revealed in sera of patients with thyroid cancer. The increase of Hsp60 expression and changes in cellular localisation in thyroid cancer tissue have been detected and it was associated with morphological signs of pathology − lymphoid infiltration and sclerotic changes of tissue.

The effect of conditioned media of mesenchymal stem cells on proliferation and apoptosis of breast cancer cell line

L. Eini[1], K. Majidzadeh[1], R. Esmaeili[1], L. Farahmand[1], K. Majidzadeh-A[2]. *[1]Cancer Genetics Research Group, Breast Cancer Research Center (BCRC) ACECR, Tehran, Iran; [2]Faculty of Medicine AJA University of Medical Sciences, Tehran, Iran*

Background: Breast cancer remains the most prevalent malignancy among women of all races in the world. Induction of apoptosis and proliferation inhibition are widely recognized approaches to control cancer progression and reduced cancer risk. Recent studies reported that bone marrow (BM) derived from mesenchymal stem cells (MSC) migrate to sites of inflammation, tumor and injury in response to signals of cellular damage. In this study, the effects of conditioned medium (CM) of MSCs on proliferation and apoptosis of breast cancer cell lines was investigated through expression analysis of STK15 and surviving genes.
Material and Methods: MCF-7 cells were seeded into 6 well in CM of pre-cultured mesenchymal stem cells comparing the control group. Sub confluent cultures were isolated and expression level of STK15 and Survivin genes were analyzed by Q-RT-PCR.
Results: MSCs-CM have altered the expression of anti-apoptotic and prolifrative genes. After indirect coculture, in comparison with the control group, the expression of survivin and STK15 were upregulated 1.3 times.
Conclusions: It is mentioned in previous studies that mesenchymal stem cells can migrate into the tumor microenviroment and they are among the ideal candidate of cancer targeting and therapy. Overexpression of Survivin and STK15 as anti-apoptotic and proliferative genes may point to the negative effect of mesenchymal stem cells on cancer cells. Further research is needed to clarify the interaction of these cells and cancer cells.

Rutin induces cyclooxygenase (COX)-2 expression and matrix metalloproteinase (MMP)-9 expression via PI3K/Akt and JNK pathway in A549 human lung cancer cell

S. Yu[1], S. Kim[1]. *[1]Kongju National University, Biological Sciences, Gong-ju, Korea*

Background: Rutin is a flavonoid with a wide range of biological activities and is found in many plants such as citrus fruits and vegetables. It is known to possess the anti-cancer and anti-inflammatory properties, although the underlying mechanisms have not been fully elucidated. In this study, we investigated the effect of rutin on COX-2 expression and MMPs expression of A549 cells.
Material and Methods: A549 human lung cancer cell was incubated for 24 h with rutin in the absence or presence of specific PI3K/Akt and JNKinase inhibitors, LY294002 or SP600125. Expression of COX-2 was performed by Western blot analysis and PGE_2 production was determined by PGE_2 assay. Expression of MMP-9 was detected by gelatin zymography.
Results: We found that rutin increases COX-2 expression and prostaglandin E_2 (PGE_2) production in a dose-dependent manner as determined by Western blot analysis and PGE_2 assay, and induces MMP-9 expression in a dose- and time-dependent manner as detected by Western blot analysis and Zymography. Rutin also stimulated the activation of PI3K/Akt and JNKinase pathways. In the presence of LY294002 or SP600125, specific inhibitor for PI3K/Akt or JNK, respectively, could significantly inhibit the COX-2 expression and PGE_2 production, and MMP-9 expression.
Conclusion: These data suggest that the activation of PI3K/Akt and JNKinase is required for rutin-caused COX-2 expression and MMP-9 expression in A549 cells.
No conflict of interest.

Salinomycin inhibits cell proliferation and causes cyclooxygenase (COX)-2 expression via the mitogen-activated protein (MAP) Kinase pathway, JNK and ERK, in HT1080 human fibrosarcoma cells

S. Yu[1], S. Kim[1]. *[1]Kongju National University, Biological Sciences, Gong-ju, Korea*

Background: Salinomycin is a monocarboxylic polyether antibiotic belonging to the group of inophores isolated from Streptomyces albus. It has recently been used to inhibit various cancer stem cells and is known to regulate various cancer cell responses including growth, proliferation, migration and apoptosis. However, the effect of salinomycin on HT1080 human fibrosarcoma cells has not yet been fully. Therefore, we investigated the effect and the regulatory mechanisms of salinomycin in HT1080 human fibrosarcoma cells.
Material and Methods: HT1080 human fibrosarcoma cells were treated for 24 h with salinomycin in the absence or presence of specific JNK and ERK inhibitors, SP600125 or PD98059. Cell proliferation was performed by MTT assay. Expression of COX-2 was detected by Western blot analysis and PGE_2 production was determined by PGE_2 assay.
Results: We found that salinomycin inhibits the cell viability and proliferation in dose- and time- dependent manner as detected by MTT assay and it significantly increases COX-2 expression and PGE_2 production as determined by Western blot analysis and PGE_2 assay. Salinomycin also increased the phosphorylation states of MAP kinases, the JNK and ERK, but not of p38. Using SP600125 or PD98059, specific JNK and ERK inhibitors, we found that JNK and ERK significantly are recovered cell viability and proliferation, and are prevented COX-2 expression and PGE_2 production.
Conclusion: These results suggest that salinomycin inhibits proliferation and increases COX-2 expression via MAP kinases, the JNK and ERK, in HT1080 human fibrosarcoma cells.
No conflict of interest.

Whole exome sequence of BON-1 and QGP-1, two human pancreatic neuroendocrine tumor cell lines, reveals loss of heterozygosity and homozygotic mutations in the TP53 and MUC genes

T. Vandamme[1], K. Op de Beeck[2], C. Vangestel[3], G. Mortier[4], P. Pauwels[5], L.J. Hofland[6], G. Van Camp[4], M. Peeters[7]. *[1]University of Antwerp, Department of Oncology, Antwerp, Belgium; [2]University of Antwerp, Department of Oncology/Center of Medical Genetics, Antwerp, Belgium; [3]University of Antwerp, Molecular Imaging Center Antwerp, Antwerp, Belgium; [4]University of Antwerp, Center of Medical Genetics, Antwerp, Belgium; [5]University Hospital Antwerp, Department of Pathology, Antwerp, Belgium; [6]Erasmus MC, Department of Neuroendocrinology, Rotterdam, Netherlands; [7]University Hospital Antwerp, Department of Oncology, Antwerp, Belgium*

Background: The human BON-1 and QGP-1 cell lines are two often used models in pancreatic neuroendocrine tumor (PNET) research. Data on mutations in these cell lines is lacking.
Methods: The identity of the BON-1 and QGP-1 cell lines was confirmed using short tandem repeat profiling. The exome of both cell lines was sequenced using the HiSeq 1000 next generation sequencing platform (Illumina). Exonic sequences were enriched using Illumina's Truseq Exome Enrichment Kit. Paired-end reads were aligned to the human reference genome using the Burrows-Wheeler aligner. Single Nucleotide Variants (SNVs) and indels were called using the Genome Analysis ToolKit. Found mutations were validated using Sanger sequencing.
Results: The average region coverage for QGP-1 and BON-1 was 425x and 266x respectively. After filtering, possible protein-altering indels and SNVs were called (Table 1). We identified 55 frameshift-indels and 969 SNVs in the BON-1 cell line. Of these SNVs, 951 were non-synonymous, 17 stopgain and 1 stoploss. The QGP-1 sequences revealed 53 frameshift-indels and 651 SNVs of which 638 were non-synonymous and 13 stopgain. Heterozygosity of filtered SNVs was 65% in BON-1 and 75% in QGP-1, indicating loss of heterozygosity (LOH) in these rare polymorphisms. Homozygous (HoZ) mutations in *TP53* with a possible loss of function (LOF) were identified in both cell lines. Different *MUC* genes, implicated in cell signaling, lubrication and chemical barriers and frequently expressed in PNET tissue samples, showed HoZ protein-altering SNVs in the BON-1 and QGP-1 cell line. No mutations were found in known NET-associated genes.

Table 1. Number of single nucleotide variansts (SNVs) and insertion-deletions (indels) per filter step.

Filter steps	BON-1		QGP-1	
	SNVs	Indels	SNVs	Indels
Predicted mutations	63209	6424	56948	5888
Quality and coding DNA	46871	4618	41643	4243
Novel mutations	5509	4616	2936	4241
Protein-altering mutations	969	55	651	53

Quality and coding DNA: total reading depth $\geqslant$10, mapping quality $\geqslant$50, Fisher-Scaled Strand Bias $\leqslant$20, allelic ratio $\geqslant$0.3, snpEff annotation = coding;
Novel mutations: only SNVs and indels not in NCBI dbSNP130 database;
Protein-altering mutations: stopgain, stoploss, non-synonymous SNVs and frameshift indels.

Conclusion: LOH is associated with aggressive tumor behaviour and is observed in both cell lines. The LOF mutations identified in *TP53* may explain how QGP-1 and BON-1 escape apoptosis. Variations found in the *MUC* genes may play a role in PNET carcinogenesis.
No conflict of interest.

576 POSTER

Roles of genetic polymorphisms in ERP29, a tumor suppressor, and in IKBKAP, a DNA transcription factor, in mRNA levels, microRNA targets and protein structure

G. Lourenco[1], C. Lima[1]. [1]*State University of Campinas, Laboratory of Cancer Genetics Department of Internal Medicine Faculty of Medical Sciences, Campinas, Brazil*

Background: Our previous genome-wide association study identified single nucleotide polymorphisms (SNPs) located in 3′ un-translated region (3′UTR) of tumor suppressor *ERP29* (c.*293A>G, rs7114) and in coding sequence (CDS) of DNA transcription factor *IKBKAP* (c.3214T>A, rs3204145) associated with higher risk for base of tongue carcinoma. The overexpression of ERP29 was inversely correlated to breast cancer cells progression and with increased radio resistance in nasopharyngeal carcinoma. Recently, the IKBKAP was related to hypoxia-inducible factor 2-alpha network, an angiogenic factor, in melanoma cell line. However, the roles of the referred SNPs in the gene expression are still unknown.
Objectives: We aimed to investigate whether the SNPs in *ERP29* (rs7114) and *IKBKAP* (rs3204145) alter the mRNA levels, microRNA targets and protein structure.
Materials and Methods: The mRNA levels of *ERP29* and *IKBKAP* were quantified by real-time PCR using total RNA from peripheral blood leukocytes of 31 healthy individuals with distinct genotypes (wild-type, heterozygous, and variant homozygous). The reference housekeeping beta-actin gene was amplified in same plate of all samples. The gene expression was calculated by comparative DDCt threshold cycle method. Bioinformatics analysis of microRNA targets and protein structure were performed by *mirsnpscore* (bigr.medisin.ntnu.no/mirsnpscore) and SIFT (sift.jcvi.org) algorithms, respectively. The comparison of groups was performed by analysis of variance model.
Results: The mRNA levels (mean (standard deviation)) of *ERP29* (AA: 0.7 (0.3), AG: 1.2 (1.0) and GG: 0.9 (0.9) arbitrary units (AUs), $P = 0.45$) and *IKBKAP* (TT: 2.1 (1.8), TA: 2.6 (3.3) and AA: 1.4 (1.5) AUs, $P = 0.65$) were similar in individuals with distinct genotypes. We found that a microRNA, the *miR-362212-3p*, shared binding site complementary with 3′UTR of 'G' variant allele of *ERP29* while the 'A' allele disrupt this target site. We also found that amino acid substitution (p.Cys1072Ser) determined by c.3214T>A SNP in *IKBKAP* predicted a damage protein (SIFT score 0.02).
Conclusions: Our data present preliminary evidence that *ERP29* (rs7114) and *IKBKAP* (rs3204145) SNPs do not alter the expression of the respective proteins, but their variants alleles alter microRNA targets of *ERP29* and structure of the protein encoded by *IKBKAP*, respectively. Functional analyzes of the variant proteins in cancer cells should be conducted to confirm their roles in carcinogenesis.
No conflict of interest.

577 POSTER

Copy number profiling of primary colorectal cancer in a South African cohort by Affymetrix® Cytogenetics Whole-genome 2.7M microarrays

R. Goosen[1], B. Robertson[2], P. Goldberg[3], R. Ramesar[4], J.M. Blackburn[1]. [1]*University of Cape Town, Blackburn Laboratory Institute of Infectious Disease & Molecular Medicine Department of Clinical Laboratory Sciences Faculty of Health Sciences, Cape Town, South Africa;* [2]*Groote Schuur Hospital, Department of Radiation Oncology, Cape Town, South Africa;* [3]*Groote Schuur Hospital, Colorectal Surgery Unit Department of Surgery, Cape Town, South Africa;* [4]*University of Cape Town, MRC/UCT Human Genetics Research Unit Division of Human Genetics Institute for Infectious Diseases and Molecular Medicine, Cape Town, South Africa*

Background: Colorectal cancer (CRC) is the second leading cause of cancer-related deaths in Europe. This particular disease is one of the top five cancers in South Africa. Furthermore, CRC patients in South Africa generally present with advanced stages of disease (i.e. TNM stage II − IV). A deeper understanding of this disease is still required, as it has been reported that there is a 20−40% likelihood of recurrent disease in stage II, and approximately 40% in stage III disease. High-throughput genomic techniques are one way to facilitate an understanding of the molecular changes underpinning the pathophysiology of this disease.
Materials and Methods: DNA was isolated from 20 paired CRC tumour and normal mucosa samples. The isolates were then subjected to high-throughput copy number profiling. These assays were performed using the Affymetrix® Cytogenetics Whole-genome 2.7M microarray platform. The resultant datasets were analysed using Affymetrix® Chromosome Analysis Suite to detect chromosomal segments with altered copy number profiles. The results were then further analysed using R: a software environment for statistical computing and graphics. In particular, the distribution of copy number alterations (CNAs) across the genome was assessed, as well as the copy number profile of the genes associated with each chromosomal segment reported to have CNAs. The Gene Ontology enRIchment anaLysis and visuaLizAtion tool (GOrilla), Reduce and Visualize Gene Ontology (REViGO), and Gene Annotations co-occurrence discovery (GeneCodis3) web-service tools were used to assess the biological relevance of the list of genes with CNAs. This study is approved by the Human Research Ethics Committee (HREC) of the Faculty of Health Sciences at the University of Cape Town (HREC ref. no. 434/2010).
Results and Conclusions: Through analysis of the distribution of CNAs across the genome we have identified potentially novel regions of the genome with CNAs. By investigating the genes associated with these regions we are able to rationalise the biological functions and pathways potentially affected by such copy number changes. These data, when assessed alongside Affymetrix® GeneChip® Human Gene 1.0 ST gene expression datasets generated on the same samples, provide in some cases a putative explanation of the etiology of altered gene expression profiles, and the consequent change in biological processes associated with disease. The results of this study will provide further insight into the molecular underpinnings driving the pathology of CRC.

Genome instability in metachronous esophageal cancer

E. Boldrin[1], E. Rumiato[1], V. Chiarion-Sileni[2], M. Rugge[3], R. Cappellesso[3], M. Cagol[4], A. Ruol[5], R. Alfieri[4], A. Amadori[5], D. Saggioro[1]. [1]*Veneto Institute of Oncology IOV-IRCCS, Immunology and Molecular Oncology, Padova, Italy;* [2]*Veneto Institute of Oncology IOV-IRCCS, Medical Oncology, Padova, Italy;* [3]*University of Padova, Department of Medicine Surgical Pathology and Cytopathology, Padova, Italy;* [4]*Veneto Institute of Oncology IOV-IRCCS, Oncological Surgery, Padova, Italy;* [5]*University of Padova, Department of Surgical Sciences Oncology and Gastroenterology, Padova, Italy*

Background: The development of novel therapeutic drugs and regimens to treat cancer has led to improvements in long-term survival but this success has been accompanied by the emergent problem of second primary therapy-induced cancers. Indeed, patients who received regional radiotherapy for Hodgkin's disease (HD) or breast cancer might develop a solid metachronous tumor many years later. Esophageal cancer is one of these malignancies that can arise in patients who have suffered of HD or breast cancer. Despite extensive epidemiological studies, little information is available regarding the genetic changes involved in the pathogenesis of these solid therapy-related neoplasias.
Material and Methods: We analyzed 18 samples from metachronous esophageal cancer patients: 12 squamous cell carcinoma (SCC) and 6 adenocarcinoma (ADC) raised in HD and breast cancers long-survivors.

As control, 19 samples (15 SCC and 4 ADC) from sporadic esophageal cancer were included in the study. The median time of appearance of the metachronous tumor was 22.5 years (range 5−40 years). Genetic instability was evaluated as the occurrence of LOH (Loss of Heterozygosity) and MSI (Microsatellite Instability) in several chromosomal regions. Three indices: FAL (Fractional Allelic Loss), FRL (Fractional Regional Loss) and MA (Microsatellites Alterations) were determined to calculate overall frequencies of LOH and MSI. Fisher's exact test was used to compare the frequencies; p value <0.05 was considered as significant.
Results: Using microsatellites markers located in chromosomal regions reported as frequently deleted in sporadic esophageal cancer (i.e. 3p24; 5p12; 5q11; 8p23; 9p21; 13q13; 17q21), and nearby genes that may contribute to carcinogenesis, we assessed LOH and MSI frequencies in both metachronous and primary esophageal cancers. No significant difference was found in LOH and MSI frequencies, with metachronous esophageal cancer exhibiting the same genomic alterations reported for the sporadic one, even when SCC and ADC were considered separately.
Conclusions: This finding may suggest that the cancerogenic pathway of primary and metachronous esophageal cancers are quite similar. The etiology of esophageal cancer is putatively related to environmental agents exposure and lifestyle (i.e. alcohol and tobacco). In this context, radiation, chemotherapeutic drugs and patients lifestyle may induce analogous damages and recapitulate the natural history of esophageal carcinogenesis.
No conflict of interest.

579 POSTER

NPM/NCL gene structure and B23/C23 expression in metastatic cutaneous melanoma

A. Lushnikova[1], E.G. Zenit-Zhuravleva[2], I.V. Tsyganova[1], I.N. Mikhailova[3], E.A. Cheremushkin[3], H.M. Treshalina[2], N.T. Raikhlin[3]. *[1]N.N.Blokhin Cancer Research Center, Carcinogenesis Institute, Moscow, Russian Federation; [2]N.N.Blokhin Cancer Research Center, Institute for Tumor Experimental Diagnostics and Therapy, Moscow, Russian Federation; [3]N.N.Blokhin Cancer Research Center, Clinical Oncology Institute, Moscow, Russian Federation*

Background: Cutaneous melanoma (CM) is characterised by an uncontrolled, clonal, cellular proliferation, as a result of numerous genetic and epigenetic aberrations. Genetic testing of CM is important for prognostication, when results are integrated with histological and clinical data. Nucleolin/C23 and nucleophosmin/B23 are major nucleolar argyrophilic proteins (AP) involved in carcinogenesis. There are none data on C23/B23 encoded genes *NCL*/*NPM* in CM although altered AP expression seems to associate with CM progression.
Material and Methods: DNA samples from 23 CM patient (CMP) metastatic nodes were analyzed by PCR for *NCL* and *NPM* gene structure followed by PAG electrophoresis of PCR products and DNA sequencing. Alterations in *NCL*/*NPM* encoded regions (23 CM samples) + *V600E BRAF* mutation (7 CMP) and 2 human CM xenografts (X) were studied. B23/C23 expression in X was estimated by specific immunohistochemical staining, quantity (density) and dispersion of positive dots per cell (>300 cells for sample) using MatLab 7.0 program.
Results: Genetic alterations in *NCL*/*NPM* gene structure in 23 CMPs and 1/2 X were grouped in several types: (1) two simultaneous nucleotide substitutions *IVS5−31G*/*A* + *IVS6+ −42G*/*A* in *NPM* gene in 13/23 (56%) CMPs and 1/2X; (2) nucleotide substitution *IVS8−63A*/*G* in *NPM* in 9/23 (39%) CMPs + two substitutions from the group (1); (3) 1 nucleotide substitution *IVS2 + 31G*/*A* in *NCL* gene; (4) germinal deletion p.D255delGAT (c.763–765delGAT − was also found in CMP blood cells) + common polymorphism p.E149E in *NCL* gene + intron structure variant in 1 CMP with 4 CM relapses. Somatic mutations *V600E BRAF* (70% in all CM cases) and *K600E BRAF* + AGT/AAA *BRAF* were revealed in 3/7 and 1/7 CMPs with 2−5 relapses, consequently. Somatic mutation *V600E BRAF* in 2CMPs with numerous metastasis was accompany by substitutions in *NPM* gene from the group (1) + group (2), except *IVS6−39A*/*G*. AP dots number and AP density was higher in X exponent growth than in slow growth phase ($p < 0.05$). AP irregular distribution in nucleoplasma was found in the majority of tumor cells during X exponent growth and more regular − in X with slow growth.
Conclusion: Some certain types of *NCL*/*NPM* gene alterations were found in 17/23 CMPs, and somatic *BRAF* mutations − in 4/7 CMPs. These genetic alterations and irregular distribution of B23/C23 with high density in nucleoplasma seems to be linked with numerous metastasis and tumor progression in CMPs.
No conflict of interest.

MicroRNA-146a controls melanoma via a novel pathway

M. Raimo[1], F. Orso[1], D. Cimino[1], C. De Pittà[2], E. Pinatel[1], E. Penna[1], A. Lembo[1], L. Primo[3], E. Medico[4], D. Taverna[1]. *[1]MBC − Molecular Biotechnology Center, Department of Molecular Biotechnologies and Health Sciences, Torino, Italy; [2]C.R.I.B.I. Biotechnology Center, Department of Biology, Padova, Italy; [3]Institute for Cancer Research and Treatment (IRCC), Department of Clinical and Biological Sciences, Candiolo (TO), Italy; [4]Institute for Cancer Research and Treatment (IRCC), Department of Molecular Biotechnologies and Health Sciences, Candiolo (TO), Italy*

MicroRNAs (miRs) are small endogenous non-coding RNAs able to post-transcriptionally downregulate the expression of target genes via sequence-specific interactions with the 3′ untranslated regions (UTRs) of cognate mRNAs. They act as fundamental regulators of a variety of biological processes, including tumour establishment and progression. As malignant melanoma is the most aggressive form of skin cancer, accounting for only 4% of cases but for as many as 74% of all skin cancer deaths at its metastatic stage, it is crucial to disclose its underlying molecular mechanisms. By taking advantage of a melanoma progression model, we identified a novel pathway controlled by miR-146a, whose expression enhances primary tumour growth while it impairs metastatization. MiR-146a's role in melanoma has been investigated by performing *in vitro* studies like proliferation assays, soft agar anchorage-independent growth, transwell migrations and invasions as well as *in vivo* injections of miR-146a-modulated cells into the flank or the tail vein of nude mice. Relevant miR-146a-modulated genes were investigated using bioinformatics and biological analyses, like quantitative real-time PCR (qRT-PCR), western-blot (WB) and luciferase assays. *In vitro* and *in vivo* phenocopy and rescue experiments were performed as well. Stable overexpression of miR-146a enhances cell growth *in vitro* as well as primary tumour growth *in vivo*, while it impairs cell movement *in vitro* and metastatic colonization *in vivo*. On the other hand, miR downmodulation by 'microRNA sponges' completely reverts these phenotypes. Such effects are exerted through repression of multiple genes; two of the targets, Numb and Lunatic Fringe (LFNG), have been described as negative regulators of Notch in breast cancer. Interestingly, both resulted strongly repressed in miR-146a-enriched cells. Numb modulation in melanoma cells reproduces miR-146a-mediated growth phenotypes. Therefore, we have found that miR-146a overexpression leads to increased Notch levels and transcriptional activity, as confirmed by enforced Hairy and Enhancer of Split 1 and 5 (HES-1 and HES-5) and N-cadherin expression. Furthermore, cyclin D1 upregulation was observed, maybe contributing to cell proliferation. Taken together, these findings suggest that miR-146a exerts a pleiotropic role in cancer. MiR-146a-dependent Numb targeting and consequent Notch signaling alteration could partly account for these phenotypes.
No conflict of interest.

Loss of epigenetic control of proto-oncogenic eEF1A2 as a potential way to cancer progression

A. Vislovukh[1], G. Kratassiouk[2], G. Pinna[2], A. El'skaya[1], A. Harel-Bellan[2], B. Negrutskii[1], I. Groisman[2]. *[1]Institute of Molecular Biology, Lab. of Protein Biosynthesis, Kiev, Ukraine; [2]Université Paris Sud Laboratoire Epigenetique et Cancer Formation de Recherche en Evolution 3377, Gif-Sur-Yvette, France*

Background: The eukaryotic translation elongation factor 1A2 (eEF1A2) is a known proto-oncogene. The overexpression of eEF1A2 has been observed in pancreatic, lung, ovarian and breast cancers. In the majority of ovarian cancer samples the overexpression of the gene was not related to the genetic or epigenetic modifications in the EEF1A2 locus. Thus, deregulation of the eEF1A2 expression can occur on the posttranscriptional level. We proposed that the eEF1A2 expression in cancer tissues is controlled by microRNAs.
Materials and Methods: Dual-luciferase assay was applied to detect the influence of miRNAs on EEF1A2 expression. For proliferation assay, human cells were transfected with miRNA precursors. After 72 h of incubation, the cells were stained and their number in each well was calculated using the Operetta® High Content Imaging System (Perkin Elmer). Changes in the eEF1A2 mRNA and miRNAs levels were quantified by qPCR.
Results: We found that eEF1A2 is a direct target of two oncosuppressor microRNAs hsa-mir-663 and hsa-mir-744. Both miRNAs were able to downregulate the expression of luciferase gene attached to the 3′UTR of EEF1A2 up to 20% and 50% respectively. Next, we examined the effect of hsa-mir-663 and hsa-mir-744 on the cellular eEF1A2 expression in MCF7 cell line. In this case, overexpression of hsa-mir-663 and hsa-mir-

744 reduced the EEF1A2 mRNA level by 44% and 68% and decreased the eEF1A2 protein level by 20 and 40% respectively.
Overexpression of both hsa-mir-663 and hsa-mir-744 inhibited the proliferation of MCF7 cell line. Treatment of MCF7 cell line with eEF1A2 siRNA showed similar inhibitory effect of the MCF7 proliferation. Hsa-mir-663 is well-known oncosuppressor and it was shown to be upregulated during resveratrol treatment of THP-1 and SW-480 cells. Resveratrol also inhibited eEF1A2 expression by blocking Akt in serum- or insulin-stimulated PA-1 cells. We observed upregulation of mir-663 and mir-744 with corresponding downregulation of eEF1A2 in resveratrol treated MCF7 cells, suggesting that resveratrol may influence the eEF1A2 expression through miRNA dependent pathway.
Conclusion: Obtained data are in favor of a novel explanation for the abnormal occurrence of the eEF1A2 isoform in tumor tissues, indicating that it may be caused by the loss of microRNA-mediated post-transcriptional control of the eEF1A2 expression.
No conflict of interest.

The role of miR-196a and HOXB9 in head and neck squamous cell carcinoma

L. Darda[1], D. Lambert[1], R. Morgan[2], C. Murdoch[1], K. Hunter[1]. *[1]The University of Sheffield, Department of Oral Pathology, Sheffield, United Kingdom; [2]The University of Surrey, Department of Microbial and Cellular Sciences, Guildford, United Kingdom*

Background: HOX genes are involved in embryogenesis and organogenesis in vertebrates. In total there are 39 HOX genes separated into 4 clusters (A-D) and 13 paralogous groups. HOX gene clusters contain conserved miRNA families including miR-196, with HOXB9 having a close spatial relationship with miR-196a-1 on chromosome 17q21. Our preliminary microarray data suggested marked up-regulation of miR-196a and HOXB9 in HNSCC.
Methods: The levels of miR-196a and HOXB9 in RNA extracted from normal (NOK), immortalised normal (iNOK), oral pre-malignant (OPM) keratinocytes and HNSCC-derived cell lines were assessed by quantitative-RTPCR (qRTPCR). Laser capture microdissection (LCM) followed by qRTPCR and immunohistochemistry were used to measure miR-196a and HOXB9 expression, respectively, on FFPE tissue samples. Anti-miR-196a and HOXB9 siRNA were transfected into OPM and HNSCC cells followed by functional assays for adhesion, proliferation, invasion and migration. Nested PCR was used to test the presence of a novel HOXB9 and miR-196a-1 primary transcript. Microarray analysis of anti-miR-196a and pre-miR-196a transfected cells was conducted using Agilent Sureprint G3 array and analysed by Qlucore Omics Explorer and gene expression changes validated by qRTPCR.
Results: 600–4000 and 400–40000 fold up-regulation of miR-196a and HOXB9 respectively was observed in OPM and HNSCC cells relative to NOK's. FFPE cancer tissue samples showed significant up-regulation compared to normal tissue for miR-196a and HOXB9 ($p < 0.05$). Transfection of anti-miR-196a resulted in reduced adhesion, invasion and migration ($p < 0.001$) and no change in proliferation of HNSCC cells. HOXB9 siRNA transfected cells showed no significant change in adhesion but migration, invasion and proliferation were decreased ($p < 0.05$). Nested PCR showed the presence of common primary transcript consisting of HOXB9 and miR-196a-1. Microarray analysis and qRTPCR validation showed HOXC8, MAMDC2 and RFC3 to be putative targets of miR-196a.
Conclusions: Our data shows that miR-196a and HOXB9 are over-expressed in HNSCC. miR-196a and HOXB9 promote functional effects in HNSCC and changes in expression of known and novel miR-196a target genes. The identification of a novel primary transcript suggests coordinated expression of HOXB9 and miR-196a-1; elucidation of factors responsible for regulating levels of this transcript may therefore represent important therapeutic targets.

miRNAs in resistance to lapatinib in HER2-positive breast cancer

V. Haley[1], F. Cavicchioli[1], A. Shia[1], K. O'Leary[1], L. Balakrishnan[1], C. Lo Nigro[2], P. Schmid[3]. *[1]University of Sussex, Brighton East Sussex, United Kingdom; [2]Laboratorio Genetica Oncologica e Oncologica Translazionale, Cuneo, Italy; [3]University of Sussex, Brighton and Sussex Medical School, Brighton, United Kingdom*

Background: Despite significant progress in HER2-directed therapy, only a subset of patients derives optimal benefit from treatment, whereas other patients have refractory disease or develop resistance. Recent studies have shown that microRNAs are potentially linked with drug resistance, however, their role in resistance to HER2-directed therapy is currently unknown.
Material and Methods: Taqman Low Density miRNA Human A and B Arrays were used to identify a panel of miRNAs differentially expressed between a lapatinib-sensitive and paired lapatinib-resistant HER2 positive breast cancer cell line (BT-474). A selection of miRNAs were chosen for further investigation based on biological relevance of putative targets. BT-474 cell lines were transfected with mirVana mimics or inhibitors and IC50 determined by AlamarBlue to determine if there was altered sensitivity to lapatinib. Cellular proliferation (AlamarBlue) and apoptosis (CaspaseGlo 3/7) was measured at 6, 10 and 24 hrs, D2, D3, D5 and D7. Putative targets of miRNAs were determined by *in silico* analysis of miRWalk predicted targets and gene expression array data (Illumina HT-12 Expression BeadChip). Targets were validated by qPCR, Western blotting and luciferase reporter assay.
Results: Sixteen miRNAs were up-regulated and 14 down-regulated in the BT474 lapatinib-resistant cell line (<2.0 fold difference) relative to the BT-474 lapatinib-sensitive cell line, which was confirmed by qPCR. Transfection of the BT-474 lapatinib-sensitive cell line with 1nM miR-127-3p, miR-409-3p or miR-495 mirVana mimic altered the sensitivity to Lapatinib and proportion of cells undergoing apoptosis at 24 hrs. *In silico* analysis identified 7, 63 and 207 mRNAs down-regulated in the BT-474 lapatinib-resistant cell line that were putative targets of miR-127-3p, miR-409-3p and miR-495, respectively. Preliminary data suggests that transfection of the BT-474 cell line with miR-495 mimic may modulate multiple components of the RAC/RHO GTPase signalling system, downstream of ErbB2.
Conclusion: These data provide the first evidence indicating miRNAs may confer resistance to lapatinib in HER2 positive breast cancer. In addition, the putative regulation of multiple components of the Rac/Rho GTPase signalling pathway downstream of ErbB2 by miR-495 suggests novel pathways involved in resistance to Lapatinib.

The role of HOXD10 in head & neck and lung cancers

F. Hakami[1], D. Lambert[1], P. Woll[2], K. Hunter[1]. *[1]The University of Sheffield, Oral & Maxillofacial Pathology, Sheffield, United Kingdom; [2]The University of Sheffield, Oncology, Sheffield, United Kingdom*

Background: Genetic alterations in non-small cell lung cancer (NSCLC) and head & neck squamous cell carcinoma (HNSCC) are variable and correlate with the cancer site and stage. Microarray analysis comparing HNSCC with normal mucosa revealed changes in HOX gene expression, particularly HOXD10. HOXD10 expression is altered in many cancers and interacts with important molecules such as miR-7 and miR-10b in breast cancer and IGFBP3 in gastric cancer. We hypothesise that the variation of HOXD10 expression in NSCLC and HNSCC development produces differential effects, with high expression giving cancer cells proliferative advantage over normal cells while low expression might support the metastasized cells to survive.
Materials and Methods: Expression of HOXD10 and associated molecules was assessed by qPCR and Western Blotting (WB). HOXD10 protein in tissues was detected by immunohistochemistry (IHC). Cloned-HOXD10 and shRNA/siRNA were transfected into low- and high-HOXD10 expressing cells, respectively. The resultant phenotype was assessed by MTS assay, fibronectin adhesion assay, and modified transwell migration assay. Novel HOXD10 putative targets and differentially activated pathways were identified using Agilent microarray. Dual luciferase reporter assay was used to detect direct targets of HOXD10.
Results: HOXD10 RNA and protein level showed low expression in normal cells; low/variable in precancerous cells; high in most primary tumours; but very low in cancer cells derived from lymph node metastases. Manipulating HOXD10 expression affected cell proliferation, adhesion to fibronectin, and migration. Microarray and DLR experiments have revealed putative and direct targets of HOXD10, respectively, in HNSCC cells that might explain some of these effects seen.
Conclusion: The results suggest that high HOXD10 expression allows primary tumours to grow and spread while its loss at the advanced front allow cancer cells to be less adhesive and have more metastasis potential. The large number of molecules identified to be direct or putative targets of HOXD10 suggests a range of effects and might explain its stage-dependent role.

Methylation status of selected microRNAs in imatinib-sensitive and imatinib-resistant chronic myeloid leukaemia (K562) cell lines

A. Rodrigues[1], M. Gromicho[1], B. Costa Gomes[1], J. Rueff[1]. [1]*Faculdade de Ciências Médicas − Universidade Nova de Lisboa, CIGMH Dep. Genetics, Lisbon, Portugal*

Background: Several microRNAs (miRs) are involved in carcinogenesis and can be either oncogenic (oncomir) when tumour suppressor genes are targeted or tumour suppressive when their targets are oncogenes. Several miRs, including 124−1, 124−3, 126, 145, 150, 17−92, 200c, 203, 34a and let7a3 are known to be deregulated in haematological malignancies and implicated in disease progression and/or drug resistance.
Material and Methods: We analyzed promoter methylation in the above referred miRs in the human chronic myeloid leukaemia (CML) cell line (K562), sensitive and resistant to the front-line standard treatment, Imatinib, using methylation-specific PCR. Expression was determined with quantitative Real-Time PCR using microRNA PCR primer sets (Exiqon).
Results: Our data revealed that in both resistant and sensitive K562 cells miRs 150, 17−92 and 145 aren't methylated, 124−3 is hypermethylated, miR 34a is heterozygously methylated (more methylated than unmethylated) and let7a3 is hemizygously methylated. MiR 126 gave opposite results depending on the CpG island studied. A distinct methylation profile between sensitive and resistant K562 cells was found for miRs 203, 124−1 and 200c. MiRs 124−1 and 200c aren't methylated in sensitive cells but are hemizygously methylated in resistant cells. MiR 203 is hemizygously methylated in sensitive cells and almost totally unmethylated in resistant cells. Preliminary results of miR expression revealed that miRs 124 and 200c are in fact more expressed in sensitive cells than in resistant cells. However, we could not detect miR 203 expression in either K562 cells.
Conclusion: Our results don't confirm previous reports which showed hypermethylation of miR 203 in CML, a tumour suppressor miR that controls the expression levels of the BCR-ABL1 translocation protein. We show that methylation of miRs 124−1 and 200c may be acquired during disease progression and after chronic treatment followed by resistance development. Therefore, studies modulating the expression levels of these miRs are warranted to ascertain if they are indeed critical targets for increasing CML sensitivity to clinical therapies.

Shifts in microRNA expression impair DNA methylation and chromatin remodeling in cancer cells

V. Halytskiy[1]. [1]*Palladin Institute of Biochemistry of the National Academy of Sciences of Ukraine, Molecular Immunology Department, Kiev, Ukraine*

Background: Epigenetic instability, deregulation of chromatin remodeling as well as impaired balance between DNA methylation and demethylation is typical of many cancer cells. Also, tumor growth is tightly associated with regular shifts in microRNA (miRNA) expression pattern. Usually, expression of miRNAs miR-16, miR-122, miR-31, miR-143, miR-145 and miR-320 is down-regulated in cancer cells whereas expression of miRNAs miR-18a/b, miR-19, miR-21, miR-29a, miR-155, miR-181, miR-206, miR-210 and miR-221/222 is up-regulated. This investigation aims to identify in what way these shifts in miRNA expression contribute to the abnormalities in DNA methylation and chromatin remodeling in cancer cells.
Material and Methods: miRNA targets within gene transcripts were predicted in silico using TargetScan software.
Results: MiRNAs miR-17-5p, miR-26 and miR-205 can silence KAT2B gene encoding histone acetyltransferase PCAF. MiRNAs miR-145, miR-206 and miR-15a/16 target transcript of gene encoding acetyltransferase Elp3. miR-204 and miR-26 suppress ATF2 gene. MiRNA miR-22 silences KAT6A/B and KAT5 genes encoding acetyltransferases MOZ, MORF and TIP60. Also, miR-320 and miR-122 can suppress KAT6B gene. MiRNA miR-143 targets transcript of MYST2 gene coding acetyltransferase HBO1. MiRNA miR-26 can silence genes encoding CREBBP and EP300 factors. Also, miR-22 and miR-17-5p target transcript of EP300 gene. At least one of miRNAs miR-204, miR-145, miR-320, miR-26, miR-17-5p, miR-125a-3p, miR-22 or miR-31 can suppress KDM1A/B, KDM2/B, KDM3A, KDM4A/B/C and KDM5A/C/D genes encoding histone demethylases. MiRNAs miR-31, miR-22, miR-122 and miR-320 can silence ARID1A/B, SMARCC2, SMARCD1/2 and ACTL6A genes coding components of SWI/SNF chromatin remodeling complex. Transcripts of HDAC1/2/4/6/7/8/9 as well as SIRT1/3/5/7 genes encoding histone deacetylases carry targets for at least one of up-regulated miRNAs miR-155, miR-23a/b, miR-375, miR-21, miR-29, miR-206, miR-19, miR-221/222, miR-181 or miR-18. Also, these miRNAs can silence ASH1L, DOT1L, EHMT1/2, EZH1, MLL, MLL2/3/5, NSD1, PRDM2, SET, SETBP1, SETD1A/B, SETD2/3/5/6/7/8, SETDB1/2, SMYD1/2/4/5, SUV39H1/2 and SUV420H1/2 genes encoding histone methyltransferases. MiRNAs miR-29, miR-221/222, miR-206, miR-21 and miR-375 suppress genes encoding de novo DNA methyltransferases DNMT3A, DNMT3B and DNMT3L.
Conclusions: MiRNAs, hyperexpression of which is essential for abnormal proliferation and surviving of cancer cells, silence also genes encoding histone deacetylases, histone methyltransferases and de novo DNA methyltransferases. Down-regulation of other miRNAs allows overexpression of genes encoding histone acetyltransferases, histone demethylases as well as components of chromatin remodeling complexes. This causes increase of overall level of chromatin acetylation and expression and, therefore, makes possible the reactivation of silent oncogenes and transposons, which can rapidly lead to DNA damage and genome destabilization. Such shifts may underlie the initial stage of carcinogenesis.
No conflict of interest.

588 POSTER

Intra-tumor heterogeneity in STAT3 activity is linked to CIP2A expression

O. Kauko[1], J. Laine[2], S. Ventelä[3], J. Westermarck[1]. [1]*Turku Centre for Biotechnology, Turku, Finland;* [2]*Turku University Central Hospital, Department of Pathology, Turku, Finland;* [3]*Turku University Central Hospital, Department of Otorhinolaryngology, Turku, Finland*

Background: Constitutive STAT3 activity plays a critical role in development and progression of many types of cancer. Head and neck squamous cell carcinoma (HNSCC) in particular is highly dependent on STAT3 activation, to the extent that it has been described as oncogene addiction. This makes STAT3 an appealing drug target, however, more detailed understanding of STAT3 regulation is needed. There is considerable intra-tumor heterogeneity in STAT3 activity, STAT3 has functions in tumor microenvironment, and in some cases STAT3 functions to limit tumor growth. We identified a potential novel mechanism for regulation of STAT3 activity in human cancers.
Materials and Methods: STAT3 phosphorylation levels were analyzed by western blotting in CIP2A depleted human cancer cell lines and CIP2A knockout MEFs. CIP2A depleted cancer cells were treated with STAT3 inhibitor S31–201 and cell viability was measured in a colony formation assay. Tissue microarray (TMA) of human HNSCC samples was stained for total STAT3, pY705 STAT3, pS727 STAT3, and CIP2A.
Results: CIP2A depletion increases STAT3 Y705 and S727 phosphorylation and sensitizes cancer cells to S31–201. Phosphoproteomics and microarray analysis of CIP2A depleted cells identified a potential molecular mechanism by which CIP2A regulates STAT3 activity. In HNSCC TMA CIP2A expression positively correlated with cytoplasmic to nuclear ratio of total STAT3 ($p = 0.0271$) and pS727 ($p = 0.0005$). Nuclear pY705 showed some correlation with CIP2A ($p = 0.0193$), however, in heterogeneous samples CIP2A and pY705 were often observed in different cell populations. Cells expressing high levels of CIP2A were generally poorly differentiated, whereas nuclear STAT3 was observed in the well differentiated cell populations.
Conclusions: Our results suggest that CIP2A is a novel negative regulator of STAT3 activity and determinant of the heterogeneity in STAT3 activity in HNSCC. Furthermore, strong CIP2A staining and predominantly cytoplasmic STAT3 staining were associated with poorly differentiated phenotype. Recent studies on HNSCC, lung, breast, and salivary gland carcinoma have associated high nuclear pY705 with better prognosis and reported reduced levels in advanced stage cancers. In our model, CIP2A is a driver of STAT3 independent phenotype. This is supported by our finding that following CIP2A depletion cells revert to a more STAT3 addicted state, in which STAT3 is highly phosphorylated and cells are more sensitive to STAT3 inhibitor.

Genetic variants in CHI3L1 influencing YKL-40 levels: Resequencing 900 individuals and genotyping 9000 individuals from the general population

A.D. Kjaergaard[1], J.S. Johansen[2], B.G. Nordestgaard[1], S.E. Bojesen[1]. [1]*Herlev Hospital, Clinical Biochemistry, Copenhagen, Denmark;* [2]*Herlev Hospital, Oncology and Medicine, Copenhagen, Denmark*

Background: Despite its important role in many serious diseases, including cancer, the genetic background for plasma YKL-40 still has not been systematically catalogued. Therefore, we aimed at identifying genetic variants in *CHI3L1* influencing plasma YKL-40 levels in the general population.
Material and Methods: We resequenced the promoter, all 10 exons and exon-flanking intron segments of *CHI3L1* in 904 individuals from the Danish general population ($n = 8\,899$) with extreme plasma YKL-40 levels, adjusted for age. To potentially identify clinically important genetic variants with

elevated plasma YKL-40 levels, we included twice as many individuals with the highest plasma YKL-40 levels (n = 603) compared to the lowest plasma YKL-40 levels (n = 301). Next, we mapped linkage disequilibrium for all variants with a minor allele frequency (MAF)>0.005. Finally, all participants were genotyped for 8 variants that had divergent MAFs in the two extreme plasma YKL-40 groups and were not in strong linkage disequilibrium (except 2 promoter SNPs).
Results: We identified 59 genetic variants in *CHI3L1*. Fifteen of the genetic variants were associated with plasma YKL-40 levels. Three promoter SNPs, 1 non-synonymous SNP, and 4 intronic SNPs tagging C*HI3L1* were associated with plasma YKL-40 levels at or below genome wide association significance levels (unadjusted p for trend: from $4x10^{-8}$ to $6x10^{-243}$; age adjusted percentiles p for trend: from $3x10^{-12}$ to $2x10^{-304}$).
Conclusion: In a systematic search to identify genetic variants influencing plasma YKL-40 levels, we identified 8 SNPs associated with plasma YKL-40 levels in the general population.

Novel alternatively spliced isoform of synuclein gamma

K. Schaal[1], M. Hirschfeld[2], M. Jaeger[1], E. Stickeler[1]. [1]*University Medical Center Freiburg, Gynecological Hospital, Freiburg, Germany;* [2]*University Medical Center Freiburg and German Cancer Research Center Heidelberg, Gynecological Hospital, Freiburg, Germany*

Introduction: Since Synuclein γ (SNCG) is found highly expressed in advanced breast cancer it was initially described as breast-cancer specific gene (BCSG1). Clinical studies demonstrate the correlation of high SNCG expression with advanced stages, metastasis and poor prognosis in breast and ovarian carcinomas, i.e. reduced relapse-free and overall survival periods. In vitro analyses revealed a SNCG-dependent stimulation of ligand-dependent transcriptional activity of estrogen receptor alpha. Thus, SNCG might be an auspicious prognostic marker and therapeutic target for the treatment of estrogen-dependent cancers. So far, four mRNA isoforms of SNCG were described, but only isoforms 1 and 2 code for active proteins. For the first time, we analyzed expression levels of SNCG mRNA isoforms in regard to hypoxia or extracellular acidosis, as typical epiphenomena of solid tumors, in vitro in endometrial cancer cells.
Material and Methods: Four different endometrial cancer cell lines with varying receptor status and one SNCG-positive breast cancer cell line (reference) were cultured under hypoxic, acidic or regular (control) conditions. RNA and protein isolation was followed by PCR, RT-PCR, Western blot and immunohistochemical analysis.
Results: In comparison to the reference breast cancer cell line, endometrial cancer cell lines displayed a general significantly reduced expression of SNCG isoform 1, 2, 3 and 4. In contrast, a novel, shortened mRNA variant of isoform 2 was identified in endometrial cancer cells. Hypoxia and acidosis triggered a marked up-regulation of the novel *isoform 2 short*, while the expression of constitutive isoform 2 did not significantly change under altered conditions. Immunohistochemistry and Western blot revealed a hypoxia- and acidosis- dependent increase in SNCG protein expression.
Conclusion: We hypothesize, that the novel SNCG *isoform 2 short* bears a specific oncogenic potential in endometrial cancer cells, since it could be detected in elevated levels under hypoxic and acidic conditions, as typical epiphenomena of solid tumors. Furthermore we postulate that this novel isoform is capable to code for a biologically active protein isoform. Since up to date no isoform-specific antibody is available for explicit SNCG isoform characterization, a definite verification is subject to current further analysis.
No conflict of interest.

CIP2A stabilizes MYC in cancer cells and during in vivo tissue regeneration

K. Myant[1], X. Qiao[2], C. Come[2], A. Laine[2], J. Partanen[3], J. Klefström[4], J. Okkeri[2], R.C. Sears[5], O.J. Sansom[1], J. Westermarck[2]. [1]*Beatson Institute for Cancer Research, Beatson Institute for Cancer Research, Glasgow, United Kingdom;* [2]*Turku Centre for Biotechnology, Turku Centre for Biotechnology, Turku, Finland;* [3]*Department of Biosciences, Department of Biosciences, Helsinki, Finland;* [4]*Institute of Biomedicine, Institute of Biomedicine, Helsinki, Finland;* [5]*Molecular and Medical Genetics Department, Molecular and Medical Genetics Department, Portland, USA*

Background: The MYC oncogene contributes to the genesis of many human cancers. Post-translational regulation of MYC stability correlates with tumorigenesis and Cancerous inhibitor of PP2A (CIP2A) has been shown to be an important mediator of MYC stability in cancer cells. However, the physiological relevance of post-translational regulation of MYC stability in normal tissues has remained very poorly understood.
Material and Methods: The importance of MYC serine 62 phosphorylation during intestinal regeneration were addressed in AhCre $Myc^{fl/fl}$ mice with mice carrying a Lox-stop-Lox c-myc or Lox-stop-Lox c-myc^{T58A} allele to generate $Myc^{fl/fl}$ $Rosa^{Myc/+}$ and $Myc^{fl/fl}$ $Rosa^{MycT58A/+}$ mice respectively. $CIP2A^{HOZ}$ mice and their wild-type controls were used to determine if increased CIP2A expression functionally contributes to MYC-dependent intestinal regeneration, crypt regeneration following irradiation. Cell autonomous function for CIP2A in regulating MYC serine 62 phosphorylation and activity was demonstrated in CIP2A-deficient MEFs. The subcellular distribution of CIP2A and MYC was examined by cell fractionation and differential detergent fractionation (DDF).
Results: Here, we found that DNA-damage-induced intestinal regeneration was significantly perturbed upon deletion of CIP2A. In regenerating intestine, deletion of CIP2A corresponded with a reduction in serine 62 phosphorylated MYC and failed induction of MYC target genes. Cell autonomous function for CIP2A in regulating MYC serine 62 phosphorylation and activity was demonstrated in CIP2A-deficient MEFs. Furthermore, we found that serine 62 phosphorylated subpopulation of MYC at nuclear lamina is exclusively sensitive to CIP2A-mediated regulation.
Conclusions: Together these results demonstrate that post-translational regulation of CIP2A-sensitive sub-population at nuclear lamina is a critical determinant of MYC's biological activity in proliferation induction, and may help to develop CIP2A-based MYC targeting therapy for cancer.
No conflict of interest.

592 POSTER

Functional characterization of NIMA (never in mitosis gene a)-related kinase 2 in hepatocellular carcinoma

E.Y.T. Tse[1], Y.P. Ching[1]. [1]*The University of Hong Kong Li Ka Shing Faculty of Medicine, Anatomy, Hong Kong, Hong Kong*

Background: The centrosomal kinase NIMA (never in mitosis gene a)-related kinase 2 (Nek2), which regulates the separation of centrosome, has been reported to be overexpressed in various cancers. Nevertheless, the expression profile of Nek2 in HCC has not been investigated and its role in HCC remains unknown. Previously our team has demonstrated the involvement of centrosomal protein TAX1BP2 in hepatocarcinogensis, prompting us to examine the functional role of Nek2 in HCC.
Material and Methods: Nek2 mRNA and protein expressions were examined in paired clinical HCC samples by RT-PCR and immunohistochemistry respectively, and the clinical significance was evaluated. Nek2 knockdown stable clones were established in HCC cell line PLC and metastatic 97L cell line by lentiviral transduction. The stable clones were then subjected to various functional assays. The effects of Nek2 on cell proliferation, migration and invasion were investigated.
Results: Overexpression of Nek2 was found in 80% (39/49) of tumours as compared to their non-tumour counterparts (P<0.0001). Nek2 expression was significantly associated with the absence of tumour encapsulation (P = 0.013), higher tumour stage (P = 0.003) and presence of venous invasion (P = 0.012). Immunohistochemistry revealed Nek2 localization at nucleus and cytoplasm, suggesting that Nek2 might have functions other than controlling centrosome separation. Nek2 expression was detected in all HCC cell lines. Diminution of Nek2 dramatically impeded the proliferation rate of HCC cells (P<0.0001) and profoundly suppressed the cell motility (P<0.0001) as well as invasiveness (P = 0.0232).
Conclusions: Our data has shown for the first time the oncogenic role of Nek2 in HCC. We believe that Nek2 expression encouraged aggressive tumour behaviour by promoting cell proliferation and invasiveness.
No conflict of interest.

Glutathione and glutathione-S-transferase in the forecast of cancer therapy in patients with non-Hodgkin's lymphoma (NHL)

S.R. Abdiganieva[1], D.A. Pulatov[1], D.A. Abdurakhmonov[1], G.A. Avezmuratova[1], M.B. Islamov[2]. [1]*National Oncological Research Centre, Chemotherapy, Tashkent, Uzbekistan;* [2]*National Oncological Research Centre, General Oncology, Tashkent, Uzbekistan*

NHL is often characterized by unpredictable clinical course, i.e. patients with the same disease stage, morphology, and treatments for this disease can be dramatically different. As a consequence, one can remain latent for many years, and others, on the contrary, rapidly progressing incurable with the spread of the disease. One possible reason for the unexpected course of the disease may be the multidrug resistance of tumor cells to chemotherapeutic drugs.
Resistance of malignant cells to chemotherapeutic drugs is a major cause of recurrence of disease and death of most patients. One of the major

causes of cellular drug resistance is over expression of the transport-gene family of multi-drug resistance, as well as the expression of specific proteins responsible for the 'neutralization' of chemotherapeutic drugs in cancer cells. These proteins include Pgp170, multidrug resistance-associated protein − MRP, LRP, glutathione transferase.
The task of the study: Evaluation of clinical perspectives of the determination of glutathione and activity of glutathione-S-transferase in the medicinal treatment of patients with NHL.
Materials and Methods: Investigation of the content of glutathione (GSH) and activity of glutathione 5-transferase (GT) in malignant tumors and in 37 NHL patients erythrocytes, who received chemotherapy according to standard procedure.
Results: It is shown that the level of GSH (0.65±0.03 mmol/g) and the activity of GT (1.85±0.05 mmol/min/g) is higher in NHL. At the same time, it was found that initially in tumors treated effectively levels of GSH and the activity of GT is lower than in progressing disease. An inverse correlation between biochemical parameters and the effectiveness of treatment ($r = -0.81$, $p = 0.003$ and $r = -0.88$, $p = 0.005$).
In patients with NHL initial GSH levels varied within wide limits (from 0.4 to 2.03 mmol/ml in erythrocytes). Retrospective analysis showed that the in case of effective treatment the initial GSH levels did not exceed 0.8 mmol/ml (at a rate of 1.19±0.17). In contrast, patients with a high content of GSH (from 0.95 to 2.03, i.e. above 0.8 mmol/mL) showed disease progression. The inverse correlation was also observed when comparing the activity of GT and the effectiveness of treatment ($r = -0.76$, $p = 0.002$). Effective treatment is accompanied by a gradual increase in the content of GSH and a decrease in the activity of GT, which may be one of the causes of resistance to the drug in the treatment process.
Conclusions: There was an inverse correlation between the level of GSH, the activity of GT and the effectiveness of treatment. Established unidirectional changes in tumors and erythrocytes gives grounds to recommend the evaluation of these parameters in NHL patients for prognostic assessment of tumor sensitivity to medication.

GDNF confers chemoresistance through specific GFR isoforms in human glioma cell line

Y.K. Ho[1], H.P. Too[2]. [1]*National University of Singapore, Department of Biochemistry, Singapore, Singapore;* [2]*National University of Singapore, Singapore-MIT Alliance, Singapore, Singapore*

Background: Malignant gliomas, the most common brain tumours in adults, are characterised by their highly aggressive nature and poor prognosis. High grade glioma develop resistance to the standard first line drug, Temozolomide (TMZ) rapidly and at high frequencies. Although the TMZ resistance was found to be associated with DNA repair pathways, the underlying mechanism of chemoresistance is largely unclear and the prognosis remains unsatisfactory. While the emerging view is that autocrine and paracrine signals can influence tumour biology, there is a lack of knowledge in the role of the growth factor signalling in TMZ resistance. We attempted to investigate the role of Glial derived Neurotrophic Factor (GDNF), a ubiquitous compound in the brain, overexpressed and released by glioblastoma in TMZ resistance.
Material and Methods: From U251MG and LN229 cell lines, glioma cell lines possessing acquired resistance to TMZ were developed. Initiating treatment at 2.5 μM, cells were cultured in the presence of incremental TMZ concentrations: 2.5, 5, 10, 20, 40, 80, 160 and finally 320 μM. During the selection of resistant clones, cells were allowed to adapt to TMZ for 30 days before exposure to the next dose. The expression of GDNF receptor complex and GDNF signalling pathway were monitored. The function of GFR receptor in TMZ resistance was examined through siRNA knockdown studies.
Results: We found that GDNF conferred chemoresistance in both LN229 and U251MG parental cell lines. We further showed that knockdown of GFR isoform 1b and RET9 but not NCAM reversed drug resistance induced by GDNF. Interestingly, expression of GFR receptor isoforms altered when cells acquired resistance to higher dose of TMZ where upregulation of RET9 but not NCAM was observed.
Conclusions: This study provides the first evidence that specific GFR isoforms are involved in chemoresistance. The identification of GDNF signalling conduit may shed new insight into the molecular mechanisms of TMZ chemoresistance and may provide novel targets for glioma prognosis or therapeutics.

595 POSTER

The role of erlotinib − induced autophagy in non-small cell lung carcinoma

Y. Li[1], J. Ho[1]. [1]*The University of Hong Kong, Medicine, Hong Kong, Hong Kong*

Background and Aim of Study: Non-small cell lung cancer (NSCLC) is one of the leading causes of cancer deaths. Tyrosine kinase inhibitor (TKI) like erlotinib is commonly used as a treatment regimen since epidermal growth factor receptor (EGFR) is frequently deregulated in NSCLC. Autophagy is a regulated cellular catabolic process in response to deprivation of nutrients or growth factors. This study aims to investigate whether autophagy confers acquired resistance to erlotinib treatment in NSCLC.
Methods: Two NSCLC cell lines (HCC827 and HCC4006) with EGFR mutations (exon 19 deletions) were selected. Proliferation (MTT) assay and annexin-V binding assay were performed to determine cell proliferation and cell death upon erlotinib treatment. Autophagy induction was monitored by ATG-5/ATG12 conjugation, p62 degradation and conversion of LC3I to LC3II using Western blot. Increase in acidic vesicular organelle (AVO) formation was determined by acridine orange staining. Autophagy inhibitor (chloroquine) and RNA interference were used to study the effect of erlotinib-induced autophagy.
Results: MTT confirmed that both cell lines were sensitive to erlotinib (IC_{50} <0.5 μM). Erlotinib treatment increased LC3II expression, ATG-5/ATG12 conjugation, formation of AVO and p62 degradation, compatible with induction of autophagy. Combination of 10uM chloroquine (autophagy inhibitor) with 0.2uM erlotinib increased apoptotic events compared to erlotinib or chloroquine alone (HCC827: 52.3±2.8% vs 21.2±4.2% vs 13.0±2.5%, $p < 0.01$; HCC4006: 49.3±4.8% vs 9.4±2.4% vs 9.0±1.8%, $p < 0.01$; chloroquine + erlotinib vs erlotinib vs chloroquine respectively). Atg5 and beclin 1 knockdown with siRNA resulted in significant autophagy inhibition. Apoptotic cell death in erlotinib combined with ATG-silencing (51.8±1.9%) or beclin-silencing (53.4±2.0%) was increased comparing with erlotinib alone (22.8±3.8%, $p < 0.01$), ATG-silencing alone (7.3±4.4%, $p < 0.01$) or beclin-silencing alone (10.3±4.6%, $p < 0.01$) in HCC827 cells. Similarly, in HCC4006, apoptotic cell death was significantly enhanced in erlotinib combined with ATG-silencing (53.1±3.4%) or beclin-silencing (61.9±5.1%), comparing with erlotinib alone (27.4±8.6%, $p < 0.01$), ATG-silencing alone (6±2.7%, $p < 0.01$) or beclin-silencing alone (11.5±4.3%, $p < 0.01$).
Conclusions: Erlotinib can induce both apoptosis and autophagy in EGFR mutated (exon 19 del) NSCLC cell lines. Inhibition of autophagy with chloroquine or siRNA can enhance erlotinib-induced cell death. Autophagy may serve as a protective mechanism for NSCLC upon treatment with erlotinib.

Effects of vitamin D binding protein-derived macrophage activating factor on human neuroblastoma cells and predicted molecular interaction with the vitamin D receptor

M. Ruggiero[1], M.G. Fiore[2], S. Magherini[3], G. Morucci[3], J.J.V. Branca[3], M. Gulisano[3], L. Thyer[4], S. Pacini[3]. [1]*Universita degli Studi di Firenze, Faculty of Sciences Mathematics Physics and Biology, Firenze, Italy;* [2]*Universita degli Studi di Firenze, Clinical and Experimental Biomedical Sciences, Firenze, Italy;* [3]*Universita degli Studi di Firenze, Experimental Medicine, Firenze, Italy;* [4]*Macro Innovations Lab, Immunotherapy, Cambridge, United Kingdom*

Background: Vitamin D binding protein-derived Macrophage Activating Factor (GcMAF) proved effective in a variety of experimental and human carcinomas. In this study we evaluated its effects on human neuroblastoma cells and we studied the predicted molecular interactions with the vitamin D receptor (VDR).
Materials and Methods: Human neuroblastoma cells (cell line SH-SY5Y, ATCC) were treated with increasing concentration (0.4−40 ng/ml) of purified GcMAF (Immuno Biotech) for 24−48−72 h. Cell viability and proliferation were assessed by MTT assay (Sigma-Aldrich). cAMP levels were measured by competitive EIA assay (Abnova) after 15 min challenge with GcMAF. Cells were observed by light microscopy (Optika, Nikon) at 24−48−72 h.
Results: GcMAF decreased human neuroblastoma cell viability and induced morphological alterations that were interpreted as induction of apoptosis. These data are consistent with the hypothesis that GcMAF exerts a direct effect on cancer cells in addition to its immunostimulating properties. GcMAF stimulated the rapid formation of cAMP that could be responsible for the induction of apoptosis. We also determined the predicted molecular interactions between GcMAF and VDR that could be

responsible for the observed non-genomic effects. GcMAF and VDR share 20% identity of amino acid (aa) sequence in the tract coded for by exons 1, 2, 3, 4, 5, i.e. aa 1–197. A higher degree of identity (40%) was observed in the tract coded for by exons 6, 7, 8, i.e. aa 217–330. The first 23 aa of the NH-terminus of GcMAF and the last 23 aa of VDR are highly hydrophobic and could represent a site of interaction for the two proteins.
Conclusions: The proposed mode of interaction between GcMAF and VDR could explain the observed association between VDR gene polymorphisms and the responsiveness of human monocytes to GcMAF. This interaction is likely to occur at the level of the plasma membrane thanks to the hydrophobic interactions between the two proteins and it could be facilitated by the presence of vitamin D binding to both proteins, with GcMAF on the outer side of the membrane and VDR on the inner side. In addition, since it had been previously observed that GcMAF induced the formation of cAMP also in normal human monocytes, it could be concluded that the cAMP signalling pathway is involved in the early event of GcMAF-stimulated cell responses independently of the cell type, possibly through interaction with VDR as part of the non-genomic responses to vitamin D-axis components.

Isoproterenol increases the expression of histone deacetylase 6 via EPAC- and Erk-dependent pathway to stimulate migration of H1299 human lung cancer cells

J. Lim[1], J. Park[1], Y. Juhnn[1]. [1]*Seoul National University College of Medicine, Biochemistry and Molecular Biology, Seoul, Korea*

Background: Isoproterenol, a beta adrenergic receptor agonist, stimulates cAMP production and regulates various cellular metabolism and gene expression. Histone deacetylases (HDACs) remove acetyl groups from histones and non-histone proteins to regulate gene expression epigenetically and other cellular functions. HDAC6 deacetylates and regulates many non-histone substrate proteins such as α-tubulin, Hsp90, cortactin, and ku70. α-Tubulin is the first identified substrate of HDAC6, and affects microtubule dynamics to regulate cell migration. This study investigates the effect of isoproterenol on the expression of HDAC6 in lung cancer cells.
Material and Methods: Lung cancer cells including H1299 cells were treated with isoproterenol, forskolin, H89, 6-Bnz-cAMP, and 8-pCPT-2'-O-Me-cAMP to activate or inhibit cAMP signaling pathway. PD98059 and PD0325901 were used to inhibit Erk pathway. Stimulatory heterotrimeric GTP-binding protein Q227L (GαsQL), EPAC shRNA, and constitutively active MEK1 (CA-MEK1) were transiently transfected with $CaCl_2$ or lipofectamine 2000®. HDAC6 protein and mRNA expression was analyzed by western blot and real time PCR. Transwell chamber was used for cell migration assay.
Results: The expression of HDAC6 mRNA and protein was increased by treatment with isoproterenol treatment in H1299 lung cancer cells. The expression of constitutively active Gαs proteins (GαsQL) and forskolin treatment also increased HDAC6 levels. Isoproterenol treatment decreased the acetylation level of α-tubulin, and stimulated cell migration. Isoproterenol-stimulated cell migration was blocked by knockdown of HDAC6 with shRNA. Treatment with H89, a selective inhibitor of PKA, or 6-Bnz-cAMP-sodium, a selective activator of PKA, did not affect HDAC6 expression levels. However, treatment with 8-pCPT-2'-O-Me-cAMP, a selective activator of EPAC, or expression of EPAC shRNA affected HDAC6 expression. Isoproterenol inhibited MAPK and Akt signaling pathways in H1299 cells. Inhibition of Erk1 by treatment with PD98059 and PD0325901 increased HDAC6 levels, and expression of constitutively active CA-MEK1 decreased isoproterenol-induced HDAC6 expression.
Conclusion: It is concluded that isoproterenol stimulates migration of H1299 lung cancer cells by increasing HDAC6 expression via EPAC- and Erk-dependent pathway.
No conflict of interest.

598 POSTER

Augmentation of histone deacetylase 8 expression by cyclic AMP signaling system in H1299 human lung cancer cells

J. Park[1], J. Lim[1], Y. Juhnn[1]. [1]*Seoul National University College of Medicine, Department of Biochemistry and Molecular Biology, Seoul, South Korea*

Background: Histone deacetyalses (HDACs) are enzymes that catalyze the removal of acetyl groups from histones to regulate gene expression epigenetically. HDAC8 belongs to class I HDAC together with HDAC1, 2 and 3 isoforms. Cyclic AMP (cAMP) signaling pathway is activated by cAMP, which is formed by adenylate cyclases activated by various extracellular signals including hormones and neurotransmitters. cAMP signaling system regulates various cellular functions such as gene expression, proliferation and apoptosis. HDAC8 has been reported to be phosphorylated by cAMP-dependent protein kinase A (PKA), which results in negative regulation of HDAC8 activity and hyperacetylation of histone H3 and H4. Moreover, HDAC8 is known to be correlated with the activity of cAMP response element binding (CREB) protein. Thus this study investigated how cAMP signaling system modulates the activity of HDAC8 to regulate gene expression epigenetically.
Material and Methods: cAMP signaling system was activated by expression of a constitutively active mutant Gαs protein (GαsQL) and by treatment with isoproterenol, a β-adrenergic receptor agonist, in H1299 human lung cancer cells. Expression of HDAC8 mRNA and protein was determined by quantitative RT-PCR and western blotting. Changes in the phosphorylation of signaling molecules were analyzed by western blotting using specific antibodies.
Results: HDAC8 expression was increased by expression of GαsQL and treatment with isoproterenol or prostaglandin E2. Treatment with forskolin also increased HDAC8 protein expression, but not mRNA levels. Both activators of PKA and Epac also increased HDAC8 expression. Inhibition of Epac2 blocked the increase in HDAC8 expression induced by treatment with isoproterenol, but the inhibition of PKA or Epac1 did not block the isoproterenol effect. Isoproterenol increased Rap1 activity, and activation of Rap1 led to an increase in HDAC8 expression. Isoproterenol decreased Akt activity. Moreover, inhibition of PI3K or Akt activity led to an increased in HDAC8 expression.
Conclusions: cAMP signaling system augments HDAC8 expression in H1299 human lung cancer cells, which involves Epac2-Rap1 or PI3K/Akt pathways.

Dolastatin, along with celecoxib, stimulates apoptosis by a mechanism involving oxidative stress, membrane potential change and PI3-K/AKT pathway down regulation

H. Honit Piplani[1], M.R. Chandan Rana[1], D.R. Vivek Vaish[1], D.R. Sankar Nath Sanyal[1]. [1]*Panjab University, Department of Biophysics, Chandigarh, India*

Background: Phosphoinositide 3-kinase (PI3-K) is an important regulator of oncogenesis and apoptosis in various types of cancers including colon. A combinatorial strategy of using Cyclooxygenase-2 inhibitor, celecoxib and dolastatin, a linear peptide from marine mollusk of Indian Ocean origin has been shown the anti-neoplastic effects in colon cancer in a rat model.
Methods: The signal transduction pathway of PI3-K/AKT and the downstream signalling proteins had been studied in an early stage of colon carcinogenesis (DMH induced) by gene and protein expression, apoptotic studies by colonocyte apoptotic bleb assay, intracellular calcium level by fluorescence spectrometry, mitochondrial membrane potential by Rhodamine 123 flow cytometry and Reactive oxygen species measurement. Molecular docking analysis was employed to study the interaction of oncogenic proteins and the ligand, celecoxib and dolastatin.
Results: Apoptotic cell index was lowered with DMH while both the drugs increased it and inhibiting PI3-K and AKT expression. Docking studies revealed both the proteins targeted by the drugs via ATP binding site. An increased expression of GSK-3β, pro-apoptotic protein Bad, transcription factor Egr-1, tumour suppressor protein PTEN while a downregulation of G1-associated cell cycle protein, Cyclin D1 and increased intracellular calcium as well as reactive oxygen species were observed. Also, the number of cells having higher mitochondrial membrane potential was lowered.
Conclusion: Celecoxib and dolastatin inhibited the tumour development through regulation of PI3-K/AKT pathway which can act as a novel target for these drugs.
No conflict of interest.

Overexpression of RUKI/CIN85 promotes the enrichment of human breast adenocarcinoma MCF-7 cells and rat pheochromocytoma PC12 cells by cancer stem-like cell population

G. Pasichnyk[1], N. Byts[1], O. Povorozniuk[1], O. Ponomarenko[1], A. Samoylenko[1], D. Petukhov[1], D. Gerashchenko[1], A. Basalii[1], L. Drobot[1]. [1]*Palladin Institute of Biochemistry of the National Academy of Sciences of Ukrain, Laboratory of Cell Signaling, Kiev, Ukraine*

Background: There is increasing evidence that a variety of human cancers are maintained by a subset of cells, cancer stem cells (CSCs), which sustain tumor growth, underlie its malignant behavior, and possibly initiate distant metastases. There are data that certain adaptor proteins may be involved in the development and maintenance of CSCs phenotype. The aim of this study was to investigate the possible role of adaptor protein Ruk_I/CIN85 in the acquisition of CSCs characteristics.

Material and Methods: All experiments were carried out on wild type human breast adenocarcinoma MCF-7 cells and rat pheochromocytoma PC12 cells as well as cells with stable overexpression of Ruk_I/CIN85. Such features of CSCs as the ability to form spheroids on low-adhesive plastic in growth factor-supplemented medium, expression of certain markers, the resistance to cytotoxic agents action were studied.
Results: When subjected to a sphere forming conditions MCF-7 and PC12 cells with Ruk_I/CIN85 overexpression effectively developed spheroids. The ability to form effectively secondary spheroids evidence for their self-renewal property. CSCs are known to be characterized by tissue specific markers. The increased expression of CD44 surface marker as well as the increased number of $CD44^+/CD24^-$ cells in Ruk_I/CIN85 overexpressing breast adenocarcinoma MCF-7 cells was revealed. High expression level of inhibitor of differentiation 1 (ID1) and low level of MATH2/NEUROD6 transcription factor was found in pheochromocytoma PC12 cells with Ruk_I/CIN85 overexpression. Another feature of CSCs is their increased resistance to cytotoxic agent action. A measure of metabolic activity of cells treated with doxorubicin (in case of MCF-7 cells) and hydrogen peroxide (in case of PC12 cells) revealed that cells with overexpression of Ruk_I/CIN85 were more resistant to studied agents than control cells.
Conclusions: The data obtained indicate the potential role of adaptor protein Ruk_I/CIN85 in the development of CSCs-like phenotype in breast adenocarcinoma MCF-7 cells and rat pheochromocytoma PC12 cells.

Nanoscopic hyperthermia by modulated electric field

O. Szasz[1]. [1]*Szent Istvan University, Biotechnics, Gödöllö, Hungary*

Background: There are numerous studies showing effects of hyperthermia in oncology, however controversial results block its wide distribution. Our objective is to show the controlled energy-liberation in nanoscopic range that solves the central problem of hyperthermia.
Method: Nano-heating, modulated electro-hyperthermia, (mEHT) is developed, which selects and heats up the membrane of the malignant cells. The nano-range energy-liberation could be precisely controlled. The nano-selection is based on the metabolic, adherents and organizing differences of the malignant cells. The technology is impedance controlled capacitive coupling; no plane-wave radiation dominates as in other capacitive (radiative) solutions. The method mEHT uses impedance matching at 13.56 MHz carrier frequency, with time-fractal modulation. The efficacy is measured immunohistochemically by mRNA and protein levels too. The surface power-density of the signal is limited by the toxic (blistering) limit 0.5 W/cm^2. The cell-killing mechanisms are proven in experiments, as well as in preclinical and clinical applications.
Results: The main medical advantages of the method are its personalized targeting together with the effective selection and distortion of the malignant cells. Selectivity and strong synergy of the temperature and the applied electric field is proven, which dominantly kills the malignant cells on apoptotic way. The macro- and micro-morphology, the β-catenin nuclear relocalization, the activated early and late apoptotic pathways as well as the DNA defragmentation by time show apoptosis. E-cadherin-β-catenin complex is reconstructed by the mEHT treatment. This coupling can suppress the dissemination and the metastatic activity. Numerous clinical studies are available with altogether more than 3700 cancer patients involved. The results show higher first-year survival than the Eurocare database, despite the only high-line treatment by the mEHT method. Some studies show monotherapy applications as a promising way of the refractory diseases. The safety of mEHT is specially presented on such a sensitive organ as the brain.
Conclusion: mEHT shows its definite advantages in local cell-killing and in blocking of the metastatic processes too. It is a feasible method for the reliable and controllable basic of the modern hyperthermia demands in clinical oncology.

602 POSTER

Galectin-3 accelerates M2 macrophage infiltration and angiogenesis in tumors

W. Jia[1], H. Kidoya[1], D. Yamakawa[1], H. Naito[1], N. Takakura[1]. [1]*Research Institute for Microbial Diseases. Osaka-University, Department of Signal Transduction, Osaka, Japan*

Background: It is widely accepted that aggressive invasion of tumor associating macrophage (TAM) resembling M2 macrophage correlates with cancer malignancy affecting cancer cell invasion, metastasis, and angiogenesis. Many chemokines that induce migration of macrophages have been isolated in the inflammatory response; however, further precise analysis of macrophage migration in tumor microenvironment is required. Here, we analyzed the function of galectin-3 (Gal3) for chemotaxis of macrophage. By using Gal3−/− mice as a host of tumor xenograft model, we induced concentration gradient of Gal3 spreading from tumor to normal organ.
Methods and Results: In this model, we found that infiltration of macrophage is enhanced in tumor developed in Gal3−/− mice compared with that in Gal3+/+ mice, resulting in enhanced tumor angiogenesis and tumor growth in Gal3−/− mice. Especially, we found that macrophages showing M2 macrophage phenotype dominantly infiltrate in Gal3−/− mice and they express low level of Gal3. When Gal3 was knocked down in macrophages by siRNA, chemotaxis of macrophages by Gal3 was enhanced. These suggested that cells like M2 macrophage originally have possibility to migrate toward Gal3 and infiltrate upon high level expression of Gal3 in tumor resulting in acceleration of angiogenesis and tumor growth. Therefore, Gal3 is one of targets for development of new strategy to inhibit tumor growth.
Conclusion: Our present model using Gal3−/− mice as a tumor host recapitulates the tumor condition in which expression of Gal3 in the tumor increases. It has been reported that Gal3 directly induces endothelial tube formation. Therefore, higher levels of Gal3 induce angiogenesis directly affecting endothelial cells (ECs) within the tumor; however, macrophage recruitment by Gal3 may also be involved in the acceleration of tumor angiogenesis. In summary, knowledge of Gal3 expression may help in the assessment of cancer patient status. Indeed, one line of evidence suggests that Gal3 expression levels are related to the degree of biological aggressiveness in human colorectal tumors. Therefore, suppression of the function or expression of Gal3 may be a promising approach for cancer therapy.

603 POSTER

Effect of E-cadherin silencing on vascularization of experimental brain metastases

E. Bugyik[1], V. Szabó[1], K. Dezso[1], P. Nagy[1], S. Paku[1]. [1]*Semmelweis University, First Department of Pathology and Experimental Cancer Research, Budapest, Hungary*

It is thought that angiogenesis is required for the maintenance of primary or metastatic tumor growth. Increasing amount of data suggest that instead of angiogenesis host vessel incorporation plays an important role in the vascularization of metastases in highly capillarized organs (e.g. brain, liver, lung). Our previous research results showed that experimental brain metastases acquire their own blood supply by incorporation of the host vessels. There was a correlation between the differentiation status, the growth pattern and the vascular structure of the five different tumor lines used. Our aim was to investigate the effect of the differentiation status on the vascularization using two variants of the same tumor cell line (human HT-25 colorectal carcinoma): wild type HT-25, E-cadherin silenced HT-25. Human HT-25 colorectal carcinoma cell line and E-cadherin silenced ($E\text{-}cad^-$) HT-25 cell line was used in the experiments. To permanently knock-down the expression of the E-cadherin gene, shRNA Plasmid (SA Biosciences) was used. In order to achieve appropriate tumor size (1−2 mm) required for the angiogenic switch, the tumor cells were injected directly into the brain of male SCID mice. Immunofluorescent labeling of vessels and tumor cells was performed on frozen sections. Intratumoral vessel density and vessel diameter was determined on micrographs.
The growth pattern of the variants differed significantly. The wild type HT25 tumor cell line showed differentiated “pushing-type” tumor growth with coherent cells and smooth tumor-parenchyma interface. The $E\text{-}cad^-$ cell line is less differentiated. There were round scattered tumor cells on the edge of the tumors of $E\text{-}cad^-$ cells. Compared to wild type HT-25 the vessel density was significantly higher, vessel diameter was significantly lower in the tumors of $E\text{-}cad^-$ cells.
Our results show that regardless of the origin, the differentiation status of the tumor determines the growth pattern and the vascular structure of the tumor.
No conflict of interest.

Histone demethylases expressed under hypoxia and nutrient starvation regulate tumor growth by modulating tumor angiogenesis and metabolism

T. Osawa[1], T. Shimamura[1], R. Tsuchida[2], M. Muramatsu[3], A. Kondo[1], T. Minami[1], S. Miyano[1], H. Aburatani[1], T. Kodama[1], M. Shibuya[4]. [1]*University of Tokyo, Tokyo, Japan;* [2]*Tokyo Medical Dental University, Tokyo, Japan;* [3]*Roswell Park Cancer Institute, Oncology, Buffalo, USA;* [4]*Tokyo Medical and Dental University, Tokyo, Japan*

Anti-angiogenic strategies can be effective for cancer therapy, but like all therapies resistance poses a major clinical challenge. Hypoxia and nutrient

starvation select for aggressive qualities that may render tumors resistant to anti-angiogenic attack. Here we show that hypoxia and nutrient starvation cooperate to drive tumor aggressiveness. In cancer cells rendered resistant to long-term hypoxia and nutrient starvation, we documented a stimulation of AKT phosphorylation, cell morphological changes, cell migration, invasion and anchorage independent growth in culture. These qualities associated in vivo with increased angiogenesis and infiltration of macrophages into tumor tissues. We identified KDM3A and KDM7A were upregulated in vitro under conditions of hypoxia and nutrient starvation and in vivo before activation of the angiogenic switch or the pre-refractory phase of antiangiogenic therapy. Inhibition of KDM3A or stable expression of KDM7A suppressed tumor growth by downregulating angiogenesis and tumor associated macrophage infiltration. Notably, KDM3A inhibition enhanced the anti-tumor effects of the anti-VEGF compound bevacizumab and the VEGFR/KDR inhibitor sunitinib. In addition, we found that KDM7A regulated expression of several kinases involved in phospholipid metabolism using ChIP-sequencing and microarray. Metabolic analysis revealed that 50–100 folds accumulation of a phosphorylated metabolite within the pathaway, suggesting phospholipid metabolism can play an important role in cancer cells under nutrient starvation. Our results form the foundation of a strategy to attack hypoxia- and nutrient starvation-resistant cancer cells as an approach to leverage anti-angiogenic treatments and limit resistance to them.
No conflict of interest.

605 POSTER

Inhibition PDGF pathway by dual antiangiogenic and proapoptotic fusion molecule is a new preclinical strategy in treat cancer

P. Rózga[1], B. Zerek[1], A. Pieczykolan[1], M. Galazka[1], K. Bukato[1], S. Pawlak[1], M. Szymanik[1], A. Jaworski[1], A. Grochot-Przeczek[2], J. Pieczykolan[1]. *[1]Adamed Ltd, Drug Discovery, Warsaw, Poland; [2]Jagiellonian University, Medical Biotechnology, Krakow, Poland*

Background: For almost two decades tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) has been under extensively development as a potential therapeutic due to its ability to induce apoptosis in cancer cells while remaining neutral to normal cells.
Tumor growth is tightly related to new blood vessel formation and tissue remodeling. Platelet derived growth factor (PDGF) is important for vascular development in physiological and pathological processes. Blockade of PDGF pathway has been shown to inhibit pathologic angiogenesis and tumor growth.
According to this knowledge, we proposed a novel protein with dualistic proapoptotic and antiangiogenic activity.
Our new molecule consists of a recombinant TRAIL variant linked with an effector peptide sequence and an activation motif recognized by tumor-specific proteases (MMP's, uPa) between. The effector peptide is formed by 19-amino acid fragment of human PDGF which binds the PDGF receptors competitively to the natural ligand while being itself devoid of activity. As a consequence, angiogenic activity of PDGF is blocked, stimulation of new blood vessels formation doesn't occur and finally tumor growth is inhibited.
Materials and Methods: AD-O54.9 protein was expressed in *E.coli* and purified by IEC chromatography. Our protein was characterized biochemically and biophysically using CD spectroscopy, HPLC-SEC, protease cleavage and MTT cell cytotoxicity assays. Its antiangiogenic activity was evaluated by HUVEC tube formation assay and mice ring aortic assay. The proapoptotic effect was tested using active caspase 3 staining. For *in vivo* potential we examined the efficacy of fusion protein on mice xenograft models of human colorectal adenocarcinoma (Colo205) and human multidrug resistant uterine sarcoma (MES-SA/Dx5) cell lines.
Results: Obtained molecule has well-defined secondary and quaternary structure and verified mechanism of activation. AD-O54.9 showed *in vitro* specific cytotoxic effect on various established and primary cancer cell lines at IC50 below 0.01 ng/ml. We demonstrated that AD-O54.9 is a very potent apoptosis activator and inhibitor of angiogenesis. The fusion protein showed superior effect displaying significant tumor volume regression compared with TRAIL and a standard anticancer chemotherapeutic agent.
Conclusions: The obtained results confirm that we developed very promising molecule with a high potential of anticancer activity that could be considered as a novel therapeutic agent.
No conflict of interest.

606 POSTER

Preclinical evaluation of anticancer potential of AD-O51.4 − novel fusion molecule with dual antiangiogenic and anticancer potential

J. Pieczykolan[1], P. Rózga[1], A. Pieczykolan[1], S. Pawlak[1], B. Zerek[1], M. Glazka[1], K. Bukato[1], M. Szymanik[1], A. Jaworski[1], A. Grochot-Przeczek[2]. *[1]Adamed SP. z.o.o, Biology, Czosnow n. Warsaw, Poland; [2]Jagiellonian University, Medical Biotechnology, Krakow, Poland*

Background: Tumor growth and development is tightly related to new vessels formation and tissue remodeling. Vascular endothelial growth factor (VEGF) is important for vascular development in physiological and pathological processes. Blockade of VEGF pathway has been shown to inhibit both pathological angiogenesis and tumor growth.
Tumor necrosis factor-related apoptosis-inducing ligand (TRAIL/Apo2L) has been under intense scientific evaluation because of its remarkable ability to induce apoptosis in cancer cells while omitting normal cells. However, its activity was too low to become the effective single therapy agent.
Here we present a novel fusion protein based TRAIL/Apo2L. The proposed new fusion protein consists of the recombinant variant of TRAIL fragment, which is linked to the repeated antiangiogenic effector peptide sequence and a motif recognized by tumor-specific proteases (MMP's, uPa) in between.
The AD-O51.4 is able to bind and sequester the VEGF receptors on malignant and endothelial cells but it is devoid of angiogenic activity. As a consequence, the peptide blocks the binding of VEGF ligand, preventing formation of new vessels. We postulate that due to the presence of VEGF receptors on cancer cells, they can be targeted by our VEGF receptor-blocking peptide making them susceptible for TRAIL-induced apoptosis.
Methods: Cytotoxic activity was examined using a MTT assay. Cell death and apoptosis markers were analyzed using flow cytometry methods. Direct antiangiogenic activity was confirmed with the ring aortic assay and HUVEC spheroid assay. Safety of the compound was confirmed by direct incubation with primary human and cynomolgus hepatocytes. *In vivo* antitumor activity was analyzed in the xenograft model of human: colorectal (Colo205), liver (HepG2), lung (NCI-H460) and pancreatic (MIA-PaCa-2) cancers.
Results: Almost 90 % of tested cell lines − primary or established − were sensitive to AD-O51.4 protein with extremely low IC50 values, showing no toxic effects towards normal cells.
Hepatotoxicity results revealed a lack of toxic effects at concentrations significantly exceeding the effective doses.
Strong antitumor activity of AD-O51.4 was confirmed in xenograft model of human colorectal adenocarcinoma Colo205 where our protein caused complete tumor remission in comparison to several of tyrosine kinases inhibitors and Bevacizumab, with similar effects on human pancreatic carcinoma MIA PaCa-2 and human hepatocellular carcinoma HepG2, as well as an orthotropic model of human lung carcinoma NCI-H460-luc2.
Conclusion: We demonstrated that AD-O51.4 protein reveals high, tumor specific cytotoxic activity against a number of cancer cell lines and superior *in vivo* activity in subcutaneous and orthotropic xenograft models. We postulate that the combination of two effectors in one protein molecule may be a novel and effective way of anticancer compounds development.
No conflict of interest.

Impact of RGMb on BMP-7 promoted angiogenesis

A.J. Sanders[1], L. Ye[1], M.D. Mason[2], W.G. Jiang[1]. *[1]Cardiff University School of Medicine, Surgery, Cardiff, United Kingdom; [2]Cardiff University School of Medicine, Oncology & Palliative Medicine, Cardiff, United Kingdom*

Background: Angiogenesis is an essential process required for normal physiological events and its imbalance is common in disease states such as cancer. Angiogenesis is vital for tumours to develop, progress and metastasise. The current study explores the potential of the Repulsive Guidance Molecule B (RGMb) to impact the regulation of angiogenic traits in response to Bone Morphogenetic Protein 7 (BMP-7) in the human endothelial HECV cell line.
Material and Methods: The expression of RGMb was targeted in HECV endothelial cells through the transfection of these cells with a plasmid containing a hammerhead ribozyme transgene specific to RGMb. Cells transfected with the ribozyme transgene were terms $HECV^{RGMbKO}$ and were used in comparison to control HECV cells transfected with a closed pEF6 plasmid ($HECV^{pEF6}$). Once established these cells were used to examine the impact of RGMb on angiogenic traits such as cell migration and tubule formation following treatment with or without 40ng/ml BMP-7 using *in vitro* Matrigel tubule formation assays and scratch/wounding migration assays.
Results: Treatment of control $HECV^{pEF6}$ cells with 40ng/ml BMP-7 brought about a notable increase in cellular migration, particularly in the end stages of the experiment (60 min, $p = 0.03$; 75 min, $p = 0.14$; 90 min, $p = 0.09$ vs.

untreated control HECV^{pEF6} cells). Additionally, treatment with 40ng/ml BMP-7 could significantly enhance the tubule formation levels in HECV^{pEF6} cells in comparison to untreated HECV^{pEF6} cells ($p = 0.005$). In contrast to this treatment of HECV^{RGMbKO} cells with 40ng/ml BMP-7 did not bring about the same promotional effects on cell migration and tubule formation. Levels of migration (60 min, $p = 0.71$; 75 min, $p = 0.73$; 90 min, $p = 0.75$ vs. untreated HECV^{RGMbKO}) and tubule formation ($p = 0.986$ vs. untreated HECV^{RGMbKO}) remained similar to the untreated HECV^{RGMbKO} cells.
Conclusions: Suppression of RGMb in HECV endothelial cells appears to negatively influence their ability to respond to the promotional impact of BMP-7 on angiogenic traits *in vitro*. RGMb may play a role in regulating tumour angiogenesis in response to BMP-7.
No conflict of interest.

608 POSTER

The expression of CTGF, THBS1, PLAU and PLAUR genes in U87 glioma cells with signaling enzyme ERN1 loss of function: effect of glucose and glutamine deprivation

K. Kubaichuk[1], D. Minchenko[2], I. Kryvdiuk[3], O. Hubenia[3], O. Minchenko[3]. [1]*Taras Shevchenko National University, Educational and Scientific Center "Institute of Biology" Department of Biochemistry, Kiev, Ukraine;* [2]*National O.O. Bogomolets Medical University, Department of Pediatrics, Kiev, Ukraine;* [3]*Palladin Institute of Biochemistry NAS of Ukraine, Department of Molecular Biology, Kiev, Ukraine*

Background: The endoplasmic reticulum stress response-signalling pathway mediated by ERN1 is linked to the processes of neovascularisation, tumour growth and cell death, and the complete blockade of this signal transduction pathway has anti-tumour effects preferentially via suppression of angiogenesis and proliferation processes. Ischemic conditions are known to induce the endoplasmic reticulum stress and are responsible for the regulation of numerous growth factors which controls cell proliferation and angiogenesis in tumours via specific adaptive changes in the cell, and that is why it is important to study the role of key regulatory factor (CTGF, THBS1, PLAU, PLAUR) gene expressions in ERN1 signalling pathways in relation to ischemia and tumour progression.
Materials and Methods: We used the human glioma cell line U87 as well as modified variant of these cells with complete (protein kinase and endoribonuclease) suppression of ERN1 enzyme function. For glucose or glutamine deprivation conditions cells were exposure with DMEM without glucose or glutamine for 16 hrs. The expression of genes in glioma cells was measured by qPCR.
Results: It was shown that blockade of ERN1 gene function in U87 glioma cell line significantly increases the expression of *CTGF* (connective tissue growth factor) and *THBS1* (thrombospondin 1) genes, but decreases the level of *PLAU* (urokinase-type plasminogen activator) and *PLAUR* (PLAU receptor) gene expressions. The changes in the expression profile of these genes are correlated with a reduction of tumor angiogenesis and growth in vivo from glioma cells with ERN1 loss of function. Moreover, the increase of *CTGF* and *THBS1* gene expression and the decrease of *PLAUR* genes expression were observed in control glioma cells under glucose or glutamine deprivation conditions; however, in glioma cells with ERN1 loss of function, more significant effect of glucose deprivation conditions on the expression level of PLAU mRNA, as well as a reversible effect on CTGF mRNA expression was shown. At the same time, the expression of *PLAUR* gene was resistant to glutamine deprivation condition in control glioma cells but decreased in glioma cells with ERN1 loss of function.
Conclusion: Results of this investigation clearly demonstrated the crucial role of CTGF, THBS1, PLAU and PLAUR in tumour progression and will be important for developing a new understanding concerning molecular mechanisms of malignant tumour growth in relation to the ERN1 signaling and defines the best targets for potential anti-tumour therapies.
No conflict of interest.

609 POSTER

Tumor vessel maturation by apelin/APJ system improves the efficiency of immunotherapy

H. Kidoya[1], N. Kunii[2], H. Naito[1], C. Takeshita[1], N. Takakura[1]. [1]*The Research Institute for Microbial Diseaes Osaka University, Department of Signal Transduction, Suita, Japan;* [2]*Graduate School of Medicine Chiba University, Department of Otorhinolaryngology and Head and Neck Surgery, Chiba, Japan*

Background: Previously, we reported that apelin is regulator of blood vessel maturation and receptor APJ is specifically expressed in endothelial cells during angiogenesis. Based on these results, we expected that apelin is useful factor for anti-angiogenic therapy in cancer. Recently, ascular normalization has been reported as a new strategy for regulating tumor growth. Therefore we investigated how apelin mediated vessels maturation affects tumor growth.
Material and Methods: The mouse Apelin gene was cloned into the pCAGSIH expression vector. Colon26 cells and PC3 cells were stably transfected and clones of cells showing stable transfection were obtained. The stably transfected colon26 clones, PC3 clones or LLC cells were inoculated subcutaneously into 6- to 8-week-old BALB/c mice, nude mice or C57BL/6 mice, respectively, and tumors were dissected at 12−15 days after implantation. DCs were administered by intravenous injection 4 days after tumor implantation. Tumors sections were stained using an An anti-CD31 monoclonal antibody.
Results: Here we show the expression of APJ in blood vessels in the colon26 and LLC derived tumor and reduction of tumor growth by overexpression of apelin in those tumor cells. By the histological analysis, we confirmed that, tumor vascular maturation was induced by apelin stimulation. This apelin induced vascular maturation enhances the efficacy of cancer dendritic cell-based immunotherapy and significantly suppresses the tumor growth by promoting the infiltration of iNKT cells to the central region of the tumor and thereby robustly inducing apoptosis of tumor cells.
Conclusions: These findings provide a new target for tumor vascular specific maturation which is expected to improve the efficacy of conventional cancer therapies.

Angiogenic inhibitors induce mature blood vessels surrounding the tumor parenchyma

K. Takara[1], H. Naito[1], T. Wakabayashi[1], H. Kidoya[1], N. Takakura[1]. [1]*The Research Institute for Microbial Diseaes Osaka University, Signal Transduction, Suita, Japan*

Background: Recently reports suggest that cancer cell invasion is induced from the edge of the tumor into peripheral areas after angiogenesis inhibitor treatment. Therefore, it is important to analyze the status of blood vessels at the tumor rim after anti-angiogenesis therapy. In the present study, we investigated that mature blood vessels in which ECs are covered with MCs are present in the outside of tumor parenchyma.
Material and Methods: We treated HT29 (human colorectal adenocarcinoma) and colo320DM (human sigmoid colon cancer) tumor-bearing mice with bevacizumab from Day 14 after tumor inoculation. To measure hypoxia and macromolecule infiltration in tumor tissues, Hyp-oxyProbe-1 (60 mg/kg, i.v.; Hypoxyprobe) or 0.5 mg of FITC-conjugated dextran (MW: 40,000) was injected 2 h before tissues were harvested. Tumor sections were stained using an anti-CD31 monoclonal antibody.
Results: We found that mature blood vessels were destroyed after treatment with angiogenesis inhibitors, but maturation of blood vessels were enhanced. Furthermore, we evaluated whether the increased numbers of blood vessels covered by MCs in the outside of tumor parenchyma resulted in any functional changes. Therefore, administration of angiogenesis inhibitor not only normalizes blood vessels in the tumor parenchyma, but also in the outside of tumor parenchyma.
Conclusions: These findings provide the importance of destroying maturing blood vessels outside of tumor parenchyma to prevent cancer cell invasion.
No conflict of interest.

Effect of nitric oxide synthase inhibitors on angiogenesis

F. Yesildal[1], F. Aydin[1], S. Deveci[2], S. Tekin[3], R. Mammadov[4], I. Aydin[1], T. Ozgurtas[1]. [1]*GATA Faculty of Medicine, Medical Biochemistry, Ankara, Turkey;* [2]*GATA Faculty of Medicine, Pathology, Ankara, Turkey;* [3]*GATA, School of Medicine, Ankara, Turkey;* [4]*Bilkent University, Unam, Ankara, Turkey*

Background: Angiogenesis is the process of generating new blood vessels from preexisting vessels and is considered essential in many pathological conditions. It was shown that nitric oxide (NO) production is closely related with the vessel proliferation, tumor growth and tumor aggressiveness. The purpose of the present study was to evaluate the effect of three NOS inhibitors (aminoguanidine, 7-Nitroindazole, N-Nitro L-Arginine [L-NAME]) on angiogenesis.
Material and Methods: Both *in vivo* (chorioallantoic membrane [CAM] assay, rat model of skin wound healing) and *in vitro* (cell viability assay-XTT method, endothelial cell tube formation assay) models were used for evaluation.
Results: In CAM assay, NOS inhibitors decreased angiogenesis in a concentration-dependent manner. Compared with the control group, NOS inhibitors significantly decreased vessel proliferation ($p < 0.001$). In rat model of skin wound healing study, wound closures and histopathological

examinations showed that NOS inhibitor groups had worse healing compared to control group and this was statistically significant ($p < 0.05$). The histopathological examination of NOS group revealed poor angiogenesis with respect to the control group. In 'endothelial cell tube formation assay' tube length/area ratio was less in NOS inhibitors group compared to the control group, proving the anti-angiogenic effect of NOS inhibitors in this model ($p < 0.05$). There was no effect of NOS inhibitors on human umbilical vein endothelial cells (HUVEC) in XTT assay. These results suggested that NOS inhibitors might have anti-angiogenic effects on other NO mediated steps beyond endothelial proliferation. The effect of L-NAME was more prominent in all models. These results provide evidence that NOS inhibitors decrease angiogenesis *in vitro* and *in vivo*.
Conclusions: According to these results; it can be considered that NOS inhibitors might have a desirable effect on patients with diseases based on angiogenesis such as cancer.
No conflict of interest.

612 POSTER

Effect of piperlongumine on angiogenesis in chick chorioallontoic membrane model

G. Kismali[1], F.N. Aydin[2], F. Yesildal[2], S. Tekin[2], T. Ozgurtas[2], T. Sel[1]. *[1]Ankara University, Biochemistry, Ankara, Turkey; [2]Gulhane Military Medical Faculty, Biochemistry, Ankara, Turkey*

Background: Angiogenesis is the process of generating new blood vessels from pre-existing vessels and is considered essential in many pathological conditions including cancer. The discovery of angiogenesis inhibitors raises the question of whether such molecules might therapeutically suppress or restrain cancer's growth. Piperlongumine, is a biologically active alkaloid/amide from peppers, as from Piper longum L. − Piperaceae. The reported pharmacological activities of piperlongumine include cytotoxic, genotoxic, antiplatelet aggregation, antinociceptive, antibacterial, antifungal, leishmanicidal, trypanocidal, and schistosomicidal activities. So the purpose of the present study was to evaluate the effect of a small molecule piperlongumine on angiogenesis in chick chorioallontoic membrane (CAM) model in vivo.
Material and Methods: Angiogenesis was evaluated using the CAM assay. Atak-S fertilized chicken eggs were used and incubated at 37°C and 85−90% relative humidity throughout the experiment. Experiments were done to determine the mode of action of piperlongumine on vascular development in the sixth day and eighth day on CAM. On day eight CAMs were screened and taken pictures by using a computer-aided stereomicroscope and images were processed with the software 'Leica Application Suite V4 Automated Image Analysis'.
Results: In this model, piperlongumine decreased angiogenesis in a concentration-dependent manner. The effects of piperlongumine over 5μM found more prominent. Compared with the control group, piperlongumine have significantly decreased vessel formation.
Conclusions: These results provide evidence that a natural compound, piperlongumine, inhibits angiogenesis *in vivo* and it may be used in treatment of the diseases; those pathologic bases are about angiogenesis such as cancer.
No conflict of interest.

613 POSTER

Anti-angiogenic treatments decrease PD-1 expression on tumor-infiltrating CD8+ T lymphocytes in colorectal cancer

M. Terme[1], T. Voron[1], E. Marcheteau[1], O. Colussi[1], S. Pernot[1], M. Nizard[1], E. Tartour[1], J. Taieb[1]. *[1]INSERM U970- Université Paris Descartes − Georges Pompidou European Hospital, "Immunotherapy and Anti-angiogenic Treatments in Oncology" Team, Paris, France*

Background: The concept of cancer immunosurveillance suggests that the immune system can recognize and destroy tumor cells. However, tumors can develop immunosuppressive mechanisms to escape the immune system. Among the immunosuppressive mechanisms, T lymphocytes can express inhibitory molecules such as Program Death-1 (PD-1) protein which impair their activation. PD-1 activation by its ligands PD-L1 and PD-L2 blocks T cell proliferation, cytolytic activity, cytokine production, and decreases survival. Multi-target anti-angiogenic tyrosine kinase inhibitors (TKI) that are routinely used as first- or second-line treatment of cancer patients, have been shown to modulate immunosuppressive mechanisms especially regulatory T cells. However, the role of specific VEGF/VEGFR blockade on PD-1 expression by T lymphocytes has not been studied.
Materiel and methods: PD-1 expression has been analyzed on tumor-infiltrating $CD8^+$ T cells in a mouse model of colorectal cancer (CT26). Tumor-bearing mice were treated by different anti-angiogenic molecules targeting VEGF/VEGFR axis.
Results: Tumor-infiltrating $CD8^+$ T lymphocytes express high levels of PD-1 in the CT26 tumor model. PD-1 expression on tumor-infiltrating $CD8^+$ T lymphocytes was decreased by sunitinib treatment a tyrosine kinase that directly targets VEGFR, PDGFR and c-kit. In the same manner, anti-VEGF-A antibody (the mouse orthologue of bevacizumab) restrains PD-1 expression on tumor-infiltrating $CD8^+$ T lymphocytes. Administration of masitinib, a tyrosine kinase inhibitor acting on KIT, PDGFR and FAK but not on the VEGF/VEGF-R pathway, was not able to modulate PD-1 expression on T cells. Analysis of VEGF receptors on tumor-infiltrating $CD8^+$T cells revealed that PD-1^+ T cells express VEGFR1 and VEGFR2. In colorectal cancer patients, PD-1 expression was observed on $CD8^+$ T cells in PD-$L1^+$ hepatic metastases.
Conclusions: These results show that anti-angiogenic treatments targeting VEGFA/VEGFR decrease PD-1-expressing T lymphocytes in colorectal cancer. These results suggest that VEGF-A could be involved in PD-1 expression and maybe in the induction of T lymphocyte exhaustion in colorectal cancer. This point is currently under investigation. We and others have shown that anti-angiogenic molecules could modulate other immunosuppressive populations such as regulatory T cells and myeloid suppressive cells, anti-angiogenic molecules might be efficiently associated with immunotherapeutic strategies in colorectal cancer.

614 POSTER

CD4+CD25+ regulatory T cells and CD8+CD28− suppressor cells in elderly cancer patients

B. Karagoz[1], O. Bilgi[1], A. Ozgun[1], T. Tuncel[1], L. Emirzeoglu[1]. *[1]GATA Haydarpasa Training Hospital, Medical Oncology, Istanbul, Turkey*

Background: Immunosenescence is an important aspect in elderly cancer patients. In aging, T cell dysfunction and increasing CD4+CD25+ Regulatory T cells (Treg cells) have been reported. On the other hand, the status of these cells has not been uncovered so far in elderly cancer patients. In this study, we aimed to investigate Treg cells, CD8+CD28− suppressor cells, and other lymphocyte subpopulations in elderly cancer patients.
Material and Methods: Seventy-five cancer patients were included in the study. Data were obtained from our previous three studies about Treg, suppressive cells and other lymphocyte populations of breast, gastric and lung cancer patients. Total CD4+CD25+ Treg cells, CD8+CD28− suppressor cells, CD8+ memory cells, CD8+ naive cells, Natural Killer (NK) cells, CD8+ and CD4+ T cells had been investigated by flow cytometry. The parameters were compared between in patients over and under the age of seventy.
Results: Eighteen patients were older than 70 years of age (Elderly group) and fifty-seven patients were not (Control group). The percentage of CD4+CD25high cells in CD4+ T cells were higher in elderly cancer patients than control patients (13.01 ± 6.59 vs 8.43 ± 5.01;p:0.02). CD8+CD28− suppressor cells in lymphocytes were similar in both groups (18.12 ± 7.73 vs 18.03 ± 8.33;p:0.97). NK cells percentage was also elevated in elderly patients. CD8+ memory cells, CD8+ naive cells, CD8+ T cells, CD4+ T cells, and complete blood count parameters were not different between groups (Table).
Conclusion: Our data suggest that CD4+CD25+ Treg cells are increased in elderly cancer patients, but not CD8+CD28− suppressor cells. This may be a cause of age-related immunosuppression in cancer patients.
No conflict of interest.

Table: Lymphocyte subpopulations in cancer patients older and younger than 70 years

	Patients <70 years	Patients ⩾70 years	*p*
CD3 + cells in lymphocytes	71.79±11.21	65.53±9.69	0.079
NK cells in lymphocytes	7.41±7.22	12.74±9.46	0.048
CD8+ T cells in lymphocytes	25.35±9.58	26.59±9.04	0.672
Memory cells in CD8+ T cells	27.15±17.15	28.33±15.80	0.771
Naive cells in CD8+ T cells	9.24±7.62	10.95±13.23	0.821
CD8+ CD28− cells in lymphocytes	18.03±8.33	18.12±7.73	0.977
CD8+ CD28+ cells in lymphocytes	6.73±3.93	7.21±3.64	0.735
CD28−/CD28+ cell ratio in CD8+ T cells	3.94±3.55	2.68±0.89	0.749
CD4+ T cells in lymphocytes	37.40±11.10	29.22±11.78	0.061
CD4+CD25high cells in CD4+ lymphocytes	8.43±5.01	13.01±6.59	0.023

Tumours modulate immune response of differentiated macrophages

M. El Refaee[1], A. Jackson[2], P. Patel[2]. [1]*City of Scientific Research and Technology Application (STRA)-City, Genetic Engineering and Biotechnology Research Institute(GEBRI), Alexandria, Egypt;* [2]*School of Molecular Medical Sciences University of Nottingham, Academic Clinical Oncology, Nottingham, United Kingdom*

Interaction between tumour and immune cells either promotes or inhibits tumour progression. Studies reported that tumour associated macrophages have M2 phenotype that were proven to elicit tumour promoting functions. We hypothesised that exposure of differentiated macrophages to tumour lysates might alter their cytokine profile resulting in reduction of inflammatory response and induction of anti-inflammatory response. We generated two human macrophages populations by differentiating $CD14^+$ cells in either granulocyte macrophage colony stimulating factor (GM-CSF), (M1) or macrophage colony stimulating factor (M-CSF), (M2). Differentiated cells were phenotypically and functionally identified. Tumour cell lysates were employed to dissect their direct effect on cytokine production by these two populations. Our results revealed that, tumour lysates significantly ($p < 0.05$) inhibit TNF-α production of both populations while significantly ($p < 0.05$) inducing IL-10 production by M2 subtype. Furthermore, colorectal cell lysates switched M1 to M2 cells which is evident by their significant ($p < 0.01$) induction of IL-10 production of M1 cells. Results in this *in vivo* model added new evidence supporting the notion of 'tumour recruit macrophages to interfere with development of protective inflammatory response and induce the generation of tumour-promoting macrophage phenotype (M2)'.

Immunoreactivity to food antigens in patients with plasmacytoma and multiple myeloma

B. Kolundzija[1], I. Matic[1], M. Dordevic[2], M. Dordic[1], A. Damjanovic[1], J. Bila[3], S. Ristic[4], B. Mihaljevic[3], D. Ristic[1], Z.D. Juranic[1]. [1]*Institute of Oncology and Radiology of Serbia, Belgrade, Serbia;* [2]*Institute of Rheumatology, Belgrade, Serbia;* [3]*School of Medicine University of Belgrade, Belgrade, Serbia;* [4]*Clinical Hospital Center "Dr Dragisa Misovic-Dedinje", Belgrade, Serbia*

Background: Increased immunoreactivity to certain food antigens (phytohemagglutinin (PHA) and cow's milk proteins (CMP)) was noticed in a number of patients with different types of haematological malignances, and it is considered partially responsable for immunological disorders observed in haematological malignancies.
Materials and Methods: This study involved 16 patients with plasmacytoma and 10 patients with multiple myeloma. The control group consisted of up to 50 healthy volunteers. Levels of IgA, IgG, IgM and IgE antibodies to food antigens were determined with ELISA test. Flow cytometry was performed for analysis of populations of white blood cells.
Results: Enhanced levels of anti-CMP antibodies were found in 13 out of 16 patients with plasmacytoma, and 5 out of 10 patients with myeloma. Immunoreactivity to PHA was increased in 8/16 plasmacytoma patients, respectively, which was not the case with patients with multiple myeloma. We found significant increase in IgE anti-CMP antibodies ($p < 0.009$) for plasmacytoma patients. Also, statistical significance was noticeable in increased levels of IgA and IgE anti-CMP antibodies ($p < 0.02$ and $p < 0.002$ respectively) in multiple myeloma patients. Decreased percentage of lymphocytes was observed in 5 patients with plasmacytoma and 5 patients with multiple myeloma. Of this number, enhanced levels of immunoglobulins to food antigens were found in 3 patients with plasmacytoma, and in 3 patients with myeloma.
Conclusions: Our results demonstrate that enhanced immunoreactivity to food antigens could contribute to accompanying disturbances in patients with haematological malignances. Involvement of larger groups of patients and further confirmation of this phenomenon will be necessary, and it is important to understand cause and mechanisms involved in immunoreacivity and the decrease in the percentage of lymphocytes.
No conflict of interest.

Cancer-associated fibroblasts mediate tamoxifen resistance by secreting IL6 in ER positive breast cancer

Y. Mao[1], X.Q. Sun[2], S.Y. Sun[3], X.S. Chen[3], Q. Qu[3], Y.Z. Zhang[3], J.J. Liu[3], X.M. Wang[2], J.H. Wang[2], K.W. Shen[3]. [1]*Shanghai Ruijin Hospital, Comprehensive Breast Health Center, Shanghai, China;* [2]*Shanghai Jiaotong University School of Medicine, Department of Biochemistry and Molecular & Cell Biology, Shanghai, China;* [3]*Shanghai Ruijin Hospital, Comprehensive Breast Health Center, Shanghai, China*

Background: Tamoxifen is an effective anti-estrogen drug for ER+ breast cancer, which has decreased 40% of recurrence and 30% of mortality. However, there are still about 33% of ER+ patients experienced tamoxifen resistance. Cancer-associated fibroblasts (CAFs), one major component of tumor microenvironment, have related to drug resistance, but whether and how they mediate tamoxifen resistance in ER+ breast cancer remain elusive.
Material and Methods: CAFs and normal fibroblasts (NFs) were isolated from fresh ER+ breast samples obtained from Ruijin hospital. Conditional medium (CM) were collected from cultured CAFs and NFs. Different secreted proteins were analyzed by RayBio human cytokine antibody Array. Cell proliferation was determined by XTT assay and colony formation assay. Protein expression was determined by western-blotting.
Results: CM from CAFs induced tamoxifen resistance in two ER+ cell lines, MCF7 and T47D. Moreover, higher level of interleukin 6 (IL6) was secreted from CAFs compared with NFs, and induced tamoxifen resistance in both cell lines. Also, this phenomenon was accompanied by ER-α downregulation and JAK/STAT3, AKT pathway activation, and epithelial–mesenchymal transition (EMT) was observed during this process. Interestingly, anti-IL6 treatment reversed CAF and IL6 mediated tamoxifen resistatnce.
Conclusions: CAFs secrete high level of IL6, mediate tamoxifen resistance through activating JAK/STAT3, AKT pathway and degrading ER-α by ubiquitination. Anti-IL6 treatment may reverse tamoxifen sensitivity in ER+ breast cancer cell lines, serving as a novel therapeutic agent for tamoxifen-resistant breast cancer patients.
No conflict of interest.

618 POSTER

NOG regulation of proliferation of breast cancer cells in cancer-bone microenvironment

S.J. Park[1], H.G. Kang[1], S.Y. Park[2], M.K. Kim[3], T.S. Kim[3], S.Y. Jung[2], S.Y. Kong[3]. [1]*National Cancer Center Korea, Orthopedic Oncology Clinic, Goyang, Korea;* [2]*National Cancer Center Korea, Breast & Endocrine Cancer Branch, Goyang, Korea;* [3]*National Cancer Center Korea, Translational Epidemiology Research Branch, Goyang, Korea*

Background: Noggin has been known as an antagonist of bone morphogenetic protein (BMP) which has the role to regulate cell proliferation and migration. However, the functional role of NOG in the development and progression of breast cancer in context of microenvironment has not been fully elucidated. Here, we investigated that NOG gene expression in a various type of breast cancer cells and examined the effect on proliferation, migration and bone resorption.
Materials and Methods: The NOG gene expression was analyzed in breast cancer cell lines including MDA-MB-231, MCF-7, SK-BR-3, and T47D by Taqman assays. To investigate the role of NOG, high metastatic MDA-MB-231 cell was transfected with NOG small interfering RNA (siRNA) or non-target siRNA. Inhibition of NOG expression was confirmed by Taqman assays. To determine the cellular effects of NOG knockdown on the MDA-MB-231 cell, we performed cell proliferation assay with cell counting kit-8 (CCK-8) and cell count at 24, 48, 72 hr. Cell cycle analysis and apoptosis measured by flow cytometry (FACS) using the PI and Annexin V/7AAD staining kit, respectively. Also we examined the motility of NOG knockdown MDA-MB-231 cell with migration assay. Moreover, pit formation assay performed using co-culture systems with osteoclasts differentiated from Raw 264.7 cell with MDA-MB-231 cell treated by siRNA.
Results: We found that NOG was strongly expressed in osteolytic breast cancer cell MDA-MB-231 more than that of MCF-7, SK-BR3, and T47D. NOG knockdown mediated by siRNA in MDA-MB-231 cell represented decreased cell proliferation and growth rate. Furthermore, decreased NOG expressed MDA-MB-231 cell induced G0/G1 phase cell cycle arrest and increased early stages of apoptosis as compared with control. Also, suppression of NOG expression reduced migration activity of MDA-MB-231 cell. NOG knockdown MDA-MB-231 cell failed pit formation in cancer-osteoclasts co-culture model.
Conclusions: These data provides evidence for NOG promoted proliferation by regulation of cell cycle. Moreover, it showed the role on migration & osteolysis in cancer-bone model system. Taken together, NOG gene

have important role on breast cancer cellular process especially in bone metastatic microenvironment.
No conflict of interest.

619 POSTER

Tetraspanin CD151 regulates expression of fibroblast growth factor receptor-2 (FGFR2) in ductal carcinoma in situ cell line

L. Turczyk[1], D. Czaplinska[1], R. Kordek[2], H.M. Romanska[2], F. Berditchevski[3], R. Sadej[1]. *[1]Intercollegiate Faculty of Biotechnology Medical University of Gdansk, Medical Biotechnology, Gdansk, Poland; [2]Medical University of Lódz, Department of Pathology, Lódz, Poland; [3]University of Birmingham, School of Cancer Science, Birmingham, United Kingdom*

Background: CD151 is a member of evolutionary conserved transmembrane-4 superfamily. CD151 was the first tetraspanin associated with cancer development and its role in promotion of invasion and migration has been demonstrated in numerous *in vitro* and *in vivo* models. Clinically, high levels of CD151 are correlated with poor prognosis in a variety of tumours including breast cancer. Increased expression of CD151 was observed in ductal carcinoma *in situ* (DCIS), a premalignant form of breast cancer suggesting that CD151 may also play a crucial role at the early, proliferative stages of the disease. There is an increasing evidence that the FGF-FGFR2 signaling axis plays an important role in breast cancer. Elevated expression of FGFR2 transcripts was associated with a higher incidence of breast cancer. On the other hand *in vitro* and animal studies show that FGFR2 inhibits tumour progression. Here we demonstrate for the first time that expression and function of fibroblasts growth factor receptor-2 (FGFR2) in an immortalized breast epithelial cell line is regulated by tetraspanin CD151.
Material and Methods: FGFR2 expression was assessed by western blotting and qPCR in HB2 (CD151+) cell line and its variant HB2 (CD151−). CD151-dependent responses to various FGFs were evaluated in cells grown in 3D collagen. In order to reveal molecular pathways underlying CD151-mediated FGFR2 expression, cells were incubated with chemical inhibitors of a panel of kinases and analysed for the presence of FGFR2 protein.
Results: We found that CD151 knock-down in HB2 cells upregulated expression of FGFR2 at both mRNA and protein level, without affecting other FGF receptors. This was reflected in in inhibition of CD151-negative cells response to FGF2 (ligand for FGFR2) grown in 3D collagen. Analysis of signaling pathways likely to be responsible for these effects revealed that CD151 impairs activation of p38 kinase which controls FGFR2 expression level. Inhibition of p38 activity or its forced overexpression, impaired or elevated FGFR2 level, respectively.
Conclusions: The results demonstrate for the first time that tetraspanin CD151 interacts with the FGF-FGFR2 signaling axis in breast epithelial cells and regulates expression and function of FGFR2 gene and protein. Further *in vivo* and clinical studies are required to define the role of this process in breast cancer progression.
No conflict of interest.

Botelho[5]. *[1]Biophysics Unit − IBILI, CIMAGO-Faculty of Medicine University of Coimbra, Coimbra, Portugal; [2]Biophysics Unit − IBILI, CICS-UBI Health Sciences Research Centre University of Beira Interior Covilhã CIMAGO-Faculty of Medicine University of Coimbra, Coimbra, Portugal; [3]Biophysics Unit − IBILI, CIMAGO-Faculty of Medicine University of Coimbra Radiotherapy Service Hospital and University Center of Coimbra, Coimbra, Portugal; [4]Applied Molecular Biology and Clinical University of Hematology, CIMAGO Faculty of Medicine University of Coimbra, Coimbra, Portugal; [5]Biophysics Unit − IBILI IBILI, CIMAGO-Faculty of Medicine University of Coimbra, Coimbra, Portugal*

Background: Recent clinical data indicate that tumor hypoxia negatively affects the treatment outcome of radiotherapy and chemotherapy in various cancers, emphasizing the need for noninvasive detection of tumor hypoxia. The application of ^{18}F-FDG PET imaging in oncology is based in the upregulation of glucose transporters and glycolytic enzymes, and tumor hyperglycolysis. On the other hand, ^{18}F-Fluorocholine (^{18}F-FCHO) is metabolized to form phosphatidylcholine, a major membrane phospholipid, because in malignant cells there is an increase on choline and phosphocholine synthesis. Once the biomedical processes that allow cancer cells to capture ^{18}F-FDG and ^{18}F-FCHO are different, these two radiopharmaceuticals can give us different information about the bioenergetics of colorectal cancer.
In this context, the main objective of this study is to determine the pattern of uptake of ^{18}F-FDG and ^{18}F-FCHO in three colorectal carcinoma cell lines in normoxia and hypoxia conditions and correlate these results with the expression of GLUT-1, −3 and p53.
Methods: Studies were performed in colorectal carcinoma cell lines (WiDr, C2BBe1 and LS1034). Uptake studies with ^{18}F-FDG and ^{18}F-FCHO were performed. After incubation in a cell suspension of 2×10^6 cells/ml (25 μCi/ml), samples were collected, radioactivity of pellets and supernatants was measured and percentage of uptake calculated. Experiments were conducted in normoxia (18% oxygen) and hypoxia (2% oxygen) environment. GLUT-1, −3, as well as p53 expression was assessed by flow cytometry and western blot, respectively.
Results: p53 protein quantification revealed that C2BBe1 cell line does not express p53 while WiDr and LS1034 do. Related to ^{18}F-FDG uptake, LS1034 and WiDr cell lines increased the uptake in hypoxic conditions in contrast with C2BBe1. When the cells were incubated with ^{18}F-FCHO, we observed that the uptake of all cell lines in hypoxic conditions was higher comparing with normoxic conditions. Concerning GLUT-1 and −3 expression we observed that hypoxia (2 and 48 hours) induced an increase of these glucose transporters.
Conclusions: With these results, we can conclude that in solid tumors, as colorectal cancer, the uptake of current radiotracers is influenced by tumor microenvironment. Besides that, characteristics like GLUTs, the main glucose transporters, can be responsible for these results. However, the genetic background also reveals be a key role in cells uptake.
No conflict of interest.

The magnetite nanoparticles manifest self-dependent antitumor activity in the experiments in vivo

L.H. Garkavi[1], G.V. Zhukova[1], O.I. Kit[1], V.A. Zernov[2], T.A. Barteneva[1], M.I. Bragina[1], A.I. Zhadobina[1], T.N. Gudzkova[1], O.E. Polozhentsev[3], V.M. Tyutyunnik[4]. *[1]Rostov Cancer Research Institute, Research, Rostov-on-Don, Russian Federation; [2]Russian New University, Research, Moscow, Russian Federation; [3]Southern Federal University, Research, Rostov-on-Don, Russian Federation; [4]International Information Nobel Centre, Research, Tambov, Russian Federation*

At present ferrimagnetic nanoparticles (NP) are used in antitumour treatment for targeted drug delivery or as factors of magnetic fluid hyperthermia. The question about self-dependent antitumour activity of such NP is almost not studied.
The self-dependent antitumour activity of magnetite NP (Fe_3O_4) was for the first time shown in the experiments on 258 white outbred rats (200–300 g) *transplantable* tumour, *sarcoma 45* and *Pliss lymphosarcoma*.
Tumours were transplanted subcutaneously into the region of the rear side of the back. Before the start of treatment course experiment the tumour volume of *sarcoma 45* reached 0.7−1.3 cm^3, the tumour volume of *Pliss lymphosarcoma* reached 0.3−2.7 cm^3. The ferrofluid based on magnetite NP (10±2 nm) *was injected into the area adjacent to the tumour at a distance of 1.5 cm from the tumour borders* twice a week, 5−6 times in total. The dose of magnetite NP varied in different experiments. The dynamics of the tumour volume, changes in the tumour and adjacent tissues, as well as in the organs of the immune system, the quantity of NP in the liver, in the kidneys, and in the lungs were studied. The methods of light and electron microscopy as well as flow cytometry and X-ray absorption spectroscopy analysis were used. The Student's t-test and the Wilcoxon signed-rank test were used for the statistical analysis.
For the rats with *sarcoma 45* the maximum effect of magnetite NP was expressed in tumour regression in 70% of animals, including complete tumour regression in 43% of cases. For the rats with the *Pliss lymphosarcoma* the maximum effect of magnetite NP was expressed in the tumour regression in 50% of animals, in these cases complete tumour regression was noted in 40% of animals including the rats whose tumour volume before the start of treatment course exceeded 2.5 cm^3. The cases of the complete tumour regression were confirmed histologically, and also by monitoring the animals' state in the course of 8 months. The activation of system and local immune processes (increase of the limfoproliferative activity in the thymus and the spleen, the infiltration of the tumour tissue by immune cells and the appearance of morphological signs of different intercellular interactions, $p < 0.05$–0.01) was observed under the effective influence of magnetite NP. Toxic reactions were not noted.
We have examined the possible mechanisms, connected with the processes in the perifocal zone of the tumours, which can determine the self-dependent antitumour activity of magnetite NP.
No conflict of interest.

Regulation of barrier function in human breast cancer can be controlled by the ROCK signalling pathway via interaction with SIPA-1

T. Martin[1], W.G. Jiang[1]. [1]*Cardiff University, Surgery, Cardiff, United Kingdom*

Background: SIPA-1 (Signal-induced proliferation-associated gene 1) is a mitogen-inducible gene encoding a GTPase-activating protein for Rap1 and Rap2 that may be involved in metastatic progression. Recent years have highlighted the role that Tight Junctions (TJ) have in cancer metastasis. However, how changes in TJs of cancer cells are controlled is still uncertain. We have previously shown that SIPA-1 is significantly reduced in breast patients with poor prognosis & metastatic disease. This study examined SIPA-1 and its relationship to TJ function in human breast cancer cells.
Materials and Methods: Two breast cancer cell lines, MDA-MB-231 and MCF7, exhibiting high levels of SIPA-1 was chosen to knockdown endogenous SIPA-1 expression. Changes in TJ function was assessed using trans-epithelial resistance (TER) & paracellular permeability (PCP) under the influence of the mitogen/mitogen, HGF. Invasion, adhesion, growth & ECIS assays were also performed. Western blotting was used to confirm binding partners for SIPA-1. In vitro & in vivo models were used to assess the effect of ROCK inhibitor on knockdown cells.
Results: Knockdown cells exhibited significantly reduced response to HGF during both TER and PCP assays ($p < 0.001$) and there was a significant reduction in invasion, adhesion and growth ($p < 0.01$). Immuno-precipitation studies confirmed SIPA-1 as a binding partner for the ROCK signalling protein. Subsequent experiments with MDA-MB-231 cells revealed that neither HGF nor the ROCK inhibitor could exert an effect on migration or barrier functions in knockdown cells. HGF had no effect on protein levels of SIPA-1 in WT cells. Crucially, the in vivo model revealed that SIPA-1 knockdown cells had significantly reduced tumour growth in contrast to wild type tumours, that treatment with the ROCK inhibitor also inhibited tumour growth but that knockdown of SIPA-1 negated an additive effect with the ROCK inhibitor. Phosphorylation studies showed that the ROCK inhibitor caused serine phosphorylation of SIPA-1 in wild type cells, but that HGF had no effect on phosphorylation status. Neither factors affected threonine or tyrosine phosphorylation.
Conclusions: We have demonstrated for the first time that SIPA-1 is involved in the regulation of TJ in human breast cancer via the ROCK signalling pathway. A reduction in SIPA-1 expression leads to breast cancer cells with reduced aggressive phenotype and significantly increased TJ functions. Moreover, we have shown that SIPA-1 is involved in regulating barrier function via the ROCK signalling pathway. This leads to interesting possibilities for the role of SIPA-1 in human breast cancer.

HGF and the regulation of tight junctions in human prostate cancer cells

T. Martin[1], M.D. Mason[2], W.G. Jiang[1]. [1]*Cardiff Univesity, Surgery, Cardiff, United Kingdom;* [2]*Cardiff Univesity, Oncology & Palliative Medicine, Cardiff, United Kingdom*

Background: A major impact of Hepatocyte growth factor (HGF) on the development & metastasis of prostate cancer may be via its action on prostate stem cells or their progeny. Understanding the sequence of events in the above process would have important implications in understanding the biology of prostate cancer and in the development of new therapies. Tight Junctions (TJ) are key to the process of metastasis & have been previously shown to be regulated by HGF. This study sought to evaluate the effect of HGF on TJ function of human prostate epithelial cell lines, prostate-stem-cell- like cells and prostate cancer cell lines.
Materials and Methods: RWPE-1 (normal adult prostate parental epithelial cells), WPE-stem (a stem-cell-like derivative of RWPE-1) and 4 human prostate cancer cell lines (PC-3, DU-145, PZHPV-7, CaHPV-10) were used to assess HGF-induced changes in TJ function via trans-epithelial resistance (TER) & paracellular permeability (PCP). ECIS assays were also performed. RT-PCR, Western blotting and immunofluorescence were used to analyse changes in TJ molecule expression/distribution. An athymic murine tumour model was used to assess tumourigenicity.
Results: We found that there was a significant difference in behaviour between the stem-cell-like WPE-stem cells, the RWPE-1 cells & the cancer cell lines that was also HGF concentration dependent. As expected, HGF reduced the TER/PCP of the RWPE-1 cells & the prostate cancer cell lines ($p < 0.0001$ & $p < 0.005$); however, the response elicited indicated that the more invasive the cell line, the more HGF was able to effect a decrease in resistance over time, with PC-3 cells being most affected. ECIS confirmed these results, with different resistance profiles for each of the cell lines ($p < 0.043$). However, in the WPE-stem cells, the effect was biphasic, with the cells seemingly resistant to HGF modulated TJ disruption. Closer examination revealed that HGF effected a redistribution of ZO-1, −2 & −3 away from the TJ of confluent PC-3 cells with concurrent loss of claudin-1 & −5. Western blotting revealed loss in TJ protein expression of ZO-1 & −2 (confirmed with RT-PCR) with an apparent increase in Occludin (65kDa) & ZO-1 exhibiting two isoforms. In contrast to PC-3 & DU-145 cells, neither RWPE-1 nor WPE-stem cells were tumourigenic in an *in vivo* tumour model even in the presence of HGF.
Conclusions: We have demonstrated for the first time that HGF regulates the function of TJ in human prostate cells. Moreover, this regulation is dependent on the tumourgenicity of the cells, with the most aggressive cells being most susceptible and the stem-cell- like cells least susceptible. This opens up a fascinating avenue of research for the future. These data offer an intriguing glimpse of how TJ affect the behaviour of prostate cancer cells and how HGF modulates the expression and function of the molecules maintaining TJ structure & function.

Metastasis suppressor 1 (MTSS1), and epithelial to mesenchymal transition (EMT) in cancer progression

J. Lane[1], W.G. Jiang[1]. [1]*University Hospital Wales, Metastasis & Angiogenesis Research Group, Cardiff Wales, United Kingdom*

Background: Acquisition of a mesenchymal-like cell phenotype is a hallmark of metastatic progression of most carcinomas. This dynamic process of epithelial to mesenchymal transition (EMT) allows polarised epithelial cells to assume a mesenchymal phenotype with enhanced migratory and invasive capabilities. Metastasis suppressor 1 (MTSS1), discovered in non-metastatic bladder cancer cell lines, but missing in metastatic bladder cancer, modifies interplay between the actin cytoskeleton and plasma membrane conserving intercellular contacts and is important in development, carcinogenesis and metastasis. This study aimed to discover any link between MTSS1, and the process of EMT in cancer progression.
Material and Methods: Two bladder cancer cell lines (EJ138 and RT112) and one breast cancer cell line (MCF-7) were studied. Genetic manipulation, utilising ribozyme technology, produced EJ138 and RT112 cells which over expressed MTSS1 and MCF-7 cells with knocked down expression of MTSS1. PCR and Western Blot analysis were performed on the wild type (WT) and manipulated cells to assess any link between MTSS1 expression and specific EMT markers. Electric cell-substrate impedance sensing (ECIS) technology was employed to investigate changes in cell motility in relation to MTSS1 expression.
Results: Over expression of MTSS1 in both bladder cancer cell lines lead to a loss of SNAI1 expression whereas knockdown of MTSS1 in the MCF7 breast cancer cell line resulted in upregulation of SNAI1. Similar results were seen for TWIST expression in the bladder cancer cells but not in the breast cancer cells. In the MCF7 cells E-cadherin expression inversely correlated with SNAI1 expression. The MCF-7-MTSS1 knockdown cells initially attached more slowly than the wild type cells but after wounding significantly attached more quickly ($p < 0.001$). Both bladder cancer cell lines over expressing MTSS1 attached more quickly than WT cells, with no significant difference seen in the migration capacity between RT112-MTSS1-Exp cells and the control RT112pEF cells, nor between EJ138-MTSS1-Exp cells and the EJ138pEF control cells.
Conclusions: The changes in EMT transcription factors SNAI1 and TWIST and in the cell-cell adhesion molecule E-cadherin, in all three cell types in relation to MTSS1 expression, together with differences in the motility of MTSS1 manipulated cells, point to a link between MTSS1 and EMT factors in these cancer types which bears further investigation.

Membrane proteome analysis of invasive human glioblastoma multiforme

D. Mallawaaratchy[1], R.I. Christopherson[1], K.L. Kaufman[1]. [1]*The University of Sydney, School of Molecular Bioscience, Sydney NSW, Australia*

Glioblastoma multiforme (GBM) is the most aggressive and prevalent malignant brain tumour in adults. GBM is diffusely infiltrative and its poor demarcation from surrounding brain parenchyma makes complete surgical resection difficult and tumour recurrence inevitable. Tumour invasion of neighbouring tissues is facilitated by cell migration and degradation of the extracellular matrix (ECM). Invadopodia are discrete ECM-degrading structures recently described on GBM and play important roles in tumour invasion. The aim of the current study is to characterize the 'invasive potential' of a panel of established GBM cell lines using an invadopodia assay and perform comparative membrane proteomic analyses of highly invasive vs less-invasive cells.

Nine GBM cell lines were characterized based on their ability to produce invadopodia using a QCM gelatin invadopodia assay (Millipore). Glass slides were coated with Cy3-gelatin before seeding GBM cells for 24 h at 37°C. Fluorescence microscopy revealed areas devoid of Cy3-gelatin indicating gelatin degradation by GBM cell invasion. The membrane proteomes from GBM cells with different invasive potentials were enriched by differential ultracentrifugation and compared using isobaric tags for relative and absolute quantitation (iTRAQ) coupled with multi-dimensional liquid chromatography and tandem mass spectrometry (LC-MS/MS).
All 9 GBM lines produced invadopodia and degraded Cy3-gelatin. There was a significant difference between the most invasive (U87MG) and least invasive (LN229) cells (65%, percentage of total cell area; $p = 0.0001$). Overall, 1667 proteins were identified from duplicate runs, of which 76% mapped to membrane structures using the David bioinformatics database (http://david.abcc.ncifcrf.gov). The abundance of 34 proteins significantly correlated to the degree of invasion ($r^2 > 0.5$ or $r^2 < -0.5$; $n \geqslant 9$; $p < 0.05$). An invadopodia assay was used to characterize the invasive potential of GBM cell lines. Differentially abundant proteins identified by iTRAQ LC-MS/MS analysis are involved in cellular motility, cell-cell signalling and interactions and angiogenesis. Such, invadopodia-associated membrane proteins could be targets for novel anti-invasive therapies.

Exercise modulates redox-sensitive mechanisms in the blood–brain barrier microenvironment during metastasis development

G. Wolff[1], M. Park[1], I.E. Andras[1], H.J. Kim[1], C. Wu[1], J.E. Balke[1], M. Toborek[1]. [1]*University of Miami, Biochemistry and Molecular Biology, Miami Florida, USA*

Background: Tumor cell extravasation into the brain requires passage through the BBB (blood–brain barrier) (BBB), which is a highly protected microvascular environment that is fortified with TJs (tight junction). Activated redox-sensitive small GTPases (Ras kinase) can target TJ proteins leading to disruption of the BBB and promoting tumor cell extravasation. There is evidence that exercise can alter the oxidation status of the brain microvasculature and protect against tumor cell invasion. However, the mechanism remains unclear.
Methods: Mice exercised voluntarily for five weeks using a running wheel. The average running distance was 9.04 ± 2.0 km/day. In order to study blood-borne brain metastasis formation we infused D122 cells (murine Lewis lung carcinoma) into mouse brain microvasculature through the internal carotid artery using a technique previously published in the lab. Mice were infused with $1x10^6$ tumor cells and observed for 48-hours or 2 weeks then brain tissues were collected.
Results: Oxidative stress measurements revealed a trend toward increased ROS (reactive oxygen species) in both the exercise and tumor cell injected groups, and a statistical correlation between running distance and ROS (DCF) in the high-running group. Ras activity was increased in the sedentary mice injected with tumor cells but was similar to control in the exercise tumor cell group. TJ (occludin and claudin-5) protein expression was similar between the exercise tumor and vehicle treated groups, however ZO-1 and junctional adhesion molecule-A protein levels trended toward increased expression in the tumor cell groups. Tumor cell bioluminescence was elevated in the sedentary group at 2 weeks compared with exercised mice.
Conclusions: These data indicate that initial steps in metastasis formation involve a localized increase in reactive oxygen species and activation of small GTPases. Also exercise may attenuate metastasis formation at later stages. Importantly, they suggest that exercise plays a role in modulating Ras signaling in the brain microvasculature.

Clinicopathological and prognostic significance of fibroblast growth factor receptor 1, 2, and 4 in gastric cancer

H. Murase[1], M. Inokuchi[1], H. Sugita[1], K. Kato[1], K. Kojima[2], K. Sugihara[1]. [1]*Tokyo Medical and Dental University, Surgical Oncology, Tokyo, Japan;* [2]*Tokyo Medical and Dental University, Minimum Invasive Surgery, Tokyo, Japan*

Background: The overexpression of fibroblast growth factor receptor (FGFR) 2 has been known as a prognostic factor and a target of treatment in undifferentiated type gastric cancer. However, role of the other FGFRs is not elucidated enough. We investigated the correlations of FGFR1−4 expressions with clinicopathological features and prognosis in gastric cancer.
Materials and Methods: Tumor samples were obtained from gastric adenocarcinomas of 222 patients who underwent a gastrectomy from 2003 to 2007. The expression of each FGFR was analyzed in the tumor by immunohistochemistry. Parametric correlations were done between FGFR expressions and the clinicopathologic findings. A univariete and multivariate analysis were done with the disease specific survival.
Results: Cytoplasmic overexpression of FGFR1 was found in 66 (30%) of all tumors, FGFR2 in 114 (51%), FGFR3 in 142 (64%), and FGFR4 in 175 (79%). Overexpression of FGFR1, 2 or 4 was significantly associated with tumor progression, including the depth of tumor invasion, involved lymph nodes, distant metastasis, tumor stage and recurrent disease. Patients with overexpression of FGFR1, 2 or 4 had significantly worse survival ($p < 0.001$, $=0.0083$, and <0.001). In addition, co-overexpression of the three FGFRs was significantly associated with a poor survival than none or one expression of those expressions ($p < 0.001$ and $=0.0015$). Although the tumor stage was the most dominant prognostic factor (hazard ratio, 22.334; 95% confidence interval, 10.054–49.613; $P<0.001$), the co-overexpression of the three FGFRs was also an independent prognostic factor (hazard ratio, 1.707; 95% confidence interval, 1.022–2.851; $P = 0.041$). In subset analysis, patients with overexpression of FGFR1, 2 or 4 had also significantly worse survival in undifferentiated type ($p < 0.001$, <0.001, and $=0.0103$), and the co-overexpression of the three FGFRs was an independent prognostic factor (hazard ratio, 2.033; 95% confidence interval, 1.066–3.878; $P = 0.031$). But it was not an independent prognostic factor in differentiated type (hazard ratio, 1.062; 95% confidence interval, 0.437–2.582; $P = 0.894$), and patients with overexpression of FGFR4 had only significantly worse survival ($p = 0.0098$).
Conclusions: Overexpression of FGFR1, 2, or 4 was associated with tumor progression and poor survival.FGFR1 and 4 may become prognostic factors and targets of treatment as well as FGFR2 in gastric cancer especially in undifferentiated type.
No conflict of interest.

628 POSTER

Soluble METCAM/MUC18 blocks angiogenesis during the in vivo tumor formation of human prostate cancer LNCaP cells

G. Wu[1]. [1]*Chung Yuan Christian University, Bioscience Technology, Chung Li, Taiwan*

Background: Human METCAM/MUC18 is a key determinant in increasing tumor-take and tumorigenesis and initiating metastasis of human prostate cancer LNCaP cells. To study the mechanisms, in this report we further study the effect of enforced expression of truncated human METCAM/MUC18 proteins on tumor-take and tumorigenesis of LNCaP cells.
Material and Methods: The wild type and/or truncated human METCAM/MUC18-expressing LNCaP cells were subcutaneously co-injected with Matrigel to nude mice, and effects of expressing different forms of human METCAM/MUC18 on angiogenesis and tumor formation compared. The effect of expressing different forms of METCAM/MUC18 in LNCaP cells on the level of VEGF protein and the micro-vessel density in the *in vivo* tumors were determined.
Results: LNCaP clones/cells overly expressing the wild type or various cytoplasmic tail-deleted METCAM/MUC18 proteins had a higher tumor-take rate (80–100%) than the cells expressing vectors (50%). LNCaP clones/cells that overly expressed the cytoplasmic tail-deleted METCAM/MUC18 proteins appeared to have larger tumors than those that overly expressed the wild type protein. The tumors formed by the LNCaP clones/cells that overly expressed a soluble METCAM/MUC18 protein, in which both the cytoplasmic tail and the transmembrane domain were deleted, were not enriched with and not engulfed by massive blood vessels, whereas the tumors formed by the LNCaP cells that overly expressed the wild type or the cytoplasmic tail-deleted METCAM/MUC18 protein were enriched with and engulfed by massive blood vessels. Majority of the tumors formed by an equal mixture of the LNCaP cells, which expressed the wild type, and the cells, which expressed the soluble METCAM/MUC18, were not enriched with and not engulfed by massive blood vessels.
The VEGF level and the micro-vessel density in the tumors formed by LNCaP clones/cells that overly expressed the wild type or the cytoplasmic tail-deleted METCAM/MUC18 proteins were at least 2 fold higher than those in the tumors formed by the LNCaP clone/cells that overly expressed a soluble METCAM/MUC18 protein.
Conclusions: The ectodomain of the METCAM/MUC18 protein is necessary and sufficient, but the cytoplasmic tail is dispensable and may be inhibitory for angiogenesis and tumorigenesis of human prostate cancer LNCaP cells in nude mice. We suggest that human METCAM/MUC18 increases tumorigenesis and initiates metastasis of LNCaP cells by inducing vascularization inside and outside of tumors and hence mediates the hematogenous spread of tumor cells. We also suggest that peptides derived from human METCAM/MUC18 protein may be useful for blocking tumorigenesis and metastasis of human prostate cancer cells.

629 POSTER

Inhibition of TGFβ induced EMT with metformin and salinomycin increases epithelial markers and reduces cell migration in lung adenocarcinoma cell lines

S. Köck[1], A. Amann[1], J.M. Huber[1], G. Gamerith[1], H. Zwierzina[1], W. Hilbe[1]. *[1]Innsbruck Medical University, Internal Medicine V, Innsbruck, Austria*

Introduction: A central pathophysiological mechanism which is involved in the development of metastases is the epithelial-to-mesenchymal transition (EMT). EMT transforms epithelial carcinoma cells into mesenchymal like cells, characterized by increased cell migration and invasiveness. These functional conversions are dependent on stimulation by different cytokines, among those the Transforming Growth Factor β (TGFβ) seems to play a key role. Recently, metformin, an antidiabetic drug, and salinomycin, known for its apoptotic effect on cancer stem cells, have demonstrated an EMT inhibitory effect, although the exact mode of action still remains unclear. The presented experiments investigated how these substances inhibit TGFβ induced EMT in non-small cell lung cancer (NSCLC) cell lines.
Material and Methods: The NSCLC cell lines A549 and HCC4006 were stimulated with TGFβ (10ng/ml) for 48 h to induce EMT. Simultaneous addition of metformin or salinomycin was applied to inhibit the TGFβ induced EMT. Western blot analysis of E-cadherin and vimentin was performed to determine changes of EMT marker expression. Wound healing assay was conducted to determine effects on cell migration. The drug effects on cell viability were investigated by MTS assays.
Results: After TGFβ stimulation, cells underwent EMT, causing a down-regulation of E-cadherin and an upregulation of vimentin in Western Blot analyses. Moreover they showed an increased cell migration. Simultaneous application of TGFβ and metformin inhibited distinctly the execution of EMT and increased the E-cadherin expression. Similarly, salinomycin also inhibited EMT, although higher doses of salinomycin increased the vimentin expression in both cell lines. Furthermore metformin and salinomycin inhibited cell migration. Finally, with additional Western Blot analyses we provided possible evidence, that both substances do not block the binding of TGFβ to its receptor, but seem to interfere with intracellular pathways.
Conclusion: As EMT is involved in the metastatic process of cancer and in the development of chemoresistance, the profound knowledge and the manipulation of this mechanism could have some clinical implication. In summary, it was observed that metformin and salinomycin have the potential to block EMT and moreover inhibit EMT induced cell migration. Therefore our results implicate that both substances are novel intracellular EMT inhibiting drugs which might help to control the metastatic process in NSCLC.

Sialyl Lewis A and sialyl Lewis X antigens mediate oral cancer cell binding to recombinant E-selectin and TNF-alpha-stimulated endothelial cells

A.M. Alkishi[1], S.A. Khurram[2], M.H. Thornhill[1], C. Murdoch[1]. *[1]University of Sheffield, School of Clinical Dentistry Unit of Oral and Maxillofacial Medicine and Surgery, Sheffield, United Kingdom; [2]University of Sheffield, School of Clinical Dentistry Unit of Oral and Maxillofacial Pathology, Sheffield, United Kingdom*

Background: Distant metastasis is becoming a major cause of mortality among oral cancer patients. The carbohydrate epitopes sialyl Lewis A (sLeA) and sialyl Lewis X (sLeX) have been shown to play a role in the extravasation and metastasis of different cancer cells through interaction with E-selectin on endothelium. The aim of this study was to investigate whether sLeA/X are involved in the binding of oral squamous cell carcinoma (OSCC) cells to endothelial E-selectin.
Materials and Methods: The relative expression of the enzymes potentially involved in sLeA/X synthesis in OSCC cell lines was measured by quantitative real-time (RT)-PCR. sLeA/X cell surface expression was assessed by flow cytometry and immunofluorescence staining. Seventeen matched-pairs of primary and nodal metastatic OSCC tissue sections were evaluated immunohistochemically using anti-sLeA (clone KM231) and anti-sLeX (clone KM93) monoclonal antibodies (mAbs). The association between sLeA/X expression profiles and OSCC cell adhesion to recombinant E-selectin (rE-selectin) and TNF-α-stimulated human dermal microvascular endothelial cells (HuDMEC) was evaluated by static and flow adhesion assays, respectively. The effectiveness of various cell adhesion prevention mechanisms was tested using anti-sLeA/X mAbs, neuraminidase, fucosidase, IELLQAR®, swainsonine and siRNA.
Results: The metastatic OSCC cell line, TR146, expressed significantly more sLeA than the non-metastatic OSCC cell lines, SCC4 and Cal27, and this was at least partially related to expression of fucosyltransferase III (FUT3). Inhibition of FUT3 expression in TR146 cells using siRNA reduced sLeX but not sLeA levels. Immunohistochemistry analysis showed sLeA/X to be mainly expressed by well- to moderately-differentiated OSCCs. No association between sLeA/X expression and lymph node metastasis of OSCC was noted. TR146 cells bound to rE-selectin and TNF-α-stimulated HuDMEC in significantly greater numbers than SCC4 cells. The adherence of TR146 cells to rE-selectin was significantly reduced after incubation with anti-sLeA/X mAbs, neuraminidase and siRNA to FUT3. Treatment of TR146 cells with neuraminidase also resulted in a significant reduction in cell binding to HuDMEC under hydrodynamic flow conditions.
Conclusions: Increased levels of sLeX in metastatic OSCC cells results from increased expression of FUT3. Elevated expression of sLeA/X enhances OSCC cell binding to rE-selectin and TNF-α-stimulated HuDMEC.
No conflict of interest.

631 POSTER

PKC as therapeutic target in glioblastoma

J. Balça-Silva[1], D. Matias[1], A. Carmo[2], A.B. Sarmento-Ribeiro[1], M.C. Lopes[3]. *[1]Faculty of Medicine of University of Coimbra (FMUC) Centre for Neuroscience and Cell Biology of University of Coimbra (CNC), University of Coimbra, Coimbra, Portugal; [2]Centre for Neuroscience and Cell Biology of University of Coimbra (CNC) University School of Vasco da Gama Coimbra, University of Coimbra, Coimbra, Portugal; [3]Centre for Neuroscience and Cell Biology of University of Coimbra (CNC) Faculty of Pharmacy of University of Coimbra (FFUC), University of Coimbra, Coimbra, Portugal*

Background: Glioblastoma (GBM) is the most malignant and the most frequent primary brain tumour. Despite all the efforts, the median survival time for GBM patients remains approximately 12−14 months. Preclinical and clinical evaluation of novel therapeutic strategies is a priority in these tumours. Actually, the *gold standard* used in clinical practice in GBM treatment is temozolomide (TMZ) (Temodar®). TMZ has a poor relative lack of success, probably due to the genetic and cellular heterogeneity of these tumours and also to the development of chemotherapeutic resistance. Tamoxifen (Novaldex®) is a member of the estrogen receptor (ER) modulator family that has been successfully used in the treatment and prevention of breast cancer (Mandlekar*et al.,* 2001). However, recent findings have suggested the possibility of a new antitumor mechanism ER-independent that led to the use of tamoxifen in glioma treatment. It was demonstrated that tamoxifen could inhibit cell proliferation *in vitro* through inhibition of protein kinase C (PKC) activity in several cancers. Therefore, this study aimed to evaluate the effect of tamoxifen in cell signaling pathways associated with glioma proliferation and modulation of cytoskeleton organization.
Material and Methods: For that, U-118 glioma cells were incubated with different concentrations of tamoxifen and the evaluation of the cytotoxic effect was determined by MTT assay. Proliferation analysis was evaluated using a BrdU assay. p-PKC expression was evaluated by western blot. Fluorescence assay to actin-filament studies were also performed.
Results: The results indicated that in GBM cells treated with tamoxifen there was a significant down-regulation of p-PKC expression, and a reduction in the proliferation rate of U-118 cells. In addition, the results also showed that tamoxifen induced a disorganization of f-actin filaments indicating that this drug may interfere with glioma cell migration.
Conclusions: Based on the inhibition of p-PKC expression by tamoxifen these results indicated that PKC contributes to the aggressive behavior of U-118 glioma cells since it reduced glioma cells proliferation and disorganized f-actin filaments. Therefore, the role of PKC signaling pathway in glioma should be better elucidated in order to determine if PKC could be considered a new therapeutic target in this tumour.

632 POSTER

The progression mechanism of hepatocellular carcinoma

S. Osada[1], H. Imai[1], Y. Sasaki[1], K. Yoshida[1]. *[1]Gifu University School of Medicine, Surgical Oncology, Gifu, Japan*

Background/Aims: To evaluate the progression of hepatocellular carcinoma (HCC), the ligand-stimulated receptor activity due to hepatocyte growth factor (HGF) and vascular endothelial growth factor (VEGF) were studied.
Methods: In the specimens of 30 HCC patients and culture cells (PLC/PRF/5) the induction values of intracellular protein were estimated by western blot. And for culture cells, the viability was determined by test method with 3-[4, 5-dimethylthiazol-2-yl]-2, 5-dephenyl tetrazolium bromide (MTT).
Results: 1. Serum HGF levels were significantly higher in invasive gross type or in intrahepatic metastasis (IM)-positive tumours. 2. The mean expression value of HGF protein in tumour was 0.56±0.35, which was not

different from non-tumour tissue, 0.59±0.40. And there was no significant differences based on tumour profiles. 3. The value of c-Met in tumour tissue, 1.36±0.12, was clearly higher than in non-tumour tissue, 1.07±0.06. The c-Met expressions were significantly higher on invasive type of HCC on gross type, vessel invasion, IM presence and histological type. 4. On individual study about the relationship between the level of serum HGF and c-Met expression in tumour tissue, the presence of IM could be easily detected. Furthermore, the level of serum HGF after hepatectomy was significantly higher than the preoperative value, and individual study with c-Met expression was associated with early recurrence. 5. The c-Met tyrosine phosphorylation in culturing cells was increased by 20 ng/ml HGF, and extracellular signal-regulated kinase (ERK) was also activated. Although VEGF receptor (Flk-1) was phosphorylated in response to VEGF, phosphorylated ERK was not detected. 6. Over 5.0 μM hydrogen peroxide (H2O2) caused rapid phosphorylation of both ERK1/2 and c-Jun NH2-terminal kinase (JNK) at 1 hour and cell death in a dose-dependent manner after 24 hours. 7. In first 6 hours, H2O2 induced cell death for 58.4±6.8%, whereas the presence of 100 ng/ml VEGF improved the survival rate to 77.2±4.2. 8. VEGF significantly decreased H2O2-induced cell death after 12 hours, whereas HGF (20 ng/ml) did not have a similar effect. 9. H2O2-induced phosphorylation of ERK and JNK was also reduced by VEGF (100 ng/ml). In contrast, HGF did not have an effect for H2O2-induced action for ERK and JNK.

Conclusion: The induction of c-Met and VEGF might be important to make IM and to survive respectively in the progress of HCC.

Small interfering RNA mediated down-regulation of ribonuclease reductase M2 subunit reduces cell proliferation, migration and invasion of clear cell renal cell carcinoma in vitro

M. Abudawood[1], W. Qiuyu[1], N. Ahmed[1]. [1]*Manchester Metropolitan University, Cell and Molecular Biology Research Laboratory, Manchester, United Kingdom*

Background: Ribonuclease reductase (RRM2) is an enzyme essential for the process of DNA synthesis. Overexpression of *RRM2* has been identified in numerous types of cancer including breast, colon, cervical and liver. Clear cell renal cell carcinoma (ccRCC) is the most common type of adult kidney tumour accounting for 75% of renal cell neoplasms. It is responsible for 2% of cancer related deaths worldwide. Our preliminary studies using Affymetrix® microarray analyses showed that *RRM2* was up-regulated up to 5 fold in ccRCC human tissues compared to normal human kidney tissues. However, the functions of *RRM2* in human ccRCC have not been clarified. The aim of this study is to investigate the effect of *RRM2* gene knockdown on proliferation, migration and invasion of human ccRCC cell line cells.

Materials and Methods: Down-regulation of *RRM2* in primary ccRCC (Caki-2, RCC-KP) and secondary metastases (Caki-1) cell line cells was achieved using pre-designed *RRM2* small interfering RNA (siRNA) at a final concentration of 20 μM for 72 h, alongside scrambled siRNA was used as a negative control. *RRM2* gene knockdown was assessed by real-time qPCR and Western Blot analyses. Cell proliferation and viability assays were carried out. *In vitro* scratch and Trans-well assays were done to investigate the effect of *RRM2* down-regulation on ccRCC cell migration. Effect of *RRM2* gene knockdown on cell invasion was assessed using Trans-well invasion assay.

Results: At least 80% *RRM2* gene knockdown was observed by quantitative RT-PCR and Western blot analyses. SiRNA mediated knockdown of the *RRM2* gene resulted in a reduction in cell proliferation ($P \leqslant 0.005$) without a concurrent reduction in cell viability in each cell line. *RRM2* knockdown had significant effect on reduction of cell invasion of primary ccRCC cell lines (Caki-2 and RCC-KP) ($P \leqslant 0.05$) but not secondary metastases Caki-1 cell line cells by Trans-well invasion assays. Furthermore, *In vitro* scratch and Trans-well assays showed a significant decrease in ccRCC cell migration of each cell line.

Conclusions: In summary, down-regulation of *RRM2* in ccRCC inhibits cell proliferation, migration and invasion of primary ccRCC cell lines. It indicates that overexpression of *RRM2* may be associated with ccRCC progression; thus suppressing its function may be a potential therapeutic strategy in ccRCC.

Supplementation with selenoglycoproteins suppresses early events in brain metastatic tumor formation via a mechanism involving NF-kB

J. Wrobel[1], J.J. Choi[1], R. Xiao[2], R. Power[2], M. Toborek[1]. [1]*University of Miami, Biochemistry and Molecular Biology, Miami FL, USA;* [2]*Alltech, Nutrigenomics Research Centre, Nicholasville KY, USA*

Background: Selenium is an essential trace element known to have a significant influence on biological systems. Beneficial impact of selenium on human health is attributed to its antioxidant activity and, in therapeutic aspects, to anticarcinogenic, anti-inflammatory and antiviral features. Feeding mice with selenium (Se) enriched yeast for 20 weeks markedly decreased growth of brain metastatic tumors. In order to identify components responsible for this protective effect soluble selenoglycoproteins (SGP) were extracted from Se-enriched yeast at pH 4.0 (SGP40) and 6.5 (SGP65).

Materials and Methods: To determine influence of SGPs on adhesion and migration of cancer cells through human brain endothelium, co-cultures of brain endothelial cells (hCMEC/D3) with lung (A549) or breast (MDA-MB231) cancer cells were treated with SGP40 or SGP65. hCMEC/D3 cells were cultured on collagen-coated transwell inserts (transmigration) or 48-well plates (adhesion) until reaching confluence. Labeled tumor cells were added in the amount of $5x10^5$ cells/ml onto endothelial monolayers. Fluorescence was measured as a marker of cell migration or adhesion at 485-nm excitation and 530-nm emission wavelengths. We then employed electrophoretic mobility shift assay (EMSA) to determine the influence of the SGPs on NF-κB activation.

Results: SGP40, but not SGP65 inhibited adhesion and migration of tested tumor cell lines through endothelial cell monolayers compared to the vehicle-treated control. SGP40 effectively suppressed TNFα-stimulated NF-κB activation in brain endothelial cells. While SPG65 also inhibited NF-κB DNA binding activity, these effects were less robust than those of SGP40. Surprisingly, pretreatment with SGP40 or SGP65 did not affect TNFα-induced expression of ICAM-1 and VCAM-1, suggesting the involvement of another adhesion mechanism. To further evaluate the active components responsible for the unique properties of SGP40, a series of experiments were performed using compounds identified to be present in Se-enriched yeast. Several of the compounds showed high activity, decreasing adhesion of cancer cells to brain endothelium and suppressing NF-κB activation.

Conclusions: The findings indicate that specific selenium compounds have the ability to inhibit adhesion and transendothelial migration of tumor cells via a process, which is likely to involve NF-κB activation.

635 POSTER

The effect of the Wilms tumour suppressor protein (WT1) on regulating cellular morphology and gene expression in endometrial stromal cells

C. Lucas[1], L. Francis[1], D. Gonzalez[1], S. Conlan[1]. [1]*Swansea University, School of Medicine, Swansea, United Kingdom*

Background: The Wilms tumour suppressor gene (WT1) is a transcription factor that functions as a key regulator of development and differentiation. WT1 encodes four major protein isoforms (WT1 +/+, +/−, −/+ and −/−), each denoted by the presence or absence of two alternative splice sites. An increase in WT1 mRNA and protein has been shown to cause a mesenchymal to epithelial transition (MET) during kidney development, aberrant function can lead to the paediatric malignancy Wilms tumour. Recently, WT1 has also been shown to be expressed within the endometrial stromal cells (ESCs) of the uterus.

Methods and Results: Using Real-time PCR, western blotting, cell culture and immunofluorescence a MET is shown to occur in ESCs, through changes in the morphology, mRNA and protein levels of the mesenchymal marker vimentin and epithelial markers E-cadherin and cytokeratin. This is demonstrated to occur during maximum levels of WT1 expression. The WT1 isoforms are shown to induce an ESC MET, through transient transfection of each WT1 isoform into ESCs. The WT1 +/+ and −/− isoforms are shown to induce the expression and bind to the promoter of E-cadherin, providing a possible role for the induction of MET. Methoxyprogesterone acetate (MPA) is also shown to effect the WT1 isoform regulation of a range of target genes, indicating a possible synergism between WT1 and MPA activated factors.

Conclusions: An ESC MET is shown to occur in ESCs at maximal WT1 expression. The ESC MET is demonstrated here to be induced by WT1 isoforms through MET markers E-cadherin, cytokeratin and vimentin and the formation of an epithelial morphology. This WT1 mediated ESC MET is thought to occur through a direct WT1 regulation of the E-cadherin

promoter. This study therefore aids the understanding of WT1 in ESCs and may prove to be useful as a possible biomarker for endometrial malignancies.

Investigation of a mechanistic link between 15-Lipoxygenase-1 (15-LOX-1) and Metastasis Associated Protein 1 (MTA1) in human colorectal carcinoma cell lines

S. Tuncay Cagatay[1], S. Banerjee[1]. [1]*Middle East Technical University, Biology, Ankara, Turkey*

Background: Metastasis Associated Protein 1 (MTA1) is a member of the nuclear remodeling and histone deacetylase (NuRD) complex that is known to repress the expression of several tumor suppressor genes. 15-lipoxygenase-1 (15-LOX-1), a member of the inflammatory eicosanoid pathway, has been shown by us and others to have an anti-tumorigenic role in colon cancer. *ALOX15* was recently shown to be repressed by the NuRD complex. Previously we have reported that ectopic expression of 15-LOX-1 in colon cancer cells reduced MTA1 expression, indicating the presence of a crosstalk and a negative correlation between 15-LOX-1 and MTA1 expressions.
To understand the mechanism behind this crosstalk, we have hypothesized the involvement of nuclear factor kappa B (NF-kB). MTA1 can be transcriptionally upregulated by NF-kB, while we and others have shown that 15-LOX-1 can inhibit the activity of NF-kB.
We have ectopically expressed 15-LOX-1 in colon cancer cell lines and examined the expression of MTA1 and NFkB p65 subunit in a panel of 5 colon cancer cell lines and the transcriptional regulation of MTA1 by NF-kB. We have also checked whether there is a correlation between the expression of 15-LOX-1 and MTA1 by analyzing publicly available human colorectal cancer gene expression datasets.
Materials and Methods: Cells were transiently transfected a 15-LOX-1 expression vector or the empty vector. Protein levels of 15-LOX-1, MTA1 and NFkB p65 were detected by Western blot analysis. NF-kB recruitment to the promoter of MTA1 was determined by chromatin immunoprecipitation and luciferase assays. Publicly available colorectal cancer dataset GSE41258 was obtained from Gene Expression Omnibus (GEO) and analyzed with GeneSpring GX 11.0.
Results: HT-29 and LoVo cells transfected with the 15-LOX-1 vector showed a decrease in nuclear levels of NF-kB p65 and MTA1 expression. Recruitment of p65 onto its consensus sequence at the MTA1 promoter was reduced in 15-LOX-1 expressing cells. Moreover, the expression of MTA1 and 15-LOX-1 was negatively correlated particularly in the Stage 3 and Stage 4 colorectal cancer patients.
Conclusion: 15-LOX-1 may inhibit MTA1 expression at least partly via reduced recruitment of NF-kB on to the MTA1 promoter. Based on recent reports by us and others on the role of MTA1 as a master regulator of cellular transformation in several tumor types, these data may help in understanding the regulation of MTA1 and open ways for therapeutic applications in the future.

Promoter methylation of the BRCA-1 gene in premenopausal breast cancer patients in West Sumatera-Indonesia

D. Arisanty[1], D. Khambri[2], S. Mubarika[3]. [1]*Andalas University Medical School, Biomedic, Padang, Indonesia;* [2]*M. Djamil General Hospital, Surgery Department, Padang, Indonesia;* [3]*Gadjah Mada University, Histology, Jogjakarta, Indonesia*

Background: Breast cancer is the most common type of cancer in Indonesian women. Around 39,831 new cases of breast cancer happens annually with the incidence of 36.2 per 100,000 women. Several researches reported that the mean age of Indonesian breast cancer patients are younger than 50 years old. The peaks of the incidence occur on the age of 48 years old and rarely are hereditary breast cancer (less than 2%). The aim of the research is to evaluate the relationship between the promoter of BRCA-1 gene with premenopausal breast cancer and its correlation with ER, PR, HER-2, BRCA-1 and Ki-67 expression.
Materials and Methods: This study is an observational study with cross-sectional design. Size and samples are 32 premenopausal breast cancer patients listed on the registration of breast cancer from department of the Division of Oncology, Dr. M. Djamil Padang General Hospital, West Sumatera. Breast cancer tissues are examined by histopathology and immunostaining for histopathological type and expression of ER, PR, HER-2, BRCA-1 and Ki-67. To determine the methylation of the promoter BRCA-1 gene, methylation specific bisulphide PCR are used. Data are analyzed using Chi-Square test.
Results: 32 patients with average age of 42.09 years, median 44.5 years, standard deviation of 5.7, oldest age is 50 years old and the youngest is 31 years old. The results of immunostaining are ER+ (34.4%), PR+ (12.5%), HER-2+++ (18.8%) and Ki-67+ (43.8%), positive methylation specific PCR are found in 20/27 patients (74%). The result of Chi-Square test found a significant relationship between age and methylation ($p = 0.037$). There was no significant association between methylation of ER ($p = 0.178$), PR ($p = 0.593$), BRCA-1 ($p = 0.266$), HER-2 ($p = 1.000$) and Ki-67 ($p = 1.000$).
Conclusion: Promoter methylation of BRCA-1 gene are in premenopausal breast cancer patients in West Sumatera (70%), but does not have significant relationship with the expression of ER, PR, HER-2, Ki-67 and BRCA-1. Age has a significant relationship with the occurrence of methylation promoter BRCA-1 gene in premenopausal breast cancer patients in West Sumatera.

Anti-60S ribosomal protein L29 antibody; new anti-cancer agent discovered from human sera

Y. Miyake[1], H. Matsushita[2], K. Yamamoto[2]. [1]*Okayama University Hospital, Okayama, Japan;* [2]*Okayama University Hospital, Gastroenterology & Hepatology, Okayama, Japan*

Background: Incidence of hepatocellular carcinoma (HCC) is lower in autoimmune hepatitis (AIH) than chronic viral hepatitis. In AIH, serum immunoglobulin G (IgG) levels are associated with the clinical features. In this study, we searched IgG showing anti-tumour effect in sera of AIH patients.
Material and Methods: Total IgG was extracted from sera of AIH patients by using protein G. Anti-tumour effects of the total IgG were evaluated by MTT assay using human HCC Huh7 cells and PLC/PRF/5 cells. Autoantigens in membrane proteins of Huh7 cells were screened by immunoprecipitation followed by liquid chromatography-mass spectrometry (LC-MS) shotgun analysis. Signalling pathways were analysed by western blotting.
Results: In one AIH patient without any cancers, addition of total IgG extracted from her serum to the culture inhibited the proliferation of huh7 cells and PLC/PRF/5 cells, and decreased intracellular levels of β-Catenin and Cyclin-D1. In this patient, autoantigens in membrane proteins were screened, and 60S ribosomal protein L29 (RPL29) was identified from the MS/MS spectra and the SwissProt database using the Mascot Search engine. RPL29 expression in human HCC cell lines including Huh7, PLC/PRF/5, Hep3B, HepG2, HLE, HLF and SK-Hep-1 were identified by Western blot. Next, in the other 25 AIH patients, we investigated the correlation between serum anti-RPL29 levels by indirect ELISA using recombinant RPL29 and anti-tumour effects of total IgG extracted from their sera. Serum anti-RPL29 levels were significantly correlated with anti-tumour effects of total IgG extracted from their sera ($P < 0.0001$). On the other hand, addition of recombinant RPL29 to the culture cancelled anti-tumour effects of total IgG extracted from sera of AIH patients showing higher serum anti-RPL29 levels. Additionally, these anti-tumour effects of total IgG extracted from sera of AIH patients were shown by MTT assay using human pancreatic cancer AsPC-1 cells and Panc-1 cells.
Conclusions: Anti-RPL29 antibodies showing anti-tumour effect were discovered from human sera. Anti-RPL29 inhibits cancer cell proliferation via down-regulation of Wnt/β-Catenin signalling pathway. Serum anti-RPL29 may be one of immune systems by which the human does not develop cancers. RPL29 will be a potential target for cancer therapy and cancer vaccine.

639 POSTER

Local irradiation to enhance the anti-tumour effect of immunotherapy with the FP-IL12 fusion protein

F. Eckert[1], D. Zips[1], J. Schmitt[2], M.A. Krüger[2], B.J. Pichler[2], R. Handgretinger[3], K. Schilbach[3]. [1]*University of Tuebingen, Radiation Oncology, Tübingen, Germany;* [2]*University of Tuebingen, Preclinical Imaging and Radiopharmacy University of Tübingen Werner-Siemens-Foundation, Tübingen, Germany;* [3]*University of Tuebingen, General Pediatrics Oncology/Hematology University of Tübingen, Tübingen, Germany*

Background: The fusion protein FP-IL12 (α-histone-antibody with interleukin 12) binds to necrotic tissues. Upon binding IL12 promotes a Th1-based anti-tumor immune response. Irradiation is an effective inducer of

necrotic cell death in tumours. We hypothesize that irradiation of tumours leads to increased binding of FP-IL12 via radiation-induced necrotic cell death and thereby to an enhanced anti-tumour effect of the fusion protein.
Material and Methods: The human rhabdomyosarcoma (A204) and prostate cancer (PC3) models were studied in vitro and xenografted in NSG (nod-scid-gamma) mice (72 tumours). Radiation sensitivity was assessed by colony forming assays. In vivo necrosis was determined with small-animal MR using the ADC values (control, single doses of 0.5 Gy, 2.0 Gy and 8.0 Gy; fractionated doses of 5 x 2.0 Gy and 3 x 5.0 Gy). Binding of the FP-IL12 fusion protein was evaluated with small-animal PET imaging (DOTA- Cu-64 labelled FP-IL12) with and without irradiation as well as ex-vivo-biodistribution and autoradiography. Tumour growth delay assays in humanized NSG mice with xenografted A204 are ongoing.
Results: A204 (D37 1.0 Gy) and PC3 (D37 1.9 Gy) differ in their intrinsic radiation sensitivity. Accordingly, radiation-induced tumour necrosis was found only in A204 with changes in ADC values after 8 Gy of +51% $\pm$ 21% and no change in PC3 with −6% $\pm$ 5%. In A204 a radiation-dose effect for necrosis-induction was observed with change in ADC values increasing from +16% $\pm$ 14% after 2.0 Gy to +51% $\pm$ 21% after 8.0 Gy. An enhanced up-take of FP-IL12 in A204 tumours was detected by PET and ex-vivo-biodistribution. Tumour-to-muscle-ratio (TMR) increased from 5.4$\pm$3.2 in unirradiated tumours to 14.8$\pm$5.2 after 8.0 Gy ($p = 0.03$). In PC3 tumours no increase in TMR was observed. Autoradiography revealed homogenous FP-IL12 binding in the tumours.
Conclusions: Local irradiation increased the tumour-specific binding of the immunotherapeutic fusion protein FP-IL12. The anti-tumour effect of this combination is currently investigated in A204 bearing mice. The observed relationship of FP-IL12 binding with necrosis-induction supports the concept that local tumour irradiation might enhance anti-tumour immunotherapy. The successfully established humanized tumour-mouse model provides a valuable tool for translational studies investigating the combination of radiotherapy and immunotherapy.

HER2 status in breast cancer patients: A comparison between borderline positive HER2 and strongly positive HER2 tumors

J. Huszno[1], E. Nowara[1]. [1]*Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Clinical and Experimental Oncology, Gliwice, Poland*

Introduction: Amplification or over-expression of the *HER2* gene occurs in approximately 30% of breast cancers. It is strongly associated with increased disease recurrence and a worse prognosis. In recent years HER2 status has evolved to become an important biomarker and therapy target. The aim of this study was to compare the group of borderline positive HER2 (++) status patients with strongly positive HER2 (+++) status group according to clinicopathological features, cardiotoxicity and treatment response.
Material and Methods: This retrospective study was conducted on HER2 positive breast cancer patients treated in Clinical and Experimental Oncology Department, Maria Sklodowska-Curie MemorialCancer Center and Institute of Oncology in Gliwice Branch in Poland (COI). The analysis included 167 early and metastatic breast cancer patients treated with trastuzumab between 2006–2012. HER2 overexpression was assessed using an immunohistochemical method (IHM). HER2 gene amplification was additionally assessed by FISH in 17% patients.
Results: In analyzed group, 17 (10%) patients were borderline HER2 positive (HER2++) tumors. Most of them were treated with trastuzumab in adjuvant seting (65%). In these study all HRE2 borderline tumors were ductal invasive adenocarcinoma. There were not find any differences between both groups in positive steroid receptor status (ER+/PR+) (47% vs 46%). The comparison between HER (++) and HER (+++) status had shown that HER (++) tumors were at lower advance stage of disease at diagnosis (54% vs 18%) $p = 0.002$. Distant metastases was observed only in strongly positive HER2 patients (8%). Skin metastases also were more often detected in this group (14% vs 6%). The decrease of LVEF occurred in the same rate in both groups (6% vs 5%). Acute cardiac side effects were presented only in strongly positive HER2 (+++) status group (2%) $p = 0.953$. Contralateral breast cancer occurred more often in borderline positive HER 2 (++) status patients ($p = 0.02$). Disease recurrence was significantly more frequent in strongly positive HER2 status patients (72 % vs 36%) $p = 0.006$. The Disease progression was significantly more frequent in strongly positive HER2 status patients (57% vs 27%) $p = 0.02$.
Conclusion: Borderline positive HER2 breast cancer patients are in lower advance stage at diagnosis and have better outcome than strongly positive HER2 tumors. They are less predisposed to the development of cardiac side effects.

641 POSTER

Comprehensive pharmacogenetic profiling of advanced colorectal cancer

J. Cheadle[1], A. Madi[1], D. Fisher[2], T.S. Maughan[1], J. Colley[1], A. Meade[2], H. Wasan[3], R. Adams[1], L. Nichols[2], R. Kaplan[2]. [1]*Cardiff University, School of Medicine ICG, Cardiff, United Kingdom;* [2]*MRC Clinical Trials Unit, Aviation House, London, United Kingdom;* [3]*Imperial College Healthcare NHS Trust, Hammersmith Hospital, London, United Kingdom*

Background: Inherited genetic factors may influence a patient's response to, and side effects from, chemotherapy and biological therapies. Here, we sought to generate a comprehensive inherited pharmacogenetic profile for advanced colorectal cancer (aCRC).
Materials and Methods: We analysed 260 potentially functional coding region and promoter variants in genes within the 5-FU, capecitabine, oxaliplatin, EGFR and DNA repair pathways in 2183 patients with aCRC treated with oxaliplatin-fluoropyrimidine chemotherapy $\pm$ cetuximab (from the MRC COIN and COIN-B trials). Primary outcomes assessed were 12-week response, skin rash (SR) (for those receiving cetuximab), dose-reduction or delay in treatment due to any toxicity and peripheral neuropathy (PN).
Results: In patients treated with chemotherapy + cetuximab, 5 and 4 coding region variants in the EGFR pathway were associated with response and SR, respectively. The most significant associations were with variants in members of phosphatidylinositol 3-kinase regulatory subunit. In patients treated with chemotherapy $\pm$ cetuximab, 8 coding region variants in the 5-FU, capecitabine, oxaliplatin or DNA repair pathways were associated with response, 8 with any toxicity and 5 with PN. The most significant associations for response were with variants in DNA repair genes and, for any toxicity, with two common and independent variants in DPYD. Given previous observations that rare variants in DPYD affect toxicity, we undertook a comprehensive analysis of both common and rare DPYD variants. Carriers of the common variant V732I and/or the rare variants D949V and IVS14+1G>A, which accounted for 10.6% of all patients, had an increase in any 12-week toxicity (OR=1.64, 95% CI 1.23–2.18, $P = 0.0007$) which included neutropenia (OR 2.30, 1.52–3.48, $P = 0.0002$).
Conclusions: Despite having considerable power to detect alleles of small effects (>85% power to detect OR=1.3), none of the associations remained significant after rigorous correction for multiple testing. We suggest that common DPYD variants may be worth re-considering in future screens for tolerance to 5-FU.
Conflict of interest: *Corporate-sponsored research: This study was part funded by an unrestricted research grant from Merck Serono (to T.S.M. and J.P.C.)*

642 POSTER

DMET (Drug Metabolizing Enzymes and Transporters) microarray analysis of colorectal cancer patients with severe 5-Fluorouracil-induced toxicity

E. Rumiato[1], E. Boldrin[1], A. Amadori[2], D. Saggioro[1]. [1]*Veneto Institute of Oncology IOV-IRCCS, Immunology and Molecular Oncology Unit, Padova, Italy;* [2]*University of Padova, Department of Surgical Sciences Oncology and Gastroenterology, Padova, Italy*

Background: 5-Fluorouracil (5-FU) is still a milestone anti-cancer drug, on the other hand, its use is often limited by the occurrence of severe toxicity. Even if the detrimental effect of some dihydropyrimidine dehydrogenase (*DPYD*) and thymidylate synthase (*TYMS*) polymorphisms is well known, no genetic predictor of severe toxicity has yet been validated. For the first time, we studied the genetic background of 5-FU-induced toxicity using the Affymetrix DMET™ Plus GeneChip, a pharmacogenetic array that interrogates 1936 variants in 231 genes involved in drug metabolism, excretion and transport.
Material and Methods: Among 119 colorectal cancer patients gathered from 2004 to 2006, we analyzed 25 patients who experienced a severe gastrointestinal toxicity (G3 or G4); control group consisted of matched patients who did not disclose adverse events (G0 or G1). Toxicity was classified according to the NCI-Common Toxicity Criteria (v.3.0). Genomic DNA from peripheral blood was analyzed with DMET™ Plus GeneChip (Affymetrix, Santa Clara, CA), appropriateness of data was evaluated with DMET™ Console and statistically relevant variants were assessed with DMET-Analyzer.
Results: No significant difference was found with respect to the 18 *DPYD* and 6 *TYMS* variants investigated by DMET™. In contrast, 11 variants in 10 new genes resulted significantly different between toxicity cases and controls, with the *CHST1* rs9787901 having the strongest inverse association ($p = 0.0008$), followed by the *GSTM3* rs1799735 ($p = 0.008$). Moreover, the number of subjects carrying the C/C genotype of the

CHST1 rs9787901 together with the AGG/- of the *GSTM3* rs1799735 was significantly higher in the group exhibiting severe toxicity compared to controls (p = 0.016). CHST1 belongs to the keratin sulfotransferase family and plays a central role in lymphocyte homing at sites of inflammation. The high frequency of the C allele in the total population might account for the elevate occurrence of gastrointestinal toxicity, ranging from milder to the most severe forms, and could also suggest that the co-presence of other variants is needed to promote severe toxicity. The *GSTM3* rs1799735 of the gluthatione S-transferase family could be one of them.
Conclusions: Though our data need to be confirmed in a larger cohort and extended to other types of toxicity, this exploratory study indicates the DMET™ array as a valid approach to discover new genetic variants involved in 5-FU-induced toxicity.
No conflict of interest.

643 POSTER

Association of killer immunoglobulin-like receptor and HLA class-I gene polymorphisms with the incidence and the clinical course of epithelial ovarian cancer

A. Boratyn-Nowicka[1], S. Giebel[2], E. Nowara[2], E. Grzybowska[2], J. Pamula-Pilat[2], K. Tecza[2], D. Kula[2], M. Kowal[2]. [1]*Center of Oncology M. Sklodowska-Curie, Gliwice, Poland;* [2]*Center of Oncology M. Sklodowska-Curie, MSC Memorial Cancer Center and Institute of Oncology Gliwice Branch Gliwice Poland, Gliwice, Poland*

Background: Inhibitory and activating killer immunoglobulin-like receptors (KIRs) regulate the function of NK cells and subsets of T cells. The HLA class-I molecules are the ligands for the inhibitory KIRs, while the specificity of the activating KIRs is mainly unknown. Both the *KIR* and *HLA* genotypes are highly polymorphic. It has been assumed that the *KIR* and *HLA* genotypes may confer susceptibility to ovarian cancer and influence the clinical course of the disease.
Material and Methods: The DNA of 179 patients was analyzed for 14 *KIR* genes and 126 samples were additionally typed for *HLA class I*. The control group consisted of 200 healthy individuals, including 83 women, who were analyzed separately.
Results: The *KIR2DS2* has been found to occur significantly less often in ovarian cancer patients than in the female controls (38.6% vs. 62.6%; p = 0.0004) and in the entire control group (vs. 55.5%; p = 0.002). The combination of *KIR2DL2+/KIR2DS2-* has been found to be present in 24.7% of the patients, whereas no such combination has been observed in the controls (p < 0.0001). The *HLA-C1* was significantly more frequent in patients (85.7%), compared with the female controls (67.5%; p = 0.003) and the entire control group (71%; p = 0.002). The *HLA-C1-/HLA-C2+* combination occurred in 13.5% of the test group patients and in 29% of the controls (p = 0.001). The frequency of *KIR2DS4* was higher in endometrioid cancer patients, compared with those with serous histology (67.9% vs. 35.7%; p = 0.004), mucinous histology (30.8%; p = 0.04) and the controls (29.5%; p = 0.002).
Conclusions: The genotype of *KIRs* and their ligands is associated with the susceptibility to epithelial ovarian cancer. In particular, the *KIR2DL2+/KIR2DS2-* combination is associated with an increased risk of the disease, as is the presence of *HLA-C1*. The *KIR2DS4* is linked to an increased incidence of endometrioid cancer. The results obtained need to be confirmed in independent patient populations. Our findings may be used for genetic screening and the protocols of cellular immunotherapy.

Circulating tumor cells (CTCs) in metastatic castration-resistant prostate cancer patients treated with cabazitaxel: A Dutch Uro-Oncology Study Group side-study

W. Onstenk[1], A.J.M. Nieuweboer[1], P. Hamberg[2], G.J.M. Creemers[3], M.M.E.M. Bos[4], J.W. Gratama[1], R. De Wit[1], R.H.J. Mathijssen[1], S. Sleijfer[1]. [1]*Erasmus MC Cancer Institute, Medical Oncology, Rotterdam, Netherlands;* [2]*Sint Franciscus Gasthuis, Prostate Cancer Center, Rotterdam, Netherlands;* [3]*Catharina Hospital, Internal Medicine, Eindhoven, Netherlands;* [4]*Reinier de Graaf Group of Hospitals, Internal Medicine, Delft, Netherlands*

Background: A circulating tumor cell (CTC) count of ⩾5 CTC/7.5 mL blood is a strong adverse prognostic factor in metastatic castration-resistant prostate cancer (mCRPC) patients before start of and during treatment with docetaxel and abiraterone. For patients treated with cabazitaxel (CBZ), this has yet to be confirmed. In this study, we prospectively evaluate the prognostic value of CTCs during CBZ therapy. Additionally, RNA is stored for future development of a gene-expression profile to predict CBZ sensitivity.
Methods: This study is a side-study of a phase II trial, initiated by the Dutch Uro-Oncology Studygroup and supported by an educational grant from Sanofi. In total, 226 patients will be randomized to CBZ/prednisone ± budesonide to investigate the effect of budesonide on CBZ-induced diarrhea. At baseline and after two cycles of CBZ, blood is obtained from patients who provided additional informed consent. CTC enumeration and isolation are both done from 7.5 mL by the CellSearch System® (Veridex, Raritan, USA). For development of a predictive gene-expression profile, RNA is stored at −80ºC. The profile will be developed as in our prior breast cancer studies [Sieuwerts, Clin Cancer Res, 2011]. A panel of genes will be selected based on changes in expression under treatment pressure and will be tested for the ability to predict CBZ sensitivity and resistance at an early stage.
Results: We here report CTC results in the first 31 patients enrolled. Of these, 28 patients (90%) had ⩾1 CTC and 19 patients (61%) had ⩾5 CTC at baseline. A CTC count at both time-points was available in 19 patients. Median CTC count dropped from 19 (IQR 3−61) at baseline to 4 (IQR 0−19) after 2 cycles. In 6/12 patients (50%) with ⩾5 CTC at baseline and a second CTC count available, there was a decrease to <5 CTC after 2 CBZ cycles and in 3/7 patients (43%) with <5 CTC at baseline there was an increase to ⩾5. Associations with clinical parameters and outcome will follow.
Conclusions: CTCs can be detected in 90% of mCRPC patients starting CBZ. In 50%, CTC counts decreased from ⩾5 CTC at baseline to <5 CTC after 2 CBZ cycles, while in 43% there was an increase from <5 to ⩾5. Future goals of this study are to associate CTC counts with clinical parameters and outcome and to develop a gene-expression profile to predict CBZ sensitivity at an early time-point.

645 POSTER

Identification and quantification of AKT isoforms and phosphoforms in breast cancer using a novel, ultrasensitive nanofluidic immunoassay

D.C. Iacovides[1], A.B. Johnson[1], N. Wang[2], S. Boddapati[2], J. Korkola[2], J.W. Gray[2]. [1]*Lawrence Berkeley National Lab, Lifesciences, San Francisco, USA;* [2]*Oregon Health and Science University, Department of Biomedical Engineering, Portland, USA*

Background: Breast cancer subtype-specific molecular variations can dramatically affect patient responses to existing therapies. It is thought that differentially phosphorylated protein isoforms might be a useful prognostic biomarker of drug response in the clinic. However, accurate detection and quantitative analysis of cancer-related protein isoforms and phospho-isoforms in tumors is limited by current technologies.
Methods: Using a novel, fully automated nanocapillary electrophoresis immunoassay (NanoPro™1000) designed to separate protein molecules based on their isoelectric point, we developed a reliable and highly sensitive assay for the detection and quantitation of AKT isoforms and phosphoforms in breast cancer.
Results: This assay enabled measurement of total and activated AKT1/2/3 across a breast cancer cell line panel, using protein produced from as few as 56 cells. AKT1 and AKT2 were found to be expressed in all cell lines, whereas AKT3 was mainly expressed in basal cells, which resemble the most aggressive, triple-negative breast cancers in the clinic. Importantly, we were also able to assign an identity to the phosphorylated S473 phosphoform of AKT1, the major form of activated AKT involved in multiple cancers including breast, and a current focus in clinical trials for targeted intervention. Using this assay, we were able to detect and measure qualitative and quantitative changes in AKT isoforms and phosphoforms in cells that were treated with AKT and PI3K inhibitors.
Conclusions: The ability of our AKT assay to detect and measure AKT phosphorylation from very low amounts of total protein will allow the accurate evaluation of patient response to drugs targeting activated PI3K-AKT using scarce clinical specimens. Moreover, the capacity of this assay to detect and measure all three AKT isoforms using one single pan-specific antibody enables the study of the multiple and variable roles that these isoforms play in AKT tumorigenesis.

Investigation of biomarkers for assessing activity of the HSP90 inhibitor AT-13387 in circulating tumor cells of ALK positive patients

F. Farace[1], A. Rodriguez-Lopez[2], E. Pailler[1], J. Lyons[2], M. Azab[3], B. Besse[1], J.C. Soria[4]. [1]*Institut Gustave-Roussy, Laboratory of Translational Research, Villejuif, France;* [2]*Astex Pharmaceuticals, Translational Biology, Cambridge, United Kingdom;* [3]*Astex Pharmaceuticals, Clinical Development, Dublin, USA;* [4]*Institut Gustave-Roussy, Medicine, Villejuif, France*

Background: Crizotinib is an effective treatment in ALK-translocated NSCLC patients; however the clinical success of this therapeutic approach is limited by the development of drug resistance. Both the EML4/ALK fusion and mutated ALK are sensitive HSP90 clients, making inhibition of HSP90 another potential approach for treating ALK-driven tumors. A key to successful development of HSP90 inhibitors in the clinic is the ability to identify predictive biomarkers of response. Demonstrating the feasibility of using Circulating Tumor Cells (CTCs) as a surrogate for invasively-obtained tumor material in the assessment of HSP90 client protein levels would provide a valuable guide in the development of these agents. AT13387 is a potent fragment-derived second generation HSP90 inhibitor currently in clinical trials. We evaluated the impact of AT13387 treatment in the lung ALK-positive cell line, H2228.
Material and Methods: Experimental conditions were established for the detection of HSP70 (a marker of tumor drug engagement) and ALK proteins by immunofluorescent staining (IF) in AT13387-treated and untreated H2228 and A549 (negative control) cells. Optimal IF conditions were first determined on slides. AT13387-treated and untreated H2228 and A549 cells were then spiked in blood from normal donors and enriched on filters using the ISET (Isolation by Size of Epithelial Tumor cells) device. Epithelial to mesenchymal transition (EMT) markers were also examined in AT13387-treated and untreated cells.
Results: A highly significant induction of HSP70 was detected in both AT13387 treated (0.8 μM for 24 hrs) H2228 and A549 cells while very little HSP70 was detected in untreated cells. As expected, ALK protein expression was detected in untreated H2228 cells and not in untreated A549. Levels of ALK protein were notably decreased in AT13387 treated H2228 cells. Studies to clarify the relationship between the effect of AT13387 treatment and the induction of EMT markers are ongoing.
Conclusion: The HSP90 inhibitor AT13387 has anti-tumor activity in ALK-driven NSCLC models. These results suggest that CTCs are amenable to biomarker analyses such as quantification of HSP70 and ALK protein levels, which could be useful as PD biomarkers of AT13387 activity in the clinical setting. This hypothesis is currently being tested by the incorporation of CTC enumeration and characterization in the Phase I/II clinical trial of AT13387 in combination with crizotinib in the treatment of NSCLC (NCT01712217).

Loss of membranous expression of the intracellular domain of EpCAM is a frequent event and predicts poor survival in patients with pancreatic cancer

A. Seeber[1], D. Fong[1], P. Moser[2], A. Kasal[3], G. Mazzoleni[3], G. Gastl[4], A. Martowicz[4], G. Spizzo[4], P. Obrist[5]. [1]*Medical University Innsbruck, Haematology and Oncology, Innsbruck, Austria;* [2]*Medical University Innsbruck, Pathology, Innsbruck, Austria;* [3]*Hospital of Bolzano, Pathology, Innsbruck, Austria;* [4]*Medical University of Innsbruck, Haematology and Oncology, Innsbruck, Austria;* [5]*Hospital of Zams, Pathology, Innsbruck, Austria*

Background: EpCAM is a widely used immunohistochemical marker for epithelial human malignancies and recently the new EpCAM-specific antibody Catumaxomab has been approved for the treatment of malignant ascites in cancer patients. Antibodies to target EpCAM are usually directed against its ectodomain (EpEX) but do not detect the intracellular domain (EpICD) and do not discriminate between full-length and cleaved variants.
Material and Methods: We developed an anti-EpICD antibody to compare membranous EpEX *vs.* EpICD expression by immunohistochemistry. Concurrent EpEX and EpICD expression were investigated retrospectively in paraffin-embedded primary tumor and normal tissue samples from a series of patients with pancreatic adenocarcinoma on a tissue microarray. In total 317 paired samples of pancreatic tissue from 88 patients were analyzed for membranous EpEX and EpICD expression and were correlated with clinicopathological parameters and clinical outcome.
Results: In non-cancerous pancreatic tissue, a high concordance of membranous EpEX and EpICD expression was observed and the full-length EpCAM variant ($EpEX^+/EpICD^+$ phenotype) was highly predominant. In tumor samples, most cases were EpEX positive. Loss of membranous EpICD expression ($EpEX^+/EpICD^-$ phenotype) was observed in one third of tumor samples and these patients had a significant shortened disease-free and overall survival independently from other prognostic factors.
Conclusion: This study demonstrates for the first time, that loss of membranous EpICD expression is a frequent event and predicts poor prognosis in patients with pancreatic cancer. Based on these observations, additional studies evaluating the predictive and prognostic value of the expression of different membranous EpCAM variants are clearly warranted in epithelial cancers.

Establishment of a diagnostic system using next generation sequencing for RET rearrangements in non-small cell lung cancer

S. Matsumoto[1], S. Mimaki[1], T. Kohno[2], K. Tsuta[3], S. Tada[1], K. Goto[4], K. Yoh[1], Y. Ohe[4], H. Esumi[5], K. Tsuchihara[1]. [1]*National Cancer Center, Exploratory Oncology Research & Clinical Trial Center, Chiba, Japan;* [2]*National Cancer Center Research Institute, Division of Genome Biology, Tokyo, Japan;* [3]*National Cancer Center Hospital, Division of Pathology and Clinical Laboratories, Tokyo, Japan;* [4]*National Cancer Center Hospital East, Division of Thoracic Oncology, Chiba, Japan;* [5]*Tokyo University of Science, Research Institute for Biomedical Science, Chiba, Japan*

Background: Recent advances of molecular-targeted treatment have revealed drastic effects in appropriate genetically defined patient populations. In addition to *EGFR* mutations and *ALK* rearrangements, *RET* rearrangements were recently identified as a novel driver mutation in approximately 2% of non-small cell lung cancers (NSCLCs). Although exact selection of the beneficial population is needed, rapid and efficient diagnostic methods for detecting *RET* rearrangements are not established yet.
Material and Methods: A target enrichment system (SureSelect ®, Agilent) capturing selected 133 cancer-related genes, including *RET, ALK, ROS1* and genomic regions of genes expected to be fused with them, were performed with genomic DNA extracted from LC2/ad, a lung adenocarcinoma cell line with a *RET* rearrangement, and formalin-fixed paraffin-embedded specimens of its xenograft in mice. The captured DNA was sequenced using the MiSeq System ®, Illumina, and gene alterations were detected by a customized algorithm. Clinically resected 43 NSCLC specimens including ones with *RET, ALK* or *ROS1* rearrangements were also analyzed. Confirmed whole exon sequencing data of 29 samples among them were used for further evaluation of the concordance of mutation detection.
Results: At least 50 ng of genomic DNA of each sample was sequenced at an average coverage of 420 x. The concordance rate for detection of single nucleotide variants with another analysis was 97%. RT-PCR- and/or FISH-confirmed 4 cases of *RET*, 5 cases of *ALK* and 5 cases of *ROS1* rearrangements were precisely detected and different break points of each cases were identified.
Conclusions: This novel molecular diagnostics has potential utility for detecting *RET* rearrangements with limited amounts of NSCLC samples.
No conflict of interest.

649 POSTER

Clinical feasibility study of a novel sorting system for detecting PIK3CA mutations from captured circulating tumor cells in patients with breast cancer

T. Sawada[1], K. Tamura[2], Y. Ito[1], M. Watanabe[3], Y. Fujimura[4], J. Hashimoto[2], M. Yunokawa[2], Y. Koh[3], Y. Fujiwara[2], F. Koizumi[1]. [1]*National Cancer Center Hospital, Shien-Lab, Tokyo, Japan;* [2]*National Cancer Center Hospital, Division of Breast and Medical Oncology, Tokyo, Japan;* [3]*Shizuoka Cancer Center Research Institute Shizuoka, Division of Drug Discovery and Development, Shizuoka, Japan;* [4]*On-chip Biotechnologies Co. Ltd, Division of Research and Development, Tokyo, Japan*

Background: Circulating tumor cells (CTCs) are cells that originate from a primary solid tumor and are found transiting the circulatory system. CTCs are expected to provide useful clinical information on biology of their primary, as 'liquid biopsy.' We have developed a novel cell-sorting system equipped with a disposable microfluidic chip (On-chip Sort, On-Chip Biotechnologies, Tokyo, JAPAN). At AACR 2013, we previously reported about its CTC enumeration capability when performed in a clinical setting. Currently, On-chip Sort enables recovery of more CTCs than conventional cell sorting systems for further characterization.

PIK3CA encoding the p110α catalytic subunit of the PI3K protein is the oncogene showing the highest frequency of gain-of-function mutations in breast cancer (approximately 20%). Therapeutics that target key nodes in the PI3K signaling pathway are currently being developed, and stratifying patients based on their PIK3CA mutation status is becoming more important. Detecting the PIK3CA mutation status from CTCs is challenging, although there is a need to detect them non-invasively.
Material and Methods: In a preclinical study, a BT-20 human breast cancer cell harboring PIK3CA mutation (H1047R) was spiked into the blood from healthy donors. After samples were negatively enriched using anti-CD45-coated magnetic beads, the spiked cancer cells in the samples were captured by On-chip Sort. The captured tumor cells were subjected to mutation detection by ARMS/Scorpion PCR assay. A clinical feasibility study was then conducted in patients with breast cancer.
Results: On-chip Sort performed recovery of the spiked BT-20 cancer cells (50 cells in 4 ml of blood)in a preclinical experiment. Successively, we were able to detect the PIK3CA mutation from the captured cells. In a clinical feasibility study, 4 blood samples from breast cancer patients were collected regardless of the PIK3CA mutation status and were evaluated. All the samples were successful in capturing CTCs by On-chip Sort. ARMS/Scorpion PCR assay detected the PIK3CA mutation (H1047R) from one of the samples (25%).
Conclusions: The preclinical study and the results of the clinical feasibility study suggested the possibility of the On-chip Sort assay to detect PIK3CA mutations from peripheral blood of patients with breast cancer. Further investigation is going to be conducted to evaluate the correlation of PIKCA mutation in captured CTCs and primary lesions.

Molecular characterization of circulating tumor cells recovered from metastatic pancreatic cancer patients using ApoStream™, a new antibody-independent dielectrophoretic device

G. Varadhachary[1], V. Melnikova[2], J. Abbruzzese[1], R. Shroff[1], C. Reeves[2], M. Garza[2], V. Gupta[2], D.W. Davis[2], R. Wolff[1], K. Anderes[2]. *[1]MD Anderson Cancer Center, Dept Gastrointestinal Medical Oncology, Houston TX, USA; [2]ApoCell Inc, Molecular Profiling and Diagnostics, Houston TX, USA*

Background: Pancreatic adenocarcinoma (PAC) remains the fourth most common cause of cancer-related mortality due to late diagnosis and limited treatment options. The available diagnostic tools and biomarkers for PAC fail at early detection and suffer from low sensitivity and specificity. Advances in the recovery and characterization of circulating tumor cells (CTCs) offer hope for the development of noninvasive techniques for earlier disease detection, monitoring response to therapy, and identification of druggable targets and biomarkers. While CTC enumeration provides prognostic information in patients with various cancer types, the biological characterization of CTCs may offer insight into the molecular determinants of disease progression and sensitivities or resistance to treatment regimens. Epithelial cell adhesion molecule (EpCAM) and cytokeratin (CK) dependent CTC technologies fare poorly in the metastatic PAC setting due to altered phenotypes acquired during epithelial mesenchymal transition (EMT). The links between EMT, KRAS, plectin-1, mesothelin and metastatic progression of PAC are emerging and underscore the need for biomarker information in real time.
Material and Methods: We used ApoStream™, a novel, antibody-independent device which uses dielectrophoretic technology in a continuous flow system to isolate CTCs from the blood of metastatic PAC patients and determine their phenotypic identities to elucidate population heterogeneity and characterize pancreatic specific markers (CA19-9, *KRAS*, plectin-1 and mesothelin). This prospective study will evaluate thirty patients. Paired blood samples from 10 metastatic PAC patients were analyzed by CellSearch® and ApoStream™. Collected cells were immunostained using antibodies against CK, CD45, DAPI, CA19-9, plectin-1 and mesothelin. A multiplexed immunofluorescent assay and laser scanning cytometry (LSC) analysis were applied to enumerate CTCs and identify cell phenotypes based on combinations of CK, CD45, plectin-1 and mesothelin marker expression.
Results: The detection of $CK^+/CD45^-/DAPI^+$ cells was comparable between CellSearch® and ApoStream™ with counts ranging from 1−10 CTCs/7.5 mL blood in 50% of patients. In addition, ApoStream™ recovered $CK^-/CD45^-/DAPI^+$ cells in 100% of patients with counts in the range of 12–166 cells/7.5 mL of blood. CA19-9^+ cells were identified in both $CK^+/CD45^-/DAPI^+$ and $CK^-/CD45^-/DAPI^+$ subpopulations isolated by ApoStream™. *KRAS*, plectin-1 and mesothelin analysis on CTCs will be presented.
Conclusions: ApoStream™ recovered classical and putative CTCs with multiple phenotypes in patients with metastatic PAC. Preliminary data is encouraging and if confirmed in a larger sample size of PAC patients, ApoStream™ combined with molecular characterization could prove to be a sensitive method for isolating and detecting biomarkers in CTCs of PAC patients.

651 POSTER

A phase II clinical trial of neoadjuvant therapy with zoledronic acid for operable breast cancer

Y. Nakayama[1], S.H. Takahashi[1], M.T. Tanabe[1], Y.I. Ito[1]. *[1]Cancer Institute Hospital, Medical Oncology, Tokyo, Japan*

Background: The neoadjuvant use of bisphosphonates has been reported to increase rates of pathological response in patients with operable breast cancer. We conducted a study to determine whether treatment with zoledronic acid (ZOL) would improve outcomes in such patients when it was added to standard neoadjuvant chemotherapy (NAC).
Methods: From April 2010 to June 2012, 30 patients with stage IIA, IIB, IIIA, or IIIB, Her2-negative operable breast cancer were eligible for the study. Written informed consent was obtained from each patient before starting chemotherapy. The patients received NAC (4 cycles of CEF: intravenous epirubicin 100 mg/m^2, cyclophosphamide 500 mg/m^2, and fluorouracil 500 mg/m^2 on day 1, then 12 cycles of weekly paclitaxel 80 mg/m^2) with ZOL. The ZOL was administered immediately after each cycle of NAC in a 4-mg dose by intravenous infusion every 3 to 4 weeks. The primary end point of the study was pathological response (pPR, rate of grade 2−3 by the Japan Breast Cancer Society Criteria) rate. The secondary end points were pathological complete response (pCR) rate, breast conservation (BC) rate, axillar lymph node complete response (ALNC) rate, adverse effects and the changes in the numbers of disseminated tumour cells (DTC), circulating tumour cells (CTC), and circulating endothelial cells (CEC). We evaluated the efficacy and safety of ZOL in the NAC in operable breast cancer patients by use of Fisher's exact test.
Result: 29 patients (luminal A: 20 patients, triple negative: 9 patients) completed surgery after NAC, and pathological analyses and the numbers of CTC and CEC were assessed. Two patients had progressive disease during NAC, with brain metastasis and bone metastasis, respectively. The pPR rate, pCR rate (triple negative: 3 patients), BC rate and ALNC rate was 31.0%, 10.4%, 27.6%, and 31.0%, respectively. CTC were detected in 3 patients at baseline, and CTC had changed to positive in one patient in D15 of the first cycle, then after NAC, all four patients changed to negative. CTC were negative in two patients at baseline, but after NAC, changed to positive. There were no factors associated with the change rates of CTC. CEC after NAC increased from baseline significantly.($p < 0.001$) The increase rates of CEC were not significantly different among permenopausal and postmenopausal, PR and non-PR, and luminal and triple negative patients. Adverse events (AE) associated with ZOL included fever in 13.3%, fatigue in 3.3%, hyponatremia in 6.7%, and increased creatinine in 3.3%, there were no severe AE to discontinue treatment.
Conclusion: These data suggested ZOL in combination with NAC might not have a significant direct anti-tumour effect. Change of CEC would be a biomarker for neoadjuvant chemotherapy, but further analyses would be necessary. We will add the report about DTC on the meeting.
No conflict of interest.

RAC1b mRNA expression and prognosis in advanced non-small cell lung cancer treated with first-line chemotherapy

A. Gasco[1], C. Costa[2], I. Rodriguez[3], L. Bonanno[4], T. Moran[5], N. Karachaliou[2], A. Gimenez-Capitan[2], S. Rodriguez[2], R. Rosell[5], J. Maurel[6]. *[1]USP-Instituto Universitario Dexeus, Oncology Institut Dr. Rosell, Barcelona, Spain; [2]USP-Instituto Universitario Dexeus/Pangaea Biotech, Oncology, Barcelona, Spain; [3]USP-Instituto Universitario Dexeus, Ginecologist, Barcelona, Spain; [4]Istituto Oncologico Veneto I.R.C.C.S, Oncology, Padova, Italy; [5]Hospital Germans Trias i Pujol, Oncology, Badalona, Spain; [6]Hospital Clínic, Oncology, Barcelona, Spain*

Introduction: Chemotherapy is the standard treatment for advanced non-small cell lung cancer (NSCLC) patients, except for those harboring EGFR mutations or EML4-ALK rearrangements. RAC1b, a RAC1 spliced variant, is over-expressed in NSCLC and impairs apoptosis by activation of nuclear-factor-kB. We evaluated the role of mRNA RAC1/RAC1b ratio as a predictor of chemotherapy efficacy in advanced NSCLC.
Methods: The expression of RAC1 and RAC1b was examined by real time reverse transcription quantitative PCR (RT-qPCR) from 104 NSCLC patients treated with platinum-doublets. We used RAC1/RAC1b ratio

(rRAC1b) to capture the RNA splicing RAC1b variant and its correlation with RAC1 expression in each patient. The mutations of *EGFR* (exons 19 and 21), *KRAS* and *BRAF* were determined using standard PCR protocols.
Results: Patient demographics: Median age 62 (range 40−81), histology − adenocarcinoma (AD) and large cell (LC) (60%), squamous cell (SCC) (40%).
Mutations in *KRAS, BRAF* and *EGFR* were found in AD and LC (17/62) and in SCC (6/42) p = 0.22.
Median rRAC1b was 0.892 (range 0.8–0.953). We found a significant association with histology and rRAC1b, but no association between age, gender, mutational status and rRAC1b. Median rRAC1b was higher in AD and LC (0.901) vs SCC (0.879) (p = 0.002). When analyzed by tertiles, we found significantly poor median survival in SCC patients with higher rRAC1b (high-4.9 months vs intermediate-10 months vs low-18.3 months) (p = 0.014), but not in AD and LC subtypes. The multivariate regression analysis identified high rRAC1b as a poor prognostic marker for PFS (p = 0.027); HR: 3.3 (95% CI 1.14−9.4) and OS (p = 0.007); HR: 6.059 (CI 1.6–22.3) in SCC.
Conclusions: High rRAC1b constitutes a marker of poor PFS and OS in SCC of the lung treated with first-line chemotherapy.
No conflict of interest.

653 POSTER

Thymidylate synthase (TS) polymorphisms (Pol) in genomic DNA as a clinical outcome predictor in patients (pts) with advanced non-small cell lung cancer (NSCLC) receiving pemetrexed (Pem)

E. Arevalo[1], I. Lopez[2], M.A. Fortuño[3], E. Castañon[1], V. Collado[2], M. Rodriguez[4], A. Olarte[4], J.L. Perez Gracia[1], A. Patiño[1], I. Gil Bazo[1]. *[1]Clínica Universidad de Navarra, Medical Oncology, Pamplona (Navarra), Spain; [2]CIMA, Medical Oncology, Pamplona (Navarra), Spain; [3]Responsible of Biobank. CIMA, Biobank, Pamplona (Navarra), Spain; [4]Clínica Universidad de Navarra, Radiation Oncology, Pamplona (Navarra), Spain*

Background: TS is the main biological target of the antifolate Pem. Some TS Pol may confer a short survival and a poor response to antifolate-treated colorectal cancer pts. Whether TS genotype has an independent prognostic/predictive impact on non-Asian advanced NSCLC pts treated with Pem is still to be determined.
Methods: Twenty-five advanced NSCLC pts treated with Pem-based regimens (1st, 2nd or 3rd line) were included. Genomic DNA was isolated from peripheral blood prior to treatment. The variable number of tandem repeat (VNTR) Pol, the G>C single nucleotide Pol (SNP) and the TS 6-bp insertion/deletion (6/6) in the 3' untranslated region (UTR) Pol were analyzed and correlated with response rate (RR), progression-free survival (PFS), overall-survival (OS) and toxicity (Tx).
Results: Regarding the VNTR Pol, most of the pts showed 2R/2R or 3R/2R Pol (17 pts; 68%), and 8 pts (32%) showed 3R/3R or 3R/4R Pol. A SNP (G>C) in VNTR was observed in 18 pts (72%). The Pol found in the 3′UTR region were +6/+6 in 12 pts (48%), +6/-6 in 11 pts (44%) and −6/-6 in 2 pts (8%). In the subgroup of T3-T4 pts, there was a significantly higher RR among those showing 3R/3R Pol than those with 2R/2R Pol (100% vs 83.8%; p = 0.029). The genotype +6/+6 predicted a higher RR among active/former smokers (A/FS) compared to +6/-6 (100% vs 37.5%; p = 0.026). A 3R/3R Pol followed by 2R/2R and 2R/3R Pol predicted a superior RR in pts without EGFR mutations (p = 0.018). Overall, a trend towards a better PFS in pts showing 2R/2R Pol was found (p = 0.076). The cohort's median overall survival (OS) was not reached during follow-up. The most frequent Tx was grade (G)1 anemia (28%) and nausea (20%) and G2 leucopenia (40%). G3−4 anemia (4%), leucopenia (16%), neutropenia (4%), astenia (8%) and dyspnea (4%) were uncommon but more frequent in pts with 2R/2R Pol (p = 0.545).
Conclusions: In this cohort of NSCLC pts 3R/3R Pol among T3-T4 pts and unmutated EGFR pts, and +6/+6 bp among A/FS pts significantly predicted a higher RR to Pem and may aid in treatment selection. Tx was not significantly correlated with a specific TS genotype. These interesting preliminary data warrant further validation in larger prospective series.

Sensitivity to glutamine deprivation is dependent on the interplay between epigenetic regulation of Glutamine synthetase (Glul) and induction of autophagy

F. Cavicchioli[1], A. Shia[1], K. O'Leary[1], V. Haley[1], T. Crook[2], A.M. Thompson[3], M. Lackner[3], L.J. Jones[4], C. Lo Nigro[5], P. Schmid[1]. *[1]Brighton and Sussex Medical School, Brighton, United Kingdom; [2]University of Dundee, Dundee, United Kingdom; [3]Genentech Inc, San Francisco, USA; [4]University of London, London, United Kingdom; [5]S.Croce-Carle Hospital, Cuneo, Italy*

Background: We identified Glutamine synthetase (Glul), key enzyme in the biosynthesis of glutamine, as subject to methylation-dependent transcriptional silencing in breast cancer cell lines and therefore as a potential target for synthetic lethality strategies. We determined the functional relevance of modulating Glul levels in breast cancer. As autophagy is a protective response to conditions of nutrient deprivation, we investigated whether glutamine deprivation was initially inducing an autophagic response in breast cancer cells.
Methods: The promoter region of Glul was analysed using methylation microarrays (Illumina 450K Methylation BeadChip), bisulphite sequencing and pyrosequencing. This was correlated with expression using qRT-PCR and Western Blot. Sensitivity to glutamine deprivation and autophagy induction was assessed using fluorescence and MTT assay respectively after culturing cells in media without glutamine and chloroquine administration. Formalin-fixed paraffin-embedded tissue from a series of 115 stage I−III primary breast cancers with linked clinical outcome data were randomly selected from the Cuneo Tissue Bank for analysis of GLUL promoter methylation and immunohistochemistry.
Results: Dense methylation of the CpG-island of Glul was detected in 46% of cell lines across all subtypes and linked with expression of Glul. We defined three subsets of cell lines; unmethylated cell lines, methylated with non-expressing (sensitive to deprivation) and methylated with expressing Glul (resistant to deprivation). When Glul is completely silenced azacytidine and trichostatin treatment induced its up-regulation. All methylated cell lines reacted to glutamine deprivation inducing autophagy as early as 2 h after glutamine starvation. Chloroquine administration was sufficient to restore glutamine deprivation sensitivity in those methylated cell resistant to the treatment. Dense methylation (26%) of the CpG island of Glul was found in 30.4% of patients, with an additional 46.9% of patients showing partial methylation (6−26%).
Conclusions: This is the first report of methylation-dependent transcriptional silencing of Glul expression in cancer with an autophagic response. We are also the first to investigate the distribution of Glul methylation and protein levels in a series of patient samples.

Oncogenic microRNAs in sera reflect diagnosis and treatment of breast cancer patients

M. Sochor[1], P. Vlcková[2], N. Dusílková[2], J. Bartos[1], T. Stopka[2]. *[1]Regional Hospital Liberec, Complex Cancer Center, Liberec, Czech Republic; [2]First Faculty of Medicine Charles University, Institute of Pathological Physiology, Prague, Czech Republic*

Background: Breast cancer is the most frequent female cancer with very different outcomes. New approaches are needed in order to improve prognosis of breast cancer using routine blood testing. MicroRNAs are new class of small and stable molecules that are produced by tumor cells and are detectable in sera with remarkable stability. Aim of this project is to compare expression of microRNAs according to diagnosis and therapy of breast cancer and their differences in high-risk vs. low-risk breast cancer.
Materials and Methods: We prospectively collect sera from patients with histologically confirmed breast cancer from 2010 year. For analysis we choose 56 consecutive women, breast cancer clinical stage I to III. Negative prognostic factors were determined: triple negativity (N = 4), grade III (N = 12), Ki-67 over 15% (N = 13). High-risk group 25 patients, low-risk group 31 patients. Serum samples were collected 1-day before surgery, 14−28 days post-surgery, 14−28 day following either chemo- or radio-therapy, and during clinical relapse. We used sera from 21 healthy controls. For total RNA isolation 200 mL sera were used followed by specific reverse transcription and TaqMan qPCR on 7900HT instrument. Oncogenic microRNAs miR-19a, miR-155, miR-181b, miR-24 were normalized on level of miR-let7a. These microRNAs were reported to be involved in breast cancer pathogenesis (Zhang 2011, Sun 2012, Volinia 2006, Du 2013).
Results: The four oncogenic microRNAs are detectable in the patient sera and are significantly elevated compared to healthy controls. Trend to a decrease of the microRNAs between pre-operative and post-therapeutic samples was observed. MiR-19a was initially (sampling 1−2) elevated

(2−25 fold) in 30 (54%) patients. MiR-155 was elevated (2−29 fold) in 33 (59%) patients. MiR-181b was elevated (2−5 fold) in 23 (41%) patients. MiR-24 was elevated (2−18 fold) in 25 (45%) patients. In whole group 10 patients (18%) displayed elevation in all four oncogenic miRNAs. In high-risk group was detected elevation in all four miRNAs in 30% patients. And interestingly, in three relapsed patients oncogenic microRNAs were detected and their changes were significantly different. We compared subgroup with negative prognostic factors (triple negativity, grade III, Ki67) and displayed significantly increased expression in some microRNAs compared to low risk patients with significantly different changes after therapy.

Conclusions: The oncogenic microRNAs appear to reflect breast cancer growth and therapy and are possibly useful for tumor monitoring. Results confirm their different expression and changes in high vs. low-risk breast cancer. Prognostic power will be known with longer follow-up. Detection of microRNAs is rapid and reproducible and can be useful for majority of breast cancer patients.

Steroid receptors in neuroendocrine tumors of the lung

A. Curioni Fontecedro[1], D. Soldini[2], W. Weder[3], R.A. Stahel[1], A. Soltermann[2]. *[1]University Hospital Zurich, Clinic of Oncology, Zurich, Switzerland; [2]University Hospital Zurich, Department of Pathology, Zurich, Switzerland; [3]University Hospital Zurich, Division of Thoracic Surgery, Zurich, Switzerland*

Background: Primary neuroendocrine tumours (NET) of the lungs include typical carcinoids (TCs), atypical carcinoids (ACs), large cell neuroendocrine carcinomas (LCNECs) and small cell lung cancer (SCLC). Knowledge about the biology and prognostic markers of NET of the lungs is scarce. It is well known that sex steroids contribute to cell proliferation in various human tissues but information about their expression as well as data on amplification or overexpression of *c-erbB-2* gene in NET of the lung is limited. Based on these data, we aimed at characterising the expression of steroid receptors and Her2 in a broad cohort of probes from NET of the lungs, correlate this with known neuroendocrine markers and evaluated their possible use as prognostic or eventually predictive markers.

Materials: A total of 192 tumour specimens of NET of the lungs were collected, which comprised 60 biopsies of SCLC, 58 of TC, 42 of AC and 32 of LCNEC. A tissue microarray was built. Analysis by immunohistochemistry for the following markers was performed: ERα, ERβ, AR, PR, TTF1, Synaptophysin, ChromograninA and Mib-1. HercepTest33 was used to determine Her2 positivity. Her-2 FISH positivity was evaluated based on HER-2/CEP17 ratio.

Results: Neuroendocrine markers were found to be diffusely expressed in all tumour subtypes as previously described. ERβ was found to be expressed in more than 60% of tumor probes in all tumour entities. Survival data were available from 126 patients. Based on ER expression, no survival differences were detected between tumour types, but a multivariate analysis on SCLC patients showed a survival benefit in the subgroup of male patients whose tumours expressed ERβ ($p = 0.008$) and all SCLC patients whose tumours expressed both ER and ChromograninA ($p = 0.02$).

Conclusions: Here we could demonstrate that ERβ expression is very frequent through all NET of the lungs. Its relevance as favourable prognostic marker for SCLC was found in male patients and in all patients expressing also ChromograninA. Our results suggest including ERβ as marker for a prospective analysis for SCLC and underline the challenges for differential diagnosis between these tumours and metastases of neuroendocrine tumours from other origin.

Comparison between HER2 extracellular domain in serum and HER2 overexpression in breast cancer tissue

J. Zidan[1], R. Mzalbat[1], S. Svalb[1]. *[1]Ziv Medical Center, Oncology, Safed, Israel*

Background: Human epidermal growth factor receptor 2 (HER-2) is an important prognostic factor and an indicator for targeted therapies in HER-2 overexpressing breast cancer (BC). Immunohistochemistry (IHC), fluorescent in situ hybridization (FISH) and chromogenic in situ hybridization (CISH) are reliable ways to identify HER-2. Each technique requires access to tumor tissue and high-quality tissue samples. HER-2 extracellular domain (ECD) may be shed to the serum and be detected in patients with BC. The importance of serum ECD in BC is not yet determined. The first aim of this study was to explore the correlation between serum ECD and tissue HER-2 expression. The second aim was to compare ECD levels with clinical and pathological features in primary BC patients.

Materials and Methods: In this prospective study only patients with stage I−III BC were included. Serum ECD levels were measured by ADVIA Centaur automated assays before surgical resection of the tumor. Tissue HER-2 was detected by IHC and CISH test. Serum ECD >15ng/ml was considered to be positive.

Results: Eighty patients with breast tumors were included. Stage I−III BC was diagnosed in 64 patients, Ductal carcinoma in situ in 9 patients and benign tumors in 7 patients. HER-2 overexpression in tumor tissue was observed in 8 of 64 patients (16.4%). Mean value of serum ECD was 10.9 ng/ml (range: 6.7 to 21.5). Four (6.2%) of the 64 patients had preoperative ECD high levels and in 60 (93.8%) patients lower levels of ECD were found. No significant relationship was found between ECD levels and tissue HER2 overexpression. ECD was significantly higher in women aged >40 than in women aged <40. There was no significant relation between ECD and tumor size, stage, histological grade, lymph node involvement, estrogen (ER) and progesterone (PR) receptors.

Conclusion: The sensitivity of HER2 ECD for the diagnosis of HER2 overexpression in primary breast cancer is poor. No significant correlation was found between ECD levels and tissue HER2 expression, clinical and pathological characteristics of primary BC.

No conflict of interest.

Serum cytokine/angiogenic factors (CAFs) and toxicity in BEP treated testicular germ cell tumor patients

D. Svetlovska[1], M. Mego[2], D. Cholujova[3], V. Miskovska[4], P. Gronesova[3], V. Usakova[4], M. Chovanec[2], B. Vertakova-Krakovska[4], J. Luha[5], J. Mardiak[2]. *[1]National Cancer Institute, Department of Clinical Trials, Bratislava, Slovak Republic; [2]National Cancer Institute, Department of Clinical Oncology, Bratislava, Slovak Republic; [3]Cancer Research Institute, Laboratory of Tumor Immunology, Bratislava, Slovak Republic; [4]St. Elisabeth Cancer Institute, Clinic of Internal Oncology, Bratislava, Slovak Republic; [5]Faculty of Medicine Comenius University, Institute of Medical Biology Genetics and Clinical Genetics, Bratislava, Slovak Republic*

Background: BEP (bleomycin, etoposide, cisplatinum) is a standard treatment in patients with testicular germ cell tumors (TGCTs). Toxicity of this chemotherapy can affect treatment compliance and decrease quality of life of patients as well. Our endpoint was to find out correlation between toxicity and CAFs in patients with TGCT receiving standard BEP treatment.

Methods: We enrolled 50 patients with TGCTs treated by BEP chemotherapy. All patients received G-CSF support after chemotherapy (48 patients pegfilgrastim, 2 patients filgrastim). Fifty one plasma CAFs were analyzed before the 1st (50 patients) and before the 2nd cycle of chemotherapy (28 patients) using multiplex bead arrays. Toxicites of grade 2 and higher were assessed according to the Common Terminology Criteria for Adverse Events (CTCAE) version 4.0. We analysed toxicity, which occured in more than 5% of patient population. Toxicities were correlated to pretreatment and also postreatment values of CAFs. Spearman's correlation test was used to analyze the relationship between toxicity and CAFs. We considered $p < 0.05$ to be significant.

Results: Toxicities with frequency of more than 5% were neutropenia, nausea, anorexia, insomnia and singultus. Elevated pretreatment levels of MCP-3 significantly correlated with neutropenia ($p = 0.045$). Neutropenia had also positive correlation to postreatment values of SDF1-a ($p = 0.033$). Increased pretreatment levels of TGF-b1, TGF-b3, FGF correlated with nausea, elevated pretreatment values of MIP-1b, RANTES, MCP-1MCAF, MIP-1a, FGF, TGF, IL-4,IL-5, IL-7, IL-8, IL-13, IL-17, GM-CSF ($p < 0.05$) were associated with anorexia. We observed no correlations with postreatment CAFs and non-hematological toxicities.

Conclusions: We suppose, that CAFs can provide prognostic information of toxicity related to BEP beyond standard measurements and can be included in patogenesis of toxicity as well. For patients with TGCTs, the ability to receive full doses of chemotherapy could improve survival rates. This data should be considered in further studies evaluating CAFs levels as prognostic information and predictive to toxicity related to BEP in TGCTs patients. This work was supported by the Slovak Research and Development Agency under the contract No. APVV-0016−11.

Morphometric analysis of malignant epithelial structures for assessment of invasive breast cancer survival

J. Pribic[1], K. Kanjer[1], N.T. Milosevic[2], I. Pantic[3], T. Vujasinovic[1], D. Nikolic Vukosavljevic[1], M. Radulovic[1]. *[1]National Cancer Research Center, Department of Experimental Oncology, Belgrade, Serbia; [2]School of Medicine University of Belgrade, Department of Biophysics, Belgrade, Serbia; [3]School of Medicine University of Belgrade, Institute of Medical Physiology, Belgrade, Serbia*

Introduction: Breast cancer is a heterogeneous disease and it is therefore essential to accurately prognosticate metastasis risk at primary diagnosis in order to avoid adverse effects in low risk patients who will not benefit from systemic cytotoxic therapy. As reliable prognostic risk-assessment parameters are still elusive, we set out to investigate the potential of the image analysis on the rare group of patients untreated with systemic therapy.
Methods: The group of primary operable breast node negative carcinoma was diagnosed in 1993 and treated with surgical therapy alone (natural course of disease), with the minimum follow-up of 12 years. Such group is particularly informative in a prognostic sense as systemic therapy is likely to modify outcome. High-risk group (distant metastasis occurrence within 3 years) and low-risk group (no metastasis during the entire follow up time of 12 years) were selected as extremes and tumour tissue sections stained with the anti-human cytokeratin monoclonal antibody AE1/AE3. Slides were scanned by use of the Nano-Zoomer Hamamatsu scanner and 68 RGB images at 50x magnification imported into Image J software, and subjected to textural, box-count and lacunarity analysis.
Results: Three of the eight morphometric parameters tested were significantly different between the groups: outline box dimension, textural contrast and entropy. The outline box dimension was higher ($p = 0.001$), while texture contrast ($p = 0.031$) and entropy ($p = 0.016$) were significantly lower in patients with high risk when compared with patients with low risk of distant metastasis occurrence.
Conclusion: On the basis of these pilot data we propose that morphometric analysis may have a potential for clinical deployment as a prognosticator in invasive breast cancer. The prognostic value of the above morphometric parameters within the entire patient group ($n = 85$) will be reported at the meeting.

Single nucleotide polymorphism (SNP) profile indicating increased risk of head and neck squamous cell carcinoma (HNSCC)

M. Olin[1], B.A. Andersson[2], M. Nilsson[3], J. Lundgren[4], L.E. Rutqvist[5], N. Laytragoon-Lewin[2]. *[1]Länssjukhuset Ryhov, Department Oncology, Jönköping, Sweden; [2]Länssjukhuset Ryhov, Department Laboratory Medicine, Jönköping, Sweden; [3]Länssjukhuset Ryhov, Futurum, Jönköping, Sweden; [4]Karolinska University Hospital, Department ENT, Stockholm, Sweden; [5]Swedish Match AB, Scientific Affairs Group, Stockholm, Sweden*

Background: Known etiological external factors can only partially explain the incidence of (HNSCC). Individual genetic variations may lead to susceptibility to HNSCC and influence the clinical outcome. Single Nucleotide Polymorphism (SNP) are inherited genetic variations derived from a single nucleotide. This study attempts to establish a correlation between SNP profile and risk of HNSCC.
Material and Methods: Forty four candidate genes were selected based on our previous study and theoretical implications in the development of cancer. These genes were analyzed with respect to 46 known SNPs in 103 HNSCC patients and 113 healthy controls. The tissue used for DNA analysis in both groups was peripheral blood or biopsy material in some of the patients.
Results: Statistically significant differences ($p \leqslant 0.05$) in the frequency of SNP between patients and controls were found in seven separate genes; ABCA1, MTHFR, TNFa, ESR, FAS, IL12RB2, Casp8 and EGF. These genes are involved in processes pertaining to cell cycle control, DNA repair, metabolism, inflammation and immune response.
Conclusion: Our results indicate that a susceptibility to HNSCC may be associated with variations in SNP. Further investigation, not only with respect to risk of disease, but for putative implications for prevention measures, prognosis and response to treatment including side effects is warranted.

Are serum tryptase and c-kit expressing cells novel bio-markers or molecular pharmacological targets in colo-rectal cancer patients?

M. Ammendola[1], I. Marech[2], E. Ruggieri[3], S. Montemurro[3], R. Patruno[4], P. Nardulli[5], F.A. Zito[6], A. Vacca[7], C.D. Gadaleta[2], G. Ranieri[2]. *[1]University of Catanzaro "Magna Graecia" Medical School, Chair of Clinical Surgery, Catanzaro, Italy; [2]National Cancer Centre "Giovanni Paolo II", Interventional Radiology Unit with Integrated Section of Translational Medical Oncology National Cancer Research Centre, Bari, Italy; [3]National Cancer Centre "Giovanni Paolo II", Surgery Unit, Bari, Italy; [4]University of Bari, Chair of Pathology, Bari, Italy; [5]Pharmacy Unit, Cancer Research Centre Istituto Tumori "Giovanni Paolo II" Bari Italy, Bari, Italy; [6]ASL BA, Pathology Unit, Bari, Italy; [7]University of Bari, Department of Biomedical Sciences and Human Oncology, Bari, Italy*

Background: Experimental data suggest that mast cells (MCs) accumulate near tumour cells before angiogenesis onset and that they are required for primary tumour progression. Mast cells contain several classical proangiogenic factors, such as VEGF, FGF and, also, non classical proangiogenic factors, such as tryptase. Tryptase can stimulate angiogenesis binding protein activated receptor-2. MCs can release tryptase following c-Kit membrane activation. Here, we detect tryptase serum concentration in 71 colorectal cancer patients (CRC) before and after radical surgery resection and c-Kit expressing cells in primary tumour tissue to achieve their possible clinical-biological value.
Material and Methods: Patients with stage B and C CRC were selected according Astler&Coller classification. Samples of blood were taken from CRC patients 1 day before and after surgical resection. Venous blood was dispensed into a tube for serum (Becton Dickinson Hemogard Vacutainer Systems, Plymouth, UK). Serum blood samples were centrifuged at 1,500*g* for 10 minutes and then aliquoted and frozen at −80ºC. Tryptase levels were measured using the UniCAP Tryptase Fluoroenzymeimmunoassay (Pharmacia,Uppsala, Sweden). Moreover, primary tissue section were immunostained with a primary anti c-Kit antibody (A4502**;** Dako, Glostrup, Denmark) by mean of immunohistochemistry. Tissue sections were than evaluated by mean of an immage analysis system (Quantimet 500, Leika).
Results: Mean$\pm$s.d. tryptase level was 6.57$\pm$4.51 μg/L and 4.92$\pm$3.71 μg/L pre and post-tumour surgical resection, respectively. A statistically significant difference between pre and post-tumour surgical resection tryptase level concentrations was found ($p = 0.000$) by student t-test. A significance association between pre-tumour surgical tryptase level and mast cell expressing c-Kit cells was, also, observed ($r = 0.82$, $p = 0.000$). There wasn't association among tryptase levels, c-Kit expressing cells and pricipal clinical-pathological features.
Conclusions: Our results showed higher serum tryptase levels CRC patients before surgical treatment, demonstrating that tryptase can be released from c-Kit positive cells infiltrating primary CRC tissue. Conversely, tryptase levels decreased after surgery. We suggest that tryptase may play a role as a novel bio-marker in CRC patients. Based on these evidences, we hypothesize that available c-Kit inhibitors may play a role targeting stromal tumour MCs. Finally, tryptase inhibitors, such as gabexate and nafamostat mesilate, might be evaluated in future clinical trials as a new anti-angiogenetic approach.

Cell line microarrays for immunohistochemical assay validation: Reliable controls for the evaluation of EGF receptors and pathway molecules

P. Uhlig[1], S. Rüger[1], J. Krüger[1], K. David[1]. *[1]Indivumed GmbH, Hamburg, Germany*

Background: Immunohistochemistry (IHC) is a strong tool to analyse the distribution and expression of biomarkers in diseased or healthy tissues. Therefore, IHC has to be valid in terms of target specificity and reproducibility. An accurate validation of antibodies is normally done by Immunoblotting, ELISA and IHC. For all validation approaches appropriate positive and negative controls are necessary, which are often not easily available.
Material and Methods: Indivumed developed cell line control slides comprising positive and negative controls for the validation of IHC assays, using secondary cell lines. All cell lines have been selected for their predicted expression or absence of target proteins and were evaluated by immunoblotting, Mesoscale Discovery Technique (MSD) and NanoPro assays. Subsequent to the confirmation of the specificity of applied antibodies and confirmation the predicted expression of target proteins in selected cell lines, formalin-fixed paraffin embedded (FFPE) cell lines were validated in IHC. The validation was performed in terms of presence and absence of positive staining results as well as the staining patter of positive

controls, which should be in accordance to the predicted subcellular distribution.
Results: The control slide panel includes controls for the detection of EGF receptors family (EGFR, HER2, HER3) as well as their activated phosphorylated forms (pEGFR, pHER2, pHER3). Furthermore, pathway molecules as well as their related phospho-proteins are included in this panel (Akt/pAkt, MAPK/pMAPK, mTOR/pmTOR, pMEK, p70s6K, pGSK3β).
Conclusion: Since IHC assays are crucial diagnostic tools their reproducibility and specificity need to fulfil highest standards. To ensure the reproducibility and specificity of IHC assay Indivumed's control slides can be applied as run controls in routine diagnostics. On-slide controls become more and more required for therapeutically relevant diagnostics. To ensure the identical analytical conditions for controls and samples of interest, tissue slices can be mounted on Indivumed's controls slides (On-slide control). In case of anti-EGFR and anti-HER2 IHC, which is used to determine the applicability of targeted drugs in cancer therapies, Indivumed's EGFR and HER2 control slides can be used as on-slide control. In addition to assay validation in routine diagnostic cell line control slides are valuable for a specificity testing of antibodies in research applications.

663 POSTER

CHK2 expression as predictor factor for tumor aggressiveness and shorter survival in metastatic colon cancer patients

K. Bento Ribeiro[1,2], A. Ribeiro Silva[3], S. Britto Garcia[3], O. Feres[4], J. Joaquim Ribeiro Rocha[4], J. Silva Zanetti[3], F. Maris Peria[1]. *[1]Ribeirão Preto School of Medicine − FMRP, Clinical Oncology Division, Ribeirão Preto, Brazil; [2]Triângulo Mineiro School of Medicine − UFTM, Internal Medicine, Uberaba, Brazil; [3]Ribeirão Preto School of Medicine − FMRP, Patology Division, Ribeirão Preto, Brazil; [4]Ribeirão Preto School of Medicine − FMRP, Proctology Division, Ribeirão Preto, Brazil*

Background: The DNA checkpoint pathway damages have been explored to better understand the process of carcinogenesis. Checkpoint kinase 2 (CHK2) activity increased following DNA damage induced by ionizing radiation, chemotherapeutic agents, or other compounds that harm DNA directly or indirectly. Reduced expression of CHK2 and activated CHK2 could be an important inactivating mechanism contributing to the development of colorectal neoplasm. However, during progression of neoplasia, activated CHK2 could contribute to the invasiveness of tumor. The purpose of this study was to evaluate CHK2 expression in metastatic colon cancer and correlate this with K-RAS status, clinicopathological features and patient survival.
Material and Methods: Tissues were obtained from 58 patients with confirmed metastatic colon cancer diagnosis, treated with capecitabine and oxaliplatin chemotherapy as standard doses. Patients included had, at least, 2 years post diagnosis of clinical following. K-RAS status was analyzed by RT-PCR and TMA immunohistochemistry was the technic used to detect CHK2 expression. Statistics analysis used SPSS 17 software and p-value <0.05 was considered statistically significant.
Results: CHK2 was positive in 69% samples and mutate K-RAS was found in 48.3% patients. There was association between expression of CHK2 and lymph node status, being more frequent in higher categories of lymph node involvement, p = 0.001. The overall survival of CHK2 negative patients was higher (72.17 versus 59.55 months, p = 0.155) and the same was observed with progression-free survival (19.27 versus 13.33 months, p = 0.293). The survival curves were different according to CHK2 expression in patients with or without lymph node involvement, being lower in patients with CHK2 positive, p = 0.028. Patients with K-RAS wild type and CHK2 positive had lower overall survival than those CHK2 negative, p = 0.031. Multivariate regression analysis identified performance status (p = 0.001), synchronous metastasis (p = 0.037), tumor cell differentiation (p = 0.029) and expression of CHK2 (p = 0.020) as independent factors to overall survival.
Conclusions: CHK2 positive expression in colon cancer was associated with tumor aggressiveness, reduced overall survival and progression free survival. Further studies with CHK2 expression could detail the activity of this pathway in colon carcinogenesis, and its possible application as a biomarker in clinical practice.
No conflict of interest.

USP2 promotes cell migration and invasion through the regulation of MMP2 in triple negative breast cancer

Q. Qu[1], Y. Mao[1], Y. Zhang[1], X. Chen[1], K. Shen[1]. *[1]Ruijin Hospital Shanghai Jiaotong University School of Medicine, Comprehensive Breast Health Center, Shanghai City, China*

Background: Triple negative breast cancer (TNBC), accounts for approximately 12−15% of all breast cancers, frequently have the worse prognosis among breast cancer subtypes. However, not all TNBCs exhibit dismal survival rates, there are still some TNBCs with long disease free survival. The aim of this study was to find out which genes contribute to the different prognosis.
Material and Methods: Ten breast tissue samples of TNBC, including 4 with metastasis and 6 without metastasis in two years after surgery, were obtained during surgery and subjected to Affymetrix gene chip (human genome U133). We found the ubiquitin-specific protease 2(USP2) was one of the up-regulated genes in the metastatic group, and it is also up-regulated in LM2–4175, a aggressive MDA-MB-231 subpopulation, than other TNBC cell lines. We built the USP2 knock-down cell model on LM2–4175 to figure its role in migration and invasion by transwell assay. Protein expression was analyzed by Western Blot. USP2 protein in tissue was detected by immunohistochemistry in a formalin-fixed paraffin-embedded human breast sample.
Results: Knocking-down USP2 expression by siRNA decreased migration and invasion in LM2–4175. The level of matrix metalloproteinase-2 (MMP-2) was also found downregulated simultaneously. On the other hand, transfect USP2 into MDA-MB-468 enhanced migration and invasion, and also increased the expression of MMP2. In 107 human breast tumors, cytoplasmic positive immunostaining was detected in tumor glands; whereas in normal breast epithelium, USP2 expression was negative. More importantly, USP2 was highly expressed in TNBC compared with other subtypes.
Conclusions: These findings suggest overexpression of USP2 enhances the migration and invasion by upregulating MMP-2 production in vitro. USP2 are expressed in tumor glands, especialy in TNBC, but not expressed in normal tissue. USP2 probably represents a therapeutic target in TNBC.
No conflict of interest.

665 POSTER

Drug sensitivity markers for approved kinase inhibitor drugs from cell panel profiling

J.C.M. Uitdehaag[1], J.A.D.M. De Roos[1], A.M. Van Doornmalen[1], J. De Man[1], R.C. Buijsman[1], G.J.R. Zaman[1]. *[1]Netherlands Translational Research Center B.V., Oss, Netherlands*

Background: Measuring drug responses in tumour cell line panels can help to identify molecular responder subtypes that predict drug sensitivity. This can then guide the design of further *in vivo* tests and clinical trials. Recently, the potential for finding responder subtypes has greatly increased with the determination of the genetic background of cell lines, and this has contributed to the development of many targeted therapies, including the kinase inhibitors (also known as TKIs).
Materials and Methods: We have established a panel of 44 genetically well-characterized cell lines, that originate from a diversity of tissues and which represent the most frequently occurring oncogenic drivers in cancer (www.ntrc.nl). The panel gives highly reproducible, high quality data, which facilitates prediction of responder cancer genotypes. We have profiled all clinically approved kinase inhibitor drugs, a set of experimental kinase inhibitors, and a representative set of classic chemotherapeutic agents. Using high throughput proliferation assays, we determined in parallel the inhibitory response for all drugs on all 44 cell lines of our panel. The data were linked to the genetic background of the cells by Anova analysis.
Results: Responses in our cell line panel confirm known associations. For instance, the B-RAF inhibitor vemurafenib is most potent on cells that carry B-RAF mutation. For clinically approved kinase inhibitors that have a more broad biochemical selectivity panel (so-called spectrum selective inhibitors), it was found that no single genetic change was predictive for response. Instead, more complex subsets of mutations correlated with drug sensitivity.
Conclusions: We have tested all approved kinase inhibitor drugs on our panel of 44 well-characterized cancer cell lines. The resulting response patterns generate hypotheses about responder populations for these modern precision drugs that could eventually lead to extended applications in newly defined patient populations. As a next step, we will systematically investigate the efficacy of combinations of kinase inhibitors and classic chemotherapeutic agents.

Analysis of arrayCGH data suggests that chromosomal copy number variation is increased in aggressive cancers when compared to less aggressive cancers

S. Madden[1], S. Aherne[1], N. O'Donovan[1], J. Crown[1]. *[1]Dublin City University, National Institute for Cellular Biotechnology, Dublin, Ireland*

Background: Array-comparative genomic hybridization (arrayCGH) technology is frequently used in cancer to identify chromosomal abnormalities.

The aim of our study is to identify if there is a correlation between an increase in the number of chromosomal abnormalities and the more aggressive phenotype associated with some cancers.
Materials and Methods: Using Gene Expression Omnibus data repository (http://www.ncbi.nlm.nih.gov/geo) we downloaded the cancer data generated using the Agilent-014693 Human Genome CGH Microarray 244A platform, the most commonly used arrayCGH platform. These data comprised over 550 samples across 10 distinct cancer types (prostate, melanoma, ovarian, lung, colon, mesothelioma, cervical squamous cell carcinomas, glioblastoma, breast and chronic lymphocytic leukemia (CLL)). In addition the breast cancer data was divided into hormone positive; HER2 (Human Epidermal Growth Factor Receptor 2) amplified and triple negative samples. The Bioconductor package snapCGH in conjunction with limma was used to identify insertions or deletions across the entire genome in each sample. The average per chromosome alteration was then compared across the different cancers. The more or less aggressive cancers were those cancers with greater than or less than 50% 5 year survival rates respectively, based on 5 year survival data from Cancer Research UK.
Results: The frequency of chromosomal alterations was identified in each of 10 cancers studied, including the three breast cancer subtypes. The more aggressive cancers (ovarian, lung, mesthelioma, glioblastoma and colon,) on average had higher levels of chromosomal alterations that less aggressive cancers (breast, prostate, cervical squamous cell carcinoma, CLL and melanoma). For example, there are a significant number of chromosomal alterations in ovarian versus breast cancer (p-value = 0006) and lung versus prostate cancer (p-value = 4.8e-07). Indeed, a difference was noted between the breast cancer subtypes, where the more aggressive triple negative subtype has a higher frequency of chromosomal alterations in comparison to the more benign hormone positive tumours (p-value = 0.001).
Conclusions: From this analysis it would appear that more aggressive cancers have a higher number of chromosomal abnormalities. Although the reasons for some cancers being more aggressive are not well defined, the increased number of chromosomal abnormalities could potentially contribute to their more aggressive phenotype.
No conflict of interest.

Phase I/II clinical trial using A24- or A02-restricted cancer/testis antigen- and/or VEGFR1/2-derived peptide-vaccine cocktails for various types of cancers

T. Mori[1]. [1]*Tohoku University Hospital, Cancer Center, Sendai, Japan*

Background: We have investigated safety and efficacy of A24- or A02-restricted cancer epitope- or VEGFR1/2-derived peptide vaccines against various human cancers in this phase I/II clinical trial (UMIN000002857).
Method: A2402-restricted cancer/testis antigen-derived peptides, URCL10, KOC1, TTK, which are highly expressed among lung, esophageal and pharyngeal cancers, A0201-restricted cancer/testis antigen-derived peptides, URCL10, and A2402-restricted or A0201-restricted VEGFR1/2-derived peptides, were used for this clinical trial. HLA-matched peptide-vaccine cocktails, each mixed with montanide as a vaccine adjuvant, were prepared by URLC10 (A24/A02), KOC1 (A24), TTK (A24), VEGFR1/2 (A24/A02) for lung, esophageal or pharyngeal cancer patients, or by VEGFR1/2 (A24/A02) for gastric, pancreatic, biliary-tract, or colorectal cancer patients. Each patient had refractory disease after standard treatments, and had given written informed consent for this clinical trial. Vaccination had been conducted weekly for each patient before PD. Primary endpoint is RECIST evaluation, and secondary endpoints are safety (adverse events), Overall survival, Responsive rate, TTF, Immunological responses by peptide vaccination (CTL response) examined by Elispot assay.
Results: Sixty-eight patients were enrolled in this trial. Among them, 8 patients were excluded before vaccination and 60 patients had undertaken vaccination by peptide cocktail described above with average of 7.7 times. Thirty-three patients reached to RECIST evaluation after 8 vaccinations, and 19 patients were diagnosed SD, while 13 were PD. Grade-3 adverse events were observed in 5 patients and all of them were thought to be a possible outcome of disease progression. Median overall survival was 143.0 days. Exploratory studies showed that patients with positive CTL from more than 2 peptides had prolonged survival (hazard ration 0.407, from 0.224 to 0.740 in 95% CI).
Conclusions: Peptide-vaccine cocktail is feasible for patients with refractory diseases after standard therapy in various cancers. Patients with positive CTL responses from multiple peptides can be beneficial from peptide cocktail examined in this trial. Results obtained in this trial encouraged us to move to later phase of clinical studies by multiple peptide cocktails.

Immunological biomarkers as surrogates for clinical response for dendritic cells vaccine therapy for non-small cell lung cancer and renal cell carcinoma

N. Khranovska[1], O. Skachkova[1], A. Ganul[2], V. Sovenko[2], V. Orel[1], N. Svergun[1], O. Gorbach[1], M. Vikarchuk[3], Y. Grinevich[1]. [1]*National Cancer Institute MPH of Ukraine, Laboratory of Experimental Oncology, Kiev, Ukraine;* [2]*National Cancer Institute MPH of Ukraine, Thoracic Oncology Department, Kiev, Ukraine;* [3]*National Cancer Institute MPH of Ukraine, Oncourology Department, Kiev, Ukraine*

Background: Immunological biomarkers have the potential to predict clinical outcome after cancer vaccine therapy. However, at present no single parameter is likely to achieve any significant degree of use. The aim of our study was to determine phenotypical and functional characteristics of T cells and evaluate dendritic cell (DC) vaccine-induced immune responses which are associated with clinical benefit.
Material and Methods: The study was conducted within the framework of two randomized clinical trials of DC-vaccine efficacy in 120 patients with IIB−IIIA stage of non-small cell lung cancer (NSCLC) and in 16 patients with IV stage of renal cell carcinoma (RCC). NSCLC patients were randomly assigned to receive surgery (S) plus DC-vaccine or S only; RCC patients − to receive S plus IFN-a and DC-vaccine or S plus IFN-a. The original construction of DC-vaccine (DC loaded with mechanical activated lyophilized microparticles of tumor cells) was used. Patients received one-two courses (4−5 intravenous injections per course) of DC-vaccine with 6 month interval in adjuvant setting. Patients were monitored for immune function measures before and 1 month after each DC-vaccine administration.
Results: Median DFS for NSCLC patients was 25 vs 6 months in DC-vaccine and control groups respectively ($p = 0.02$). Median OS for RCC patients was 18.4 months in DC-vaccine group in comparison with 13 months in control group. At 24 months, signs of disease progression were noted in 10 vs 25% of NSCLC patients (HR = 2.6; 95% CI: 0.60–7.93; $p = 0.009$) and in 33% vs 43% of RCC patients ($p = 0.21$) in DC-vaccine vs control groups respectively. The most pronounced changes in the immune system have been defined only after fourth DC-vaccine injection. In disease free groups of patients these changes consist in the significant reduction of T-reg number and their ability to secrete TGF-β, significant increasing the $CD8^+IFN^+$ number, Th1-polarization of immune responses, significant increasing of the RANTES/MIP-1α mRNA ratio ($p < 0.001$). A significant increase of T-regs number, mRNA TGF-β level, MIP-1a/RANTES ratio was associated with therapy failure. Significant increase of the $CD4^+$ memory cell number after 2nd course DC-vaccine (10 administrations) was observed.
Conclusions: T-regs and $CD8^+IFN^+$ number, level of mRNA TGF-β, MIP-1a/RANTES mRNA ratio are the most important immunological biomarkers which associated with clinical outcome after DC-vaccine therapy in NSCLC and RCC patients.

Oncolytic vaccinia virus combined with standard TNF/Melphalan chemotherapy delays tumour growth and prolongs survival in a rat sarcoma isolated limb perfusion model

M. Wilkinson[1], T. Pencavel[1], Y. Yu[2], K. Harrington[1], A. Hayes[1], A. Szalay[2]. [1]*The Royal Marsden Hospital, Department of Academic Surgery, London, United Kingdom;* [2]*Genelux Corporation, San Diego Science Center, San Diego, USA*

Background: Isolated Limb Perfusion (ILP) is an established surgical technique for the treatment of locally advanced extremity melanoma and sarcoma. Oncolytic virotherapy is a promising novel cancer therapy that has been limited by its inability to reach tumour cells in sufficient titres. Extending ILP methodology to include administration of cancer-selective oncolytic viruses allows for targeted, direct delivery of virus to cancer cells, increasing viral uptake through TNFα mediated disruption of the tumour vasculature and initially evading both immune and reticuloendothelial clearance. This represents an exciting approach to improving both oncolytic viral delivery and the therapeutic efficacy of ILP. In addition, it raises the possibility of using a locoregional therapy to prime a systemic anti-tumour immune response.
Methods: Single agent and combinatorial activities of melphalan, tumour necrosis factor-alpha (TNF-α) and oncolytic vaccinia virus (GLV-1 h68) were assessed *in vitro* against a range of melanoma and sarcoma cell lines.
Then, a reliable model of hyperthermic, oxygentated lower limb perfusion was developed in a Brown Norway rodent. Next an orthotopic model of advanced lower limb extremity sarcoma was constructed using a syngenic sarcoma cell line (BN175). These models were then amalgamated to test

treatment efficacy of single agent and combination therapy with TNFα, Melphalan and the oncolytic vaccinia virus (GLV-1 h68) in vivo. Furthermore the locoregional and systemic biodistribution of GLV-1 h68 after delivery by ILP alone and in combination with TNFα and melphalan was evaluated using viral plaque assays and quantitative PCR.
Results: The combination of melphalan and GLV-1 h68 was synergistic *in vitro* when assessed using the median-dose effect principle of Chou and Talalay. ILP with virus was well tolerated with no increase in side effects compared to standard ILP therapeutics. In an advanced disease model, the triple therapy significantly delayed tumour growth and enhanced survival when compared to other treatment regimens ($p = 0.0001$) (Table 1). Live vaccinia virus was recoverable at high titres from perfused regions, but at lower levels from distant organs.
Conclusions: The addition of GLV-1 h68 to existing TNFα/melphalan-based ILP strategies increased survival in an immunocompetent rat model of advanced extremity sarcoma. Further evaluation and clinical translation of this model has been granted ethical approval and will be evaluated in a Phase I study. This will be conducted in the pre-existing surgical ILP programme at The Royal Marsden Hospital.

Table 1. Median survival (n = 8 per group) post treatment with ILP.

ILP Treatment Group	Median survival post engraft (days)
Control	11
Melphalan only	14
Vaccinia Virus only	15
TNF/Vaccinia Virus	16
TNF/Melphalan	16
Melphalan/Vaccinia Virus	19
TNF/Melphalan/Vaccinia Virus	24

Peptide-mediated siRNA delivery: Chronic myeloid leukemia therapy targeting the BCR/ABL fusion gene

I. Figueiredo[1], J. Freire[2], F. Enguita[3], M. Costa[3], S. Marinho[3], M.A.R.B. Castanho[2]. *[1]Faculdade de Medicina de Lisboa Instituto de Medicina Molecular, Physical Biochemistry Unit and Cellular Biology Unit, Lisboa, Portugal; [2]Instituto de Medicina Molecular, Physical Biochemistry Unit, Lisboa, Portugal; [3]Instituto de Medicina Molecular, Cellular Biology Unit, Lisboa, Portugal*

Background: Chronic Myeloid Leukemia (CML), a myeloproliferative disorder caused by a single genetic mutation, that originates the BCR-ABL gene with constitutive tyrosine kinase activity, is an excelent pathology for RNA silencing therapy (siRNA), which has been pointed as a promising therapy technology. We developed a siRNA-based therapeutic approach in which the siRNA is delivered by Dengue Virus Capsid Protein-derived peptides against CML. Previous results showed that the Dengue Virus Capsid protein was a valid template to design Cell Penetrating Peptides (CPP) − pepR and pepM − as drug delivery systems of nucleic acids.
Objectives: To use siRNA molecules to target BCR-ABL gene expression and act as a therapeutic approach for CML. Design and synthesize siRNA molecules that target specifically the BCR-ABL fusion region were designed. To test effective siRNA delivery by both pepM and pepR in a BCR-ABL$^+$ cell line (Human B-cell precursor leukemia BV-173 cell line).
Methods: pepR and pepM ability to transfect siRNA we evaluated using an anti-TLR3 siRNA in Baby Hamster Kidney (BHK-21) cells, followed by expression levels quantification by RT-PCR. Positive BCR-ABL$^+$ Cell Line (BV-173) transfection was tested with a GFP encoded plasmid with pepR or pepM, and evaluated by confocal microscopy. Anti-BCR-ABL siRNA design was performed using a siRNA design web-tool using BCR-ABL mRNA sequence as template. The siRNA effect against BCR-ABL after transfection by pepM or pepR was evaluated by RT-PCR in BV-173 cell line in a time course from 48 h to 120 h after transfection.
Results: Both pepM and pepR are able to deliver functional siRNA into mammalian cells (BHK-21) and, positive GFP expression was observed in BV-173 cell line by confocal microcopy using both peptides. The design of the siRNA targeting the BCR-ABL fusion region retrieved 148 potential siRNA sequences, reduced to 10 BCR-ABL specific sequences after comparison with the *wt* BCR and ABL, being selected 5. Positive efficacy of siRNA transfection was tested using a commercial transfection agent. Significant decrease in expression levels of BCR-ABL gene was observed for siRNA #3 and #4 and mix #1−#5 (60 h after transfection). Successful BCR-ABL gene silencing was observed when delivered by pepM with maximum decrease at 120 h. PepR delivery was unsuccessful.
Conclusions: The design of the siRNA molecules was successful with significant decrease in BCR-ABL gene expression levels, which reveal a potential output for an alternative CML gene therapy.

Anticancer drugs effect on NK cell-mediated cytotoxicity via the regulation of NKG2D ligand expression in non-small-cell lung cancer cells

R. Okita[1], Y. Nojima[1], K. Yasuda[1], A. Maeda[1], T. Yukawa[1], S. Saisho[1], Y. Hirami[1], K. Shimizu[1], M. Nakata[1]. *[1]Kawasaki Medical School, Department of General Thoracic Surgery, Kurashiki, Japan*

Background: A nucleoside analog Gemcitabine inhibits DNA replication, resulting in apoptosis in cancer cells, while an EGFR-tyrosine kinase inhibitor Gefitinib interrupts signalling through the EGFR in cancer cells with EGFR driver mutation. Both Gemcitabine and Gefitinib have shown impressive activity in terms of clinical benefit for patients with non-small-cell lung cancer (NSCLC), however, almost all patients develop resistance to these drugs. Although much research is focusing on the mechanisms of drug resistance in tumor cell, the role of anticancer drugs in tumor escape from the host immune system is poorly understood. Here we demonstrate Gemcitabine enhances NK group 2 member D (NKG2D) ligand MHC class I-related chain A and B (MICA/B) and UL16 binding protein (ULBP), resulting in enhancement of NK cell-mediated cytotoxicity, while Gefitinib downregulates these molecules, resulting in attenuation of NK killing, in NSCLC cells.
Material and Methods: A possible influence of anticancer drugs (Gemcitabine and Gefitinib) on expressions of MICA/B and ULBP1−3 in non-small-cell lung cancer cell lines (A549, PC-9, and RERF-LC-AI) was investigated by flow cytometry. NK cell-mediated cytotoxicity against cancer cells was assessed by ^{51}Cr release assay and flow cytometry based CD107a degranulation assay.
Results: Treatment with Gemcitabine promoted MICA/B, ULBP1−3 in both A549 and RERF-LC-AI cells but not in PC-9 cells. Gemcitabine induced MICA/B expressions were blocked by ATM-ATR inhibitor caffeine in A549 cells. On the other hand, Gefitinib downregulated both MICA/B and ULBP2 in PC-9 cells, but did not in other lines. As expected, Gemcitabine enhanced NKG2D ligands induced NK cell-mediated cytotoxicity, and anti-NKG2D blocking antibody attenuated Gemcitabine induced NK killing in A549 cells. In contrast, Gefitinib attenuated NK killing in PC-9.
Conclusions: We conclude that each anticancer drug effects on NK cell-mediated cytotoxicity against tumor cells in different way via the regulation of NKG2D ligands expression.

Ex vivo activated autologous NK cells efficiently lyse tumor cells from metastatic colon carcinoma patients: A perspective for immunotherapeutic approaches

S. Brugnatelli[1], I. Turin[2], M. Maestri[3], S. Delfanti[1], F. Ferulli[2], M. Tanzi[2], M.C. Canepa[3], F. Lombardo[1], D. Lisini[4], D. Montagna[2]. *[1]Fondazione IRCCS Policlinico San Matteo − Pavia, Oncology, Pavia, Italy; [2]Fondazione IRCCS Policlinico San Matteo e Università di Pavia, Immunology and Transplantation Laboratories − Pediatric Clinic, Pavia, Italy; [3]Fondazione IRCCS Policlinico San Matteo − Pavia, Surgery, Pavia, Italy; [4]Fondazione IRCCS Istituto Neurologico Besta − Milano, Production Unit for Cell Therapies, Milano, Italy*

Background: Over the last decade the development of new treatments for advanced disease improved survival of metastatic colorectal (mCRC) patients, but therapies are still associated with a poor prognosis and significant morbidity. Immune-based therapies could limit treatment related adverse effects, such as morbidity and/or mortality. The functional behavior of natural killer (NK) cells makes them appealing potential effectors for cancer immunotherapy, however in mCRC patients only anecdotal experiences have been reported so far.
In this study we evaluated the capacity of autologous NK cells, freshly or after cytokine activation, to lyse mCRC cells and the expression of ligands for adhesion and triggering NK receptors involved in CRC recognition and killing to clarify the mechanisms involved in tumor susceptibility or resistance to NK cells.
Methods: 23 mCRC patients who underwent surgery on tumor or metastases were enrolled so far. mCRC cells were isolated and expanded *in vitro* and, after evaluation of pathologic characteristics to confirm their

neoplastic origin, were analyzed for the expression of HLA class I and of ligands for NK triggering receptors. NK cells were purified and analyzed for the presence of receptors involved in NK-mediated cytotoxicity. The expression of NK receptors and levels of cytotoxic activity against patients mCRC cells were also evaluated after overnight (ON) activation of NK cells with IL-2 and IL-15.
Results: mCRC cells were successfully expanded from 20 out of 23 samples. Results of experiments performed in 10 patients documented a substantial inability of patients freshly NK cells to lyse mCRC cells (<5% lysis at E:T ratio of 20:1). ON cytokine activation results in an greatly increase of NK cytotoxicity in all patients evaluated (IL-2: mean 28%; range:10−71; IL-15: mean 40%; range 16−76 at E:T ratio of 20:1). NKp30 and NKp46 are highly expressed by patients NK cells and are further up-regulated after ON activation, while TC expressed variable levels of most NK ligands.
Conclusions: Further experiments are in progress to evaluate the effect of a more days activation on cytotoxic activity and on the up-regulation of NK receptors and the possibility to augment the susceptibility at lysis of mCRC cells.
Reported preliminary data on the ability of *ex vivo* activated autologous NK cells to lyse patients tumor cells can offer the possibility of designing immunotherapy approaches for mCRC patients with a worse prognosis.

microRNA-15b expressed in lung cancer-infiltrated CD8-positive memory T cell inhibit cell apoptosis by repressing DEDD

L. He[1], G. Zhong[1], B. Zhu[2]. *[1]Institute of Cancer, Xinqiao Hospital Third Military Medical University, Chongqing, China; [2]Insitute of Cancer, Xinqiao Hospital Third Military Medical University, Chongqing, China*

Background: CD8+ T cells are key members of adaptive immunity against tumorigenesis. As subset of CD8+ T cells, effector T cells (Te) and memory T cells (Tm) have different biological activities. The former can kill tumour cells but come into apoptosis in a certain period and the latter is static with the ability of self-renewal. Previous studies showed that microRNAs (miRNA) played critical roles in regulating adaptive immunity. This study aimed to identify the different expression of miRNAs between Te and Tm cells in tumour-bearing mice and to sort out the target miRNAs which can be regulated to improve anti-tumour activities of CD8+ T cells.
Methods: miRNA expression profiling was performed on CD8+ Te and Tm cells from mice with Lewis lung carcinoma. Differentially expressed miRNAs were chosen and analysed by qRT-PCR. Then, flow cytometry, ELISA, and CFSE kit were used to evaluate the biological effects of target miRNA on apoptosis, cytokine secretion, phenotype, and proliferation of CD8+ T cell. The possible downstream target genes of this miRNA were also analysed.
Results: Analysis of miRNA microarray and qRT-PCR showed that the level of miRNA-15b was higher in CD8+ Tm cells than in Te cells. Higher expression of miRNA-15b was observed in CD8+ T cells from tumour-bearing mice than those from healthy ones. Transfection of CD8+ T cells with miRNA-15b mimics could prevent T cells from apoptosis by inhibiting the translation of DEDD (Death Effector Domain-containing DNA binding protein). Moreover, ectopic miRNA-15b could inhibit the activation of CD8+ T cells via repressing the production of IL-2 and IFN-γ and expression of CD69 and promote CD44 expression through unknown pathways.
Conclusion: Up-regulation of miRNA-15b in tumour environment might negatively regulate anti-tumour immunity through inhibiting function of CD8+ T cells. miRNA-15b might be a potential therapeutic target for immunotherapy.

A translational research program to evaluate the synergistic activity of CRLX101, a nanopharmaceutical in phase 2 clinical trials, with antiangiogenic therapies mediated through HIF-1 alpha inhibition

E. Garmey[1], S. Conley[2], S. Keefe[3], R. Kerbel[4], C. Krasner[5], D. Lazarus[6], C. Peters[6], E. Pham[7], M. Wicha[8], S. Eliasof[6]. *[1]Cerulean Pharma, Medical Affairs, Cambridge, USA; [2]University of Michigan Comprehensive Cancer Center, Research, Ann Arbor, USA; [3]University of Pennsylvania Abramson Cancer Center, Division of Hematology/Oncology, Philadelphia, USA; [4]Sunnybrook Health Sciences Centre, Dept. of Medical Biophysics, Toronto, Canada; [5]Massachusetts General Hospital, Hematology/Oncology Dept. of Medicine, Boston, USA; [6]Cerulean Pharma, Research, Cambridge, USA; [7]Sunnybrook Health Sciences Centre, Research, Toronto, Canada; [8]University of Michigan Comprehensive Cancer Center, Dept. of Internal Medicine, Ann Arbor, USA*

Background: Antiangiogenic drugs reduce blood flow to tumors and thereby inhibit tumor growth by starving tumors of oxygen and nutrients. However, antiangiogenic drugs have achieved limited success as monotherapies, in part because of their induction of hypoxia and the concomitant up-regulation of hypoxia-inducible factor 1α (HIF-1α), now well implicated in the promotion of tumor angiogenesis, invasion, metastasis, and cancer stem cell formation. We describe here a translational research program to investigate whether the efficacy of antiangiogenic drugs can be improved through combination with CRLX101, a camptothecin (CPT) containing nanopharmaceutical that inhibits both topoisomerase-1 and HIF-1α.
Material and Methods: We will present preclinical and clinical projects conducted across several major research institutions intended to demonstrate the anti-HIF-1α activity of CRLX101, the capacity of this drug to block the epithelial–mesenchymal transition (EMT) and the formation of cancer stem cells, and the synergistic activity of CRLX101 given in combination with antiangiogenic drugs. We will further describe two ongoing clinical trials evaluating these hypotheses, one at the University of Pennsylvania in advanced renal cell carcinoma (RCC) and one at the Massachusetts General Hospital in relapsed ovarian cancer following progression through prior platinum-containing chemotherapy.
Results: A single dose of CRLX101 durably inhibits HIF-1α protein levels across multiple tumor types. Evaluation of CRLX101 in combination with bevacizumab, aflibercept or pazopanib in the A2780 ovarian xenograft tumor model demonstrates synergistic inhibition of tumor growth inhibition as well as increases in the rate of long-term survivorship. While all three antiangiogenic drugs alone increased HIF-1α protein levels, levels were inhibited in response to combination with CRLX101. In clinical evaluations, a CRLX101-bevacizumab combination appears safe and well tolerated with no dose limiting toxicities observed to date. Notable tumor decreases and long periods of progression free survival have been noted among patients treated with CRLX101-based mono and combination therapy.
Conclusions: Results generated through this translational research program suggest that CRLX101 can overcome HIF-1α-mediated acquired resistance to antiangiogenic drugs, supporting the use of CRLX101 in combination with antiangiogenic drugs as an exciting new paradigm for the treatment of cancer.

Context and tumor cell dependent consequences of autophagy inhibition revealed by targeting ATG4B

E. Tran[1], A. Chow[1], T. Goda[1], A. Wong[1], M. Rocha[1], S. Taeb[1], V.C. Hoang[1], S.K. Liu[1], U. Emmenegger[1]. *[1]Sunnybrook Research Institute, Biological Sciences, Toronto, Canada*

Background: Autophagy is an adaptive cellular response to stress that plays an important role in resistance to cancer therapies. While being the most advanced autophagy inhibitor in clinical testing, hydroxychloroquine has pharmacodynamic and pharmacokinetic shortcomings that limit its use as an anticancer agent. Therefore, the development of more potent and more specific autophagy inhibitors is a very active area of research, and the cysteine protease ATG4B (also named autophagin-1) is a particularly interesting drug target in this respect. However, the role of ATG4B during cancer therapy is poorly documented.
Methods: By utilizing a dominant negative mutant of ATG4B (i.e., $ATG4B^{C74A}$), we derived syngeneic pairs of autophagy-deficient versus autophagy-competent PC-3 and C4−2 human prostate cancer cells. We analyzed the autophagic properties of these cells, and studied their behavior in proliferation and colony formation assays following chemotherapy and radiation therapy, respectively. Finally, we studied the in vivo growth properties of tumor xenografts and their response to doxorubicin chemotherapy.
Results: Autophagy inhibition due to $ATG4B^{C74A}$ expression was more pronounced in C4−2 cells compared to PC-3 despite similar expression levels of endogenous ATG4B and of $ATG4B^{C74A}$ in both cell lines. While ATG4B inhibition sensitized C4−2 to doxorubicin and radiation therapy in vitro, conversely $ATG4B^{C74A}$ expression promoted resistance to doxorubicin and radiation in PC-3. On the other hand, $ATG4B^{C74A}$ expression did not modulate the effects of docetaxel in PC-3 or C4−2. Of note, the diametrical response of $ATG4B^{C74A}$ expressing C4−2 versus PC-3 cells to doxorubicin observed in vitro did not predict the response of corresponding tumor xenografts. In a reversal of patterns $ATG4B^{C74A}$ expression promoted resistance of C4−2 tumors to doxorubicin, whereas PC-3 tumors were sensitized to doxorubicin by ATG4B inhibition.
Conclusions: Our findings position ATG4B as a valuable alternative treatment target to the use of hydroxychloroquine. However, the data also

add to a growing body of evidence that the clinical translation of autophagy inhibitor therapy will be challenging. The outcome of autophagy inhibition appears to be highly tumor, drug and context dependent. Our cell models are a promising tool to study the molecular mechanisms of such differential responses, and to ultimately identify predictive markers of response to ATG4B inhibition.

Study of different mutations in chronic myeloid leukemia in India and their co-relation with drug resistance

P. Mitra[1], S. Dasgupta[2], C.K. Basu[1], F.H. Gharami[1], S. Mandal[1], A. Mukhopadhyay[3]. *[1]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Clinical Research, Kolkata, India; [2]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Molecular Biology, Kolkata, India; [3]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Haematological Oncology, Kolkata, India*

Background: Emergence of ABL point mutations is the most frequent cause for imatinib resistance in CML. Aim of our study is to investigate two potential resistance mechanisms i.e., mutations of the BCR-ABL tyrosine kinase domain (TKD) and Additional chromosomal abnormalities (ACA), during TKI treatment in CML.
Materials and Methods: Karotyping and BCR-ABL TKD mutation screening are performed in 120 imatinib resistant CML patients who were on imatinib at the time of loss of hematologic response (HR), cyto-genetic(CyR) or molecular response (MR). Imatinib-Resistance Mutation Analysis (Qualitative) were detected by Nested RTPCR and Sanger's Sequencing. In 120 cases, 39 received escalated imatinib, 38 nilotinib and another 43 dasatinib.
Results: In 120 BCR-ABL positive imatinib, nilotinib and dasatinib resistant cases, 11 different BCR-ABL TKD mutations were detected. Analysis revealed no mutations in 49 cases, M351T 12 cases, G250E 14 cases, F317L 11 cases, M244V 8 cases, E255K 7 cases, V379I 4 cases, F359V 3 cases, H396R 3 cases, Y253F 3 cases, E355G 3 cases, T315I 3 cases. 11 novel mutations (F317L, G250E, M244V, Y253F, E255K, M351T, F359V, H396R, V379I, E355G, T315I) conferring imatinib resistance, 10 nilotinib-resistant mutation (M244V, F359V, T315I, E355G, G250E) and 8 dasatinib-resistant mutation (H396R, F317L, H396R, T315I, M351T) were seen in our patient population. T315I was found more frequently in patients on dasatinib than on imatinib therapy.
Conclusions: T315I which confers resistance to all TKIs was detected only in 3/120 patients who demonstrate loss of response in our population. As compared with other western studies, the incidence of T315I mutation was very low in our study. In addition analysis of mutation patterns at baseline may help in stratifying patients for treatment. For cases with TKI resistance, mutation and ACA screening may play a role in identifying patients with poorer prognosis. In our practice if nilotinib-resistant mutation was detected, dasatinib was preferred and if a dasatinib-resistant mutation was detected, nilotinib was preferred. We are planning for using bosutinib, panotinib and omacetaxine (SC route) in third line therapy in imatinib resistant different mutation positive chronic myeloid leukemia.
No conflict of interest.

Protein phosphatase 2A reactivation by PME-1 depletion and multi-kinase inhibition: a novel combination therapy for glioblastoma

A. Kaur[1], E. Peuhu[2], H. Haapasalo[3], J. Eriksson[4], P. Laakkonen[5], J. Westermarck[2]. *[1]University of Turku and Åbo Akademi University, Turku Centre for Biotechnology & Turku Doctroral Programme of Biomedical Sciences, Turku, Finland; [2]University of Turku and Åbo Akademi University, Turku Centre for Biotechnology, Turku, Finland; [3]Fimlab Laboratories, Department of Pathology, Tampere, Finland; [4]Åbo Akademi University, Department of Biosciences, Turku, Finland; [5]University of Helsinki, Molecular Cancer Biology Program and Institute of Biomedicine, Helsinki, Finland*

Glioblastoma multiforme (GBM) is a devastating disease with negligible prognosis. Although deregulated kinase pathways have been identified as drivers of GBM progression, inhibition of receptor tyrosine kinases (RTK) or serine/threonine kinases (STK) has not been successful GBM therapy (Chen et al., Cell. 2012). Tumor suppressor protein phosphatase PP2A is the major negative regulator of STKs and oncogenic phospho-proteins, and is inhibited in many cancers. Several PP2A inhibitor proteins are known to be overexpressed in cancers (Westermarck et al., Trends Mol Med. 2008). PP2A inhibitor, protein phosphatase methylesterase 1 (PME-1) is shown to promote the proliferation and progression of glioblastoma in patient samples (Puustinen et al., Cancer Res. 2009). Here, we study the RNAi based PME-1 depletion as a potential PP2A reactivation strategy to induce synthetic lethality with kinase inhibitors in GBM.
Small scale screening of small molecule compound library targeting different parts of the human kinome, and further screening lead to the identification of a group of structurally related multi-kinase inhibitors with marked synthetic lethality in PME-1 depleted GBM cells. Many of these inhibitors are in clinical development for various cancer types. The efficacy of these compounds in combination with PME-1 siRNA is demonstrated in a series of GBM cell lines *in vitro,* including CD133-enriched GBM cells. The *in vivo* assessment of this therapy combination in tumor xenograft mouse model is in progress.
We propose the activation of specific PP2A complexes and, thereby, inhibition of oncogenic PP2A target phospho-proteins as a mechanism behind increased chemosensitivity of PME-1 depleted GBM cells. We have identified histone deacetylase HDAC4, as such a potential PME-1 regulated PP2A target. The siRNA based HDAC4 silencing phenocopies the synthetic lethal cell killing as seen in PME-1 depleted cells. Furthermore, the HDAC4 expression correlates with the PME-1 status as well as disease progression in human astrocytic glioma patient samples.
In summary, we have identified PME-1 or HDAC4 depletion and multi-kinase inhibitor combination as a potential new therapy for glioblastoma. These results may also have direct clinical implication in patient stratification for treatment with multi-kinase inhibitors currently in advanced phases of clinical trials. Generally these results emphasize the potential of concomitant inhibition of kinase signaling and reactivation of their antagonist protein phosphatases as a cancer therapy approach.
No conflict of interest.

Potential functional implications of NSSR1 in endometrial carcinogenesis

H. Emhamed[1], M. Hirschfeld[2], M. Jaeger[1], E. Stickeler[1]. *[1]University Medical Center Freiburg, Gynecological Hospital, Freiburg, Germany; [2]University Medical Center Freiburg and German Cancer Research Center Heidelberg, Gynecological Hospital, Freiburg, Germany*

Introduction: NSSR1 (Neural salient serine/arginin rich protein) is a member of the serine/arginin rich protein family and acts as a repressor of alternative splicing processes. Initially NSSR1 expression was detected in neural tissues. Later, NSSR1 expression was found in tissues of reproductive systems, e.g. testes, uterus, epithelial endometrium and glands suggesting a potential functional role in regulation of gene expression in these organs. Overexpression was found as a characteristic of tumor cell lines. High NSSR1 expression levels distinguish malignant from physiological ovarian tissues. NSSR1 is one potential novel target gene that might play crucial roles in endometrial carcinogenesis and metastasis. Functional in vitro analyses were designed to investigate potential alterations in expression profiles of NSSR1. In detail, typical microenviromental epiphenomena of solid tumors (hypoxia, extracellular acidosis) as well as therapeutic approaches (hyperthermia) were mimicked in cell culture models.
Materials and Methods: Endometrial cancer cell lines were cultured to more than 80% confluence. Experimental setup mimicked hypoxic conditions, extracellular acidosis or hyperthermia vs. regular conditions (control). mRNA expression levels of NSSR1 were analyzed by quantitative RT-real-time PCR, followed by statistical analyses. Protein expression levels were determined by Western blot and immunocytochemistry. Protein expression levels were determined by Western blot and immunocytochemistry.
Results: Functional analysis revealed variable effects of hypoxia, acidosis and hyperthermia on the mRNA and protein expression of NSSR1 in regard to different cell lines. Acidic conditions induced a significant up-regulation of NSSR1 mRNA expression in all endometrial cell lines, under hypoxia and hyperthermia differing response reactions were observed in the cell lines tested. In contrast; NSSR1 protein translocated from the nucleus to the cytoplasm after acidosis and hypoxia, and variant responses were observed after hyperthermia.
Conclusion: Hypoxia, extracellular acidosis and heat shock response are known as tumor microenviromental epiphenomena or exogenous stresses. We have demonstrated their effect *in vitro*, and based on our results we reached a better understanding of molecular NSSR1 gene regulation under these conditions.
No conflict of interest.

679 POSTER

Potential functional role of EZH2 in endometrial carcinogenesis

H. Emhamed[1], M. Hirschfeld[2], M. Jaeger[1], E. Stickeler[1]. [1]*University Medical Center Freiburg, Gynecological Hospital, Freiburg, Germany;* [2]*University Medical Center Freiburg and German Cancer Research Center Heidelberg, Gynecological Hospital, Freiburg, Germany*

Introduction: Endometrial cancer represents the most common gynecological malignancy in the western world and the eighth leading cancer related cause of death in women. EZH2 is one potential novel target gene that might play crucial roles in endometrial carcinogenesis and metastasis. Functional *in vitro* analyses were designed to investigate potential alterations in expression profiles of EZH2. In detail, typical microenviromental epiphenomena of solid tumors (hypoxia, extracellular acidosis) as well as therapeutical approaches (hyperthermia) were mimicked in cell culture models. The polycomb group protein EZH2 acts as a transcriptional repressor and controls cellular memory and methylation processes. So far, the factor was found highly expressed in malignant vs. physiological tissues in several tumor entities. In particular, EZH2 over expression was described in various tumors with epithelial origin, e.g. endometrium, bladder, urothelial tissues, colon, esophagus, gastric tissue. Recently, it has been found that EZH2 overabundance is clearly associated with tumor aggressiveness and with an ascending histological grade and /or advanced stages of tumor progression, hence correlating with poor prognosis and reduced patient survival.
Materials and Methods: Endometrial cancer cell lines were cultured to more than 80% confluence. Experimental setup mimicked hypoxic conditions, extracellular acidosis or hyperthermia vs. regular conditions (control). mRNA expression levels of EZH2 were analyzed by quantitative RT-real-time PCR, followed by statistical analyses. Protein expression levels were determined by Western blot and immunocytochemistry.
Results: Acidic conditions as well as hyperthermia were identified as strong inductors of increased EZH2 expression levels in all cell lines tested. In contrast, hypoxia uniformly caused a down-regulation of EZH2 expression. EZH2 protein localization switched from complete nuclear expression under regular culture conditions to nearly complete deficiency of nuclear protein under hypoxia, acidosis and hyperthermia.
Conclusion: The obtained results clearly indicate the regulatory effects of acidosis, hypoxia and hyperthermal treatment on both, the mRNA and protein expression levels of EZH2. Thus, this factor might be of important relevance for tumor progression and metastasis with inferential therapeutic implications.

Variable DNA methylation profiles and protein expressions in breast cancer patients

I. Fridrichova[1], I. Zmetakova[1], B. Smolkova[1], M. Mego[2], Z. Cierna[3], V. Kajabova[1], T. Krivulcik[1], L. Danihel[3]. [1]*Cancer Research Institute of SAS, Laboratory of Cancer Genetics, Bratislava, Slovak Republic;* [2]*National Cancer Institute, 2nd Department of Oncology Faculty of Medicine Comenius University, Bratislava, Slovak Republic;* [3]*University Hospital, Institute of Pathological Anatomy Faculty of Medicine Comenius University, Bratislava, Slovak Republic*

Background: During the process of tumorigenesis many tumour suppressor genes are inactivated that lead to the decreasing of relevant protein expressions and functions. The aim of this study was to investigate the role of epigenetic inactivation through evaluation of DNA methylation in promoters of 11 cancer associated genes in relevant protein expression changes in breast cancer patients. We selected genes responsible for self-sufficiency in growth signals (*ESR1*, *PGR B, RASSF1A, SOCS1, SYK and APC*) or inhibiting of cell invasion and metastases forming (*CDH1, TIMP3, ADAM23, CXCL12 and BRMS1*). Promoter methylation in these genes could cause decreasing of corresponding protein expression that will contribute to invazivity and metastasis forming processes in breast cancer.
Material and Methods: DNA methylation levels in paraffin embedded tumour tissues and blood cell samples from 34 patients with invasive breast carcinomas and peripheral lymphocytes from 50 control women were quantitatively evaluated by pyrosequencing. Protein expressions were estimated by immunohistochemical analyses using histoscore (intensity of staining x % of stained cells).
Results: The higher levels of promoter methylation in cancers were shown in *RASSF1A*, *APC*, *CXCL12*, *ADAM23 and PGR B* up to 86, 86, 64, 53 and 48%, respectively. The methylation levels in genomic DNA of patients and controls were significantly different in *APC*,*CXCL12*, *ESR1, PGR B and TIMP3* genes. Moreover, the significant differences between methylation levels in tumours and genomic DNA of patients were observed in *APC*, *ADAM23, CXCL12*, *ESR1, CDH1, RASSF1A, SYK, BRMS1* and *SOCS1* genes. Variable spectrum from high to none expressions were presented in tumour tissues in all of evaluated proteins; however, the significant negative association between protein expression and DNA methylation level in tumours was found for *APC* gene only.
Conclusion: DNA methylation profiles observed in our group of breast carcinomas are cancer specific, but they are not the only cause that affects the silencing of evaluated genes and decreasing of relevant protein products.

681 POSTER

Antidromic NFATc1 and p53 signaling at the edge of differentiation and stemness in pancreatic cancer

S. Singh[1], S. Vogt[1], N. Völker[1], I. Esposito[1], T. Gress[1], V. Ellenrieder[1]. [1]*Universitätklinikum Marburg, Signal Transduction and Transcription Laboratory Dept. of Gastroenterology and Endocrinology, Marburg, Germany*

Background: The current concept suggests a direct link between EMT and stemness induction in pancreatic cancer, thereby coupling cell motility and de-differentiation with self-renewal capacities and drug resistance. Both key features of cellular plasticity are controlled by distinct intracellular signaling and transcription pathways. We have shown that activation of the NFATc1 transcription factor promotes pancreatic cancer development and metastasis through its ability to integrate extrinsic stimuli into coordinated gene regulation.
Aim: To assess whether NFATc1 controls transcription of EMT genes and stemness in PDAC, particularly upon p53 inactivation.
Material and Methods: We generated mouse strains with combined pancreas-specific expression of NFATc1, $p53^{R172H}$ and $Kras^{G12D}$ using Cre-Lox technology. These mice showed a highly aggressive tumor growth (median survival of <50 days). Mouse primary tumour cells were used to identify NFATc1 targets by gene expression profiling and pathway analyses (ChIP seq, miRNA analyses and GSEA). NFATc1 mediated EMT and stemness were assessed in human and murine pancreatic cancer models using migration and spheroid assay as well as xenograft mouse models.
Results: Here, we identified antidromic NFATc1 and p53 signaling pathways in transcriptional control over EMT and stemness. We show that p53 activation prevents cells from EMT in a miR200 dependent manner. However, disruption of the tumor suppressor pathway enables NFATc1/Sox2 chromatin complex formation and transcription of EMT programmes, resulting in highly invasive and metastatic PDACs. Finally, re-expression of miR200c or NFATc1 inactivation suppresses EMT/stemness genes and re-sensitizes PDAC to chemotherapy.
Conclusion: Antidromic NFATc1 and p53 signaling pathways control key features of cellular plasticity and tumor progression at the level of gene transcription. These findings implicate key roles for NFATc1 in transcriptional regulation of differentiation and self-renewal in PDAC.

Genetic and pharmacological targeting of mast cells inhibits inflammation-associated gastric tumourigenesis

M. Eissmann[1], A. Jarnicki[2], R. O'Donoghue[1], T. Phesse[1], I. Kiess[3], M. Buchert[1], M. Ernst[1]. [1]*Walter and Eliza Hall Institute of Medical Research, Cell Signalling & Cell Death, Melbourne, Australia;* [2]*University of Newcastle, School of Biomedical Sciences and Pharmacy, Newcastle, Australia;* [3]*CSL Limited, Research and Development, Melbourne, Australia*

Background: Mast cells (MC) are innate immune cells, which are important in microbial defence and allergic responses. The role of MCs in tumourigenesis and cancer progression is less well understood. Elevated MC numbers in the tumour stroma were correlated to human gastric cancer progression and promotion of angiogenesis. In this study we explore the role of MCs in tumourigenesis and tumour maintenance in a spontaneous mouse model for gastric cancer.
Material and Methods: Here we study the role of MCs in the $gp130^{FF}$ knockin mouse model, a validated preclinical model for Stat3-dependent inflammation-associated gastric cancer. MC-dependent tumour formation was investigated in the MC-deficient compound $gp130^{FF}$;$ckit^{wsh/wsh}$ mutant mice. To establish whether MCs are potential therapeutic targets, we also treated tumour-bearing $gp130^{FF}$ mice with either Cromolyn (MC degranulation inhibitor) or a dual inhibitor for the c-fms and c-kit receptor kinases (MC and macrophage (MΦ) inhibitor).

Results: We find increased numbers of MCs in the submucosa of gastric tumours and adjacent unaffected submucosa in gp130^{FF} mice compared to gp130^{wt} mice. Genetic depletion of MCs in gp130^{FF};ckit$^{wsh/wsh}$ mice led to a substantial decrease in tumour mass and tumour numbers. Furthermore, therapeutic treatment of tumour bearing mice with Cromolyn decreased the overall tumour weight compared to vehicle treated mice. MC depletion and inhibition were associated with decreased MΦ numbers. Pharmacologic targeting of both MCs and MΦs with a dual inhibitor completely blocked tumour growth of gp130^{FF}-driven gastric tumours. This anti-tumour effect was independent of the Stat3 and mTOR signalling status, which is required for the growth and maintenance of these tumours. Instead genetic and therapeutic targeting of MCs reduced cancer cell proliferation and tumour vascularisation.
Conclusion: The decreased tumour burden of the MC-deficient gp130^{FF};ckit$^{wsh/wsh}$ compound mice suggests that MCs play a critical role in the formation and maintenance of inflammation-associated gastric cancer. Furthermore, pharmacologic targeting of MCs and dual inhibition of MCs and MΦs impedes gastric tumour growth independent of the activation status of Stat3 and mTOR, the two major cancer promoting signalling pathways in gp130^{FF} mice and in a majority of human gastric cancers. Therefore, MCs represent a novel therapeutic target for inflammation-associated gastric cancer.

Immunological subtypes in breast cancer are prognostic for invasive ductal but not for invasive lobular breast carcinoma

D.B.Y. Fontein[1], C.C. Engels[1], E. Bastiaannet[2], E.M. De Kruijf[1], G.J. Liefers[1], J.W.R. Nortier[3], C.J.H. Van de Velde[1], P.J.K. Kuppen[1].
[1]Leiden University Medical Center, Surgery, Leiden, Netherlands; [2]Leiden University Medical Center, Gerontology & Geriatrics, Leiden, Netherlands; [3]Leiden University Medical Center, Clinical Oncology, Leiden, Netherlands

Background: Classical patient and tumor characteristics are currently the benchmark of personalized breast cancer (BC) management. However, this risk stratification proved suboptimal and recent evidence stated immune and molecular profiling of BC to be a crucial contribution. Most studies are performed on the BC population as a whole, failing to observe differences between invasive ductal (IDC) and lobular (ILC) BC. Despite increasing evidence that IDC and ILC are distinct entities, they are still treated in similar manners. The purpose of this study was to investigate the relevance of the tumor immune response in the major histological subtypes of BC to further potentiate tailored therapy.
Methods: 714 patients who underwent primary surgery in our center between 1985–1996, with or without AST were included. Immunostains were done for classical HLA type I, non-classical HLA-E and HLA-G, Treg, NK-cells and CTL for the composition of the immune profiles. Additionally, Caspase-3 and Ki67 were stained to objectify the apoptotic and proliferative rate in the tumor. Missing data were imputed with multiple imputations; 25 iterations were generated and results were combined using Rubin's Rules. Multivariable logistic regression was used to assess differences between IDC and ILC. The association with disease-free period (DFP) was analysed with Cox proportional hazard models, stratified for IDC and ILC.
Results: No significant difference was found between IDC (90.6) and ILC (9.4) regarding the association with tumor immune subtyping ($p = 0.4$). However, for DFP our data showed that tumor immune subtyping is prognostic ($p = 0.002$) in IDC, but not for ILC. In contrast to ILC, IDC patients more frequently expressed high levels of Caspase3 and Ki67, which was of prognostic value (Caspase3:$p = 0.02$; Ki67:$p = 0.03$). Intermediate immune susceptible IDC expressing high levels of Caspase3 or Ki67, showed worse DFP than low expression hereof (Caspase3:$p = 0.004$; Ki67:$p = 0.002$), this was not seen for ILC or in high or low immune susceptible tumor types for neither IDC nor ILC.
Conclusion: Tumor immune characteristics and host immune responses are prognostic indicators in IDC, but not in ILC. Therefore, IDC and ILC are separate entities and may be better managed as such.
No conflict of interest.

684 POSTER

Clinical relevance of VEGF, VEGFR, PDGFR, HIF and ERCC1 gene polymorphisms on thymic malignancies outcome

R. Berardi[1], A. Brunelli[2], S. Pagliaretta[1], V. Paolucci[1], G. Goteri[3], M. Refai[2], C. Pompili[2], P. Mazzanti[1], A. Onofri[1], S. Cascinu[1]. *[1]Ospedali Riuniti Umberto I, Clinica di Oncologia Medica, Ancona, Italy; [2]Ospedali Riuniti Umberto I, Chirurgia Toracica, Ancona, Italy; [3]Ospedali Riuniti Umberto I, Anatomia Patologica, Ancona, Italy*

Background: Improving our understanding of the molecular biology of thymic malignancies represents a key challenge in the treatment of these rare tumors.
Material and Methods: The genomic DNA of 57 consecutive patients (31 females and 26 males; 43 thymomas and 14 thymic carcinomas) submitted to total thymectomy at our Institution was extracted from paraffin-embedded tissue.
We selected polymorphisms in the following genes: Hypoxia Inducible Factor-1 alpha (HIF1a: rs2057482T>C, rs1951795A>C, rs2301113C>A, rs10873142C>T, rs11158358G>C, rs12434438G>A, rs11549465C>T, rs11549467G>A), Vascular Endothelial Growth Factor-A (VEGF-A: rs2010963G>C, rs699947A>C), VEGF Receptor 2 (VEGFR-2: rs2305948C>T, rs1870377T>A), VEGFR-3 (rs307826T>C, rs307821C>A), Platelet-Derived Growth Factor-A (PDGFR-A: rs35597368C>T) and Excision Repair Cross-Complementing 1 (ERCC1: rs11615A>G).
Gene polymorphisms were determined by Real-Time PCR using TaqMan assays.
Results: The allele frequency of PDGFR-A rs35597368 T (95.24%) was significantly higher than general population (86%, $p = 0.012$), while the frequency of alleles HIF1-A rs2057482C (76.98%), rs1951795C (68.25%), rs2301113A (68.55%), rs10873142T (68.85%), rs11158358C (74.6%), rs12434438A (65.87%), rs11549465C (83.33%) were significantly lower than those of the control group (90%, 87%, 82%, 87%, 86%, 84%, 92%, respectively, $p < 0.01$).
VEGFR-3 rs307821C was significantly higher in thymomas vs. thymic carcinomas (79.5% vs 72%, $p = 0.0371$).
The following factors were significantly correlated with a better overall survival: VEGFR-3 rs307826T, VEGFR-2 rs1870377T, PDGFR-A rs35597368T/C, HIF1a rs2301113A/C, rs2057482C/T, rs1951795C, rs11158358G/C and rs10873142T/C, ERCC1 rs11615A ($p < 0.05$).
Conclusions: To the best of our knowledge this is the largest monocentric study analyzing the angiogenetic variants in thymic tumors representing a further asset in the definition of high-risk patients after curative resection. The selection tool deriving from this analysis may allow an optimal use of innovative treatment strategies including targeted agents such as sunitinib and sorafenib.

The role of the COP9 signalosome during HIPEC: consequences for clinical application

M. Feist[1], B. Rau[2], W. Dubiel[1]. *[1]Charité University Hospital, Division of Molecular Biology Department of General Visceral Vascular and Thoracic Surgery, Berlin, Germany; [2]Charité University Hospital, Department of General Visceral Vascular and Thoracic Surgery, Berlin, Germany*

Peritoneal carcinomatosis (PC) is a common manifestation in patients with colorectal cancer and has long been considered to be with no curative treatment options. Local treatment strategies have been developed combining cytoreductive surgery and hyperthermic intraperitoneal chemotherapy (HIPEC). The most frequently used chemotherapeutic agent mitomycin C (MMC) has alkylating properties. It inhibits DNA synthesis by interstrand cross-linking and generating double-strand breaks. The DNA damage induces repair mechanisms including the COP9 signalosome (CSN), a regulator of the ubiquitin proteasome system (UPS). The CSN is a protein complex composed of 8 subunits (CSN1-CSN8). It regulates the degradation of important regulatory proteins via the UPS. It controls protein stability of DNA damage repair effectors and is involved in cell cycle regulation. It determines the activity of tumor suppressor proteins such as p53. The coordinated expression of CSN subunits is modulated by miRNAs of the let-7 family. miRNA let-7 binds to the mRNA of CSN subunits and acts as a negative regulator of their expression.
We investigated the role of the CSN during the treatment with MMC. Treatment of colon cancer HT29 cells with different concentrations of MMC in medium heated to 42°C for 1 h or 4 h increased CSN subunit expression. Significant apoptosis was measured only after 4 h. We hypothesize that the increase of the CSN is part of the DNA damage response program, which counteracts apoptosis and decreases the efficiency of HIPEC. One possibility to increase the effect of MMC is to block CSN expression with miRNAs. Therefore, to accelerate apoptosis we transfected HT29 cells

with miRNA let-7 mimic. miRNA mimics act as endogenous miRNAs and block the expression of the CSN. After transfection with miRNA cells were incubated with different concentrations of MMC for 4 h. Our data shows that let-7 miRNA mimic prevented the increase of CSN subunits induced by MMC treatment.
We conclude that let-7 mimic impairs the DNA damage response and potentially increases the efficiency of HIPEC.

Vinflunine promotes the differentiation of bladder tumour cells by the induction of e-cadherin based cell-cell contacts and β-catenin inhibition

L.M. Aparicio[1], R. Carballo[2], M. Rodriguez[2], M. Haz[2], J. Gayo[3], A. Figueroa[2]. *[1]Complejo Hospitalario Universitario A Coruña (CHUAC), Medical Oncology Unit, A Coruña, Spain; [2]Instituto de Investigación Biomédica A Coruña (INIBIC-CHUAC), Traslational Cancer Research Group, A Coruña, Spain; [3]Pierre Fabre Ibérica S.A., División de Oncología, Barcelona, Spain*

Background: Vinflunine (VFL) is a third-generation, semi-synthetic vinca alkaloid that, similar to other microtubule-targeting drugs, suppresses microtubule (MT) dynamics both *in vitro* and in living cancer cells. VFL is an option treatment for patients with transitional-cell-carcinoma (TTC) progressing after first-line platinum-containing chemotherapy. In the last ten years, it was established the impact of MT dynamics on E-cadherin-based cell-cell contacts. E-cadherin is the prototype and best characterized member of adherens junctions in mammal's epithelial cells and is regarded as a tumour suppressor. Its loss is associated with poor prognosis in carcinoma, and it is considered as a hallmark of epithelial–mesenchymal transition (EMT). In this work we investigate the effect of VFL in bladder TCCs during EMT.
Material and Methods: Five bladder transitional carcinoma cell lines (HT1376, 5637, SW780 and UMUC3) were analysed after VFL treatment. By MTT assay, cell viability was determined and the effect on cell phenotype by contrast phase microscopy was examined under increasing concentrations of VFL. Western blotting and qRTPCR were performed to explore VFL effect on the expression protein and miRNAs markers implicated during EMT.
Results: By phase contrast, we have shown that VFL treatment exerts its action on the reversion of the mesenchymal to epithelial phenotype. We have also analyzed the effect of VFL on EMT protein markers. In E-cadherin-expressing bladder tumour cells it was detected an up-regulation of epithelial marker, such as E-cadherin, accompanied to the downregulation of mesenchymal markers, such as N-cadherin; moreover, Hakai, a posttranslational regulator of E-cadherin was also downregulated by VFL. miR-200 family members are also strongly associated to epithelial differentiation during EMT. miR-200a and miR-141 were upregulated by VFL further confirming its action in the regulation of EMT. Moreover, as β-catenin is connected to E-cadherin at cell-cell contacts and it is also reported to influence the microtubule network; therefore our results shows the effect of VFL on β-catenin degradation and also the molecular mechanism by which VFL can regulate EMT through β-catenin action.
Conclusion: Our results show that VFL induces E-cadherin and modulates β-catenin levels exerting its action on the EMT process, opening a new research approach, particularly promoting the differentiation of bladder tumour cells and reverting the epithelial–mesenchymal transition.

Capillary morphogenesis gene 2 inhibits growth of breast cancer cells and is inversely correlated with the disease progression and prognosis

L. Ye[1], M. Mason[2], W.G. Jiang[2]. *[1]Cardiff University School of Medicine, Cardiff, United Kingdom; [2]Cardiff University School of Medicine, Institute of Cancer and Genetics, Cardiff, United Kingdom*

Background: Capillary morphogenesis gene 2 (CMG2) was identified as a gene being up-regulated in capillary morphogenesis. It is also known as a receptor of anthrax toxin. It has been shown to be involved in the cell adhesion and motility which are also critical capacities of cancerous cells for their dissemination. Present study aims to examine the expression of CMG2 in a breast cancer cohort and its implication in the disease progression.
Materials and Methods: Breast primary tumours and background tissues were collected immediately after the surgery and stored at −80°C with approval by the local ethics committee and written consent from patients. The expression of CMG2 in 127 breast cancer tumour samples and 33 normal mammary tissues was determined using real time PCR. Knockdown and over-expression in breast cancer cells were established using constructed plasmid vectors carrying either anti-CMG2 ribozyme or full-coding sequence of human CMG2. The effect on growth of breast cancer cells was examined using *in vitro* and *in vivo* models.
Results: The CMG2 transcript levels were reduced in advanced tumours compared with its expression in tumours of early stage according to their TNM staging. The reduced expression was associated with poorer overall survival, $p = 0.004$ compared with patients had higher expression. The knockdown of CMG2 resulted in an increased *in vitro* growth of MDA-MB-231 cells which express this gene at relatively higher level. This is consistent with the finding from MCF-7 cells express lower level of CMG2 and exhibited an inhibition on the growth following over-expression of CMG2. The over-expression of CMG2 also demonstrated an inhibitory effect on *in vivo* growth of breast cancer cells.
Conclusion: Reduced expression of CMG2 is associated with disease progression and poor prognosis of breast cancer. CMG2 has inhibitory effect on growth of breast cancer cells. Further investigation is required to shed light on the prognostic and therapeutic potential of targeting this molecule.
No conflict of interest.

Polymorphisms in estrogen metabolizing genes in gallbladder cancer

A. Agarwal[1], K.L. Sharma[2], V. Kumar[3], B. Mittal[2], S. Misra[3]. *[1]Dr. RML Institute of Medical Sciences, Surgical Oncology, Lucknow, India; [2]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Medical Genetics, Lucknow, India; [3]King George's Medical University, Surgical Oncology, Lucknow, India*

Background: Gallbladder Cancer (GBC) is more common in females suggesting that sex hormones may play a role in its etiopathogenesis. We hypothesised that genetic polymorphisms in Estrogen Metabolising Enzymes (EMEs) are linked with susceptibility to GBC.
Material and Methods: We selected three single nucleotide polymorphisms(SNPs)- *CYP1A1 Msp1*, *CYP1A1 Ile462Val* and *CYP1B1 Val432Leu* involved in estrogen metabolism for this study. 142 patients of GBC and 142 age and sex matched healthy controls were included in this study. Clinical data was collected from patients along with 5 ml blood venous blood samples from both patients and controls. High molecular weight DNA was extracted by salting out method. SNP analysis in the three genes was based on PCR-RFLP method. Binary logistic regression was used for all analysis variables to estimate risk as the odds ratio (OR) with 95% confidence intervals (CIs) using age and sex as covariates. Tests of statistical significance were two sided and *P* values were considered significant at <0.05 level.
Results: No significant association between risk for GBC and the presence of SNPs in the three EME genes studied. The age- and sex adjusted ORs for the CYP1A1 *TC* and *CC* genotypes were 0.74 and 1.5 (95% CI=0.4−1.3 and 95% CI=0.3−4.9, respectively) using the *TT* genotype as reference group. The age- and sex adjusted ORs for the *CYP1A1 Ile462Val IleVal* genotype was 1.3 (95% CI=0.6−2.4) using the *Ile*/*Ile* genotype as reference group. The age & sex adjusted ORs for the *CYP1B1 Val432Leu Leu*/*Val* and *Val*/*Val* genotype were 1.38 (95% CI=0.7−2.6) and 1.68 (95% CI=0.9–28.9) using the *Leu*/*Leu* genotype as reference group. However, an increased association between risk of GBC in patients who consumed tobacco & non vegetarian food and *CYP1A1 Msp1* gene polymorphism was seen. The frequency of *TC* and *CC* homozygote genotypes were dissimilar in GBC patients who consumed tobacco when compared to patients who did not consume tobacco and were statistically different in the two groups in the *TC* genotype ($p = 0.009$) but not in the *CC* genotype ($p = 0.387$). The age & sex adjusted ORs for the *CYP1A1 TC* and *CC* genotypes were 3.34(95% CI=1.36–8.65) and 0.43(95% CI=0.34–15.8) respectively, using the *TT* genotype as reference group. Similarly, the frequency of *TC* and *CC* homozygote genotypes were dissimilar in GBC patients who consumed non vegetarian food when compared to patients who consumed vegetarian food and were significantly different in the two groups in the *CC* genotype ($p = 0.045$) but not in the *TC* genotype ($p = 0.19$). The age and sex adjusted ORs for the *CYP1A1 TC* and *CC* genotypes were 1.63(95% CI=0.77–3.43) and 9.18(95% CI=1.05–79.9) respectively, using the *TT* genotype as reference group. Similarly, the *C* allele was significantly associated with gallbladder cancer in non vegetarians ($p = 0.016$) and the age and sex adjusted OR was 2.07 (95% CI=1.14–3.76) with *T* allele as the reference.
Conclusions: Similar studies with larger number of patients may show significant association if adequately powered to detect smaller associations. Similarly, polymorphisms in other EMEs need to be studied to look for possible associations with risk of GBC.
No conflict of interest.

Effect of sample DNA impurities on MLPA

L. Atanesyan[1], C. Hettinga[1], W. Rifi[1], M. Steenkamer[1], B. Ben Saddik[2], J.P. Schouten[2], S.P. Savola[1]. [1]*MRC-Holland, Tumour Diagnostics, Amsterdam, Netherlands;* [2]*MRC-Holland, R&D, Amsterdam, Netherlands*

Background: MLPA® (Multiplex Ligation-dependent Probe Amplification) is a PCR-based technique that allows copy number detection of up to 50 different genomic sequences in one reaction. MLPA can be also used for methylation and point mutation detection and requires only 50 ng DNA input. MLPA is routinely used in tumour diagnostics and in cancer research. One of the critical factors for MLPA is the quality of DNA, which depends on the tissue source and on DNA extraction procedure. As tumours occur in all types of tissues with each tissue having certain chemical content, various potentially inhibitory substances can be co-extracted with DNA and affect the downstream molecular applications. Hence, it is important to know to what extent these substances affect the MLPA reaction. Here we have estimated concentrations of several substances in DNA sample, present in human tissues or added during tissue processing, that have a negative influence on the MLPA reaction.
Materials and Methods: MLPA was performed on 50 ng of human genomic DNA in the presence of various amounts of inhibitory substances: sodium chloride, calcium(II) chloride, iron(III) chloride, EDTA, haemoglobin, heparin and melanin. P377-A1 probemix that contains 54 MLPA probes was used for all the tests. Data analysis was performed using Coffalyset.Net software and overall variability of MLPA probes was assessed. The MLPA reaction was considered affected when at least three probes showed >30% variation.
Results: The highest concentration of the inhibitory substance in DNA sample where MLPA is not affected was determined: sodium chloride (20 mM), calcium (II) chloride (2 mM), iron (III) chloride (0.1 μM), EDTA (2 mM), haemoglobin (100 ng/μl), heparin (0.02 U/ml) and melanin (3.0 ng/μl).
Conclusions: It is important to consider the nature of biospecimen, such as chemical content of tumour tissue and processing of it, for MLPA analysis on copy number, methylation and point mutation detection. DNA purification methods should be used that eliminate the presence of naturally occurring substances such as heparin and melanin in the DNA samples tested. Our experience with various methods will be presented. Furthermore, simple precautions to be made during DNA purification and handling will be presented that can eliminate the presence of inhibitory concentrations of substances such as sodium chloride and EDTA.

691 POSTER

Targeting cancer stem cells with platinum anti-cancer drug-incorporated polymeric micelles

M. Wang[1], Y. Miura[2], H. Cabral[1], N. Nishiyama[3], K. Kataoka[1]. [1]*University of Tokyo, Material Engineering, Tokyo, Japan;* [2]*University of Tokyo, Medicine, Tokyo, Japan;* [3]*Tokyo Institute of Technology, Chemical Resources Laboratory, Tokyo, Japan*

Background: Within tumor populations are subsets of 'cancer stem cells', cells that overexpress the glycoprotein CD44v, a marker for stem cell-like qualities as it involved in cell differentiation, cell proliferation and cell migration. These types of cells are more likely to re-initiate both tumor growth and metastasis if left un-eradicated after therapy.
Two polymer-encapsulated platinum nanocarrier micelles, NC-6004 (cisplatin-encapsulating) and NC-4016 (DACHPt-encapsulating) are currently in clinical trials as alternatives to their conventional cisplatin and oxaliplatin 'free drug' counterparts. In this report, we show that these polymer-Pt micelle nanocarrier drugs can target cancer stem cell populations in tumor masses, an occurrence that contributes to their effect on tumor growth suppression.
Materials and Methods: Upon treatment with cisplatin, oxaliplatin, NC-6004 or NC-4016, OSC19 and HSC2 (oral squamous carcinoma, CD44v-expressing cells) subcutaneous tumors were measured and then analyzed for CD44v expression (IHC or western blot) or for Pt content (ICPMS). For *in vitro* studies, cells were treated with polymer-Pt micelles or free Pt drugs for 48 hours before analysis for CD44v content (flow cytometery, Alexa488-anti-CD44v9 antibodies).
Results: Treatment with polymer-Pt micelles suppressed growth rates of subcutaneous CD44v-expressing OSC19 and HSC tumors, as well as reduced the expression of CD44v within the tumor masses. Minimal or adverse effects on tumor progression were observed by treatment with free Pt drugs at comparable doses. As previously reported, polymer-micelle-assisted delivery can improved accumulation of Pt drug into tumor sites, which could have aided in their superior anti-tumor effect. Furthermore, it was found that cellular internalization of whole polymer-Pt micelle complexes followed by slow release of Pt from the micelle compartment was important for CD44v suppression, as opposed to internalization of free drug *via* permeation through the cell membrane.
Conclusions: A major problem for cancer therapy is the existence of chemoresistant and dormant cancer cells within a tumor population. Conventional free Pt anticancer drugs are ineffective at eradicating these populations, thereby increasing the chances of post-therapy relapse and metastasis. Here we show that polymer-micelle nanocarrier-mediated delivery of Pt drugs can overcome this resistance by reducing the expression of cancer stem cells within solid tumors.

692 POSTER

Effect of dosing time on sunitinib pharmacokinetics

J.S.L. Kloth[1], L. Binkhorst[1], P. De Bruijn[1], H. Burger[1], P. Hamberg[2], E.A.C. Wiemer[1], G.T.J. Van der Horst[3], R.H.J. Mathijssen[1]. [1]*Erasmus MC, Medical Oncology, Rotterdam, Netherlands;* [2]*St. Franciscus Gasthuis, Internal Medicine, Rotterdam, Netherlands;* [3]*Erasmus MC, Genetics, Rotterdam, Netherlands*

Background: There is increasing evidence that biochemical processes that determine the pharmacokinetics (PK) of drugs are subject to a circadian rhythm. Sunitinib, an active multi-targeted tyrosine kinase inhibitor used for RCC, GIST and pNET, is mainly metabolized by CYP3A4 into its even active metabolite, which is further converted into several inactive compounds. The aim of this study was to investigate a possible circadian rhythm in sunitinib PK.
Materials and Methods: We performed PK studies in mice and humans treated with sunitinib. Six groups of 18 mice were administered sunitinib through gavage in 4 hour (h) intervals. In each group, blood for PK analysis was collected at 6 time points after gavage. In patients, a prospective randomized cross-over study was performed. Patients were randomized to take sunitinib at 8 AM during the 1st course and at 6 PM during the 2nd course in arm A, or *vice versa* in arm B. During both courses patients were hospitalised for 24 h for blood withdrawal at multiple time-points for PK measurements. Primary endpoint in both studies was the difference in area under the curve (AUC) of sunitinib + metabolite between dosing times. Paired t-test was used for statistical analysis.
Results: A clear 12 h rhythm in AUC was seen in mice (table). The AUC increased with 32% when sunitinib was administered at 12 noon, compared to 8 AM (see table). In the study in human 21 patients were included so far (arm A n = 10, arm B n = 11) of whom 12 patients had PK sampling during 2 treatment cycles. Preliminary data indicate that there is a difference in trough levels (C_{trough}) of sunitinib + active metabolite between morning *vs* evening dosing (mean C_{trough} respectively 49 ng/mL and 61 ng/mL, p = 0.006). Thus far, no clear difference in AUC was seen between morning *vs* evening intake of sunitinib.
Conclusions: These observations indicate that sunitinib PK follows a 12 h rhythm in mice. In humans, a difference in trough levels was seen between morning and evening dosing. Taken together, these data suggest that sunitinib PK may be subject to circadian rhythmicity. Further research is necessary to reveal the underlying molecular mechanisms.
No conflict of interest.

Table: AUC at different dosing times of sunitinib in mice

Dosing time	AUC_{0-inf} (ng·h/mL)
8 AM	8944
12 noon	11850
16 PM	11134
20 PM	9774
12 midnight	11183
4 AM	11317

693 POSTER

Hepatitis A virus cellular receptor (1HAVcR1) enhances the aggressive behaviour of breast cancer cells and is linked to hepatocyte growth factor (HGF) regulation of the tight junction complex

T. Martin[1], W.G. Jiang[1]. [1]*Cardiff University, Surgery, Cardiff, United Kingdom*

Background: HAVcR1 acts as a cellular receptor for the hepatitis A virus and has been indicated in atopic & allergic diseases. It has recently been shown that HAVcR1 may have a role in cancer & is involved in the regulation of tight junctions (TJ) in human endothelial cells via interaction with ZO-1 &

ZO-2, both proteins involved in TJ assembly. This study sought to discover the role of HAVcR1 in human breast cancer.
Material and Methods: HAVcR-1 expression was assessed by Western blotting, immunohistochemistry & RT-PCR in MDA-MB-231 & MCF7 human breast cancer cell lines. A hammerhead ribozyme transgene was used to knockdown HAVcR-1; moreover, forced expression was obtained by insertion of a transgene into wild type cells. TJ function was assessed using trans-endothelial resistance (TER) & paracellular permeability under the influence of HGF (40ng/ml). ECIS (electrical cell impedance sensing) was used to evaluate changes in attachment, migration & barrier integrity. Breast cancer primary tumours (n = 114) & matched background tissue (n = 30) were processed for frozen sections (IHC) & RNA extraction (for analysis by Q-PCR).
Results: HAVcR1 was expressed in MDA-MB-231 & MCF7 human breast cancer cells. HGF increased localisation of HAVcR1 to cell membranes. Successful knockdown resulted in cells with increased TJ function ($p < 0.05$) & no response to HGF. ECIS revealed that knockdown cells had reduced attachment, migration & increased barrier function & were not affected by HGF. Closer investigation using phosphorylation studies revealed that HGF hyper-phosphorylated HAVcR1. HAVcR1 expression was significantly higher in tumour tissues, node positive tumours & in patients with poor prognosis ($p < 0.02$). Patients with metastasis & who died from breast cancer had significantly higher levels of HAVcR1, compared with patients who remained disease free over a 10 year follow-up ($p < 0.027$). Survival analysis revealed a significant relationship between high levels of HAVcR1 & poor overall survival ($p = 0.0057$) as well as disease-free survival ($p = 0.0279$).
Conclusions: In human breast cancer cells HAVcR1 is involved in TJ regulation via HGF. HAVcR1 is associated with poor prognosis & survival in patients with breast cancer & is therefore a potential prognostic factor & therapeutic target. These results demonstrate for the first time that HAVcR-1 may have a previously undiscovered role in the regulation of TJ integrity in human breast cancer.

The DNA repair inhibition by Dbait enhances the treatment efficacy of colorectal cancer metastases in a preclinical model

F. Devun[1], N. Herath[2], J. Biau[3], J.S. Sun[1], A. Denys[4], M. Dutreix[2].
[1]DNA Therapeutics SA, Evry, France; [2]Institut Curie, Research, Orsay, France; [3]Centre Jean Perrin, Hospital, Clermont-Ferrand, France; [4]Centre Hospitalier Universitaire Vaudois, Interventional Radiology, Lausanne, Switzerland

Background: Majority of the patients with advanced colorectal cancer develop liver metastasis, even after primary tumor resection. Depending on the disease stage, systemic chemotherapy (CT) or radiofrequency ablation (RFA) can be considered. As these two treatments induce DNA damage, their efficacy could be enhanced by DNA damage repair inhibition. Dbait are a new class of molecules that inhibit the complete DNA double-strand break repair machinery. Here, we assess the combination of Dbait and CT or RFA in the treatment of a human colorectal cancer xenograft models.
Materials and Methods: For association with CT, HT29 cells were grafted in the liver of 49 nude mice. Two weeks post graft, mice were administered NaCl (n = 9), CT (oxaliplatin and 5-fluorouracil) (n = 10), systemic treatment with Dbait (n = 10) or a treatment associating Dbait and CT (n = 10). Efficacy was assessed by a blinded pathological study. For association with RFA, 113 mice were flank-grafted with HT29. When tumors reached 500 mm^3, mice were sham treated (n = 18), treated by Dbait (n = 22), RFA using an incomplete ablation scheme (n = 21) or with a combination of Dbait and RFA (n = 52 separated in three Dbait regimens). Subsequently, 39 mice were sacrificed for a blinded pathological study, and 74 were followed for survival analysis.

Treatment	Survival study		Pathological study			
	Median (days)	Complete response	Number of tumor samples	Ki67 (%)	Necrosis (%)	Tumor area (mm^2)
CT*						
Sham treated	N.D.	0/9	9	77±9	35±5	60±29
Dbait	N.D.	0/10	10	80±4	47±7	59±19
CT	N.D.	0/10	10	80±2	29±5	39±21
CT + Dbait	N.D.	0/10	10	4±4	86±7	40±14
RFA**						
Sham treated	28	0/11	7	57±4	26±8	24±22
Dbait	37	1/14	8	50±5	46±18	14±4
RFA	40	1/13	8	52±3	60±17	13±7
RFA + Dbait	87	7/12	8	32±7	83±19	6±4

Histological analyses were performed * 22 days or ** 3 days after the treatment.

Results: Histological studies of tumor sections demonstrate a significant decrease in tumor volume, cancer cell viability and proliferation in the groups treated with CT and RFA in combination with Dbait, compared to the CT or RFA alone groups. Additionally, survival was significantly increased in mice treated with RFA in combination with Dbait compared to RFA alone (median survival: 84 *vs* 40 days, $p < 0.001$). A standalone effect of RFA was also observed compared to controls (median survival: 40 *vs* 28 days, $p < 0.001$).
Conclusions: Our results show that the addition of Dbait to CT or RFA enhances their antitumor activities in this model of colorectal cancer metastases and provide an experimental basis for the use of Dbait as a global adjuvant therapy.

Implementation of an individual-level clinical quality audit for community based surgeons and pathologists

C. McFadyen[1]. *[1]Peel Regional Cancer Center-Credit Valley Hospital, Oncology, Mississauga Ontario, Canada*

Background: Clinical audits are an important quality assurance tool. Quality data has been sporadically reported as aggregate data to community clinical groups. Our hypothesis was that data consistently reported at the individual level would have a greater impact.
Materials and Methods: Over a 15 month period we identified 'sub optimal' surgical specimens; colorectal cancer excisions which had less than 12 lymph nodes and pT2 prostate cancer which had an R1 margins from a centralized data base at Cancer Care Ontario.
We surveyed the 54 surgeons and pathologists, who removed or evaluated the resected specimens about the usefulness, confidentiality and validity of the data.
The raw data was validated by independent review before scores were created for clinicians. Cases were excluded from the quality scores because of data quality issues, incorrect grossing of the specimen or mitigating clinical situations such as emergency surgery.
Subsequent to 5 quarterly feedback reports to each clinician we surveyed the surgeons and pathologists again.
Results: 23% of suboptimal cases were excluded from surgeons' scores after independent review because they were not handled properly by the pathologists or for mitigating clinical reasons such as emergency or palliative surgery.
With respect to agree/strongly agree responses, two-thirds of clinicians surveyed felt the data provided was valid. both before and after the study.
Prior to receiving the data almost all clinicians agreed that having access to this data was important. That dropped to a 74% positive response after the study period.
Only 53% of respondents believed that the results were useful to them in their practice but paradoxically, almost all believed that access to such data would improve the performance of the healthcare system.
General surgeons and pathologists did well in lymph node retrieval with many clinicians attaining 100% compliance after validation.
Pathologists did less well on handling prostate specimens. 10% of suboptimal specimens were rejected after review.
Urologists had the poorest quality performance as a group at the beginning of the study with over 40% of the resected pT2 prostate specimens having an R1 margin. Only 30% of urologists responded to the surveys.
As of December 2012, a latency of 18 months from the first audit feedback, R1 margins in pT2 to prostate resections have fallen to 26%.
Conclusions: Clinicians have confidence in the process we have established to provide individual clinical audit data in terms of confidentiality and validity but are less inclined to believe the feedback was a benefit to their practice. This observation maybe due to the fact that general surgeons did extremely well on their metric and urologists had a very poor response rate to our surveys.
All clinicians believed that individual level clinical audits would have a positive effect on quality in healthcare.
There has been a positive impact on R1 margin rates in pT2 prostate cancer.
No conflict of interest.

A potent enantiomer of gossypol, AT-101: Screening of anti-angiogenic protein targets in glioblastoma multiforme cells

Z. Surmeli[1], E. Bozkurt[2], B. Karaca[1], B. Karabulut[1], C. Sezgin[1], U.A. Sanli[1], R. Uslu[1]. [1]*Ege University School of Medicine, Medical Oncology, Izmir, Turkey;* [2]*Celal Bayar University, Department of Biology, Manisa, Turkey*

Background: Glioblastoma multiforme (GBM) is the most common malignant glioma in adults with extremely high morbidity and mortality. Angiogenesis in cancer strongly correlates with the risk of invasion and metastasis. Inhibition of angiogenesis by bevacuzimab shows modest activity in highly-vascular GBMs, but more therapeutic options are needed. AT-101, the (−)- enantiomer of gossypol, is a natural polyphenolic compound extracted from the cotton plant with potent cytotoxic effects on various tumor types. In the present study, we investigated the anti-angiogenic protein targets of AT-101 in GBM cell lines (U-87MG and T98G).
Material and Methods: Real time monitoring of cell proliferation was assessed by xCELLigence system in U-87MG and T98G cells after AT-101 (1−40 μM) exposure. Changes in angiogenesis-related protein expressions were investigated by human angiogenesis antibody array. Changes in protein levels were accepted as significant if there was at least a 1.5-fold change in expression when compared to untreated control.
Results: AT-101 inhibited cell proliferation in a dose and time dependent manner in tested cell lines. The IC_{50} values of AT-101 in U-87MG and T98G cells were 2.4 and 2.7 μM, respectively, at 20 h. The exposure of AT-101 in both cell lines resulted in significant inhibition of expression of angiogenesis-related protein levels which are known to have pivotal roles in invasion, angiogenesis and metastasis.
Conclusions: We found out that AT-101 potently inhibited angiogenesis-related cytokines in GBM cells. AT-101 shows preliminary but promising results for the future treatment strategies for GBM.

The influence of metformin on the breast cancer phenotype

A. Damjanovic[1], Z. Milovanovic[2], Z. Neskovic-Konstantinovic[3], K. Roki[2], S. Nikolic[2], K. Kanjer[1], Z. Juranic[1]. [1]*Institute of Oncology and Radiology of Serbia, Department of Experimental Oncology, Belgrade, Serbia;* [2]*Institute of Oncology and Radiology of Serbia, Clinic for Oncology Surgery, Belgrade, Serbia;* [3]*Institute of Oncology and Radiology of Serbia, Clinic for Medical Oncology, Belgrade, Serbia*

Background: Metformin is frequently used in the treatment of diabetes mellitus (DM) type 2. To get insight whether the therapy of diabetes or hyperglycemia with metformin might induce the changes in biology of cancer cells, we determined the prevalence of breast cancer patients with enhanced HER-2, estrogen and progesterone receptor expression on tumor cells and compared it with those found in general breast cancer population.
Patients and Methods: In this study 768 patients in the period November 2011-December 2012 with surgically removed tumors were included. From this group 42 patients had DM type 2 or hyperglycemia and were pretreated (not less than one month) with metformin alone or sometimes in combination with other antidiabetic drugs. In 37 out from these 42 patients malignant tumors were found (three of them were with bilateral tumors), while 5 out from 42 patients were with benign breast disease. It needs to be mentioned that 14 of 37 additionally were treated with some sulfonylurea derivatives, while 3 of 37 used additionally insulin as the antidiabetic therapy. Receptor status was assessed analyzing tumor cells obtained at diagnosis by immunohistochemistry. Estrogen and progesterone receptor expression was scored from 0 to 8; scores 3 and above were considered positive. Intensity of HER-2 expression were graded from 0 to 3+; scores 3+ and 2+ (after confirmation of HER-2/neu amplification by additional analysis, chromogenic in situ hybridization) were considered as positive.
Results: In 30 out from 37 patients' tumor enhanced ER/PR positive protein expression was found (81.1%). Score 3+ of HER-2 receptor expression was not found on examined patients tumor cells, even more, tumors with HER-2 expression 2+ (found in five patients) were without HER-2 amplification. Frequency of patients with ER/PR positive tumors in general breast cancer population in Institute of Oncology and Radiology of Serbia (from data obtained analyzing 1410 patients' tumors in the period November 2011-December 2012) was 85.5%. HER-2 expression score 3+ was found in 16.6%. Obtained data show that metformin used alone, or in combination with other antidiabetic drugs could modify biology of breast cancer regarding downregulation of HER-2 amplification and/or expression.
Conclusions: Results from this work show that metformin might influence changes in the biology of malignant breast cancer cells downregulating HER-2 expression.
No conflict of interest.

Gene expression profiles of circulating tumor cells (CTCs) in patients with metastatic breast cancer (MBC) treated with aromatase inhibitors (AI)

E.A. Reijm[1], A.M. Sieuwerts[1], J. Bolt-de Vries[1], W. Onstenk[1], L.Y. Dirix[2], A.P. Hamberg[3], J. Kraan[1], J.W.M. Martens[1], P.M.J.J. Berns[1], S. Sleijfer[1]. [1]*Erasmus MC Cancer Institute, Medical Oncology, Rotterdam, Netherlands;* [2]*Translational Cancer Research Group, Laboratory of Pathology, Antwerp, Belgium;* [3]*Sint Franciscus Gasthuis, Internal Medicine, Rotterdam, Netherlands*

Background: Enumeration of CTCs can be used to assess prognosis in MBC and to evaluate treatment response. Besides enumeration, molecular characterization of CTCs is a promising tool to develop a more personalized treatment approach. In this study, we evaluated the association between mRNA expression of 96 measurable genes in CTCs and response to first-line AI in MBC patients with estrogen receptor (ER)+ primary tumors.
Materials and Methods: CTCs were isolated and enumerated from the blood of 25 MBC patients prior to start of first-line therapy with an AI. Fourteen patients received a non-steroidal AI (8 letrozole, 6 anastrozole) and 11 patients were treated with exemestane. mRNA expression levels of 96 genes were measured by quantitative RT-PCR as previously described (Sieuwerts et al. Clin Cancer Res. 17:3600–3618, 2011). Expression levels of these genes were studied for their association with time to progression (TTP) after start first-line AI.
Results: Median TTP was 338 (range 14–1239) days and median baseline CTC count for the 25 patients was 14 (range 0–753). In this relatively small cohort, the clinically relevant cut-off level of $\geqslant$5 CTCs in association with TTP did not reach statistical significance (Hazard Ratio [HR] 4.76, 95% Confidence Interval [CI]: 0.59–38.22, $P = 0.14$). For type of AI, when comparing steroidal with non-steroidal AI, the measures in Cox univariate regression analysis were HR 2.54 (95% CI: 0.67–9.64), $P = 0.17$. A 10-gene CTC predictor was constructed based on the Wald statistics of the contribution of the individual genes in univariate Cox regression analysis of TTP. To identify patients with good and poor outcome, the Wald corrected sum of the 10 genes was used to dichotomize the continuous 10-gene predictor (HR 12.87 [95% CI: 1.60–103.56], $P = 0.016$). In multivariate analysis, corrected for the clinically relevant variables type of AI and CTC count, only the 10-gene CTC predictor was an independent factor associated with TTP (HR 12.46 [95% CI: 1.29–120.08], $P = 0.029$).
Conclusions: A 10-gene CTC expression profile was constructed which distinguishes good and poor outcome to first-line AI in MBC patients. This profile is currently being validated in an independent group of patients.
Conflict of interest: *Corporate-sponsored research: Veridex*

699 POSTER

Nanofluidic digital PCR for improved selection of metastatic colorectal cancer patients to anti-EGFR therapies

D. Azuara[1], C. Santos[2], A. Lopez-Doriga[3], R. Montal[2], X. Sanjuan[4], V. Moreno[3], J. Tabernero[5], C. Montagut[6], R. Salazar[2], G. Capellá[1]. [1]*Catalan Institute of Oncology-IDIBELL, Translational Research Laboratory, Hospitalet de Llobregat, Spain;* [2]*Catalan Institute of Oncology-IDIBELL, Translational Research Laboratory and Department of Medical Oncology, Hospitalet de Llobregat, Spain;* [3]*Catalan Institute of Oncology-IDIBELL, Biomarkers and Susceptibility Unit, Hospitalet de Llobregat, Spain;* [4]*University Hospital of Bellvitge-IDIBELL, Department of Pathology, Hospitalet de Llobregat, Spain;* [5]*Vall d'Hebron Institute of Oncology, Department of Medical Oncology, Barcelona, Spain;* [6]*Hospital del Mar, Department of Medical Oncology, Barcelona, Spain*

Background: Concomitant detection of mutations in downstream signalling molecules of the EGFR pathway (*KRAS*, *BRAF*, *PIK3CA* and *NRAS*) has been suggested to improve the selection of candidate metastatic colorectal cancer (mCRC) patients that will respond to anti-EGFR therapy. In addition, *EGFR*(S492R) point mutation has been associated with acquired resistance to cetuximab. We assessed the feasibility of a nanofluidic digital PCR array platform to simultaneously detect hotspot mutations with high sensitivity.
Methods: 26 primary tumor FFPE tissues from patients (15M/11F; 3 stages I−II; 23 stages III−IV) with chemotherapy-refractory mCRC treated with cetuximab plus chemotherapy in the pre-*KRAS* selection era (between 1997 and 2006) were included in the mutational analysis. Digital PCR was performed using the Digital Array Chip. Conventional genotyping was

performed using LightCycler 480. A panel of 17 hotspot mutations were assessed: all codon 12, G13D, Q61H and A146T9 *KRAS*, V600E *BRAF*, M1043I, H1047R, H1047L and H1047Y in exon 20 of *PIK3CA,* Q61K and Q61R *NRAS* and S492R *EGFR.*
Results: Analytical sensitivity of digital PCR for mutant alleles was 0.05%-0.1% whereas LightCycler detected 1−5%. Eight of 26 (31%) patients were positive for at least one mutation with the Light Cycler. Digital PCR increased this number to 11/26 (42%) confirming all positives. Digital PCR identified multiple mutant alleles in 5 cases. Digital PCR reclassified as mutant 1 of the 5 cases with progressive disease. The case with a G13D mutation identified showed partial response (Table).
Conclusions: Digital PCR provides a robust and highly sensitive detection of EGFR-pathway hotspot mutations that may result in better classification prior to anti-EGFR treatment.

18F-misonidazole positron-emission tomography (FMISO-PET) as an early biomarker of vascular normalization in response to antiangiogenic therapy

E. Hernández-Agudo[1], M.L. Soto-Montenegro[2], T. Mondéjar[1], J. Sánchez[1], F. Mulero[3], M. Desco[2], M. Quintela-Fandino[1]. *[1]Centro Nacional de Investigaciones Oncológicas (CNIO), Breast Cancer Unit Clinical Research Programme, Madrid, Spain; [2]University Hospital Gergorio Marañón, Experimental Imaging Unit, Madrid, Spain; [3]Centro Nacional de Investigaciones Oncológicas (CNIO), Molecular Imaging Unit, Madrid, Spain*

Background: Vascular normalization (VN) is a mechanism by which antiangiogenic drugs (AD) improve vessel function and oxigenation in tumors, enhancing chemotherapy effect. A non-invasive VN marker would allow clinical decisions in patients receiving AD. We evaluated 18F-misonidazole (FMISO) positron-emission tomography (PET) imaging of tumor hypoxia as an early marker of VN, using the AD dovitinib (DOV) in pancreas tumografts (TG).
Methods: Two pancreas TG with characterized gemcitabine (GEM) response (Panc286-resistant; Panc215-sensitive) were implanted in nude mice. Tumor perfusion, hypoxia and glucose uptake before/after 4-day DOV course were explored as potential VN parameters using perfusion computed tomography (P-CT) (HU in 4 ROIs/mice), FMISO-PET (tumor SUV mean), and fluorodeoxyglucose (FDG)-PET (tumor SUV max). Tumor samples at the same timepoints were collected for VN microscopical analysis. Microvessel density and tumor hypoxia were quantified with CD31-pimonidazole co-staining. Perfusion was assessed measuring tumor extravasation of a fluorescent 10KDa-dextran. Whether DOV improved GEM efficacy was studied comparing tumor growth in DOV+GEM *vs* GEM treated animals. Stats: t-test for pairwise comparisons, ANOVA for tumor growth comparisons. Minimum number of tumors per conditionant parameter: 10. All shown data $p < 0.05$.
Results: Total animals in study: 194. In GEM-resistant TG Panc286, DOV+GEM caused a tumor growth inhibition (TGI) of 35.1% *vs* GEM alone at 59 days of treatment ($p = 0.044$). 4-day-DOV course significantly lowered FMISO uptake in Panc286 tumors (SUV mean DOV 0.60, Vehicle 1.16 $p < 0.001$) and tumor perfusion by P-CT (HU mean DOV 123, vehicle 249; $p < 0.001$). Microscopical changes mirrored image findings, as tissue hypoxia was 10-fold decreased and 10KDa-dextran clearance in tumors was 5-fold increased *vs* controls after 4-day DOV course in preliminary analysis. In GEM-sensitive TG Panc215, DOV+GEM also caused a TGI of 54.1% *vs* GEM alone at 116 days of treatment ($p = 0.005$). However, no changes in FMISO-PET and P-CT were observed after 4-day DOV course, neither changes in tissue hypoxia and vascular perfusion in microscopical analysis.
Conclusion: FMISO-PET can tract hypoxia evolution after a short course of DOV. In tumors in which AD reverse chemoresistance by means of VN, FMISO-PET could be an early marker of AD efficacy. However, as evidenced by Panc215 results, other mechanisms than VN may play a role in AD response.
No conflict of interest.

701 POSTER

Erlotinib in EGFR wild type platinum resistant NSCLC: now a predictor factor

A. Orlandi[1], M. Di Salvatore[2], F. Mannavola[2], M.A. Calegari[2], A. Inno[3], C. Bagalà[4], A. Cassano[4], A. Astone[4], C. Barone[4]. *[1]Catholic University "A. Gemelli" Hospital, Roma, Italy; [2]Catholic University "A. Gemelli" Hospital, Medicina Interna, Roma, Italy; [3]Ospedale "Santa Maria della Misericordia", Oncologia Medica, Rovigo, Italy; [4]Catholic University "A. Gemelli" Hospital, Medicina interna, Roma, Italy*

Background: Erlotinib (Erl) is effective in first-line treatment in patients affected by metastatic NSCLC harboring an EGFR mutation. Erl is also approved in the subsequent lines of therapy regardless of EGFR mutational status, although its use is debated in patients with NSCLC EGFR WT. In a retrospective clinical study, we previously demonstrated that EGFR overexpression is associated with a remarkable effectiveness of Erl in second line therapy after a platinum-based treatment in patients with NSCLC EGFR wt. The aim of this *in vitro* study is to investigate whether the exposure to Cisplatin (CDDP) may result in EGFR overexpression, thus determining the acquisition of sensitivity to Erl.
Materials and Methods: We used two EGFR-WT cell lines (A549 and H460) and two EGFR-MT cell lines (H1650 and HCC4006). For each cell line we assessed the sensitivity to CDDP and to Erl performing a MTT-test and the expression of EGFR, pEGFR, c-MET, IGF1-R using PCR and Western Blot.
Results: Among the EGFR WT cell lines, H460 resulted sensitive to CDDP and resistant to Erl. This cell line was subsequently made resistant to CDDP by a continuous exposure to increasing concentrations of the cytotoxic agent (CR-H460). A new MTT-test was then performed on CR-H460, confirming the acquisition of resistance to CDDP and sensitivity to Erl (OR: H460-CR vs H460 0.44, 95% CI 0.27–0.71, $p < 0.001$). CR-H460 showed an increased EGFR and pEGFR mRNA and protein expression compared to the parental cell line (OR: H460 vs H460-CR, 95% CI 3.87–9.30, $p < 0.001$). This increased EGFR expression in H460-CR correlated with the increase of sensitivity to Erl ($r -0.957$, r^2 0.916, $p = 0.043$).
Conclusions: Our *in vitro* model suggests that Erl efficacy in patients affected by NCSCLC EGFR wild-type and previously treated with chemotherapy may be related to the induction of EGFR expression subsequent to the exposure to platinum derivatives. Therefore, a new evaluation of EGFR and pEGFR expression after first-line platinum-based therapy could be a predictor of response to Erl in clinical practice.

Endoxifen and fulvestrant regulate gene expression of estrogen receptor alpha and its co-activators DEADbox5 and 17

V. Neumann[1], M. Hirschfeld[2], M. Jaeger[1], T. Erbes[1], E. Stickeler[1]. [1]*University Medical Center Freiburg, Gynecological Hospital, Freiburg, Germany;* [2]*University Medical Center Freiburg and German Cancer Research Center Heidelberg, Gynecological Hospital, Freiburg, Germany*

Background: Application of anti-estrogens remains a standard approach as endocrine treatment of erstrogen-receptor alpha (ERα) -positive breast cancer. ERα antagonists trigger a competitive blockade of the receptor. Tamoxifen, with its active metabolite endoxifen, acts as a selective receptor down-modulator (SERM) by inhibition of activating function 1 (AF-1) of ERα. Fulvestrant acts as a selective receptor down-regulator (SERD) via an increased ERα degradation created by inhibition of both ERα activating functions (AF-1, AF-2). In some cases, both active agents show an inefficacy by lack of the expected therapeutic effects or therapy-resistance occurs due to gain of ERα-independency accompanying tumor progression. The two RNA helicases p68 (DEADbox5, DDX5) and p72 (DEADbox17; DDX17) act as co-activators of several tumor-associated proteins, such as ERα. Overexpression of both factors could be demonstrated in various malignant tumors. DDX17 expression correlates to decreased Her2/neu levels, extended relapse-free periods, and an increase in overall survival rates. In contrast, DDX5 expression is associated with increased Her2/neu levels and higher tumor grading, but no correlation with relapse-free or overall survival became significant so far. This study aimed for the investigation of potential regulatory effects of endoxifen and fulvestrant on the expression of ERα and its co-activators DDX5 and 17.
Material and Methods: Four ERα-positive and one ERα-negative breast cancer cell line underwent 24 hrs treatment with endoxifen or fulvestrant, respectively, mimicking therapeutic concentrations. In parallel, a negative control, treated with solvent DMSO only, was included in analysis. mRNA and protein levels of ERα, DDX5 and DDX17 were analyzed by RT-PCR and Western blot.
Results: Both ERα antagonists created a significant decrease of mRNA and protein expression levels of all target genes. DDX5 and 17 expression levels generally decreased, whereat endoxifen treatment triggered a stronger effect than fulvestrant. While both ERα antagonists caused a uniform decrease in ERα protein levels, DDX protein levels were differentially affected. Fulvestrant triggered a uniform downregulation of DDX5 and 17. In contrast, endoxifen stimulation resulted in an up-regulation of DDX5 and 17 protein levels in some ERα-positive cell lines.
Conclusion: Both ERα antagonists show regulatory effects on ERα, DDX5 and 17 mRNA and protein expression. However, differing effects could be observed on protein levels in different cell lines. The obtained *in vitro* data might explain individual therapeutic efficacy or the occurrence of resistance against endocrine therapy dependent on cellular context. Furthermore, the elucidation of DDX status might serve as a useful prognostic tool to estimate efficacy of anti-estrogen treatment in breast cancer therapy.

Monitoring cancer treatment responses using cancer-testis antigen microarrays

J. Duarte[1], N. Beeton-Kempen[1], A. Shoko[2], J.M. Serufuri[1], J. Cebon[3], J. Blackburn[1]. [1]*University of Cape Town, Clinical Laboratory Sciences, Cape Town, South Africa;* [2]*Centre for Proteomic and Genomic Research, Cape Town, South Africa;* [3]*Ludwig Institute for Cancer Research, Melbourne, Australia*

Background: There is increasing evidence that the aberrant expression of cancer-testis (CT) antigens − a family of approximately 150 proteins that are both (auto)immunogenic and overexpressed in tumours in various types of human cancers − makes them potentially attractive immunotherapy targets, as well as possible cancer diagnostic markers. More specifically, since none of the CT antigens appear to be cell surface antigens, they are currently considered potential cancer vaccine targets rather than targets for antibody-based therapy. The underlying hypothesis of our study is that there are measurable differences in autoantibody repertoires between pre- and post-vaccinated cancer patient samples, potentially augmented by prior chemo- or radiotherapy, which will correlate with likelihood of response of individual patients to a given therapeutic treatment.
Material and Methods: A novel protein microarray platform containing 123 cancer antigens of interest was developed, optimised and tested, with the intent of allowing the quantification of broad cancer-related autoantibody profiles of cancer patient serum samples collected pre- and post-vaccination, chemotherapy or radiotherapy, and to correlate that data with patient responder phenotypes (Ethical consent: LICR HREC number 2003/01660, UCT HREC number 240/2011). An efficient bioinformatic pipeline of data extraction, filtering, graphing and analysis was also developed, as a means to facilitate and automate processing and analysis of the large volumes of generated microarray data.
Results: Using our CT antigen microarray platform, we have developed a robust, sensitive, high-throughput and highly multiplexed means to assay patient autoimmune responses to an experimental treatment. Our data suggests a limit of detection of 10–100pg/ml − which is competitive with Luminex assays − as well as linearity over 3 orders of magnitude, which is strongly encouraging for future quantitative analyses. Using this platform in preliminary assays on a cohort of melanoma patient sera, we have observed robust, reproducible and relevant patient autoimmune profiles.
Conclusions: A glimpse of the clinical utility of our new array tool is evident, with possible applications in monitoring therapeutic responses to an experimental treatment. However, studies involving larger patient cohorts are necessary to explore these preliminary results in more depth.

Predictive efficacy of low burden EGFR mutation detected by next-generation sequencing on response to EGFR TKIs in non-small-cell lung carcinoma

H. Kim[1], S.Y. Lee[1], Y.J. Choi[1], J.S. Kim[1], S.T. Kim[1], K.H. Park[1], S.W. Shin[1], Y.H. Kim[1]. [1]*Korea University Anam Hospital, Hemato-Oncology, Seoul, Korea*

Background: Direct sequencing is the standard method for the detection of epidermal growth factor receptor (EGFR) mutations in lung cancer; however, its relatively low sensitivity limits its clinical use. Therefore, this study was conducted to investigate sensitivity of PNA-LNA PCR clamp and Ion Torrent PGM compared to direct sequencing and predictive value of those sequencing techniques for EGFR-TKI efficacy.
Material and Methods: EGFR mutational status were assessed by direct sequencing, PNA-LNA PCR clamp and Ion Torrent PGM in 57 NSCLC patients who undergone lung resection. We evaluated predictive efficacy of PNA-LNA PCR clamp on the EGFR-TKI treatment in 36 patients with advanced NSCLC retrospectively.
Results: Compared to direct sequencing (16/57, 28.1%), PNA LNA PCR clamp (27/57, 47.4%) and Ion Torrent PGM (26/57, 45.6%) detected more EGFR mutations. Among the EGFR mutant patients from PNA-LNA PCR clamp, EGFR mutant patients had significantly longer PFS (14.31 vs. 21.61 months, P = 0.003) than EGFR wild patients. However, there was no difference in response rate (75.0% vs. 82.4%, P = 0.195), overall survival (34.39 vs. 44.10 months, P = 0.422) between EGFR mutant by direct sequencing and PNA-LNA PCR clamp.
Conclusions: Our results demonstrate firstly that patients with EGFR mutations were detected more sensitively by PNA-LNA PCR clamp and Ion Torrent PGM than direct sequencing. EGFR mutations detected by PNA-LNA PCR clamp may be as a predicative factor for EGFR TKI response in NSCLC patients.

705 POSTER

Angiogenic marker associated with resistance to neoadjuvant chemoradiotherapy in rectal cancer

H.J. Kim[1], T.S. Ahn[2], S.C. Lee[1], S.B. Bae[1], K.T. Lee[1], M.S. Lee[2], M.J. Baek[2]. [1]*Soonchunhyang University, Internal Medicine, Cheonan, South Korea;* [2]*Soonchunhyang University, Surgery, Cheonan, South Korea*

Purposes: The ability to achieve pathologic down staging after neoadjuvant chemoradiotherapy (CRT) is correlated with improved survival. However, there is no effective method of predicting which patients will response to neoadjuvant CRT. Neoadjuvant CRT can change the expression of angiogenic factors. However, little is known about its possible changes in response to preoperative CRT. We examined the expression of angiogenic factors in rectal cancer tissues before preoperative CRT and after surgery.
Materials and Method: Fifty five patients with locally advanced rectal cancer were studied. All patients were given preoperative CRT of 5040 cGy for 5−6 weeks with concurrent administration of 5-fluorouracil and leucovorin. Surgical resection was performed 6−8 weeks later in all patients. Immunohistochemical staining for angiogenenic markers (vascular endothelial growth factor [VEGF], placenta growth factor [PLGF], hypoxia inducible factor 1α [HIF 1α], stromal cell derived factor [SDF 1α]) were performed on specimens obtained before preoperative CRT and after surgery. A semiquantitative-immunohistochemical score established from the extension and intensity of the angiogenic factors was used for analysis.
Results: The positive expression rate of VEGF, PLGF, SDF 1α, and HIF 1α was 56.4% (31/55), 65.5% (36/55), 70.9% (39/55), and 47.3% (26/55), respectively. The expression rate of VEGF, PLGF, SDF 1α, and HIF 1α was increased by 3.6% (2/55), 7.3% (4/55), 30.9% (17/55), and 1.8% (1/55)

after neoadjuvant CRT, respectively. Expression of VEGF, PLGF, and HIF 1α protein was downregulated after neoadjuvant CRT in the rectal cancer tissues (P <0.001, P = 0.001, P = 0.044, respectively). However, SDF 1α was upregulated after neoadjuvant CRT (P <0.001). And also, upregulated expression of SDF 1α after neoadjuvant CRT was significantly associated with resistance to CRT (P = 0.035). However, SDF 1α showed no correlation with other clinical factors (age, sex, clinical stage).
Conclusion: Expression of SDF-1α was increased in the rectal cancer tissue after neoadjuvant CRT, as well as has been associated with CRT resistance. Our data suggests that SDF 1α should be evaluated as new target for antiangiogenic therapy.
No conflict of interest.

706 POSTER

Differential molecular analysis of non small cell lung cancer by laser capture microdissection of formalin-fixed, paraffin-embedded tissue

F.T. Unger[1], M. Schoeppler[1], J. Krüger[1], K. Pursche[1], H. Juhl[1], K.A. David[1]. [1]*Indivumed GmbH, R&D, Hamburg, Germany*

Background: The introduction of molecular analysis and targeted therapy significantly improved the therapy of lung cancer. In the targeted treatment of lung cancer, monoclonal antibodies such as cetuximab and small molecules such as iressa have shown to be effective subtypes of lung cancer harboring certain molecular characteristics. The predictive biomarkers for the effectiveness of these therapies are mutations in the corresponding targets or in pathway related molecules. In order to accurately determine the molecular signatures of a histological heterogeneous cancer such as lung cancer, microdissection of tumor tissue compartments is mandatory to reveal tumor specific alterations. However, the recovery of good quality RNA from FFPE sections can be challenging due to fixation processes.
Material and Methods: The protocol for Laser Capture Microdissection was implemented on an Axiovert 200/PALM R MICROBEAM IV instrument. Slides were deparaffinized and stained with cresyl violet to enable a betterevaluation of cell morphology. Tumor areas of a homogenous cell type as well as stromal areas were microdissected. RNA as well as DNA was isolated from these different compartments using the Qiagen Allprep Kit and quality control was performed using the Agilent 2100 bioanalyzer. Isolated DNA was used for mutation analysis of hot spot regions of three clinical relevant genes: KRAS, BRAF, and EGFR.
Results: In this study, we have successfully isolated tumor and stromal compartments from five formalin fixed and paraffin embedded NSCLC biospecimen. Total RNA was extracted with overall yields ranging from 1.0 to 279 ng. Extracted RNA was suitable for subsequent RT-PCR. Furthermore, hot spots regions of three genes KRAS, BRAF, and EGFR have been successfully sequenced even with very small amounts of extracted DNA of less than 1 ng. Therein, an EGFR mutation was detected in case 2 and a KRAS mutation in case 3. Mutations were only found in microdissected tumor samples and not in stromal samples, confirming the accuracy of microdissection.
Conclusion: Human tissues, in particular, tumor tissues, are complex structures composed of heterogeneous mixtures of morphologically and functionally distinct cell types. The described workflow is suitable for preparing RNA and DNA from very small amounts of microdissected FFPE tissue samples of <2 mm^2 in sufficient quality and quantity for further applications such as mutation analyses and RT-PCR for gene expression analysis.

707 POSTER

HPV16 detection in HNSCC and correlation with p16 expression and overall survival

D. Vivenza[1], M. Monteverde[1], N. Denaro[2], M. Fortunato[3], A. Comino[3], M. Merlano[2], C. Lo Nigro[1]. [1]*S. Croce General Hospital, Laboratory Translational Oncology Oncology Department, Cuneo, Italy;* [2]*S. Croce General Hospital, Medical Oncology Oncology Department, Cuneo, Italy;* [3]*S. Croce General Hospital, Pathology Department, Cuneo, Italy*

Background: We sought to determine the presence of Human papillomavirus type 16 (HPV16) in tumor samples from patients (pts) with locally advanced HNSCC through E1, E6 and L1 viral fragments detection.
Our aim was to establish their prognostic role in oropharynx tumors (OT) and in non-OT, then to correlate positive (pos) or negative (neg) samples for each fragment with p16 expression.
Materials and Methods: We analyzed 206 samples (OT/non-OT: 66/140) from pts treated with CRT between 1997 and 2011 (175M/31F; median age 59.6, range 20.6–85.6).
E1, E6 and L1 fragments were detected by PCR on DNA extracted from PFFE tissues using specific primer pairs; DNA of pos and neg control cell lines was added at each session. Amplicons were visualized on 2% agarose gel. p16 expression was analysed by IHC.
Results: Although we found a different % of pos samples for each fragment studied, OT showed, overall, a significantly higher % of pos samples vs non-OT: E1 pos was 19.7% in OT and 4.3% in non-OT (p < 0.001), while E6 pos was 68.2% in OT and 50.7% in non-OT (p = 0.02) and L1 was pos 45.5% in OT and 20.7% in non-OT (P < 0.001).
When PCR positivity was correlated to OS, we observed a significant correlation in the OT population with E1 (p = 0.016; median OS = 161.8 in pos *vs* 15 months in neg).
Neither E1 in non-OT (p = 0.145) nor E6 nor L1 in OT and non-OT (p = 0.189 in OT and p = 0.242 in non-OT for E6; p = 0.426 in OT and p = 0.97 in non-OT for L1) reached any difference in overall survival (OS).
p16 pos was 68% in OT and 50% in non-OT (p < 0.007). We have previously demonstrated that p16 high positivity (>50%) confers a survival advantage in patients with OT, while in the non-OT the same pos values correlate with a non significant negative prognostic effect.
A significant correlation between E1 pos samples and p16 high expression was found in OT (p < 0.001). This correlation was not seen in non-OT with E1 neither with E6 nor L1 in the whole population. We identified 3 OT pts E1 pos but p16 neg and 35 pts E1 neg but p16 pos. Analysis of OS suggested E1 pos to be a stronger prognostic marker in OT then p16 pos (p = 0.005).
Conclusions:
1. E1 positivity by PCR may be of clinical relevance in OT. Discrepancies seen with E6 and L1 should be further investigated considering the biological cycle of HPV16.
2. E1 positivity has an even stronger effect as p16 high pos (>50%) in OT. Moreover, where both determinations were not consistent, E1 positivity seems to correlate with OS better than p16.

No conflict of interest.

708 POSTER

Wiskott-Aldrich Syndrome protein (WASP) and WASP interacting protein (WIP) are tumor suppressor in ALK-mediated lymphomagenesis

M. Menotti[1], C. Ambrogio[2], C. Martinengo[1], I.M. Anton[3], V. Minero[1], R. Piva[1], C. Voena[1], R. Chiarle[1]. [1]*University of Torino, Department of Molecular Biotechnology and Health Sciences, Torino, Italy;* [2]*Centro Nacional de Investigaciones Oncologicas (CNIO), Molecular Oncology Program, Madrid, Spain;* [3]*Centro Nacional de Biotecnología (CNB-CSIC), Cellular and Molecular Department, Madrid, Spain*

Background: Anaplastic Large Cell Lymphoma (ALCL) is a T-cell lymphoma that frequently carries the t(2;5) translocation that fuses the ALK gene to Nucleophosmin (NPM1) gene. NPM-ALK transforms lymphocytes by inducing different signaling pathways that control cell proliferation and survival.
Material and Methods: We performed gene expression profiling (GEP) analysis on different lymphomas samples and immunohistochemistry with WASP and WIP antibodies on human samples of ALK+ALCL. To investigate signaling, we infected ALK+ ALCL cell lines (TS and SU-DHL1) with a specific shRNA against ALK and against Stat3 or CEBP/β. To measure WIP and WASP mRNA and protein levels, we used qRT-PCR and western blot analysis, respectively. Finally, we crossed mice deficient for WASP or WIP gene ($WASP^{-/-}$ or $WIP^{-/-}$) or conditionally deficient for Cdc42 (Cdc42f/f) with NPM-ALK Tg mice to check for lymphoma development and overall survival.
Results: ALK+ ALCL had significantly lower expression of WIP and WASP proteins than normal T cells or other T cell lymphomas, as determined by GEP, immunohistochemistry and WB on cell lines and primary tumor samples. In ALK+ ALCL cell lines, we demonstrated that ALK inhibition resulted in up-regulation of WIP and WASP, thus indicating that ALK directly repressed WIP and WASP expression. Such regulation was dependent on a Stat3 and CEBP/β-mediated transcriptional repression.
In mouse models, we showed that WASP protein levels were strongly reduced in lymphomas from NPM-ALK Tg/$WIP^{-/-}$ mice. Remarkably, WIP and WASP worked as tumor suppressors, as either $WASP^{-/-}$ or $WIP^{-/-}$ backgrounds significantly accelerated NPM-ALK lymphomagenesis. Haploinsufficiency of Cdc42 in NPM-ALK Tg/ $WASP^{-/-}$/$Cdc42^{f/-}$ mice restored normal lymphoma incidence, thus suggesting that WASP deficiency accelerated lymphomagenesis by deregulating downstream Cdc42 activity.
Conclusions: In the present study we demonstrated that the expression levels of WASP and WIP are down-regulated by oncogenic ALK in lymphoma. Remarkably, reduced levels of WASP and WIP have key roles in lymphomagenesis as they accelerate NPM-ALK lymphoma progression in *in vivo* mouse models. Thus, for the first time we demonstrate WASP and WIP as tumor suppressors in lymphoma. Our data implicate that lymphoma arising in Wiskott-Aldrich syndrome (WAS) patients, where WASP function

is impaired, could be better explained by an intrinsic tumor suppressor function of WASP rather than a general immunosuppression of the patients.
No conflict of interest.

709 POSTER

Bevacizumab exposure is accompanied by EGFR activation in colorectal cancer (CRC) models providing a rationale for combinations of bevacizumab and erlotinib in the GERCOR DREAM phase III trial

P. Mésange[1], V. Poindessous[1], A. Battistella[1], A. Savina[2], C. Tournigand[3], T. André[4], A. De Gramont[4], A.K. Larsen[1]. *[1]INSERM and UPMC, Cancer Biology & Therapeutics Saint-Antoine Research Center INSERM U938, Paris 12, France; [2]ROCHE France, Roche Scientific Partnerships, Boulogne-Billancourt, France; [3]INSERM UPMC and Hôpital Henri Mondor, Cancer Biology & Therapeutics Saint-Antoine Research Center INSERM U938 and Medical Oncology Hôpital Henri Mondor, Créteil, France; [4]INSERM UPMC and Hôpital Saint-Antoine, Cancer Biology & Therapeutics Saint-Antoine Research Center INSERM U938 and Medical Oncology Hôpital Saint-Antoine, Paris 12, France*

Background: Combinations of EGFR and VEGF(R)-targeted agents have consistently shown at least additive activity in preclinical CRC models when the targeted agents were administered alone (*Larsen et al., Pharmacol Therap 131:80, 2011; Poindessous et al., Clin Cancer Res 17:6522, 2011*) paving the way for the GERCOR DREAM-OPTIMOX3 phase III trial, an optimized chemotherapy + bevacizumab strategy ± erlotinib in metastatic CRC patients (*Tournigand et al., ASCO 2012, A 3500*). Currently, the mechanistic basis for the additive activities of the two types of targeted agents is not well understood. Although use of EGFR-directed mAbs are counter-indicated in CRC patients with mutant *KRAS*, the situation is less clear for EGFR-targeted TKIs like erlotinib.
Material and Methods: Three human CRC xenograft models expressing wt *KRAS*/*BRAF*, mutant *KRAS* or mutant *BRAF* were established in nude mice. Animals were treated with bevacizumab and erlotinib, alone or in combination, and the influence on tumor growth, viability and the presence of phosphorylated ErbB/HER family members was determined. Treatment-related toxicity was estimated by weight loss.
Results: Combinations of bevacizumab and erlotinib were significantly more active than either agent alone for all three xenograft models although the advantage of combining the two agents was particularly striking for the *KRAS*/*BRAF* wt xenograft model. Unexpectedly, erlotinib alone showed strong antitumor activity in the *BRAF* mutant HT-29 xenograft model. The bevacizumab plus erlotinib combination was less toxic, as determined by weight loss, compared to erlotinib alone. Interestingly, IHC analysis showed that bevacizumab activates EGFR in all three xenograft models which is attenuated in the presence of erlotinib. Erlotinib also attenuates the active phosphorylated form of HER3/ErbB3, in particular when combined with bevacizumab.
Conclusions: We here report that bevacizumab and erlotinib combinations are significantly more active than either agent alone in CRC models with different *KRAS* and *BRAF* status. We further demonstrate that bevacizumab activates EGFR signaling similar to what has been described for irinotecan and ionizing radiation. Although bevacizumab selectively recognizes human VEGF, this is unlikely to influence our findings, since murine VEGF is believed to play a relatively minor role in CRC xenograft models. Taken together, our findings suggest that mutant *KRAS* and *BRAF* have lesser influence on the sensitivity to EGFR-targeted TKIs than is the case for the anti-EGFR mAbs and provide a mechanistic basis for the increased activity of the bevacizumab and erlotinib combination.

DOK7 expression in colorectal cancer cells and association with patient survival

L. Satherley[1], L. Ye[1], R. Hargest[1], W.G. Jiang[1]. *[1]Institute of Cancer and Genetics, Department of Surgery, Cardiff, United Kingdom*

Background: The downstream of tyrosine kinase (DOK) protein family is presently known to have seven members, so called DOK1−7. The precise role of the DOK proteins is not entirely clear; some authors have suggested a potential tumour suppressor role for these proteins whilst others have shown an association between expression of these proteins and cell migration. Our study aimed to determine the expression profile of DOK7 in human colorectal cancer cell lines and its association with clinical and prognostic outcome.
Material and Methods: Three human colorectal cancer cell lines (HRT18, HT115 and RKO) were analysed using polymerase chain reaction (PCR) to determine DOK7 expression. Primary colorectal cancer tissue collected at operation from 94 patients was examined by a consultant pathologist. Anti-DOK7 transgenes and expression constructs for human DOK7 were prepared and used for transfection and creation of sublines with differential expression of DOK7. Frozen sections of each tissue sample were used to extract RNA and this was used to generate cDNA which was analysed using quantitative transcript analysis to determine DOK7 expression. Patients were routinely followed up clinically and radiologically after surgery and the median follow up period was 65 months. The expression profile was then analysed against the clinical, pathological and outcome data.
Results: DOK7 transcript expression was highly positive in HRT18 cells. HT115 and RKO cells on the other hand were negative for DOK7 expression. Knockdown in HRT18 cells (HRT18$^{\Delta DOK7}$) resulted in reduced expression of DOK7. The reduction of DOK7 in the cells resulted in a reduced rate of growth compared to wild-type cells and those transfected with control vector. Analysis of clinical data revealed that DOK7 expression was significantly negatively correlated with grade of tumour differentiation, TNM stage and Dukes stage. Furthermore, DOK7 expression was inversely correlated with patient survival ($p = 0.011$).
Conclusions: DOK7 expression was higher in non-aggressive tumour cells (HRT18) compared with aggressive tumour cells (HT115). However, DOK7 expression was also found to be negatively associated with patient survival suggesting a diverse role for this protein in malignant tumours. Further work is necessary to further elucidate the effect of DOK7 expression on cell function and cell migration response to mitogens and motogens.
No conflict of interest.

711 POSTER

In vitro studies on irradiation and Akt inhibition in human malignant glioma

P. Sminia[1], C.A. Fedrigo[1], R.S. Narayan[1], L.J.A. Stalpers[2], B.G. Baumert[3], G.J. Peters[4], B.J. Slotman[1]. *[1]VU University Medical Center, Radiation Oncology, Amsterdam, Netherlands; [2]Academic Medical Center, Radiation Oncology, Amsterdam, Netherlands; [3]MediClin Robert-Janker-Clinic & University of Bonn Medical Centre, Cooperation Unit Neurooncology, Bonn, Germany; [4]VU University Medical Center, Medical Oncology, Amsterdam, Netherlands*

Background: Glioblastoma multiforme (GBM) is the most common, invasive and deadly primary type of malignant brain tumor. The Phosphatidylinositol-3-Kinase-Akt pathway is commonly overexpressed in GBM and has been associated with resistance to therapy. The aim of the study was to investigate the cytotoxic and radiosensitizing effects of the Akt inhibitor MK-2206 on human malignant glioma cells and spheroids in vitro.
Materials and Methods: Experiments were performed on a panel of five GBM cell lines (U251, T98, D384, U87, VU122). Cells were treated with the allosteric Akt inhibitor MK-2206 alone and in combination with irradiation (0−8 Gy). Endpoints: cell survival (clonogenic assay), cell invasion (transwell Boyden chamber technique) and expression of the proteins PTEN, Akt and pAkt (Western blot). U87 multicellular spheroids were analysed in a growth − volume − assay following the combination treatment of MK-2206 (1microM), fractionated irradiation (5 x 2 Gy) and repeated administration of temozolomide (TMZ; 5 x 5microM).
Results: MK-2206 reduced the expression of the phospho-Akt key protein of the PI3Kinase-Akt pathway. The drug was cytotoxic for all glioma cells in the dose range between 1 and 10mM for 24 hours, but no radiosensitizing effect was found on clonogenic cell survival. The invasion capacity was assessed at doses between 1 and 10 microM MK-2206 for 16 hours. A dose-dependent inhibition of invasion was observed for all but one of the cell lines. Irradiation (4 Gy) alone increased the expression of pAkt, which was inhibited (30min, 1 h, 2 h and 4 h) following pre-incubation with MK-2206 (1microM and 10microM for 1 h). When the drug was administered additional to irradiation, a further inhibition of cell migration and invasion was observed, which was not found after irradiation alone. The radio-enhancing effect of MK-2206 was most pronounced in inhibition of the growth of glioma spheroids in the fractionated irradiation regimen.
Conclusion: Targeting of the PI3K-Akt pathway enhanced the effect of radiation and TMZ in a series of *in vitro* assays, in particular regarding cell invasion and migration, and on spheroid growth. Taken together, Akt pathway inhibition yields promising perspective in the therapy of GBM patients.
No conflict of interest.

Smads expression is changed following receptor-like protein tyrosine phosphatase kappa (PTPRK) knockdown in prostate cancer cell

P. Sun[1], L. Ye[1], M. Mason[1], W.G. Jiang[1]. [1]*Cardiff University School of Medicine, Institute of Cancer and Genetics, Cardiff, United Kingdom*

Background: Smad-dependent pathway is part of TGF-β pathway which regulates different cell function such as proliferation, adhesion and migration. Recently, it has been reported that PTPRK is up-regulated by TGF-β and is probably involved in TGF-β dependent anti-proliferation and migration effects in keratinocyte. Furthermore, PTPRK has been indicated as a potential tumour suppressor in primary central nervous system lymphomas. Our recent works have shown certain implications of PTPRK in both breast cancer and prostate cancer. However, the role played by PTPRK in the Smad dependent signalling and the influence on epithelial mesenchymal transition (EMT) of prostate cancer cells remains largely unknown. Present study aimed to study the effect of PTPRK knockdown on Smad signalling and EMT of prostate cancer cells.
Material and Methods: Ribozyme transgenes were constructed to knock-down PTPRK expression in PC3 cells, following verification of the knockdown was carried out using RT-PCR, real time q-PCR and Western blot. The expression of Smads and relevant EMT markers have been assessed using both PCR and Western blots.
Results: Knockdown of PTPRK resulted in alterations of SMADs expression. SMAD1 and SMAD3 expression were significant decreased at both mRNA and protein levels following PTPRK knockdown; nevertheless, SMAD4 expression was increased at both mRNA and protein levels. Other Smads expression was not affected by the PTPRK knockdown. Furthermore, expression of Snail and Slug were reduced in PTPRK knockdown cells; however, there were no effects on other EMT markers including uPA and Vimentin.
Conclusions: Knockdown of PTPRK can reciprocally regulate the expression of certain Smads in prostate cancer cells and may be involved in the EMT triggered by Smad signaling. However, the underlying mechanism is yet to be investigated.
No conflict of interest.

713 POSTER

Association between c-Met and lymphangiogenic factors in patients with colorectal cancer

H.J. Kim[1], T.S. Ahn[2], S.C. Lee[1], S.B. Bae[1], K.T. Lee[1], M.S. Lee[2], M.J. Baek[2]. [1]*Soonchunhyang University, Internal Medicine, Cheonan, South Korea;* [2]*Soonchunhyang University, Surgery, Cheonan, South Korea*

Background: Lymphangiogenesis plays an important role in cancer metastasis. Although animal models show a strong relationship between lymphangiogenesis and lymph node metastasis and survival, the clinical significance of lymphangiogenesis in colorectal cancer (CRC) remains uncertain. The goal of this study was to evaluate the association between c-Met and lymphangiogenic factors and to elucidate their prognostic significance for patients with CRC.
Methods: A total of 379 tissue samples were obtained from surgically resected specimens from patients with CRC in Soonchunhyang University Cheonan Hospital between January 2002 and December 2010. The expressions of c-Met, vascular endothelial growth factor (VEGF)-C, VEGF-D, VEGF receptor (VEGFR)-3, and podoplanin were examined by immunohistochemistry. The expression of each marker and clinical factors were analyzed.
Results: Three hundred and one of 379 (79.4%) tissues had c-Met expression. High expression of c-Met in tumor cells was significantly associated with high expression of VEGF-C ($P < 0.01$) and VEGFR-3 ($P = 0.01$). But, there was no statistically significant association with podoplanin (P =. 587) and VEGF-D ($P = 0.96$). Of the 103 evaluable patients, expression of c-Met in tumor cells was significantly associated with advanced clinical stage ($P = 0.20$), positive lymph node status ($P = 0.38$), and high expression of VEGF-C ($P = 0.20$). But, there was no statistically significant association with podoplanin (P =. 518), VEGFR-3 ($P = 0.85$), VEGF-D (P =. 203), and overall survival (P =. 360).
Conclusion: Our results provide indirect evidence for an association and possible regulatory link of c-Met with the lymphangiogenic factors. But, c-Met expression in patients with CRC are not prognostic indicator for overall survival in this retrospective study.

Improving cell based models through viral vector technology − chances for target research and screening approaches

K. Schmitt[1], M. Salomon[1], V. Jagusch[1], S. Schrödel[1], C. Thirion[1]. [1]*SIRION Biotech Gmbh, Martinsried, Germany*

Overexpression (Oex) and knockdown (KD) studies are indispensable tools for basic and clinical research in functional genomics and target research. Here, we demonstrate a systematic method for generation of cell models with near perfect inducible KD rates.
Commercially available and in-house platforms for inducible RNAi were compared and a screening platform for highly active shRNAs developed. The screening platform was adapted to both, RNA Polymerase III- and RNA Polymerase II-dependent shRNA expression. Our fine-tuned combination of shRNA validation and viral vector design enable us to translate high knockdown rates (near 100%) into stable cell lines as well as primary cells, even in inducible systems.
These novel cell systems are likely to leverage cell-based models for target research and screening applications. As a case study we present the potent, inducible knockdown of a G-protein coupled receptor in HEK293 cells.

MAPK and PI3K activation in esophageal carcinomas

N.V. Michalopoulos[1], K.E. Tasioudi[2], S. Sakellariou[2], G. Levidou[2], P. Kontogianni[1], D. Theodorou[1], P. Korkolopoulou[2], E. Patsouris[2], A. Saetta[2]. [1]*Hippocratio Hospital Athens Medical School, 1st Department of Propaedeutic Surgery, Athens, Greece;* [2]*Medical School National and Kapodistrian University of Athens, 1st Department of Pathology, Athens, Greece*

Background: MAPK (Mitogen-Activated Protein Kinase) and PI3K (Phosphatidyloinositol 3- kinase) pathways play significant role in cell survival and have been implicated in various types of cancer including esophageal carcinomas (EC). The aim of our study was to investigate the possible prognostic significance of MAPK and PI3K pathways in EC in the Greek population.
Material and Methods: Forty four samples from patients with EC were screened for the presence of activating mutations at exons 18, 19, 20, 21 of EGFR gene, codons 12 and 13 of K-RAS gene, exon 15 of B-RAF gene, exons 9 and 20 of PIK3CA gene as well as exon 4 of AKT1 gene by High Resolution Melting Analysis and Pyrosequencing. In 29 cases immunohistochemistry was performed in order to evaluate expression levels of pERK (Extracellular − signal Regulated Kinase) and pAKT.
Results: The analysis of genomic DNA from 44 esophageal samples revealed no mutation in the examined genes except of a somatic K-RAS mutation at codon 12, which was detected in one laser microdissected squamous cell carcinoma. Elevated nuclear as well as cytoplasmic pERK (100% and 62% of cases) and pAKT (90.5% and 52% of cases) expressions were observed. Increasing pERK nuclear and cytoplasmic expression along with the intensity of nuclear staining was found to be significantly correlated with tumor grade in univariate and multivariate statistical analysis. In adenocarcinomas subgroup pAKT cytoplasmic expression was negatively correlated with stage.
Conclusions: Our current study demonstrates the presence of activated ERK and AKT despite the absence of upstream alterations (except one K-RAS mutation). ERK activation is a rather late event, contributing to the acquisition of a more aggressive phenotype in esophageal cancer while AKT activation appears more crucial during early stages in esophageal adenocarcinomas.

Tumor infiltrating B cells in primary cutaneous T-cell lymphomas correlate with disease progression and might represent a potential target for therapy

M. Von Bergwelt[1], M. Schlaak[2], P. Kurschat[2], R. Stadler[3], S. Theurich[4]. [1]*Uniklinik, Köln, Germany;* [2]*Uniklinik, Dermatology, Köln, Germany;* [3]*Klinikum Minden, Dermatology, Minden, Germany;* [4]*Uniklinik, Hematology, Köln, Germany*

B cells have been recently described to mediate tumor biology but so far their role as tumor promoting or tumor repressing lymphocyte population remains controversial. Mycosis fungoides (MF) and other primary cutaneous T cell lymphomas (CTCL) are characterized by an indolent course in early stages. However, advanced stage MF (⩾ EORTC Stage IIB) and the follicular MF subtype (FMF) as well as Sézary syndrome

(SS) show a more aggressive pattern with a median survival of less than two years. The pathogenesis of these more aggressive courses is still incompletely understood. Anecdotal reports have previously described CD20 positive cells in CTCL but further characterization of these cells have not been performed. We systematically analyzed the B cell infiltrate in paraffin samples of CTCL patients by immunohistochemistry (CD20 and CD79a) and correlated these data with the stage, subtype and clinical course. Advanced stage MF, FMF and SS samples contained significantly increased numbers of infiltrating B cells per lymphoma infiltrate. Moreover, time to progression showed a significant inverse relationship with the density of the B cell infiltrate. Based on our results, we hypothesized that infiltrating B cells might be a therapeutic target. In a 77-year old patient suffering from advanced stage FMF with a significant B-cell infiltration and progression after standard treatments, intralesional B-cell depletion with the anti-CD20 monoclonal antibody rituximab resulted in a sustained local tumor regression. In summary, we present first evidence on the potential tumor promoting role of infiltrating B cells in CTCL which warrants further study as a potential therapeutic strategy.

Spontaneous canine mast cell tumour as a model to study the correlations between infiltrating c-Kit positive cells and angiogenesis: possible translation for human cancer

R. Patruno[1], I. Marech[2], N. Zizzo[1], M. Ammendola[3], C. Gadaleta[1], G. Capriuolo[4], G. De Sarro[5], D. Ribatti[6], C. Damiano Gadaleta[2], G. Ranieri[2]. *[1]Veterinary Medical School University of Bari, Chair of Pathology, Bari, Italy; [2]National Cancer Research Centre "Giovanni Paolo II", Interventional Radiology Unit with Integrated Section of Translational Medical Oncology, Bari, Italy; [3]University of Catanzaro "Magna Graecia" Medical School, Chair of Clinical Surgery, Catanzaro, Italy; [4]ASL BAT, Department of Prevention and Animal Ealth, Barletta, Italy; [5]University of Catanzaro, Chair of Pharmacology, Catanzaro, Italy; [6]University of Bari, Department of Basic Medical Sciences Neurosciences and Sensory Organs, Bari, Italy*

Background: Canine cutaneous mast cell tumour (CMCT) is a c-Kit driven tumour that share similar c-Kit mutations found in human Gastro-Intestinal Stromal Tumour (GIST) and other human malignancies. CMCT is a common cutaneous tumour in dog, with an higher incidence than in human. It is classified in three subgroups, well and intermediately differentiated (G1 and G2), corresponding to a benign disease, and poorly differentiated (G3), corresponding to a malignant disease which metastasize to lymph nodes, liver, spleen and bone marrow.
Materials and Methods: In this study, we have evaluated c-Kit expression status, microvascular density (MVD), mast cell granulated and degranulated status density (MCGD and MCDD) and in a series of 97 CMCTs and we have correlated these parameters each to other, by means of histochemistry, immunohistochemistry double staining and image analysis system.
Results: Date show that diffuse cytoplasmic and focal paranuclear (Golgi-like) immunostaining c-Kit expression correlates with high MVD, G3 histopathological grade and MCDD. On the other hand, cell membrane c-Kit expression status correlates with low MVD, G1-G2 histopathological grade and MCGD.
Conclusion: We suggest that these findings may play a role as highlight the key role of c-Kit in the biopathology of canine MCTs indicating a link between aberrant c-Kit expression, increased angiogenesis and higher histopathological grade. Finally CMCT seems to be a useful model to study the role of c-Kit activated MCs in tumour angiogenesis and inhibition of MCs degranulation or activation by mean of novel c-Kit tyrosine kinase inhibitors might be a useful anti-tumour and anti-angiogenic strategy worthy to further investigations.

Continuous low-dose topotecan treatment selectively induces premature senescence in MYCN-amplified neuroblastoma cells in vitro and in vivo

S. Taschner-Mandl[1], M. Schwarz[1], I.M. Ambros[1], N. Frank[1], M. Hohenegger[2], P.F. Ambros[1]. *[1]C.C.R.I., Department for Tumour Biology, Vienna, Austria; [2]Medical University of Vienna, Institute of Pharmacology, Vienna, Austria*

Recurrent disease is a major challenge in high-risk neuroblastoma (NB), demanding new strategies for consolidation treatment. Previous reports have indicated that DNA-damage inducing drugs trigger a cellular program called premature senescence, a state of proliferative arrest, assumed to limit tumor growth *in vitro* and *in vivo*. We have shown that continuous, low-dose treatment with the chemotherapeutic drug hydroxyurea (HU) leads to senescence in primary NB-cell lines *in vitro*. In this study, we have explored, whether senescence can be induced by other low-dose chemotherapeutic drugs in primary *MYCN*-amplified NB-cell lines and in a xenograft mouse model and whether this will limit tumor growth and aggressiveness.
We found that camptothecin (CPT), a topoisomerase I-inhibitor, triggered apoptosis and senescence within 2−3 weeks when added to cultured primary NB-cells at a low concentration of 3−5 nM. CPT-treated NB-cells were G1/0-arrested and stained positive for the senescence-associated-beta-galactosidase. Importantly, HU- and CPT-treated senescent cells secreted less angiogenesis-, metastasis- and inflammation-associated factors, such as VEGF, MMP-9 and MCP-3, compared to the positive control, BrdU-treated NB-cells. However, HU- and CPT-treated cells expressed the favorable CD44, MHCI and activating NK/NKT-cell receptor ligands, which are absent on non-treated cells. For confirmation *in vivo*, topotecan (TPT), a CPT derivative, was injected i.p. at a clinically low dose of 0.1 mg/kg/d over 2 weeks daily in xeno-transplanted nude mice. Preliminary data suggest a higher frequency of senescent tumor cells, a reduction of tumor size and vascularization in TPT-treated mice. Furthermore, analysis of the gene expression profile of 3 CTRL and 3 TPT-treated tumors, revealed up-regulation of p21, CD44 − both up-regulated in senescent NB-cells *in vitro* - and ATRX, which has been associated with favorable outcome in NB patients. These *in vitro* and *in vivo* studies shall enable future clinical application of tumor cell senescence as therapeutic strategy.
No conflict of interest.

A phase 1 study of S-222611, an oral reversible dual tyrosine kinase inhibitor of EGFR and HER2, in patients with solid tumours

N. Cresti[1], D. Jodrell[2], T. Arkenau[3], M. Forster[4], K. Donaldson[5], J. Posner[5], I. Kawabata[5], R. Plummer[1], J. Spicer[6]. *[1]Northern Centre for Cancer Care, Newcastle upon Tyne, United Kingdom; [2]University of Cambridge, Department of Oncology, Cambridge, United Kingdom; [3]Sarah Cannon Research UK, London, United Kingdom; [4]University College Hospital, London, United Kingdom; [5]Shionogi & Co. Ltd., Osaka, Japan; [6]King's College London Guy's Hospital, London, United Kingdom*

Background: S-222611 is a novel, oral, reversible tyrosine kinase inhibitor of EGFR, HER2 and HER4 with potent and long lasting *in vitro* and *in vivo* pre-clinical activity. A dose-escalation study in patients (pts) has been completed and an expansion phase is on-going.
Material and Methods: Doses from 100 to 1600 mg daily were tested in the dose escalation in previously treated pts with solid tumours expressing EGFR or HER2 with expansion in selected tumours at 800 mg. Pharmacokinetics (PK) and pharmacodynamic assessment of serial tumour biopsies, were included. Responses (RECIST) were assessed by imaging at 8-week intervals.
Results: A total of 33 patients (24 male; aged 25−80 y) were included in the dose-escalation. S-222611 was generally well tolerated with two dose-limiting toxicities (rash at 1200 mg; diarrhoea at 1600 mg). A maximum tolerated dose was not defined. To date 17 patients (6 male; aged 32−75 y) have been included in the expansion phase. Diarrhoea was the most frequent toxicity in the 50 pts, but was rarely worse than grade 1/2. Nausea, rash, anorexia, vomiting and fatigue were also seen. Bilirubin rises with normal transaminases were observed.
Plasma concentrations increased with dose up to 800 mg, which was selected for the expansion. Steady state values of C_{max} and AUC_{0-24} at this dose are in the effective range of concentrations in mouse models. Average $t_{1/2}$ of 33 h is consistent with once daily dosing.
Tumour responses were seen over the full dose range tested (100–1600 mg). Of the 50 treated pts, there were 10 tumour responses, of which one was a clinical complete response (a pt with HER2 positive breast carcinoma previously treated with trastuzumab and lapatinib), 3 were partial responses (PRs) confirmed on repeat scans 2 months later, and 6 were unconfirmed PRs. The confirmed PRs were in HER2 positive breast and EGFR positive renal and oesophageal tumours and the 6 unconfirmed PRs were in breast and oesophageal tumours. An additional 3 pts with vaginal, pancreatic and gastric tumours showed stable disease for $\geqslant$26 weeks. Four pts have received treatment for more than 80 weeks.
Conflict of interest: *Other substantive relationships: Donaldson, Posner and Kawabata are all employees of Shionogi Ltd. Other authors have received funding to cover clinical trials costs only*

Administration of continuous/intermittent olaparib in ovarian cancer patients with a germline BRCA1/2 mutation to determine an optimal dosing schedule for the tablet formulation

J. Mateo[1], M. Friedlander[2], C. Sessa[3], K. Leunen[4], S. Nicum[5], C. Gourley[6], A. Fielding[7], K. Bowen[7], S. Kaye[1], L.R. Molife[1]. [1]*The Royal Marsden NHS Foundation Trust and Institute of Cancer Research, Sutton, United Kingdom;* [2]*Prince of Wales Hospital, New South Wales, Australia;* [3]*Oncology Institute of Southern Switzerland, Bellinzona, Switzerland;* [4]*University Hospitals Leuven, Leuven, Belgium;* [5]*Oxford University Hospitals NHS Trust, Oxford, United Kingdom;* [6]*Edinburgh Cancer Research Centre MRC IGMM University of Edinburgh Western General Hospital, Edinburgh, United Kingdom;* [7]*AstraZeneca, Macclesfield, United Kingdom*

Background: Initial studies with the oral PARP inhibitor olaparib identified 400 mg BID as a tolerable and efficacious dose requiring 16 capsules (CAP)/day. We report final results of a study aimed at identifying an optimal dose of the more practical tablet (TAB) formulation, for which we previously reported a dose-response relationship. An expansion cohort was recruited to this multistage Phase I trial to evaluate alternative administration schedules (NCT00777582; sponsor, AstraZeneca).
Materials and Methods: In this expansion cohort, patients (pts) with *BRCA1/2* mutation and relapsed ovarian or primary peritoneal cancer were randomized 1:1:1:1 to one of two continuous (cont; 200 mg TID, 400 mg QD) or two intermittent (int; 250 mg TID: 2 wks on/1 wk off; 400 mg BID: 1 wk on/1 wk off) schedules. Primary objective was safety and tolerability. Secondary objectives included antitumour effect. Results were compared with previously reported groups receiving 400 mg CAP BID, 400 mg TAB BID or 300 mg TAB BID (all cont; Molife *et al* ASCO 2010, 2012).
Results: 62 patients were randomized. Median lines of prior chemotherapy was 3 (range: 1−11). 6 pts (10%) discontinued treatment due to toxicity. The table shows key safety and antitumour effect data.
Conclusions: 400 mg BID TAB (int and cont) were not considered tolerable for long-term use. 250 mg TID (int) and 400 mg QD (cont) failed to match the efficacy seen in prior cohorts. 200 mg TID did not improve tolerability vs 300 mg BID, so 300 mg BID (cont) is the recommended tablet dose for Phase III studies in *BRCA1/2*-mutant ovarian cancer, including the maintenance therapy setting. These findings simplify olaparib administration from 16 CAP to 4 TAB per day.

MEDI4736, an anti-PD-L1 antibody with modified Fc domain: Preclinical evaluation and early clinical results from a phase 1 study in patients with advanced solid tumors

S. Khleif[1], J. Lutzky[2], N. Segal[3], S. Antonia[4], A. Blake-Haskins[5], R. Stewart[6], P. Robbins[7], A. Shalabi[8], R. Ibrahim[5], J. Wolchok[3]. [1]*Georgia Regents University, GRU Cancer Center, Augusta, USA;* [2]*Mount Sinai Medical Center, Oncology/Hematology, Miami Beach, USA;* [3]*Memorial Sloan-Kettering Cancer Center, Medicine, New York, USA;* [4]*H. Lee Moffitt Cancer Center and Research Institute, Thoracic Oncology, Tampa, USA;* [5]*MedImmune LLC, Clinical Development, Gaithersburg, USA;* [6]*MedImmune LLC, Research & Development, Gaithersburg, USA;* [7]*MedImmune LLC, Translational Sciences, Gaithersburg, USA;* [8]*MedImmune LLC, Product Development, Gaithersburg, USA*

Background: Tumors can evade immune detection by expressing the programmed cell death ligand 1 (PD-L1). Blockade of PD-L1 may help overcome immunosuppressive effects and restore T-cell activity against tumors. In nonclinical experiments, inhibition of PD-L1 was shown to produce durable antitumor activity as a single agent and in combination with other therapies. MEDI4736, a human monoclonal antibody that binds specifically to PD-L1, was engineered with a triple mutation in the Fc domain to abrogate Fc-mediated effector function, and is currently being evaluated in Phase 1 studies.
Materials and Methods: The properties of MEDI4736 were determined via *in vitro* assays, and anti-mouse PD-L1 was used in murine models of cancer to explore pharmacodynamic markers and combinations with other therapies. An ongoing Phase 1, multicenter, open-label study is evaluating the safety profile, pharmacokinetics, biomarkers, and antitumor activity of MEDI4736 administered IV in subjects with advanced solid tumors.
Results: MEDI4736 demonstrated potent and specific binding to PD-L1 with picomolar affinity. It blocks the interaction of PD-L1 with PD-1 and CD80 resulting in increased T-cell activation *in vitro*, but does not trigger cytokine release in whole blood assays. Three point mutations in the Fc domain have abrogated Fc-mediated effector function *in vitro*. Treatment of tumor-bearing mice with anti-mouse PD-L1 resulted in changes in peripheral immune markers and antitumor responses in a subset of mice. The combination of anti-mouse PD-L1 and CTLA-4 antibodies significantly enhanced this activity, leading to tumor regression in all mice treated.
As of 15 April, preliminary results from the Phase 1 study include 8 subjects (med. age 65 yrs, range 46−71), ECOG 0−1, with a median of 4 (3−10) prior treatments, received a median of 6 doses (1−13) of MEDI4736. No dose limiting toxicitites or drug-related grade ⩾3 adverse events were reported (no pneumonitis or colitis of any grade). An early signal of clinical activity was observed as evidenced by RECIST-based responses and prolonged disease stabilization in different tumor types, including patients with extensive disease. Tumor shrinkage was observed as early as 7 weeks and was sustained at subsequent time points.
Conclusions: Preliminary safety and clinical activity data for MEDI4736 are encouraging at the initial dose levels explored and warrant further investigation of this molecule alone and in combination with other therapies.
Conflict of interest: *Corporate-sponsored research: MedImmune sponsored the study. SK, JL, NS, SA, JW are investigators and received research funding for the conduct of the study. ABH, RS, PR, AS, RI are employees of MedImmune. Other substantive relationships: ABH, RS, PR, AS, RI own stock/stock options in Astrazeneca*

803 ORAL

Evaluation of tolerability and anti-tumor activity of GDC-0980, an oral PI3K/mTOR inhibitor, administered to patients with advanced solid tumors or non-Hodgkin's lymphoma (NHL)

S. Dolly[1], J.C. Bendell[2], H.L. Kindler[3], J.O. Lauchle[4], L.M. Krug[5], T.Y. Seiwert[3], H.A. Burris[2], J.S. DeBono[1], A.J. Wagner[6]. [1]*Royal Marsden Hospital and Institute of Cancer Research, Drug Development Unit and Cancer Therapeutics, Sutton, United Kingdom;* [2]*Sarah Cannon Research Institute, Medical Oncology, Nashville TN, USA;* [3]*University of Chicago, Medical Center, Chicago IL, USA;* [4]*Genentech Inc., Exploratory Clinical Development, South San Francisco CA, USA;* [5]*Memorial Sloan-Kettering Cancer Center, Department of Medicine Thoracic Oncology Service, New York NY, USA;* [6]*Dana-Farber Cancer Institute, Medical Oncology, New York NY, USA*

Background: The PI3K-AKT-mTOR signaling pathway is dysregulated in a wide variety of cancers. GDC-0980 is a potent and selective oral dual inhibitor of class I PI3K and mTOR kinases that demonstrates broad activity in various xenograft cancer models.
Materials and Methods: A phase I dose-escalation study, PIM4604g, was conducted in 2 Stages: Stage 1 evaluated oral, daily (QD) doses of 2−70 mg GDC-0980 in a 3+3 design. Stage 2 evaluated 30 mg and 40 mg GDC-0980 QD. Safety and tolerability of GDC-0980 was assessed, as well as pharmacokinetics (including proton pump inhibitor (PPI) interaction), pharmacodynamic (PD) assessment of PI3K pathway inhibition and PIK3CA mutations, and anti-tumor activity.
Results: 113 patients were enrolled, 57 in Stage 1 and 56 in Stage 2. The MTD was 50 mg QD. DLTs were Grade 3 rash and symptomatic Grade 3 hyperglycemia at 70 mg QD. Grade $\geqslant$3 pneumonitis was observed in 3 patients in Stage 1 at doses of $\geqslant$40 mg, including 1 mesothelioma patient with Grade 5 pneumonitis. Based on Stage 1 tolerability data, a recommended phase 2 dose of 40 mg QD was evaluated in Stage 2 for all tumor types, with the exception of malignant pleural mesothelioma (MPM) where the recommended dose was 30 mg QD. The most frequent Grade $\geqslant$3 drug-related adverse events (AEs) at 30 mg and 40 mg GDC-0980 were hyperglycemia (15%), rash (12%), diarrhea (8%) fatigue and abnormal LFTs (7%), and pneumonitis (6%), and 17% of the patients discontinued due to an AE (4% at 30 mg, 24% at 40 mg). The exposure of GDC-0980 was dose-proportional and no interaction with the PPI rabeprazole was detected at 40 mg GDC-0980. RECIST anti-tumor activity was observed in Stage 1 at GDC-0980 doses of 8−50 mg, with 2 PRs (MPM patients, 1 at 50 mg and 1 with a PIK3CA mutation at 8 mg). At the recommended phase 2 dose, 2 PRs for MPM patients at 30 mg and 1 PR for a head and neck cancer patient with a PIK3CA mutation at 40 mg were observed. GDC-0980 doses of $\geqslant$16 mg demonstrated significant PI3K pathway inhibition (pAKT and insulin/glucose levels). Additionally, pathway inhibition by FDG-PET responses was observed in 50% of the patients.
Conclusions: GDC-0980 was generally well-tolerated at the recommended phase 2 doses of 30 mg and 40 mg. Significant PI3K pathway inhibition was observed in PD assays at doses of $\geqslant$16 mg. Anti-tumor activity has been observed at the recommended phase 2 doses. Updated data on clinical outcomes and biomarker correlates will be presented.

804 ORAL

Phase Ib study of oral pan-PI3K BKM120 in combination with the oral MEK1/2 inhibitor GSK120212 in patients with selected advanced solid tumors and RAS / BRAF mutations

F. Janku[1], A. Stathis[2], J. Pérez-García[3], Z. Wainberg[4], L. Paz-Ares[5], J. Vansteenkiste[6], E. Van Cutsem[7], N. Le[8], A. Zubel[9], P. Bedard[10]. [1]*The University of Texas MD Anderson Cancer Center, Oncology, Houston, USA;* [2]*Oncology Institute of Southern Switzerland, Oncology, Bellinzona, Switzerland;* [3]*Vall d'Hebron University Hospital, Oncology, Barcelona, Spain;* [4]*UCLA University of California, Oncology, Los Angeles, USA;* [5]*Hospital Universitario Virgen del Rocio, Oncology, Seville, Spain;* [6]*UZ KU Leuven, Respiratory Oncology, Leuven, Belgium;* [7]*UZ KU Leuven, Digestive Oncology, Leuven, Belgium;* [8]*GlaxoSmithKline, Collegeville PA, USA;* [9]*Novartis Pharma AG, Basel, Switzerland;* [10]*Princess Margaret Hospital, Oncology, Toronto Ontario, Canada*

Background: MAPK and PI3K/AKT/mTOR pathways regulate proliferation, differentiation and cell death in different human cancers. A cross-talk interaction between these two pathways provides the rationale for combining PI3K and MEK inhibitors.
Methods: Primary objective of this phase Ib trial is to determine the maximum tolerated dose (MTD) and/or recommended phase II dose (RP2D) for daily oral administration of the PI3K inhibitor BKM120 with the MEK inhibitor GSK1120212. Secondary objectives include safety, tolerability, pharmacokinetics and efficacy.
In dose escalation part, patients (pts) with *RAS*/*BRAF* mutated (mt) solid tumors, pancreatic cancer or triple negative breast cancers were enrolled. A Bayesian logistic regression model with overdose control guided dose escalation was utilized. In dose expansion part, pts with RAS/BRAF mt ovarian, pancreatic and non-small cell lung cancer (NSCLC) were enrolled.
Results: As of June 2012, 75 pts were treated with BKM120 + GSK1120212 and have been evaluated for safety, 66 in dose escalation and 9 in dose expansion part. The MTD was reached at 70 mg BKM120 + 1.5 mg GSK1120212. The dose was later reduced due to adverse events (AEs) to 60 mg BKM120 + 1.5 mg GSK1120212, the RP2D. Most frequent AEs (>25%) irrespective of relationship, were diarrhea (60%), dermatitis acneiform (57%), nausea (42%), vomiting, CK elevation (39% each), asthenia (33%), reduced appetite (31%), pyrexia, stomatitis (29% each), maculopapular rash (27%), hyperglycemia and rash (25% each). The most common grade 3/4 AEs (>5%) irrespective of relationship were CK elevation, maculo-papular rash (12% each), ALT increase (9%), AST increase, thrombocytopenia (8% each), stomatitis (7%), diarrhea, acneiform rash, macular rash and acute renal failure (5% each). No deaths were related to treatment. 28 (37%) pts had treatment discontinuation and 48 (64%) dose reductions/delays dues to AEs. As of February 2013, 21 KRAS/ BRAF mt ovarian cancer pts have been treated and 19 were evaluable ($\geqslant$1 post-treatment tumor assessment) for response. 7/19 (37%) evaluable pts achieved a best overall response (BOR) of partial response (confirmed in 6 of them) and 9 had a stable disease (SD). 19/24 pancreatic pts were evaluable for efficacy and 12/19 achieved a BOR of SD. For the 17 NSCLC pats, 11 pts were evaluable and 7 had a BOR of SD.
Conclusions: BKM120 and GSK1120212 can be safely combined. Promising clinical activity has been observed in pts with KRAS/BRAF mt ovarian cancer.

805 ORAL

Final results of a first-in-human clinical trial of OSI-027, a small molecule dual mTORC1/mTORC2 inhibitor in patients with advanced malignancies

P. Schöffski[1], J. Mateo[2], D. Olmos[3], S. Barr[4], S. Poondru[5], J. Van Tornout[6], H. Dumez[7], P.M. LoRusso[8], S.B. Kaye[2]. [1]*Leuven Cancer Institute University Hospitals Leuven and KU Leuven, Department of General Medical Oncology and Department of Oncology, Leuven, Belgium;* [2]*The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research, Drug Development Unit, Sutton, United Kingdom;* [3]*formerly of The Royal Marsden NHS Foundation Trust and The Institute of Cancer Research, Drug Development Unit, Sutton, United Kingdom;* [4]*OSI Pharmaceuticals a wholly owned subsidiary of Astellas US LLC, Translational Research, Farmingdale, USA;* [5]*Astellas Pharma Global Development Inc., Global Clinical Pharmacology and Exploratory Development, Northbrook, USA;* [6]*Astellas Pharma Global Development Inc., Global Medical Oncology, Northbrook, USA;* [7]*University Hospitals Leuven, Department of General Medical Oncology, Leuven, Belgium;* [8]*Karmanos Cancer Institute, Experimental Therapeutics, Detroit, USA*

Background: OSI-027 is an orally available selective inhibitor of mTORC1 and mTORC2. We report a phase I trial to evaluate its safety, tolerability, pharmacokinetics (PK), maximum tolerated dose (MTD) and pharmacodynamics (PD) in tumor and surrogate tissues. (NCT00698243; sponsor Astellas Pharma Inc).
Material and Methods: Patients (pts) with refractory malignancies, ECOG performance status $\leqslant$2 and adequate organ function were enrolled in one of 3 administration schedules (S); S1: once daily for 3 of every 7 days (qd 3/7d), S2: once weekly (qwk) or S3: continuous qd, in 21-day cycles. Dose limiting toxicities (DLT) were assessed in cycle 1 (CTCAE v3). Dose escalation was pursued for each schedule with a 3+3 design. Safety and PK were studied after single and multiple dosing. PD analyses were performed in expansion cohorts using paired pre/post-dose tumor biopsies.
Results: 123 pts were treated (S1−54pts, S2−39pts, S3−30pts). Main tumor types were colorectal (n = 32), melanoma (12) and renal (11). Doses ranged from 10–480 mg per week (S1:10–160 mg qd 3/7d; S2:10–240 mg qwk; S3:5−50 mg qd). DLTs were grade (G) 3 fatigue (n = 4), G2 elevated

serum creatinine (2), G3 cardiomyopathy (1), G2 decreased left ventricular ejection fraction (1), G3 hyperglycemia (1), G3 rash (1) and G3 bone pain (1). The MTD for S1 is 120 mg qd 3/7d. Dose escalation in S2 was limited due to high burden of capsules required; no MTD was identified. The MTD for continuous dosing (S3) is 35 mg qd; however, schedule was halted due to renal toxicity, showing insufficient PD inhibition at tolerable dose-levels. G $\geqslant$3 adverse events (AE) included G3 fatigue (n = 6), G3 diarrhea (2), G3 nausea/vomiting (2), G4 myocardial infarction (1) and G5 acute renal failure (1). Expansion cohorts were initiated for S1 at 90 mg and 120 mg based on safety data. 5/13 (38%) pts in S1–120 mg required a dose-reduction or discontinuation due to AE. C_{max} and AUC were dose-linear. PD inhibition was associated with drug exposure, with the most substantial inhibition in tumor biopsies seen at the highest doses. Stable disease (RECIST 1.0) after 24 weeks was seen in 5 pts, including 1 pt with GIST (exons 11 and 17 KIT mut) who was on treatment 45 weeks.
Conclusions: OSI-027 inhibits mTORC1/2 in a dose-dependent manner. The most significant AEs were fatigue, renal and cardiac events. Intermittent schedules were better tolerated. S1–120 mg qd 3/7d achieved substantial target inhibition but was not tolerated by a proportion of patients.
No conflict of interest.

806 POSTER

A new approach to integrate the grade of toxicity and later cycles in the analysis and reporting of phase I dose finding trials

A. Doussau[1], R. Thiebaut[1], B. Geoerger[2], M.C. Le Deley[3], P. Schöffski[4], A. Floquet[5], S. Mathoulin-Pélissier[6], E. Rizzo[7], P. Fumoleau[8], X. Paoletti[9]. *[1]Inserm U 897- Université Victor Segalen, Case 11, Bordeaux, France; [2]Institut Gustave Roussy CNRS UMR8203 University Paris-Sud XI, Department of Pediatric and Adolescent Medicine, Villejuif, France; [3]Institut Gustave Roussy University Paris-Sud XI, Biostatistics and Epidemiology Department, Villejuif, France; [4]University Hospitals Leuven KU Leuven, Department of General Medical Oncology and Laboratory of Experimental Oncology, Leuven, Belgium; [5]Institut Bergonié, Service d'oncologie gynécologique, Bordeaux, France; [6]Institut Bergonié INSERM CIC-EC7, Unité de Recherche et Epidémiologie Clinique, Bordeaux, France; [7]EORTC, Statistics Department, Brussels, Belgium; [8]Centre de Lutte contre le Cancer Georges-François Leclerc, Department of Medical Oncology, Dijon, France; [9]Institut Curie INSERM U900, Service Biostatistique, Paris, France*

Background: In oncology, the maximum tolerated dose (MTD) is commonly defined as the dose of a given treatment associated with a certain level of dose limiting toxicities (DLT), evaluated during a predefined time window, typically one or two cycles of treatment. Adverse events (AE) are usually assessed sequentially, using NCI-CTCAE grading criteria. Our working hypothesis is that the longitudinal assessment of AEs can provide relevant additional information for defining the optimal dose and schedule of a new treatment. To illustrate our approach, we retrospectively reanalysed three phase I clinical trials of anticancer agents.
Material and Methods: We developed a new dose-finding method that uses all the data collected at the end of the trials. A mixed effect proportional odds model was used to account for repeated measurements. We collected individual patient data from two continual reassessment method phase I clinical trials (aviscumine in solid tumours and erlotinib with radiotherapy in brainstem gliomas). A third trial was included (classical 3+3 design of DoxLipeg + cyclophosphamide in ovarian carcinoma). The outcome of interest was the worst grade (G) of toxicity in each cycle, using three grading categories (G0−1/G2/G3−5). We estimated the probability of G2−5 and G3−5 toxicity per cycle for each evaluated dose level. We defined the dose associated with a per cycle probability of severe toxicity close to 20% as the recommended phase II dose. The risk of toxicity over time was also investigated.
Results: In the three trials a total of 83 patients were included and treated at 14, 3 and 5 dose levels, respectively. In the first two trials, four and two DLT occurred respectively; 94 and 96 cycles were administered (worst grade: 38 G2, 22 G3 AEs; 19 G2, 7 G3−5 AEs, respectively). No increased risk of toxicity was detected with time for the first two trials. We could not disentangle late toxic AEs from cumulative AEs as time is confounded with cumulative dose. The per cycle risk of G3−5 toxicity was slightly lower with the mixed effect proportional odds model analysis, as compared to an analysis restricted to the first cycle. Analysis of the third trial is in process.
Conclusions: Dedicated methods, whose operating characteristics were evaluated elsewhere, allows for analysing toxic adverse events from all cycles of treatment. They should be integrated in recommended phase II dose assessment.
No conflict of interest.

807 POSTER

Investigating the antiproliferative activity of high affinity DNA aptamer on cancer cells

H. Kaur[1], J.J. Li[2], B.H. Bay[3], L.Y.L. Yung[1]. *[1]National University of Singapore, Chemical and Biomolecular Engineering, Singapore, Singapore; [2]National University of Singapore, Chemical and Biomolecular Engineering and Yong Loo Lin School of Medicine, Singapore, Singapore; [3]National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore*

Background: The purpose of the study is to investigate the antiproliferative activity of SL_2-B aptamer on cancer cells.
Materials and Methods: *Surface plasmon resonance (SPR)*: The binding affinity of SL_2-B aptamer sequence was investigated using SPR, where $VEGF_{165}$ acted as ligand. The binding analysis was carried out with aptamers at different concentrations and sensorgrams were analysed in BIAevaluation software to calculate the equilibrium dissociation constant K_d.
Antiproliferative activity: SL_2-B aptamer was incubated with Hep G2 cells for 3 days in hypoxia conditions. The antiproliferative effect was determined using MTT assay. For flow cytometry, after 3 days of aptamer treatment, the cells were incubated with anti-human Jagged-1 fluorescein antibody for 1 hr and analysed using flow cytometry.
Results: *Binding analysis by SPR*: Due to presence of nucleases, the unmodified aptamer exhibits low structural stability in the cellular conditions. To alleviate this problem, the SL_2-B aptamer was chemically modified with phosphorothioate (PS) linkages at 5′ and 3′-terminus. The K_d value for the PS-modified SL_2-B was found to be 0.56nM, which is similar to K_d for unmodified. Introducing PS-modification does not appear to affect the binding affinity of the aptamer.
Antiproliferative activity: Lower cell proliferation was observed at 15μM modified SL_2-B concentration after 72 hrs of aptamer treatment (52±2.1%). On the contrary, the unmodified sequence did not exhibit significant inhibitory activity on cellular proliferation. This could be due to the degradation of the unmodified sequence by nuclease enzymes in the media before pronouncing its effect. The incubation of cells with scrambled sequence showed minimal decrease on the cell proliferation, confirming that the inhibitory effect by modified SL_2-B was sequence specific. Due to the crosstalk between VEGF and notch signalling pathways in tumour progression, the effect of PS-modified SL_2-B aptamer was tested on Jagged-1, which is one of the notch ligands via flow cytometry. Compared to the untreated sample, modified SL_2-B exhibited decrease in the fluorescent signal indicating the downregulation of Jagged-1 expression in Hep G2 cells. In western blotting, the modified aptamer appears to induce lower expression of the Jagged-1 protein in Hep G2 cells as compared to the scrambled sequence. This confirms the sequence specific inhibition of the aptamer. Based on these results, it can be concluded that the binding of modified SL_2-B to VEGF exhibits its antiproliferative activity in Hep G2 cells not only by inhibiting VEGF pathway but also the interconnected notch signalling pathway.
Conclusions: From the data, we conclude that post-modification, the PS-modified SL_2-B aptamer retained its binding affinity and exhibited sequence specific antiproliferative activity on Hep G2 cancer cells. Hence, it appears that chemical modification can be a useful approach in prolonging the half-life of SL_2-B aptamer in the *in vitro* conditions.

808 POSTER

Capillary morphogenesis gene 2 is a potential target for anti-angiogenic therapy

L. Ye[1], M. Mason[2], W.G. Jiang[2]. *[1]Cardiff University School of Medicine, Cardiff, United Kingdom; [2]Cardiff University School of Medicine, Institute of Cancer and Genetics, Cardiff, United Kingdom*

Background: Capillary morphogenesis gene 2 (CMG2) was identified as a gene being up-regulated in capillary morphogenesis. It is also known as a receptor of anthrax toxin. It has been shown to be involved in the cell adhesion and motility of various cell types, including epithelia and endothelia. Present study aims to examine to investigate the therapeutic potential of targeting CMG2 to prevent tumour related new vasculature.
Materials and Methods: Full-length of human CMG2 gene and different fragments of the same gene were amplified and constructed into a mammalian expression plasmid vector. The effect of CMG2 and its different fragmented protein products on functions of vascular endothelial cells was examined using various *in vitro* and *ex vivo* angiogenesis models, and *in*

vivo tumour growth which including tubule formation of endothelial cells, aorta ring assay and xenograft mouse model.
Results: The overexpression of CMG2 enhanced the adhesion of endothelial cells to extracellular matrix, but was negatively associated with cell migration. Over-expression of certain fragments (extracellular domains) inhibited the tubule formation and migration of endothelial cells. Small peptides mimicking the amino acid sequence of the fragments potently inhibit the *in vitro* tubule formation and *ex vivo* angiogenesis. Tests of certain small peptides showed an inhibitory effect on in vivo tumour growth of cancer cells which we have examined.
Conclusion: CMG2 is a potential target for treating tumour related angiogenesis. Small peptides mimicking the extracellular domain of CMG2 can potently inhibit the in vitro and ex vivo angiogenesis, which may contribute to its inhibitory effect on in vivo tumour growth. The mechanisms underlying require further investigation.

809 POSTER

Safety and efficacy of bevacizumab as front-line treatment of brain metastases from solid tumors

F. Zustovich[1], A. Ferro[1], P. Farina[1], G. Lombardi[1], V. Zagonel[1]. [1]*Veneto Institute of Oncology IOV − IRCCS, Oncologia Medica 1, Padova, Italy*

Background: B is approved for the treatment of advanced colorectal, lung, kidney, breast cancers and high-grade gliomas. Despite the large employment of B in the treatment of brain primitive tumors, there is only a very limited experience with BM and none in the treatment of previously untreated secondary brain lesions.
Material and Methods: We have treated the patients (PTS) with BM not suitable for local treatment with a B-based therapy associated with chemotherapy or INF-alfa as indicated for the primary cancer type.
Results: From March 2010 to June 2012 we collected 18 PTS with BM mostly from lung and renal adenocarcinoma and the majority of patients had a treatment-naive brain disease (see table). B has proved to be safe and effective: RR was 82% of PR with 18% of SD. PFS was 14 months (95% CI: 3.0–25.0) and OS was 15 months (95% CI: 3.7–26.3). Moreover, B has a high capability to give clinical benefit in PTS with BM, mostly reducing perilesional edema, sometimes with a long lasting effect. The general toxicity we detected was the same as known in clinical practice: no cerebral hemorrhagic events were reported, even if two cases of cerebral ischemia and 1 of gastric perforation were recorded.
Conclusion: B for BM is feasible and safe and the efficacy data are very promising.
No conflict of interest.

810 POSTER

Phase 1b study of multiple dosing schedules of pazopanib in combination with epirubicin or doxorubicin in patients with advanced solid tumors

A. Fasolo[1], C. Sessa[2], L. Viganò[1], A. Locatelli[1], D. Hess[3], K. Homicsko[4], G. Capri[5], B. Suttle[6], H. Tada[7], L. Gianni[1]. [1]*Ospedale San Raffaele IRCCS, Medical Oncology, Milan, Italy;* [2]*Istituto Oncologico della Svizzera Italiana, Medical Oncology, Bellinzona, Switzerland;* [3]*Kantonsspital Department of Internal Medicine, Oncology/Hematology, St. Gallen, Switzerland;* [4]*Service of Medical Oncology, Department of Oncology CHUV, Lausanne, Switzerland;* [5]*Istituto Nazionale dei Tumori, Oncology, Milan, Italy;* [6]*GlaxoSmithKline, Oncology, Research Triangle Park, USA;* [7]*GlaxoSmithKline, Oncology, Collegeville, USA*

Background: Pazopanib (PAZ) is an oral, multitargeted inhibitor of VEGFR-1/2/3, PDGFR-α/β, and c-Kit. Optimal dose and schedule for combining PAZ with epirubicin (EPI) and doxorubicin (DOX) need to be established.
Methods: Part 1 of the VEG109603 trial explored PAZ+EPI in dose-escalation cohorts to define the optimally tolerated regimen (OTR) for 3 concomitant dosing schedules (21-day [d] cycles): Arm A (PAZ d1−21, EPI d3); Arm B (PAZ d1−8, EPI d3); Arm C (PAZ d14−21, EPI d1). The OTR of each schedule was further evaluated in 3 concomitant cohorts of up to 12 patients (pts) to select the regimen for Part 2, which combined PAZ+DOX (Arm D) based on safety and tolerability results. Blood samples were obtained for pharmacokinetic and pharmacodynamic analysis.
Results: Overall, 111 pts were treated, including 65 pts in the OTR cohorts. The OTRs were PAZ 400 mg/EPI 75 mg/m^2 (Arm A), PAZ 800 mg/EPI 90 mg/m^2 (Arms B and C). Dose-limiting toxicities (DLTs) were evaluated during the first and subsequent cycles to assess prolonged feasibility. In the dose-escalation cohorts, DLTs included grade (Gr)4 neutropenia, Gr3 nausea/vomiting/dehydration, and Gr3 deep vein thrombosis. In the PAZ+EPI OTR cohorts, DLTs included Gr4 neutropenia, Gr4 pulmonary thrombosis, and Gr4 febrile neutropenia. The most common adverse events (AEs; any Gr) in all cohorts were neutropenia, nausea, and asthenia, and the most common Gr⩾3 AEs were neutropenia and leukopenia. Tolerability of PAZ+EPI worsened with repeated doses. Based on the safety profile of Part 1, the Arm B dosing schedule was selected for PAZ+DOX in Part 2, which defined the OTR as PAZ 800 mg/DOX 60 mg/m^2. DLTs in Arm D included Gr4 neutropenia, Gr5 febrile neutropenia, and Gr1 LVEF decrease. Neutropenia and leukopenia were the most common Gr⩾3 AEs.
Pharmacokinetic analysis showed that EPI may increase exposure to PAZ ($AUC_{(0-24)}$ and C_{max} were ~18% greater when PAZ was administered concomitantly with EPI in Arm A). PAZ did not significantly interfere with EPI disposition. In the PAZ+EPI OTR cohorts, 11 evaluable pts had best response as partial response: 2 (13%) in Arm A; 3 (16%) in Arm B; and 6 (38%) in Arm C. In the PAZ+DOX OTR cohort (Arm D), there was 1 complete (7%) and 1 partial response (7%).
Conclusions: The OTRs of PAZ+EPI and PAZ+DOX were PAZ 800 mg d1−8 plus EPI 90 mg/m^2 or DOX 60 mg/m^2 d3 of a 21-d cycle. These regimens showed an acceptable safety profile and should be considered for further evaluation.

811 POSTER

Omega-3 polyunsaturated fatty acids-derived drugs as potential anti-angiogenic treatment for solid tumours

N. Petrovic[1], K. Hoang[1], M. Murray[2]. [1]*University of South Australia, Pharmacy and Medical Science, Adelaide SA, Australia;* [2]*University of Sydney, Faculty of Pharmacy, Sydney NSW, Australia*

Background: Polyunsaturated fatty acids (PUFA) can be divided into n-6 and n-3 PUFA depending on the position of the first double bond. Although n-3 PUFAs are found to be cancer-suppressing, n-6 PUFAs are disease-promoting. Mechanisms of such effects are still unknown. Both n-3 and n-6 PUFA undergo bio-conversion by two major enzymes: cyclooxygenases and cytochrome P-450s. Potential reason for different activity of n-3 and n-6 PUFA-derived metabolites could be related to the observed conformational differences between these two fatty acid types and mediators derived from them.
Angiogenesis (creation of new blood vessels from the existing vasculature) is very important process in tumour growth. In this work we have assessed effects of two major classes of n-3 PUFA metabolites: a) cyclooxygenase-2 (COX-2)-derived and b) cytochrome P-450, subgroup 2J2 (CYP2J2)-derived products. PUFA products of these two enzymes have been implicated in regulation of angiogenesis.
Material and Methods: Four types of MDA-MB-468 (human breast cancer cells) clones were constructed by permanent transfection with either control or plasmids expressing COX-2, CYP2J2 or both. These clones were incubated with n-3 PUFA (Eicosapentaenoic acid) and medium or extract from these cells was tested for suppression of two angiogenic processes *in vitro* using human umbilical vein endothelial cells (HUVEC): 1) Tube formation assay and 2) Migration assay. Tube formation assay consisted of observing formation of vascular precursors or 'tubes' after plating HUVEC on the layer of artificial extracellular matrix (Matrigel). HUVEC migration was investigated using our unique 'Matrigel droplet' assay.
Results: Our findings suggest that both types of mediators derived from n-3 PUFA inhibit angiogenesis. COX-derived metabolites suppress both EC

migration and tube formation whereas CYP2J2-derived mediators suppress only tube formation.
Conclusions: Our results provide evidence that both COX-2 and CYP2J2 derived n-3 PUFA metabolites suppress angiogenesis *in vitro* and new molecules derived from them could serve as future anti-cancer therapeutics.
No conflict of interest.

812 POSTER

Phase 1 dose-escalation study of E7820, a novel anti-angiogenic agent, administered orally twice-daily to patients with advanced, refractory solid tumors

R. Kristeleit[1], R. Plummer[2], M. Ranson[3], S. Slater[4], P.O. Witteveen[5], L. Reyderman[6], B. De las Heras[7], D. Verbel[8], B. Ink[7], J.H.M. Schellens[9]. *[1]UCL Cancer Institute, London, United Kingdom; [2]Sir Bobby Robson Cancer Trials Research Centre, Medical Oncology, Newcastle, United Kingdom; [3]The Christies NHS Foundation Trust, Department of Medical Oncology, Manchester, United Kingdom; [4]Beatson West of Scotland Cancer Centre, Medical Oncology, Glasgow, United Kingdom; [5]University Medical Center Utrecht, Department of Medical Oncology, Utrecht, Netherlands; [6]Eisai Inc., Clinical Pharmacology and Translational Medicine, Woodcliff Lake NJ, USA; [7]Eisai Ltd, Oncology, Hatfield, United Kingdom; [8]Eisai Inc., Biostatistics, Woodcliff Lake NJ, USA; [9]Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Division of Molecular Pathology, Amsterdam, Netherlands*

Background: E7820 is a novel sulfonamide derivative with potent anti-angiogenic activity based on the inhibition of endothelial cell proliferation and tube formation. The antitumor effects of E7820 were associated with inhibition of integrin alpha2 expression in endothelial cells *in vitro*. E7820 MTD for single daily administration was achieved at 100 mg. PK/PD analysis integrating preclinical and clinical data showed that twice-daily (BID) dosing results in a greater reduction of integrin alpha2 expression. BID dosing may also ameliorate toxicity associated with high maximum plasma concentration (Cmax) and may allow a greater total daily dose and drug exposure. This Phase 1 study was performed to determine MTD, safety and PK of E7820 following BID dosing.
Patients and Methods: Patients (pts) with advanced solid tumors, ECOG 0−1, ⩾18 years (yrs) and adequate organ function were eligible. E7820 was administered orally, BID continuously in 28 day cycles. Blood samples for PK analysis were collected on Day 1 and Day 8 over 12 hr post dose.
Results: 24 pts (M/F: 18/6; median age 57 yrs (range 38−77) were treated at 50 and 60 mg. Tumor types were colorectal (n = 8), renal (n = 3), GIST (n = 2), and others (n = 11). DLTs were observed in 2 pts at 60 mg BID and included Gr 3−4 leukopenia, Gr 3 neutropenia and neutropenic sepsis and Gr 3 fatigue. MTD was determined to be 50 mg BID. Frequently occurring adverse events ([AEs] all grades with ⩾10% incidence) were fatigue (42%), constipation (33%), diarrhea, nausea and vomiting (29% each), abdominal pain (25%) and dyspepsia (17%). E7820 exposure was dose-related with Cmax observed 0.5−5 hr post-dose. BID E7820 dosing resulted in 1.6−3.8 fold accumulation on multiple dosing. The highest E7820 exposure and highest accumulation (R=3.31, 3.38) was observed on day 8 in subjects who experienced DLTs. Cmax values in patients who had DLTs were comparable to those in other subjects in this dose cohort. The best overall response observed was stable disease.
Conclusions: E7820 at an MTD of 50 mg BID has manageable toxicity. DLTs were associated with high E7820 exposure, but not with Cmax. Twice-daily dosing of E7820 does not appear to offer a better toxicity profile compared to daily administration.

813 POSTER

Allosteric inhibition of FGFR2 affects angiogenesis and cancer cell proliferation

E. Stepanova[1], E. Solomko[1], N. Peretolchina[1], O. Ryabaya[1], D. Khochenkov[1], I. Tsimafeyeu[2], M. Byakhov[3], S. Tjulandin[4]. *[1]N.N. Blokhin Russian Cancer Research Center, Laboratory of Tumor Angiogenesis, Moscow, Russian Federation; [2]Kidney Cancer Research Bureau, Moscow Office, Moscow, Russian Federation; [3]Russian Railways Cancer Center, Medical Oncology, Moscow, Russian Federation; [4]N.N. Blokhin Russian Cancer Research Center, Clinical Pharmacology and Chemotherapy, Moscow, Russian Federation*

Background: The recent identification of fibroblast growth factor receptor 2 (FGFR2) overexpression or mutations in different cancer types has generated an opportunity for a novel target-based therapy. Here we explore the effects of allosteric inhibition of FGFR2 on angiogenesis and cancer cell proliferation.
Material and Methods: To assess the efficacy of RPT835, novel extracellular allosteric inhibitor of FGFR2 (RusPharmTech, LLC) on FGF-mediated cell proliferation, endothelial cells (SVEC-4−10), human umbilical vein endothelial cells (HUVEC), and breast cancer (T47D), gastric cancer (Kato III), lung cancer (A549) FGFR-expressing cells were incubated in a 96-well microculture plate and were treated with serially diluted RPT835. Brivanib was used as a control. Basic FGF was added at a concentration of 25 ng/ml. Control wells were left untreated. Cell growth inhibition was determined using Promega's Cell Titer-Glo® assay. SVEC-4−10 cell migration was evaluated in the Boyden Chamber assay. In vivo angiogenesis was measured with subcutaneously implanted Matrigel plugs containing bFGF (100 ng/ml) or bFGF (100 ng/ml) + RPT835 (15 mg/kg). Negative control group was without stimulation and treatment. Number of endothelial cells/vessels was calculated.
Results: Basic FGF significantly increased proliferation of the HUVEC, SVEC-4−10 and cancer cells in untreated control group (P = 0.001). RPT835 significantly inhibited FGF-triggered endothelial cell proliferation when compared with control (P<0.001) or brivanib (P<0.001, IC50=289 nmol/L) with IC50 of 11 nmol/L (HUVEC) and 10 nmol/L (SVEC-4−10). RPT835 significantly decreased proliferation of A549 (IC50=10 nmol/L) as well as T47D (IC50=0.97 umol/L) cells. There was no impact on Kato III cells (IC50 >10 umol/L). In Boyden Chamber assay, RPT835 reduced endothelial cell migration up to 60%. In vivo, bFGF induced proliferation of endotheliocytes and mature vessels formation (P<0.001). There were no vessels in FGFR2 inhibitor and negative control groups.
Conclusions: Allosteric inhibition of FGFR2 affects endothelial and cancer cell proliferation, migration as well as mature vessel formation.
No conflict of interest.

814 POSTER

The pterocarpanquinone LQB118 alters the subcellular localization of Nrf2 and reduces XIAP expression sensitizing acute myeloid leukemia cells to apoptosis

F.R.S. Reis[1], P.R.R. Costa[2], R.C. Maia[1]. *[1]Laboratório de Hemato-oncologia Celular e Molecular, Instituto Nacional de Câncer, Rio de Janeiro, Brazil; [2]Laboratório de Química Bio-orgânica (LQB), NPPN CCS UFRJ, Rio de Janeiro, Brazil*

Background: Despite advances in chemotherapy, the five-year survival rate for patients with acute myeloid leukemia (AML) is about 20%. There have been efforts in recent years to establish new antileukemic drugs with decreased side effects and lower toxicity to healthy cells of AML patients. Pterocarpanquinone LQB118 [2-hydroxy-3-(3-methyl-2-butenyl)-1,4-naphthoquinone] has emerged as a promising molecule for therapeutic applications. Recently, we have shown that LQB118 is effective in inducing apoptosis in cells from patients with AML and chronic myeloid leukemia (CML). Our partner group has shown that LQB118 increases the reactive oxygen species (ROS) levels in a leukemia cell line, suggesting a possible role of this pathway in its mechanism of action. Nrf2 is a transcription factor that controls the expression of various genes that encode proteins involved in detoxification, transport of xenobiotics, apoptosis inhibition, which are all involved in the response to oxidative/electrophilic stress to preserve cell life. XIAP is a member of the inhibitor of apoptosis family of proteins (IAP) which, in addition to being a caspase inhibitor, may be up-regulated under oxidative/electrophilic stress. Our objective is to elucidate the molecular mechanism of LQB118.
Material and Methods: The effect of LQB118 (3 and 6 μM) and idarubicin (0.01 μM), a chemotherapeutic agent used in AML therapy, on XIAP gene expression by real-time PCR and subcellular localization of Nrf2 transcription factor by immunofluorescence was evaluated in the AML cell line, Kasumi-1.
Results: In previously published reports, we have shown that LQB118 sensitizes Kasumi-1 cells to apoptosis and induces DNA fragmentation. XIAP mRNA expression was decreased by LQB118, whereas idarubicin increased said expression. Thus, after incubation with both concentrations of LQB118 for 24 and 48 h, the subcellular localization of Nrf2 was cytosolic as compared to untreated and also with idarubicin-treated Kasumi-1 cells, where Nrf2 localization was predominately nuclear.
Conclusions: In agreement with literature data, we found that a decrease in XIAP expression may contribute to sensitization of AML cells to ROS, after treatment with LQB118. In addition, Nrf2 cytosolic localization is a mechanism of maintenance of oxidative homeostasis, guaranteed by an efficient molecular complex. However, in AML there is constitutive nuclear activation of Nrf2, which contributes to the resistance to chemotherapy. Together, these findings may contribute to understand chemotherapy resistance in AML. Further investigation is currently in progress.

Antitumor activities and drug resistance overcoming of novel nogalamycins

Y. Senkiv[1], D. Klymyshin[2], V. Fedorenko[3], R. Stoika[1]. [1]*Institute of Cell Biology National Academy of Sciences of Ukraine, Department of Regulation of Cell Proliferation and Apoptosis, Lviv, Ukraine;* [2]*Danylo Halytsky National Medical University, Department of Biochemistry, Lviv, Ukraine;* [3]*Lviv National Ivan Franko University, Department of Genetics and Biotechnology, Lviv, Ukraine*

Background: *Streptomyces nogalater* Lv65 is a producer of an anticancer antibiotic nogalamycin. Its derivatives are used in chemotherapy of tumors. Certain aspects of the regulation of nogalamycin production have been characterized. However, most enzymatic reactions of nogalamycin biosynthesis have not been studied. The mechanisms controlling formation of the sugar moieties of nogalamycin and their enzymatic modification, particularly methylation, are not known.
Material and Methods: The anticancer activity of modificated nogalamicine was compared with doxorubicine after 72 h treatment in 12 cancer cell lines. To identify the alterations in cell cycle distribution induced by the nogalamicine, PI staining was performed. Changes in the expression levels of diverse cell regulatory proteins were investigated by Western Blotting.
Results: Bioinformatic analysis of the *snogM,* gene revealed that the product of these gene was involved in methylation of the nogalose moiety of nogalamycin. Disruption of the *snogM* gene in the chromosome of *S. nogalater* Lv65 resulted in *S. nogalater* strains ΔsnogM. The fact of gene disruption was confirmed by DNA−DNA hybridization. Inactivation of the *O*-methyltransferase genes had no affect on morphological features of the recombinant strains. One of the main goals of our work was also verify activity of this new modification of nogalamicine against several tumor cell lines. We have found that IC50 all used cell lines is between 4.3 nM (SW1573 lung adenocarcinoma cell line) and 15.21 nM (MCF-7 brest cancer cell line). By the way, the IC50 of famous anticancer drug doxorubicin is between 31.74 nM (SW1573 lung adenocarcinoma cell line) and 79.31 nM HCT116 p53 −/− human colorectal carcinoma cell line). Also nogalamicine was very efectiv against MRP1-overexpressing sublines HL60/adr and SW1573/2R120, which are srong resitence to the action of doxorubicine. Interesting, HCT116 cells with deleted p53 gene are almost 2 times more sensitive to the new nogalamicine as its wild type cell line. And in case of doxorubicine, human colorectal carcinoma HCT116 cells with deleted p53 −/− gene are more resistance, as its wild type cell line. This data show that such kind of modification of nogalamicine can be a new word in overcoming of p53 dependent drug resistance.
Conclusions: Genetic manipulations with the *snogM* gene of the nogalamycin biosynthetic gene cluster is a potentially valuable tool for generation of novel anthracycline antibiotics which can permit overcoming resistance of various human tumor cells.

Trichosanthin, a type I ribosome-inactivating protein, inhibits lymphoma cell growth by promotion of apoptosis

Y. Sun[1], Y.J. Zhu[1], O. Sha[2], W.Q. Jiang[2]. [1]*Sun Yat-sen University Cancer Center, Medical Oncology, Guangzhou, China;* [2]*School of Medicine Shenzhen University, Department of Medicine, Shenzhen, China*

Background: Trichosanthin (TCS) is a 27 kDa type I ribosome-inactivating protein purified from the root tuber of a traditional Chinese medicine herb *Trichosanthes kirilowii*, which has been reported to have an anti-tumor activity. The aim of this study was to explore the growth inhibition effect of TCS on lymphoma cells and its possible mechanism. A total of 9 non-Hodgkin's lymphoma (NHL) cell lines were included in the experiment, including 5 diffuse large cell lymphoma (DLBCL) and 3 Burkkit lymphoma and one T cell lymphoma cell lines.
Methods: After different doses of TCS were added to the cultured cells, MTT assay, flow cytometry and Western blotting methods were used to investigate the effects and mechanism of TCS on the growth of lymphoma cells.
Results: The results showed that TCS could inhibit the proliferation of all NHL cells especially DLBCL cells. And the growth inhibition activity was associated with the expression levels of Mcl-1, Bcl-2 and Puma. Higher expression of Bcl-2 and Puma and lower expression of Mcl-2 were associated with higher efficacy. Flow cytometric analysis disclosed that TCS mainly induced apoptosis in those cell lines. Furthermore, the TCS-induced apoptosis was attributed to the activations of caspased-3 and PARP-1.
Conclusions: Therefore, TCS can inhibit NHL cell growth through inducing apoptosis, and the expression of Mcl-1, Bcl-2 and Puma maybe predicts its efficacy (JCYJ 20120613113228732, NSFC 81171154, GJHS 20120621153317134).

Autophagy modulation with mTOR inhibitor sirolimus and anti-EGFR monoclonal antibody cetuximab: phase I study in patients with advanced cancers

R. Agarwal[1], A. Naing[1], D.S. Hong[1], S.A. Piha-Paul[1], H.J. Huang[1], K.S. Culotta[2], J.J. Lee[3], R. Islam[1], R. Kurzock[4], F. Janku[1]. [1]*University of Texas MD Anderson Cancer Center, Department of Investigational Cancer Therapeutics, Houston, USA;* [2]*University of Texas MD Anderson Cancer Center, Department of Experimental Therapeutics, Houston, USA;* [3]*University of Texas MD Anderson Cancer Center, Department of Biostatistics, Houston, USA;* [4]*University of Texas MD Anderson Cancer Center, Moores Cancer Center, La Jolla, USA*

Background: EGFR kinase activates PI3K/mTOR and MAPK pathways and EGFR nonkinase function is important for SGLT glucose transport. Preclinical data suggest that knocking down EGFR increases autophagy, which in combination with mTOR inhibition can lead to autophagic cell death. In addition, PI3K/mTOR activation can mediate resistance to EGFR targeting therapies, which can be abrogated by simultaneous mTOR inhibition.
Methods: Patients (pts) with refractory advanced cancers received IV cetuximab (day 1, 8, 15, 22) with oral sirolimus (day 1−28) in 28-day cycles. Doses were escalated in a 3+3 schema. Endpoints were maximum tolerated (MTD) or phase 2 recommended dose (RP2D), safety, response, and PD/PK analyses.
Results: To date, 112 pts were treated in 8 dose levels and 4 expansion cohorts at RP2D of sirolimus 6 mg and cetuximab 400 mg/m^2 followed by 250 mg/m^2 since MTD has not been reached. Dose limiting toxicities included grade (G) 3 mucositis (n = 3), and grade 4 thrombocytopenia with bleeding (n = 1). Other significant drug related toxicities included G3 mucositis (n = 1), G3 acneiform skin rash (n = 4), $\geqslant$ G3 hypersensitivity reaction (n = 3), G3 proteinuria (n = 1), G3 hyperglycemia (n = 1), G3 hyperlipidemia (n = 1), G4 lymphopenia (n = 5) and G4 thrombocytopenia (n = 3). Shrinkage per RECIST of more than 20% tumor was observed in 7 pts (head and neck squamous cell [HNSCC, n = 4], non-small cell lung [NSCLC, n = 2], and parathyroid cancer [n = 1]) including 4 partial responses (5 received prior EGFR therapies). PK data (n = 31) shows dose proportional increase in sirolimus weekly trough levels and the median trough level at RP2D was 15.7 ng/mL. PD data showed adequate mTOR inhibition as measured by pS6K activity in PBMC (ELISA) in 25 tested pts ($p < 0.001$) and decreased accumulation of autophagosomes as measured by % of LC3 positive PBMCs (flowcytometry) in 23 tested pts ($p < 0.001$). Some spots are still open in the expansion cohorts. Updated clinical, PK and PD data (including pre- and post-treatment biopsies) will be presented.
Conclusions: Cetuximab and sirolimus is well tolerated and demonstrates early antitumor activity in patients with refractory HNSCC, NSCLC, and parathyroid carcinoma.

4,4'-dimethoxybenzophenone thiosemicarbazone: Underlying mechanism of action of a compound with selective proapoptotic novel activity in human leukemia cells

M. Cabrera[1], N. Gomez[1], F. Remes Lenicov[2], A. Moglioni[1], C. Shayo[3], N. Fernandez[1], C. Davio[1]. [1]*Facultad de Farmacia y Bioquímica Universidad de Buenos Aires, Cátedra de Química Medicinal, Buenos aires, Argentina;* [2]*Instituto de Investigaciones Biomédicas en Retrovirus y SIDA Universidad de Buenos Aires, Facultad de Medicina, Buenos aires, Argentina;* [3]*Instituto de Biología y Medicina Experimental (IBYME)-CONICET, Laboratorio de Patología y Farmacología Molecular, Buenos aires, Argentina*

Thiosemicarbazones have shown wide pharmacological versatility and their application as antibacterial, antiviral and anticancer agents make them valuable candidates for the development of new drugs.
In the search for new potential anti-leukemic drugs, a family of benzophenone thiosemicarbazones were synthesized and tested for antiproliferative activity in human acute leukemia U937 cell line. From this initial screening the 4,4'-dimethoxybenzophenone thiosemicarbazone (T44Bf) was identified as the most potent. Based on that, the aim of the present study was to elucidate the mechanisms that mediate the antiproliferative effects of T44Bf over different models of human acute leukemia (KG1a, HL60, U937 and Jurkat cell lines). T44Bf treatment of the cell lines led to a significant reduction in cell growth in a dose/time

dependent manner (IC50=5μM). To evaluate whether this inhibition was due to the induction of apoptosis, we analyzed by western blot, caspase 3 and poly (ADPribose) polymerase (PARP) cleavage. The results obtained in the apoptosis studies correlates in time and concentration with the observed inhibition of proliferation for the four cell lines. Similar results were obtained when we measure caspase-3 activity by a colorimetric assay and phosphatidylserine extrusion by Anexine V staining. On the other hand, peripheral blood monocytes and lymphocytes isolated from healthy blood donors were treated with T44Bf up to 20 μM. Interestingly, T44Bf did not promote death of normal cells indicating selectivity of the compound at the working concentrations.

To elucidate the action mechanism involved in the pro-apoptotic activity of T44Bf we studied by Western blot, the phosphorylation state of MAPKs: ERK, Akt, p38 and JNK, using phospho-specific antibodies. T44Bf treatment increased phosphorylation in a time dependent manner of ERK1/2, while p-Akt, p-p38 and p-JNK levels remained unchanged. To evaluate whether the observed ERK1/2 modulation was involved in the pro-apoptotic activity of T44Bf, we measured caspase 3 and PARP clevage in cells treated with T44Bf in presence of the MEK inhibitor U0126. Inhibition of ERK phosphorylation by U0126 blocked T44Bf induced apoptosis, indicating that phosphorylation of ERK is a necessary step to achieve apoptosis by T44Bf.

Our results shed new light in the mechanism of action of thiosemicarbazones as anticancer agents and postulated T44Bf as a promising compound for the development of novel and selective antileukemic drugs.

819 POSTER

The novel peroxisome proliferator-activated receptor gamma (PPARg) agonists CB11 and CB11d, induced apoptosis through DNA damage by reactive oxygen species (ROS) in a human non-small cell lung cancer (NSCLC) cell line H460

S. Hong[1], J.W. Park[1], C.N. Im[1], D.W. Hong[1]. [1]*Korea Institute of Radiological & Medical Sciences, Radiation Cancer Research, Seoul, Korea*

Background: PPARγ agonists have been shown to induce apoptosis a variety of cancer cells. Lung cancer is the most common cause of cancer death in the world and the second most common cancer in the Republic of Korea. PPARγ is known to be highly expressed in human lung cancer cell lines. In this study we investigated effects of novel PPARγ agonists CB11 (8-(2-aminophenyl)-3-butyl-1,6,7-trimethyl-1H-imidazo[2,1-f]purine-2,4(3H,8H)-di-
one) and its derivative, CB11d1(8-(2-aminophenyl)-3-butyl-1,7-dimethyl-1H-imidazo[2,1-f]purine-2,4(3H,8H)-dione) on a human lung cancer cell line H460.

Material and Methods: CB11 was selected using chemical library (ChemBridge, USA) screening and its derivative CB11d1 was purchased from the same company. These chemicals as PPARγ agonists were confirmed by Oil Red O staining or effect of specific antagonist GW9662 in differentiated 3T3L1 cells. Cell viability was measured by WST assay. The subdiploid cellular DNA fraction, mitochondrial membrane potential (MMP) collapse and ROS were analyzed by flow cytometry. Activation of the caspase pathway by PPARγ agonist treatment was detected by Western blot analysis and caspase activity assay.

Results: Both CB11 and CB11d1 dose-dependently inhibited cell growth and induced apoptosis in H460 cells. Pretreatment of H460 cells with GW9662, a PPARγ specific antagonist did not recover cell viability showing that both CB11 and CB11d1 induced apoptosis in a PPARγ-independent pathway. These agonists increased activation of caspase −3, −8 and −9 as well as cleavage of poly (ADP-ribose) polymerase (PARP). Moreover, MMP collapse was increased by these agonists and blocked by pretreatment of cell with cyclosporin A, MMP inhibitor, suggesting that these agonists induced apoptosis via a mitochondria-dependent pathway. Concomitantly, both CB11 and CB11d1 increased ROS generation and DNA damage in H460 cells. ROS inhibitors such as N-acetyl-cystein (NAC) suppressed ROS generation, apoptosis and DNA damage suggesting that apoptosis by CB11 and CB11d1 is involved in ROS generation.

Conclusions: Our results suggest that novel PPARγ agonists, CB11 and CB11d1, may be used for the treatment of NSCLC.

Niclosamide radiosensitizes non-small cell lung cancer cells through activation of c-Jun

J. Ahn[1], S. Lee[1], J. Song[1]. [1]*Korea Institute of Radiological & Medical Sciences, Dep. of Radiation Cancer Sciences, Seoul, South Korea*

Background: Radiotherapy is one of the effective modalities in the clinical treatment of cancers, and currently has been tried to combine with chemotherapy to improve therapeutic efficacy. Therefore, we aimed to develop small molecules that enhance the cytotoxic effects of radiotherapy. In this study, we provide evidence that Niclosamide can be an effective radiosensitizer in non-small cell lung cancer cells.

Material and Methods: To identify small molecules that increase cell death following radiotherapy in H1299 lung cancer cells, we screened a chemical library (a US-Drug Collection) containing 1,040 compounds using a cell viability assay system with Cell Counting Kit-8 in a 96-well plate format. A potent radiosensitizer among hits was validated by clonogenic survival assay, annexin V/PI staining and immunoblotting.

Results: Using a cell-based high-throughput screening with the 1,040 compounds in combination with irradiation, we found Niclosamide, an FDA-approved antihelminthic agent, exhibited radiosensitizing effect on H1299 human lung cancer cells. Combination treatment with Niclosamide and IR significantly reduced clonogenic survival of H1299 lung cancer cells in a dose-dependent manner and induced more apoptotic cell death than IR or Niclosamide alone, determined by increased level of PARP cleavages via caspase-3 activation and annexin V-positive cells. Given that IR induced apoptosis through generation of reactive oxygen species (ROS), we next examined ROS-induced molecular target signaling by the combination treatment of Niclosamide with IR. The combined treatment significantly induced phosphorylation of c-Jun in H1299 cells. Moreover, Niclosamide combined with H_2O_2 which was employed another ROS generator also induced c-Jun and its phosphorylation, leading to more increased apoptosis. N-acetyl-L-cysteine (NAC) treatment abolished c-Jun activation as well as apoptosis. Inhibition of c-Jun by siRNA also decreased PARP cleavages and attenuated clonogenic cell death of H1299 cells.

Conclusions: Our findings suggest that Niclosamide could be a promising radiosensitizer in lung cancer patients through activation of c-Jun which plays a pivotal role in ROS-induced apoptosis.

No conflict of interest.

821 POSTER

NFkB subcellular modulation and gene expression profile of chronic myeloid leukemia cell lines after treatment with the new compound LQB-118

F. Costas[1], M.B. Pinho[2], P.R.R. Costa[3], R.C. Maia[1]. [1]*Instituto Nacional do Câncer, Laboratório de Hemato-oncologia Celular e Molecular, Rio De Janeiro, Brazil;* [2]*Instituto Nacional do Câncer, Coordenação de Pesquisa Clínica e Inovação Tecnológica, Rio De Janeiro, Brazil;* [3]*Universidade Federal do Rio de Janeiro, laboratório de Química Bioorgânica, Rio De Janeiro, Brazil*

Background: Development of drugs more capable of overcoming tyrosine kinase inhibitors (TKIs) resistance, observed in about 30 % of chronic myeloid leukemia patients (CML), is of great importance nowadays. It was recently demonstrated by our group that treatment of CML cell lines (K562 and Lucena) with the new compound pterocarpanquinone LQB118 reduced the cellular viability and induced high levels of apoptosis. It was also observed a reduction in protein levels of glycoprotein-P (Pgp), and the inhibitor of apoptosis proteins (IAPs), XIAP and survivin. The NFkB transcription factor, which is capable of activating the transcription of Pgp, survivin and XIAP, is related to oncogenesis since regulates the expression of a variety of genes related to apoptosis, cellular proliferation and differentiation. The aim of the study was to evaluate the mechanism of LQB118 in inducing apoptosis and the gene expression profile of CML cell lines K562 and Lucena after treatment with LQB118.

Material and Methods: After treatment with LQB118 the levels of caspase-8 and IkBa, NFkB endogenous inhibitor, were analyzed by Western blotting. For NFkB subcellular localization, an immunofluorescence assay was performed. Proteasome activity was measure using Proteasome-Glo™. DNA microarray was performed to evaluate the differential gene expression profile of the CML cell lines treated with LQB118.

Results: LQB118 induced the activation of caspase-8 in both cell lines and maintained or induced IkBa levels, suggesting that NFkB was inactive in the cytoplasm. These results were confirmed by immunofluorescence, once NFkB was predominantly observed in the cytoplasm of the cell lines treated with LQB118. Further analysis also demonstrated that LQB118 was able to inhibit proteasome activity in both cell lines. DNA microarray results showed that LQB118 altered the expression of 109 and 75 genes, in K562 and Lucena, respectively. *TOB2, TAP2, NCF1* and *IKZF5* genes were differentially expressed after treatment with LQB118.

Conclusions: Our results suggest that LQB118 induced high levels of apoptosis in both CML cell lines through the extrinsec pathway of apoptosis and seems to be able to modulate NFkB activity, preventing its translocation to the nucleus, probably by avoiding IkB degradation by proteasome and, therefore, preventing XIAP and survivin expression. The study of the gene expression profile allowed us evaluate the putative genes involved in LQB118 mechanism.

Evaluation of tolerability and anti-tumor activity of GDC-0032, a PI3K inhibitor with enhanced activity against PIK3CA mutant tumors, administered to patients with advanced solid tumors

D. Juric[1], J.R. Infante[2], I.E. Krop[3], C. Kurkjian[4], M.R. Patel[5], R.A. Graham[6], T.R. Wilson[6], J.Y. Hsu[6], J. Baselga[7], D.D. Von Hoff[8]. [1]*Massachusetts General Hospital Cancer Center, Boston, USA;* [2]*Sarah Cannon Research Institute/Tennessee Oncology PLLC, Nashville, USA;* [3]*Dana Farber Cancer Institute, Boston, USA;* [4]*University of Oklahoma, Oklahoma, USA;* [5]*Sarah Cannon Research Institute/Florida Cancer Specialists, Sarasota, USA;* [6]*Genentech Inc., South San Francisco, USA;* [7]*Memorial Sloan-Kettering Cancer Center, New York, USA;* [8]*Virginia G. Piper Cancer Center/TGen, Scottsdale, USA*

Background: GDC-0032 is an orally bioavailable, potent, and selective inhibitor of Class I PI3K alpha, delta, and gamma isoforms, with 30-fold less inhibition of the PI3K beta isoform relative to the PI3K alpha isoform. Preclinical data show that GDC-0032 has enhanced activity against PI3K alpha isoform (PIK3CA) mutant cancer cell lines.
Material and Methods: A Phase I dose escalation study was conducted with evaluation of GDC-0032 doses ranging from 3−16 mg QD in a modified 3+3 design. Dose expansion cohorts at 9 mg QD were conducted in patients with solid tumors or with HER2-positive breast cancer. Safety and tolerability of GDC-0032 was assessed, as well as pharmacokinetics (PK), pharmacodynamic (PD) assessment of PI3K pathway inhibition by paired tumor biopsies and by FDG-PET, and anti-tumor activity by RECIST.
Results: Enrollment onto the dose escalation stage has been completed (n = 34). Two DLTs (G4 hyperglycemia and G3 fatigue) were observed at the 16 mg cohort. As of Nov 30, 2012, adverse events (AEs) assessed by the investigator as related to GDC-0032 in ⩾10% of patients, were diarrhea, fatigue, hyperglycemia, decreased appetite, nausea, rash, stomatitis, and vomiting. GDC-0032 has dose-proportional PK and a mean half-life of 40 hours, from 3−16 mg QD. PD inhibition of the PI3K pathway was observed via paired tumor biopsies as assessed by reverse phase protein array. Metabolic partial responses via FDG-PET (⩾20% decrease in $mSUV_{max}$) were observed in 12 out of 17 patients assessed (71%). Confirmed partial responses (PRs) have been observed in 5 patients who were treated at doses ranging from 3−12 mg QD. Of the 6 patients with PIK3CA mutant breast cancer (RECIST −30 to −70%), there have been 4 confirmed PRs observed. One confirmed PR has been observed in a patient with PIK3CA mutant NSCLC. Enrollment onto the solid tumor cohort (n = 13) and the HER2-positive breast cancer cohort (n = 10) has been completed. Preliminary PK and safety data from these expansion cohorts are consistent with those observed in the dose-escalation portion of this study. Updated data on clinical outcomes and biomarker correlates will be presented.
Conclusions: GDC-0032 is a next-generation PI3K inhibitor with promising anti-tumor activity observed in patients with PIK3CA mutant tumors. GDC-0032 is being investigated in combination with endocrine therapies such as letrozole and fulvestrant for patients with hormone receptor-positive breast cancer.

823 POSTER

Reactivation of apoptosis in cancer cells with new class of fusion proteins

S.D. Pawlak[1], J.S. Pieczykolan[1], B. Zerek[1], A. Pieczykolan[1], P.K. Rózga[1], M. Galazka[1], K. Bukato[1], M. Szymanik[1], A. Jaworski[1], M. Teska-Kaminska[1]. [1]*Adamed Group, Drug Discovery, Warsaw, Poland*

Introduction: Tumor necrosis factor-related apoptosis-inducing ligand (TRAIL/Apo2L) was going to be promising, natural therapeutic that selectively targets tumor cells while omitting normal cells. However it occurs that many cancer cell lines have developed a number of resistance mechanisms to TRAIL. Among recently discovered, overexpression of X-linked IAP (XIAP) molecules is considered as the main cause of TRAIL resistance.
There are many strategies, regarding chemo- and radio-sensitization, enhancing TRAIL efficacy, however combining TRAIL with chemotherapy may also sensitize normal cells to TRAIL induced apoptosis.
Here we present a recombinant variant of TRAIL fused with the peptide derived from Smac/DIABLO protein. The peptide we used is responsible for the interaction with BIR domains of IAP molecules. The fusion protein contains membrane transduction motif followed by sequences recognized by tumor-specific proteases (MMPs). General mechanism of action of this protein is considered as specific targeting the tumor by TRAIL, followed by activation (release) and transduction of pro-apoptotic peptide into cancer cells. Delivery of the Smac/DIABLO peptide blocks X-linked IAP (XIAP) proteins activity and reactivates apoptosis in cancer cell.
Methods: TRAIL/APO2L-SMAC/DIABLO fusion protein was expressed in *E.coli* and purified by IEC chromatography. Obtained protein was tested regarding *in vivo* distribution, apoptosis induction, protease cleavage and MTT cell cytotoxicity assays. For *in vivo* potential we examined the efficacy of fusion protein on mice xenograft model of colorectal adenocarcinoma (Colo205) and uterine sarcoma (MES-SA/Dx5) cells in comparison to reference − active TRAIL.
Results: We had obtained molecule and verified its mechanism of action. Our Smac/DIABLO-TRAIL fusion variant showed *in vitro* specific cytotoxic effect on various cancer cell lines at the level of IC50 below 0.1 ng/ml. In contrast to IC50 values obtained for cancer cell lines the fusion molecule showed no or very low activity on normal cells. The fusion protein showed specific targeting into the xenograft tumor and superior effect displaying significant tumor volume regression *in vivo* when compared with TRAIL.
All those results confirm that we had developed very promising molecule with high potential of pro-apoptotic activity that could be considered as a novel anticancer therapeutic agent showing clear synergistic effect of TRAIL and pro-apoptotic peptide.
No conflict of interest.

824 POSTER

A phase 1 study of oral rucaparib in combination with carboplatin

P. Roxburgh[1], L.R. Molife[2], A. Gupta[3], R. Wilson[4], T.R.J. Evans[1], N. Cresti[5], H. Giordano[6], D. Simpson[7], S. Jaw-Tsai[6], R. Plummer[5]. [1]*Beatson West of Scotland Cancer Centre, Medical Oncology, Glasgow, United Kingdom;* [2]*The Royal Marsden and Institute of Cancer Research, Surrey, United Kingdom;* [3]*Oxford University Hospitals NHS Trust, Oxford, United Kingdom;* [4]*Queen's University Belfast, Belfast, United Kingdom;* [5]*Northern Institute for Cancer Research, Newcastle upon Tyne, United Kingdom;* [6]*Clovis Oncology Inc., San Francisco, USA;* [7]*Clovis Oncology Inc., Cambridge, United Kingdom*

Background: Targeting poly (ADP-ribose) polymerase (PARP), an enzyme involved in DNA damage repair, may increase efficacy of DNA-damaging agents. This study evaluated the tolerability of oral rucaparib, a potent and selective PARP1/2 inhibitor, in combination with carboplatin (CP).
Methods: Patients (pts) aged ⩾18 with advanced solid tumors were included. Pts received lead-in doses of IV and oral rucaparib on Days −10 and −5, respectively, followed by CP on Day 1 and oral rucaparib on Days 1−14 q21 days. Treatment continued until disease progression. Pts with benefit could continue rucaparib monotherapy once CP dosing was completed. Dose escalation was based on toxicities observed in Cycle 1 in cohorts of n = 3−6. PK was assessed during Cycle 1.
Results: 26 pts (median age 60.5 yrs [range 20−76]; 19 female; 10 ECOG PS=0; 7 ovarian/peritoneal (OC), 6 breast (BC), 2 NSCLC, 11 other tumor) were enrolled. Rucaparib doses of 80, 120, 180, 240, and 360 mg were administered with AUC3 CP, followed by 360 mg rucaparib with AUC4 and AUC5 CP. Two of 5 pts treated with AUC5 CP/360 mg rucaparib experienced dose-limiting toxicity (Gr 3/4 neutropenia & thrombocytopenia). Evaluation of AUC5 CP and 240 mg rucaparib is being completed. Treatment-related adverse events in ⩾5 pts, all grades, include fatigue (n = 11), anemia (n = 10), neutropenia (n = 8), thrombocytopenia (n = 8), nausea (n = 7), lethargy (n = 6), and constipation (n = 5). One pt (OC, $BRCA^{wt}$, AUC3 CP/180 mg rucaparib) had a PR of 5.1 mo duration and 1 pt (BC; $BRCA2^{mut}$, AUC5 CP/360 mg rucaparib) is ongoing in week 10 with confirmation of PR pending. Three pts (1 CRC, 2 OC; 2 $BRCA^{unk}$, 1 $BRCA^{wt}$) discontinued CP (after 4 or 8 cycles) and continued on rucaparib (additional 2, 5, or 10+ cycles). An additional 3 pts (mesothelioma, NSCLC, pseudomyxoma peritoneii; all $BRCA^{unk}$) had stable disease (SD) >12 wks. Overall disease control rate (CR+PR+SD>12 wks) in evaluable OC pts across all dose levels was 50% (3/6). Dose-proportional increase in rucaparib exposure was observed with steady state achieved by Day 14 and mean $t_{1/2}$ of 15 h. Oral bioavailability was 38% and dose-independent. Rucaparib exposure was not changed by CP co-administration.
Conclusions: The combination of oral rucaparib and CP exhibits activity at clinically relevant doses of each agent. Further studies in platinum-sensitive and homologous recombination repair deficient populations are warranted.

Magnetic nanoparticle-entrapping liposomes for localized hyperthermia and controlled drug release in solid tumours

W.J.M. Lokerse[1], S. Belaïd[2], S. Laurent[2], T.L.M. Ten Hagen[1], A.M.M. Eggermont[1], H. Gruell[3], R.N. Muller[2], G.A. Koning[1]. *[1]Erasmus Medical Center, Experimental & Surgical Oncology, Rotterdam, Netherlands; [2]Université de Mons, General Organic & Biomedical Chemistry, Mons, Belgium; [3]Technical University Eindhoven/ Philips, Biomedical Engineering, Eindhoven, Netherlands*

Background: Hyperthermia is a powerful tool to trigger content release from thermosensitive liposomes (TSL) encapsulating chemotherapeutic drugs. A major challenge of nowadays' hyperthermia and TSL-mediated chemotherapy treatment, is the precise heat delivery to only trigger drug release in the tumour area, preventing healthy tissue toxicity. Nanometre scale magnetic iron oxide nanoparticles (MNPs) can, when exposed to an alternating magnetic field (AMF), generate heat and can also be imaged by magnetic resonance imaging (MRI). When MNPs are co-encapsulated with chemotherapeutics into TSL, a drug carrier is obtained, which under imaging-guidance can be heated to release its contents at any desired moment using a non-invasive AMF impulse. The aim of this study is to develop such MNP entrapping thermosensitive liposomes.
Material and Methods: We have applied various liposome preparation methods, to optimize incorporation of hydrophobic MNPs into liposome bilayers or hydrophillic MNPs in the aqueous core. Magnetoliposomes were analysed by dynamic light scattering for size, polydispersity index and zeta potential, followed by transmission electron microscopy. Magnetic properties of these samples were determined by T1, T2 measurements and NMRD profiling.
Results: When using film hydration, hydrophllic MNPs were loaded in aqueous core of 100 nm liposomes. For hydrophobic MNPs, more delicate approaches were required for incorporation into liposomal bilayers. The magnetic properties of MNPs after liposome incorporation remained unaltered.
Conclusions: Hydrophilic and hydrophobic MNP were incorporated in TSL. Current studies focus on optimising MNP loading efficacy and further characterization. After this stage hyperthermia potential and heat triggered drug release will be studied in vitro and in vivo.

Dual inhibitors of NFkappaB and Akt activation: Synthesis, in vitro anticancer activity and molecular docking studies

M. Sharma[1], S. Kumar[2], N. Tailor[2]. *[1]Jaypee University of Information Technology, Waknaghat, India; [2]Jaypee University of Information Technology, Pharmacy, Waknaghat, India*

Background: The C-2 arylidene analogs of pentacyclic triterpenoid Lantadene A **(1)** and B **(2)** were synthesized as dual inhibitors of NF-kappaB (NF-κB) and Akt. The compounds were further evaluated for *in vitro* anticancer activity against four human cancer cell lines (HL-60, MCF-7, A549 and HCT-116).
Material and Methods: The cytotoxicity was evaluated by using MTT assay, the NF-κB and Akt inhibition was evaluated by NF-κB luciferase assay and Akt kinase inhibition assay respectively. Automated molecular docking was performed to find out molecular interaction and optimized geometry by using docking software AutoDock 4.2.
Results: Analogs **3, 4, 7** and **8** showed enhanced inhibitory activity as compared with parent compounds **1** and **2**. These analogs were found more active than standard drug cisplatin with selective toxicity towards cancer cells and were inactive against normal cells (VERO). Furthermore, the mechanistic studies to investigate the effects of the new compounds on Akt protein in lung cancer cell line A549 and the NF-κB signalling pathway suggested that the compounds may exert their inhibitory activity on cancer cells through inhibition of both Akt and NF-κB activation. The docking studies of most potent analog **(7)** with 3D crystal structure of the nuclear factor kappa-B (NF-κB) P50 homodimer (PDB ID: 1NFK) revealed that carbonyl group of ester side chain and C-28 carboxylic acid groups were mainly involved in hydrogen bonding interaction. The oleanane frameworks was involved in strong hydrophobic interaction with amino acid phenylalanine and structure of lead compound have the potential to be developed as potent NF-κB inhibitor and anticancer agent.
Conclusions: Novel dual inhibitors of NF-κB and Akt activation inhibitors were synthesized and found to have potent selective anticancer activities in low micro molar range.

A phase I of study of Everolimus (EVE) in combination with LBH589B (LBH) [HDAC inhibitor] in advanced malignancies with enrichment for EBV driven tumors

D. Tai[1], C. Lim[2], L. Zhong[3], Q.S. Ng[1], T.T. Tan[4], M.K. Ang[1], J. Connolly[5], E.H. Tan[1], W.T. Lim[1], S.W. Tan[1]. *[1]National Cancer Centre, Medical Oncology, Singapore, Singapore; [2]National Cancer Centre, Biostatistics Unit, Singapore, Singapore; [3]National Cancer Centre, Clinical Trials and Epidemiology, Singapore, Singapore; [4]Singapore General Hospital, Department of Infectious Disease, Singapore, Singapore; [5]Agency of Science Technology and Research, Singapore Immunology Network, Singapore, Singapore*

Background: Pre-clinical evidence suggests that combination of HDAC and m-TOR inhibition abrogates multiple EBV-driven oncogenic pathways by increasing expression of EBV lytic genes coupled with immune-modulatory and anti-angiogenic effects.
Material and Methods: Patients with advanced malignancies enriched for EBV-driven cancers were enrolled to determine the safety, tolerability, maximum tolerated dose (MTD), pharmacokinetics, pharmacodynamics and preliminary anti-tumor activities in a 3+3 dose escalation design. LBH was administered 7 days prior to initiation of combination treatment. NPC patients received either acyclovir or val-acyclovir prophylaxis. Serum EBV-DNA levels were measured weekly and plasma cytokines profiled using a 31-plex luminex panel.
Results: 20 patients have been treated [male:female 15:5, median age 52.5 (37−63, 11 nasopharyngeal carcinoma (NPC) and 9 non-NPC] at 4 dose levels − LBH (3x/week)-EVE (daily):10 mg-2.5 mg (3pts), 10 mg-5 mg (6pts), 15 mg-2.5 mg (exploratory) (6pts) and 15 mg-5 mg (5pts). 73 cycles of treatment were administered in total. Two dose limiting toxicities of G4 (grade) thrombocytopenia were observed at LBH 15 mg-EVE 5 mg. Significant adverse events (AE) (G⩾3) were dysphagia (1),diarrhoea (1), epistaxis (1) and thrombocytopenia (3). Common AEs (G1/2) included mucositis (70%), fatigue (65%), anorexia (50%), fever (40%), cough (30%) and diarrhoea (30%). One patient experienced a partial response (lymphoma) and 6 patients (3 NPC, 2 breast and 1 renal cell carcinoma) had prolonged stable disease (>16 weeks). Modulation of EBV DNA titres was seen only in NPC patients, with median fold-change from baseline of 9 (0.9–174). In a limited patient subset (n = 9, 30 timepoints), plasma cytokine profiles were consistent with a T- cell response, specifically, elevated levels of FLT3L, IFN-gamma, IL-13 and IL-17. Target engagement was also observed with increased histone-3 acetylation as early as 4 hours after administration of LBH. Results of the PK studies would be presented during the meeting.
Conclusion: Combination of LBH and EVE resulted in induction of EBV DNA titres with concomitant T-cell host response. The recommended phase 2 dose is LBH 10 mg 3x/week and EVE 5 mg daily in an Asian population comprising of predominantly NPC patients.

p21Cip1/Waf1-mimetic peptide bound to elastin-like polypeptide carrier enhances bortezomib cytotoxicity in androgen-independent prostate cancer cell lines

A.M. Mikecin[1], L.R. Walker[2], D. Raucher[2]. *[1]Institute Rudjer Boskovic, Division of Molecular Medicine, Zagreb, Croatia; [2]University of Mississippi Medical Center, Department of Biochemistry, Jackson, USA*

Background: Bortezomib is a proteasomal inhibitor approved for the clinical use in hematological tumors. However, due to a narrow therapeutic window it has a limited potential to be utilized as a treatment for solid tumors. In this work we have investigated the effect that externally delivered $p21^{Cip1/Waf1}$-mimetic peptide (aa 139–164) has on bortezomib cytotoxicity in DU-145 and PC-3 androgen-independent prostate cancer cell lines.
Materials and Methods: In this research elastin-like polypeptide (ELP) was used for the intracellular delivery of the p21-mimetic peptide. ELP is a genetically engineered, thermally responsive macromolecular carrier previously shown to be able to improve the stability of therapeutic peptides as well as to mediate their targeted delivery in response to mild hyperthermia. The effect that ELP-bound p21 peptide has on bortezomib cytotoxicity was measured using MTT test. Flow cytometry was used to quantify ELP-p21 peptide cellular uptake, as well as changes in the cell cycle distribution, apoptosis and autophagy induction after the combination treatment with bortezomib and ELP-p21 peptide. Western blot technique was used to monitor the change in the expression of various proteins involved in cell cycle regulation, while the senescence-associated beta-galactosidase assay was used to assess changes in the senescence activation.

Results: We demonstrated that co-treatment with bortezomib and ELP-bound p21-mimetic peptide carrier enhanced bortezomib cytotoxicity in both androgen-independent prostate cancer cell lines. In our research the ELP-p21 polypeptide led to a 1.5-fold decrease in the bortezomib IC_{50} value in the two cell lines tested. The combination treatment affected the cell cycle distribution and caused an intra-S phase cell cycle arrest. Additionally, the combination treatment augmented autophagy and apoptosis induction. On the protein level, we detected a different pattern in the cyclin D1, E and B1 expression, which we believe is due to the different status of the Rb protein in the two cell lines tested. Moreover, in contrast to PC-3 cell line that possesses wild type Rb protein, DU-145 cells, that contain non-functional Rb protein, did not display increase in the senescence induction upon the combination treatment.
Conclusion: In summary, our results suggest that ELP-bound p21-mimetic peptide may prove to be useful tool in combination therapy with proteasomal inhibitors.

829 POSTER

Immunoliposomes with single-domain antibodies targeted against mucin 1 (MUC1)

M. Bolkestein[1], D. Drabek[2], T.L.M. Ten Hagen[1], F.G. Grosveld[2], G.A. Koning[1]. [1]*Erasmus Medical Center, Laboratory of Experimental Surgical Oncology, Rotterdam, Netherlands;* [2]*Erasmus Medical Center, Department of Cell Biology, Rotterdam, Netherlands*

In response to the lack of specificity in anti-cancer drugs, we want to use anti-MUC1 antibodies to improve targeting of drug-loaded liposomes to cancer cells. Liposomes can be used as carrier for various molecules, including targeting moieties and chemotherapeutics, to increase specificity or reduce toxicity. After extravasation the drug needs to be targeted to the tumor cells to be most effective. We use MUC1 as target, since it is overexpressed in pancreatic cancer, which is difficult to treat and has a 5-year survival rate of 6%. In this project we will use liposomes targeted with human single domain antibodies, i.e. antibodies containing only the variable domain of the antibody's heavy chain. Due to their small size (10−15 kDa) they are likely to be much less immunogenic than whole antibodies coupled to liposomes, but with all complementary determining regions intact, they can still show high affinity for their targets.
A transgenic mouse has been developed, which enables the production of heavy-chain-only antibodies of human origin. After immunization with MUC1, antibodies have been isolated and expressed to create a clone library. These clones have been screened for affinity on FortéBio Octet and have been used for subcloning of heavy chain variable domains with an additional cysteine. This cysteine will be used for thiol-maleimide conjugation to the polyethylene glycol (PEG) chains of liposomes. Affinity measurements of the single-domain antibodies and the antibody-liposome complex will be performed on MUC1 positive cell lines, such as CFPAC-1, by flowcytometry and immunostaining.
After immunization of several mice, and selection steps against MUC1, twelve related heavy-chain-only-antibodies have been found with dissociation constants (Kd) between 1E-9 to 1E-10 M. These twelve will be tested on MUC1 positive cell lines and a selection will be made into a single-domain format, which can be used for liposome conjugation and further affinity measurements. Liposomal conjugation with other antibodies has been performed, where antibodies are conjugated to micelles, which are post-inserted into preformed liposomes. These liposomes will be optically labeled to enable *in vivo* biodistribution studies.
Research on liposomes equipped with single-domain antibodies will help to identify novel targeted liposomal chemotherapy formulations that combine the liposomal drug encapsulation together with improved cell targeting and intracellular drug delivery.

Paclitaxel resistance is associated with drug accumulation in intracellular compartments and paclitaxel-binding proteins in human lung cancer cell lines

M. Shimomura[1], T. Yaoi[2], K. Itoh[2], D. Kato[1], J. Shimada[1], S. Fushiki[2]. [1]*Kyoto Prefectural University of Medicine, General Thoracic Surgery Dept., Kyoto, Japan;* [2]*Kyoto Prefectural University of Medicine, Pathology and Applied Neurobiology Dept., Kyoto, Japan*

Background: Several mechanisms have been suggested for paclitaxel resistance in cancer cells, including overexpression of the multidrug transporter gene, ATP-binding cassette, sub-family B, member 1 (*ABCB1*), and the presence of a point mutation in the β-tubulin gene at the paclitaxel-binding site. However, the mechanisms underlying resistance to this agent have not yet been completely elucidated.
Material and Methods: Three human lung cancer cell lines, II18, A549, and RERF-LC-KJ, were analysed; their 50% inhibitory concentrations of paclitaxel were −8.33, −7.69, and −4.51 logM, respectively. The cell lines did not have any β-tubulin mutation. We evaluated the expression levels of *ABCB1*, intracellular accumulation of paclitaxel, paclitaxel-induced stabilisation of microtubules, and intracellular localisation of Oregon Green® 488-conjugated paclitaxel in these cell lines. Moreover, we prepared paclitaxel conjugated ferriteglycidyl metacrylate (FG) beads to purify paclitaxel-binding proteins from whole cell lysates of these cells.
Results: The *ABCB1* expression level was strongly correlated to intracellular [^{3}H]-paclitaxel accumulation (r^2 = −0.804) but was not related with paclitaxel resistance. The changes in the quantities of polymerized tubulin and acetylated tubulin after paclitaxel exposure were not related to paclitaxel resistance. Differences were observed between the intracellular localisation of paclitaxel in RERF-LC-KJ, the most resistant cell line, and in the other 2 cell lines. The use of Oregon Green® 488-conjugated paclitaxel enabled visualization of not only the normal microtubule formation in the partial cells but also the aggregated vesicle formation in RERF-LC-KJ cells; aggregated vesicle formation was not remarkable in the other cell lines. Affinity purification by paclitaxel immobilised beads revealed several specific bands in RERF-LC-KJ; these bands were not revealed in the other cell lines.
Conclusions: We propose that paclitaxel resistance is associated with intracellular compartments in which paclitaxel accumulates and paclitaxel-binding proteins expressed specifically in resistant cell line.
No conflict of interest.

831 POSTER

Naturally occurring isothiocyanates potentiate doxorubicin cytotoxicity in doxorubicin-resistant colon cancer cells

M. Psurski[1], J. Wietrzyk[2], J. Oleksyszyn[1]. [1]*Wroclaw University of Technology, Division of Medicinal Chemistry and Microbiology, Wroclaw, Poland;* [2]*Institute of Immunology and Experimental Therapy, Division of Experimental Oncology, Wroclaw, Poland*

Background: Doxorubicin and other anthracyclines are well-known, widely used and very efficient cancer therapeutics agents. Unfortunately, prolonged administration very often causes severe toxic effects and leads to resistance, thereby limiting the usability in chemotherapy. One of potential strategies to lower the toxicity and overcome resistance is to use an additional compound as a sensitizing agent making cancer cells more susceptible to cytostatics. Naturally occurring isothiocyanates (ITC), due to their low toxicity and multi-targeted mechanism of action, have been recently introduces as a potentially effective agents in combined therapy.
Material and Methods: Isothiocyanates, including benzyl, 3,4-dimetoxybenzyl and 6-hydroxyhexyl isothiocyanate were tested in combined therapy with doxorubicin in two colon cancer cell lines − drug-sensitive LoVo and its doxorubicin-resistant subline LoVoDX. Several different schedules of treatment were checked and their outcome was analyzed using MTT assay. Further studies on the combination mechanism of action involved determination of: ROS production, doxorubicin accumulation and caspase-3/7 activity, as well as cell cycle and glutathione level analysis.
Results: Short, 1 hour pretreatment with isothiocyanates (concentration in the range of 10−2.5μM) followed by medium removal and doxorubicin treatment for next 48 hours led to the most pronounced synergistic effect (Combination index CI, calculated using Chou-Talalay method 0.28–0.45). Isothiocyanate concentration proved to be an important factor affecting observed effect − concentrations lower than 2μM used in above mentioned schedule gave additive or even an antagonistic effect. In LoVoDX cell line 3,4-dimetoxybenzyl isothiocyanates almost completely abrogated doxorubicin resistance (resistance index RI calculated as a LoVoDX/LoVo IC_{50} ratio − 9 without isothiocyanate, and 1.6 for combination). Doxorubicin accumulation remained at the same level after isothiocyanates pretreatment, thereby increased drug concentration appears to be not involved in increased cytotoxicity. Further studies showed that glutathione depletion caused by isothiocyanates (30%-45% decrease in glutathione content after 1 hour) led to increased ROS-production in cells treated with combinations. Moreover, isothiocyanates pretreatment induced cell cycle arrest in G2/M phase which might be also associated with increased doxorubicin cytotoxicity. The final outcome of combined treatment was apoptotic cell death indicated by caspase-3/7 increased activity.
Conclusions: Naturally occurring isothiocyanates proved to be a potent sensitizing agents when used along with the doxorubicin in properly designed schedule. Their main mechanism of action in combined treatment appears to be based on the modulation of cell cycle and redox status.
No conflict of interest.

832 POSTER

Gene resilencing following decitabine therapy is initiated by nucleosome reoccupancy and is related to CpG island shore methylation

V. Patil[1], M. Sloane[2], J.W.H. Wong[2], J. Liu[2], A.C. Nunez[2], R.L. Ward[2], L.B. Hesson[2]. *[1]Lowy Cancer Centre, Sydney NSW, Australia; [2]Lowy Cancer Centre, Medicine, Sydney NSW, Australia*

Decitabine is a front line therapy for myelogenous leukaemias and is in clinical trials for various solid tumour types. This DNA demethylating agent reactivates genes silenced by promoter hypermethylation in cancer. However upon drug withdrawal reactivated genes undergo resilencing which may underlie drug resistance. While resistance is associated with resilencing of genes, the mechanism underlying this resilencing is unknown. We aimed to decode the ordered sequence of epigenetic events associated with resilencing in order to improve the clinical effectiveness of Decitabine. Using biallelically methylated MLH1 as a model gene, we profiled epigenetic changes at the MLH1 promoter associated with reexpression and resilencing in a colorectal cancer cell line before, during and after Decitabine treatment. In contrast to the closed chromatin structure observed before treatment, Decitabine induced increased MLH1 expression and 54% decreased promoter methylation. Using single molecule analysis at multiple time points, we show that gene resilencing, which occurs 6−8 days following removal of therapy, was initiated by nucleosome reassembly on demethylated DNA and only then was followed by remethylation and stable silencing. Furthermore, long-term monitoring of cells following treatment showed MLH1 resilencing never reverts to pretreatment levels with low-level MLH1 expression and demethylated MLH1 promoter alleles persisting up to 118 days after withdrawal of Decitabine. Genome-wide methylation profiling was used to categorise promoter CpG Islands (CGI) based on their degree of demethylation after treatment. This revealed that CGIs with persistence of demethylated promoter alleles after long-term recovery ($n = 108$) showed significantly lower levels of CGI shore methylation ($p = 0.0231$). Our findings suggest a role for shore methylation in susceptibility to CGI remethylation. The data also establishes the importance of nucleosome positioning in mediating resilencing of drug-induced gene reactivation and suggest a role for therapeutic targeting of nucleosome assembly as a mechanism to overcome drug resistance.

New pharmacological approaches against human epidermal growth factor receptor 2 (HER2+) resistant breast cancer

A. Blancafort[1], A. Giró[1], G. Oliveras[1], V. Puigneró[2], A. Viqueira[3], M.V. Bolos[3], A. Urruticoechea[4], T. Puig[1]. *[1]University of Girona, Medical Sciences, Gerona, Spain; [2]Roche Farma SA, Breast and Ovarian Oncology Department, Madrid, Spain; [3]Pfizer, Medical Department, Madrid, Spain; [4]Catalan Institute of Oncology (ICO), Medical Oncology, Barcelona, Spain*

Background: Therapeutic acquired resistance of HER2 positive breast cancer represents a major health care problem given the lack of curative interventions for a large subset of patients bearing this disease. Many efforts are being devoted to find new pharmacological strategies for patients unresponsive to existing treatments. Our group has shown that HER2+ tumors also overexpress fatty acid synthase (FASN+).

The purpose of this study is to test drugs inhibiting different molecular targets to assess the effects in HER2+ breast cancer, even in those resistant to anti-HER2 drugs.

Materials and Methods: We have developed long term HER2+ breast cancer cell lines (SKBr3) resistant to the HER2-monoclonal antibody (trastuzumab, herceptin®) (SK**TR**), the EGFR/HER2-tyrosine kinase inhibitor (lapatinib, tykerb®) (SK**LR**) or both (SK**LTR**). Once established, we have characterized these cells by studying a panel of EGF receptors signaling proteins with western blot analysis, changes in adherence to extracellular matrix proteins and invasion capacity with colorimetric assays. Using MTT assay, we have assessed the effect of a HER2 dimeritzation-inhibitor (pertuzumab, perjeta®), an mTOR-inhibitor (temsirolimus, torisel®) and a new FASN inhibitor developed in our laboratory (G28UCM) on the viability of parental and resistant cells. Currently, we are establishing orthotopic xenograft mice models to test the anti-cancer effect of these drugs, alone or in combination.

Results: Resistant cells maintained downstream HER2 pathway activation by stimulating the expression/activation of alternative EGF family receptors and/or those specific ligands. Moreover, these cells increased adherence to extracellular matrix proteins and invasion capacity.

The HER2-dimerization inhibitor (perjeta®, 50 μg/ml) produced a decrease of approximately 20−40% in cell viability, even in resistant cells non-responding to trastuzumab and lapatinib. Inhibition of mTOR had a potent effect in parental and resistant breast cancer cells, producing a drop of 30% in cell viability with 4.8−6 μM of temsirolimus. The inhibition of 30% in cell proliferation was obtained with 5.5–11.6 μM of G28UCM. Moreover G28UCM improved the cytotoxic effects of other known FASN inhibitors (C75 and EGCG).

Conclusions: FASN inhibition, alone or in combination with other targets (such as mTOR or EGF family receptors) could be a new pharmacological strategy to fight HER2+ breast cancer resistant to trastuzumab and lapatinib. New studies in ortoxenopatients are needed to strengthen this study.

Conflict of interest: *Other substantive relationships: Puigner V. is employed by Roche Farma SA, which kindly yielded us pertuzumab, perjeta™. Viqueira A, Bolos MV are employed by Pfizer, which kindly yielded us temsirolimus, torisel™.*

Epithelial–mesenchymal transition confers resistance to FGFR inhibitors in gastric cancer cell line

P. Grygielewicz[1], D. Zdzalik[1], B. Dymek[1], A. Bujak[1], P. Gunerka[1], A. Stanczak[1], M. Lamparska-Przybysz[1], M. Wieczorek[1], K. Dzwonek[1]. *[1]Celon Pharma, Molecular Biology and Preclinical Research, Kielpin/Lomianki, Poland*

Background: Targeted therapies based on kinase inhibitors may bring encouraging results but they frequently elicit resistance that makes the therapy ineffective and is often accompanied with cross-resistance to other drugs. Understanding and anticipation of the resistance mechanism for novel targeted drugs provides new approaches to use alternative or combine therapy which would improve patients' chances for recovery.

Fibroblast growth factor receptor (FGFR) comprises a promising target for anticancer therapy as it's amplification, mutation or overexpression is considered to be an oncogenic driver in various types of human neoplasms. Several clinical trials are currently carried out with the use of FGFR inhibitors but there still lacks the information about possible mechanisms of resistance to therapy in treated patients. The aim of the study was to define the mechanisms of acquired resistance to FGFR inhibitors: AZD-4547, BGJ 398 and PD173074 in selected in vitro models.

Material and Methods: To explore the mechanism of acquired resistance to FGFR inhibitors we have applied SNU16 human gastric cancer cell line with FGFR2 amplification. The cells were cultured with increasing concentrations of each inhibitor: AZD-4547, BGJ398 or PD173074 until reaching a concentration exceeding the IC50 value ten times. The mechanism of resistance was verified using immunoblotting techniques.

Results: In the following study we have established three gastric cancer cell lines SNU16R AZD, SNU16R BGJ, SNU16R PD, resistant to selective FGFR inhibitors AZD-4547, BGJ398 or PD173074, respectively. Since we found the loss of FGFR phosphorylation in all three lines we concluded that the resistance results from activation of alternative signaling pathways and is not evoked by mutation in FGFR kinase gene. We found however loss of several cell surface growth factor receptors like cMet or EGFR in these lines. Concurrently, the protein profile of established cell lines indicated epithelial–mesenchymal transition (EMT). We found the decrease in E-cadherin level and an increase of vimentin which are markers of EMT.

Conclusion: Our results reveal that one of the mechanisms of acquired resistance to FGFR selective inhibitors can be epithelial–mesenchymal transition. To our best knowledge it is the first time to show EMT as mechanism of resistance to the therapy targeting at FGFR. This finding indicates that EMT could emerge in patients treated with FGFR inhibitors.

835 POSTER

Molecular mechanisms of resistance to protein kinase B inhibitors of the alkylphosphocholine family

S. Oeck[1], R. Handrick[1], V. Jendrossek[1]. *[1]University Hospital Essen, IFZ, Essen, Germany*

Background: Resistance of solid tumors to standard chemotherapy and radiotherapy remains challenging to successful treatment. But new hypothesis based on current studies reveal that tumor cells also show resistance to small molecule signal transduction inhibitors, including the membrane-targeted apoptosis modulators of the alkyllysophospholipid drug family (van der Luit A, Biochem J 2007). Drugs of the ALP or alkylphosphocholine (APC) drug families potently induce apoptotic cell death in various cancer cells and enhance radiation-induced cell death as well as radiation induced eradication of clonogenic tumor cells.

Aim of the proposed project was to mimic clinically relevant long-term treatment with the intravenously applicable APC erucylphosphocholine (ErPC) to select for ErPC resistance and to use a proteomics approach

to identify proteins and signaling networks that promote acquired drug resistance in these cells.
Material and Methods: Non-small cell lung cancer cells (A549) were treated in 20 cycles with increasing concentrations of ErPC (10 to 50μM). Drug resistance was confirmed by using standard short term (proliferation, apoptosis) and long-term (clonogenic survival) assays. Potential cross-resistance to treatment with ionizing radiation (IR) was determined accordingly. Proteome analysis was performed by 2D differential gel electrophoresis (DIGE) and subsequent mass spectrometry of altered protein spots. Changes in protein expression ratio were calculated from related spot intensities.
Results: Chronic treatment with rising ErPC concentrations resulted in the selection of A549 with increased resistance to ErPC. Surprisingly, the drug-resistant cells displayed increased susceptibility to IR compared to the non-selected controls. Fluorescence microscope pictures showed morphological changes featuring multiple vesicle-like structures with high auto-fluorescence. Proteome analysis via 2D differential gel electrophoresis and mass spectrometry evidenced changes in expression level of structural proteins and of proteins involved in stress defense.
Conclusions: The role of specific deregulated proteins for cellular sensitivity to ErPC and IR is subject to current investigations. Understanding the mechanisms underlying drug resistance will allow the design of combination strategies that exploit predicted adaptive changes to prevent or overcome drug resistance and improve treatment outcome.
No conflict of interest.

836 POSTER

Curcumin-mediated oxaliplatin resistance reversal in CRC cell lines through modulation of NF-kB, STAT3 and CDK5 signaling pathways

V. Ruiz de Porras[1], A. Ginés[1], S. Vallejo[1], A. Martínez-Cardús[1], J.L. Manzano[2], A. Abad[2], E. Martínez-Balibrea[2]. *[1]Health Sciences Research Institute of the "Germans Trias i Pujol" Foundation, Badalona Barcelona, Spain; [2]Institut Català d'Oncologia.Health Sciences Research Institute of the "Germans Trias i Pujol" Foundation, Badalona Barcelona, Spain*

Background: Oxaliplatin (OXA) is a chemotherapeutic drug widely used in the treatment of colorectal cancer (CRC). Unfortunately, acquired resistance results in a major obstacle for effective treatment. In previous work we observed an up-regulation of Cyclin-dependent kinase 5 (CDK5), pS727-STAT3 and p-P65 (NF-κβ) in the HT29-derived OXA-resistant cell line, HTOXAR3. Curcumin (diferuloylmethane), the major active ingredient of turmeric (*Curcuma longa*), without discernable toxicity, has been shown to inhibit the growth of transformed cells and colon carcinogenesis in rodent models. Curcumin has also been shown to suppress activation of transcription factors NF-κβ and STAT3. The aim of this work was to demonstrate whether the combined treatment of curcumin and OXA could revert the acquired resistance to the latter in HTOXAR3 cells.
Material and Methods: Curcumin IC50 determination and the effect of curcumin and OXA treatment on the proliferation of HT29 and HTOXAR3 cells was determined by a MTT assay and data were analysed by Chou and Talalay method. Curcumin time-dependent phosphorylation status of CDK5 (tyr-15), STAT3 (S727) and P65 (Ser536) was studied by Western Blotting at different times after curcumin treatment.
Results: Curcumin IC50 (μM) was approximately the same for both cell lines (HT29 IC50: 10.2±0.85, HTOXA IC50: 11.2±0.43). HT29 and HTOXAR3 cells were treated with 10μM curcumin for 4, 8, 24 and 48 h. As compared with untreated cells, maximum effect was observed after 48 h. pSTAT3 inhibition was 40% in both HT29 ($p = 0.0036$) and HTOXAR3 ($p = 0.0016$); pCDK5 inhibition was 60% in both HT29 ($p = 0.0006$) and HTOXAR3 ($p = 0.0073$) and pP65 inhibition was 30% in HT29 ($p = 0.0067$) and 40% in HTOXAR3 ($p = 0.0011$). We investigated the effect of sequential and concomitant treatment of OXA and curcumin. Preliminary results indicate that the highest effect is obtained in the concomitant schedule for 24 h as compared with sequential treatments (24 h-treatment with OXA or curcumin followed by an additional 24 h-treatment with OXA or curcumin). Cell viability was 27% (curcumin + OXA), 9% (OXA + curcumin) and 2% (concomitant treatment) as compared with individual exposures.
Conclusions: We demonstrated that curcumin suppressed activation not only of NF-κβ, STAT3 but also CDK5 in HT29 and HTOXAR3 cell lines, providing evidence that curcumin can be used in therapeutic regimes directed against CRC and suggesting that in combination with OXA, it could revert the resistant phenotype to this drug. Further experiments are ongoing in order to elucidate the best combination schedule.

837 POSTER

A novel 3D cell culture system for in vitro evaluation of anticancer compounds

T. Nishino[1], T. Kanaki[1], A. Otani[1], K. Saruhashi[2], M. Tomura[2]. *[1]Nissan Chemical Industries LTD., Biological Research Laboratories, Saitama, Japan; [2]Nissan Chemical Industries LTD., Chemical Research Laboratories, Chiba, Japan*

Background: Traditional method for evaluating chemo-therapeutic drug has generally employed single layer of cells grown on plastic surface (2-dimentional cell (2D) cultures), which is physiologically different from the natural environment of the cells. Screening compounds by using the method therefore has the potential to result in less effective anticancer drugs than anticipated when tested in clinical trial. Recently, a number of approaches have been developed to generate 3D cell culture models for cancer study; e.g. scaffolds, microcarriers, and spheroids. However, many challenges remain, such as applying them into high throughput screening systems and improving the efficiency of anticancer drug discovery.
Material and Methods: In this study, we screened large-molecule compounds for the ability to suspend cancer cells homogeneously in liquid culture medium with keeping the medium low-viscosity, and identified FP001 as the most potent compound. We also established a novel method for the generation of cancer cell spheroids in suspension by using FP001 in ultra-low attachment multiwell plates. The cultured spheroids of cancer cells were characterized in terms of cell growth, apoptosis, cell cycle, and susceptibility to anticancer drugs to demonstrate the competency of the method.
Results: We cultured A549, HCT116, and HeLa cells for 5 days in medium containing FP001 and observed their cellular appearance and growth. The spheroids formed in the 3D culture medium were appropriate in size and suspended homogeneously, which led to easy handling for various assay. The cultures with FP001 exhibited a >10-fold increase in the number of living cells and contained decreased numbers of $BrdU^+$ cells and increased numbers of Annexin V^+ cells as compared to those with vehicle. Furthermore, the cells cultured in the medium were more sensitive to Mitomycin C, and the inhibition concentration obtained by the method was closer to actual blood level than that by 2D cultures. These data suggest that FP001 promotes the proliferation of spheroid forming-cancer cells which allow practical sensitivity to anticancer compounds. We are now investigating the feasibility of the method for development of automated and miniaturised screening systems.
Conclusions: We have identified FP001 as a novel substrate for the 3D culture of cancer cells. The approach using FP001 would facilitate the development of novel models for in vitro evaluation of anticancer compounds.

High-throughput assay for screening cancer metastasis inhibitors in human cancer cells using adenoviral knock-down

C. Oerlemans-Bergs[1], R. De Pril[1], D. Schluep[1], E. Elstak[1], D. Van Steenhoven[1], J. Ronken[1], I. Maghrani[1], A. Lekkerkerker[1], R. Janssen[1]. *[1]Galapagos B.V., Leiden, Netherlands*

The de-differentiation from a normal non-invasive epithelial cell into an immortalized, metastatic cell requires deregulation of multiple cellular processes. Our aim was to establish a high-throughput assay in human cancer cell lines to identify novel drug targets that reverse this deregulation by inducing Mesenchymal-to-Epithelial transition (MET).
Invasive mesenchymal cells express vimentin whereas non-invasive epithelial cells express E-cadherin, and the ratio between these markers reflects the identity of the cancer cells. We established an image-based functional high throughput assay measuring these markers in different cancer cell lines. Images were acquired on an INCell2000 Analyzer and an in-house written algorithm was used to calculate vimentin and E-cadherin expression. Using this assay, we screened an adenoviral shRNA knock-down library directed against human drugable genes for their potential to induce MET.
We successfully developed an automated high-throughput MET assay in multiple cancer cell lines which can be used for discovery and validation of novel targets for their potential to inhibit metastasis. Using this approach, we identified new targets as well as known players involved in MET. Knock-down of the transcription factor Snail, known to control epithelial–mesenchymal transitions, induced MET, similar to knock-down of members of the Wnt-signaling pathway.
Discovery of novel targets in metastasis may lead to the development of small molecule compounds or antibody therapeutics in cancer therapy.

839 POSTER

A novel cell assay to screen for wnt pathway inhibiting drugs

J. Apfel[1], P. Reischmann[1], O. Müller[1]. [1]*University of Applied Science, Molecular Biology, Zweibrücken, Germany*

The wnt pathway is one of the most crucial pathways in colon cancerogenesis: In most colorectal cancers (CRC) wnt correlated genes are mutated. Since screening assays for drugs modifying this important pathway are still rare we generated a stable cell line transfected with a new fluorescence-based reporter.
Therefore, we designed a reporter gene construct based on the well-established TOPFLASH reporters coupled with eGFP instead of luciferase and then stably transfected into SW480 cells. As the wnt-state in this cell line is known to be active the new cell line named SW480-SuperTopEGFP can easily be used as a screening tool for new inhibitors the pathway.
In preliminary experiments the known wnt inhibitory compounds acetylsalicylic acid, XAV939 (tankyrase inhibitor; Hollande et al., 2010), PKF118–310 (Tcf4/β-catenin complex inhibitor; Wei et al., 2010) or FH535 (β-catenin inhibitor, Handeli et al., 2008), bleached the fluorescence of the tested well and measured the fluorescence recovery 24 hours after treatment compared to the untreated control. This resulted in a lower fluorescence signal in treated cells than in untreated cells. Following this treatment we used a self-made set-up to bleach cells seeded in a 96-well plate simultaneously. For quantification the fluorescence recovery time can be measured after treatment to have a dimension for the effectiveness for specific wnt inhibitors.
In conclusion we established an assay-set-up capable for use in automated image screening assays. In comparison to already established assays this new approach is much more cost-effective and easy to perform. Therefore this is a further step towards in specific compound research targeting the wnt pathway.

XenoBase enabled growth rate analysis improves xenograft study design

S. Guo[1], J. Li[1], J. Zhang[2], W. Qian[1], Q. Shi[2]. [1]*Crown Biosciences, Biomarker Discovery, Santa Clara − CA, USA;* [2]*Crown Biosciences, Cancer Pharmacology, Santa Clara − CA, USA*

Xenograft models are widely used in the oncology drug discovery and development process. However, the lack of available information regarding the Xenograft models, such as growth curves, standard of care treatment results, IHC analysis of biomarkers, as well as target gene expression, mutation and amplification, hampers the selection of suitable models for accurate evaluation of therapeutic molecules. We have created XenoBase™ that combines public cell line profiling data with our own data on >180 xenograft models. A searching engine is also built in the database to search for models based on gene mutation, expression, amplification, as well as SOC information, types (orthotopic, subcutaneous, systemic) of the xenograft models. The XenoBase™ will enable informed decision in selecting the most relevant models for the development of targeted therapeutics.
Armed with hundreds of xenograft studies available in the XenoBase™, we analyzed the tumor growth rate of each study in order to compare the results with traditional T/C analysis. The T/C analysis is the current standard, and a T/C value less than 0.42 is widely accepted as an indication of efficacy in evaluating a test article. However, this T/C analysis is limited in using only the data points on one day, overlooking the fact that tumor growth curves are generated over a long period of time (months) and with many days of data collection. To take advantage of the tumor growth curves, we analyzed tumor growth rate utilizing every data points, and derived growth rate based on slopes. Our analysis with the XenoBase™ data indicated that the growth rate based approach is more powerful in evaluating test articles for efficacy. If adopted by the industry, this approach may save hundreds of millions of dollars spent in excess number of animals and prolonged observations that may not be necessary.

841 POSTER

High-throughput 3D screening reveals differences in drug sensitivities between culture models of JIMT1 breast cancer cells

V. Hongisto[1], S. Nyberg[1], V. Fey[1], J.P. Mpindi[2], O. Kallioniemi[2], M. Perälä[1]. [1]*VTT Technical Research Centre of Finland, Biotechnology for Health and Well-being, Turku, Finland;* [2]*University of Helsinki, Institute for Molecular Medicine Finland, Helsinki, Finland*

Background: Many cellular features are impaired in the traditional 2D cell culture conditions and big alterations in gene expression in comparison to tumors have been reported. Three-dimensional (3D) cell culture models are suggested to be better models than 2D monolayers due to improved cell-to-cell contacts and structures that resemble in vivo architecture.
Materials and Methods: The aim of this study was to develop a simple high-throughput 3D drug screening method and to compare drug responses in JIMT1 breast cancer cells when grown in 2D, in polyHEMA induced anchorage independent 3D models and in Matrigel 3D cell culture models. We screened 102 compounds with multiple concentrations and biological replicates for their effects on cell proliferation. Gene expression patterns of cells in the different culture models were also compared to xenografts.
Results: Big variations in drug responses were observed between the models. We show that, in general, JIMT1 cells grown on Matrigel were significantly more sensitive to drugs than cells grown in 2D cultures, while responses of cells grown in polyHEMA resembled those of 2D. Furthermore, comparison of gene expression profiles of the cell culture models to xenograft tumors indicated that cells cultured in Matrigel and as xenografts most closely resembled each other.
Conclusions: 3D cultures can provide a platform for systematic experimentation of larger compound collections in a high-throughput mode and can be used as alternatives to traditional 2D screens towards better comparability to in vivo state.
No conflict of interest.

842 POSTER

5-FU Monitoring in clinical practice: Pharmacokinetic variability

M. Biffi[1], F. Petrelli[2], K. Borgonovo[2], M. Cabiddu[2], M. Ghilardi[2], A. Coinu[2], M. Cremonesi[2], E. Cavalleri[2], A. Pesenti[1], S. Barni[2]. [1]*Azienda Ospedaliera Treviglio, Clinical Pathology, Treviglio, Italy;* [2]*Azienda Ospedaliera Treviglio, Oncology, Treviglio, Italy*

Background: Current dosing of 5-Fluorouracil (5-FU) is based on body surface area (BSA). However BSA dosing has been associated with clinically significant pharmacokinetic (PK) variability. Dosing based on BSA has been seen to result in low exposure and loss of efficacy, or high exposure and severe toxicity. The reported target area under the concentration vs. time curve (AUC) for 5-FU is 20−30 mg.h.l^{-1}. 5-FU therapy which achieves this AUC has been shown to improve response rates and minimize toxicity. The aim of this study was to evaluate the practicality of sampling 5-FU for dose management and evaluate the PK variability resulting from BSA dosing in commonly used continuous infusion (CI) regimens for colorectal cancer (CRC).
Material and Methods: Blood samples were obtained from 24 patients with colorectal cancer receiving 5-FU CI: 9 patients received FOLFOX 4, 7 received FOLFIRI, 7 received De Gramont and 1 5FU/LV. The mean dose of 5-FU administered was 1151 mg/m^2 (range 440–1270 mg/m^2). In total 57 EDTA samples were drawn a minimum of 1 hr before the end of the 5-FU CI at 5-FU steady state concentration. The 5-FU concentrations were subsequently quantified on a Roche Cobas® 6000 using a homogeneous immunoassay (MyCARE™ 5-FU, Saladax Biomedical, Inc.). The 5-FU AUC was calculated from the reported plasma concentrations and one result was discarded as it was clearly an outlier.
Results: The 24 patients analyzed demonstrated a wide range of AUCs: ranging from 2.7 to 37 mg.h.l^{-1} with a mean of 12.2 mg.h.l^{-1} and a standard deviation (SD) of 6.19 mg.h.l^{-1}. There was no significant correlation observed between 5-FU dose and AUC for any of the regimens − overall R^2=0.0312; p = 0.576.

Regimen	Patients/ Samples	AUC, mg·h·l^{-1}		Number of patients below range
		Mean	SD	
Folfox 4	9/24	13.7	7.0	8 (89%)
Folfiri	7/18	8.4	2.7	7 (100%)
DeGramont	7/13	14.4	6.2	6 (86%)
5-FU/LV	1/1	15.3	−	1 (100%)

Conclusions: These data support the previous reports that standard BSA dosing of 5-FU leads to a high PK variability. Using the optimal AUC range of 20−30 mg.h.l^{-1}, out of the 24 patients, 22 (92%) were under the target level with only 2 out of the 24 receiving an initial dose resulting in an AUC within the target range. Exposure appeared independent of regimen. Based on the results of this small study it appears that sampling and measuring concentrations of 5-FU during CI to adjust the dose to reach optimal exposure is practical and may be a rational approach to delivering effective treatment.
No conflict of interest.

843 POSTER

Nanostructured silica functionalized with an organotin compound induces differentiation of B16 melanoma cells

M. Bulatovic[1], C. Bensing[2], D. Miljkovic[1], M. Mojic[1], S. Gómez-Ruiz[3], S. Mijatovic[1], D. Maksimovic-Ivanic[1], G. Kaluderovic[2]. *[1]Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Belgrade, Serbia; [2]Institut für Chemie, Martin-Luther-Universität Halle-Wittenberg, Halle, Germany; [3]Departamento de Química Inorgánica y Analítica, Universidad Rey Juan Carlos, Madrid, Spain*

Background: Cancer nanotechnology is a promising area of research in science and medicine that finds application for molecular imaging, molecular diagnosis, and targeted therapy. Using targeted nanoparticles with anti-cancer drugs offers the possibility of destroying tumors with minimal damage to healthy tissue and organs using significantly lower doses of toxic chemotherapy. Nanostructured silica-based materials proved to be an excellent candidates as drug carrier for cancer therapy. Here we evaluated potential of silica nanoparticles SBA-15p grafted with an organotin(IV) compound [$SnPh_3\{(CH_2)_8OH\}$] against B16 melanoma cells.
Material and Methods: Cell viability was estimated by MTT and CV tests. Flow cytometric analysis was done on cells stained by Propidium Iodide, Annexin V-FITC/PI, Apostat, DAF-FM, DHR or CFSE dye. Differentiation of melanoma cells was evaluated by measuring intracellular amount of melanin and activity of key enzyme involved in melanin synthesis − tyrosinase and microscopic analysis of cells stained with hematoxylin dye.
Results: SBA-15pSn as well as [$SnPh_3\{(CH_2)_8OH\}$] strongly suppressed the viability of B16 cells. The amount of [$SnPh_3\{(CH_2)_8OH\}$] in MC_{50} concentration of SBA-15pSn is approximately 100 times lower than IC_{50} dose of free [$SnPh_3\{(CH_2)_8OH\}$]. Carrier alone had no influence on cell viability. Reduced cell viability was the consequence of inhibited cell proliferation. In parallel, small percentage of cells died by caspase dependent apoptosis. The rest of the cells were transformed into large, granulated cells. Observed granules were in fact melanosomes since it was determined that SBA-15pSn strongly enhanced tyrosinase activity and melanin quantity. On the other hand free compound slightly increased tyrosinase activity and production of melanin. Amount of reactive oxygen and nitrogen species was not significantly changed in the presence of SBA-15pSn suggesting that antitumor activity was not associated with their production. Free compound reduced the production of ROS which can be explained as a defense mechanism against toxic stimuli.
Conclusion: Overall results show that packaging of toxic metal-based drug in nanoparticles achieved a stronger antitumor effect with less toxicity.
No conflict of interest.

844 POSTER

Physical and chemical compatibility of fosaprepitant dimeglumine for injection with concomitantly dosed medications

B. Duersch[1], M. DeSouza[2], J. Seno[3], H. Kawada[3]. *[1]Merck, Whitehouse Station NJ, USA; [2]Merck, Early Development, Whitehouse Station NJ, USA; [3]Ono Pharmaceutical Co., Research, Osaka, Japan*

Background: Fosaprepitant (EMEND IV®, IVEMEND® and PROEMEND®) is a key anti-emetic therapy for highly emetogenic chemotherapies (MASCC/ESMO Antiemetic Guideline 2011). As fosaprepitant is frequently co-administered with other agents, it is important to understand which combinations of drugs will not adversely impact the chemical or physical stability of Fosaprepitant. Therefore, we explored the impact of concomitantly dosed medicines on the physical and chemical stability of fosaprepitant (and only fosaprepitant). Mixtures included combinations of other anti-emetics, corticosteroids, anti-histamines, H2 blockers, anti-spasmodics, B vitamins, Vitamin K, diuretics and infusion solutions (including saline, glucose solution and multiple electrolyte solutions).
Materials and Methods: 172 different combinations of fosaprepitant with up to four other agents were prepared together to simulate simultaneous administration from a single IV bag. The impact on fosaprepitant stability was determined by visual observation and HPLC analysis after storage under ambient conditions for 24 hours.
Results: Fosaprepitant was found to be compatible with many of the admixtures. Degradate growth was determined to the most sensitive predictor of stability. The extent of degradation of fosaprepitant was strongly dependent on the solution pH. These results are consistent with the known chemistry of fosaprepitant. The only degradate observed was the active pharmaceutical ingredient aprepitant, which readily forms via hydrolysis from the prodrug fosaprepitant.
Conclusions: Acceptable in-vitro physical and chemical stability of fosaprepitant was demonstrated with many of the concomitantly dosed medicines. The pH of the admixture was shown to have a significant impact on the stability of fosaprepitant.
Conflict of interest: *Other substantive relationships: BD and MDS are employees of Merck and may own stock/stock ownership in the company.JS and HK are employees of Ono Pharmaceuticals Co., Ltd.*

846 POSTER

Safety results from a Phase I study with a new tablet formulation of olaparib (O) in combination with carboplatin (C) and paclitaxel (Pa)

R. Van der Noll[1], J. De Grève[2], A. Jager[3], S. Marchetti[1], M. Mergui-Roelvink[1], M.J.A. De Jonge[3], D. Van der Biessen[3], I. Tchakov[4], K. Bowen[4], J.H.M. Schellens[1]. *[1]The Netherlands Cancer Institute, Amsterdam, Netherlands; [2]Oncologisch Centrum UZ Brussel Vrije Universiteit Brussel, Brussels, Belgium; [3]Erasmus University Medical Center, Rotterdam, Netherlands; [4]AstraZeneca, Macclesfield, United Kingdom*

Background: This Phase I study evaluated safety/tolerability and preliminary antitumour activity of the PARP inhibitor O with C and Pa in patients (pts) with advanced solid tumours refractory to standard therapies (NCT00516724; sponsor, AstraZeneca). Previously, we reported data from cohorts 1−15 that evaluated the capsule form of O and identified a tolerable schedule with CPa: O 200 mg bid (d1−10) plus CPa AUC4/175 mg/m^2 q 3 weeks (van der Noll *et al* ASCO 2013). Here, we report data from cohorts evaluating a new tablet form of O with higher bioavailability and improved pt convenience vs the capsule.
Materials and Methods: O tablets were introduced at 200 mg bid (days 1−10 per 21-day cycle) with CPa AUC4/175 mg/m^2 q 3 weeks (both on day 1 per cycle); as this proved non-tolerable, other regimens were explored. AEs were graded by CTCAE v3.0. Objective tumour response was evaluated by RECIST.
Results: 102 pts were enrolled in 3 centres. The table shows dose schedules for tablet cohorts.

Cohort (pts, n)	O, mg bid (days)	C, AUC
16 (8)	200 (1−10)	4
17 (6)	100 (1−10)	4
17b (15)	100 (1−10)	4
18 (6)	100 (1−10)*	4
19 (6)	100 (1−5)	4
20 (6)	100 (3−12)	4
21 (13)	50 (1−5)	5
22 (6)	200 (1−2)	5
23 (6)	100 (1−2)	6
24 (6)	100 (1−5)	5
25 (6)	100 (1−2)	5
26 (6)	50 (1−2)	6
27 (6)	50 (1−2)	5
28 (6)	50 od (1−5)	5

Pa dose: 175 mg/m^2 in all cohorts. *100 mg od on day 1 (6 h post-C).

Most common tumour types were breast (53%) and ovarian (33%); 90 (88%) pts had received prior chemotherapy. 40 (39%) pts were known to have a *BRCA1/2* mutation. Common haematological AEs included neutropenia (53%), thrombocytopenia (41%) and anaemia (20%). Other common AEs included fatigue (82%) and nausea (73%). Neutropenia leading to delays in chemotherapy cycles was the main dose-limiting toxicity. Toxicities in tablet cohorts were generally consistent with those in capsule cohorts, but lower O tablet doses and/or treatment durations were needed to manage increased haematological toxicity (neutropenia) and treatment delays. Cohort 19 was tolerable but, due to the low C dose (AUC4), further dosing schedules were assessed leading to identification of a second tolerable schedule with C AUC5 (cohort 27). Preliminary antitumour activity was encouraging with 5 (5%) pts achieving a complete response and 39 (38%) a partial response.
Conclusions: When combined with CPa, a lower dose of the tablet formulation of O (vs capsule) is required to optimize tolerability. O 50 mg

bid plus CPa AUC5/175 mg/m^2 was considered tolerable, but with limited duration of O use (2 days per cycle).
Conflict of interest: *Ownership: I. Tchakov & K. Bowen are employees of AstraZeneca and own AstraZeneca stock*

847 POSTER

Discovery of naturally occurring toll-like receptor-4 signalling inhibitors: Their anticancer effects and mechanisms of action

C.W. Mai[1], Y.B. Kang[1], A.S. Hamzah[2], M.R. Pichika[1]. [1]*International Medical University, Pharmaceutical Chemistry, Kuala Lumpur, Malaysia;* [2]*Universiti Teknologi MARA Shah Alam Selangor Malaysia, Institute of Science, Shah Alam, Malaysia*

Background: Toll-like receptor 4 (TLR-4) plays a key role in pathogen recognition and activation of innate immunity. Very recent studies have suggested aberrant TLR-4 activation by tumour cells promotes their proliferation and survival. To the best of our knowledge, there are no studies on the potential use of TLR-4 signalling inhibitors in cancer treatment. Therefore with the aim of exploring the potential of TLR-4 signalling inhibitors in cancer treatment.
Materials and Methods: We have employed the target- and ligand-based *in silico* screening to discover novel natural products as TLR-4 signalling inhibitors. The best drug-like compounds were selected for *in vitro* studies to measure their efficacy in inhibiting the actions of lipopolysaccharide (LPSEc) in TLR-4/MD-2/CD-14 transfected HEK-293 cells. Their IC_{50} value was determined using dose-response curves. The IC_{50} value is defined as the concentration of these compounds inhibit the 50% of LPSEc's activity. The anticancer effects of these compounds were evaluated in 12 human cancer cells using MTT assay. We also evaluated the apoptotic induction effects of these compounds using fluorescence microscope and enzyme linked immunosorbent assay (ELISA).
Results: The majority of the selected compounds were shown significant inhibition of LPSEc induced TLR-4 activity. The experimental results are in good agreement with virtual screening results suggesting the constructed *in silico* model is a good model and can be used in discovering novel TLR-4 signalling inhibitors. The results suggested the TLR-4 signalling inhibitors are effective in inhibiting cancer progression. The cytotoxic effects exhibited by these compounds were also confirmed to be more selective towards cancer cells rather than non-cancerous cells. Our results suggested the TLR-4 signalling inhibitors induced apoptosis in cancer cells rather than necrosis.
In conclusion, we have discovered a natural product that inhibits TLR-4 signalling and have proven that TLR-4 signalling inhibitors play a a role in preventing cancer progression.
No conflict of interest.

848 POSTER

Targeting Immuno-liposomes using TCR-like antibodies directed against melanoma antigens

M. Saeed[1], E. Schooten[2], M. Bolkestein[1], T. Ten Hagen[1], A. Eggermont[1], R. Debets[3], G. Koning[1]. [1]*Erasmus Medical Center, Lab Experimental Surgical Oncology, Rotterdam, Netherlands;* [2]*Erasmus Medical Center, Lab Tumor Immunology, Rotterdam, Netherlands;* [3]*Erasmus Medical Center, Lab Experimental Tumor Immunology, Rotterdam, Netherlands*

Chemotherapeutic treatment of solid tumors is greatly hampered by factors like toxicity, rapid drug clearance and poor perfusion of the drug to tumor areas. Nanocarriers such as liposomes make an attractive alternative to free cytotoxic drug by reducing toxicity and promoting drug accumulation in tumors. When coupled to a ligand they can be internalized selectively by target tumor cells. Here, we aim to improve liposomal chemotherapy by developing drug-loaded liposomes that specifically target cell surface-expressed peptide-MHC complexes which constitute the natural targets for T-cells and are uniquely or overexpressed on melanoma cells.
Single chain Fv's G8 and Hyb3 against Melanoma Antigen 1 presented by human leukocyte antigen class 1 (MA1/A1) were derived from a phage-display library. scFv for liposome conjugation are cloned in a modified vector pABC4 which holds an additional cysteine at the C′ terminus of scFv during the production. These scFv are produced in periplasmic fractions and extracted by immobilized metal ion affinity chromatography. Purified scFv are validated by flow cytometry on APD cells pulsed with MA1/A1. Liposomes are prepared by film hydration and extrusion method and characterized by size, polydispersity and lipid concentration and then coupled to scFv via a thio-ether bond. Various analytical approaches are applied to validate this immunoconjugate.
scFv with C-terminal cysteins were produced and purified in considerable yield. Purified scFv were tested for target specificity toward MA1/A1 complex and demonstrated desired affinity for the ultimate molecular target. G 8 and Hyb 3 differ with respect to their ligand-binding affinity towards wild type MA1/A1, expressed by native tumor cells: KD's of 250 and 14 nM, respectively. The difference in ligand-binding affinity will allow us to compare the importance of this parameter for multivalent nanoparticles. The process of coupling scFv to liposomes is being optimized with regard to efficiency and antibody density. Produced immunoliposomes demonstrated cell specific targeting using flow cytometry, in vitro. Various cell assays will be done using fluorometry and confocal microscopy to confirm binding and internalization.
TCR like antibodies have been produced in a scFv format ready for coupling to liposomal nanocarriers. Preliminary data suggest cell specific binding of the newly produced immunoliposomes. Final aim is to evaluate these immuno-conjugates in vivo in relevant tumor models.
No conflict of interest.

First in human phase I study of PankoMab-GEXTM: a novel glyco-optimized anti-TA-MUC1 monoclonal antibody

C. Sessa[1], W. Fiedler[2], J. Weidmann[2], S. DeDosso[1], S. Cresta[3], G. Del Conte[3], M. Salzberg[4], H. Baumeister[4], S. Goletz[4], L. Gianni[5]. [1]*Oncology Institute of Southern Switzerland, Osp. Reg. Bellinzona e Valli, Bellinzona, Switzerland;* [2]*Hubertus-Wald University Cancer Center, University Medical Center Hamburg-Eppendorf, Hamburg, Germany;* [3]*Fondazione IRCCS, Istituto Tumori, Milano, Italy;* [4]*Glycotope GmbH, Berlin, Germany;* [5]*Universitá Vita-Salute San Raffaele, Oncology, Milano, Italy*

Background: PankoMab-GEX is a potent humanized and glyco-optimized IgG1 recognizing the novel carbohydrate-induced conformational TA-MUC1 epitope expressed on the majority of tumor cells in a wide variety of cancers. Its epitope comprises a tumor specific carbohydrate antigen (TF or Tn) together with the immunodominant peptide region of MUC1, is human-specific and virtually only expressed on malignant cells. PankoMab-GEX promotes potent tumor cell killing via ADCC, phagocytosis, apoptosis induction and proliferation inhibition.
Methods: Eligible patients with TA-MUC1 positive (IHC reactivity score $\geqslant$3 on a 12 grade scale) advanced solid tumors, progressing after standard treatments, were enrolled into this first in humans phase I trial. Primary endpoints were safety and tolerability. Pharmacokinetics (PK), immunogenicity and anti-tumor activity were also assessed.
Results: Of the 74 pts included, 73 were treated per protocol: 52 (51) q3w (13 dose levels (DL) from 1–2200 mg), 18 q1w (5 DL from 300–700 mg), 4 q2w (1200 mg + 900 mg start dose one week prior). No MTD was reached. Infusion-related reactions (IRRs), mostly of º1/2 during and after cycles 1 or 2 occurred in ~50 % of the pts starting at the DL of 300 mg q1w. IRR consisted of dyspnea, rash, erythema and flushing, but no cytokine release, and no increases of factor C3a or eosinophilic cationic protein and hence no allergic reactions were observed. Premedication reduced IRRs at 1st inf. from 86% (6/7pts) to 53% (19/36pts) at DL $\geqslant$600 mg. PK was linear and dose-independent with a mean t1/2 =184 h (q3w). In pts with at least one post-baseline CT (62) overall confirmed clinical benefit rate (CBR) was 32% (20/62 pts) across all DL and schedules and 50% (17/34) at DL $\geqslant$600 mg including 1 CR with normalization of CA125 in an ovarian cancer case for 483 days at 1100 mg q3w, and 1 PR for 295 d in a NSCLC case at 600 mg q1w. Confirmed CBR in pts with OvCa was 45% (9/20) over all DL, and for DL $\geqslant$600 mg 60% (9/15). All 5 pts sensitive to their last platinum based therapy experienced CB. Maximum CB duration was in a pseudomyxoma peritonei pt (−21% SLD ongoing for >700 d at 900 mg q3w).
Conclusions: PankoMab-GEX is safe and demonstrated clinical activity in heavily pre-treated pts. The q1w, q2w and q3w administration schedules were feasible and associated with CB.

S100A4 neutralizing mAbs for the treatment of cancer

J.L. Hernandez[1], L. Padilla[1], S. Dakhel[1], R. Messeguer[1], M. Masa[1], J.M. Martinez[1], J. Adan[1], M. Rivas[1], F. Mitjans[1]. [1]*Leitat Technological Center, Biomed Division, Barcelona, Spain*

Background: S100A4 belongs to the S100 family of small Ca-binding proteins. Secreted by tumor and stromal activated cells, plays an important role in tumor progression, angiogenesis and metastasis and therefore it turns out into a very compelling target for cancer therapy. S100A4 has gained increasing attention over the last two decades because of its metastasis-promoting properties and its over-expression has been reported to be associated with poor prognosis of cancer correlates. Although extracellular roles of S100A4 are closely associated with tumor invasion and metastasis, the mechanism by which it promotes an invasive phenotype is not fully understood. This study aimed to determine the role of S100A4 in tumor growth, angiogenesis and metastasis and we

addressed the use of a neutralizing monoclonal antibody (5C3) targeting the extracellular activity of S100A4, to inhibit tumor progression.
Materials and Methods: Endothelial cell-based studies were used pointing to the involvement of S100A4 in at least two steps in the angiogenic cascade: remodeling of the extracellular matrix and cell migration.
We have developed the 5C3 neutralizing monoclonal antibody against S100A4 protein. To examine the inhibitory effect of our antibody a panel of *in vitro* and *in vivo* experiments were run. We used several subcutaneous, orthotopic and intrasplenic mouse tumor models to test the efficacy in tumor development.
Results: Boyden chamber migration assay showed that S100A4 synergizes with VEGF on HUVECs migration and the combination of 5C3 mAb with Bevacizumab is more effective than the two drugs separately. In addition, S100A4 induces the secretion of active forms of MMP-9 and 5C3 mAb blocks this effect.
We observed that treatment with 5C3 reduced in vivo angiogenesis on MiaPACA-2, M21 and HT29 subcutaneous tumor model thereby affecting tumor growth ($p < 0.05$).
Treatment with 5C3 revealed a potent decrease in lung and liver metastasis using the 4T1 orthotopic model and the KM12L4luc intrasplenic model respectively.
Finally, we have also observed that extracellular S100A4 induces metastasis formation by building the pre-metastatic niche on the CT26 intrasplenic model.
Conclusions: Our results highlight the relevance of extracellular S100A4 in tumor development and prove it as a novel therapeutic target in cancer.
No conflict of interest.

851 POSTER

Assessing the potential of S100A7 as target for tumor therapy using neutralizing monoclonal antibodies

J.L. Hernandez[1], L. Padilla[1], S. Dakhel[1], R. Messeguer[1], M. Masa[1], J.M. Martinez[1], J. Adan[1], F. Mitjans[1]. *[1]Leitat Technological Center, Biomed Division, Barcelona, Spain*

Background: S100A7, a member of the S100 calcium-binding protein family, is a low molecular weight protein whose expression have been reported in several cancer types such as breast, lung, bladder, skin, esophageal, gastric and head and neck, correlating in most of them with a poor prognosis. It has been described that extracellular S100A7 can act as a pro-inflammatory, pro-angiogenic and pro-metastatic factor, but its mechanism of action remains poorly understood. In this study, we have developed neutralizing monoclonal antibodies against S100A7 and tested its functionality in different in vitro and in vivo models as therapeutic and diagnostic tools.
Materials and Methods: Cell migration and MTT assays were performed to test the capacity of the obtained specific monoclonal antibodies to neutralize extracellular S100A7 activity. We also studied the downstream signaling pathways and the secretion of pro-inflammatory factors in response to extracellular S100A7 and its blockade by our antibodies. Finally, we assessed the usefulness of the monoclonal antibodies as diagnostic tools for the detection of S100A7 in biofluids and in tumor samples by ELISA and immunohistochemistry respectively.
Results: Extracellular S100A7 induced an increase on MDA-MB-231 breast cancer cell migration and secretion of pro-inflammatory factors possibly by the activation of the MAPK pathway. Furthermore, S100A7 promoted the proliferation of HT1080 fibrosarcoma cells. Our anti-S100A7 specific monoclonal antibodies were effective in neutralizing the *in vitro* activity of S100A7 protein. Finally, we have demonstrated that our antibodies can be used in diagnosis and prognosis by determining the presence of S100A7 in tissue samples and in plasma from tumor bearing mice. A positive correlation between the S100A7 plasma levels and the tumor presence and tumor burden was found.
Conclusions: We have elucidated the extracellular action of S100A7 in tumor cells and obtained useful tools for cancer diagnosis and therapy by the blockade of this protein as a therapeutic target.
No conflict of interest.

852 POSTER

Targeting extracellular S100P: therapeutic potential of monoclonal antibodies

J.L. Hernandez[1], S. Dakhel[1], L. Padilla[1], R. Messeguer[1], M. Masa[1], J.M. Martinez[1], J. Adan[1], M. Rivas[1], F. Mitjans[1]. *[1]Leitat Technological Center, Biomed Division, Barcelona, Spain*

Background: S100P has gained increasing attention over the last two decades because of its cancer-promoting properties, via its specific roles in survival, cell proliferation, angiogenesis, metastasis and drug resistance. Furthermore, high S100P expression has been identified as a significant marker for poor prognosis in several cancer types (such as pancreatic, breast, colon, prostate and lung) when compared with their matched normal tissues and associated to an increased incidence of metastasis. S100P have also shown to be a potential marker with diagnosis and prognosis value for several cancers. The purpose of this study was to validate S100P as a promising target for therapeutic and diagnostic applications by using neutralizing monoclonal antibodies.
Materials and Methods: Specific monoclonal antibodies able to neutralize the extracellular activity of S100P were obtained.
To better understand the role of S100P in tumor cell proliferation and survival, we used two cell lines; one expressing S100P (human pancreatic BxPC3) and one no-expressing (fibrosarcoma HT1080). Proliferation, drug resistance and migration properties were studied *in vitro*. *In vivo* tumor models (subcutaneous, orthotopic and intrasplenic) were developed to assess the efficacy of anti-S100P mAbs on tumor growth and metastasis.
Results: Here we have clearly demonstrated the inhibitory effect of our mAbs on S100P-induced tumor cell proliferation. Additionally, S100P protected BxPC3 and HT1080 cell lines to the cytotoxic effect induced by chemotherapeutic drugs by increasing their survival while anti-S100P mAbs reversed this effect.
Moreover, anti-S100P mAbs blocked tumor growth *in vivo* on a BxPC3 subcutaneous model either by i.t or i.p. route. Moreover, a clear reduction on liver metastasis formation and in the final staging of the disease was observed in an orthotopic and an intrasplenic tumor model when treated with anti-S100P mAbs.
Finally, we have demonstrated a positive correlation between S100P plasma levels and tumor incidence.
Conclusion: These results have shown the importance of S100P in tumor progression and aggressiveness. Therefore, blocking S100P is a valid therapeutic approach and it might improve the response to other therapeutic treatments as well as to decrease the metastatic capacity of the tumor.
No conflict of interest.

Immunogenicity assessment of PF-05280014, a potential biosimilar to trastuzumab, in healthy subjects (REFLECTIONS B327−01)

D. Yin[1], C.H. Cai[2], C.T. Taylor[3], C.M. Zacharchuk[4], D. Rudin[5], S.D. Reich[3], K.B. Barker[6], R. Li[6], A.D. Ricart[7], X.U. Meng[1]. *[1]Pfizer Inc, Clinical Pharmacology/Pharmacometrics, San Diego CA, USA; [2]Pfizer Inc, Clinical Assay Group, Groton CT, USA; [3]Pfizer Inc, Oncology Clinical Research, San Diego CA, USA; [4]Pfizer Inc, Oncology Clinical Research, Cambridge MA, USA; [5]Pfizer Inc, Clinical Research Unit, New Haven CT, USA; [6]Pfizer Inc, Biostatistics, Cambridge MA, USA; [7]Pfizer Inc, Oncology Cliinical Research, Buenos Aires, Argentina*

Background: PF-05280014, a proposed biosimilar to trastuzumab, was evaluated for immunogenicity in a phase 1 pharmacokinetic (PK) similarity study.
Methods: In this double-blind trial (NCT01603264), 105 healthy male subjects with no known prior biologics exposure, were randomized to receive a single 6 mg/kg IV dose of PF-05280014, or trastuzumab sourced from the US (trastuzumab-US) or the EU (trastuzumab-EU) and followed for 10 weeks for PK, safety, and immunogenicity assessments. Serum samples for detecting anti-drug antibodies (ADA) and neutralizing antibodies (Nab) were collected at 0, 336, 672, 1008, and 1680 hours post-dosing. ADA was detected using two validated electrochemiluminescent immunoassays, one each to detect antibodies against PF-05280014 and reference drugs. Samples were first tested for antibodies against the dosed product. Confirmed positive samples were further tested for Nab using a validated semi-quantitative competitive ligand binding assay, and for ADA cross-reactivity. All subjects provided informed consent.
Results: Samples for immunogenicity assessment were collected from all 105 subjects. Only 2 samples tested positive; the rest (99.6%) tested negative in the ADA assay specific for the dosed product. One positive sample was collected at 1680 hours after dosing from a subject who received trastuzumab-EU (Subject 1). This sample had a low titer of ADA and tested negative against PF-05280014. There were no adverse events attributable to the ADA finding for this subject. The other sample testing positive was collected before dosing from a subject who subsequently received PF-05280014 (Subject 2). This low false-positive rate (1/105) of ADA at baseline was consistent with assay validation requirements to ensure high probability of identifying all subjects who develop ADA. The 2 ADA-positive samples were negative for Nab. The 3 study agents were well-tolerated and adverse events were similar. The PK profile of Subject 1 was similar to other subjects in the trastuzumab-EU group. The PK of the 3 study agents were shown to be similar based on C_{max}, AUC_t, and AUC_{inf} and the standard bioequivalence criteria of 80–125%.
Conclusions: Consistent with reported data for trastuzumab in patients with cancer, PF-05280014 appears to have low immunogenic potential

when given as a single IV infusion to healthy subjects. Overall, PF-05280014 demonstrated PK similarity and comparable safety and immunogenicity profiles to trastuzumab in healthy subjects.

854 POSTER

Neoadjuvant-adjuvant treatment of breast cancer: A model for extrapolation of clinical data for trastuzumab biosimilar candidates

F. Scappaticci[1], H.U. Burger[2], F. Bisordi[3], F. Ruiz de Erenchun[4], T. Schreitmueller[4]. *[1]Genentech Inc., BioOncology, South San Francisco CA, USA; [2]F. Hoffmann-La Roche Ltd, Biostatistics, Basel, Switzerland; [3]F. Hoffmann-La Roche Ltd, Regulatory affairs, Basel, Switzerland; [4]F. Hoffmann-La Roche Ltd, Medical affairs, Basel, Switzerland*

Background: Trastuzumab (Herceptin®) is approved for HER2-positive EBC, MBC and MGC. Trastuzumab biosimilars raise questions about how best to conduct mandatory, head-to-head clinical equivalence studies, to show similarity in efficacy, safety and immunogenicity and mitigate risks associated with extrapolation to indications not investigated by the biosimilar mAb. EMA mAb biosimilar guidelines recommend sensitive and homogenous populations and sensitive endpoints for such studies. MBC patient (pt) populations are generally heterogenous, and pts may have a compromised immune response. Establishing clinical similarity in the neoadjuvant–adjuvant setting may be the better risk mitigation strategy for extrapolating clinical data to MBC and may be more acceptable to regulators than the reverse.
Materials and Methods: Data from NOAH (neoadjuvant–adjuvant trastuzumab + CTx vs. CTx, N = 231) were used to retrospectively assess treatment effect size (difference between arms) and identify a sensitive, homogenous population, as per the EMA guidelines. tpCR treatment effect differences were evaluated as a sensitive endpoint for investigation of clinical benefit. This can then allow assessment of equivalence only based on tpCR endpoint.
Results: tpCR treatment effect size was 19%. Based on the study results, a 15−20% difference in tpCR rate may translate to a clinically meaningful difference in disease-free survival. If biosimilars were evaluated using an equivalence design and margins of 10% based on the tpCR endpoint (40% response), the sample size would be 500 pts per arm (80% power, 18% drop-out rate). In trials of this sort, similarity in immunogenicity could be assessed when pts are given trastuzumab monotherapy excluding bias or immunosuppressive effects due to concomitant CTx.

	tpCR %
Trastuzumab + CTx (n = 115)	40
CTx alone (n = 116)	21
Effect size	**19**

Conclusions: Sensitive populations as defined by EMA regulations are those that are homogenous, often the most responsive to therapy and are treatment naive. If equivalence in efficacy, safety and immunogenicity of trastuzumab (reference product) and a trastuzumab biosimilar candidate is demonstrated in the neoadjuvant–adjuvant setting, this may provide a reasonable basis for extrapolation to other indications not specifically studied during biosimilar development. This may be a more sensitive approach than one based on ORR in MBC, as ORR is less sensitive to treatment differences and only weakly correlated with clinical endpoints.
Conflict of interest: *Other substantive relationships: All authors are employees of Genentech or F. Hoffmann-La Roche Ltd*

855 POSTER

Anti-FGFR1 humanized monoclonal antibody OM-RCA-01 inhibits FGF-induced angiogenesis

I. Tsimafeyeu[1], E. Stepanova[2], N. Golub[3], E. Zaveleva[3]. *[1]Kidney Cancer Research Bureau, Moscow, Russian Federation; [2]N.N. Blokhin Russian Cancer Research Center, Laboratory of Tumor Angiogenesis, Moscow, Russian Federation; [3]OncoMax LLC, Moscow, Russian Federation*

Background: The growth of new blood vessels is regulated by several proangiogenic factors. We believe that the angiogenesis induced by basic fibroblast growth factor (bFGF) is resistant to anti-VEGF/R therapy and can be targeted by anti-FGFR1 monoclonal antibody.
Methods: In our in vivo study, angiogenesis was measured with subcutaneously implanted Matrigel plugs containing: 1) bFGF; 2) VEGF; 3) bFGF+bevacizumab; 4) VEGF+bevacizumab; 5) bFGF+anti-FGFR1 monoclonal antibody OM-RCA-01 (Tsimafeyeu et al. 2012 ASCO meeting); 6) VEGF+OM-RCA-01. Control group was without stimulation or treatment. Doses of bFGF, VEGF-A (R&D Systems), bevacizumab (Roche), OM-RCA-01 (OncoMax) were 100 ng, 200 ng, 10 mg/kg, and 10 mg/kg per animal, respectively. Number of endothelial cells/vessels was calculated.
Results: There was no neovascularization in bFGF negative, VEGF negative group (mean, 0). bFGF and VEGF strongly induced angiogenesis ($P<0.001$). There were no vessels and endothelial cells in anti-FGFR1 antibody FGF-stimulated group (mean, 0). In bFGF-induced angiogenesis, bevacizumab did not impact on neovascularization in comparison with bFGF positive control ($P = 0.5$). The angiogenic effect of VEGF was significantly inhibited by bevacizumab in comparison with VEGF positive control ($P<0.0001$). OM-RCA-01 not significantly inhibited growth of vessels in VEGF positive group ($P = 0.064$).
Conclusion: Anti-FGFR1 monoclonal antibody OM-RCA-01 inhibited FGF-induced angiogenesis. Targeting VEGF(R) by bevacizumab significantly impacted on VEGF-induced angiogenesis and not on bFGF-induced neovascularization.
Conflict of interest: *Other substantive relationships: N. Golub, E. Zaveleva are employers of OncoMax LLC*

Eudesmol isomers induce caspase-mediated apoptosis in human hepatocellular carcinoma HepG2 cells

D.S. Bomfim[1], R.P.C. Ferraz[1], N.C. Carvalho[2], M.B.P. Soares[2], M.L.B. Pinheiro[3], E.V. Costa[4], D.P. Bezerra[2]. *[1]Federal University of Sergipe, Department of Physiology, São Cristóvão, Brazil; [2]Fundação Oswaldo Cruz − Fiocruz, CPqGM-Bahia, Salvador, Brazil; [3]Federal University of Amazonas, Department of Chemistry, Manaus, Brazil; [4]Federal University of Sergipe, Department of Chemistry, São Cristóvão, Brazil*

Background: Eudesmols are naturally occurring sesquiterpenoid alcohols that present cytotoxic effect to cancer cells. In this work, we studied the mechanisms of cytotoxic action of eudesmol isomers (α-, β- and γ-eudesmol) in human hepatocellular carcinoma HepG2 cells.
Material and Methods: In first, Three tumour cell lines (HepG2, K562 and B16-F10) were treated with increasing concentrations of eudesmol isomers for 72 h and analysed by methyl-[^{3}H]-thymidine incorporation assay. The pro-apoptotic affect of these compounds was assessed in HepG2 cells by morphological analysis (using hematoxylin/eosin staining and acridine orange/ethidium bromide staining), flow cytometry (cell membrane integrity, mitochondrial transmembrane potential, cell cycle distribution and internucleosomal DNA fragmentation analysis) and caspase-3 activation assay after 24 h incubation.
Results: All eudesmol isomers displayed cytotoxicity to different tumour cell lines. α-Eudesmol showed IC_{50} values ranging from 5.38 to 10.60 μg/mL for B16-F10 and K562 cell lines, β-eudesmol showed IC_{50} values ranging from 16.51 to 24.57 μg/mL for B16-F10 and HepG2 cell lines and γ-eudesmol showed IC_{50} values ranging from 8.86 to 15.15 μg/mL for B16-F10 and K562 cell lines, respectively. After 24 h incubation, HepG2 cells treated with eudesmol isomers presented typical hallmarks of apoptosis, as observed by morphological analysis in cells stained with hematoxylin–eosin and acridine orange/ethidium bromide. Significant increases in internucleosomal DNA fragmentation without affecting membrane integrity were also found. In addition, eudesmol isomers induced loss of mitochondrial membrane potential and an increase of caspase-3 activation in HepG2 cells, suggesting that this apoptotic cell death was caspase-dependent.
Conclusions: In conclusion, the eudesmol isomers herein investigated are able to reduce cell proliferation and to induce tumour cell death through apoptotic pathways.
No conflict of interest.

857 POSTER

Eusynstyelamide B: a novel topoisomerase II inhibitor isolated from an ascidian from the Great Barrier Reef

M. Liberio[1], M. Sadowski[2], A. Rockstroh[2], R. Vasireddy[2], R.J. Quinn[1], R.A. Davis[1], C. Nelson[2]. *[1]Griffith University, The Eskitis Institute, Brisbane, Australia; [2]The Translational Research Institute, Australian Prostate Cancer Research Centre, Brisbane, Australia*

Researchers have shown that marine ascidians are an excellent source of new anticancer compounds that can exhibit new mechanisms of action. The Great Barrier Reef is a rich environment harbouring a prolific ascidian biodiversity, and many of the species have never been explored for bioactive natural products. The aim of this project was to isolate and characterize

anticancer compounds from ascidians belonging to the family Didemnidae. We tested a total of 143 ascidian specimens from the Eskitis Biota Library for anti-proliferative effects in the prostate cancer cell line LNCaP using the real-time cell analyser xCELLigence System. Twenty-one hit extracts were identified, and the most interesting extracts were selected for bioassay-guided fractionation in order to purify the bioactive compound(s). From these studies we identified a previously reported modified tryptophan-arginine dipeptide dimer, named eusynstyelamide B (EB). We found that EB inhibited proliferation of LNCaP cells with an IC_{50} of 5 μM. Cell cycle studies and analysis of histone H3 phosphorylation showed that EB arrested LNCaP cells in the G2 phase. RNA expression profiling by micro array and qRT-PCR suggested that the EB-induced G2 arrest was caused through DNA damage pathways. Western blotting experiments confirmed phosphorylation of ChK2, but not of p53 or ChK1, and down-regulation of CDC2 protein expression. EB-induced DNA damage was confirmed by neutral comet assay and the formation of γH2AX foci. Intercalation displacement assays and melting curve analysis demonstrated that EB did not interact with DNA. Importantly, when incubated with kDNA and topoisomerase II EB strongly inhibited the decatenation of kDNA. These data indicate that EB is a novel topoisomerase II inhibitor which causes DNA damage in LNCaP cells. Studies are ongoing to further characterize the potential anti-cancer properties of this compound and validate the findings in additional cancer cell lines.
No conflict of interest.

858 POSTER

Allylbenzenes as potential chemosensitizers and P-glycoprotein inhibitors

C. Martins[1], A. Armada[2], M. Viveiros[2], J. Rueff[1], A.S. Rodrigues[1].
[1]Universidade Nova de Lisboa − Faculty of Medical Sciences, Department of Genetics, Lisbon, Portugal; [2]Instituto de Higiene e Medicina Tropical Universidade Nova de Lisboa (IHMT/UNL), Unit of Mycobacteriology, Lisbon, Portugal

Background: Allylbenzenes are a family of compounds found essentially in spices. Some of them can induce apoptosis in tumour cells. In our previous studies we determined that eugenol can inhibit topoisomerase II and induce apoptosis in mammalian cells, while myristicin can also induce apoptosis in human leukaemia K562 cells. Eugenol was genotoxic while myristicin was non-genotoxic. The apoptotic activity of the allylbenzenes raised the possibility of them potentiating the activity of standard chemotherapeutic drugs, particularly in cases of multidrug resistance, a major cause of failure of cancer chemotherapy. Multidrug resistance can also occur as the result of drug extrusion due to up-regulation of membrane efflux pumps (EP) such as P-glycoprotein (P-gp, ABCB1). Much research has been performed to identify EP inhibitors, and a large number of natural compounds have shown promise in inhibiting EP.
Material and Methods: We analysed five allylbenzenes for their ability to inhibit the function of P-gp by using a Semi-automated Fluorimetric Method that monitors ethidium bromide (EB) uptake and extrusion, on a real-time basis by L5178 mouse T-cell lymphoma cells expressing the human ABCB1 (P-gp) gene. Monitoring of uptake and extrusion of EB was assessed using the Rotor-gene™ 3000 (Corbett Research). MDA-MB-231 breast metastatic cancer cells were used to analyse synergy with doxorubicin using the MTT assay.
Results: We observed that eugenol, α and β-asarone potentiated the cytotoxicity mediated by doxorubicin in MDA-MB-231 breast metastatic cancer cells. Extrusion of EB took place readily in control cells expressing ABCB1. In cells exposed to known inhibitors of efflux pumps (verapamil and cyclosporine A) there was marked EB accumulation. The allylbenzenes α and β-asarone strongly inhibited EB efflux, followed by myristicin and eugenol. The allylbenzene trans-anethole did not present significant inhibitory activity.
Conclusions: In conclusion, α and β-asarone can potentiate the cytotoxicity of doxorubicin and also inhibit P-gp efflux pumps and can be regarded as promising candidates, in co-treatments, to increase cell death and overcome resistance to known chemotherapeutics.
No conflict of interest.

859 POSTER

Population pharmacokinetics (PPK) of eribulin in cancer patients

O. Majid[1], A. Gupta[1], M. Olivo[2], L. Reyderman[2], Z. Hussein[1]. *[1]Eisai Europe Limited, Clin Pharm SOCS CFU, Hatfield Herts, United Kingdom; [2]Eisai Inc., ONC PCU, Woodcliff Lake NJ, USA*

Background: Eribulin mesylate (Halaven®) is a non-taxane microtubule dynamics inhibitor, approved for the treatment of certain patients with breast cancer. A combined population PK analysis was conducted using data from seven Phase 1 studies, one Phase 2 study and one Phase 3 study in cancer patients to characterise eribulin PK profile and identify covariates that affect eribulin exposure. Eribulin mesylate was administered intravenously at doses between of 0.25 and 2 mg/m^2.
Materials and Methods: Data from 69 males and 444 females (389 with breast cancer), aged 27 to 81 years and weighing 39 to 161 kg were available for PPK analysis. The pooled dataset comprised of 4093 eribulin concentrations. PPK was conducted using NONMEM with first-order conditional estimation method with interaction (FOCEI). Stepwise covariate building was performed and the final model was evaluated using bootstrap analysis and predictive check simulations. Covariates tested were age, weight (WGT), hepatic function markers (albumin (ALB), alanine aminotransferase (ALT), alkaline phosphatase (ALP), aspartate trasnferase (AST), bilirubin (BILI)), renal function (creatinine clearance (CLCr)), gender, race, ECOG status and tumor type (breast vs. other).
Results: Eribulin PK was characterised by a three-compartment model where both volume (V_1, V_2, V_3) and clearance (CL, Q_2, Q_3) parameters were proportional to WGT according to an allometric model. Other covariates were related to hepatic function with effects of ALB, ALP and BILI levels significantly affecting CL. Population estimates were: CL = 3.11 L/h, $V_{1=}$ 4.06 L, Q_2 = 2.64 L/h, $V_{1=}$ 4.06 L, V_2 = 2.42 L, Q_2 = 6.60 L/h and V_2 = 121 L. Eribulin CL increased proportionally with ALB levels (exponent: 0.946) and decreased proportionally with ALP (exponent: −0.209) and BILI levels (exponent: −0.180). Inter-individual variability was moderate ranging between 37 % for V3 and 52 % for CL. Proportional residual variability in eribulin concentrations was moderate (24 %). Evaluation from bootstrap and predictive checks suggested robustness of the final model for all patients. Eribulin PK was unaffected by age, renal function, gender, race, ECOG status and tumor type.
Conclusions: The population model adequately described eribulin PK in breast and other cancer patients. WGT, ALB, ALP and BILI were significant predictors of eribulin CL. The current model can be utilised to characterise eribulin PK and predict eribulin exposure in cancer patients.

860 POSTER

Lurbinectedin (PM01183) in combination with doxorubicin (DOX): Preliminary results of a phase Ib study

E. Calvo[1], M. Forster[2], S. Szyldergemajn[3], V. Boni[1], S. Benafif[2], C. Kahatt[3], S. Turnbull[2], A. Cubillo[1], C. Fernandez Teruel[3], A. Soto Matos-Pita[3]. *[1]START Madrid Centro Integral Oncológico Clara Campal, Madrid, Spain; [2]University College of London Hospital, London, United Kingdom; [3]PharmaMar, Madrid, Spain*

Background: PM01183 has wide antitumour activity through minor groove DNA-binding. Synergism with DOX was observed preclinically. PM01183 monotherapy is undergoing clinical evaluation in pancreatic, ovarian and breast cancer patients (pts). Reversible neutropenia and high emetogenic potential are its main side effects.
Methods: Pts were included in successive cohorts aiming to define the recommended dose (RD) of PM01183 combined with 50 mg/m^2 of DOX (fixed dose) q3wk, with or without colony-stimulating factors (CSF) prophylaxis. Less than 1/3 of at least 9 pts had to have dose-limiting toxicities (DLTs) in Cycle 1, at the RD. Pharmacokinetics (PK) were assessed. Consenting adults ⩽75 years, ECOG PS 0−1, adequate organ function and up to 2 prior chemotherapy lines were included. Prior adjuvant DOX was allowed. DOX had to be withdrawn before exceeding 450 mg/m^2 of cumulative dose. PM01183 could be continued alone if clinical benefit.
Results: As of March 2013, 43 pts were treated: 53.5% were males, median age was 61 years (r: 22−78). SCLC (30%), STS (21%) bladder (12%), and gynaecological, stomach and NET (9%, each) were the most frequent locations. DLTs occurring at the MTD, 5.0 mg flat dose (FD) of PM01183, with or without CSF, were febrile neutropenia (FN=3), sepsis, grade 4 thrombocytopenia and grade 3 diarrhoea (1 each). PM01183 at 4.0 mg FD combined with DOX, 50 mg/m^2 without CSF is the RD; 1 pts out of 9 had a DLT (FN). Toxicities in ⩾10% of pts, in addition to myelosuppression, were generally mild, including anaemia, ALT/AST increases, fatigue, alopecia, mucositis, nausea/vomiting, diarrhoea, anorexia and constipation. One pt had >10% asymptomatic decrease in left ventricular ejection fraction (LVEF). Out of 41 evaluable pts, 14 responded, for an ORR = 34% (95% CI: 20−51%), including 3 radiological CRs (7%). Of note, 5 out of 12 evaluable SCLC pts had PRs (42%). Over 1/3 of pts received ⩾6 cycles. There are ongoing pts at cut-off. DOX and PM01183 clearance (CL) were not affected, whereas doxol CL decreased with PM01183 dose.
Conclusions: The RD is PM01183 4.0 mg + DOX 50 mg/m^2. Toxicity is manageable and predictable. CSF prophylaxis is not required. This combination showed impressive response rates, including CRs

in relapsed/refractory solid tumour pts. This activity warrants further investigation in specific disease-settings, including SCLC.

861 POSTER

Ruta chalpensis: a promising phytotherapeutic candidate against multiple forms of cancer

R.M. Sghaier*[1], D. Khlifi[2], M. Hamdi[3], J. Bouajila[4], D. Laouini[5].
[1]Institut Pasteur Tunis, Laboratoire de Transmission Contrôle et Immunologie des Infectionsechnologie Microbienne/Laboratoire des Interactions Moléculaires et Réactivité Chimique et Photochimique, Tunis, Tunisia; [2]Institut National des Sciences Appliquées et de la Technologie (INSAT)/UMR CNRS 5623 Université Paul-Sabatier, Laboratoire d'Ecologie et de Technologie Microbienne/Laboratoire des Interactions, Tunis, Tunisia; [3]Institut National des Sciences Appliquées et de la Technologie (INSAT), LLaboratoire de Transmission Contrôle et Immunologie des Infectionsechnologie Microbienne/Laboratoire des Interactions Moléculaires et Réactivité Chimique et Photochimique, Tunis, Tunisia; [4]UMR CNRS 5623 Université Paul-Sabatier, Laboratoire des Interactions Moléculaires et Réactivité Chimique et Photochimique, Toulouse, France; [5]Institut Pasteur Tunis, LLaboratoire de Transmission Contrôle et Immunologie des Infectionsechnologie Microbienne/Laboratoire des Interactions Moléculaires et Réactivité Chimique et Photochimique, Tunis, Tunisia

Background: Studies on medicinal plants are mostly based on information provided by traditional healers in ethno botanical surveys. The treatment of cancer is mainly based on the use of Doxorubicin as chemotherapeutic agent, despite its potential to elicit serious cardiotoxicity often leading to degenerative cardio-myopathy/heart failure. The proposed mechanism of DOX-toxicity is complex and involves increased oxidative/nitrosative stress. Thus, inflammatory responses could be in the top of induction of cancer and hence treatment target. Based on Tunisian traditional medicine, *Ruta chalpensis* was explored for its anti-cancer activities and modulation of immune responses.
Material and Methods: The activity of *Ruta chalpensis* methanolic extract was tested against different cancerous cells; human carcinoma of bladder (RT112), of laryngeal (Hep2) and myelogenous leukemia (K562). Cellular viability was evaluated by MTT assay and microscopic count of nucleus upon extract treatment. In addition, annexinV staining and [^{3}H]Thymidine incorporation assays were used to control the viability within K562 cells. Furthermore, the release of free radicals was analyzed within the lipid peroxidation by AAPH assay and iNOS mRNA and NO production.
Results: In this study, biological activities of *Ruta chalpensis* methanolic extract related probably to its high tenor in phenolic compounds were investigated. This extract showed high antioxidant activity, and inhibited the production of NO, in murine macrophages, *via* transcriptional regulation indicating appreciable anti-inflammatory activities. Cytotoxicity assay results indicate a specific anticancer therapeutic property while there was no effect on healthy PBMC.
The observed decrease of viability was not due to cellular death but to an anti-proliferative effect of *Ruta chalpensis* methanolic extracts with ERK-dependent growth inhibition.
Conclusion: The use of plant compounds of *Ruta chalpensis* may be a novel approach for specifically inhibiting cancer cells' growth, which will lead to the development of new anti-cancer agents. Interestingly, our findings show, in opposite to the doxorubicin treatment, that *Ruta chalpensis* inhibits nitrosative stress. These results demonstrate the remarkable potential of traditional medicinal plants as valuable source of anti-oxidants exhibiting anti-inflammatory and anticancer properties.

Phase I study of U3-1565, a fully human anti-HB-EGF monoclonal antibody, in Japanese patients with advanced solid tumors

T. Yoshino[1], N. Fuse[1], T. Doi[1], A. Ohtsu[1], S. Fujitani[2], Y. Aramaki[3], H. Murakami[4], H. Yasui[5], N. Takahashi[6], N. Yamamoto[4]. *[1]National Cancer Center East, Gastrointestinal Oncology/Gastroenterolgy, Kashiwa, Japan; [2]Daiichi Sankyo CO.LTD., Translational Medicine & Clinical Pharmacology, Tokyo, Japan; [3]Daiichi Sankyo CO.LTD., Clinical Planning, Tokyo, Japan; [4]Shizuoka Cancer Center, Thoracic Oncology, Shizuoka, Japan; [5]Shizuoka Cancer Center, Gastrointestinal Oncology, Shizuoka, Japan; [6]Shizuoka Cancer Center, Gynecology, Shizuoka, Japan*

Background: Human heparin-binding epidermal growth factor-like growth factor (HB-EGF) is a member of an EGF family and a ligand that binds to and activates the EGF receptor and human epidermal growth factor receptor 4 (HER4). U3-1565 is a fully human monoclonal antibody directed against HB-EGF that has demonstrated anti-tumor activity in preclinical models. This phase I study explored safety, tolerability, pharmacokinetics (PK) and potential anti-tumor activity of U3-1565 in Japanese patients with solid tumors.
Material and Methods: This study was conducted using a 3+3 design and tested U3-1565 at 2, 8, 16, and 24 mg/kg once every two weeks (with the second dose given three weeks after the first), and at 24 mg/kg weekly.
Results: Fifteen patients (6 females) were enrolled, 3 in each dose level cohort, and median age of 62 (range 52−73) years. Tumor types were colorectal (10), ovarian (2) and others (3). No dose-limiting toxicities and no treatment-related serious adverse events were observed; the MTD was not reached. PK data indicated serum U3-1565 concentration was dose-proportional, similar to US phase I study in parallel, though slightly lower exposure was observed. The highest administered dose of 24 mg/kg weekly generated Ctrough above the predetermined target concentration resulting in 90% tumor growth inhibition in preclinical study. Drug related AEs included malaise(20.0%), dermatitis acneiform(13.3%), and decreased appetite(13.3%), which were G1 or G2. Of 15 patients enrolled, 3 patients(20.0%) had stable disease and 12 patients had progressive disease as best response based on RECIST, and the median duration of stable disease was 15 (range 13−20) weeks with no decrease in tumor volume.
Conclusions: U3-1565 was well tolerated without DLT up to the dose level of 24 mg/kg weekly in Japanese patients. The dose of 24 mg/kg weekly was considered to be appropriate for the following phase. Biomarker evaluation in serum and tumor biopsy specimens and exploratory anti-tumor activity are ongoing in the additional study at the dose level of 24 mg/kg weekly as dose expansion part of this phase I study. (Trial Registry Number: JapicCTI-111484.)

864 POSTER

Phase I study of LOR-253, a novel inducer of Kruppel-like factor 4, in patients with advanced solid tumors

A. Cercek[1], J. Wheler[2], E. Weisberger[1], R. Anderson[2], E. Hollywood[1], S. Zhou[3], P. Murray[3], Y. Lee[3], R. Zinner[2], L. Saltz[1]. *[1]Memorial Sloan-Kettering Cancer Center, Department of Medicine, New York, USA; [2]MD Anderson Cancer Center, Department of Medicine, Houston, USA; [3]Lorus Therapeutics, Toronto, Canada*

Background: LOR-253 is a novel small molecule inducer of tumor suppressor Kruppel-like factor 4 (KLF4) that has shown potent antitumor activity in NSCLC and colon tumor xenograft models. Objectives are to determine the maximum tolerable dose (MTD) or target-appropriate dose (TAD), and to characterize safety.
Materials and Methods: Patients with advanced solid tumors who progressed on standard therapies received LOR-253 by i.v. infusion on Days 1, 2, 15, and 16 of each 28 day cycle. The study design consisted of a brief run-in (Stage I) with 100% dose escalation until 2 patients with grade 2 toxicity or 1 patient with grade 3 toxicity, followed by a standard 3+3 design with escalating doses (Stage II). Dose limiting toxicity (DLT) was defined as $\geqslant$ grade3 other than reversible electrolyte abnormalities. RECIST 1.1 assessments were performed every 2 cycles (8 weeks). Serum samples for PK were collected in Cycle 1 pre-treatment, 0, 0.5, 1, 2, 4 and 7 hours (hr.) after end of infusion on Day 1 & on Day 2 omitting the 7 hr. sample and adding 24, 48 and 144 hr. samples.
Results: Twenty seven patients have been enrolled, with a mean age of 59 (range, 39−75), 67% male, and a mean of 4 (range, 1−7) prior regimens. Primary tumors included 16 colorectal, 3 appendiceal, 2 non small cell lung, 2 esophageal and, 4 others. Of 24 patients dosed only 1 patient experienced a $\geqslant$ grade 3 toxicity at least possibly related to drug (grade 3 hypophosphatemia). The most frequent grade 2 toxicity was hypersensitivity (2 patients) preventable by pre-treatment. Dosing was at 20, 40, and 80 mg/m^2 in Stage I until a DLT of grade3 hypophosphatemia, and at 80, 104, 135, 176, and 229 mg/m^2 in Stage 2. Of 17 pts evaluable for RECIST assessment, 7 (41%) had stable disease as best response. Stable disease of $\geqslant$4 cycles (4 Pts; mean 154 days) was seen exclusively at the higher dose levels from 176 to 229 mg/m^2 which corresponds to a preclinically efficacious KLF4 inducing dose. PK elimination appeared biphasic with mean $T\frac{1}{2}$ at doses $\geqslant$80 mg/m^2 ranging from 48−61 hr. AUC(0-t) was dose proportional with a median accumulation ratio of 4 on Day 2 vs. Day 1.

Conclusions: LOR-253, a first-in-class molecule, is well tolerated to a TAD of 229 mg/m^2 without significant toxicity. A biomarker investigation has therefore been initiated with continued evaluation of PK and expansion for pre- and post-dose biopsies and correlative tissue analyses.
Conflict of interest: *Other substantive relationships: P. Murray, S. Zhou and Y. Lee work are employed by Lorus Therapeutics, the manufacturer of the drug LOR-253.*

865 POSTER

Evaluation of the interaction of copper(II) and ruthenium(II) compounds with fibronectin and tubulin proteins: two potential chemotherapeutic targets

A. Rodriguez[1], J. García[2], P. Gamez[1], J. Lorenzo[2], V. Moreno[1]. [1]*University of Barcelona, Bioinorganica, Barcelona, Spain;* [2]*Universitat Autònoma de Barcelona, Institut de Biotecnologia i Biomedicina, Barcelona, Spain*

Most current research efforts with respect to the quest for novel metal-based drugs are devoted to investigating their interaction with the DNA double helix, considering the accepted mechanism of action for the well-established anticancer drug cisplatin. However, this approach neglects the fact that other cellular components may be targeted by metal complexes. In the present study, fibronectin and tubulin, two proteins involved in fundamental cellular processes that are cell division and cell migration, have been chosen as (cytotoxic) targets for copper(II) and a ruthenium(II) compounds.
The potential interaction of a series of metal-based molecules with these two proteins was first assessed by circular dichroism (CD) and atomic-force microscopy (AFM). MTT assays were subsequently used to determine the cell-growth inhibitory activities (IC_{50}) of the compounds in HeLa and HL60 cell lines. Immunofluorescence assays were then carried out with the two most cytotoxic metal complexes, with HeLa cells, using anti-α-, anti-β-tubulin and anti-fibronectin antibodies to investigate their effect on microtubules and the extracellular matrix. The microtubule-depolymerizing agent Nocodazole was used as positive control. Cell cycle analyses by flow cytometry and annexin V-FITC + PI apoptosis assays (with cisplatin as positive control) were performed with both cell lines to better understand the mechanisms of action of the two compounds.
The AFM and CD experiments clearly evidenced the interaction of the Cu(II) and Ru(II) compounds with both proteins, the most efficient being the copper molecule. IC_{50} values lower than those of the reference compound cisplatin® were obtained for both the Ru(II) (13.01 μM HeLa; 2.48 μM HL60) and the Cu(II) (3.63 μM HeLa; 14.50 μM HL60) complexes. The immunofluorescence assays revealed a microtubule-depolymerizing behaviour for the copper molecule and the formation of apoptotic nuclei with both compounds. The cell cycle tests did not show an arrest at the G2 phase, which would have indicated microtubule stabilization (that prevents cell division), therefore suggesting that the cells had died by apoptosis, as confirmed by the annexin assays.
In summary, fibronectin and tubulin are legitimate target proteins for potential metal-based anticancer drugs such as the two compounds evaluated herein, which showed apoptotic cytotoxic activities.

Factors predisposing to development of hyperglycaemia in phase 1 studies involving PI3K, mTOR, AKT and mTORC1 and mTORC2 inhibitors

M. Wong[1], K.H. Khan[2], K. Rihawi[1], S. Bodla[3], B. Amin[1], K. Shah[1], D. Morganstein[4], S.B. Kaye[1], U. Banerji[1], L.R. Molife[1]. [1]*Royal Marsden Hospital, Drug Development Unit, London, United Kingdom;* [2]*Royal Marsden Hospital, GI/Lymphoma Unit, London, United Kingdom;* [3]*Royal Marsden Hospital, Statistics Department, London, United Kingdom;* [4]*Royal Marsden Hospital, Endocrinology, London, United Kingdom*

Background: Dysregulation of the PI3K/AKT/mTOR pathway is implicated in human cancer growth and progression. Agents targeting this pathway can be associated with on target effects of hyperglycaemia due to partial compensation of the insulin-glucose regulatory axis. Identifying those factors predictive of developing hyperglycaemia in patients (pt) treated with these agents may help direct future management.
Materials and Methods: Clinical characteristics and outcomes of pts treated consecutively with PI3K, AKT or mTOR inhibitors in the Drug Development Unit, The Royal Marsden between 2007 and 2012 were recorded. Baseline variables and their association with grade (G) 3 hyperglycaemia (CTCAE version 3.0) were analysed, using chi-square test and significant values were further analysed by multivariate regression analysis (MVA).
Results: 341 pts were identified and treated on 12 phase I trials of PI3K/AKT/mTOR inhibitors, during the study period. Clinical, laboratory and demographic data including personal and family history of diabetes, use of steroids, body mass index (BMI), and baseline blood sugar levels (BSL), biochemistry, treatment and outcomes of hyperglycaemia were recorded. 81.5% of pts developed hyperglycaemia during treatment. Majority had G1 (n = 217, 63.6%) and G2 hyperglycaemia (n = 61, 17.9%). Development of G $\geqslant$3 (n = 20, 5.9%) hyperglycaemia was associated with age <65 (p = 0.03), previous history of diabetes (p = 0.003) and treatment with AKT and mTOR inhibitors (p = 0.00). On MVA, maximum BSL at Cycle (C) 1 [inter quartile range (IQR) =6.3−8.5 mmol/l; odds ratio (OR) =2.4(1.66–3.46)] and fasting BSL at C2 [IQR=4.9−5.9 mmol/l; OR=2.07(1.09–3.95)] were associated with development of G $\geqslant$3 hyperglycaemia. BMI>30, history of steroid use, tumour type or histology, fasting BSL and HbA1C were not predictive of the risk of developing G3 hyperglycaemia. The majority of patients did not require intervention for hyperglycaemia [n = 316; 92.7%]; however, metformin [n = 20; 5.9%] and/or insulin [n = 2; 0.6%] were the most common pharmacological agents used, where required. One pt required a dose reduction and there were no permanent drug discontinuations.
Conclusion: Pts aged <65 y, with a history of diabetes, treated with AKT/mTOR inhibitors are more likely to develop significant hyperglycaemia on study. These predictive factors may warrant further validation in a prospective setting, and may help in the future management of pts treated with this important class of agents.
No conflict of interest.

867 POSTER

Fatty acid synthase inhibition as a potential therapeutic target in triple-negative breast cancer

A. Giro[1], A. Blancafort[1], G. Oliveras[1], F. Pérez-Bueno[2], J. Dorca[3], G. Viñas[3], T. Puig[1]. [1]*University of Girona, Medical Science, Gerona, Spain;* [2]*Catalan Institute of Health (ICS), Pathology Department, Gerona, Spain;* [3]*Catalan Institute of Oncology (ICO), Medical Oncology Department, Gerona, Spain*

Background: Triple-negative breast cancer (TNBC) are defined by the lack of detectable expression of estrogen receptor, progesterone receptor and do not have amplification of HER2. There is no clinically validated molecularly targeted therapy for TNBC and patients have a poor prognosis due in part to the high probability of relapse after chemotherapy. Thus, the identification of novel targeted therapies for TNBC patients is needed.
The expression levels of FASN, a multi-enzyme protein that catalyses de novo synthesis of fatty acids, are low or undetectable in normal tissues. In contrast, high levels of FASN expression have been detected in several human carcinomas. Some reports highlight that FASN over expression correlates with progression, aggressiveness and metastatic potential of the disease.
The aim of our study is determine the FASN tumor expression levels in TNBC patients and in parallel evaluate the therapeutic effect of FASN inhibition (alone or in combination with current treatments) in a panel of TNBC cells sensitive and resistant to conventional therapies (such as doxorubicin and paclitaxel).
Methods: FASN and EGFR expression was retrospectively evaluated in 29 paraffin-embedded core-biopsies of patients with TNBC by Immunohistochemistry (IHC).
TNBC cell lines were long-exposed to increasing doses of doxorubicin (DR), paclitaxel (PR) or both (DPR) to establish long-term chemoresistant cells. Western-Blot (WB) analysis were performed to evaluate the main signaling pathways in both sensible and resistance cells. The cytotoxic effect of the anti-FASN compounds were determined by an MTT assay. Quantitative Real-Time PCR (qRT-PCR) was used to analyze the expression of basal and mesenchymal markers to determine the molecular subtypes and for the study of cell population changes under chemotherapy.
Results: FASN staining was positive in all 29 TNBC tumor samples, with low (69%) and moderate (31%) levels. EGFR were positive in 76% of the tumors respectively. Analysis by WB and qRT-PCR showed higher levels of FASN in TN CK5/6$^+$ and EGFR$^+$ cells than in TN VIM$^+$ cells. FASN pharmacological inhibition (alone and in combination) was cytotoxic and induced apoptosis in all TNBC cells treated.
Conclusions: FASN is expressed in TNBC tumors and *in vitro* FASN inhibition (alone and in combination) induces apoptosis in TN cells. The absence of target therapies for this breast cancer subtype and its poor prognosis lead to the exploration of FASN as a therapeutic target for TNBC patients.
No conflict of interest.

868 POSTER

Phase 1 dose escalation study of the investigational drug TAK-960, an oral polo-like kinase 1 (PLK1) inhibitor, in patients (pts) with advanced solid tumors

E. Calvo[1], K.P. Papadopoulos[2], S. Sharma[3], A. Cubillo[1], D. Rasco[2], H. Shi[4], S. Faucette[5], X. Zhou[5], K. Kuida[6], C. Oliva[7]. [1]*The START Center, Hospital Universitario, Madrid, Spain;* [2]*The START Center, Medical Drive, San Antonio, USA;* [3]*Huntsman Cancer Institute, Department of Internal Medicine, Salt Lake City, USA;* [4]*Millennium: The Takeda Oncology Company, Biostatistics, Cambridge, USA;* [5]*Millennium: The Takeda Oncology Company, Clinical Pharmacology, Cambridge, USA;* [6]*Millennium: The Takeda Oncology Company, Translational Medicine, Cambridge, USA;* [7]*Takeda Global R&D Centre (Europe), Oncology clinical Research, London, United Kingdom*

Background: PLK1 is involved in mitosis and DNA integrity and is over-expressed in various tumor types, presenting a target for cancer therapy. This first-in-human study evaluated TAK-960 in pts with advanced solid tumors to determine safety, tolerability, MTD/RP2D, pharmacokinetics (PK), anti-tumor activity and pharmacodynamics (PD) (NCT01179399; sponsored by Millennium: The Takeda Oncology Company).
Materials and Methods: Key eligibility: ⩾18 y with metastatic solid tumor unresponsive to current treatment, ECOG status of 0−1. TAK-960 PO QD in a 3+3 design for 21-d in a 28-d cycle. Samples for plasma PK assessment were taken pre-dose and at time points post-dose on d 1 and 21 of cycle 1. 25 pts provided skin biopsies at screening, pre-dose and 6 hr post-dose on day 7 of cycle 1. Average mitotic index and phosphorylated keratin (pKeratin) intensity were determined by immunohistochemistry.
Results: 32 pts (median age 65 y [range 47−84]) received 1−28 mg TAK-960 (median 2 cycles, range 1−12; 7 pts ⩾6 cycles). Safety population was 32 pts, 1 dose limiting toxicity reported (grade 4 neutropenia). 20 pts (63%) had a drug-related AE, fatigue (34%), decreased appetite (25%), nausea (19%). 6 pts (19%) had a grade ⩾3 drug-related AE; 1 pt (3%) had a drug-related serious AE and discontinued (grade 4 neutropenia); 3 (9%) unrelated on-study deaths. The study was terminated due to business reasons before the MTD or RP2D were established, a further 21-d cycle was considered (7-d QD then 14-d rest period). In 31 PK evaluable pts, TAK-960 was characterized by a median T_{max} of 6 hr, low fluctuation at steady-state (overall mean peak-to-trough ratio of 1.4), and moderately long mean $t_{1/2}$ of 48 hr. Overall mean accumulation ratio was 3.8-fold following repeated QD dosing for 21 d. Steady-state exposures (d 21 AUC, Time 0 to end of dosing interval $AUC_{(0-tau)}$,) increased in an approximately dose proportional manner over 1 to 28 mg. Average mitotic indices were <1 at screening, with indices >2 in 2 pts (1, 20 mg; 1, 28 mg) on day 7 of cycle 1. No trends in pKeratin intensity were observed. Best response was stable disease (14 pts, 3 pts >3 months, 3 pts >6 months: pancreas, CRC, breast, ovarian, H and N x2, squamous, bladder, thyroid, colon x2, prostate, rectal, unknown). Progressive disease observed in 17 pts.
Conclusions: TAK-960 was generally well tolerated, exhibiting linear PK and characteristics that support QD dosing. Stable disease in 14 pts with a range of tumor types.

869 POSTER

Rapid validation of a novel kinase target FAM20C through integration of large scale genomic databases and matched patient derived tumor models

T. Broudy[1], S. Sanga[1], J. Ricono[1], M. Trikha[1], C. Mirsaidi[1], K.N. Praveen[1]. [1]*Molecular Response, San Diego, USA*

Background: Target discovery and validation in oncology has largely relied on molecular and functional studies performed in cell lines. Recent advances in genomics have now created large databases based on well-characterized tumor tissue, which has enabled direct investigation of patient tumors for novel targets.
Material and Methods: We have developed a target validation platform based on a large scale genomic database matched to patient-derived tumor models. The platform relies on Molecular Response's proprietary bank of more than 144,000 patient derived tumor cells, of which nearly 400 tumors have been genomically characterized and databased for target discovery studies. The database is growing, but currently features the following cancer indications: colon carcinoma, NSCLC, melanoma, ovarian carcinoma, prostate cancer and Non-Hodgkins Lymphoma. Upon discovery of a novel target, tumors of interest are immediately implanted into mice to perform functional studies in direct patient derived models–either in vivo or ex vivo.
Results: Through use of this platform, we have identified the novel kinase target FAM20C for therapeutic development. We investigated prevalence of target overexpression across 7 cancer indications, and identified melanoma as a clinical indication of high interest. We examined growth characteristics from patient tumors featuring high kinase gene expression vs. low expression to help characterize the role of this target in oncology disease progression. Finally, we performed functional knockdown studies in patient derived models to further validate this novel kinase as a druggable target of pharmaceutical interest. Studies are ongoing to develop small molecule and antibody-based therapeutics which will serve as drug candidates for further development.
Conclusions: FAM20C represents a novel molecular target for development of targeted therapeutics in the treatment of melanoma, and potentially other cancers.
No conflict of interest.

870 POSTER

Novel receptor-mediated transport of the anticancer agent Dp44mT

A. Merlot[1], S. Menezes[1], N. Pantarat[1], D.R. Richardson[1], D. Kalinowski[1]. [1]*University of Sydney, Pathology, Sydney NSW, Australia*

Background: Defective iron homeostasis in cancer cells, owing to the perturbed expression of iron-related proteins, may confer a survival advantage to neoplastic cells and poorer patient prognosis (*Cancer Res* 2011;71:1511–1514). Iron chelators have emerged as anti-tumour agents that disrupt vital iron and copper trafficking of cancer cells. Several *in vitro* and *in vivo* studies have demonstrated the potent anti-cancer and anti-metastatic activity of the chelator, di-2-pyridylketone 4,4-dimethyl-3-thiosemicarbazone (Dp44mT; *PNAS* 2006;103:14901−6; *EMBO Mol Med* 2012;4:93–108). Recent investigations have shown that Dp44mT accumulates within the lysosome, disrupting lysosomal membrane integrity and resulting in apoptosis (*Cancer Res* 2011;71(17):5871−80). However, the mechanism by which this drug is transported into cells to induce cytotoxicity is unknown.
Materials and Methods: ^{14}C-Dp44mT was employed to assess membrane transport mechanisms using 3 tumour cell lines, namely: SK-N-MC neuroepithelioma, SK-Mel-28 melanoma and DMS-53 lung carcinoma and mortal MRC-5 fibroblasts.
Results: The cellular uptake of ^{14}C-Dp44mT as a function of concentration was saturable in SK-N-MC cells (B_{max} 4.28 x 10^7 molecules of chelator/cell and K_d 2.45 μM), suggesting it enters cells *via* a receptor-mediated process. Saturable uptake was also observed in DMS-53 and SK-Mel-28 cells as well as MRC-5 fibroblasts. The uptake of ^{14}C-Dp44mT was examined in the presence of its unlabelled precursors, namely dipyridyl ketone (Dp) and 4,4-dimethyl-3-thiosemicarbazide (44mT), in order to decipher the stereospecificity of the transport mechanism involved. ^{14}C-Dp44mT uptake was significantly (p<0.01) decreased in the presence of unlabelled Dp44mT, while its unlabelled precursors, Dp or 44mT, had no significant effect (p>0.05) on ^{14}C-Dp44mT transport in SK-N-MC cells. A range of structurally similar and diverse thiosemicarbazones were also screened to determine the specificity of the receptor, including the DpT series (DpT, Dp4mT, Dp4eT, Dp4aT, Dp4pT and DpC); the BpT series (BpT, Bp4mT, Bp44mT, Bp4eT and Bp4aT); the ApT series (ApT, Ap4mT, Ap44mT, Ap4eT and Ap4pT); as well as the well know chelators, Triapine® and PIH. All unlabelled ligands of the DpT series and unlabelled Bp44mT, Bp4mT and Ap44mT significantly (p<0.01) inhibited the uptake of ^{14}C-Dp44mT in comparison to the control (^{14}C-Dp44mT alone). The other members of the BpT and ApT series as well as Triapine® and PIH had no significant (p>0.05) effect on ^{14}C-Dp44mT uptake. As may be expected, unlabelled Dp44mT appeared to most markedly (p<0.001) decrease the cellular uptake of ^{14}C-Dp44mT.
Conclusion: The receptor involved in the uptake of Dp44mT by cells shows high affinity for Dp44mT. Our studies highlight the importance of the saturated N4 structural moiety in the receptor-mediated transport of our ligands. The uptake of Dp44mT through a receptor-mediated system may reveal a potential mechanism to selectively target chemotherapeutics to malignant cells. These findings have great clinical implication for the extent of uptake and bioavailability of the drug within the circulation.
No conflict of interest.

871 POSTER

Syntactic analysis for single agent phase I trials in Japan, from National Cancer Center Hospital (NCCH) experience

H. Mizugaki[1], N. Yamamoto[1], S. Kitazono[1], Y. Fujiwara[1], H. Nokihara[1], Y. Yamada[2], T. Tamura[1]. *[1]National Cancer Center Hospital Tokyo, Thoracic Oncology, Tokyo, Japan; [2]National Cancer Center Hospital Tokyo, Gastrointestinal Oncology, Tokyo, Japan*

Background: In Japan, to develop investigational new drug, most phase I trials, especially 'first in human' trials are starting from about 50% of MTDs of dosage to the MTD levels based on the initial phase I studies and results in the West, from where the trials are usually started. However, little has been well recognized about actual status in phase I trials in Japan. This study is aimed to evaluate the toxicity profiles including MTD levels as compared with those in the West, anti-tumor response, and survival of patients enrolled in phase I trials in Japan.
Patients and Methods: Between July 1995 and December 2012, we retrospectively analyzed the data of patients enrolled in single agent phase I trials at NCCH. The doses with anti-tumor response observed, DLT profiles, and MTDs were compared with those in the West. Cox proportional hazards model was examined to assess potential prognostic factors for survival.
Results: A total of 777 patients were enrolled in 44 phase I trials including 5 first in human trials. The median age was 57 (range, 18−76) years and 57.9% were male. ECOG performance status (PS) of 0 and 1 were 38.6 and 61.1%, respectively. The common cancer types were lung cancer (31.9%), colorectal cancer (21.0%), sarcoma (13.8%), esophagus cancer (4.6%). DLTs were observed in 12.1% of the patients. The dose levels in which DLTs observed were as follows: 5.3% were in +1 dose level as compared with those in the West, 31.9% were in the same dose level, 28.7% in −1 dose level, 14.9% in −2 dose level, and 3.2% in −3 dose level. Tumor shrinkage was observed in 20.8% of the patients and the response rate was 6.3 (95% CI: 4.6−8.0)%. Almost all (93.9%) responding patients were in and around the MTD levels (34.7, 32.7 and 26.5% were in the MTD, −1, and −2 dose levels, respectively). Median OS was 11.5 (95% CI: 10.5–12.4) months. Male, PS of 1, body weight loss (⩾5% within 3 months), liver metastasis, elevation of AST and LDH (⩾ upper limit of normal), and hypoalbuminemia were independent poor prognostic factors for survival.
Conclusions: This is the first report of syntactic analysis for single agent phase I trials in Japan. Dose levels with DLTs and observed responders were almost similar to those in the West, and these were around the MTD levels (from −2 to +1 dose levels from MTD). Prognostic factors were similar to those in previous reports in the West. Phase I studies in Japan are practically carried out on the same time lines and study qualities with those in the West.
No conflict of interest.

872 POSTER

Cumulative safety experience of telotristat etiprate in clinical trials supports advancement to phase 3

D. Fleming[1], G.L. Ye[1], J. Jackson[1], S. Jackson[1], D. Murgai[2], P. Lapuerta[1]. *[1]Lexicon Pharmaceuticals Inc., Clinical Development, The Woodlands, USA; [2]Lexicon Pharmaceuticals Inc., (Consultant) Clinical Development, The Woodlands, USA*

Background: Telotristat etiprate (TE) (or LX1606) is a novel, oral inhibitor of serotonin synthesis being developed for treatment of carcinoid syndrome (CS). Telotristat etiprate reduced CS symptoms such as diarrhea in Phase 2 studies. In preparation for Phase 3, we conducted a systematic review of safety data up to 19 January 2013 from 3 completed studies of healthy subjects and 2 ongoing clinical studies of patients (pts) with CS.
Material and Methods: To detect potential signals, cumulative safety databases were pooled and examined using analyses of: 1) 77 special MedDRA queries covering 22 disease areas, 2) adverse event (AE) accumulations by study day, 3) System-Organ class (SOC) and preferred term, and 4) laboratory testing. Serious adverse events (SAEs) and other cases of interest were reviewed for potential relationship to study drug.
Results: Of the 121 subjects in this analysis, 88 were healthy subjects who received single- or multiple-dose levels of up to 1500 mg/day for up to 14 days; 33 were pts with CS exposed to at least one dose of TE, with dose levels up to 1500 mg/day for up to 12 weeks of initial treatment, with an option to continue into an open-label phase for a total of 124 weeks. Of the 33 pts with CS, 16 were on TE for ⩾6 months, 11 were on TE for ⩾12 months, and 6 patients were on TE for ⩾24 months. Across the studies, there was no common theme in AEs. All SAEs reported by subjects receiving TE were assessed as unrelated to study drug with the exception of 1 case of severe nausea and vomiting, which resolved in 10 days. Most AEs were assessed as of mild to moderate intensity, and most resolved spontaneously while continuing study drug. In Phase 1 studies of healthy subjects, mild increases in hepatic transaminase levels (mostly <2 x ULN) were noted, with 1 subject discontinuing from therapy at the 500 mg bid dose level. In Phase 2 studies, no signal for transaminase abnormalities has been observed to date. In both active drug and placebo, the most common SOC in which AEs were reported was Gastrointestinal (GI) Disorders. Nausea and vomiting accounted for a large proportion of events in this SOC, and occurred relatively early in treatment, usually without recurrence.
Conclusions: This safety review supports advancement of telotristat etiprate to Phase 3 for treatment of CS. Treatment-related SAEs and discontinuations due to AEs have been rare. The majority of events identified in studies thus far are GI symptoms, consistent with the underlying disease.

873 POSTER

Clinical outcomes of patients treated within early phase cancer trials: An audit of the NIHR/Wellcome UCLH clinical research facility

S. Ganguli[1], S. Benafif[1], A. Kirkwood[2], M. Flynn[1], M. Forster[3], R. Kristeleit[3], T. Meyer[3]. *[1]UCLH, Clinical Research Facility, London, United Kingdom; [2]UCL, Cancer Research UK and UCL Cancer Trials Centre, London, United Kingdom; [3]UCL, UCL Cancer Institute, London, United Kingdom*

Background: A number of centres have devised prognostic scores to predict the outcome of patients treated within Phase I trials using baseline characteristics. The Royal Marsden Hospital (RMH) score has demonstrated significantly increased risk with the presence of 2 or 3 of the following factors; low albumin (<35 g/L), elevated lactate dehydrogenase (>upper limit normal) or more than 2 sites of metastases. We assessed the clinical outcomes of patients treated within our early phase trial unit and analysed the relevance of the RMH score within this patient population.
Methods: We retrospectively analysed baseline characteristics and clinical outcomes including best response, progression free (PFS) and overall survival (OS) in 165 sequential patients treated between April 2010 and January 2013. Survival distributions were estimated and differences in survival according to RMH score were analysed using the log-rank test.
Results: Of 165 patients treated in 24 trials, 107 were treated within Phase 1 trials and 58 within Phase II. Median age was 60 years (range 21−83). Best overall response was; partial response in 14%, stable disease in 51% and disease progression in 21%. Ninety-day mortality rate for patients treated in a Phase I trial was 11.9% and 30-day mortality was 3.8%. The median OS for all patients (Phase I and II) was 12.8 months and median PFS was 4.8 months. OS was significantly longer in patients treated within phase II trials than those treated in a phase I trial (median 14 vs 12.5 months, p = 0.043). The RMH score could be applied in 81 patients of which 71% of patients had a 'good' prognostic score of 0−1, and 29% a 'poor' score of 2−3 (no patients scored 3). OS in the 0−1 group was not significantly better compared to the 2−3 group (0−1 group HR = 1.0, 2−3 group HR = 1.02, p = 0.95).
Discussion: In our series of patients, the RMH score was not prognostic however no patients had a high risk score of 3. This may reflect the increasingly stringent eligibility criteria required for current trials. Overall survival and 90-day mortality of our Phase I patient population compares favourably with data reported by other centres. This study demonstrates the possible clinical benefit gained by patients recruited into early phase trials and is in keeping with recently published data.
No conflict of interest.

Improving patient selection and outcomes in phase I trials: validating the Royal Marsden Hospital prognostic score

Y. Drew[1], S. Haney[1], J. Graham[1], M. Pilkington[1], F. Chapman[1], J. Hoben[1], J. Charlton[1], R. Plummer[1]. *[1]Sir Bobby Robson Cancer Trials Research Centre Northern Centre for Cancer Care, Medical Oncology, Newcastle upon Tyne, United Kingdom*

Background: Phase I clinical trials remain an essential step in the development of novel anti-cancer agents. Patient selection is pivotal to maximising patient benefit and avoiding premature study withdrawal of unfit patients and the need for additional recruitment. Performance status (PS) and a life expectancy ⩾3 months are often used to define patients' fitness and trial eligibility. However these methods are subjective and it is reported that up to 20% of patients die within 90 days of starting a phase I trial. The Royal Marsden Hospital (RMH) prognostic score, based on three variables: Lactate dehydrogenase (LDH) > upper limit of normal, albumin <35 g/l and >2 sites of metastases has been shown to predict patient survival. We sought to validate this score in our phase I patient population.

Materials and Methods: Retrospective review of patient referrals for phase I trials to the Sir Bobby Robson Cancer Trials Research Centre, Northern Centre for Cancer Care, Newcastle, UK between January 2009 and December 2011. Baseline characteristics: age, sex, tumour type, WHO PS, number of metastatic sites and baseline blood parameters including haemoglobin, albumin and LDH collected. Clinical outcome assessed by: ⩽90 day mortality rates, best response by RECIST and overall survival defined by date of death or last follow-up. Reasons why individual patients failed to enter phase I trials were recorded.
Results: Data for all 287 patient referrals reviewed. In our centre volume of referrals exceeded trial availability and many patients deteriorated waiting for a trial. 80 (28%) of these patients with a range of advanced solid malignancies entered a total of 21 phase 1 trials (48% combination studies of a novel agent + cytotoxic and 52% single agent). The commonest reason for not taking part was declining PS (59%) and 39% of patients failed screening (52% due to impaired liver function). Median age of trial participants was 63 years (range 23−79) with 23% aged ⩾70 years. Baseline PS was 0 (23%), 1 (70%), 2 (3%). Best response was: partial response 5%, complete response 1% with 50% of patients achieving stable disease. The median survival of all 80 patients was 221 days and the ⩽90 day mortality rate was 9%. Patients with a good RMH score (0−1) at baseline had a longer median survival than patients with poor prognostic scores (2−3); 225 days vs. 207 days; P <0.05. In multivariate analysis the RMH score was an independent variable that predicted survival.
Conclusions: The poor RMH prognostic score predicted a shorter survival in our patients, validating further its use in phase I patient selection.
No conflict of interest.

Phase I clinical trial investigating maximum tolerated dose, safety and pharmacokinetics of volasertib in Japanese patients with advanced solid tumours

H. Nokihara[1], N. Yamamoto[1], Y. Fujiwara[1], Y. Yamada[2], H. Wakui[1], S. Nakamichi[1], S. Kitazono[1], T. Taube[3], Y. Takeuchi[4], T. Tamura[1].
[1]National Cancer Center Hospital, Thoracic Oncology, Tokyo, Japan; [2]National Cancer Center Hospital, Gastrointestinal Oncology, Tokyo, Japan; [3]Boehringer Ingelheim Pharma GmbH & Co. KG, TA Oncology, Biberach, Germany; [4]Nippon Boehringer Ingelheim Co. Ltd., Oncology Clinical Research, Tokyo, Japan

Background: Polo-like kinase 1 (Plk1) is a key regulator of mitosis and is a promising therapeutic target in cancer. Volasertib (BI 6727; an investigational agent) is a selective and potent Plk inhibitor that induces mitotic arrest and apoptosis. The maximum tolerated dose (MTD) for volasertib was established and volasertib had a manageable safety profile and favourable pharmacokinetics (PK) in Caucasian patients (Phase I studies). Here, for the first time the MTD, safety, PK and clinical benefit of volasertib were investigated in Japanese patients (NCT01348347; sponsored by Boehringer Ingelheim), and the results were compared with those of Caucasian patients.
Material and Methods: In this ongoing, open-label, dose-escalation Phase I study, Japanese patients with refractory advanced solid tumours were treated with escalating doses of volasertib (200, 300 and 350 mg). The primary endpoint of this study was the MTD of volasertib. Secondary endpoints included safety, PK and clinical benefit.
Results: Fifteen patients with advanced solid tumours were treated. Dose-limiting toxicities (DLTs; Common Terminology Criteria for Adverse Events [CTCAE] grade 4 neutropenia for ⩾7 days and CTCAE grade 4 thrombocytopenia) were experienced by 2/6 patients in the 350 mg cohort. The MTD of volasertib in Japanese patients was 300 mg; this is consistent with the recommended Phase II dose (300 mg) and comparable to the MTD (400 mg) in the Caucasian Phase I study. In this study, the most common (⩾3 patients) drug-related non-haematological adverse events included fatigue, decreased appetite and nausea. Exposures of volasertib and its metabolite increased with increasing doses and were comparable with those of Caucasian patients (Phase I). Partial response (n = 1; gastric cancer) and stable disease (n = 11, including 3 patients for >12 weeks prior to disease progression) were observed.
Conclusions: In Japanese patients, volasertib had a manageable safety profile up to the MTD determined as 300 mg. Reversible myelosuppression (neutropenia and thrombocytopenia) constituted DLTs as expected from the mode of action. The results on safety and PK of volasertib in Japanese cancer patients are comparable with those previously obtained in Caucasian patients and support enrolment of Japanese patients in global clinical trials without dose modification.

876 POSTER

Exploratory study of health-related quality of life in a phase I trial studying Idarubicin-loaded beads for chimioembolization of hepatocellular carcinoma

A. Anota[1], M. Boulin[2], S. Dabakuyo[3], L. Bedenne[2], F. Bonnetain[4].
[1]CHU Besancon, Quality of Life in Oncology Platform & Methodological and Quality of Life in Oncology Unit, Besançon, France; [2]University of Burgundy, INSERM U866, Dijon, France; [3]Centre Georges-François Leclerc, Biostatistics and Quality of Life Unit, Dijon, France; [4]CHU Besancon, Quality of Life in Oncology Platform & Methodology and Quality of Life in Oncology Unit, Besançon, France

Background: Phase I trials aim to identify the recommended phase II dose: the maximum-tolerated dose (MTD) that will be investigated in further trials. In this context, the added value of health-related quality of life (QoL) of patients to complement the usual toxicity assessment should be questioned. The objective was to investigate QoL in a phase I trial.
Methods: A phase I dose-escalation trial of transarterial chemoembolization (TACE) with idarubicin-loaded beads was performed in cirrhotic patients with hepatocellular carcinoma. Idarubicin dose was escalated according to a modified continuous reassessment method. MTD was defined as dose level closest to that causing dose limiting toxicity (DLT) in 20% of patients.
QoL was evaluated using the EORTC QLQ-C30 at baseline and at days 15, 30 and 60 after TACE. Changes in QoL scores were described using mean difference in scores with baseline as reference and scores at each follow-up, for all patients and according to the idarubicin dose level. The time to QoL score deterioration (TTD) was investigated as a modality of longitudinal analysis. TTD was defined as the time from randomization to a first QoL score deterioration with a 5-point MCID as compared to the baseline score or death. Univariate Cox analyses were performed to identify factors influencing TTD.
Results: Between March 2010 and March 2012, 21 patients were included: 9, 6, and 6 patients were treated at idarubicin dose levels of 5-, 10-, and 15-mg, respectively. Calculated MTD of idarubicin was 10 mg. The median TTD was 0.76 months [95% CI 0.62-NA] for Global Health Status, 0.69 months [0.59-NA] for fatigue and 2.50 months [0.76-NA] for pain. At 10-mg idarubicin dose level, patients presented a longer TTD than at 5-mg dose level for Global Health Status (HR 0.87 [95% CI 0.14–5.36]), physical functioning (HR 0.67 [0.11–4.13]), fatigue (HR 0.77 [0.13–4.71]) and pain (HR 0.52 [0.09–3.16]). Women presented a shorter time to pain deterioration than men (HR 14.7 [1.31–164.7]).
Conclusions: These results show the importance to study QoL in phase I trials. These results are consistent to the idarubicin dose level of 10 mg retained. Nevertheless, if we had integrated TTD in DLT, we could retain idarubicin dose level of 15 mg as the MTD. Moreover, it raises the issue of a specific questionnaire for phase I trial which would be more focused on toxicities.
No conflict of interest.

877 POSTER

Adverse and expected drug reactions to therapy with mistletoe extracts (Viscum album L.) in cancer patients

M.L. Steele[1], J. Axtner[1], A. Happe[1], M. Kröz[2], H. Matthes[2], F. Schad[2].
[1]Forschungsinstitut Havelhöhe, Network Oncology, Berlin, Germany; [2]Gemeinschaftskrankenhaus Havelhöhe, Oncology, Berlin, Germany

Background: Mistletoe (*Viscum album L.)* is one of the most frequently prescribed complementary treatments for cancer in Europe. As an immunomodulating substance it can induce local and systemic immune responses. According to product information, dose-finding is related to local reactions (3−5 cm) and temperature increase (up to 38ºC). Formally, these parameters are defined as adverse drug reactions (ADRs). In terms of safety, therefore, it is necessary to distinguish between adequate immune reactions (expected reactions like local erythema, induration or pain and increased body temperature) and other ADRs. The present study investigates ADRs that occurred in cancer patients treated with mistletoe in an integrative oncological setting.
Material and Methods: The Network Oncology is a conjoint clinical registry of German hospitals and out-patient practitioners that systematically records cancer diagnoses, therapies, ADRs and disease progress. This database was analysed for mistletoe related ADRs, which were classified as MedDRA terms (15.0) and rated on severity. Logistic regression analyses were performed.
Results: A total of 1657 cancer patients (1194 females [72%]; 463 males [28%]) were treated with mistletoe extracts by subcutaneous application. Of these, 378 patients (23%) reported a total of 692 formal ADRs. The majority of formal ADRs (64%) were rated as grade I (mild) in severity, while 10 cases (1%) were rated as grade II (moderate) and 9 cases (1%) as

grade III (severe). No cases were judged as grade IV (life threatening). More than 99% of all formal ADRs were expected (increased temperature [49%], erythema [29%], induration [4%] and pain [3%]). Only 11 patients had other ADRs (chills, headache, nausea and vomiting), collectively making up less than 1% of formal ADRs. Based on logistic regression analysis, females were more likely to experience a formal ADR (OR = 1.5; CI = 1.07, 2.12; p = 0.02), while older age (OR = 0.98 per year; CI = 0.97, 0.99; p < 0.001) and UICC stage IV (OR = 0.53; CI = 0.31, 0.92; p < 0.02) were associated with a lower risk.
Conclusions: Less than a quarter of cancer patients treated with mistletoe reported a formal ADR. These were almost exclusively expected reactions, such as increased body temperature and injection site erythema indicating stimulation of the immune system. With increasing age and tumour stage immunoreactivity decreased. Based on these results, treatment with mistletoe extracts is safe.
Conflict of interest: *Advisory board: Weleda AG*

878 POSTER

Chymase inhibitor, TY-51469, attenuates monocrotaline-induced sinusoidal obstruction syndrome in hamsters

S. Masubuchi[1], S.T. Takai[2], D.J. Jin[2], K.T. Tashiro[3], K.K. Komeda[3], Y.I. Inoue[3], M.H. Hayashi[3], K.U. Uchiyama[3]. [1]*Hirakata City Hospital, Surgery, Hirakata, Japan;* [2]*Osaka Medical College, Pharmacology, Takatsuki, Japan;* [3]*Osaka Medical College, General and Gastroenterological Surgery, Takatsuki, Japan*

Background: The recent chemotherapy regimens of adding oxaliplatin improve the survival of patients with metastatic colorectal cancer. However, treatment with oxaliplatin induces hepatic sinusoidal dilation and haemorrhage, and sinusoidal obstruction syndrome (SOS) is observed in the most of hepatectomy specimens from these patients as well. To date, however, any useful strategy for prevention of SOS has not been established. Previous reports have demonstrated a significance of matrix metalloproteinase (MMP)-9, which is formed from a precursor proMMP-9 by chymase stored in mast cells, in the progression of SOS. In this study, we investigated the preventive effect of a chymase inhibitor, TY-51469, on monocrotaline (MCT)-induced SOS in hamsters.
Material and Methods: Hamsters were orally administrated with a single dose of MCT (120 mg/kg) to induce SOS. Treatment with TY-51469 (1 mg/kg per day) or placebo was started 3 days before the MCT administration. Blood samples and liver tissue were examined two days after the MCT administration. Furthermore, to determine the survival rate, either TY-51469 or placebo was administered from 3 days before up to 14 days after MCT administration.
Result: Two days after the MCT administration, significant increases of aspartate aminotransferase, alanine aminotransferase and total bilirubin and a significant reduction of albumin were observed in plasma, but their changes were significantly attenuated by treatment with TY-51469. The numerous hepatic necrosis areas were observed in the placebo-treated group, but the ratio of necrotic area to total area in liver was significantly reduced by treatment with TY-51469. Chymase activity and the levels of MMP-9 and tumour necrosis factor (TNF)-α in the liver were significantly augmented in the placebo-treated group. However, these were significantly attenuated in the TY-51469-treated group. Furthermore, both gene expressions of chymase and MMP-9 were significantly augmented in the placebo-treated group, which were significantly attenuated in the TY-51469-treated group. Until 14 days after MCT administration, survival rates in the placebo- and TY-51469-treated groups were 25% and 70%, respectively, and there was a significant difference between the two groups.
Conclusion: Chymase inhibition by TY-51469 may prevent the accelerating of severity in MCT-induced SOS in hamsters.
No conflict of interest.

MPDL3280A (anti-PDL1): Clinical activity, safety and biomarkers of an engineered PD-L1 antibody in patients with locally advanced or metastatic tumors

F.S. Hodi[1], T. Powles[2], P. Cassier[3], M. Kowanetz[4], R.S. Herbst[5], J.C. Soria[6], A. Mokatrin[7], M. Stroh[8], D.S. Chen[9], J. Tabernero[10]. [1]*Dana-Farber Cancer Institute, Department of Medicine, Boston MA, USA;* [2]*Barts Cancer Institute QMUL Barts Health NHS Trust, Experimental Cancer Medicine, London, United Kingdom;* [3]*Centre Léon-Bérard, Medical Oncology, Lyon, France;* [4]*Genentech Inc., Oncology Biomarker Development, South San Francisco, USA;* [5]*Yale School of Medicine, Medical Oncology, New Haven, USA;* [6]*Institut Gustave Roussy, Medical Oncology, Villejuif, France;* [7]*Genentech Inc., Biostatistics, South San Francisco, USA;* [8]*Genentech Inc., Pharmacokinetics, South San Francisco, USA;* [9]*Genentech Inc., Oncology Development, South San Francisco, USA;* [10]*Vall d'Hebron University Hospital, Medical Oncology, Barcelona, Spain*

Background: PD-L1 and PD-L2 have been reported to regulate Th1 and Th2 immune responses. Tumor-expressed PD-L1, when bound to PD-1 or B7.1 on activated T cells, can mediate cancer immune evasion. Inhibiting the binding of PD-L1 to its receptors represents an attractive strategy to restore tumor-specific T-cell immunity. However, PD-L2 expressed in the tumor microenvironment may also bind PD-1-expressing T cells, dampening their function. MPDL3280A (anti-PDL1), a human monoclonal antibody containing an engineered Fc-domain designed to promote a Th1-driven response to optimize efficacy and safety, is described here along with Phase I results.
Materials and Methods: A study was conducted with MPDL3280A administered IV q3w in pts with locally advanced or metastatic solid tumors, including 3+3 dose-escalation and expansion cohorts. ORR was assessed by RECIST v1.1 and includes u/cCR and u/cPR. PD-L1 was measured by IHC (pos vs neg), and PD-L2 was measured by qPCR (high vs low) in archival tumor specimens.
Results: As of Feb 1, 2013, 171 pts were evaluable for safety. Administered doses include $\leqslant$1 (n = 9), 3 (n = 3), 10 (n = 35), 15 (n = 57) and 20 mg/kg (n = 67). Pts in the dose-escalation cohorts did not experience DLTs. No MTD was identified. Pts had received MPDL3280A for a median duration of 147 days (range 1–450). 41% of pts reported G3/4 AEs, regardless of attribution. No acute pneumonitis was observed. 122 pts enrolled prior to Jul 1, 2012 were evaluable for efficacy. RECIST responses were observed in multiple tumor types including NSCLC (9/37), RCC (5/39), melanoma (9/35), CRC (1/4) and gastric cancer (1/1). An ORR of 21% (25/122) was observed in nonselected solid tumors with a duration of response range of 1+ to 253+ days. Other pts had delayed responses after apparent radiographic progression (not included in the ORR). The 24-week PFS was 42%. 94 pts had tumors evaluable for PD-L1 status, and 81 pts had tumors evaluable for PD-L2. Median PD-L2 expression was $\approx$2x higher in PD-L1-pos tumors versus PD-L1-neg tumors. The ORR was 39% (13/33) for pts with PD-L1-pos tumors versus 13% (8/61) for pts with PD-L1-neg tumors. Pts with PD-L2^{High} tumors showed an ORR of 27% (11/41), versus 13% (5/40) for pts with PD-L2^{Low} tumors. Updated data will be presented.
Conclusions: MPDL3280A was well tolerated, with no pneumonitis-related deaths. Durable responses were observed in a variety of tumors. PD-L1 and PD-L2 tumor status appears to correlate with responses to MPDL3280A.

Survival and long-term safety in patients (pts) with advanced solid tumors receiving nivolumab (anti-PD-1; BMS-936558; ONO-4538)

F.S. Hodi[1], S.L. Topalian[2], J.R. Brahmer[3], D.F. McDermott[4], D.C. Smith[5], S. Gettinger[6], J.M. Taube[7], D.M. Pardoll[3], J.M. Wigginton[8], M. Sznol[9]. *[1]Dana-Farber Cancer Institute, Melanoma Center, Boston, USA; [2]Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Department of Surgery, Baltimore, USA; [3]Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Department of Oncology, Baltimore, USA; [4]Beth Israel Deaconess Medical Center, Department of Hematology/Oncology, Boston, USA; [5]University of Michigan, Department of Internal Medicine, Ann Arbor, USA; [6]Yale Cancer Center, Department of Oncology, New Haven, USA; [7]Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins University, Departments of Dermatology and Pathology, Baltimore, USA; [8]Bristol-Myers Squibb, Department of Immuno-Oncology Early Clinical Research, Princeton, USA; [9]Yale Cancer Center, Department of Internal Medicine/Medical Oncology, New Haven, USA*

Background: Blockade of programmed death-1 (PD-1), a co-inhibitory receptor expressed by activated T cells, can overcome immune resistance and mediate tumor regression (Topalian et al, NEJM 2012). We present survival and long-term safety results from a clinical study of nivolumab, a PD-1 receptor blocking monoclonal antibody, in pts with advanced solid tumors.
Methods: Pts received nivolumab (0.1−10 mg/kg IV Q2W) in an outpatient setting during dose escalation and/or cohort expansion. Tumors were assessed by RECIST 1.0 after each 4-dose cycle. Pts received ⩽12 cycles or until discontinuation criteria were met.
Results: 306 pts with non-small cell lung cancer (NSCLC; n = 129; squamous and non-squamous), melanoma (MEL; n = 107), renal cell (RCC; n = 34), colorectal (n = 19) or prostate cancer (n = 17) were treated. Objective responses (OR) were observed in NSCLC, MEL and RCC (Table). Additional pts with NSCLC, MEL and RCC manifested stable disease (SD) for ⩾24 weeks (Table). In these heavily pretreated pts (47% with 3−5 prior systemic therapies), median OS in NSCLC, MEL, and RCC was 9.6, 16.8 and >22 months, respectively. Drug-related adverse events (AEs; any grade) occurred in 75% (230/306) of pts, the most common being fatigue (28%), rash (15%), diarrhea (13%), and pruritus (11%). Grade 3−4 drug-related AEs occurred in 17% (52/306) of pts. Drug-related pneumonitis (any grade) occurred in 4% (12/306) of pts, with grade 3−4 drug-related pneumonitis occurring in 1% (4/306) of pts and associated with 3 deaths in the trial. Exploratory data correlating PD-L1 expression to outcomes using an automated assay with the 28−8 anti-PD-L1 antibody will be presented.
Conclusions: Nivolumab produced durable tumor regression, and was associated with OS and landmark 1−2 year survival values which are unexpected in such heavily pre-treated pts with advanced NSCLC, MEL and RCC. We observed an acceptable safety profile with long-term drug administration in the outpatient setting. These findings support the ongoing clinical development of nivolumab in phase 3 trials with survival endpoints.

Tumor type	Dose, mg/kg	OR Rate, n/N (%)	SD ⩾24 wk, n/N (%)	Median OS, mo (95% CI)	OS Rate, % (95% CI); pts at risk, n 1 y	2 y
NSCLC	1−10	22/129 (17)	13/129 (10)	9.6 (7.8−12.4)	42 (33−51); 43	14 (4−24); 5

881 POSTER

A phase I dose-escalation and pk study of continuous oral rucaparib in patients with advanced solid tumors

M. Flynn[1], G. Shapiro[2], P. LoRusso[3], R. Kristeleit[1], M. Patel[4], J. Infante[5], H. Giordano[6], J. Borrow[6], S. Jaw-Tsai[6], H. Burris III[5]. *[1]University College of London Cancer Institute, London, United Kingdom; [2]Dana-Farber Cancer Institute, Boston, USA; [3]Karmanos Cancer Institute, Detroit, USA; [4]Florida Cancer Specialists/Sarah Cannon Research Institute, Sarasota, USA; [5]Sarah Cannon Research Institute, Drug Development Program, Nashville, USA; [6]Clovis Oncology Inc., San Francisco, USA*

Background: Rucaparib, a potent, oral small molecule inhibitor of poly (ADP-ribose) polymerase (PARP) 1 and −2, is being developed for treatment of homologous recombination repair deficient (HRD) ovarian cancer. This study evaluated rucaparib as monotherapy. Primary objectives were to define the maximum tolerated dose (MTD), recommended Phase 2 dose (RP2D), and PK of continuous oral rucaparib.
Materials and Methods: A standard 3+3 dose escalation design was used. Intra-patient dose escalation was allowed. Patients (pts) aged ⩾18 with advanced solid tumor that progressed on standard treatments were recruited. Measurable disease was not required. Rucaparib was taken orally qd or bid continuously until disease progression. Plasma PK assessments included full profile, trough levels, and food effect.
Results: 33 pts (median age 49 yrs [range 21−71]; 30 female; 17 ECOG PS=0; 18 breast cancer (BC), 10 ovarian/peritoneal cancer (OC), 5 other tumor) were enrolled in 7 dose cohorts (40, 80, 160, 300 and 500 mg qd, and 240, 360 mg bid). One pt at 360 mg bid experienced DLT of CTCAE grade 3 nausea. No pts discontinued treatment due to toxicity. Treatment-related adverse events (primarily grade 1−2) reported in ⩾10% of pts include fatigue (n = 8), nausea (n = 5), anorexia (n = 4), vomiting (n = 4), and diarrhea (n = 3). Grade 3/4 toxicities have been minimal and no myelosuppression has been observed. To date, two pts (1 BC, 1 OC; both $BRCA1^{mut}$; 300 mg qd) achieved a PR (duration 14 and 21+ wks, respectively). An additional 10 pts (5 OC, 4 BC, 1 CRC; 7 $BRCA^{mut}$, 2 $BRCA^{unk}$, 1 $BRCA^{wt}$) achieved a best response of stable disease (SD) >12 wks thus far. Three pts (all $BRCA^{mut}$ OC) are ongoing in wks 26, 27, and 40. Five recently enrolled pts are also ongoing. Overall disease control rate (CR+PR+SD>12 wks) to date in all evaluable OC pts across all dose levels is 86% (6/7). Dose proportional PK was observed up to 500 mg qd with mean $t_{1/2}$ of 15 h (range 4.3−29 h). Following qd dosing, steady state was achieved by Day 8. As expected, bid dosing increased trough levels above 2 μM target with low interpatient variability.
Conclusion: Continuous oral rucaparib is well tolerated, with encouraging clinical activity, including objective responses and durable SD, observed during dose-escalation. Once confirmed, the RP2D will be evaluated in platinum-sensitive OC pts with a gBRCA mutation.

882 POSTER

A phase I dose-escalation study of buparlisib (BKM120), an oral pan-PI3K inhibitor, in Chinese patients with advanced solid tumors

L. Zhang[1], B. Xu[2], K. Hazell[3], A. Gaur[4], J. Xu[5], L. Trandafir[6], Y.L. Wu[7]. *[1]Sun Yat-sen University, Cancer Center, Guangzhou, China; [2]Chinese Academy of Medical Sciences and Peking Union Medical College, Cancer Institute & Hospital, Beijing, China; [3]Novartis Pharma AG, Clinical Trials, Basel, Switzerland; [4]Novartis Healthcare Pvt. Ltd., Biostatistics, Hyderabad, India; [5]Novartis Pharmaceuticals (China) Oncology, Clinical Pharmacology, Beijing, China; [6]Novartis Pharma SAS, Clinical Trials, Paris, France; [7]Guangdong General Hospital and Guangdong Academy of Sciences, Guangdong Lung Cancer Institute, Guangzhou, China*

Background: Activation of the PI3K/Akt/mTOR signaling pathway promotes tumor growth. Buparlisib is an oral pan-class I (α, β, γ, δ) PI3K inhibitor that has demonstrated clinical antitumor activity in a range of cancer types. In a first-in-man Ph I study (NCT01068483) conducted in Western patients (pts) with advanced solid tumors (aST), the maximum tolerated dose (MTD) of single-agent buparlisib was declared as 100 mg/d. Here, we present interim results of a Ph Ib trial of single-agent buparlisib in Chinese pts with aST (NCT01626209).
Material and Methods: The primary objective was to determine the MTD or recommended Phase II dose (RP2D) of single-agent buparlisib in Chinese pts, based on clinical safety profile, and supported by PK results. Pts (age ⩾18 y, ECOG PS⩽2) with advanced breast cancer or

other cancers with squamous cell (SC) histology, who progressed on standard therapy, or for whom no standard anticancer therapy exists, received once-daily oral buparlisib. Other key eligibility criteria included availability of archival/fresh tumor biopsy to determine PI3K pathway activation status and measurable/non-measurable disease (RECIST v1.1). A Bayesian logistic regression model guided dose escalation.
Results: As of March 11, 2013, 14 pts (median age 45.5 y [range 24−75]; 43% male; primary cancer site: breast (5), SC lung (6), head and neck (3); 43% ⩾4 prior antineoplastic therapy lines) had received buparlisib at 80 mg/d (n = 6) or 100 mg/d (n = 8). Median exposure duration was 47 d [range 9–105]. DLT only occurred in 1 pt at 80 mg (Grade [G] 3 depression). The MTD was declared as 100 mg/d. Other drug-related G3/4 AEs (CTCAE v4.03) occurred in 2 pts at 80 mg/d (anemia and depression) and 3 pts at 100 mg/d (increased alanine and aspartate aminotransferases [1 pt], decreased platelet count [1 pt], and hyperglycemia [1 pt]). Primary reasons for treatment discontinuation were progressive disease (n = 8), AEs (n = 2 [G3 depression and G3 pneumonia]), patient/guardian decision (n = 2), and death (n = 1 [terminal lung cancer]). Preliminary PK analysis revealed no major difference in PK parameters between Chinese and Western pts.
Conclusions: In these Chinese pts with aST, buparlisib had a favorable safety profile and a similar PK profile to that seen in Western pts. The MTD for single-agent buparlisib in Chinese pts was declared as 100 mg/d. Short duration on treatment may reflect heavily pretreated disease. Antitumor activity is under evaluation in expansion cohorts and will be presented at the meeting.

883 POSTER

A multiple ascending dose phase I clinical, pharmacokinetic, and pharmacodynamic study of CG200745, a histone deacetylase (HDAC) inhibitor, in patients with advanced solid tumors

S.J. Park[1], J.E. Kim[1], K.P. Kim[1], Y.S. Hong[1], J.L. Lee[1], K.S. Bae[2], J.S. Lee[1], E.K. Choi[3], T.W. Kim[1]. *[1]Asan Medical Center University of Ulsan College of Medicine, Department of Oncology, Seoul, South Korea; [2]Asan Medical Center University of Ulsan College of Medicine, Department of Clinical Pharmacology and Therapeutics, Seoul, South Korea; [3]Asan Medical Center University of Ulsan College of Medicine, Department of Radiation Oncology, Seoul, South Korea*

Background: The aim of this study was to assess the safety, maximum tolerated dose (MTD), pharmacokinetics, pharmacodynamics, and efficacy of multiple dose of intravenous CG200745, a novel histone deacetylase (HDAC) inhibitor, in patients with advanced solid malignancies.
Materials and Methods: Two to six patients received intravenous CG200745 weekly for 3 weeks, then 1 week off according to the '2+4' dose-escalating method. Pharmacokinetic sampling and pharmacodynamic sampling of acetylated histone H4 (Acetyl-H4) in peripheral blood mononuclear cells (PBMCs) were performed on day 1 and 15 of the 1st cycle. Pre- and post-biopsy for acetyl-H4 in tumor tissue was performed in accessible patients.
Results: Eighteen patients were treated at one of nine doses (24.0–250 mg/m^2) and received 1.5 (1−11) cycles of CG200745 (median, range). No dose-limiting toxic effects or QTc prolongations were noted. Dose proportionality was observed for both Cmax and AUC. The elimination half-life and mean residual time was 5.67±2.69(mean±SD) and 3.97±1.63 hrs. An increase in PBMC acetyl-H4 correlated with dose and Cmax up to 51 mg/m^2 and plateaued in higher dose levels. At 24 hrs post administration, acetyl-H4 values higher than two times of baseline values in tumor tissue were observed in 50% (4/8) of measured patients. Stable disease was seen in half of the patients (9/18).
Conclusions: CG200745 can be safely administered at the effective dose levels that inhibit HDAC in PBMCs and tumor tissue. Although MTD was not reached, further escalation was not performed as the acetyl-H4 plateaued at dose levels higher than to 51 mg/m^2. Further phase II trials are recommended at 250 mg/m^2 due to the tolerability.
No conflict of interest.

Hyperglycemia in patients treated with the pan-PI3K inhibitor buparlisib (BKM120): characterization, management, and assessment for pharmacodynamics

A. Azaro[1], J. Rodon[1], J.F. Vansteenkiste[2], Y. Ando[3], T. Doi[4], D. Mills[5], C. Sarr[6], E. Di Tomaso[7], C. Massacesi[8], R.W. Naumann[9]. *[1]Vall d'Hebron University Hospital, Medical Oncology, Barcelona, Spain; [2]University Hospital Gasthuisberg, Respiratory Oncology Unit, Leuven, Belgium; [3]Nagoya University Hospital, Department of Clinical Oncology and Chemotherapy, Nagoya, Japan; [4]National Cancer Center Hospital, Gastrointestinal Oncology Division, Chiba, Japan; [5]Novartis Pharma AG, Statistics, Basel, Switzerland; [6]Novartis Pharma AG, Modeling, Basel, Switzerland; [7]Novartis Institutes for Biomedical Research, Correlative Science, Cambridge MA, USA; [8]Novartis Oncology, Global Clinical Program, Paris, France; [9]Carolinas Medical Center, Division of Gynecologic Oncology, Charlotte NC, USA*

Background: PI3K serves a central role in glucose homeostasis. Here, we characterize hyperglycemia (HG) observed in two clinical trials of the pan-class I PI3K inhibitor buparlisib (BKM120), assess its relevance as a pharmacodynamic marker, and evaluate the relationship of HG and insulin release (assessed by C-peptide [C-pep]) with clinical response.
Methods: Pts were treated with single-agent buparlisib in two completed studies in pts with advanced solid tumors: S1 − a Ph I dose-escalation (DE) study (CBKM120X2101; 12.5–150 mg/d [N = 83]); and S2 − a Ph I DE study in Japanese pts (CBKM120X1101; 25–100 mg/d [N = 15]). Here, we report observations for pts treated with 80 mg/d (n = 11) and 100 mg/d (n = 55) in S1, and 100 mg/d (n = 9) in S2, unless otherwise stated. C-pep was measured throughout the studies. HG was assessed according to CTCAE v3. Clinical response was assessed by best % change from baseline in sum of longest diameters (SLDs) and best overall response as per RECIST v1.0 and v1.1 in S1 and S2, respectively.
Results: In S1, mean max % change in C-pep at baseline and at C_{max} on C1D1 was −10, 13, 58, 41, 70, and 72% at 12.5, 25, 50, 80, 100, and 150 mg/d, respectively. There was a slight inverse correlation between max post-baseline C-pep value in C1 and best % change in SLDs (Pearson's r = −0.17) in pts treated at 80 or 100 mg in S1. All-grade (G) HG was noted in 25 of 75 (33%) pts at 80/100 mg in S1/S2; although most cases were mild (G1/2) and transient, G3/4 HG was noted in 6 (8%) pts. HG was managed with glucose-lowering medications, such as metformin and insulin when needed, and with buparlisib interruption/dose reduction. Only 1 pt permanently discontinued buparlisib due to HG (treated at 100 mg in S1). Among pts reporting no HG (n = 50), 2% had PR, 44% had SD, and 46% had PD; among those with HG G1−4 (n = 25), 36% had SD and 48% had PD.
Conclusions: HG is observed in buparlisib clinical trials and is well managed with glucose-lowering agents. Buparlisib exhibited a dose-dependent effect on C-pep levels and is a potential pharmacodynamic marker. There was a slight inverse correlation between C-pep and tumor shrinkage in this preliminary analysis, indicating a potential relationship between PI3K pathway inhibition and tumor response. No clear relationship between HG grade and clinical response was observed. Further analyses investigating the relationship between HG/change in C-pep and tumor shrinkage in additional single-agent buparlisib studies will be presented at the meeting.

885 POSTER

Phase 1b study of albumin-binding doxorubicin (aldoxorubicin) plus free doxorubicin

S. Chawla[1], K. Sankhala[2], V. Chua[3], V. Narasimahan[3], M. Sodhi[3], D. Quon[3], H. Dinh[4], S. Wieland[4], D. Levitt[4]. *[1]Sarcoma Oncology Center, Santa Monica CA, USA; [2]University of Texas Medical Center, Medical Oncology, San Antonio TX, USA; [3]Sarcoma Oncology Center, Medical Oncology, Santa Monica CA, USA; [4]CytRx Corporation, Medical Oncology, Los Angeles CA, USA*

Background: Preclinical studies of aldoxorubicin, a doxorubicin conjugate that binds covalently to circulating albumin, plus free doxorubicin, have demonstrated complete and prolonged remissions of pancreatic and ovarian cancer xenografts when administered at 50% of their MTD, and with less toxicity than each drug administered at their MTD. The safety

and activity of a fixed dose of free doxorubicin and escalating doses of aldoxorubicin were evaluated in patients with advanced solid tumors who had no other accepted therapeutic options.
Methods: Open label dose-escalation study of aldoxorubicin administered at either 175, 240 or 320 mg/m^2 (130, 180 or 240 mg/m^2 doxorubicin equivalents) iv + 35 mg/m^2 doxorubicin iv, both on Day 1 of 21 day cycles, up to 8 cycles. MTD is the dose level immediately below where 2/6 patients experience a dose limiting toxicity (DLT), or the maximum dose of 320 mg/m^2 of aldoxorubicin.
Results: 10 subjects have been treated as of March 31, 2013. 7 subjects received 230 mg/m^2 aldoxorubicin and 3 patients received 320 mg/m^2 aldoxorubicin. No DLT was observed. The MTD thus was 320 mg/m^2 aldoxorubicin + 35 mg/m^2 doxorubicin administered as above. Patients were able to receive 4.5 cycles (median). 4 subjects were terminated either due to progressive disease or death. No subjects stopped treatment due to an adverse event. Grade 3/4 neutropenia occurred in 8/10 patients, grade 3/4 thrombocytopenia in 6 patients and grade 3/4 anemia in 4 patients. Febrile neiutropenia was observed in 3 patients. Grade 3/4 liver enzyme elevations or fatigue occurred in 1 and 2 patients, respectively. An objective partial tumor response was documented in one patient with advanced soft tissue sarcoma that had not responded to previous doxorubicin as well as a patient with advanced breast cancer. 7 patients had stable disease.
Conclusion: The combination of aldoxorubicin at 320 mg/m^2 and doxorubicin at 35 mg/m^2 can be safely administered to patients with solid tumors and shows anti-tumor activity. Since neutropenia is very common, prophylactic use of G-CSF is rexcommended. The dose of aldoxorubicin is 90% of the MTD of aldoxorubicin. Thus, doxorubicin does not appear to add to the toxicity of this combination.
Conflict of interest: *Ownership: CytRx Corporation. Corporate-sponsored research: CytRx Corporation. Other substantive relationships: Employment, CytRx Corporation*

886 POSTER

Pharmacokinetic study of aldoxorubicin, a novel albumin-binding drug, in solid tumor patients

D. Levitt[1], R. Natale[2], E. Wolin[2], B. Laabs[2], H. Dinh[3], S. Wieland[3], A. Mita[2], M. Mita[2]. *[1]CytRx Corporation, Los Angeles CA, USA; [2]Cedars-Sinai Medical Center, Samuel Oschin Comprehensive Cancer Institute, Los Angeles CA, USA; [3]CytRx Corporation, Medical Oncology, Los Angeles CA, USA*

Background: Aldoxorubicin consists of doxorubicin conjugated to a pH sensitive linker that binds covalently to the cycteine 34 position in circulating serum albumin. Previous studies demonstrated that aldoxorubicin can be administered at doses up to 350 mg/m^2 (260 mg/m^2 doxorubicin equivalents) every 21 days for up to 8 cycles. We have investigated aldoxorubicin pharmacokinetics, including albumin-bound and free doxorubicin, and doxorubicinol after administration of 2 dose levels of aldoxorubicin in patients with advanced solid tumors.
Methods: Patients with solid tumors and no standard therapy were eligible. Other entry criteria: ECOG PS 0−2; LVEF>45% of predicted normal; ANC. 2000/mm^3; platelets >100,000/mm^3; Hct >25% (male), 28% (female). Patients were administered either 230 mg/m^2 aldoxorubicin (165 mg/m^2 doxorubicin equivalents) or 350 mg/m^2 aldoxorubicin (260 mg/m^2 doxorubicin equivalents) iv over 30 minutes on day 1 of each cycle. Blood samples were taken prior to administration and at multiple time points up to 72 hr post administration during cycles 1 and 3. Serum concentrations of albumin-bound doxorubicin, unbound doxorubicin and doxorubicinol were analyzed.
Results: As of March 31, 2013, 10 subjects have been entered in the study. 7 subjects have received 230 mg/m^2 aldoxorubicin and 3 patients 350 mg/m^2 aldoxorubicin. No serious adverse events have been reported. Grade 3 and 4 adverse events include neutropenia, thrombocytopenia and anemia. A partial response has been documented in 1 patient with small cell lung cancer that had received 3 prior chemotherpy regimens, and ongoing stable disease in another patient with previously-treated small cell lung cancer, both at the 230 mg/m^2 dose. Results for the 230 mg/m^2 cohort are complete and show for the albumin-bound doxorubicin during cycle 1: C_{max}=64 μg/mL; t_{max}= 0.25 hr; $t_{1/2}$= 19.7 hr; $AUC_{t-\infty}$=1500 h*μg/mL; CL_{pred}= 0.153 L/h/m^2; V_{sspred}= 3.91 L/m^2. Results are similar for cycle 3. Free doxorubicin accounted for less than 0.8% of total doxorubicin at each time point, and doxorubicinol for less than 0.0007% of total drug. Results from the 350 mg/m^2 cohort are pending.
Conclusion: Aldoxorubin binds rapidly and almost completly to albumin, has a narrow V_d and is cleared slowly from circulation, which distinguishes it from doxorubicin. Very little free doxorubicin is released into the circulation, potentially mitigating some of the drug's toxicity.
Conflict of interest: *Ownership: CytRx Corporation. Corporate-sponsored research: CytRx Corporation. Other substantive relationships: Employment, CytRx Corporation*

887 POSTER

Description and impact of topotecan dosing in ovarian cancer and SCLC

J. Hoverman[1], J.S. Garey[2], R.N. Schwartz[2], R. Harrell[3], M. Clayton[3], R.A. Beveridge[3]. *[1]Texas Oncology The US Oncology Network, Austin, USA; [2]The US Oncology Network/McKesson Specialty Health, The Woodlands, USA; [3]The US Oncology Network/McKesson Specialty Health, The Woodlands, USA*

Background: Topotecan (topo) is a treatment (tx) for advanced ovarian and small cell lung cancer (SCLC). Weekly (WK) dosing vs. conventional (daily x 5, Q21D) (CO) has shown similar outcomes in both diseases with less severe neutropenia. We describe patterns of use in the community, measure tx duration, and capture WBC growth factor (GF) utilization during topo.
Methods: Eligible pts: in US Oncology's (USO) iKnowMed^{TM}(iKM) EHR; SCLC or ovarian cancer diagnosis; tx with single agent topo. Pts were classified as WK or CO dosing cohorts. Percent of pts crossed over from CO to WK was captured. Age, sex, KPS, line of therapy (LOT), tx duration, and GF use were collected. Chi squared tests assessed the association of clinical factors with CO vs. WK dosing. Wilcoxon rank sum tests assessed continuous variables.
Results: From 1/1/2007 to 10/31/12, 2,534 pts were included (1071 ovarian; 1463 SCLC). CO: WK dosing for ovarian and SCLC were 168: 903 and 624: 839, respectively. Characteristics for SCLC pt were similar for both cohorts. In the ovarian population, a higher percent of pts age >65 yo received WK ($p = 0.005$). Less than 1% of pts crossed over from CO to WK. Pts receiving CO topo received more administrations in ovarian and SCLC (mean: 15 vs. 6, $p < 0.001$ SCLC and 18 vs. 10, $p < 0.001$ ovarian), but overall treatment duration was not different for CO dosing. Pegfilgrastim (PEG) was used less frequently with WK tx in ovarian and SCLC (OR: 0.1, $p < 0.01$) and average number of PEG admin was greater in CO tx (SCLC: 2 vs. 1, $p < 0.01$; ovarian: 3 vs. 2, $p = 0.014$).
Conclusions: Published data support topo WK as an alternative to CO dosing with less toxicity. This report shows more use of WK topo in a community oncology setting in ovarian and SCLC; more PEG use in CO topo dosing and similar tx duration for CO and WK dosing.
No conflict of interest.

Phase I, open-label, dose-escalating clinical and pharmacokinetic study of the novel antimicrotubulin agent PM060184 administered over 10 Minutes on day 1 and 8 every three weeks to patients with advanced malignant solid tumors

M. Hidalgo[1], A. Tolcher[2], A. Cubillo[3], D. Rasco[2], V. Boni[3], A. Patnaik[4], E. Calvo[2], A. Amaya[2], A. Soto Matos Pita[5], K. Papadopoulos[4]. *[1]Centro Nacional de Investigaciones Oncológicas: CNIO, Oncology, Madrid, Spain; [2]START Madrid Centro Integral Oncológico Clara Campal, Madrid, Spain; [3]HM Universitario Sanchinarro, Madrid, Spain; [4]START South Texas Accelerated Research Therapeutics, Texas, USA; [5]PharmaMar, Madrid, Spain*

Background: PM060184 is a new chemical entity that inhibits tubulin polymerisation, causing microtubular fragmentation and mitotic arrest. *In vitro*, it has activity against solid tumours, especially breast, colon, renal and ovarian tumour cell lines. *In vivo,* evaluation of PM060184 demonstrated significant antitumour activity in patient-derived xenograft models (AVATAR) of gastric, NSCLC and pancreatic ductal adenocarcinoma.
Materials and Methods: Patients (pts) with advanced solid tumours were enrolled in a phase I, open-label, accelerated dose-escalating clinical and pharmacokinetic (PK) study of intravenous (i.v.) PM060184 given over 10 min on Day 1 and 8 every 3 weeks.
Results: 30 pts were distributed in 9 dose levels (DLs). Median age was 60 y (range, 36−78 y), 19 pts (63%) were males. ECOG PS was 1 in 67% of pts (range, 0−2). Most common tumours were colorectal (33%), GIST, NSCLC and breast cancer (13% each). Most pts were heavily pretreated, with a median of 4 (range, 1−13) lines. Pts received a median of 2 (range, 1−23) PM060184 cycles. Starting DL was 1.3 mg/m^2. DLTs occurred at 10.4 mg/m^2 [1 pt G3 peripheral neuropathy (PN)], 11.6 mg/m^2 (1 pt G3 PN), 14.5 mg/m^2 (2 pts G3 PN; and G3 vomiting and G4 neutropenia), and 12.0 mg/m^2 (3 pts G3 abdominal pain; symptomatic G3 hyponatremia; and G3 myalgia and G3 arthralgia). The MTD was 12.0 mg/m^2 and the RD was 9.3 mg/m^2. Most toxicities and abnormalities were mild. G3 AEs were: peripheral neuropathy (n = 3 pts), vomiting, fatigue, abdominal pain, intestinal obstruction, arthromyalgia, hyperkalaemia and hyponatraemia (n = 1 each). Haematological abnormalities were G3 thrombocytopenia (n = 2), G3 neutropenia (n = 2) and G4 neutropenia (n = 1). Preliminary PK data show a short half-life (4.4 h), wide distribution (251 L) and moderate inter-patient variability. Evidence of activity was observed in 2 breast carcinoma pts with tumour shrinkage around 20% and one partial response as per Choi criteria in one pt with GIST (resistant to 2 prior lines of standard therapy) who is still on treatment after 23 cycles. Overall, stabilisation for >3 mo has been observed in 4 pts.
Conclusions: The RD of PM060184 for further development was 9.3 mg/m^2 and has shown an acceptable safety profile; early non-cumulative PN was the main DLT. The antitumour activity observed in heavily pretreated pts warrants further study.
Conflict of interest: *Corporate-sponsored research: Funding to STAT for conduct of clinical trial*

889 POSTER

First-in-man phase I, open-label, dose-escalating clinical and pharmacokinetic study of the novel antimicrotubulin agent PM060184 administered over 10 minutes on days 1, 8, and 15 every four weeks to patients with advanced malignant solid tumours

J.P. Delord[1], E. Elez[2], C. Gomez Roca[1], C. Coronado[3], N. Lignon[1], L. Martinez de Arenzana[2], S. Fudio[3], B. De Miguel Lillo[3], A. Soto Matos Pita[3], J. Tabernero[2]. *[1]Institute Claudius Regaud, Oncology, Tolouse, France; [2]Hospital Vall d'Hebrón, Oncology, Barcelona, Spain; [3]PharmaMar, Clinical Oncology, Madrid, Spain*

Background: The new chemical entity PM060184 inhibits tubulin polymerization, causing microtubular fragmentation and mitotic arrest. It has activity *in vitro* against several solid tumours (especially breast, colon, renal and ovarian tumour cell lines). *In vivo,* evaluation of PM060184 demonstrated significant antitumour activity in patient-derived xenograft models of gastric, NSCLC and pancreatic ductal adenocarcinoma.
Materials and Methods: Patients (pts) with advanced solid tumours were enrolled in a phase I, open-label, accelerated dose-escalating clinical and pharmacokinetic (PK) study of PM060184 given i.v. over 10 min on Days 1, 8 and 15 every 4 weeks.
Results: 22 pts were distributed in 8 dose levels (DLs) during escalation. Median age was 58 y (range, 22−72 y), 15 pts (68%) were males. ECOG PS was 1 in 36% of pts (range, 0−1). Most common tumours were colorectal (50%) and pancreas (14%). Most patients were heavily pretreated, with a median of 4 (range, 1−9) lines. Pts received a median of 2 (range, 1−7) PM060184 cycles. The starting DL (DL1) was 1.3 mg/m^2. The highest DL (DL7) 14.5 mg/m^2 was the MTD, as 2 pts (both pretreated with oxaliplatin) had DLT (G3 peripheral sensory neuropathy). One DLT (G3 peripheral sensory neuropathy) occurred at (DL8) 12.0 mg/m^2 in the expansion cohort, which is still ongoing. Common toxicities were fatigue, alopecia, peripheral sensory neuropathy, nausea, vomiting, musculoskeletal pain and diarrhoea. Most were mild (G1−2); G3 toxicities were peripheral sensory neuropathy (3 pts), fatigue and abdominal pain (1 pt each). Myelosuppression was mild, 5 pts had G2 neutropenia and 3 pts had G3 anaemia. G3 biochemical abnormalities comprised transient AST increase (2 pts) and AP increase (2 pts). Preliminary PK data show a short half-life (5 h), a wide distribution (286 L) and moderate inter-patient variability. Remarkable tumour shrinkage (~20%) occurred in 2 pts: 1 with head and neck carcinoma and 1 with breast carcinoma. Stabilization >3 mo also occurred in 3 pts with colorectal carcinoma.
Conclusions: PM060184 has acceptable safety and tolerability profile; non cumulative peripheral neuropathy is the only DLT observed. Evidence of activity has been found. Recruitment into the expansion cohort is ongoing; updated data will be presented at the meeting.
Conflict of interest: *Advisory board: PharmaMar*

890 POSTER

A phase I study in patients with advanced solid tumors for the human monoclonal antibody vantictumab (OMP-18R5; anti-Frizzled) targeting the WNT pathway

K.P. Papadopoulos[1], L. Rosen[2], R. Chugh[3], J. Goldman[2], L. Xu[4], A. Kapoun[4], R.K. Brachmann[4], R. Stagg[4], A.W. Tolcher[1], D. Smith[3]. *[1]South Texas Accelerated Research Therapeutics (START), San Antonio, USA; [2]University of California, Los Angeles, USA; [3]University of Michigan, Ann Arbor, USA; [4]Oncomed, Redwood City, USA*

Background: The WNT pathway is a key oncologic pathway in numerous tumor types and implicated in cancer stem cell (CSC) function. Vantictumab is a first-in-class anti-CSC antibody that interacts with the extracellular domain of 5 Frizzled receptors (Fzd 1, 2, 5, 7, 8) and blocks canonical Wnt signaling. In patient-derived xenograft models, vantictumab inhibits growth of many tumor types, reduces CSC frequency, promotes differentiation of tumor cells, and synergizes with many chemotherapy agents (*PNAS 109, 11717*).
Methods: Using a 3+3 design, vantictumab was given intravenously, first every 1 week (q1w) or q2w, and, ultimately, q3w. Objectives were to determine maximum tolerated dose, safety, pharmacokinetics (PK), pharmacodynamics (PD), and efficacy.
Results: 23 patients have been treated in 7 dose-escalation cohorts (0.5 & 1 mg/kg q1w; 0.5 mg/kg q2w; 1, 2.5, 5 and 10 mg/kg q3w). Most common related Grade 1 and 2 adverse events (AEs) included fatigue, vomiting, abdominal pain, constipation, diarrhea and nausea. Only related Grade $\geqslant$3 AEs were dose-limiting toxicities of Grade 3 diarrhea and vomiting in one patient at 1 mg/kg q1w. Vantictumab clearance was dose-dependent, consistent with target-mediated drug disposition, with the half-life ranging from 1.5 (0.5 mg/kg) to 3.3 days (5 mg/kg). Exposure at current dose levels correlates with efficacy in nonclinical tumor models. PD biomarkers indicate inhibition of WNT pathway in patient tumors and surrogate tissue. One patient at 0.5 mg/kg q1w had a bone fracture on Day 110 and a ~4-fold increase by Day 28 of β-C-terminal telopeptide (β-CTX), a marker of increased bone turnover. A revised safety plan, including Vitamin D_3 and $CaCO_3$ prophylaxis, and q3w dosing enabled further dose escalation. Upon β-CTX doubling, 2 patients received zoledronic acid, and β-CTX returned to baseline. Three patients with neuroendocrine tumors (NETs) with investigator-confirmed progressive disease on prior therapy had stable disease (SD) for ~4, 9+ and 12+ months; 2-, 0.8- and 8.4-fold length, respectively, of prior therapy. One patient with pancreatic NET (12+ months) had tumor shrinkage of −21%.
Conclusions: Vantictumab is well tolerated at current dose levels. An increase in bone turnover can be managed with increased monitoring and intervention with zoledronic acid. Prolonged SD in 3 NET patients, with a minor response in a pancreatic NET patient, may represent single-agent activity. The cohort for 10 mg/kg q3w continues to enroll.
Conflict of interest: *Corporate-sponsored research: KP Papadopoulos, AW Tolcher: Oncomed support for conduct of clinical trials to START. LS Rosen: research funding to institution from OncoMed. 891 POSTER

Properties of pyrrol derivate as potential anticancer compound

H. Kuznietsova[1], M. Danylov[1], I. Kotlyar[1], V. Luzhenetska[2], V. Rybalchenko[1]. [1]*Taras Shevchenko National University, Institute of Biology, Kiev, Ukraine;* [2]*The State Administration, Scientific and Practical Center of Preventive and Clinical Medicine, Kiev, Ukraine*

Introduction: Gastrointestinal organs are the first to be affected by drugs including anticancer ones and provide major alterations because gut epithelium sensitivity through its high proliferative activity and liver vulnerability through xenobiotics detoxification. Targeted inhibitors of proliferative activity such as protein kinase inhibitors are known as high-efficiency and low-toxic anticancer agents, but only few ones have received US Food and Drug Administration approval as colorectal cancer treatments. Therefore, evaluation of 'small molecule' protein kinase inhibitor pyrrol derivate (D1, 5-amyno-4-(1,3-benzothyazol-2-yl)-1-(3-methoxyphenyl)-1,2-dihydro-3H-pyrrol-3-one) as anticancer agent, based on assessment of its anticancer efficacy and gut toxicity in comparison with common therapeutic 5-fluorouracil (5FU) ones was aimed.
Methods: Macroscopic analysis of colon internal surface, histological (light microscopy and morphometry of stomach, liver, small and large intestine sections), biochemical (serum liver enzymes activities, urinary 7,8-dihydro-8-oxoguanine (8-oxoG) concentration as a marker of DNA oxidative damage).
Results: D1 ingested for 10, 50 and 190 days (2.3 mg/kg daily) to normal rats didn't alter gut mucosa unlike 5FU, inhibited colon mucosa cell proliferation by 27% only after 190 days action (as opposed to 40−50% inhibition by 5FU after all investigated terms), caused no inflammation, had practically no effect on submucosa vascular bed, caused no hepatotoxicity. 1,2-Dimethylhydrazine(DMH)-induced rat colon cancer model was used to evaluate D1 antitumor activity. Total tumor lesions area decrease by 41−46% caused by D1 when acts concomitantly or following DMH (by 43% caused by 5FU) was revealed. Concomitant action of D1 and 5FU following DMH increased this rate to 54%.
Protective effect of D1 against DMH alterations in 'normal' gut mucosa and liver, manifested by recovery of gut mucosa and liver morpho-functional state and vascular bed, decrease of inflammation in stomach and intestine mucosa, normalization of serum aspartate aminotranspherase and alkaline phosphatase, diminution of elevated (by 5 times) urinary 8-oxoG, was found. On the contrary 5FU caused aggravation of DMH alterations in gut organs, urinary 8-oxoG further enhancing. Partially neutralization of 5FU toxic effects, caused by D1 under concomitant action, was also detected.
Conclusions: Low toxicity of pyrrol derivate and its efficacy against experimental colorectal cancer was concluded, so further D1 preclinical investigations are suggested.
No conflict of interest.

892 POSTER

A phase I trial assessing the safety and pharmacokinetics of afatinib and weekly vinorelbine in patients with advanced solid tumours

A. Hollebecque[1], R. Bahleda[1], Y. Bergé[2], C. Massard[1], M. Uttenreuther-Fischer[3], H. De Mont-Serrat[4], I. Tschoepe[4], D. Schnell[3], J.C. Soria[1], J.P. Delord[2]. [1]*Institut Gustave Roussy, Villejuif Cedex, France;* [2]*Institut Claudius Regaud, Toulouse, France;* [3]*Boehringer Ingelheim GmbH & Co. KG, Biberach, Germany;* [4]*Boehringer Ingelheim France S.A.S., Reims, France*

Background: Afatinib (A) is an irreversible ErbB Family Blocker. Final safety and pharmacokinetic (PK) data from a phase I trial of A + vinorelbine (V) intravenous (iv) or oral (po) are presented. PK data focus on V po, as data for V iv were previously shown.
Methods: Eligible patients (pts) were ⩾18 years old with refractory advanced, non-resectable and/or metastatic tumours known to overexpress EGFR and/or HER2, had an ECOG performance status (PS) 0−1, and adequate organ and bone marrow function. In a 3+3 dose-escalation design, pts received escalating doses of daily A po (20/40/50 mg) continuously + V iv (25 mg/m^2; Part A) or V po (60 mg/m^2 for 3 weeks, escalated to 80 mg/m^2 thereafter; Part B) on Days 1, 8, 15 and 22 of a 4-week course. Primary endpoint was maximum tolerated dose (MTD) of A + V iv or po (the dose at which ⩽1/6 pts had a dose-limiting toxicity [DLT] during Course 1). A and V PK parameters were analyzed by intra-individual comparison to assess possible drug–drug interactions.
Results: 55 pts were treated (24 male/31 female) with A + V iv (n = 28) or A + V po (n = 27); median age 54 years, ECOG PS 0/1 36%/64%. MTD for both combinations was A 40 mg daily based on 1/6 DLTs in the MTD cohort (Table). Febrile neutropenia (8/55 pts) and diarrhoea (7/55 pts) were the most frequently reported DLTs during Course 1. Three pts had a confirmed partial response (PR) at A 40 mg + V po (RECISTv1.0); median duration of response was 114 days. Stable disease was seen in 16 pts in the A + V iv arm (4 of which had an unconfirmed PR at A 40 mg/50 mg [1/3]) and in 11 pts in the A + V po arm. In PK expansion cohorts for both combinations at the MTD, geometric mean $C_{max,ss}$ and $AUC_{\tau,ss}$ of A with/without V iv/po were similar, as were C_{max} and AUC_{0-24} of V iv/po with/without A. Intra-individual comparisons did not show any systematic trend with higher/lower exposure of A in the presence of V iv/po or *vice versa*.

	DLTs in Course 1					
	A + V iv − Part A			A + V po − Part B		
	20 mg A	40 mg A	50 mg A	20 mg A	40 mg A	50 mg A
MTD cohort	0/3	1/6	4/6	0/4	1/6	3/5
PK expansion cohort	NE	7/13	NE	NE	2/12	NE

NE = not evaluated.

Conclusions: The recommended Phase II/III dose of A was determined to be 40 mg daily in combination with iv or po V weekly. Final PK analyses suggest no drug–drug interactions between A and V iv or po. Both combinations had a manageable safety profile and showed signs of clinical activity in pretreated pts with solid tumours.

893 POSTER

Design and development of active and selective FGFR kinase inhibitor CPL-043 as potential anticancer targeted therapy

D. Zdzalik[1], P. Grygielewicz[1], J. Lipner[2], A. Bujak[1], B. Dymek[1], P. Gunerka[1], A. Stanczak[1], M. Lamparska-Przybysz[1], M. Wieczorek[1], K. Dzwonek[1]. [1]*Celon Pharma, Molecular Biology and Preclinical Research, Kielpin/Lomianki, Poland;* [2]*Celon Pharma, Medicinal Chemistry, Kielpin/Lomianki, Poland*

Background: Fibroblast growth factor receptors (FGFRs) family of receptors with tyrosine kinase activity comprises a group of extensively studied targets for small molecule inhibitors development. Alterations in gene copy number of different FGFRs and their point mutations have been correlated with many types of cancer, making FGFR kinases an interesting target for novel anticancer therapy. There are several FGFR inhibitors in clinical development but there is still a niche for the drug with properly balanced selectivity profile.
Material and Methods: Using sophisticated drug design methods we have designed CPL-043 − a small molecule FGFR kinase inhibitor with high potency in vitro. To establish the activity and the selectivity of the compound we have used kinase activity assay based on recombinant kinases and cell proliferation assay, using the cell lines dependent on FGFR signaling − SNU-16 and UM UC-14. To confirm biological activity of the inhibitor we performed immunoblot assay detecting the level of FGFR pathway related proteins.
Results: Our results indicate that CPL-043 inhibits FGFR1, 2 and 3 activity in vitro in low nanomolar concentrations. Concurrently the IC50 for the most common FGFR off-targets − KDR and PDGFR is over ten times higher. CPL-043 inhibits proliferation of FGFR-dependent cell lines including SNU-16 and UM-UC-14. Treatment of cells with CPL-043 for 1 h evokes dramatic decrease in the level of pFGFR, pFRS and pErk proteins in a dose dependent manner. Moreover the inhibitor has no effect on the lines with low FGFR activity like HCT-116 or H1703, suggesting that the compound is not cytotoxic.
Conclusion: We have designed a very potent and selective FGFR inhibitor, which displays biological activity in selected cellular models without evoking cytotoxic effects on the FGFR-independent cell lines. The compound has proper ADME predicted profile as is currently under investigation in the in vivo study.
No conflict of interest.

894 POSTER

First-in-human phase I trial investigating the oral selective c-Met inhibitor MSC2156119J (EMD 1214063) in patients (pts) with advanced solid tumors

G.S. Falchook[1], D.S. Hong[1], H.M. Amin[2], S. Fu[1], S.A. Piha-Paul[1], F. Janku[1], M.B. Klevesath[3], K. Köhler[4], A. Johne[5], R. Kurzrock[1]. *[1]M.D. Anderson Cancer Center, Department of Investigational Cancer Therapeutics (Phase I Clinical Trials Program), Houston Texas, USA; [2]M.D. Anderson Cancer Center, Department of Hematopathology, Houston Texas, USA; [3]Merck KGaA, Early Clinical Development, Darmstadt, Germany; [4]Premier Research Gemany Ltd, Biostatistics, Darmstadt, Germany; [5]Merck KGaA, Clinical Pharmacology, Darmstadt, Germany*

Background: MSC2156119J is a highly selective, reversible, ATP-competitive inhibitor of c-Met, a frequently deregulated oncoprotein. In preclinical models, MSC2156119J inhibited tumor growth and induced regression of hepatocyte growth factor-dependent and -independent tumors.
Methods: This phase I dose-escalation trial (3+3 design) included pts with advanced solid tumors not amenable to standard therapy (NCT01014936; ongoing; sponsored by Merck KGaA). Primary objective was to assess the MTD of MSC2156119J; secondary endpoints included safety, antitumor activity, pharmacokinetics (PK), and pharmacodynamics (Pd). Pts were treated once/d with oral MSC2156119J: d1−14 followed by 7d rest (regimen [R]1), continuously 3 times/wk (R2), or continuously d1−21 (R3), all 21-d cycles. In Aug 2011, an optimized formulation (OF) was introduced.
Results: Until Dec 04, 2012, 100 pts were treated (R1=42; R2=41; R3=17). Doses were escalated from 30–230 mg/d in R1 and 30–115 mg/d in R2 with the initial formulation, and from 30–400 mg/d in R1, 60–175 mg/d in R2, and 300–500 mg/d in R3 with the OF. Bioavailability was higher with the OF; AUC and C_{max} increased with dose. DLTs were reported in 4 pts: G4 lipase and G3 amylase increase (R1; 115 mg/d), G3 lipase increase (R2; 60 and 100 mg/d OF), and G3 nausea and vomiting (R2; 130 mg/d OF). One pt experienced drug-related G3 peripheral edema (R3; 300 mg/d OF). G2 drug-related AEs (R1−3) included fatigue (n = 8), lipase increase (n = 3), nausea (n = 2), decreased appetite (n = 2), vomiting (n = 2), and neutropenia (n = 2). Most pts (80%) had no drug-related AE >G1. Paired tumor biopsies (pre-/on-therapy) revealed phospho–c-Met inhibition in 13/15 evaluable pts. Two pts (NPC and NSCLC) experienced unconfirmed partial responses. Fifteen pts had SD >4 mo, including 1 pt with SD >32 mo. This pt (sarcomatoid bladder cancer) had multiple MET copies due to Chr 7 polysomy. In line with preclinical PK/Pd models, 500 mg was considered biologically active and sufficient for target inhibition. In the 500-mg cohort, no DLTs were observed in 12 evaluable pts. 500 mg once/d was confirmed as the recommended phase 2 dose (RP2D). Since the cutoff date in Dec, doses were further escalated to 700 and 1000 mg to explore effects of MSC2156119J above the RP2D. At 1000 mg, one DLT was observed (G3 AST/ALT elevation). This cohort is currently expanded to 6 pts.
Conclusions: MSC2156119J was well tolerated and showed antitumor activity. 500 mg was defined as the RP2D.

895 POSTER

Epidermal growth factor receptor (EGFR)-mediated adverse events (AEs) in patients (pts) with EGFR mutation positive (EGFR M+) non-small cell lung cancer treated with afatinib

J. Chih-Hsin Yang[1], L. Sequist[2], K. O'Byrne[3], M. Schuler[4], T. Mok[5], S. Geater[6], D. Massey[7], D. O'Brien[8], V. Zazulina[7], Y.L. Wu[9]. *[1]National Taiwan University Hospital, Graduate Institute of Oncology and Cancer Research Center, Taipei, Taiwan; [2]Massachusetts General Hospital Cancer Center, Boston, USA; [3]St. James Hospital, Dublin, Ireland; [4]University Duisburg-Essen, West German Cancer Center, Essen, Germany; [5]The Chinese University of Hong Kong, Hong Kong, China; [6]Prince of Songkla University, Songkhla, Thailand; [7]Boehringer Ingelheim Limited, Bracknell, United Kingdom; [8]Boehringer Ingelheim Pharmaceuticals, Ridgefield, USA; [9]Guangdong General Hospital, Guangzhou, China*

Background: Afatinib (A) is an oral, irreversible ErbB Family Blocker showing superior efficacy to first-line pemetrexed/cisplatin (PC) in EGFR M+ pts. In the LUX-Lung 3 trial, median progression-free survival was 11.1 months for A and 6.9 months for PC (hazard ratio=0.58; p = 0.0004). A similar Phase III trial, LUX-Lung 6, comparing A with gemcitabine/cisplatin in Asian pts was recently reported (ASCO 2013). Here, we present the data on common EGFR-mediated AEs from both Phase III trials.
Methods: 345 (LUX-Lung 3) and 364 (LUX-Lung 6) EGFR M+ pts were randomized (2:1) to receive A or chemotherapy. A was administered until progression or intolerable AEs. The A starting dose of 40 mg could be escalated to 50 mg daily or reduced to 30 mg or 20 mg daily based on study criteria. On-treatment AEs were summarized by preferred and grouped terms. No AE diaries were supplied; pts recalled start and stop dates for each AE during clinic visit. AEs were graded using NCI-CTCAE version 3.0.
Results: In LUX-Lung 3, 229 pts received A and median exposure was 336 days (range 7–827 days). All pts reported at least one AE and the commonly observed EGFR-mediated AEs in LUX-Lung 3 are included in the table.

	Diarrhoea	Rash*	Stomatitis*	Paronychia
All grades (%)	96.1	90.0	73.4	56.8
Grade 3 (G3) (%)	14.8	16.2	8.7†	11.4
First G3 before/after 6 weeks (%)	11.8/3.1	3.9/12.2	6.6/2.2	0.4/10.9
Median duration of G3 (days)	5.0	10.0	8.0†	14.0
G3 recurred after dose reduction (%)	2.6	1.3	0.4	1.3
Serious AE (%)	6.6	0.4	1.3	0.0
Led to dose reduction (%)	19.7	19.2	10.0	13.1
Led to treatment discontinuation (%)	1.3	0.0	0.0	0.9

*Group term; † Includes one pt with G4 AE.

Two-thirds of pts who reported diarrhoea experienced two episodes (25%) or less (46%). The majority of pts with G3 diarrhoea, rash, stomatitis or paronychia had a single occurrence. Other drug-related EGFR-mediated AEs included dry skin (29.3%), cheilitis (12.2%), conjunctivitis (8.3%) and dry eyes (4.8%). Related interstitial lung disease-like events occurred in three pts (one G1, one G3 and one G5). Additional information on the AE profile of A and data from LUX-Lung 6 will be presented.
Conclusions: The most common AEs observed with A were characteristic of EGFR-inhibiting agents. G3 AEs were short-lived, and responded to dose interruptions/reductions with little recurrence at a lower dose of A. Treatment discontinuation due to EGFR-related AEs was low, which indicates that A has a manageable safety profile and is suitable for the long-term treatment of EGFR M+ lung cancer pts.

896 POSTER

Pharmacokinetic analysis of Asian patients in a phase 2 study of dovitinib (TKI258) in metastatic renal cell carcinoma

C.C. Lin[1], Y.C. Ou[2], Y.H. Chang[3], E. Angevin[4], V. Grünwald[5], J. Chang[6], E. Tan[6], N. Pirotta[7], M. Shi[6], B. Escudier[4]. [1]*National Taiwan University Hospital, Department of Oncology, Taipei, Taiwan;* [2]*Taichung Veterans General Hospital, Division of Urology Department of Surgery, Taichung, Taiwan;* [3]*Taipei Veterans General Hospital, Division of Urology Department of Surgery, Taipei, Taiwan;* [4]*Institut de Cancérologie Gustave Roussy, SITEP & Clinical and Translational Division, Villejuif, France;* [5]*Medical School Hannover, Department of Hematology Hemostasis Oncology and Stem Cell Transplantation, Hannover, Germany;* [6]*Novartis Pharmaceuticals Corporation, Oncology, East Hanover, USA;* [7]*Novartis Pharma AG, Oncology, Basel, Switzerland*

Background: Dovitinib potently inhibits FGFR (IC_{50} = 8−40 nM) as well as VEGFR and PDGFR (IC_{50} <40 nM), drivers of tumor growth, angiogenesis, and anti-angiogenic escape in renal cell carcinoma (RCC) and other solid tumors. In a phase 2 study of dovitinib in patients with RCC, tolerability was within the known safety profile of dovitinib (Angevin E, et al. ASCO 2011, abstract 4551). Here, we provide the pharmacokinetic (PK) results from this study in Asian and non-Asian patients.
Materials and Methods: Patients with advanced or metastatic RCC with predominant clear cell histology who failed both VEGF and mTOR therapy were eligible, as were small subsets of patients who were refractory to standard treatment or treated with agents that were not VEGFR or mTOR inhibitors. Patients of Asian ethnicity who failed standard treatment or for whom no standard treatment existed were also included. Patients were treated with dovitinib 500 mg/day on a 5-days-on/2-days-off schedule. PK parameters were determined using a noncompartmental method for area under the curve (AUC), maximum concentration (C_{max}) and time to maximum concentration (T_{max}).
Results: PK results for Asian (n = 12) and non-Asian (n = 53) patients are summarized in the Table. Asian patients had a higher coefficient of variation (as high as 68%) due to a smaller number of patients than that of non-Asian patients. Both day 1 AUC and C_{max} for Asian patients were similar to those for non-Asian patients. For both Asian and non-Asian patients, the day 15 AUC and C_{max} were 16%-33% lower than those of day 1.
Conclusions: PK parameters were similar between Asian and non-Asian patients. Day 15 PK was lower than that of Day 1 in both Asian and non-Asian patients due to auto-induction of CYP1A2 as shown in other in vitro and in vivo studies.

PK Parameter	Asian patients n = 12 (day 1) n = 11 (day 15)	Non-Asian patients n = 53 (day 1) n = 45 (day 15)
Geometric mean AUC_{0-last}, h·ng/mL (coefficient of variation [CV%])		
Day 1	5381 (68)	5221 (29)
Day 15	4428 (50)	3501 (34)
Geometric mean C_{max}, ng/mL (CV%)		
Day 1	333 (62)	300 (31)
Day 15	281 (41)	239 (36)
Median T_{max}, h		
Day 1	7.1	6.1

A phase I/II study of cancer peptide vaccine S-288310 in patients with advanced urothelial carcinoma

W. Obara[1], N. Mitsuhata[2], H. Mimata[3], M. Eto[4], K. Kohri[5], I. Miura[6], T. Shuin[7], T. Miki[8], H. Fujimoto[9], T. Fujioka[1]. [1]*Iwate Medical University, Department of Urology, Morioka, Japan;* [2]*Kure Kyosai Hospital, Department of Urology, Kure, Japan;* [3]*Oita University Faculty of Medicine, Department of Urology, Yufu, Japan;* [4]*Faculty of Life Sciences Kumamoto University, Department of Urology, Kumamoto, Japan;* [5]*Nagoya City University Graduate School of Medical Sciences, Department of Nephro-Urology, Nagoya, Japan;* [6]*Shonan Kamakura General Hospital, Department of Urology, Kamakura, Japan;* [7]*Kochi University, Department of Urology, Nankoku, Japan;* [8]*Graduate School of Medical Science Kyoto Prefectural University of Medicine, Department of Urology, Kyoto, Japan;* [9]*National Cancer Center Hospital, Urology Division, Tokyo, Japan*

Background: S-288310 is a cancer peptide vaccine composed of two kinds of HLA-A*24:02-restricted peptides, S-288301 and S-288302, that were developed from two oncoproteins, DEP domain containing 1 (DEPDC1) and M-phase phosphoprotein 1 (MPHOSPH1), highly expressed in urothelial carcinoma (UC).
Purpose: The objective of this study was to examine the safety, tolerability and immune response (induction of cytotoxic T lymphocytes, CTLs) specific to S-288301 and S-288302 in patients with advanced UC.
Patients and Methods: HLA-A*24:02-positive patients with histologically confirmed UC after documented progression or intolerance to prior platinum-based chemotherapy(ies) were eligible. 1 or 2 mg of each peptide emulsified with Montanide ISA51VG was administered s.c. once a week in the axillary or inguinal region.
Results: Three patients each were treated with S-288310 at 1 or 2 mg/each peptide in the phase I study. S-288310 was well-tolerated and no DLTs were observed. In the phase II study, 32 patients were treated with either 1 or 2 mg/shot in a random manner. The protein expression of DEPDC1 and MPHOSPH1 was confirmed by immunohistochemical analysis in 36 (97.3%) and 35 (94.6%) of the 37 tissues examined, respectively. The CTL responses to S-288301 and S-288302 were detected in 22 (66.7%) and 24 (72.7%) of the 33 patients so far examined, respectively, and 87.9% of the patients responded to at least one peptide. No significant difference in CTL induction or safety was observed between the 1 and 2 mg groups. In the phase II study, 2 of the 32 cases (6.3%) revealed irPR, and 16 of the 32 (50.0%) were judged to be irSD assessed by the immune-related response criteria. Seven of the 16 patients with irSD showed tumor necrosis or regression although they did not meet the criteria of partial response. The median progression-free survival and overall survival (OS) was 1.9 months (90% confidential interval [CI] of 1.2−2.2 months) and 9.4 months (90% CI of 4.2–12.2 months). The OS of cases, in which CTL induction to both peptides was observed, tended to be improved, compared with those that showed the response to one peptide. The most frequently observed AE was the injection site reaction.
Conclusion: S-288310 was well-tolerated and induced antigen-specific CTLs in 87.9% of the patients and revealed clinical responses. Our results suggested S-288310 is a promising drug for the treatment of UC.

Poster Session (Sat, 28 Sep)
Regulatory/Trial Methodology/Pharmacy

900 POSTER

Defining dose limiting toxicity (DLT) for phase I testing molecularly targeted agents: results of an international survey

X. Paoletti[1], J. Verweij[2], J.C. Soria[3], S. Postel-Vinay[3], D. Lacombe[4], L. Collette[4], D. Olmos[5], C. Massard[3], L. Seymour[6], C. Le Touneau[7]. [1]*Institut Curie, Department of Biostatistics, Paris Cedex 05, France;* [2]*Erasmus University Medical Centre, Division of Translational Pharmacology, Rotterdam, Netherlands;* [3]*Institut Gustave Roussy, Service des Innovations Thérapeutiques Précoces, Villejuif, France;* [4]*EORTC, Headquarters, Bruxelles, France;* [5]*Spanish National Cancer Research Centre, Prostate Cancer & Genitourinary Tumours Clinical Research Unit, Madrid, Spain;* [6]*National Cancer Institute Canada, Investigational New Drug Program, Kingstom, Canada;* [7]*Institut Curie, Investigational Unit, Paris, France*

Background: Using traditional definitions of dose limiting toxicity (DLT) in phase I trials of molecularly targeted agents (MTA) is challenged by their specific toxicity profiles and often continuous administration. For instance we recently reported that 50% of patients receiving MTAs have their worst toxicity after cycle 1 (Postel-Vinay, JCO 2011). An international survey to

collect expertise on defining DLT for MTA phase 1 trials was initiated by the EORTC-led research group.
Material and Methods: A 15-question electronic survey was sent to corresponding authors of phase I reports identified in EJC, JCO, Annals of Oncology, Lancet as well as to phase I experts identified by the co-authors. Questions included: DLT assessment period duration, incorporation of specific grade 1 (G1) or G2 adverse events (AEs), and their minimum duration to qualify as DLT, exclusion of specific G3 AEs, inclusion of dose modification/delay, and relative worsening of AEs. The potential impact of schedule, both oral and IV dosing was considered.
Results: Among the 400 investigators contacted, 119 replied; 67 questionnaires were 100% complete. In the last 5 years, 30% participated in more than 10 trials, 35% were principal investigators of 5 or more. 11% (8/67) opted for a DLT assessment period of 1 cycle, 33% for 2 cycles and 54% requested all cycles to be assessed, with the proviso not to delay patient accrual. Suggestion was made to define maximum tolerated dose on cycle 1 data only, to reanalyze all accumulated data before the expansion cohort and to recommend the phase II dose based on the toxicity data from multiple cycles. 90% evaluated pre-existing symptoms to qualify a DLT. 92% suggested including dose modification and temporary interruption in the DLT definition when dose intensity drops down to 50−60% (13% of the responders) and to 70−80% (50%).
Moderate toxicity was deemed relevant by 70% (IV treatment) and 80% (oral). Selected G1/2 varied: visual disorders and confusion (30%); QTc prolongation, dyspnoea, some GI disorders (diarrhoea, pancreatitis) (20%). For G2 events, >1 week duration was relevant by 40 to 58% depending on AEs. Responses for IV and oral routes were consistent in 70%.
Conclusions: The majority of experts favoured a longer assessment period as well as the incorporation of specific G2 AE. However, no clear agreement on a re-definition of DLT was reached. A large international data warehouse is being evaluated to develop guidelines.
No conflict of interest.

901 POSTER

A population-based analysis of outcomes in cancer patients who do not satisfy clinical trial eligibility criteria (CTEC)

W. Cheung[1], H. Kennecke[1], H. Lim[1], D. Renouf[1], S. Gill[1], C. Speers[1], O. Goktepe[1], K. Javaheri[1]. *[1]British Columbia Cancer Agency, Medical Oncology − GI, Vancouver BC, Canada*

Background: Trials have stringent inclusion and exclusion criteria in order to maintain internal validity. However, study findings are subsequently applied to patients in routine practice who frequently do not meet CTEC. Our aim was to characterise the outcomes and magnitude of treatment benefit, if any, in these patients.
Material and Methods: Patients diagnosed with stage 3 colon cancer from 2006 and 2008, referred to any 1 of 5 regional cancer centers in British Columbia, and assessed for adjuvant chemotherapy (AC) within 12 weeks of surgery were analysed. Patients were considered trial-eligible (TE) if aged 18 to 79 years, ECOG 0/1, CEA <10, did not receive prior chemotherapy or radiation, and had adequate blood counts and normal cardiac, liver and kidney function. All other patients were deemed trial-ineligible (TI).
Results: A total of 820 patients were identified: median age was 69 years (range 60−76), 423 (52%) were men, 365 (45%) were ECOG 0/1 and 592 (72%) received AC. Among patients treated with AC, 370 (63%) were TE and 222 (37%) were TI. Compared to TI patients, those who were TE were younger (63 vs 70 years, $p < 0.01$) and more likely to receive combination rather than single agent AC (56 vs 33%, $p < 0.01$). Outcomes were significantly different among patients who were TE, TI, and those who did not receive AC (Table). In multivariate analyses that adjusted for confounders such as age, ECOG and T and N stages, both TI patients and those not treated with AC had worse prognoses than TE patients (HR for colon cancer deaths 1.32, 95% CI 0.86–2.02 and 2.77, 95% CI 1.92–3.99, respectively, p trend <0.01; HR for all deaths 1.24, 95% CI 0.85–1.80 and 2.95, 95% CI 2.17–4.00, respectively, p trend <0.01).

Group	5 year CSS rate	p-value	5 year OS rate	p-value
TE and received AC	82%		74%	
TI and received AC	75%	<0.001	65%	<0.001
No AC	57%		35%	

CSS=cancer-specific survival; OS=overall survival.

Conclusions: In this population-based cohort, patients who did not fit CTEC were frequently treated with AC. Outcomes in this TI group were inferior to those in the TE group, but they were better than the subset that did not receive AC. Trials specifically designed for patients traditionally deemed TI are needed.
No conflict of interest.

902 POSTER

Adherence to CONSORT adverse event reporting guidelines in medical oncology clinical trials, a systematic review

J. Peron[1], D. Maillet[2], H.K. Gan[3], E.X. Chen[4], B. You[5]. *[1]Hospices Civils de Lyon − Centre Léon Bérard, Lyon, France; [2]Hospices Civils de Lyon, Medical Oncology, Lyon, France; [3]Austin Hospital, Joint Austin-Ludwig Oncology Unit, Melbourne, Australia; [4]Princess Margaret Hospital University Health Network, Department of Medical Oncology and Hematology, Toronto, Canada; [5]Hospices Civils de Lyon, Department of Medical Oncology, Lyon, France*

Background: The Consolidated Standards of Reporting Trials (CONSORT) guidance was extended in 2004 to provide a set of 10 specific and comprehensive guidelines regarding adverse event (AE) reporting in randomized controlled trials (RCTs). There is little data though regarding adherence to these guidelines by published oncology RCTs.
Material and Methods: All phase III RCTs published between 2007 and 2011 were reviewed using a 16-point adverse event reporting quality score (AERQS) based on the 2004 CONSORT extension. Multivariable linear regression was used to identify features associated with improved reporting quality. All statistical tests were two-sided.
Results: A total of 325 RCTs were reviewed. The mean AERQS was 10.1 on a 0-to-16 scale. The most common items that were poorly reported were the way adverse event data were collected (adequately reported only in 10% of studies), the description of AEs' characteristics leading to withdrawals (15%) and the attribution of AEs to trial interventions (38%). Even when reported, the methods of AE data collection and analysis were highly heterogeneous. The multivariable regression model revealed that industry funding, intercontinental trials and trials in the metastatic setting were predictors of higher AERQS. The quality of AEs reporting did not improve over time and was not better among manuscripts published in high-impact-factor journal.
Conclusion: In conclusion, our findings show that methodological aspects of AEs collection and analysis were poorly reported. Given the potential impact of poorly reported trials, oncology journals should emphasize the importance of conformity to the 2004 CONSORT guidelines regarding adverse event reporting.
No conflict of interest.

903 POSTER

Area-based measures for assessing survival benefit in Kaplan–Meier's curves

E.J. Alegre-Del Rey[1], J. Diaz-Navarro[1], S. Fenix-Caballero[1], J.F. Lopez-Vallejo[1], C. Martinez-Diaz[1], E. Rios-Sanchez[1], M.A. Blanco-Castaño[1], M.J. Gandara-LadronDeGuevara[1], C. Palomo-Palomo[1], J.M. Borrero-Rubio[1]. *[1]Puerto Real Universitary Hospital, Pharmacy Department, Puerto Real (Cádiz), Spain*

Background: Medians comparison in survival curves is erratic and doesn't sometimes provide good assessment of survival benefit.
Objectives: The aim is to test a new area-based method for assessing survival in a set of Kaplan–Meier's curves. The primary outcome is to analyze the correlation between survival increments by the area method and excess risk calculated by hazard ratio (HR). A second outcome is to compare area-based vs. median-based results.
Methods: A 30 curves sample for R 0.7, α 0.05 and β 0.8 was calculated, and a Pubmed search for articles with survival analysis in colon, lung and breast cancer was conducted. Articles with an overall survival figure showing patients at risk, both curves reaching the median and $p < 0.05$ for HR, were included.
Three lines were defined for each figure: V: vertical cut line intersects abscissa at the longest time (t) with at least 10 patients at risk in each group or 30 in total. H: horizontal cut line crosses the intersection of V with the upper survival curve. T: Horizontal top line intersects ordinates in its maximum value (100%). Area under curve (AUC) was defined among the ordinates axis, the curve and H. Reference area (RA) was defined as the rectangle among ordinates axis, V, H and T. It represents the survival time in case no patient died (t). Survival was calculated as AUC/RA*t. SISA, R-code and Photoshop CS6 were used.
Pearson's correlations were calculated between excess risk in A vs. B group (HR-1)% and survival increment in B vs. A (B survival time/A survival time −1)%, assuming longer survival for B group. Survival increments were calculated by medians and area methods. Steiger's z-test was used to compare which method (area or medians) correlated better with HR-calculated excess risk. A Bland-Altman's concordance analysis was performed.
Results: The search identified 485 articles, 41 of them had survival curves that met inclusion criteria. By excluding tails with few patients at risk, area-based measures included survival data from 71% patients.
Concordance analysis showed a standard deviation of 85%, and a mean difference in survival (area minus median) of −1.9 months.

Method	Correlation survival increment – excess risk (HR-based)	
	R	p
Medians	0.854	<0.01
Area	0.922	<0.01
p(Medians vs Area)	0.036	

Conclusions: Area- and medians-based results show discrepancies between them. Area method benefits more from curve information, correlates better with HR-based excess risk and provides a measure of survival time.
No conflict of interest.

904 POSTER

Quality of reporting of phase II trials in oncology in highly ranked oncology journals

T. Grellety[1], A. Petit-Monéger[1], A. Diallo[1], S. Mathoulin-Pelissier[1], A. Italiano[1]. [1]*Institut Bergonié, Bordeaux, France*

Background: Phase II trials represent an essential step in the development of anti-cancer drugs. The aim of this study was to assess the quality of their reporting in highly-ranked oncology journals, to investigate predictive factors of quality and to develop better reporting guidelines for authors.
Material and Methods: We reviewed the tables of contents of 8 peer-reviewed oncology journals published between January 2011 and December 2011 and with a 2011 impact factor >4: Ann Oncol, Br J Cancer, Clin Cancer Res, Eur J Cancer, J Clin Oncol, J Natl Cancer Inst, Lancet Oncol and Oncologist. Two reviewers assessed the quality of each report by using a 44-point overall quality score (OQS; range, 0 to 44 points) inspired from the revised Consolidated Standards of Reporting Trials statement. Primary endpoint definition, justification of sample size and definition of the evaluable population for each endpoint, were assessed separately because of their crucial methodological importance using a 3-point key methodological score (KMS; range, 0 to 3). Exploratory analyses were used to identify predictive factors associated with the different scores.
Results: 156 articles were included. Agreement between the reviewers for each item was good (kappa coefficient range: 0.62−1). The median OQS was 28 (range: 9−35). OQS sub-score analysis showed that reporting of statistical methods was particularly low with a mean of 2.5 (6 items). The median KMS was 2 (range 0−3). Primary endpoint definition, justification of sample size and definition of the evaluable population were reported only in 107 (68.6%), 121 (77.6%), and 52 (33.3%) cases, respectively. On multivariate analysis, reporting of clinicaltrials.gov registration was associated with improved OQS, OR = 3.2 (95CI, 1.5 to 7.1). No predictive factor for KMS were identified.
Conclusions: Phases II trials reporting is still poor even in journals with strict editorial policies. This may lead to biased interpretation of phase II trial results. We have developed a checklist for use by authors, reviewers, and editors to improve reporting of these studies. As well as using a checklist during the preparation of their manuscript, we recommend that authors provide reviewers and readers with the last version of the study's protocol.
No conflict of interest.

905 POSTER

Quality of reporting of chemotherapy compliance in randomized controlled trials of breast cancer treatment

A. Altwairgi[1], A. Alfakeeh[1], W. Hopman[2], W. Parulekar[3]. [1]*King Fahad Medical City, Comprehensive Cancer Center, Riyadh, Saudi Arabia;* [2]*Queen's University, Department of Community Health and Epidemiology, Kingston, Canada;* [3]*Queen's University, NCIC Clinical Trials Group, Kingston, Canada*

Background: The adoption of any therapy in clinical practice requires a detailed knowledge of treatment administration and expected compliance as reported in the literature. The Consolidated Standards of Reporting Trials (CONSORT) statement requires detailed reporting of interventions in publications of randomized controlled trials (RCTs). We hypothesized that there was variable reporting of chemotherapy compliance in published randomized controlled trials in breast cancer and surveyed the literature to assess the quality of reporting chemotherapy compliance and to determine the study characteristics associated with a reporting quality.
Materials and Methods: MEDLINE, EMBASE, and CENTRAL were searched systematically for published original articles (Jan 2005 through Dec 2011; English language) of Phase III RCTs evaluating chemotherapy in breast cancer. Selected articles were scored 1 point for reporting each of 4 measures − number of chemotherapy cycles, dose modification, early treatment discontinuation and relative dose intensity (RDI). Logistic regression was performed to identify study characteristics associated with higher reporting quality score of $\geqslant 2$.
Results: Key study characteristics of the eligible 115 RCTs were: published in high impact journals, 79 (69%); published 2008 onward, 66 (57%); advanced-stage disease, 43 (37%); industry sponsorship, 37 (32%). RDI, number of cycles received, dose modification, and early treatment discontinuation rates were mentioned in 70 (61%), 53 (46%), 65 (57%) and 81 (70%) of the articles, respectively. Only 25 (22%) articles mentioned all 4 compliance measures. Quality score was $\geqslant 2$ for 82 (71%) articles. Study characteristics associated with a significantly higher quality of reporting chemotherapy compliance were articles published 2008 onward ($P = 0.035$) and advanced-stage disease ($P < 0.001$).
Conclusions: Our study demonstrates that there is variable reporting of chemotherapy compliance in published RCTS, although a modest improvement is seen in recent years. Incorporating standards for reporting chemotherapy compliance in scientific guidelines or the journal peer review process may decrease the variability and improve the quality of reporting.
No conflict of interest.

906 POSTER

Poor quality of adverse event reporting in oncology phase III trials: A systematic review

D. Maillet[1], B. You[1], J. Peron[1]. [1]*Hôpital Lyon Sud, Pierre Bénite, France*

Background: In the present study, we assessed the quality of toxicity reporting (description and impacts of AEs) in oncology phase III trials.
Material and Methods: This is a systematic review of all medical oncology phase III studies published in 10 major oncology journals (NEJM, JCO,

Table 1 (abstract 906). Reporting of the consequences of AEs on trial or patient outcomes (n = 325)

Adverse event reporting	RCTs	
	n	%
AEs leading to patient death: lethal adverse events		
Existence of lethal adverse events		
Not reported: unknown	88	27
Reported	237	73
• No lethal AE (n = 0)	60	18
• One or more lethal AEs (n⩾1)	177	54
• Including those with reporting of type of specific adverse events leading to death	130	73% of RCT with n⩾1 lethal AEs reported
Adverse events leading to drug discontinuation		
Existence of AEs leading to trial discontinuation		
Not reported: unknown	85	26
Reported	240	74
• No AE leading to drug discontinuation (n = 0)	4	1
• One or more AEs leading to discontinuation (n⩾1)	236	73
• Including those with type of adverse events reported	49	21% of RCT with n⩾1 AEs leading to drug discontinuation reported
Adverse events leading to dose modification		
Existence of AEs leading to dose modification		
Not reported	197	61
Reported	128	39
Type of AEs reported	32	10

Lancet, Lancet Oncol, JNCI, Ann Onc, EJC, BJC, BCRT, Cancer) between 2007 and 2011 using PubMed. For each publication, we analyzed the trial characteristics; the presentation of AEs (including the description clarity) and the reporting of AE consequences on trial or on patient outcomes (i.e. AEs leading to patient death or to trial discontinuation/dose modification).
Results: Total of 325 published randomized control trials (RCT) were analyzed. Results are presented in Table 1. The potential existence of lethal AEs was reported in only 73% of them. Among 177 RCT publications where one or more lethal AEs were mentioned, the specific type of AE leading to patient death was mentioned in 73%. The existence of AEs leading to trial discontinuation was mentioned in 74% RCT publications. Among them, the types of AEs responsible of discontinuation were reported in only 21%. Only 39% of publications reported the existence of AEs leading to dose modifications. Regarding descriptions of AEs, aggregations of AEs were used in 29% of studies. For example, the most commonly reported aggregated outcomes were reported as 'dermatologic AEs' (45%); 'cardiologic AEs' (33%), and 'neurologic AEs' (26%) without any additional definitions. Although these aggregations were considered, only 25% were clearly described. Sources of confusion in definition of AEs were found in 10% reports.
Conclusions: Our findings suggest the quality of AEs reporting in oncology RCTs published in 10 major oncology journals is insufficient. In particular, the proper reporting of potential lethal AEs, as well as the types of AEs leading to death, to trial discontinuation or dose alteration is found in 50% of the trials only. Moreover, although unclear in essence, aggregated AE outcomes are too frequently used in publications.
No conflict of interest.

907 POSTER

Pneumatic conveying systems and physical stability of monoclonal antibodies: example of cetuximab

V. Vieillard[1], A. Ramssamy[1], K. Rilcy[1], A. Bellanger[2], A. Astier[1], M. Paul[1]. *[1]APHP Hôpital Mondor, Pharmacy, Créteil, France; [2]APHP Hôpital Pitié Salpêtrière, Pharmacy, Paris, France*

Background: Proteins such as monoclonal antibodies (mAb) are sensitive products which could undergo complex degradation pathways during the various manipulation steps also during transport. Aggregation can be induced by mechanical stresses which can occur during manipulations and transport and could induce loss of efficacy and/or toxic effects such as immunogenicity. Currently pneumatic conveying systems are in place in some hospitals but are not currently used for transport of proteins. Previous studies with Rituximab showed that the use of these systems were possible on the condition of removing air of bags. The objective of this study was to confirm these results with another antibody, Cetuximab.
Material and Method: Various protein characterization methods: size exclusion chromatography (SEC), dynamic light scattering (DLS) describing submicronic populations and corresponding mean diameters, turbidity (350 nm) and infra-red spectroscopy (FTIR) were used to determine changes in physical properties of Cetuximab aggregation mechanically induced. Several conditions were tested: presence of residual air in bags, travel time, number of travel cycles (1 to 3). One concentration was tested (2 mg/ml). All experiments were performed in the same day.
Results and Discussion: Considering the results obtained with Rituximab, we have limited our experiments to 3 travel cycles. Up to 3 travel cycles and without head space or bubbles into the bags, no modification was noticed in comparison with the control (no run). Indeed, we observed only one peak by SEC with a retention time of 18, 42$\pm$0.01 min, a monodisperse population (polydispersity index $\leqslant$ to 0.1) with a mean diameter of 12.56$\pm$0.121 nm by DLS, a slightly increased of optical densities (OD) at 350 nm (0.00123 up to 0.00216) and no modification of the FT-IR spectra (similarity coefficients were close to one). In the opposite, in presence of air, significant modifications were found after 1 cycle since OD reached to 0.00264 and 2 populations were found by DLS with a polydispersity index of about 0.22. Moreover, modifications of FTIR spectra were also observed (similarity coefficient <1) suggested alteration of the secondary structure.
Conclusion: As shown for Rituximab, aggregation of monoclonal antibodies during the pneumatic conveying is strongly dependant on the presence of air/liquid interfaces.

Randomised phase II trial comparing therapy based on tumour molecular profiling versus conventional therapy in patients with refractory cancer: results of the feasibility part of the SHIVA trial

C. Le Tourneau[1], E. Mitry[2], A. Goncalves[3], N. Isambert[4], C. Gavoille[5], O. Tredan[6], J.P. Delord[7], M. Campone[8], X. Paoletti[9], M. Kamal[10]. *[1]Institut Curie, Medical Oncology, Paris, France; [2]Institut Curie, Medical Oncology, Saint-Cloud, France; [3]Institut Paoli-Calmettes, Medical Oncology, Marseille, France; [4]Centre Georges-François Leclerc, Medical Oncology, Dijon, France; [5]Centre Alexis Vautrin, Medical Oncology, Nancy, France; [6]Centre Leon Berard, Medical Oncology, Lyon, France; [7]Institut Claudius Regaud, Medical Oncology, Toulouse, France; [8]Centre René Gauducheau, Medical Oncology, Nantes, France; [9]Institut Curie, Biostatistics, Paris, France; [10]Institut Curie, Translational Research, Paris, France*

Background: Two recent studies suggest that a histology-independent approach consisting in selecting molecularly targeted agents based on the molecular profile of patients' tumours, whatever the tumour location and histology are, improves patients' outcome [Von Hoff et al., 2010; Tsimberidou et al., 2012]. However, the lack of randomisation versus standard of care in these studies did not allow drawing robust conclusions.
Material and Methods: The SHIVA trial is a multicentric randomized proof-of-concept phase II trial comparing molecularly targeted therapy based on tumor molecular profiling versus conventional therapy in patients with any type of refractory cancer. The primary endpoint is progression-free survival (PFS). The molecular profile performed on a mandatory biopsy includes the assessment of 1) hot spots mutations using the AmpliSeq cancer panel on Ion Torrent/PGM (Life Technologies), 2) gene copy number alterations using Cytoscan HD/Affymetrix, and 3) expression of oestrogen, progesterone and androgen receptors by immunohistochemistry on formalin-fixed sample. The algorithm used by a Molecular Biology Board (MBB) to guide treatment in the experimental arm is presented in the Table. The efficacy analysis will be performed on 200 randomized patients. A cross-over is proposed at disease progression. Feasibility included the first 100 patients.
Results: Between 10/2012 and 04/2013, 143 patients have been included in the study. Results of the feasibility part are available for the 53 first patients at the time of the abstract submission. Full feasibility results will be presented at the meeting. Biopsy was performed in 50 out of 53 patients (94%). Complications occurred in 1 patient (2%). Median time between the biopsy and the MBB was 26 days [range: 14−42]. Mutations, gene copy number alterations and IHC profile were obtained in 32 (64%), 34 (68%) and 45 (90%) patients, respectively. A molecular abnormality leading to randomisation was present in 21 patients (42%).
Conclusions: The establishment of a comprehensive tumour molecular profile is safe, feasible and compatible with clinical practice. A molecular abnormality matching with the approved drugs available in the trial was present in 42% of patients.
No conflict of interest.

Molecular abnormalities	Type of molecular abnormality	Molecularly targeted agents
KIT, ABL, RET	Activating mutation or amplification	Imatinib
PI3KCA, AKT1	Activating mutation or amplification	Everolimus

Evaluation of HER2 expression status using multiple chromosome 17 reference probes

M. Kruse[1], S. Abedin[2], R. Bhargava[3], K. Cooper[4], D. Dabbs[3], A. Brufsky[5]. [1]*University of Pittsburgh Cancer Institute, Pittsburgh PA, USA;* [2]*University of Michigan Health System, Internal Medicine, Ann Arbor MI, USA;* [3]*Magee-Womens Hospital of the University of Pittsburgh Medical Center, Pathology, Pittsburgh PA, USA;* [4]*University of Pittsburgh Medical Center, Biostatistics, Pittsburgh PA, USA;* [5]*University of Pittsburgh Cancer Institute, Hematology/Oncology, Pittsburgh PA, USA*

Background: Targeted therapies to HER2(+) breast cancer have improved outcomes in this aggressive phenotype. A recent unconfirmed study suggested that HER2 gene status may be misidentified in a small group of patients due to co-amplification of HER2 and CEP 17, leading to low HER2/CEP17 ratio with high HER2 gene copy number. We used alternate probes to chromosome 17 to reinterpret HER2 status in a group of patients in a single center to attempt to confirm these findings.
Methods: We identified 60 breast cancer biopsies done at the University of Pittsburgh Medical Center in 2012 with equivocal HER2 protein expression (2+ on IHC) that underwent FISH, had an increased HER2 copy number ($\geqslant$4), but were categorized as either equivocal or negative due to an elevated CEP17 (>2.6) copy number. We used Abbott Laboratory probes to SMS (17p11.2) and RARA (17q21.2) to reclassify cases based on HER2:SMS and HER2:RARA ratios. Equivocal was defined if either ratio was 1.8−2.2; and positive if either ratio was >2.2.
Results: For 60 cases, the average HER2 copies/cell ranged from 4 to 7.83. Eight cases had >6 HER2 copies/cell. Of these 8 cases, 7 (88%) became unequivocally positive on re-interpretation using HER2:SMS or HER2:RARA ratio. Fifty-two cases had 4−6 HER2 copies/cell. Of these 52 cases, 18 (34%) became unequivocally positive on re-interpretation using HER2:SMS or HER2:RARA ratio. The status remained negative on 30 cases (58%), 2 (4%) changed from negative to equivocal and 2 (4%) changed from equivocal to negative. Overall, the HER2 status changed in 29 of 60 cases (48%) using an alternate probe; however, the alternate probe that resulted in change of status was SMS in 23 cases (79%), both SMS and RARA in 5 cases (17%) and RARA alone in 1 case (4%).
Conclusions: Tumors with a HER2 gene copy number >6/cell may be assumed to be HER2(+) as they generally have ratios >2.2 using alternate reference probes. The reference probe implicated in changing amplification status in majority of cases is SMS, which is located on 17p while RARA is located on 17q (similar to HER2). Elevated CEP17 and RARA mean copy numbers may skew the ability for these probes to accurately assess HER2 gene status, especially when average HER2 copies/cell range between 4−8 copies.

Feasibility and safety of image-guided biopsy procedures for personalized cancer treatment

C.G.M. Gadellaa-van Hooijdonk[1], G.A. Cirkel[1], S.M. Willems[2], M.J. Koudijs[1], M.J.A. De Jonge[3], N. Steeghs[4], S. Sleijfer[3], J.H.M. Schellens[4], E.E. Voest[1], M.P.J.K. Lolkema[1]. [1]*University Medical Center Utrecht, Medical Oncology, Utrecht, Netherlands;* [2]*University Medical Center Utrecht, Pathology, Utrecht, Netherlands;* [3]*Erasmus MC Cancer Institute, Medical Oncology, Rotterdam, Netherlands;* [4]*Antoni van Leeuwenhoek Netherlands Cancer Institute, Medical Oncology, Amsterdam, Netherlands*

Background: For implementing tumor DNA guided personalized cancer treatment in daily clinical practice it is important to determine the feasibility and safety of real-time image-guided fresh frozen tumor biopsies.
Material and Methods: An umbrella protocol (CPCT-02; NL35781.041.11) has been developed by the Dutch Center for Personalized Cancer Treatment (www.CPCT.nl), a collaboration between three Dutch cancer centers, to prospectively acquire fresh frozen tumor tissue as well as radiological response data from patients with advanced solid tumors. Image-guided biopsy procedures were performed before initiation of systemic anti-cancer treatment. The protocol allowed 2−4 specimens per time point with a maximum of four time points. DNA isolation of macrodissected tumor rich areas was performed if tumor cellularity exceeded 20%. Another pre-set criterium for performing Next Generation Sequencing (NGS) was a DNA yield of >50 ng for limited (but deep) sequencing of common somatic mutations in approximately 50 genes. A tumor cellularity of at least 50% and DNA yield >500 ng was required for performing extended sequencing of nearly 2000 cancer related genes using sequence enrichment technology. All clinical and genetic data was stored in the CPCT database allowing us to identify biomarkers for response. CPCT-02 (sponsored by the UMC Utrecht) is still recruiting.
Results: Currently, we report on 189 consecutive biopsy procedures performed in 182 patients, the majority being ultrasound-guided liver biopsies (40%). There were over 30% superficial tissue biopsies and in 9% CT-guided lung biopsy was performed. Biopsies were generally well tolerated. No pneumothorax $\geqslant$ grade 2 occurred and no bleeding or other major complications were observed. In 1.1% local pain at the biopsy site (grade 3) occurred. In almost 50% of samples tumor cellularity exceeded 70% and in general more than sufficient quantities of DNA were isolated (85% over 1000 ng). Given the pre-set criteria limited sequencing could be performed on 86% and extended sequencing on 65% of samples.

Feasibility of image-guided tumor biopsies for personalized oncology

	Feasibility (%)
Tumor percentage	
<20%	12
20−50%	20
>50%	68
DNA yield	
<500 ng	7
500–1000 ng	8
>1000 ng	85
Sequencing	
No	14
Limited	86
Extended	64

Conclusions: In daily clinical practice, image-guided tumor biopsies are feasible yielding sufficient material to perform NGS in 86% of patients and can be safely (99%) performed and implemented for personalized cancer treatment.

953 POSTER

Genomic testing in cancer (GTC): Patient knowledge, attitudes and expectations

P. Blanchette[1], F. Miller[2], A. Spreafico[3], J. Bytautas[2], K. Chan[4], A. Eisen[4], P.L. Bedard[3], L. Potanina[5], J. Holland[5], L.L. Siu[3]. [1]*University of Toronto, Division of Medical Oncology, Toronto, Canada;* [2]*University of Toronto, Institute of Health Policy Management and Evaluation, Toronto, Canada;* [3]*Princess Margaret Cancer Centre, Division of Medical Oncology and Hematology, Toronto, Canada;* [4]*Sunnybrook Odette Cancer Centre, Division of Medical Oncology and Hematology, Toronto, Canada;* [5]*University Health Network, Research Ethics Board, Toronto, Canada*

Background: Genomic testing in cancer (GTC) characterizes oncogenic genes within a patient's cancer. This form of DNA testing is currently being studied for its ability to guide cancer therapy. The objective of this study was to describe patients' knowledge, attitudes and expectations towards GTC.
Materials and Methods: The 42-item self administered GTC questionnaire was developed by a multidisciplinary group (n = 9) and pilot patient pretesting (n = 8). The questionnaire was distributed to advanced stage cancer patients referred to The Drug Development Program at Princess Margaret Cancer Centre, Toronto, Canada, for a phase I clinical trial or for GTC testing as part of an ongoing research study.
Results: Results are reported from 93 surveyed patients with a response rate of 75% (n = 70). Patient characteristics: female 52 (74%); median age 57 years (range 22−77), prior chemotherapy 65 (93%), prior targeted therapy 35 (50%), current or prior clinical trial enrollment 49 (70%), high school diploma 16 (23%), university degree 30 (43%). A total of 73% of patients were interested in learning more about GTC and 60% reported that GTC would significantly improve their cancer care. The mean score of a 12-item questionnaire to assess knowledge of cancer genomics = 8/12 (67%) (SE: 0.25; 95% CI: 7.57–8.55). Patients' knowledge scores significantly correlated with their education level ($p < 0.0001$) and desire for further genetic counseling ($p = 0.004$). A needle or surgical biopsy for GTC if required would be acceptable to 66% and 37% of patients respectively. The primary reason for testing reported by 69% of patients was to help guide their ongoing treatment. The risk of a serious biopsy complication and potential for a treatment delay were listed as the most important reasons to avoid GTC. More than 78% of patients requested disclosure of incidental test results that might impact their own health or increase their family's risk of developing cancer. A reported 87% of patients agreed with biobanking their GTC results and tissue samples for future scientific research. Only

42% of patients reported having sufficient knowledge to make an informed decision to pursue GTC while 36% of patients indicated a need for formal genetic counseling prior to GTC.
Conclusions: Advanced cancer patients are motivated to participate in GTC. Educational tools and counseling programs need to be developed to support understanding and decision-making among patients interested in pursuing GTC.
No conflict of interest.

Integrated microRNA and mRNA signature associated with the transition from the locally confined to the metastasized renal cell carcinoma

Z. Wotschofsky[1], J.N. Billaud[2], C. Stephan[1], K. Jung[1], H. Meyer[1]. *[1]Charite, Urology, Berlin, Germany; [2]Ingenuity Systems, Redwood City, USA*

Background: MicroRNAs (miRNAs) are endogenous small non-coding RNAs that regulate gene expression by interfering translation or stability of target transcripts. One miRNA can interact with several hundred mRNAs, while one mRNA can be regulated by several miRNAs. This interplay between miRNA and their mRNA has been proposed as an important process in cancer development and progression. We have investigated molecular networks impacted by predicted mRNA targets of differentially expressed miRNAs in patients with clear cell renal cell carcinoma (ccRCC) diagnosed with or without metastasis.
Material and Methods: miRNA and mRNA microarray expression profiles derived from primary clear cell renal cell carcinomas from patients with (in total 16 samples) or without diagnosed metastasis (in total 22 samples) were used to identify anti-correlated miRNA-mRNA interaction in ccRCC. For this purpose, Ingenuity pathway analysis microRNA Target Filter, which enables prioritization of experimentally validated and predicted mRNA targets was used. By applying an expression pairing tool, the analysis was focused on targets exhibiting altered expression in our analysis, finding miRNAs and their target genes with opposite or same expression. The resulting identified interactions were revalidated by RT-qPCR in another cohort of RCC patients. The predicted miRNA-mRNA interactions were also tested by functional analyses using miRNA knock-down and over expression experiments in renal cancer cell lines.
Results: Among the significantly differentially expressed miRNAs, we have identified 3 miRNAs (miR-146a, miR-128a and miR-17-5p) that were upregulated in primary tumors from patients without metastasis and down regulated in primary tumors from patients with metastasis. We have further identified the mRNA targets which expression were inversely correlated to these 3 miRNAs, and have been previously experimentally demonstrated in cancer setting in humans. Specifically we showed that BRAC1, MCM10, CDKN3, UHRF1, IL8 were downregulated and targeted by miR-146a-5p. The relation between these identifies target genes and miRNA-146a was validated in cell culture experiments.
Conclusions: We identified novel target genes of dysregulated miRNA which are involved in the transition from primary RCC without metastases into tumors generating distant metastasis.
No conflict of interest.

Clinical application of molecular profiling in treatment selection for rare and advanced refractory solid tumours: An Australian experience

A. Dean[1], R. Wallace[1]. *[1]St John of God Hospital Subiaco, Medical Oncology, Subiaco, Australia*

Background: Patients with advanced refractory solid tumours including rare cancer types present significant treatment challenges. In many cases, patients have either exhausted standard of care options or, for the more rare cancer types, there are limited treatment options known to be effective. The correlation of biomarkers to associated clinical treatments in a number of cancer types, has allowed for a more targeted and personalised approach to cancer management. The aim of this study was to explore molecular profiling (MP) as a tool for guiding treatment selection in these difficult-to-treat patients within a clinical practice setting.
Materials and Methods: Tissue samples from rare cancer patients (n = 10) and heavily pre-treated ($\geqslant$2 lines of prior therapy) advanced cancer patients (n = 30) with an ECOG performance score $\leqslant$2 underwent MP based on immunohistochemistry, microarray, q/RT-PCR, Sanger and Next-Generation Sequencing (NGS) analyses (Caris Molecular Intelligence®; Caris Life Sciences, Irving, USA).
The rare cancer cohort included: ethmoid sinus, adrenal cortex adenocarcinoma, anaplastic thyroid, fibro sarcoma, astroblastoma, cervical carcinosarcoma, pseudopapillary mucinous neoplasm, endometrial stromal sarcoma, and medullary thyroid. The heavily-pretreated cohort included: cervical, gall bladder, skin (Merckel), colorectal, lung, pancreas, gastric, breast, ovarian, melanoma, oesophagus, cholangiocarcinoma and mesothelioma. MP-guided therapy was considered to have clinical benefit if the patient showed complete response, partial response or stable disease.
Results: In the rare cohort, two patients showed progression and two had non-evaluable disease. Six of the eight (75%) evaluable patients with rare tumours were shown to have clinical benefit following MP-guided treatment. In the heavily pre-treated cohort, 17 of the 30 evaluable patients (56.7%) have demonstrated clinical benefit, while 13 (43.3%) progressed following MP-guided therapy. Of the 23 patients with clinical benefit, eight have sustained clinical responses ranging from 140 days (breast cancer $ER^{-}HER2^{+}$patient) to 365 days (lung pleomorphic patient).
Conclusion: MP-guided treatment selection resulted in clinical benefit in over half of the patients in this study. While requiring further clinical validation, these data lend support to the use of MP in identifying therapeutic interventions for advanced refractory and rare solid tumours who have limited treatment options and poor prognosis.
No conflict of interest.

956 POSTER

DNA damage response deficiency signature predicts response to platinum-based therapy in ovarian cancer

L.A. Hill[1], J.M. Mulligan[1], S. Deharo[1], K.E. Keating[1], F.A. McDyer[1], T.S. Davison[1], C. Gourley[2], D.P. Harkin[1], R.D. Kennedy[1]. *[1]Almac, Diagnostics, Craigavon, United Kingdom; [2]University of Edinburgh Cancer Research UK Centre, MRC IGMM, Edinburgh, United Kingdom*

Background: Ovarian cancer is the leading cause of death from gynaecological malignancies among women. The standard first line therapy is a combination of carboplatin and paclitaxel. Although this treatment regimen confers a response rate in the region of 70%-80%, the majority of women subsequently relapse. Acquired resistance to further chemotherapy is generally responsible for treatment failure, resulting in an overall 5-year survival rate of only 10−30% for late-stage ovarian cancer. At present, empiric-based treatment strategies are used and result in a significant number of patients with chemotherapy-resistant disease, receiving multiple cycles of toxic therapy before the lack of efficacy is identified.
Materials and Methods: We have developed and validated a DNA damage response deficiency (DDRD) signature from microarray data, which predicts response to DNA damaging agents in breast cancer. This assay is based on a molecular subgroup defined by loss of the DNA damage response FA/BRCA pathway, which results in extreme sensitivity to DNA damaging chemotherapeutic agents. We have investigated the utility of the DDRD signature in its ability to predict response to platinum based therapy in 1078 ovarian cancer samples profiled on the Affymetrix microarray platform. Samples were tested with the signature and using the 70th percentile cut-off value, 30% of samples were classified as DDRD-positive and 70% as DDRD-negative.
Results: For overall survival, the DDRD signature yielded HR = 0.56 (95% confidence interval [CI] = 0.46 to 0.68) with a 5-year overall survival rate of 0.42 and 0.24 for patients in the gene signature DDRD-positive and DDRD-negative groups respectively. For relapse free survival, the DDRD signature yielded HR = 0.57 (95% CI = 0.48 to 0.69). The 5-year relapse free survival rate was 0.17 and 0.10 for patients in the DDRD-positive and DDRD-negative groups respectively.
Conclusions: This analysis demonstrates that the DDRD assay, identifying the DDRD molecular subgroup, enriches for patients with an improved overall and relapse free survival following DNA damaging carboplatin-based chemotherapy. We propose that the DDRD assay could be used as a patient stratification tool for existing chemotherapy or as a clinical trial enrichment tool for DNA-damaging or repair targeted drugs in development for use in ovarian cancer.

Soluble CXCL16 in urine as biomarker for bladder cancer diagnostics

K. Lang[1], N. Bonberg[1], F. Sommerer[2], T. Deix[3], V. Harth[4], T. Behrens[1], J. Noldus[3], A. Tannapfel[2], T. Brüning[1], H.U. Käfferlein[1]. *[1]Institute of Prevention and Occupational Medicine of the German Social Accident Insurance-Institute of the Ruhr-University Bochum (IPA), Bochum, Germany; [2]Institute of Pathology Ruhr-University Bochum, Bochum, Germany; [3]Marienhospital Herne Ruhr University Bochum, Urology, Bochum, Germany; [4]Institute of Occupational and Maritime Medicine, Hamburg, Germany*

Background: The non-invasive thus patient-friendly detection of bladder cancer by determination of protein biomarkers in urine remains a challenge in cancer diagnostics. Here we present the identification of soluble CXCL16

in urine as a sensitive and specific biomarker for diagnosis of bladder cancer.
Material and Methods: Urine samples from patients with primary bladder cancer and healthy control volunteers were collected. Differential protein expression analysis in urine was carried out using antibody arrays. The results were reproduced in an additional and independent set of urine samples of 31 tumour patients and 31 healthy controls using immunoassays. In addition, urine samples from 21 patients with acute inflammation of the bladder were analysed in order to further verify the diagnostic specificity of CXCL16. Finally, we evaluated expression and distribution of CXCL16 and its receptor, CXCR6, in formalin-fixed patient tissue by immunohistochemistry.
Results: Urinary CXCL16 was found to be significantly higher in patients with primary bladder cancer (median 332.7pg/mg creatinine) in comparison to healthy controls (median 150.1pg/mg creatinine; $p = 0.0026$). In addition, soluble CXCL16 in bladder cancer patients was significantly increased compared those with bladder inflammation only (median 132.7 pg/mg creatinine; $p = 0.0002$). Results did not differ between men and women, smokers and non-smokers, or patients with and without leukocytes in urine. In contrast to the results in urine, most prominent expression of transmembraneous CXCL16 was detected in tissue samples from patients with urocystitis, whereas cancer cells from tumour patients showed only weak or no immunoreactivity.
Conclusions: We were able to identify and successfully confirm soluble CXCL16 as a promising target protein for the diagnosis of bladder cancer. Thereby, CXCL16 is capable of distinguishing tumour patients from patients with urocystitis rather than tumour patients and healthy controls only. Thus, analysis of CXCL16 offers a significant step forward in non-invasive bladder cancer diagnosis.
No conflict of interest.

Osteomodulin expression profile in human breast cancer

S. Owen[1], A.J. Sanders[1], L. Ye[1], M.D. Mason[2], W.G. Jiang[1]. *[1]Cardiff School of Medicine Cardiff University, Metastasis and Angiogenesis Research Group, Cardiff Wales, United Kingdom; [2]Cardiff School of Medicine Cardiff University, Oncology and Palliative Medicine, Cardiff Wales, United Kingdom*

Background: Osteomodulin (OMD) a cell-binding keratin sulphate proteoglycan, also referred to as osteoadherin, was originally isolated from bovine bone. OMD belongs to the family of leucine rich repeat proteins found in the mineralised matrix of bone and is primarily expressed by mature osteoblasts, whilst also been shown to bind other osteoblasts via the $\alpha_5\beta_3$ integrin. Breast cancer preferentially metastasises to the bone primarily forming osteolytic lesions characterised by loss of bone density. OMD has been proposed to be involved in the regulation of cell proliferation and migration, and therefore this may of particular interest in breast cancer progression to bone metastasis.
Materials and Methods: The expression profile of OMD transcript was examined in a cohort of human normal breast (n = 22) and breast cancer specimens (n = 122) using quantitative polymerase chain reaction (qPCR). This was subsequently used in conjunction with clinical and pathological data, as well as clinical outcome after 10 years follow up, to explore the importance of this molecule in breast cancer progression.
Results: In patients with a good prognosis and survival OMD transcript levels were shown to be high. OMD transcript levels were significantly lower in patients with a Nottingham Prognostic Index of $\geqslant 5.4$ ($p = 0.032$) compared to those who have an index of $\leqslant 3.4$. When comparing clinical outcomes, patients who were disease free at the time of 10 year follow up had significantly higher levels of OMD compared to patients with metastasis ($p = 0.0009$), local recurrence ($p = 0.0079$) and those who had died of the disease ($p = 0.0025$). This trend continued when comparing patients who had developed bone metastasis ($p = 0.009$).
Discussion: In our cohort high OMD expression is associated with a better prognosis and clinical outcome. Reduced levels were associated with metastasis, local recurrence and of particular interest in this study bone metastasis. OMD might therefore provide a potentially novel new biomarker for breast cancer progression and clinical outcome.
No conflict of interest.

A microarray-based gene expression analysis identified diagnostic biomarkers for unknown primary cancer

Y. Fujita[1], I. Kurahashi[2], T. Arao[3], T. Kurata[4], Y. Koh[5], K. Sakai[3], K. Nakagawa[4], K. Nishio[3]. *[1]Kinki University School of Medicine, Osaka-Sayama, Japan; [2]University of Tokyo, Department of Planning Information and Management, Tokyo, Japan; [3]Kinki University School of Medicine, Department of Genome Biology, Osaka-Sayama, Japan; [4]Kinki University School of Medicine, Department of Medical Oncology, Osaka-Sayama, Japan; [5]Shizuoka Cancer Center Research Institute, Division of Drug Discovery and Development, Shizuoka, Japan*

Background: Patients with cancer of unknown primary (CUP) present with metastatic disease for which the primary site cannot be found, despite extensive standard investigation. Clinically, CUPs exhibit common characteristics, such as rapid progression and early dissemination, with a silent primary tumor that may either have a slow growth pattern or may become involuted and undetectable. Existence of such common properties prompts us to hypothesize that there may be potential biological markers that elucidate CUP as a whole.
Methods: We are presently involved in a multicenter clinical study to predict the primary site of CUP based on the analysis of gene expression patterns. Tumor mRNA samples from 60 patients with CUP were measured for the expression of ~22,000 genes using the Affymetrix U133A Plus 2.0 GeneChip® and analyzed by applying normalization and classification algorithms to the gene expression data. The similarity of each tumor specimen's gene expression pattern is then compared to the gene-expression profiles specific to non-CUP groups (containing tumors from 24 known primary sites) that were constructed using publicly available raw microarray datasets. The t-tests were performed to compare the CUP with non-CUP groups and the top 59 CUP specific genes with the highest fold change were selected (p-value <0.001).
Results: This study enabled the identification of genes that exhibited a unique expression pattern in CUP. As a high metastasis potential and vulnerability to apoptosis would explain the properties of CUP well, we first searched for genes related to metastasis and apoptosis and found 14 genes among 44 that were up-regulated by more than 2.5-fold in the CUP samples. Some of these genes were associated with the epithelial-to-mesenchymal transition (EMT), a function that has been increasingly recognized as a key step in cancer metastasis. We also identified 6 genes for ribosomal proteins among 44 up-regulated genes, two of which (*RPS7* and *RPL11*) were known to be involved in the Mdm2 − p53 pathway. Of 15 genes that were down-regulated by more than 2.5 fold in the cup samples, we focused on *CD24*, *KRAS* and *DICER1*.
Conclusions: The protein products of the up-regulated and down-regulated genes identified in this study suggest a biological attribute of CUP and, therefore, may become clinically useful biomarkers for CUP.
No conflict of interest.

960 POSTER

Serological detection of specific protein fingerprints of collagen and laminin degradation can differentiate cancer patients from healthy controls

N. Willumsen[1], A.C. Bay-Jensen[1], C.L. Bager[1], D.J. Leeming[1], V. Smith[2], M.A. Karsdal[1], D. Dornan[2]. *[1]Nordic Bioscience, Biomarkers & Research, Herlev, Denmark; [2]Gilead Sciences Inc., Biology, Foster City CA, USA*

Background: In normal tissue extracellular matrix (ECM) remodeling and composition is tightly controlled to ensure homeostasis. In the tumor microenvironment, however, stromal cells deposit increased amounts of ECM components and the proteolytic activity is altered with matrix metalloproteinase (MMPs) as key actors in ECM protein degradation. As the ECM is an important and dynamic part of the tumor microenvironment due to the mutual interaction between cells and the ECM, many cancer hallmarks are promoted by an abnormal ECM composition. Thus, the alterations in the ECM remodeling and composition associated with cancer has a significant impact on the development and progression of the disease. The aim of this study was to investigate whether specific MMP generated ECM protein fragments (neoepitopes) of the ECM components collagen type I, III, IV and laminin may differentiate cancer patients from healthy controls when measured in serum.
Material and Methods: Using well-characterized and validated competitive ELISAs the levels of MMP degraded collagen type I (C1M), III (C3M), IV (C4M, C4M12) and laminin (LAM) were assessed in serum from patients with gastric cancer (n = 11), non-small cell lung cancer (NSCLC) (n = 10), pancreatic cancer (n = 10) and healthy controls (n = 9).
Results: In all three groups of cancer patients analyzed, serum biomarkers reflecting MMP-9 degraded collagen type IV (C4M, $p < 0.001$) and laminin (LAM, $p < 0.05$) were elevated compared to healthy controls. Biomarkers of

MMP-12 degraded collagen type IV (C4M12) were elevated only NSCLC ($p < 0.05$) and gastric cancer ($p < 0.01$) and MMP degraded collagen type III (C3M, $p = 0.05$) only in NSCLC ($p < 0.05$). No significant differences were observed with the biomarkers reflecting MMP degraded collagen type I (C1M).
Conclusion: Serum biomarkers reflecting specific MMP generated ECM-protein neoepitope fragments of collagen and laminin are able to differentiate cancer patients from healthy controls. Although validation in larger clinical settings is needed, this small study emphasizes that highly specific biomarkers for assessing alterations in the ECM remodeling and composition may prove valuable for diagnosing cancer.

Expression profile of amphyphysin I in normal and breast cancer specimens

A. Sobkowicz[1], A. Sanders[1], F. Ruge[1], W.G. Jiang[1]. [1]*Cardiff School of Medicine Cardiff University, Metastasis & Angiogenesis Research Group, Cardiff Wales, United Kingdom*

Introduction: Breast cancer is currently the second leading cause of cancer-related death among women. Amphyphysin, a neuronal protein encoded by the *AMPH I* gene, is not only the auto-antigen of Stiff-Man Syndrome (patients are positive for auto-antibodies against this protein) but is also associated with breast cancer. Currently there is little data on the role of AMPH I in the biology and involvement in breast cancer progression therefore our study looked at the expression profile of *AMPH I* gene in a cohort of breast cancer patients.
Methods: The expression profile of Amphyphysin I was examined in a cohort of human normal (n = 20) and breast cancer specimens (n = 91) with 10 year follow-up. Gene transcript expression in the samples was analysed using Real Time RT-PCR and compared to patient data. Additionally, immunohistochemistry technique was used to visualise amphyphysin protein in normal and cancerous tissue sections.
Results: Immunohistochemistry results show expression of the amphyphysin protein to be higher in normal tissues when compared to tumour tissues. Normal breast epithelial cells stain mostly within the cytoplasm with some degree of staining in the nuclei regions. These results seem to correlate with gradually lowered expression levels of *AMPH I* observed throughout breast cancer grading: the highest expression for low grade 1 (mean = 633) and the lowest for the high grade 3 (0.2) breast cancer specimens.
Especially significant are the *AMPH I* expression differences between samples from patients classified as disease free (expression level mean=299) and patients with cancer metastasis (mean=8.8) and local recurrence of breast cancer (mean=1.25) with *p values* 0.037 and 0.032, respectively. The slight increase in expression of *AMPH I* in the samples from patients who died of breast cancer was revealed (mean=28) but it was still significantly lower (*p value* = 0.055) than in cancer-free samples.
Elevated *AMPH I* gene expression seems to correlate with Nottingham prognosis index staging. Its expression levels means were increased from 93.2 in samples from patients with good prognosis to 278 in moderate stage with the highest expression level mean of 526 being observed for patients with the poorer prognosis.
Conclusion: Together the data suggests that amphyphysin I expression may be a useful molecule to identify poorer prognostic breast cancers in patients.
No conflict of interest.

962 POSTER

PRAME gene and protein expression in bone marrow of patients with acute myeloid and lymphoid leukemia

N. Lyzhko[1], T. Akhlynina[1], A. Misiurin[1], Y. Finashutina[1], E. Aksenova[1], I. Soldatova[1], I. Shaforostova[2], V. Savchenko[2], E. Parovichnikova[2]. [1]*Federal Research Center of Pediatric Hematology Oncology and Immunology, Laboratory Molecular Oncology and Genetic Engineering, Moscow, Russian Federation;* [2]*Center of Hematology of Russian Ministry of Health Moscow Russian Federation, Moscow, Russian Federation*

PRAME is a cancer-testis antigen highly expressed in a number of solid and leukemia tumors. PRAME protein has brought attention due to its ability to activate T-cell cytotoxic PRAME-specific antitumor response. It is used as a diagnostic marker of MDR in leukemia. While RT PCR is used for PRAME expression evaluation, PRAME-based immunophenotyping has not yet been involved into leukemia diagnosis due to the lack of appropriate anti-PRAME antibodies. We have developed recently two hybridoma cell lines producing anti-PRAME moAbs highly specific to detect PRAME protein both in Western blotting and inimmunophenotyping tests.
Aims: To evaluate PRAME expression and cellular localization of this protein in bone marrow (BM)cells of leukemia pts by means of anti-PRAME moAbs and to compare these results with the data of RT PCR analysis. To stain PRAME protein in BM cells we have used two moAbs produced by hybridoma cell lines 5D3F2 and 6H8F12. In order to generate fluorescent signal we have performed additional treatment by secondary fluorescent Ab (Invitrogen) giving green signal. Images were analyzed by Karl Zeiss Axiovert 40CL and AxioVision software to detect the exact cellular PRAME localization.
Results: BM of AML (N = 8) and ALL (N = 2) leukemia pts has been investigated. According to the level of PRAME gene expression all pts subdivided into two groups with relatively high PRAME expression (0.587−6.3% PRAME/Abl) and with low level of PRAME expression (0–5.87×10^{-3}%). Using PRAME staining on the fixed cells we have obtained the following results. In the group of high PRAME expression (AML M7,M5) we have observed PRAME protein both inside the cells (in the nuclei − 33.3%, in the cytoplasm − 23.3%) and on the cell surface (43.3%). In the group of low PRAME expression (AML M7, M3, ALL) there have been no PRAME signal in nuclei, in the cytoplasm it has been observed in 26.6% cases, in most cases it has been on the cell surface (46.2%), some cases (27.2%) have been PRAME-protein negative. When we have performed PRAME staining on the alive none-fixed cells, fluorescent signals have been found in 13.5−14% on the cell surface of both group. Our study suggests that in leukemia pts PRAME protein is very frequently localized on the cell surface. In the cases with low PRAME expression it is nether found in thenucleus. When PRAME expression in leukemia BM cells is increased, it is localized not only on the cell surface and within the cytoplasm but also in the nucleus.

963 POSTER

Oncomodulin is a novel early marker of urinary bladder carcinogenesis in F344 rats

M. Okumura[1], M. Wei[1], S. Yamano[1], M. Fujioka[1], A. Kakehashi[1], H. Wanibuchi[1]. [1]*Osaka City University Graduate School of Medicine, Pathology, Osaka-city, Japan*

Background: Short-term carcinogenicity assay using molecular biomarkers that can predict the results of long-term rodent cancer bioassays is greatly desired. The purpose of the present studies is to identify early markers of bladder carcinogenesis in F344 rats.
Material and Methods: Microarray analyses were conducted on 12 *N*-butyl-*N*-(4-hydroxybutyl)nitrosamine (BBN)-induced rat bladder cancers, 11 dimethylarsinic acid (DMA)-induced rat bladder cancers and 4 normal bladder urothelium using Affymetrix GeneChip Rat Genome 230 Array. mRNA expression analysis was perform using Taqman real-time PCR.
Results: Microarray analyses of BBN and DMA-induced bladder cancers revealed that 85 genes were commonly overexpressed in all cancers compared to control bladder urothelium. To select the candidate markers capable of predicting carcinogenicity of chemicals at the early stage of bladder carcinogenesis, mRNA expression levels of 20 of above genes which were selected based on the overexpression levels and the results of ingenuity pathway analysis, were examined in bladder urothelium of rats treated with BBN for 2, 4 and 8 weeks, respectively. Twelve of the above 20 genes were found to be consistently overexpressed from the week 2, and therefore were selected as candidate early marker genes and their mRNA expression levels were examined in bladder urothelium treated with 7 genotoxic and nongenotoxic bladder carcinogens ((DMA, 2-acetylaminofluorene, sodium o-phenylphenol, phenethylisothiocyanate, benzyl isothiocyanate, uracil and BBN)), bladder carcinogens and 3

nonbladder carcinogens (liver carcinogen: diethylnitrosamine; kidney carcinogen: N-ethyl-N-hydroxyethylnitrosamine; colon carcinogen: 1.2-dimethyhydrazine) and 3 nonbladder carcinogens(liver carcinogen: diethyl-nitrosamine; kidney carcinogen: N-ethyl-N-hydroxyethylnitrosamine; colon carcinogen: 1.2-dimethyhydrazine) respectively, for 4 weeks. Oncomodulin was consistently significantly overexpressed in all urothelium treated with various bladder carcinogens regardless of the degree of histopathologic changes, but not in the urothelium treated with any of nonbladder carcinogens. The functional analysis of oncomodulin is in progress.
Conclusion: Oncomodulin is a novel early marker of bladder carcinogenesis in rats. The 4-week oncomodulin-based bioassay is useful to predict bladder carcinogenicity of chemicals in rats.

Is HPV-16 integration a predictor biomarker of cervical lesions?

J. Ribeiro[1], D. Teixeira[1], J. Dias[1], I. Baldaque[1], R. Medeiros[1], H. Sousa[1].
[1]*Portuguese Institute of Oncology, Virology Service, Porto, Portugal*

Background: Persistent infection with oncogenic types of *human papillomavirus* (HPV) has been established as the main etiological factor for the development of cervical lesions and invasive carcinoma. The integration of HPV genome into hosts' genome is considered the hallmark of HPV-associated carcinogenesis, however, the significance of HPV physical status detection remains unclear. The aim of this study was to characterize the physical status of HPV-16 in samples with different histological classifications.
Material and Methods: We have selected 53 cervical specimens from women with different histological classification that have been identified with HPV-16 infection (45 single infection and 8 co-infections). The physical status of HPV16 was analyzed using a multiplex Real-time PCR that allows simultaneous amplification of the E2 and E6 regions. HPV-16 status classification was based on the principle that, when integration occurs, the E2 gene is partially or totally disrupted while the E6 gene remains intact.
Results: In this study, the prevalence of HPV16 integration was of 26.4% (14/53, 13 mixed forms and 1 integrated only). Results showed no significant differences when comparing HPV-16 integration within single vs co-infections ($p = 0.647$). The prevalence of HPV-16 integration among different cervical lesions was 28.6% (2/7) in samples without cytological lesion (normal), 13.3% (2/15) in atypical squamous cells of unknown significance (ASC-US), 33.3% (4/12) in low-grade squamous intraepithelial lesions (LSIL), 33.3% (5/15) in HSIL high-grade squamous intraepithelial lesions and 25.0% (1/4) in invasive cervical cancers (ICC). Additionally, we no found statistical significant differences among the histological specimens ($p = 0.735$).
Conclusion: Our study revealed that HPV16 integration is not exclusive event of high-grade lesions/ICC. Moreover, it was not possible to detect integrated forms in all cases of HSIL/ICC. This study shows that HPV16 integration occurs early during HPV-associated carcinogenesis and therefore there is an emergent requirement to reconsider the role of viral genome integration in HPV-associated carcinogenesis.

966 POSTER

An innovative approach for in-vivo isolation of circulating tumor cells (CTCs)

S. Herold[1], L. Gasiorowski[2], P. Nowaczyk[3], A. Schumann[4], G. Theil[4], K. Haubold[1], T. Krahn[5], W. Dyszkiewicz[2], D. Murawa[3], K. Lücke[1]. [1]*GILUPI GmbH, Clinical Trials, Potsdam, Germany;* [2]*Medical University Poznan, Thoracic Surgery, Poznan, Poland;* [3]*Wielkopolska Cancer Centre, Surgical Oncology and General Surgery, Poznan, Poland;* [4]*Martin-Luther-University Halle-Wittenberg, Urology and Kidney Transplant Center, Halle, Germany;* [5]*Bayer Pharma AG, Global Biomarker Research, Berlin, Germany*

Background: Currently, circulating tumor cells (CTCs) are isolated *in vitro* from a small volume of blood samples. Furthermore, CTC results for different kinds of cancer as a prognostic and stratification biomarker are scarce. The aim was to assess a medical device (CellCollector) for *in vivo* isolation of CTCs directly from the blood of non-small cell lung cancer (NSCLC), breast cancer (BC), prostate cancer (PC) and colorectal cancer (CRC) patients prior surgery/ therapy start and partially in the course of therapy. Additionally, CTC enumerations were compared to the Cell Search® method.
Material and Methods: The device was inserted in a cubital vein through a standard cannula for thirty minutes. The interaction of target CTCs with the CellCollector was mediated by an antibody directed against the epithelial cell adhesion molecule (EpCAM). To confirm the CTCs binding to the wire, the immunohistochemical staining against EpCAM and/or Cytokeratin as well as CD45 for negative cell selection was performed. There were more than 380 applications of the wire in NSCLC, BC, PC and CRC patients and over 45 applications in control subjects. Enumeration data was available for 159 cancer patients and 37 control subjects. For 98 cancer patients and 22 control subjects, samples were also tested in the CellSearch® system.
Results: The device was well tolerated in more than 380 applications without side effects. We obtained in vivo isolation of CTCs in 126 of 159 cancer patients (79.2%) with a median (range) of 3 (0–515) CTCs and a mean of 17 CTCs. The sensitivity was similar for early and late stage in cancer patients. In the control groups, only in 6 of 37 subjects CTCs were detected (84% specificity). The sensitivity and specificity for CTC detection by the CellSearch® method was 16.7% and 79.5%, respectively. With exception of three samples, in all 78 paired samples the number of CTCs detected with the CellCollector was higher or equal to CellSearch®, regardless of the disease stage.
Conclusions: Whilst well tolerated without side effects, the CTC detection rate of the CellCollector in NSCLC, BC, PC and CRC patients was 79.2%. In contrast, 16.7% detection was obtained using the CellSearch® analysis. A specificity of the medical device of 84% could be reached. This innovative method may have important clinical implications, as the implementation of the device into clinical practice may improve early detection, prognosis and therapy monitoring of NSCLC, BC, PC and CRC patients. The method may also allow the molecular analysis of the CTCs, with the possibility of establishing more personalized treatment regiments.

Early technology foresight for the development of biomarkers for prostate cancer screening: Prospective Health Technology Assessment (ProHTA)

C. Niederländer[1], C. Kriza[1], P. Wahlster[1], A. Djanatliev[2], P. Kolominsky-Rabas[1], on behalf of the ProHTA Project Group[3].
[1]*University of Erlangen-Nuremberg, Interdisciplinary Centre for Health Technology Assessment (HTA) and Public Health, Erlangen, Germany;* [2]*University of Erlangen-Nuremberg, Department of Computer Science, Erlangen, Germany;* [3]*ProHTA Project Group, Erlangen, Germany*

Background: Currently, screening for prostate cancer is mostly performed using the digital rectal examination (DRE) and the measurement of the prostate-specific-antigen (PSA). Although PSA-testing is very sensitive, it lacks in specificity. Therefore an additional biomarker with high specificity could lead to a significant reduction of the biopsies performed unnecessarily.
Foresight methods such as modeling and simulation can help to assess the impact of future health technologies. 'Prospective Health Technology Assessment' (ProHTA) aims to develop a platform targeting health care manufacturers and decision makers that facilitates the assessment of innovative health technologies prior to their launch.
Methods: The objective of this work is to reduce the number of biopsies by introducing a novel and fictive biomarker additional to PSA-measurement. The potential impact of this biomarker is investigated in a simulation. Using clinical pathways, a model for the diagnostic process of prostate cancer is designed. This model serves as the basis for 'hybrid simulation' that consists of system dynamics models for macro-simulation and discrete event models for micro-simulation.
Results: The simulation shows that the use of a fictive biomarker in addition to DRE and PSA measurement will reduce the biopsies performed. The extent of the reduction depends on the sensitivity and specificity of PSA and DRE testing, as well as on the parameters determined for the biomarker. For example, if the estimated sensitivity of the biomarker is 100% and the specificity is 80%, then 25% of all biopsies can be avoided.
Conclusions: The ProHTA simulation approach is innovative and shows with the example of the fictive prostate cancer biomarker the potential to predict if an innovation and research in this field will be successful. Thus, ProHTA represents a useful decision-making tool for foresight and adds value to existing methodologies for pre-assessing health technology at a very early stage of technology research and development. It offers a valuable approach with an emphasis on strategic planning and therefore helps to improve the efficiency of health care delivery in different care settings.
Funding: This project is supported by the German Federal Ministry of Education and Research (BMBF) as part of the National Cluster of Excellence 'Medical Technologies − Medical Valley EMN' (Project grant No. 13EX1013B).

968 POSTER

Opportunities and pitfalls in developing imaging biomarkers (IB) in oncology clinical trials

S. Collette[1], Y. Liu[2], L. Collette[1]. [1]*European Organisation for Research and Treatment of Cancer, Statistics Department, Brussels, Belgium;* [2]*European Organisation for Research and Treatment of Cancer, TR Radiotherapy and Imaging Department, Brussels, Belgium*

Background: The assessment of tumor progression is fundamental to cancer clinical trials. Progression-free survival or disease-free survival tend to substitute overall survival as trial endpoint whenever feasible and meaningful. Those endpoints are based on imaging evaluation of tumor size. However, new technologies have been developed that provide additional information according tumor location or treatment administered, e.g. metabolic assessment provided by FDG-PET. Those advanced techniques have been widely used in routine clinic for staging or evolution of the disease. Up to date, they also play an increasingly important role in response assessment. Nevertheless, the assessment by functional imaging is different from that by anatomic imaging, where tumor size is a reproducible measure. Functional imaging has the additional requirement that an observed change of the parameter in response to treatments must be greater than the intrinsic and extrinsic variability of the parameter in the absence of treatment.
Methods: In order to use IB in clinical practice, robust criteria taking into account all the sources of variability of the measurement must be developed. Four steps are needed in such development: 1) evaluation of the different source of variability (multicentric test-retest) 2) development of imaging guidelines (standardization, quality assurance, central review) 3) evaluation of the treatment effect on the imaging measurement (correlation with pathological assessment) 4) validation studies (correlation with long term endpoints).
Results: We will detail the process and trial designs needed to fully develop robust IB and will illustrate how to do this in an imaging protocol that fits with the constraints of the primary clinical trial to which it is attached. When an IB is developed through a clinical trial as an (optional) translational research project, the imaging protocol has to be adapted to not negatively impact on the main protocol as the assessment of the tumor with the new techniques will not be blinded to the investigator. The sample size of the imaging protocol will also be constrained by that of the main clinical trial.
Conclusion: Appropriately used, IB could offer interesting treatment options and help fasten and target treatment development in clinical trials. Therefore we propose guidelines to help researchers to develop add-on IB protocols to therapeutic trials.

NGS panel V1.1 for the routine deep sequencing-based diagnostic of somatic hotspot theranostic mutations on FFPE tumours: A prospective study of 500 cancer samples

A. Lespagnol[1], B. Ndiaye[2], A. Mosser[1], C. Chaplais[1], H. Gourdet[1], F. Guenot[1], R. Bouvet[1], G. Moron[1], J. Mosser[1], M. De Tayrac[1]. [1]*University Hospital Centre of Rennes, Molecular Genetics and Genomics Department, Rennes, France;* [2]*University of Rennes1, Health Genomics Platform Biogenouest − UMS 3480 Biosit, Rennes, France*

In cancer, targeted therapies development induces an increasing number of mutations with theranostic values. Improving of patient care now relies on tumour genetic profiling that will guide treatment strategy. This implies the ability of parallel genotyping of a growing number of mutations. By providing an increase in sequencing throughput, NGS technology is suitable for routine implementation of such diagnostic in the near future. To address this challenge, we tested whether NGS sequencing detects somatic alterations in formalin-fixed, paraffin-embedded tumour samples. We aimed at determining the sensitivity and specificity of NGS compared to pyrosequencing (PS) and allele-specific PCR (ARMS) methods on 500 patients. A panel of 48 amplicons covering a 5kb region was designed to detect hotspot mutations in 17 key cancer genes. Low amount of input FFPE DNA was used to generate libraries on 48.48 Fluidigm access arrays for targeted sequence library. Libraries were sequenced using 150bp paired-end reads on an Illumina MiSeq. Trimmed reads were aligned to the hg19 genome using BWA in single end mode. Local indel realignment was performed with GATK. Calling algorithms were used to detect mutations even at a low frequency (SNVmix, lofreq, samtools, GATK and freebayes). NGS data was obtained on 500 patients (240 NSCLC, 230 colorectal cancers and 30 melanomas) and compared with reference technics (PS and ARMS) used in the routine molecular diagnostic. Deep sequencing of our custom gene panel results in a minimum of 3000X coverage for all amplicons with a mapping quality greater than 30. NGS detects 219 mutations in the 500 patients, including single nucleotide substitutions, small deletions (*EGFR* exon 19) and insertions (*ERBB2* exon 20). Among theses, 193 were also found with the two reference methods. NGS lead to 10 false negative mutations due to poor DNA quality. Sixteen false positive mutations were detected very likely due to the increased sensibility of NGS. Considering pyrosequencing and ARMS as references, deep sequencing provides a 95% sensitivity and a 98% specificity. We demonstrate that our deep sequencing approach can be reliably implemented as a diagnostic test for routine detection of somatic mutations. Our strategy allows the simultaneous analysis of more than 100 somatic hotspot mutations in 17 key cancer genes for 96 samples in a single assay and thus improves the molecular diagnosis of tumours in a cost and time efficient manner.

970 POSTER

A comprehensive low-cost germline genetic test for over 260 conditions, including 50 affecting cancer diagnosis and treatment

J.M. Hagenkord[1], M. Sommargren[2], E.M. Hare[2], J. Sorenson[3], R.K. Hart[3], E.C. Olivares[4], S.E. Lincoln[3], M. Cargill[2]. [1]*InVitae, Medical, San Francisco, USA;* [2]*InVitae, Curation, San Francisco, USA;* [3]*InVitae, Informatics, San Francisco, USA;* [4]*InVitae, Molecular, San Francisco, USA*

Background: Historically it has only been feasible to sequence 1 or 2 genes to test for hereditary cancer in a patient. Hence, cancer-related genetic conditions such as Bloom syndrome and Fanconi anemia can go undiagnosed. Also, conditions not directly related to a patient's cancer often go untested, although they can affect treatment and outcome, such as bleeding syndromes (i.e. surgery) and cardiomyopathies (i.e. chemotherapy).
Materials and Methods: A single assay was developed to test for 264 germline genetic conditions, including 50 hereditary cancer conditions. This assay covers nearly all published clinically-relevant variants (both coding and non-coding) in the associated genes and also detects novel likely-pathogenic variants, such as previously unseen loss-of-function mutations in tumor suppressors, in the full gene sequence. Extensive scientific review was conducted to curate these clinical conditions, storing the validated genes, variants and risk models in a database that informs our targeted next-generation sequencing platform. Custom variant interpretation software describes known and novel substitutions, insertions and deletions, and copy number variants, including those in traditionally hard to assay sites such pseudogenes and homopolymer stretches. Clinical reports are automatically generated and variants reported according to ACMG guidelines, with an additional category for variants observed in patients but which have uncertain pathogenicity. This test requires less than 2 weeks from arrival of blood sample to clinical report delivery.
Results: Analytical validation was performed on a panel of reference samples with >11,000 known variant sites and ~2.1 million non-variant sites. For coding sequence substitutions, we demonstrated 99.7% sensitivity and 99.998% specificity. For insertions/deletions in coding sequence, we demonstrated 98.3% sensitivity and 99.994% specificity. In direct comparisons against established diagnostic laboratories using traditional Sanger sequencing, we saw 100% concordance with those results, both in terms of analytical concordance and clinical interpretation.
Conclusions: We report progress in aggregating many genetic tests into one comprehensive assay at low cost, including a comprehensive inherited cancer test. This curation approach enables scalable, automatable, and reproducible diagnostic reporting, using accurate and scalable DNA sequencing methods.

971 POSTER

The diagnostic value of one step nucleic acid amplification (OSNA) for sentinel lymph nodes in colon cancer

J. Vogelaar[1], M.S. Reimers[2], R.L.A. Van der Linden[3], J.C. Van der Linden[3], V. Smit[4], H. Takata[5], D.J. Lips[6], C.J.H. Van de Velde[2], K. Bosscha[6]. [1]*VieCuri Medical Center, Surgery, Venlo, Netherlands;* [2]*Leiden University Medical Center, Surgery, Leiden, Netherlands;* [3]*Jeroen Bosch Hospital, Pathology, 's-Hertogenbosch, Netherlands;* [4]*Leiden University Medical Center, Pathology, Leiden, Netherlands;* [5]*Sysmex Europe, Strategic Planning, Norderstedt, Germany;* [6]*Jeroen Bosch Hospital, Surgery, 's-Hertogenbosch, Netherlands*

Background: Colorectal carcinoma (CRC) is the second most commonly diagnosed malignancy in the Netherlands. Determining the lymph node (LN) status is a good prognostic factor in CRC and is critical in the staging of these tumors. Earlier studies have shown that 20−30% of the Dukes stage I−II patients will still develop metastases within 5 years. Literature has also shown that with the use of the ex vivo sentinel lymph node

mapping procedure (SLNM) and the immunohistochemical Keratin Pan staining at 4 levels an upstaging of 20% can be achieved in these patients. The examination of SLN in breast cancer with One Step Nucleic acid Amplification (OSNA) has been proved to be valuable. The aim of this study was to determine the value of the sentinel node mapping procedure and the diagnostic value of OSNA in colorectal cancer.
Materials and Methods: In this study 313 SLNs of 122 patients from the Jeroen Bosch Hospital in 's-Hertogenbosch and the Leiden University Medical Center were investigated by the routine examination (H&E), fine examination (H&E and Keratin Pan immunohistochemical straining) and OSNA. The SLNs were harvested by the ex vivo sentinel lymph node mapping procedure, using Patent blue or Indocyanine green. Half of the SLN was used for the routine and fine examination and the other half for the OSNA assay. OSNA uses the reverse-transcription loop-mediated isothermal amplification (RT-LAMP) for mRNA amplification.
Results: The diagnostic value of OSNA, determined on all 122 patients was 81% and 100% for the fine examination and combined method (OSNA and fine examination together). An upstaging rate of 21% was obtained with the use of OSNA and 37% with the use of fine examination. An upstaging rate of 48% was obtained by combining these two methods together.
Conclusion: SLNM proved to be of value in CRC. OSNA and Fine examination both showed a good diagnostic value. The combination of OSNA and Fine examination was associated with an increased diagnostic value and also showed more upstaging of patients. Future research needs to be done to show whether routine examinations should be replaced by the investigation of sentinel lymph nodes using the OSNA assay and the fine examination together and the amount of SLNs to be investigated.
No conflict of interest.

972 POSTER

High resolution in vivo imaging for cancer detection and evaluation of tumor heterogeneity

V. Ermolayev[1], J. Salichs[1], P. Mohajerani[1], A. Nunes[1], A. Ale[1], V. Ntziachristos[1]. *[1]Helmholtz Zentrum Muenchen, Institute for Biological and Medical Imaging, Munich, Germany*

Background: Early tumor diagnostics and imaging of solid tumors are critical areas of cancer research. Imaging of tumor heterogeneity gives insights into proliferation, metastases and response to therapies. The majority of imaging methods does not demonstrate competitive resolution, penetration depth or cannot utilize fluorescent imaging agents widely used in preclinical research. In this work, we analyze *in vivo* spatial distribution of nanoparticle-based vascular and targeted contrast agents using novel imaging methods: hybrid fluorescent molecular tomography-X-Ray computer tomography (FMT-XCT) and high-resolution multispectral optoacoustic microscanner (microMSOT) in different animal models: transgenic model for Non-Small Cell Lung Cancer (NSCLC) and tumor xenograft/allograft one.
Material and Methods: The animals of transgenic K-ras model for NSCLC were injected with different targeted and activatable contrast agents and imaged *in vivo* with FMT-XCT imaging system. Foxn athymic nude mice were used for inoculation of subcutaneous (s.c.) 4T1 murine breast cancer allografts or HT29 human colorectal xenografts. The tumors were grown up to the size of 7−8 mm. Then the animals were injected with nanoparticles or vascular contrast agents and imaged with microscanner MSOT. The results of *in vivo* imaging were validated and analyzed with cryo-slicing epifluorescence imaging system and immunofluorescence.
Results: FMT-XCT *in vivo* imaging demonstrated the potential of $\alpha v\beta 3$-integrin targeting for detection of early lesions in K-ras mouse model of NSCLC. $\alpha v\beta 3$-integrin targeted fluorescence could selectively resolve pulmonary lesions in mice from 2 weeks of age vs. wild type. FMT-XCT imaging showed tumors and heterogenic profiles for $\alpha v\beta 3$-integrin spatial distribution in the lung tumors of 4-week-old animals. *In vivo* studies were verified versus immunofluorescence.
Heterogenic profiles of s.c. tumors were studied by microMSOT visualizing development of tumor vasculature with high resolution. Distribution profiles of nanoparticles, oxy- and deoxygenated hemoglobin were detected *in vivo* through entire tumor. *In vivo* optoacoustic signal correlated with *ex vivo* cryo-slicing and immunofluorescence profiles.
Conclusions: Our results demonstrated potential of FMT-XCT imaging of targeted contrast agents for early detection of lung lesions and *in vivo* study of heterogenic tumors.
MicroMSOT could offer high resolution imaging of intrinsic contrast and extrinsically applied probes for *in vivo* investigation of tumor vascular properties with impact on cancer research.
No conflict of interest.

973 POSTER

Development of a next generation sequencing assay for the identification and quantitation of fms-like tyrosine kinase internal tandem duplication sequences, and mutation analysis

B. Lee[1], M. Landers[1], Y. Wang[1], R. Meredith[1], J. Lee[1], H. Kim[1], J. Monforte[1]. *[1]AltheaDx, San Diego California, USA*

Background: Activating mutation in fms-like tyrosine kinase (FLT3) gene aberrations, internal tandem duplication (ITD) and tyrosine kinase domain (TKD) mutations, play an important role in pathogenesis of acute myeloid leukemia. FLT3 Internal Tandem Duplications (ITD) are in frame duplications occurring most frequently in the juxtamembrane and less frequently in the tyrosine kinase domains. FLT3 ITDs cause ligand independent dimerization and activation of FLT3 leading to uncontrolled cellular proliferation. About 30% of AML patients are FLT3 ITD+ and demonstrate a worse prognosis and response to chemo therapy. Treatment of FLT3 ITD+ patients with the appropriate tyrosine kinase inhibitor represents a viable option for these patients. Selection of the appropriate tyrosine kinase inhibitor is dependent on patient FLT3 genotype and the presence of any resistance conferring mutations vs. the candidate treatment. To this end, we developed and characterized a next generation sequencing assay for the simultaneous detection, identification, and quantitation of FLT3 ITDs and TKD point mutations.
Methods: DNA fragment libraries prepared from 100 or 1000 ng of test sample gDNA are hybridized to enrichment oligos specific for FLT3 exonic sequences. Captured libraries are amplified and sequenced via Ion Torrent. TMAP aligned data were realigned for larger INDELs and filtered for the identification/quantitation of ITD sequences. Additionally, point mutations were called by VarScan and further characterized by SIFT/PolyPhen2/COSMIC for their damaging effects.
Results: Using model cell lines (MV4−11, MOLM-13), the assay demonstrates a sensitivity (LOD) of 10% for the detection of ITD sequences and 5% for point mutations. Further assay validation in AML patient samples demonstrates detection of ITDs between 30–178 bp at frequencies as low as 10% in addition to identifying resistance conferring point mutations within the tyrosine kinase domain.
Conclusions: The developed FLT3 genomic assessment assay simultaneously determines FLT3 ITD status, monitors ITD clonal populations for the presence of specific ITD's and TKD point mutations, and may be useful in determining patient response to tyrosine kinase inhibitors.
No conflict of interest.

974 POSTER

Automated large-volume extraction of circulating, cell-free DNA to improve the sensitivity of tumor biomarker detection

A. Nocon[1], M. Horlitz[1], A. Wolf[1], P. Scholtysik[1]. *[1]Qiagen GmbH, R&D, Hilden, Germany*

Background: Because of its low concentration and high degree of fragmentation, the extraction and detection of tumor-derived circulating cell-free DNA (ccfDNA) is technically challenging. An optimized ccfDNA extraction method was developed and evaluated by comparison to existing manual and automated reference methods.
Material and Methods: ccfDNA was bound from 5.8 ml EDTA plasma of healthy donors (with IRB approval) to novel magnetic particles and recovered in 150 µl. The QIAamp® Circulating Nucleic Acid (CNA) Kit was used as a reference and for the purification of any residual ccfDNA from the plasma supernatant after binding. Alternatively, the 'Virus cell-free 1000 protocol' using the QIAsymphony® DSP Virus/Pathogen Midi Kit was modified for the processing of higher sample volumes. ccfDNA was extracted from 4 ml plasma and eluted in 90 µl. ccfDNA yield was quantified by qPCR (66bp within the 18S rDNA). To determine the DNA fragment size-dependent recovery, targets from 67bp to 475bp within the APP gene were quantified by qPCR.
Results: The mean ccfDNA recovery (18S 66bp target; compared to the QIAamp® CNA Kit) was 7% (N = 12; +/−4.1%) for the supernatant and 95% (N = 12; +/−19.2%) for the eluate. For the APP assay, ratios between the copy numbers of different target sizes were calculated. The mean ratios were: 67/476bp = 11 (N = 12; +/−6.2), 180/476bp = 8.1 (N = 12; +/−3.6) and 67/180bp = 1.4 (N = 12; +/−0.3). The modified Virus cell-free 1000 protocol led to a mean ccfDNA recovery of 140% (N = 24; +/−48.4) compared to the QIAamp® CNA Kit.
Conclusions: The automated protocol versions led to an overall similar ccfDNA recovery compared to the QIAamp® CNA Kit (complete ccfDNA binding to magnetic particles). Using the new extraction chemistry an improved recovery of tumor-derived ccfDNA is possible and allows for a higher sensitivity of tumor DNA detection, which is, besides a high specificity, critically important for the application of tumor ccfDNA biomarkers as a tool in cancer diagnosis and prognosis. The presented

applications are for research use only. Not for use in diagnostic procedures. This work has received funding from the European Union FP7 Programme under grant agreement no. 222916, SPIDIA project (www.spidia.eu).

Background: Bladder cancer detection and surveillance are traditionally performed by cystoscopy and urine cytology. Recently, *Urothelial Carcinoma Associated 1 (UCA1)* was identified as a very sensitive and specific urinary marker of bladder cancer. This study aimed to compare the clinical value of the *UCA1* test with routine diagnostic methods.
Material and Methods: Between October 2009 and December 2011, 564 *UCA1* tests were performed on urinary samples collected from 467 patients. Histological diagnoses were available in 108 cases. Patients were divided into screening and follow-up groups based on the absence or presence of prior urothelial carcinoma. The test performance was evaluated in each group and compared to cystoscopy, urine cytology and routine follow-up results.
Results: The overall sensitivity, specificity and positive and negative predictive values for the *UCA1* test were 69, 67, 86 and 42%, respectively. We observed no difference in performance for tumors of higher grade or stage, but sensitivity was increased in the screening population (84%) compared to patients under follow-up (58%). The *UCA1* test successfully detected 8/8 cases of *carcinoma in situ* and 2/4 cases of urothelial dysplasia. The positive predictive value of the test was comparable to cystoscopy.
Conclusion: The *UCA1* test can be used as a complementary method to cystoscopy and cytology for the detection of bladder cancer. While we found no evidence supporting the use of the *UCA1* test as a replacement for cystoscopy, it does seem beneficial for detection of *carcinoma in situ* lesions and, in some cases, for urothelial dysplasia.

976 POSTER

Prevalence of KRAS-LCS6 polymorphism (rs61764370) within three different tumour types (breast, colorectal and non small cell lung cancer, NSCLC): A study of Czech population

B. Kubova[1], J. Simova[2], M. Uvirova[1], I. Urbanovska[1], D. Konvalinka[1], R. Mech[1], J. Mazurova[1], A. Hopenstokova[1], J. Dvorackova[2]. [1]*CGB laboratory Inc., Laboratory of Molecular Genetics and Pathology, Ostrava, Czech Republic;* [2]*University of Ostrava, Faculty of Medicine, Ostrava, Czech Republic*

Background: KRAS is one of the most frequently mutated oncogenes in human cancer, with almost a quarter of different tumor types showing altered functions of KRAS. The let-7 family of microRNAs were found to regulate KRAS activity by binding to the 3'UTR of human KRAS gene. A germline SNP (rs61764370) is located in a let-7 complementary site (LCS6) in the 3'UTR of KRAS oncogene. The LCS6 SNP consists of a T-to-G base change and it was found to alter the binding capability of the mature let-7 miRNA to the KRAS mRNA. In several studies G-allele of rs61764370 was found to be associated with higher risk of breast cancer, colorectal cancer, melanoma, oral cancer and ovarian cancer. It is potential biomarker of poor response to targeted therapies in colon cancer too. Controversially, other authors did not find significant association with cancer risk. Thus, the relevance of rs61764370 in cancer predisposition is still debated and deserves further investigations.
Material and Methods: DNA of tumours tissues was isolated from fixed, fresh-frozen, cytology specimens and formaline fixed paraffin embedded tissue from 262 mCRC, 158 breast and 117 NSCLC patients. DNA from 387 healthy controls was isolated from peripheral blood. Analysis of SNP rs61764370 (KRAS-LCS6) was performed by PCR and RFLP method.
Results: The KRAS-LCS6 G-allele (T/G genotype) was detected in 9.9% (26/262) of mCRC cases; 15.2% (24/158) of breast cancer cases and 14.5% (17/117) of NSCLC patients. T/G genotype of the SNP (rs61764370) was identified in 15.8% (61/387) of healthy controls. In our study we did not find G-allele carriers in homozygous state (G/G genotype) among the cancer patients and healthy controls.
Conclusions: The frequency of the LCS6 G-allele varies across geographic populations, with European populations exhibiting the variant allele most frequently 5−10%. In our study, in healthy Czech population (controls), frequency the LCS6 G- allele was 15.8%. Prevalence of the KRAS-LCS6 G-allele was not significantly different among stadied tumours (NSCLC, breast cancer) and the healthy controls. The acquisition of new data from different populations could have a paramount importance to establish the real contribution of each polymorphism to the cancer risk. The study of polymorphisms, affecting miRNA-dependent pathways and involved in cancer susceptibility is rapidly growing and is becoming increasingly important on the fast growing field of the personalized medicine.

977 POSTER

microRNA expression in BRCA 1/2 hereditary breast cancer: Exploratory analysis

A. Clara[1], P. Machado[2], A. Luís[1], A. Opiniao[1], C. Simoes[3], J. Parreira[3], P. Rodrigues[3], S. Esteves[4], F. Vaz[1]. [1]*Instituto Portugues Oncologia, Medical Oncology, Lisboa, Portugal;* [2]*Instituto Portugues Oncologia, Molecular Research Center, Lisboa, Portugal;* [3]*Instituto Portugues Oncologia, Breast Cancer Risk Evaluation Clinic, Lisboa, Portugal;* [4]*Instituto Portugues Oncologia, Clinical Research Unit, Lisboa, Portugal*

Background and Objectives: microRNAs (*mirs*) are small non-coding regulatory RNAs involved in gene expression regulation at posttranscriptional level. *mirs* expression is deregulated in breast cancer, but there is very limited data about their expression in hereditary breast cancer (HBC). The objectives of this study are: 1- to analize if there is any difference in the expression of a *mirs* pannel (*mir*21, *mir*155, *mir*195, *Let*7a and *mir*16) between sporadic breast cancer (SBC) and *BRCA1/2* HBC; and 2- to analize the change of expression of the mirs pannel, prospectively, in *BRCA1/2* HBC.
Methods: RNA was extracted from whole peripheral blood, reverse transcribed and quantified by real-time quantitative polymerase chain reaction analysis for *mir* 21, *mir* 155, *mir* 195, *Let* 7a and *mir* 16 (endogenous control). We have 3 groups of patients (pts): (A) 20 with *BRCA1/2* HBC, (B) 13 with SBC (*BRCA1/2* wildtype) and (C) 15 healthy individuals. Five of 20 *BRCA1/2* HBC started this study prospectively, at breast cancer diagnosis, and *mir* expression was evaluated before surgery, 2 weeks after surgery and after adjuvant treatment. All other pts in group A were breast cancer survivors. All pts in group B were breast cancer survivors.
Results: Group A- 18 female, 2 male; BRCA1: 3 pts, BRCA2: 17 pts; median age: 58 years. Group B- 12 female, 1 male; median age: 45 years. Group C- 11 female, 4 male; median age: 45 years. For *mir*21, *mir*155 and *mir*195 *BRCA1/2* HBC and SBC cancer survivors had significant different levels of *mir* 195 expression. In the exploratory analysis of the first 4 prospective pts a trend for decreasing levels of *mirs* 21, 155 and 195 after surgery was observed (but not significant after log conversion). The only case already measured after adjuvant treatment had more pronounced descent of *mirs* 21 and 155 than after surgery. Analysis for *Let*7a is not yet complete.
Conclusions: This exploratory analysis, suggests two study hypotheses: 1- *mirs* expression may not be similar in HBC and SBC and 2- change in *mirs* expression before and after cancer treatment of HBC may be more significant after completion of adjuvant treatment than after surgery. These are very rare pts but enrollment in the prospective study continues.
No conflict of interest.

978 POSTER

Sensitive detection of EGFR mutations using mutant-enriched PCR and reverse-hybridization teststrips

M. Novy[1], B. Rauscher[1], C. Oberkanins[1]. [1]*ViennaLab Diagnostics GmbH, R&D, Vienna, Austria*

Background: Activating mutations in the epidermal growth factor receptor gene (EGFR) allow the therapeutic use of tyrosine kinase inhibitors (TKI), such as erlotinib or gefitinib in non-small cell lung cancer (NSCLC) therapies. In contrast, the presence of the T790M mutation in tumor tissue predicts resistance to TKI.
Materials and Methods: We have developed a reverse-hybridization StripAssay for the detection of three mutations in exon eighteen, twenty-four deletions and complex mutations in exon nineteen, the T790M mutation in exon twenty and two mutations in exon twenty-one of the EGFR gene. The test is based on mutant-enriched PCR in the presence of EGFR wild-type suppressors, followed by hybridization of biotinylated PCR products to teststrips presenting a parallel array of allele-specific oligonucleotide probes. The hybridization and detection steps can be carried out fully automated using commercially available instrumentation.
Results: StripAssay performance was evaluated using genomic DNA obtained from cultured cell lines and formalin-fixed paraffine-embedded

(FFPE) tumor tissue. Plasmid clones harbouring the respective EGFR mutations served as reference templates to control for test specificity. By using normal DNA spiked with serial dilutions of DNA from EGFR-mutant tumor cell lines all mutations were shown to be detectable at a level of 1%.
Conclusions: The simultaneous detection of EGFR mutations with a sensitivity of 1% makes the StripAssay a very useful tool for the assessment of the EGFR mutation status of cancer patients.
No conflict of interest.

979 POSTER

Relationship between insulin resistance and tumor burden in cancer patients

S. Hescot[1], J.P. Durand[1], J. Alexandre[1], F. Goldwasser[1]. *[1]Groupe Hospitalier Cochin, Oncology, Paris Cedex 14, France*

Background: Insulin resistance (IR) is a risk factor for various cancers in many epidemiologic and preclinical studies. Prevalence of IR remains unknown in cancer patients.
Methods: We measured homeostasis model assessment (HOMA) defined as fasting glycaemia (mmol/l) x fasting insulinemia (mU/l)/22.5 and recorded criteria of metabolic syndrome (waist circumference, hypertension, triglyceridemia, HDL cholesterol level and fasting glycaemia) and C Reactive Protein (CRP) in a cohort of cancer patients. Patients with diabetes mellitus and corticosteroid treatment were excluded.
Results: We included 101 patients, 54 males, with a median age of 59 years (range 20−89), and with a WHO Performance Status $\geqslant$2 in 21.8%. Median HOMA was 2.1 [95% CI 2.148–2.719] and 23% of patients had a metabolic syndrome. HOMA was not related to waist circumference, BMI or CRP. The most frequent primary tumors were sarcoma, genito-urinary and gastro-intestinal (21.8% each). HOMA was found in the highest quartile (HOMA>3.15) in 8 out of 22 (36%) patients with sarcoma. Cancer status was long-term remission (n = 11), adjuvant setting (n = 10) and macroscopic disease (n = 80). HOMA was significantly lower in long-term remission patients versus adjuvant setting and macroscopic disease ($p = 0.0149$ and $p = 0.0011$ respectively). Among the 25 patients with HOMA>3.15, median age was 55 years (range 24−82) and all had macroscopic disease ($p = 0.003$ by Chi2 test). Twenty of these patients (80%) had no metabolic syndrome.
Conclusion: We could identify insulin resistant cancer patients. These results should guide the selection of the patients for inclusion in metformin or IGF-R inhibitors clinical trials.
No conflict of interest.

980 POSTER

Neutrophil gelatinase-associated lipocalin in platin induced renal injury

M. Seker[1], K. Deveci[2], E. Sancakdar[2], A.L.I. Yilmaz[3], A. Turesin[3], T. Kacan[1], N. Babacan[1]. *[1]Cumhuriyet University Medical Faculty, Medical Oncology, Sivas, Turkey; [2]Cumhuriyet University Medical Faculty, Biochemistry, Sivas, Turkey; [3]Cumhuriyet University Medical Faculty, Internal Medicine, Sivas, Turkey*

Background: Acute renal injury (ARI) is an important issue in chemotherapy receiving patients. Neutrophil gelatinase-associated lipocalin (NGAL) is a novel marker used in early detection of ARI. In this study we aimed to assess the role of urine NGAL levels in patients receiving platin compounds.
Material and Method: Patients who had treated with cisplatin or carboplatin or oxaliplatin containing regimens at Cumhuriyet University Medical Faculty Cancer Center, included in this study. Patient's baseline and postchemotherapy serum urea, creatinine, urine NGAL and urine creatinine level had determined. To avoid false urine NGAL levels due to hydration during chemotherapy infusion urine NGAL/urine creatinin ratio had used to determine ARI. To examine the relationship between pre and post chemotherapy urine NGAL change, Wilcoxon Signed Ranks Test had used. A p-value of <0.05 had considered significant. The analysis had performed by SPSS version 14.0 software (SPSS Inc., Chicago, USA).
Results: A total of 42 patients, receiving platin compounds, included in this study. Fourteen of them (33.3%) received cisplatin containing regimes, 14 patients (33.3%) received carboplatin and 14 patients (33.3%) received oxaliplatin. The median age was 60 (37−76) years. Sixteen of the patients (38.1%) were lung cancer, 15 were (35.7%) colorectal cancer and 11 were (26.2%) other cancers. The median pre and post chemotherapy urine NGAL/urine creatinin ratio in cisplatin group was 15.6 ng/mg and 35.8 ng/mg ($p = 0.016$), in carboplatin group was 32.5 ng/mg and 86.3 ng/mg ($p = 0.019$) and in oxaliplatin group was 40.9 ng/mg and 62.3 ng/mg ($p = 0.3$).
Conclusion: Nephrotoxicity is a serious side effect of chemotherapeutic agents. Although not statistically significant, oxaliplatin may also have nephrotoxic effect. So all platin compounds must be used carefully and urine NGAL measurement seems to be promising in detecting ARI earlier then creatinin.
No conflict of interest.

HER2-based treatment decisions in breast cancer (BC): Test accuracy and its clinical, economic and social impact

M. Vyberg[1], S. Nielsen[1], R. Røge[1], B. Sheppard[2], J. Ranger-Moore[3], E. Walk[4], J. Gartemann[5], V. Teichgräber[6], U.P. Rohr[6]. *[1]Aalborg University Hospital, Institute of Pathology, Aalborg, Denmark; [2]Ventana Medical Systems Inc., Global Standards, Tucson, USA; [3]Ventana Medical Systems Inc., Biostatistics and Data Management, Tucson, USA; [4]Ventana Medical Systems Inc., Medical & Scientific Affairs, Tucson, USA; [5]F. Hoffmann-La Roche, Diagnostics Division, Rotkreuz, Switzerland; [6]F. Hoffmann-La Roche, Diagnostics Division, Basel, Switzerland*

Background: Treatment choice for patients with BC is guided in part by HER2 status. Although FDA-approved *in vitro* diagnostic (IVD) tests are available, nonapproved IVDs are used in many laboratories (approx 30% in Nordic region). Incorrect HER2 results can impact greatly on patient outcomes and healthcare budgets. We analysed the accuracy of HER2 testing approaches using pooled data from the Nordic Immunohistochemical Quality Control (NordiQC) real-world testing programme and used the results in an economic BC treatment model.
Methods: Data were obtained from the NordiQC HER2 BC test programme run from 2008–2012 (www.nordiqc.org). False-negative (FN; a 3+/2+ amplified tumour but stained as 0 or 1+) and false-positive (FP; a 0/1+/2+ unamplified tumour but stained as 3+) rates were calculated for approved vs nonapproved IVDs and used to calculate economic costs of inaccurate results, loss of survival, productivity benefit and QALYs. Costs were extrapolated to numbers of US patients with BC (early BC [EBC] n = 209 737; metastatic BC [MBC] n = 20 743) using a 1-y time horizon. US costs and population sizes were used because of the homogeneity of the US healthcare system pricing framework.
Results: 1703 tests were performed (1145 [67%] approved IVDs; 558 [33%] nonapproved IVDs). Pooled FN rates were 11% and 25%, respectively; FP rates were 0% and 5%, respectively. Incorrect results were largely due to misclassified 2+ samples. The total direct cost/patient of inaccurate tests in the model was $69 for approved and $263 for nonapproved IVDs. Extrapolation to the US EBC population gave a potential $41 million cost saving for approved vs nonapproved IVDs. Costs and benefits are shown below. Results were similar for MBC although cost savings were reduced due to the lower incidence of MBC.

Outcome	EBC		
	Approved IVD	Nonapproved IVD	Difference
Total direct cost of inaccurate test, $	14,378,394	55,112,205	40,733,810
Missed QALYs	158	361	203
Lost productivity, $	3,285,434	7,510,050	4,224,615
Missed survival benefit, y	187	426	239

Conclusions: This analysis suggests that incorrect HER2 test results have far-reaching clinical, social and economic consequences that should be considered when requesting a test. Oncologists and pathologists need to be aware that differences between available tests impact patient outcome in terms of missed survival benefit and exposure to unnecessary toxicity, as well as costs. Adhering to testing guidelines ensures accurate results and correct treatment for patients with BC.

982 POSTER

A new imaging biomarker to predict anti-angiogenic therapy efficacy in phase 1 trials: AUC changes with dynamic contrast enhanced-ultrasonography (DCE-US)

R. Cohen[1], S. Koscielny[2], J.C. Soria[1], J.P. Armand[1], B. Benatsou[3], N. Lassau[3]. [1]*Institut Gustave Roussy, Service Innovations Thérapeutiques Essais Précoces (SITEP), Villejuif, France;* [2]*Institut Gustave Roussy, Service de Biostatistiques et d'Epidémiologie, Villejuif, France;* [3]*Institut Gustave Roussy, IRCIV. IR4M − UMR8081, Villejuif, France*

Background: Antiangiogenics compounds are widely prescribed but lack a predictive biomarker of efficacy. The objective of this analysis was to confirm the decrease of AUC in DCE-US at day 15 and day 30 as a tool able to predict time to progression (TTP) in phase 1 trials enrolling patients exposed to anti-angiogenic compounds.
Material and Methods: All patients (pts) included in phase 1 trials with anti-angiogenic compounds, between 2005 and 2013 in our institution and having underwent standardized DCE-US evaluation at baseline, D15 and D30 were retrospectively reviewed. DCE-US methodology: a bolus injection of contrast medium, 3 minutes of recorded raw linear data with 4 frames per second and the quantification using ESFUMB guidelines. Pts were identified from a prospective database. TTP and OS were calculated from the initiation of the new agents, according to clinical data and using RECIST v1.1 criteria. A decrease of more than 40% of AUC at D15 and one month was assumed to be predictive of TTP.
Results: Two hundred and seven patients were analyzed from September 2005 to March 2013. Seventy pts were excluded: no anti-angiogenic agents (n = 31), screen failure (n = 27), discontinuation of study participation before day 30 (n = 2), no US-evaluation at 1 month (n = 7), no US-target (n = 3). A total of 137 pts from 7 trials were included: 32 pts with vascular disrupting agent (VDA), 93 pts with a TKI, 2 pts with monoclonal antibodies (mAb), 10 pts with both VDA and mAb. The median overall survival was 15.5 months, with 110 deaths at the time of statistical analysis. In the training cohort (n = 26), pts with a decrease of more than 40% of AUC at one month had a median TTP of 5.5 months, versus a median TTP less than 2 months for the other patients. The decrease of AUC at one month was correlated to TTP (p = 0.004). The 111 patients from the validation cohort are under radiological review (349 CT scans) for TTP.
Conclusion: The decrease of more than 40% of AUC with DCE-US at one month is a potential predictive biomarker of response for anti-angiogenic treatments in metastatic patients. The final results will be presented on 137 patients.
No conflict of interest.

983 POSTER

Tumor–stroma ratio as a predictor for response to neoadjuvant chemotherapy (TAC) in breast cancer (BC): A Dutch Breast Cancer Trialists' Group (BOOG) side-study

T.J.A. Dekker[1], A. Charehbili[1], V.T. Smit[2], E.M. Meershoek-Klein Kranenbarg[1], R.A.E.M. Tollenaar[1], C.J.H. Van de Velde[1], G.J. Liefers[1], J.W.R. Nortier[3], W.E. Mesker[1], J.R. Kroep[3]. [1]*Leiden University Medical Center, Department of Surgery, Leiden, Netherlands;* [2]*Leiden University Medical Center, Department of Pathology, Leiden, Netherlands;* [3]*Leiden University Medical Center, Department of Medical Oncology, Leiden, Netherlands*

Background: Intra-tumoral stroma has profound influences on tumor behavior. The tumor–stroma ratio (TSR) has previously been shown to be of prognostic value in breast cancer and other types of solid tumors. However, the role of this parameter regarding the prediction of pathological complete responses (pCR) after neoadjuvant chemotherapy is unknown.
Methods: 250 patients were included in the NEOZOTAC trial: a national, multicenter, randomized study comparing the efficacy of TAC (docetaxel, adriamycin and cyclophosphamide i.v. day 1) chemotherapy followed by G-CSF on day 2 with or without zoledronic acid 4 mg i.v. 3 weeks in patients (pts) with stage II/III, measurable, HER2-negative BC. The percentage of intra-tumoral stroma was visually estimated on diagnostic sections from primary tumor tissue by two observers. A third independent observer was consulted in case of outcome discordances. The cut-off point between stroma-rich and stroma-poor tumors was set to 50% (as determined in previous investigations). Tumor–stroma ratio was related to centrally revised pCR data. Reproducibility of results will be further investigated by comparing CNB and resection specimens.
Results: 194 specimens were evaluated. Cohen's kappa coefficient for inter-observer agreement showed a substantial agreement in classification (k=0.64, 82% concordance). 37% of the specimens were classified as stroma-rich. Stroma-rich tumors were significantly associated with T-stage (P = 0.08) and ER-status (P = 0.004). In univariate analysis, TSR predicted for pathological complete response (P = 0.03) with greater pCR rates observed in tumors with a a low percentage of intratumoral stroma (22.7% vs. 10.3%). After multivariate analysis, this effect did not persist (OR 1.58, 95% C.I. 0.63–3.93), presumably because of a current low number of patients across groups. Final results will be presented at the ECCO.
Conclusions: These results suggest that the TSR is a reproducible marker for response to treatment with neoadjuvant chemotherapy. Considering the simplicity and low cost of TSR assessment, it should be considered as a candidate for further investigation and eventually for implementation in pathology reports.
No conflict of interest.

984 POSTER

Evaluation of a chemoresponse assay as both a prognostic and predictive marker in the treatment of persistent or recurrent ovarian cancer

R. Coleman[1], D. Sargent[2], T. Krivak[3], M. Gabrin[4], S. Brower[4], C. Tian[4]. [1]*University of Texas MD Anderson Cancer Center, Gynecologic Oncology and Reproductive Medicine, Houston TX, USA;* [2]*Mayo Clinic, Health Sciences Research, Rochester MN, USA;* [3]*Magee-Womens Hospital of UPMC, Gynecologic Oncology, Pittsburgh PA, USA;* [4]*Precision Therapeutics Inc., Product Development, Pittsburgh PA, USA*

Background: A recent study demonstrated significant improvement in clinical outcome in recurrent epithelial ovarian cancer (EOC) patients treated with therapies identified as sensitive (S) based on an in vitro chemoresponse assay. Together with previous studies, these results support that the assay provides prognostic value. The assay's ability to function as a predictive biomarker of patient outcome is investigated in this analysis.
Material and Methods: Women with persistent or recurrent EOC (n = 262) were treated with one of 15 therapies based on the medical judgment of the treating physician, blinded to assay results. Each patient's tumor was assayed for response to the 15 therapies in vitro. Three approaches were used for estimating the assay's predictive value. First, the assay's relative ability to predict progression-free survival (PFS) for patients treated with a therapy for which they were considered to be S vs. resistant (R) (match) was compared to the average prognostic value of S vs. R to a randomly selected treatment (mismatch) based on repeated resampling of the patient population. Next, patients were classified into groups based on assay results and clinical treatment: S to all tested therapies and treated with a S therapy (SA), S to some therapies and treated with a S therapy (SP), R to all therapies and treated with a R therapy (RA), and R to some therapies and treated with a R therapy (RP). Clinical outcome was compared among groups whose response was primarily dependent on tumor biology (SA, RA; prognostic) and groups whose assay results were heterogeneous and may benefit from specific treatment choice(s) (SP, RP; predictive). Third, the percentage of S therapies was included in multivariate analysis.
Results: The assay result for 'match' was significantly associated with PFS (HR = 0.67, 95% CI=0.50–0.91, p = 0.009). Based on 1000 simulations, the mean HR[mismatch] was 0.81 (95% range = 0.67–0.91), suggesting that HR[match] was predictive of response to a specific treatment. The improvement in median PFS for both SA vs. RA (HR = 0.72, 95% CI=0.44–1.18, p = 0.191) and SP vs. RP (HR = 0.70, 95% CI=0.46–1.05, p = 0.081) was consistent. The association between assay result for administered therapy and PFS remained statistically significant in multivariate analysis (HR = 0.61, 95% CI=0.41–0.89, p = 0.010), independent of the percentage of S therapies, indicating the value of the assay for predicting outcome was not due to tumor biology alone.
Conclusions: These results support that the chemoresponse assay is likely both predictive and prognostic of patient outcome. Further, these results suggest that recurrent EOC patients treated by assay-sensitive therapies may obtain improved clinical outcomes.
Conflict of interest: *Ownership: M Gabrin, S Brower, C Tian hold stock options from Precision Therapeutics, Inc. Other substantive relationships: D Sargent received consulting income from Precision Therapeutics, Inc.*

985 POSTER

Relationships of peripheral blood lymphocyte counts (PBLC) with antitumor activity of NGR-hTNF in combination with chemotherapy (CT)

M.G. Viganò[1], V. Gregorc[1], G. Rossoni[1], A. Bulotta[1], G. Todisco[1], A. Lambiase[2], C. Bordignon[2]. [1]*Istituto Scientifico San Raffaele, Department of Oncology, Milan, Italy;* [2]*MolMed, Clinical Development, Milan, Italy*

Background: NGR-hTNF, a tumor-targeted antivascular agent, produces antitumor effects at low dose by inducing an early vessel stabilization that greatly improves both intratumoral CT uptake and T-cell infiltration.

Synergism with CT has been shown in immunocompetent mice, but not in nude mice lacking functional T cells.
Methods: The associations of baseline PBLC with the antitumor activity of N (with or without CT) and CT alone was assessed by means of an individual patient pooled analysis of 427 patients (pts) from 7 phase II trials in 6 tumor types. NGR-hTNF was given at low dose (0.8 μg/m^2) in combination with CT in 183 pts. As control groups, 140 and 104 pts receiving N and CT alone, respectively, were also analyzed. CT consisted of doxorubicin or a platinum-based regimen. In all trials, response to treatment according to RECIST was evaluated every 6 weeks. Endpoints of interest were response rate (RR, complete plus partial response), disease control rate (DCR, RR plus stable disease), duration of response (DOR) and progression-free survival (PFS). Continuous PBLC data were categorized into high vs low levels using the median cutpoint (1.5/mL; 95% CI, 1.4−1.6). In multivariate logistic and Cox regression models, age, sex, PS and tumor type were included as covariates.
Results: There were no statistically significant differences in treatment effect according to baseline PBLC in both N-alone and CT-alone groups. Conversely, in the N plus CT group, high PBLC were related to better outcomes, as compared with low PBLC. In this N plus CT group, high PBLC (vs low) were associated with higher RR (OR=2.3; 95% CI, 1.0−5.3; p = 0.04) and DCR (OR=2.7; 1.4−4.9; p = 0.002), and with longer DOR (HR = 0.31; 0.12–0.79; p = 0.01) and PFS (HR = 0.59; 0.43–0.81; p = 0.001). For high vs low PBLC, RR was 23% vs 11%, DCR 74% vs 51%, median DOR 8.7 vs 6.3 months, and median PFS 5.0 vs 3.0 months, respectively. On multivariate analyses, high PBLC remained an independent predictor of increased RR (OR=2.4; 1.0−5.5; p = 0.04) and DCR (OR=2.7; 1.4−5.2; p = 0.003), and improved DOR (HR = 0.24; 0.08−0−80; p = 0.02) and PFS (HR = 0.59; 0.43–0.82; p = 0.002).
Conclusions: Consistently with preclinical data, these results highlight the potential value of PBLC in predicting tumor response to NGR-hTNF in combination with CT, which merits further clinical investigation.
No conflict of interest.

986 POSTER

Identification of the activated form of the estrogen receptor (ER) in breast cancer (BC)

E. Gilles[1], J. Bosq[2], S. Fuqua[3], A. Zukiwski[4], J.M. Caillaud[5], B. Gilles[6], J. Bonneterre[7]. *[1]Invivis Pharmaceuticals, Bridgewater, USA; [2]Institut Gustave Roussy, Pathology, Villejuif, France; [3]Baylor Breast Center, Biology, Houston, USA; [4]Arno Therapeutics, Research, Flemmington, USA; [5]Biodoxis, Pathology, Paris, France; [6]Invivis Pharmaceuticals, Research, Bridgewater, USA; [7]Oscart-Lambret, Medicine, Lille, France*

Background: About 50% of ER positive (ERpos) BC are resistant to hormone treatment. In absence of ligand, ERs are evenly distributed in nuclei in normal tissue. Upon ligand binding, ERs dimerizes and form a discrete focal subnuclear distribution pattern (FDP), which are associated with transcriptional activation of ER. This ER FDP is observed in BC. We hypothesized that in BC that the presence/absence of ER in the FDP could predict antiestrogen activity. This study describes an immunohistochemistry (IHC) method, by which a biomarker could be developed to investigate this hypothesis.
Methods: 37 paraffin embedded, formalin fixed archived BC samples were processed using 4 ER-alpha antibodies (Ab) under different IHC conditions to develop and refine this biomarker, the ER nuclear morphology was analyzed with standard microscopy at x1000. Interpretation of the IHC slides was done by an experienced pathologist. Standard ER, progesterone receptor (PR), and Ki67 testing were done. Tumor grade was obtained from the patients' records. Analysis of the different Ab was with the kappa statistics. Comparison of the IHC technique to immunofluorescence (IHF) was done on 8 samples.
Results: Consistent with prior research observations, tumors had two ER nuclear morphologies: 1. Diffuse pattern (D) where the ER was distributed evenly in a fine granular pattern, 2. Aggregate pattern (A) where the ER is distributed in distinct clumps or aggregates.
This defined 3 tumor phenotypes: A cells only (A) 1% (4/37), D cells only (D) 65% (24/37), and a heterogenous mix of A + D cells (AD) 18% (7/37), ER Neg 14% (5/37). IHC and IHF analysis for ER nuclear morphology was concordant. The ER activation status (A/AD or D) was not correlated with staining ER intensity, ERpos %, PRpos%, but was correlated with % Ki67 staining (p = 0.09) and tumor grade (0.035).
Conclusions: ERpos early BC biopsies can be grouped in two categories based on ER nuclear morphology: A group with diffuse and homogenous nuclear staining, and a different group with heterogeneous area of cells having a nuclear pattern consistent with a functional or activated ER. These observations warrant clinical pathological studies to determine if this biomarker is potentially predictive of clinical outcomes.

987 POSTER

Pharmacogenetic assessment of toxicity in patients treated with taxane-based chemotherapy for solid tumors

V. Durante[1], R. Giusti[1], V. Sini[1], S. Angelini[1], P. Pellegrini[1], G. Gentile[2], M. Simmaco[2], P. Marchetti[1]. *[1]Sant' Andrea Hospital − Sapienza University of Rome, Medical Oncology Unit, Rome, Italy; [2]Sant' Andrea Hospital − Sapienza University of Rome, Advanced Molecular Diagnostics Unit, Rome, Italy*

Background: Taxanes are active agents widely used to treat many solid tumors. However, the utility of taxane-based therapy could be limited by gastrointestinal toxicities, hematological toxicities, hypersensitivity and cumulative neurotoxicity. Taxanes are metabolized by CYP3A4 and CYP3A5 isoenzymes, and they are a substrate for the ATP binding cassette multidrug-transporters ABCB1. Metabolic pathways of these antitumor agents need a thorough evaluation to understand why some patients experience severe adverse effects. Aim of our study was to evaluate the association between taxane-related toxicities and their metabolism-related genetic polymorphisms in patients affected by solid cancers undergoing taxane-based chemotherapy regimens.
Material and Methods: We examined 182 adult patients, ECOG Performance Status ⩽1, affected by solid tumors who underwent treatment with taxane-based regimens in adjuvant or metastatic setting, planned for at least 3 courses of therapy. Through a peripheral venous blood sampling we genotyped them for selected polymorphisms and ABC-transporters that may influence cellular sensitivity to taxanes: CYP3A4*1B (A> G), CYP3A5*3 (G> A) and ABCB1 (1236 C> T; 3435 C> T). SNPs (Single Nucleotide Polymorphism) were characterized by pyrosequencing. Statistical analysis was conducted by MINITAB 16.2.3 software. A value of p < 0.05 was considered statistically significant.
Results: Toxicities and polymorphisms were evaluated in 182 patients (12 males and 170 females). Median age of patients was 59 (range 30−82). Patients who received taxanes were 95 in adjuvant setting and 87 in the metastatic one. We observed a significant association between normal homozygous genotype for ABCB1 polymorphism (3435 C> T) and lower toxicity during therapy with taxane-based regimens (p = 0.012). An association between mutant homozygous and normal homozygous genotypes with dose limiting toxicities was demonstrated, even though not statistically significant (p = 0.058). A larger cohort of patients must be investigated. The multivariate analysis results were independent from the different taxane-based regimens adopted, age and stage of disease.
Conclusions: ABCB1 3435 C>T polymorphism seems a toxicity predictive biomarker for taxanes. On the other hand, a larger cohort of patients must be investigated to define the role of CYP3A4, CYP3A5 and ABCB1 (1236 C>T) polymorphisms.

EGFR homodimers in tumor samples quantified by a new antibody based TR-FRET assay are associated with colorectal cancer progression

E. Lopez-Crapez[1], A. Ho-Pun-Cheung[1], J. Ramos[2], F. Boissière-Michot[1], F. Bibeau[1], C. Larbouret[3], M. Ychou[3], H. Bazin[4], P. Garnero[4], E. Assenat[1]. *[1]Institut du Cancer de Montpellier, Montpellier Cedex 5, France; [2]Center Hospital University, Montpellier, France; [3]Institut de Recherche en Cancérologie de Montpellier, Montpellier Cedex 5, France; [4]Cisbio Bioassays, Codolet, France*

Background: Following the development of targeted therapies against EGFR and HER2, two members of the human epidermal receptor (HER) family of receptor tyrosine kinases, much interest has been focused on their expression in tumors. EGFR is frequently expressed on colorectal cancer tumors and EGFR targeted therapies are currently used in the metastatic setting. Data on EGFR homodimerization, an index of receptor activation, are lacking.
The aim of the study was the description and clinical relevance of EGFR protein and dimer expression levels in colorectal tumors.
Material and Methods: Analysis of EGFR was assessed in a series of 60 frozen tumor samples from patients with colorectal cancer by using recently developed antibody-based time-resolved Förster resonance energy transfer (TR-FRET) assays. Quantification of EGFR protein expression levels was determined together with EGFR:EGFR homodimers. EGFR and EGFR-EGFR fluorescence signals were normalized for cell content in the tumor samples and correlated to clinicopathological parameters and outcome of patients.
Results: The median absolute EGFR protein expression levels was 7 400 (range 2 700−1 474 400) and EGFR:EGFR homodimers were detected in 19 (31.7%) tumors. Correlations with clinicopathological patients' characteristics demonstrate that EGFR:EGFR homodimer presence was

significantly associated with advanced pTNM stage (P = 0.003). The potential role of EGFR:EGFR dimers as predictive markers could be assessed in twenty chemotherapy-refractory metastatic patients that were treated with cetuximab. In this subgroup of patients no significant correlation was observed between EGFR activation observed through EGFR:EGFR homodimer presence and response to EGFR-targeted therapy.
Conclusion: Quantitative measurement of expression and dimerization of EGFR by the novel TR-FRET assays provides new information on colorectal cancer patients. Indeed, the signaling pathways triggered by EGFR:EGFR homodimers seems to play an important role in colon cancer dissemination. Validation is ongoing in an independent cohort of 134 patients with colorectal cancer and will be presented.

Fragmented peptides of prostate-specific antigen (PSA) as novel urinary biomarker candidates for diagnosis of prostate cancer

K. Nakayama[1], T. Inoue[1], S. Sekiya[2], N. Terada[1], T. Hara[3], S. Kawabata[2], S. Iwamoto[2], K. Shimizu[4], K. Tanaka[2], O. Ogawa[1]. *[1]Graduate School of Medicine Kyoto University, Department of Urology, Kyoto, Japan; [2]Shimadzu Corporation, Koichi Tanaka Laboratory of Advanced Science and Technology, Kyoto, Japan; [3]Graduate School of Medicine Kyoto University, Center for Genomic Medicine, Kyoto, Japan; [4]Graduate School of Pharmaceutical Sciences Kyoto University, Department of Nanobio Drug Discovery, Kyoto, Japan*

Background: Prostate cancer (PCa) will affect one in five men and is now the second leading cause of cancer deaths among men in the Western countries. Biomarkers, such as prostate specific antigen (PSA) level in serum, play pivotal roles in the management of the cancer patients. However, currently used biomarkers for PCa are sub-optimal. Therefore, great emphasis has been placed on the need to discover novel biomarkers for PCa diagnosis.
Methods: We focused on urine samples voided after prostate massage (digital rectal examination [DRE]) and conducted peptidomic and proteomic analyses of the urine samples using matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF/MS^n). The urinary biomaterials were concentrated and desalted by a weak cation-exchange resin prior to MALDI-TOF/MS analyses.
Results: A high-resolution and high-sensitivity MALDI digital ion trap (DIT) TOF/MS^n was utilized in order to analyze the urinary peptides and protein-fragments in this study. Mass profiles of urine samples from healthy, BPH, and PCa subjects were compared. Several differences among these mass profiles were detected, especially between PCa and BPH. The most pronounced peak was detected around m/z 2,300. Other characteristic peaks in PCa were also detected around m/z 1,200, 1,300 and 4,700. Two peaks around m/z 1,200 and 1,300 became larger than those in the BPH mass profiles, whereas the peak around m/z 4,700 of the BPH became larger than that of PCa. The most pathognomonic peptide around m/z 2,300 in the DRE urine samples of PCa patients was confirmed as a C-terminal PSA fragment. It was verified that the C-terminal peptide was produced from PSA in prostate glands and was secreted into the urine by DRE. The two peptides around m/z 1,200 and 1,300 were also confirmed as the fragments of PSA near the center.
Conclusions: Our findings indicate: 1) the peptide fragments, especially the C-terminal fragment, of PSA in the DRE urine may become a novel pathognomonic biomarker candidate for PCa diagnoses; and 2) the fragmentation may be a pathognomonic bio-reaction in microenvironment of the PCa cells. Further examinations are underway to prove this possibility regarding the PSA fragmentation in the urine samples after prostate massage.

The predictors for micro-invasion of hepatocellular carcinoma ⩽2 cm

Y. Yamashita[1], K. Shirabe[1], T. Toshima[1], N. Harimoto[1], T. Ikegami[1], T. Yoshizumi[1], Y. Soejima[1], T. Ikeda[1], Y. Maehara[1]. *[1]Kyushu University, Department of Surgery and Science, Fukuoka, Japan*

Background and Aims: Hepatocellular carcinoma (HCC) of 2 cm diameter or less (⩽2 cm) is considered to have a low potential for malignancy based on the so-called stepwise progression hypothesis. But in fact, there have been cases with HCC⩽2 cm accompanied by micro-invasion (MI) and poor prognosis based on an alternative hypothesis of de novo development. The aim of present study was to identify independent predictors for MI of small HCC⩽2 cm.
Methods: A retrospective review was undertaken of 149 patients with primary solitary HCC⩽2 cm who underwent initial hepatic resection. The independent predictors of the MI such as portal venous, hepatic vein, or bile duct infiltration and/or intra-hepatic metastasis were indentified using multivariate analysis. Prognosis of patients with HCC⩽2 cm accompanied by MI was compared to that of patients with HCC⩽2 cm without MI.
Results: Forty-three patients with HCC⩽2 cm had MI (28.9%). Three independent predictors of the MI were revealed: invasive gross type (simple nodular type with extranodular growth or confluent multinodular type), des-γ-carboxy prothrombin (DCP) ⩾100 mAU/ml, and poorly differentiated. The sensitivity of DCP>100 mAU/ml for MI in HCC⩽2 cm of 53.5% (23/43 cases) was not very high, but its positive predictive value of 79.3% (23/29 cases) was relatively high. The sensitivity of preoperative imaging diagnosis for invasive gross type in HCC⩽2 cm was low 30.0% (6/20 cases), but the positive predictive value was relatively high 66.7% (6/9). Disease-free survival rates of patients with HCC⩽2 cm with MI were significantly worse than those for HCC⩽2 cm without MI (3-year; 44% vs. 72%). This disadvantage of disease-free survival rate of patients with HCC⩽2 cm with MI could be dissolved by hepatic resection with a wide tumor margin ⩾5 mm (p = 0.04).
Conclusion: Even in cases of HCC⩽2 cm, patients who are suspected of having invasive gross type tumors in preoperative imaging diagnosis or who have a high DCP level (⩾100 mAU/ml) are at risks for MI. Therefore, in such patients, hepatic resection with a wide tumor margin should be recommended.

992 POSTER

Predictive value of plasma D-dimer for asymptomatic metastasis in cancer patients

D. Diao[1], Y. Cheng[1], Z. Wang[2], C. Dang[1], L. Ren[1], Q. Guo[1], Y. Song[1], K. Zhu[1], K. Li[1], D. Liu[1]. *[1]First Affiliated Hospital of Xi'an Jiaotong University, Department of Oncology Surgery, Shanxi, China; [2]First Affiliated Hospital of Xi'an Jiaotong University, Department of Thoracic Surgery, Shanxi, China*

Background: Plasma D-dimer levels are high in patients with advanced tumors and can be used to predict the outcomes of cancer patients. At most advanced tumor stages, patients have asymptomatic metastasis, which contributes to early tumor recurrence after surgery. We hypothesize that plasma D-dimer can be used to identify patients with potential metastasis.
Methods: We first verified our hypothesis in different in vivo murine metastasis models (subcutaneous tumor, intraperitoneal metastasis and hematogenous metastasis), and we examined the plasma D-dimer levels using the enzyme-linked immunosorbent assay (ELISA) method. We then enrolled and examined plasma D-dimer levels by the latex-enhanced immunoturbidimetric assay (LEIA) method in 1268 primary cancer (1042 gastric cancer, 96 esophageal cancer, 50 lung cancer, 37 melanoma, 43 pancreatic cancer) patients in 3 cancer centers in northwestern China. We also followed 395 of 1042 gastric cancer patients at one cancer center to analyze the 2-year survival rate and early tumor recurrence.
Results: Among the three in vivo murine metastasis models, the plasma D-dimer level was extremely elevated in the hematogenous metastasis and intraperitoneal metastasis murine models but not in the subcutaneous tumor model and control group model. These results supported our previous hypothesis. In this large-scale clinical study, we found that plasma D-dimer levels were increased in distant metastasis, especially in patients with hematogenous metastasis. The cut-off value of the D-dimer levels was determined to be 1.5 mg/ml based on the ROC cure, and the sensitivity and specificity for predicting metastasis were 63.2% and 88.5%, respectively. In addition, patients with increased plasma D-dimer levels displayed early hematogenous-associated tumor recurrence and bad outcomes during the follow-up study.
Conclusion: Plasma D-dimer is a potential marker that is easy to measure at a low cost, and this marker can be considered for routine testing in cancer patients to predict asymptomatic metastasis.
No conflict of interest.

993 POSTER

Predictive role for pemetrexed sensitivity of thymidylate synthase expression in advanced cancer patients

J. Garcia-Foncillas[1], M. Domine[1], S. Zazo[1], C. Chamizo[1], C. Carames[1], G. Serrano[1], F. Lobo[1], A. Leon[1], T.C. Hernandez[1], F. Rojo[1]. *[1]Fundacion Jimenez Diaz, Translational Oncology Division, Madrid, Spain*

Background: High expression of thymidylate synthase (TS) in malignant cells has been proposed as a resistance mechanism to the antifolate pemetrexed. This study is aimed to evaluate the association of TS expression by a quantitative assessment in tumor cells with the efficacy of pemetrexed in patients with advanced non-small cell lung cancer, small cell lung cancer (SCLC) and mesothelioma.

Methods: 54 patients were studied: 40 stage IV NSCLC (26 adenocarcinomas, 11 large cell, and 3 squamous cell carcinoma), 3 SCLC and 11 mesothelioma. 21 patients received platins-pemetrexed as first line NSCLC, 20 pemetrexed in monotherapy as second and further lines and 3 carboplatin-pemetrexed fo extensive disease SCLC. RNA was obtained from FFPE tumor sections and the expression of TS was analyzed by RT-qPCR using appropriate mRNA specific primers and probes. TS levels was calibrated to expression in normal tissue.
Results: From 54 cases, TS expression was available in 32 cases, detecting overexpression in 23 (71.8%) and low expression in 9 (28.2%) patients. The response rate for patients with low TS expression was 0.63 compared with 0.15 in patients with overexpression ($p = 0.015$). A significant benefit in time to progression was observed in patients with low expression (median TTP 12 vs. 2 months respectively, $p = 0.002$), whereas did not impact on overall survival (median OS 20 vs. 19 months respectively, $p = 0.595$).
Conclusions: TS overexpression in tumor is associated with a reduced response to pemetrexed-containing chemotherapy and might be used as a predictive biomarker in advanced lung and mesothelioma cancer patients.
No conflict of interest.

994 POSTER

Predictive impact for bevacizumab of VEGF-A 165 family of isoforms in patients with non-squamous non-small cell lung cancer (NSCLC)

F. Rojo Todo[1], S. Zazo[1], C. Chamizo[1], M. Dómine[1], N. Perez-González[1], C. Carames[1], C.L. Aúz[1], G. Serrano[1], F. Lobo[1], J. García Foncillas[1]. *[1]IIS-Hospital Universitario Fundación Jiménez Díaz, Translational Oncology Division, Madrid, Spain*

Background: Bevacizumab is a recombinant monoclonal humanized antibody against vascular endothelial growth factor (VEGF) that improves Time to Progression (TTP) in patients with advanced non-squamous NSCLC, but currently no proven predictive markers exist. The VEGF-A 165 splice variant has been described as the most abundant and active isoform in cancer, where exon 8 modifications generates two family of isoforms with opposite *in vivo* effects, one pro-angiogenic (VEGF 165a) and other anti-angiogenic (VEGF 165b). The objective of this study is to explore the predictive role of $VEGF_{165}$a and $VEGF_{165}$b isoforms in patients with non-squamous NSCLC treated with a doublet of platin plus bevacizumab.
Methods: 22 patients were included (20 adenocarcinomas and 2 large cell carcinomas): 5 received carboplatin–taxol–bevacizumab, 14 carboplatin–taxotere–bevacizumab and 3 cisplatin–gemcitabine–bevacizumab. RNA was obtained from routine clinical samples and $VEGF_{165}$a and $VEGF_{165}$b expression was analyzed by RT-qPCR. Individual $VEGF_{165}$a and $VEGF_{165}$b family of isoforms expression was calibrated to normal tissue and the ratio between both isoforms was calculated.
Results: $VEGF_{165}$a overexpression was detected in 14 (63.6%) cases and $VEGF_{165}$b overexpression in 15 (68.2%) tumors. A predominant expression of the pro-angiogenic $VEGF_{165}$a in tumor was correlated with a significant benefit compared with cases with a predominant $VEGF_{165}$b expression (median TTP, 15 vs. 8 months respectively, $p = 0.005$). However, the expression of these isoforms did not impact on Individual overexpression of these isoforms was not associated with benefit to bevacizumab therapy ($p = 0.933$ and 0.166) or overall survival ($p = 0.477$).
Conclusion: The overexpression of $VEGF_{165}$a isoforms associated with a low expression of $VEGF_{165}$b was correlated with a clinical benefit to bevacizumab therapy in stage IV non-squamous NSCLC patients, supporting a potential use as predictive biomarkers.
No conflict of interest.

995 POSTER

Risk factors of thrombotic microangiopathy in patients treated by antiangiogenics in phase I trials

E. Boissier[1], A. Hollebecque[1], E. Lanoy[2], H. Izzedine[3], R. Bahleda[1], A. Varga[1], A. Gazzah[1], C. Massard[1], E. Carton[1], J.C. Soria[1]. *[1]Institut Gustave Roussy, Sitep, Paris, France; [2]Institut Gustave Roussy, Paris, France; [3]Hôpital Pitié Salpètrière, Néphrology, Paris, France*

Background: Antiangiogenics are effective treatments for several advanced cancers. Thrombotic microangiopathy (TMA) is a well known vascular and renal side effect of these drugs and such adverse event may limit its use. No risk factor of TMA has been described so far. Our objective was to assess the association of high blood pressure (HBP) and other prognostic factors with TMA.
Methods: Our retrospective study included data on all patients recruited from 2010 to 2012 at Gustave Roussy Institute in phase I trials evaluating antiangiogenesic drugs. The definition of TMA was clinical or histological. Patients with and without TMA were compared according to HBP defined as superior to 140 and/or 90 mmHg, sex, age, body mass index, history of antiangiogenic therapy, history of nephrectomy, various biological results, using a multivariable logistic regression model.
Results: Among the 56 patients exposed to antiangiogenic therapy, TMA occurred in 17 patients (30%). The diagnosis of TMA was histologically confirmed in 10 (59%) of 17 patients and schizocytes were present in one patient.
Proportion of women (59%), median age (57 years), history of partial or total nephrectomy (7%) and exposure to bevacizumab for more than 6 months (38%) did not differ in patients with or without TMA. Median level of fibrinogen in g/L was lower in patients with TMA (3.9) than in patients without TMA (5.1, $p = 0.0108$). In the multivariable analysis, TMA was associated with fibrinogen level (OR= 2.27 (95% CI=1.22; 4.35)) and with a clear trend was observed with history of treated hypertension (OR= 3.35(95% CI=0.73;15.34)). Analysis of data on sarcopenia and HBP characterization are on-going.
Conclusion: In our population antiangiogenic, TMA is only correlated with low level of fibrinogen at baseline. However, patients with a history of HBP exhibit a trend to present a higher risk of TMA. Further studies are warranted in order to better select the population eligible to antiangiogenic treatment.
No conflict of interest.

996 POSTER

RRM1 protein expression heterogeneity between diagnostic biopsies and resection specimens and changes in expression during carboplatin and paclitaxel treatment in non-small cell lung cancer

J. Jakobsen[1], E. Santoni-Rugiu[2], J.B. Sørensen[1]. *[1]Rigshospitalet Copenhagen University Hospital, Department of Oncology, Copenhagen, Denmark; [2]Rigshospitalet Copenhagen University Hospital, Department of Pathology, Copenhagen, Denmark*

Background: It is of interest if potentially predictive biomarkers such as RRM1 expression changes during chemotherapy if they are to be used for deciding treatment beyond first line.
Materials and Methods: RRM1 immunohistochemistry was performed on tumor samples from a total of 118 NSCLC patients T1−4N0−2M0. Samples from 65 patients, among which 53 had paired samples from before and after paclitaxel and carboplatin and 53 patients which had not been treated with chemotherapy, were included.
Results: No change in RRM1 expression was observed between paired samples of primary tumors in the NAC-group ($p = 0.524$) nor in the OP-group ($p = 0.171$). A mean H-score decreased of 0.2 in both groups ($p = 0.905$). RRM1 expression was higher after chemotherapy than before in N2-node metastases ($p = 0.010$). A discordant RRM1 expression (low vs. high) was observed in 32% paired diagnostic and subsequent resection specimen in the OP-group.
Conclusion: The substantial discordance between paired samples emphasizes the need of sufficient tumor tissue in biopsies when evaluating RRM1 expression. No change in RRM1 expression was observed in primary tumors but RRM1 was increased in N2-lymph node metastases following chemotherapy. Potential post-chemotherapy changes in RRM1 expression may be considered when basing treatment decisions beyond first line on RRM1 expression.
No conflict of interest.

997 POSTER

Significance of smudge cell on blood smear in chronic lymphocytic leukemia patients: A prospective single institutional study from India

A. Gogia[1], V. Raina[1], A. Sharma[1], L. Kumar[1], R. Gupta[2], S. Gajendra[2], S. Vishnubhatla[3]. *[1]All India Institute of Medical Sciences, Medical Oncology, Delhi, India; [2]All India Institute of Medical Sciences, Lab Oncology, Delhi, India; [3]All India Institute of Medical Sciences, Biostatistics, Delhi, India*

Background: Smudge cells are ruptured lymphocytes seen on routine blood smears of chronic lymphocytic leukemia (CLL) patients. We evaluated significance of smudge cells percentage on a blood smear in CLL patients.
Methods: We calculated smudge cell percentages (ratio of smudged to intact cells plus smudged lymphocyte) on blood smears of 175 consecutive untreated CLL patients registered at I.R.C.H, AIIMS, New Delhi over a period of 5 years (2006–2010).
Results: There were 130 males and 45 females. The median age was 59 years (30−88). Median absolute lymphocyte count was 40 $X10^9$/L. Clinical Rai stage distribution was: stage 0−5%, stage I − 25%, stage II − 40%, stage III −10 % and stage IV − 20%. The median smudge cells percentage was 28% (4% −76%). There was no correlation of proportion of smudge cells with age, sex, lymphocyte count, lymphocyte doubling time, beta 2 microglobulin, organomegaly, ZAP 70 + or CD 38 + CLL patients, but there was significant correlation with stage of disease. Median smudge cell

percentage in stage 0 & I −36% (12−76), stage II- 30% (12−61) and stage III&IV-20% (4−51) [p < 0.001]. Eighty five patients of early stage (0, I &II) patients required treatment during follow up [65% required treatment with smudge cell <30%, against 35% patients requiring treatment with smudge cells >30%, p = 0.01]. The percentage of smudge cells as a continuous variable correlated with OS [HR 0.96, p < 0.001]. The 5-year survival rate was 51% for patients with 30% or less smudge cells compared with 76% for patients with more than 30% of smudge cells. Median OS was 4.8 years with median follow up period of 3.6 years. Smudge cells percentage (<30% vs. >30%) had significant association with OS [HR 0.97, 95% CI (0.62–1.21), p = 0.001)].
Conclusions: Simple and inexpensive detection of smudge cells on blood smears on routine diagnostic test useful in predicting progression free and OS in CLL patients and may be beneficial in countries with limited recourses.
No conflict of interest.

998 POSTER

Circulating endothelial cells and dynamic contrast enhanced magnetic resonance imaging (DCE-MRI) parameters as predictive biomarkers for survival benefit in patients with advanced non-small cell lung cancer (NSCLC) treated with sorafenib and metronomic oral vinorelbine

E. Tan[1], Q.S. Ng[1], W.Y. Li[2], B. Haaland[2], M.K. Ang[1], C.H. Thng[3], B. Chowbay[4], K.M. Hui[5], D.S.W. Tan[1], W.T. Lim[1]. *[1]National Cancer Centre, Medical Oncology, Singapore, Singapore; [2]Duke-NUS, Centre for Quantiative Medicine, Singapore, Singapore; [3]National Cancer Centre, Diagnostic Imaging, Singapore, Singapore; [4]National Cancer Centre, Pharmacology, Singapore, Singapore; [5]National Cancer Centre, Molecular Biology, Singapore, Singapore*

Background: Biomarkers to predict benefit from anti-angiogenic therapy are still lacking. RECIST response criteria are inadequate for accurate evaluation of response. Sorafenib and metronomic oral vinorelbine combination was explored in this study and changes in blood and DCE-MRI parameters were investigated as potential predictive biomarkers of benefit.
Material and Methods: Eligible patients with advanced NSCLC who failed multiple prior lines of palliative chemotherapy were recruited to 3 successive cohorts. Each cohort was given a fixed metronomic (thrice a week) dose of oral vinorelbine at 60 mg/week, 90 mg/week, and 120 mg/week respectively. Each patient within each cohort received a starting dose of sorafenib at 200 mg bid for 4 weeks. In the absence of dose-limiting toxicities, the dose of sorafenib would be escalated to 400 mg bid for 4 weeks, 600 mg bid for 4 weeks and finally 800 mg bid. Biomarkers measured serially include DCE-MRI parameters, circulating endothelial cells (CECs) and circulating endothelial progenitor cells (CEPs), and plasma thrombospondin-1 level (TSP-1). The following DCE parameters were analyzed: blood flow(F), permeability surface area product(PS), fractional intravascular blood volume (v1), and extracellular-extravascular volume (v2).
Results: 46 evaluable patients were analysed. There were 5 partial responders (10.9%) and 22 with stable disease lasting at least 4 months (47.8%). Evaluation for biomarker response was performed only for the first 2 cycles of treatment due to the subsequent high attrition rate. There was no significant change in the biomarker parameters between the 3 cohorts. Collective analyses of the 3 cohorts demonstrated a significant near-universal decline in CEP, TSP and PS, and a significant increase in V2 after 2 cycles of treatment. These parameters however, were not predictive of survival benefit. Using multivariate modeling, high baseline or rise in CEC and lower baseline V1 predicted for improved overall survival(OS), while a low baseline or a decline in F predicted for improved progression-free survival (PFS).
Conclusions: Sorafenib and metronomic oral vinorelbine is active in advanced NSCLC. Baseline levels and changes in DCE parameters (F and V1) and CEC may be useful predictive biomarkers for survival benefit with this anti-angiogenic regimen.
No conflict of interest.

999 POSTER

Class-III-β-tubulin expression levels remains unchanged during carboplatin and paclitaxel treatment in non-small-cell lung cancer

J. Jakobsen[1], E.S.R. Santoni-Rugiu[2], J.B.S. Sørensen[3]. *[1]Rigshospitalet Copenhagen University Hospital, Onkologisk afd. 5073, Copenhagen, Denmark; [2]Rigshospitalet Copenhagen University Hospital, Department of Pathology, Copenhagen, Denmark; [3]Rigshospitalet Copenhagen University Hospital, Department of Oncology, Copenhagen, Denmark*

Introduction: Class-III-beta-tubulin (TUBB3) is a tubulin isoform involved in microtubule formation during mitosis. Its expression may be a potential predictive factor for outcome in non-small cell lung cancer during microtuble interfering cytotoxic treatments such as vinca alcaloids and taxanes. We investigated for changes in TUBB3 expression during neoadjuvant chemotherapy including taxanes, which may be of interest if future choice of chemotherapy is to be based on TUBB3 expression. If the biomarker expression changes during chemotherapy, biopsies before initiation of chemotherapy beyond 1st line may be required. Thus, the aim was to explore on TUBB3 expression heterogeneity and changes during chemotherapy.
Materials and Methods: TUBB3 expression immunohistochemístry on diagnostic biopsies and on available subsequent resection specimens in 65 non-small cell lung cancer (NSCLC) patients stage T1−3N0−2 (NAC-group). These patients received preoperative carboplatin and paclitaxel. Another group of 53 NSCLC patients stage T1−4N0−1 were treated with surgery alone without preceding chemotherapy (OP-group). Paired samples of diagnostic and resection specimens were compared in order to evaluate for changes in TUBB3 expression.
Results: No statistically significant change in TUBB3 expression was observed between initial diagnostic biopsies and subsequent surgical resections of primary tumors in either the OP-group (p = 0.124) or the NAC-group (p = 0.414). When dichotomized into high and low TUBB3 expression, discordance between diagnostic biopsies and resection specimens of the primary tumors occured in 22% and 40% in the OP-group and NAC-group, respectively (p = 0.169). Changes in TUBB3 expression were not associated with prognosis but significantly more patients having low TUBB3 expression experienced down-staging during neoadjuvant chemotherapy compared to patients having high TUBB3 expression (p = 0.0220).
Conclusion: We observed a high degree of discordance of TUBB3 expression between paired serial tumor samples, which likely reflects intratumoral heterogeneity. This emphasizes a need for sufficient tumor tissue in order for stratification of patients based on TUBB3 expression. However, there were no significant changes in TUBB3 expression after neoadjuvant carboplatin and paclitaxel chemotherapy, suggesting no need for rebiopsy in case of need for second line chemotherapy with microtubule interfering cytotoxic treatments. Low TUBB3 expression predicts down-staging during neoadjuvant chemotherapy.
No conflict of interest.

Expression of progesterone receptor membrane component-1 in non-small cell lung cancer

T. Bogush[1], M.V. Nureev[2], A.A. Kamensky[2], B.E. Polotsky[3], S.A. Tjulandin[3], M.I. Davydov[3]. *[1]N. N. Blokhin Russian Cancer Research, Laboratory of Medical Chemistry, Moscow, Russian Federation; [2]M. V. Lomonosov Moscow State University, Department of Physiology, Moscow, Russian Federation; [3]N.N. Blokhin Russian Cancer Research Center of the Russian Academy of Medical Sciences, Laboratory of Medical Chemistry, Moscow, Russian Federation*

Background: The progesterone receptor membrane component-1 (Pgrmc1) protein is upregulated in cancer, and it is required for tumor cell proliferation, motility and tumor formation in vivo. Inhibition of Pgrmc1 suppressed the growth of lung, breast and cervical cancer cell lines. Recent studies in vitro have shown that one of the reasons of platinum resistance can be overexpression of the Pgrmc1. Taking in account that treatment of non-small cell lung cancer (NSCLC) is based on platinum included chemotherapy and its efficacy is not satisfactory because of tumor resistance, we have proposed this resistance mechanism dealing with Pgrmc1expressin in cancer patients. To answer the question we have studied level and frequency of Pgrmc1expression in NSCLC tissues.
Materials and Methods: NSCLC surgical biopsy specimens of smoking male patients with squamous cell carcinoma (40) and adenocarcinoma (20) were analyzed by flowcytometry. Single-cell suspensions obtained from the tumors were incubated with primary rabbit polyclonal IgG to Pgrmc1 antibodies (Abcam) overnight and with secondary FIT?-conjugated goat polyclonal to rabbit IgG antibodies (Abcam) for 1.5 h. Mean number of specifically stained cells were analyzed by WinMDI software and Kolmogorov-Smirnov statistical approach. Pgrmc1 expression was estimated as ratio of the specific parameter to the same isotype one. Two indexes of Pgrmc1 expression were used: high level − Pgrmc1was revealed in 20−50% of the cells, low − less than in 20%.
Results: 1. Pgrmc1 expression (specific fluorescence more than in 10% of the cells) was revealed in 70% of NSCLC patients. High level (29.9±8.1%) was in 36% of the tumors, 67% of which were adenocarcinomas. Low level (14.8±2.4%) was in 64% of the tumors, 81% of which were squamous cell carcinomas. 2. In squamous cell carcinomas mean Pgrmc1 level was 15%, but in adenocarcinomas − 1.7 times higher (26%, p = 0.013). 3. In squamous cell carcinoma patients low Pgrmc1 level was revealed in 81% of cases, but high − in 19% only. In contrast, in adenocarcinoma patients high Pgrmc1 level was revealed in 67%, but low − in 33% only.

Conclusion: Pgrmc1 expression was revealed in the majority of NSCLC patients. In adenocarcinomas mean Pgrmc1 level and frequency of high level of Pgrmc1 expression were about 2−3 times higher than in squamous cell carcinomas. Taking into account our results and clinical observations that squamous histologic features as compared with adenocarcinomas is factor associated with improved survival platinum included chemotherapy, we believe that Pgrmc1 could be predictive marker of platinum resistance in NSCLC patients. 1001 POSTER

Clinical and pathological correlation of the activated form of the progesterone receptor (PR) in breast cancer (BC)

P. Jamme[1], E. Gilles[2], J. Bosq[3], J.M. Caillaud[4], S. Fuqua[5], C. Lange[6], J. O'Shaughnessy[7], A. Zukiwski[8], J. Bonneterre[1]. *[1]Centre Oscart-Lambret, Medicine, Lille, France; [2]Invivis Pharmaceuticals, Research, Bridgewater, USA; [3]Institut Gustave Roussy, Pathology, Villejuif, France; [4]Biodoxis, Pathology, Paris, France; [5]Baylor Breast Center, Biology, Houston, USA; [6]University of Minnesota, Masonic Cancer Center, Mineapolis, USA; [7]US Oncology Research, Baylor-Sammons Cancer Center, The Woodlands, USA; [8]Arno Therapeutics, Research, Flemmington, USA*

Background: Ligand binding of the PR in normal tissue causes the formation of discrete transcriptionally active subnuclear foci. The presence of these activated PRs (APR's) in post menopausal patients with BC and endometrial cancer suggests that the PR is activated by pathways requiring minimal or no PR ligand or is constitutively active. The goal of this study is to correlate the APR status in BC biopsies to any clinical and/or pathological relationships. APRpos was defined as any tumor with more than 5% APR cells.
Methods: 303 archived BC biopsies were analyzed for standard HES, ER, PR and Ki67. Clinical and pathology data was obtained from patient (pts) records. APR status (PR nuclear morphology) was determined with distinct antibodies for the PR A & B isoforms and the nuclear morphology patterns were analyzed at $\times$1000 magnification. The APR determination by PRA & PRB was combined as appropriate for the analysis.
Results: Average age was 58 (17−89). Histology: ductal 85%, lobular 13%, other 2%. 86% ERpos and 83% were either PRApos or PRBpos; 7% were only ERpos, 7% were only PRApos or PRBpos. All but 3 PRpos pts had received antiestrogens. Staging: I 50%, II 43%, III 6%, IV 1%. Tumor grade; I: 24%, II: 51%, III: 25%. Median follow up was 31 months. Local or distant progression (PD) was observed in 19% of the pts. APR status was positive in 22%, negative in 61%, and PRneg 17% of the biopsies. PD was not associated with PR status ($p = 0.68$). With DFS defined as time to PD or death with a 5 year cut off, PRpos was superior to PRneg (HR = 0.3, $p = 0.002$). DFS (5 year cut off) was superior for APRpos vs APRneg (HR = 0.58, $p = 0.48$). In univariate analyses, APRpos was associated with higher tumor grade ($p = 0.001$). No association was found between APR status and age, stage of disease, Ki67 or HER2 status.
Conclusions: Although there was an association with higher tumor grade, the APR status was not clearly linked or associated with other clinical characteristics, markers for proliferation, ER or PR positivity, disease stage; indicating that APR cannot be predicted by routine clinical data or pathological testing. Further work on the APR is warranted, as this biomarker may be able to determine which patients could benefit from antiprogestin treatment.
Conflict of interest: *Ownership: Invivis Pharmaceuticals, Arno Therapeutics*

1002 POSTER

Clinical and pathological correlation of the activated form of the progesterone receptor (APR) in endometrial cancer (EC)

E. Hutt[1], J. Bosq[2], M.A. Powell[3], E. Leblanc[4], K. Fujiwara[5], T.J. Herzog[6], R.L. Coleman[7], D. Graham[8], C. Clarke[9], B. Monk[10]. *[1]Centre Oscar-Lambret, Lille, France; [2]Institut Gustave Roussy, Pathology, Villejuif, France; [3]Washington University School, Medicine, St. Louis, USA; [4]Centre Oscart-Lambret, Chirurgie, Lille, France; [5]Saitama Medical University, International Medical Center, Hidaka, Japan; [6]Columbia University, Cancer Center, New York, USA; [7]The University of Texas, MD Anderson Cancer Center, Houston, USA; [8]Westmead Institute for Cancer Research, Sydney Medical School, Sydney, Australia; [9]Westmead Institute for Research, Sydney Medical School, Sydney, Australia; [10]Creighton University School of Medicine, St Joseph's Hospital and Medical Center, Phoenix, USA*

Background: Ligand binding of the progesterone receptor (PR) in normal tissue causes the formation of discrete subnuclear foci, which are known to be transcriptionally active (APR). The presence of APR's in menopausal EC and breast cancer suggest that the PR is constitutively active or activated by pathways requiring minimal or no PR ligand. The goal of this study is to determine the APR status in EC and to describe any clinical or pathological relationships with the ultimate goal to develop a companion diagnostic predicting the efficacy of anti-progestins in patients with EC.
Methods: 72 archived 1º ECs were processed with standard IHC for estrogen receptor (ER) and PR & proliferation (Ki67). APR was determined using antibodies specific to the A and B isoforms of the PR (PRA and PRB) and evaluating nuclear morphology. Pathology and clinical information was collected from patients' records.
Results: Histology; endometrioid 78%, clear cell 8%, serous/papillary 7%, other 7%. 2 PR nuclear distribution patterns were observed: an aggregated pattern (A) indicative of APR, and a diffuse or finely granular pattern (D), indicative of an inactivated PR. This resulted in three tumor phenotypes: A cells only, D cells only, and a mix of A + D cells (AD). For endometrioid cancers, 84% and 68%, respectively, were PRpos or ERpos. APR was present with PRA in 33% and PRB in 37%, and 48% either PRA or PRB. The mean age was 65 in both the APRpos/neg groups. APR status was not associated with Ki67 expression, tumor grade, lymphatic or vascular invasion or FIGO stage, progression of disease or death, but was associated with lower ER positivity. 8 progressions were observed and not associated with APR status. More deaths from any cause were observed in the PRB APRneg group.
Conclusions: Lack of association with clinical characteristics suggests APR status is distributed across clinical sub-groups of EC and cannot be predicted by routine clinical or pathological testing. The small number of progressions/deaths does not allow APR to be tested as a prognostic variable. Further work on a larger cohort is warranted, as this biomarker may be able to select patients who may have increased benefit/risk ratio of antiprogestin treatment.

Cholesterol and its esters as serum biomarkers in malignant obstructive jaundice: A single step 1H NMR metabonomic approach

A.A. Sonkar[1], H. Gupta[1], J.K. Kushwaha[1], R. Roy[2], D. Singh[1], A.A. Chandra[1], S. Srivastava[2], S.K. Singh[1]. *[1]King George Medical University, Surgery, Lucknow, India; [2]S.G.P.G.I., C.B.M.R, Lucknow, India*

Introduction: In obstructive jaundice (OBJ), composition of bile and cholesterol metabolism changes drastically with growing severity towards malignancy. The timely diagnosis of underlying malignancy with OBJ is complex, as malignant tumors are often asymptomatic in their earlier course and thus preclude its curative resection. The complex regional anatomy of hepatopancreatobiliary system confounds the recognition of potentially resectable lesion and hinders the pre-operative histological confirmation of malignancy. Therefore, objectives of the present study include: (i) identification of the variations in low molecular weight metabolites of serum under the pathological state of benign OBJ and hepatopancreatobiliary malignancy induced obstructive jaundice from normal conditions, (ii) to explore the role of serum cholesterol (Chol) and cholesterol esters (CE) and their relative ratio estimation in sera of benign and malignant OBJ with the help of H NMR spectroscopy and, (iii) the evaluation of status of bile acids, cholesterol and choline containing compounds in bile and their contribution towards differentiating between malignant and benign OBJ.
Material and Methods: Serum and bile specimens from benign OBJ patients ($n = 28$), malignant OBJ patients ($n = 36$) and serum of healthy controls ($n = 57$) were analysed by H NMR spectroscopy. Relative- and semi-quantitation of serum metabolites viz. isobutyrate, lactate, alanine, acetone, glutamine, creatine, threonine and 1-methylhistidine, total cholesterol (tCho), cholesterol (Chol) and cholesterol ester (CE) were performed. In bile, total bile acids (BA), cholesterol, phosphatidylcholine (PC) and glycerophosphatidylcholine (GPC) were quantified. The effect of benign and malignant OBJ on small metabolites and lipids was analysed by non-parametric Mann-Whitney U test.
Results: Serum levels of isobutyrate, alanine, acetone, glutamine, threonine and 1-methylhistidine were significantly lower in both classes OBJ patients and glutamine levels were further lowered in malignant OBJ. Serum Chol and CE were significantly altered in healthy control, malignant and benign OBJ. Malignant OBJ had significantly decreased levels of tCho, Chol/CE and lipid content when compared with benign OBJ.
Conclusions: The single step estimation of alterations in serum Chol and CE may have potential for early and differential diagnosis of malignant and benign OBJ. This may augment the novel insights in local and systemic effects of OBJ patients.

Circulating tumor cells counts in advanced and metastatic colorectal cancer by immunomagnetic labeling: Results reflect the reality?

S.M. Sanches[1], M.F. Fanelli[1], E. Abdallah[1], B.M.M. Rocha[1], M.E.C. Buim[1], N.B. Mingues[1], A.L. Dettino[1], M.S. Tariki[1], L.M.M. Ocea[1], L.T.D. Chinen[1].
[1]AC Camargo Cancer Center, Medical Oncology, SAO PAULO, Brazil

Background: According to Jemal et al. (2011), colorectal cancer (CRC) was the third most commonly diagnosed cancer in men in the world, and the second in women in 2008. The first strategy for treatment is complete resection of the lesion. However, some patients experience recurrence, believed to be due to residual micrometastases. Traditional diagnostic methods are unable to detect CTCs present in these sites and released into the circulation. Our objective was to count and correlate CTCs levels and MRP-5 (multidrug resistance associated protein 5) expression with progression free survival (PFS).
Materials and Methods: Prospective study made by blood collection of patients with metastatic or advanced CRC. Blood was collected before the beggining of chemotherapy and after 60 days, in accordance with image exams. The enrichment of CTCs was made by direct immunomagnectic labeling of positive cytokeratin (CK) cells. These cells were permeabilized and labeled with antibody against pan- CK conjugated to ficoeritrin to identify epithelial cells. Leucocytes were identified by anti-CD45 antibody. CTCs were analysed by immunofluorescence and by light microscope and quantified by 8 mL of blood. The protein expression of CTCs was analysed after blood filtration by ISET (Isolation by Size of Epithelial Tumor Cells). Blood was collected in EDTA tubes and diluted in buffer for filtration. Then, membranes were stored at −20°C until analysis. After incubation with antibodies (MRP-5), the membranes were counterstained with DAB. PFS curves were made by Kaplan Meier method and the difference between curves were analysed by log-rank.
Results: There were included 16 patients treated with FOLFOX or FOLFORI and bevacizumab. The median age was 63.5 years (30−81). The majority of patients was men (62.5%) and included at stage IV (68.7%). The PFS after the treatment was observed by image exams and showed a media of 6.14 months (0.79–8.55 months). The median CTCs numbers detected in these patients were 23.5 CTCs/8 mL at baseline. Patients with lowest levels of CTCs (above the median) showed worse PFS (4.15 months) in relation to those with higher levels of CTCs (7.78 months, $p = 0.037$). The same was true for the CTCs counts in the first follow-up (4.20 $\times$ 7.73 months, $p = 0.047$, respectively). Only 11 patients were analysed for MRP-5 protein expression and no correlation was observed between this expression and PFS.
Conclusion: Although our CTCs counts seems conflicting, the lowest counts found in patients with worst PFS can be explained by the inhibition of tumor angiogenesis by bevacizumab, which may lead to hypoxia, invasive cell behaviour and epithelial mesenchymal transition (EMT), as postulated by Gazzaniga et al. (2011). As the method used was based on epithelial markers, it is possible that these patients with poorest PFS were under EMT. The expression of EMT and endothelial cells markers in CTCs filtered on ISET are under investigation in our lab.

Quantitative assessment of lymph vascular space invasion (LVSI) provides important prognostic information in node-negative breast cancer patients

T.J.A. Dekker[1], C.J.H. Van de Velde[1], D. Van Bruggen[1], W.E. Mesker[1], J.J.M. Van der Hoeven[2], R.A.E.M. Tollenaar[1], J.R. Kroep[2], V. Smit[3].
[1]Leiden University Medical Center, Department of Surgery, Leiden, Netherlands; [2]Leiden University Medical Center, Department of Medical Oncology, Leiden, Netherlands; [3]Leiden University Medical Center, Department of Pathology, Leiden, Netherlands

Background: The prognostic value of lymph vascular space invasion (LVSI) has been in investigated in multiple studies, some of which have demonstrated an association of this phenomenon with disease-free survival. Clear definitive criteria and optimal determination of this parameter remain unclear, especially whether some sort of quantification of LVSI is clinically relevant.
Materials and Methods: EORTC trial 10854 investigated the efficacy of perioperative chemotherapy in 2795 patients with T1-T3, N0−2 and M0 breast cancer. A subset of 427 node-negative breast carcinomas from premenopausal patients from this trial were selected and scored for LVSI. The number of LVSI foci were counted and the cell number was determined in the largest tumor embolus within the lymph vessels. These two parameters were multiplied in order to calculate the LVSI tumor burden (LVSI-TB). The optimal cut-off for this parameter was calculated in a discovery set and tested in a validation set. This parameter was also compared to simple quantitation of the number of LVSI foci regarding the sensitivity and specificity for identifying patients with disease relapse.
Results: Tumors with a single LVSI focus are not at increased risk for disease relapse (HR 1.423, 95% CI 0.762–2.656) which indicates that quantitation of LVSI is necessary. The LVSI-TB had the highest sensitivity and specificity for performing quantitative LVSI assessment compared to simple determination of the number of LVSI foci. This parameter was independently associated with disease-free survival in the validation set (HR 2.366, 95% CI 1.369–4.090, $P = 0.002$) in multivariate analysis and provided prognostic information in both the low- and high-risk node-negative breast cancer groups ($P<0.001$ and $P = 0.007$ respectively).
Conclusion: In order to optimally implement determination of LVSI into the standard clinical care for breast cancer patients, this parameter needs to be quantified. This study shows that the determination of the number of LVSI foci multiplied by the number of tumor cells in the largest tumor embolus provides the most reliable quantitative assessment of this parameter.

1006 POSTER

Facilitates chromatin transcription (FACT) complex as a marker and target of aggressive poorly differentiated cancers

H. Garcia[1], J.C. Miecznikowski[2], A. Safina[1], R.W. Leach[3], A. Ruusulehto[4], S. Kilpinen[4], A. Omilian[5], C. Morrison[5], K. Gurova[1].
[1]Roswell Park Cancer Institute, Cell Stress Biology, Buffalo, USA; [2]University of Buffalo, Biostatistics, Buffalo, USA; [3]University of Buffalo, Center for Computational Research, Buffalo, USA; [4]MediSapiens Ltd, Helsinki, Finland; [5]Roswell Park Cancer Institute, Pathology, Buffalo, USA

Background: The Facilitates Chromatin Transcription (FACT) is involved in chromatin remodeling during transcription, replication and DNA repair and was considered to be aubiquitously expressed complex that had no known associations with any disease. However, we discovered that FACT is expressed in very limited number of cells of the adult mammalian organism, mostly presented by stem and undifferentiated cells (Garcia, 2011). Moreover a novel anti-cancer agents, Curaxins, entered recently Phase I clinical trials, exert tumor cell killing though inhibition of FACT function (Gasparian, 2011). The goal of this study was to elucidate what role FACT plays in cancer.
Material and Methods: We assessed expression of FACT in normal and cancerous tissues of different organs on mRNA (>20,000 samples) and protein (>800 samples) levels to evaluate the correlation between FACT expression and clinical features of different cancers. We also ran *in vitro* and *in vivo* experiments to evaluate how modulation of FACT levels affects tumorigenic transformation and tumor cell properties. Finally we obtained genome wide distribution of FACT using ChIP-seq to identify genes which transcription requires FACT assistance.
Results: FACT expression is significantly higher in tumors of patients with poor overall survival (all cancers, breast cancer (BC), NSCLC), higher incidence of metastasis (BC, NSCLC, RCC) and the presence of other markers associated with poor prognosis (BC, NSCLC, colon cancer). Ectopic expression of FACT in normal cells does not drive transformation, but increases efficiency of oncogene-driven transformation. Conversely a reduction of FACT level, using a RNAi approach, reduces transformation efficiency and interferes with tumor, but not normal cell growth.
Genome wide analysis revealed non-random FACT distribution in tumor cells with significant enrichment over the bodies of genes regulated by transcriptional factors associated with cancer (Myc, AP1-, ets-families, YY1), stress response (NF-kB, HSF1, HIF1a) and pluripotent cell state (Oct3/4, Myc, Hox family). This pattern suggests selective assistance of FACT to the transcription of genes involved in cancer and early development.
Conclusion: FACT is an attractive target and marker of poorly differentiated aggressive cancers based on its role as an accelerator of oncogenic transformation through selective chromatin remodeling of genes involved in cancer stress response and maintenance of pluripotent cell state.

Combined use of estrogen receptor status and TP53 mutation status regulated gene expression data to predict risk of relapse in neoadjuvant chemotherapy treated breast cancer patients

B. Gyorffy[1], G. Bottai[2], J. Lehmann-Che[3], G. Kéri[1], C. Desmedt[4], F. Andre'[5], C. Coutant[6], H. De The'[3], L. Pusztai[7], L. Santarpia[2]. *[1]Semmelweis University, Bioinformatics, Budapest, Hungary; [2]Istituto Toscano Tumori, Translational Research Unit, Prato, Italy; [3]University Rene Diderot Paris 7 Saint Louis Hospital Assistance Publique Hôpitaux de Paris, Biochemistry and INSERM U944, Paris, France; [4]Université Libre de Bruxelles Jules Bordet Institute, Breast Cancer Translational Laboratory, Bruxelles, Belgium; [5]Institut National de la Santé et de la Recherche Médicale Unit U981 Institut Gustave Roussy, Oncology, Villejuif, France; [6]Georges Francois Leclerc Cancer Center The University of Bourgogne, Surgical Oncology, Dijon, France; [7]Yale Cancer Center, Oncology, New Haven, USA*

Background: Breast cancers (bc) carry a complex repertoire of nucleic acid variations including polymorphisms, germline and somatic mutations that can influence gene expression and the clinical behavior of the disease. In the present study we aimed to identify a gene signature driven by *TP53* mutations and to assess its clinical relevance in ER-positive and ER-negative bc.
Methods: Bc data containing *TP53* mutation status and gene expression (for 22,277 genes) derived from five independent datasets were used (n = 695; ER+ n = 511 and ER− n = 184). The gene expression data was obtained using Affymetrix HGU133A microarrays. The raw array data was normalized in the R environment using the affy Bioconductor package. In this discovery cohort, ROC analysis was performed for each gene separately and the genes were ranked by their achieved AUC values. Kaplan–Meier analysis was performed by employing an updated version of our online available KM-plotter using 635 neoadjuvant chemotherapy-treated patients − none of these patients was included in the discovery cohort. Statistical significance was set at $p < 0.01$. *In vitro* assay with specific inhibitors against selected kinases were performed.
Results: Single genes were highly capable to discriminate *TP53* mutant and wild type tumors as well as patients with high and low risk of relapse in ER positive patients. The combination of multiple genes did not significantly improve classification. Among the most significant genes were: TTK (AUC = 0.82), *CDC20* (0.804), *STC2* (0.780), *CDCA8* (0.780), *CCNB2* (0.800) and *MYBL2* (0.79). All of the top *TP53*-regulated genes correlated to survival as well. Identical analysis in ER negative tumors did not reveal any gene associated with survival. Notably, TTK inhibitor (SP600125) was used in 2 TP53 mutated bc cell lines, MDA-MB-231 (ER−) and T47D (ER+) with a significant reduction in cell proliferation and increase in cell death, particularly in the T47D.
Discussion: By using a new statistical approach, we identified *TP53*-mutation driven genes highly correlated to shorter survival in ER-positive chemotherapy-treated breast cancer patients. We identified an important kinase, TTK, regulated by mutant TP53. Inhibition of TTK caused a significant cell death in ER+/TP53 mutated bc cells.

1008 POSTER

Prognostic role of neutrophil to lymphocyte ratio (nlr) in solid tumors: A systematic review and meta-analysis

A.J. Templeton[1], M.G. McNamara[1], F.E. Vera-Badillo[1], P. Aneja[1], A. Ocaña[2], B. Seruga[3], R. Leibowitz-Amit[1], J.J. Knox[1], E. Amir[1]. *[1]Princess Margaret Cancer Centre, Medical Oncology and Hematology, Toronto, Canada; [2]University Hospital, Medical Oncology, Albacete, Spain; [3]Institute of Oncology, Medical Oncology, Ljubljana, Slovenia*

Background: Inflammation may play an important role in cancer progression, and a high NLR has been reported to be a poor prognostic indicator in several malignancies. However, the exact magnitude of the prognostic impact of this readily available and inexpensive potential biomarker remains unclear.
Methods: A systematic review of electronic databases was conducted to identify publications exploring the association of blood NLR and overall survival (OS) in all solid tumors. Data from studies reporting a hazard ratio (HR) and 95% confidence interval (CI) or a *P*-value were pooled in a meta-analysis. The pooled HRs for OS by disease group and by extent of disease (non-metastatic versus metastatic versus mixed) were computed using inverse-variance and random-effect modeling.
Results: 68 studies comprising 31,026 patients were included in the analysis. 50 (74%) of the studies were published in 2011 or later and 21 (31%) reported on metastatic disease alone. The median cut-off for high NLR was 4.0 (range 1.9−5.0). Overall, NLR above the cut-off was associated with a HR for OS of 1.68 (95% CI 1.57–1.80, $P<0.001$). The magnitude of effect on OS was non-significantly greater in lower gastrointestinal (GI) and genitourinary tumors compared to other cancer sites (*P* for subgroup difference = 0.10, table). Compared with patients with non-metastatic disease, high NLR was associated with a differentially worse survival in those with metastatic cancer (*P* for subgroup difference = 0.004, table).

	Studies (N)	Patients (N)	Median cut-off NLR	HR for OS	95% CI	*P*-value
Site						
Upper GI	21	5429	3.3	1.59	1.39–1.83	<0.001
Lower GI	17	4542	5.0	2.00	1.59–2.53	<0.001
Lung	10	1977	3.9	1.53	1.31–1.80	<0.001
Genitourinary	8	2379	3.0	2.15	1.71–2.69	<0.001
Gynecological	3	1488	2.6	1.48	0.98–2.23	0.06
Other	9	15211	4.0	1.67	1.45–1.93	<0.001
Stage						
Non-metastatic	19	3981	4.8	1.39	1.24–1.56	<0.001
Mixed	28	20744	4.0	1.68	1.52–1.87	<0.001
Metastatic	21	6301	3.5	1.83	1.64–2.04	<0.001

Conclusion: A high NLR is associated with an adverse OS in many solid tumors. The magnitude of association of high NLR with worse OS is greater for metastatic than for non-metastatic disease. The addition of NLR to established prognostic scores warrants further investigation.
No conflict of interest.

1009 POSTER

PD-1+ immune cell infiltration inversely correlates with survival of patients with operable breast cancer

S. Sun[1], X. Fei[2], Y. Mao[1], X. Wang[3], D. Garfield[4], K. Shen[5]. *[1]Ruijin Hospital, Comprehensive Breast Health Center, Shanghai, China; [2]Ruijin Hospital, Pathology Department, Shanghai, China; [3]Shanghai Jiao Tong University School of Medicine, Department of Biochemistry and Molecular Cell Biology, Shanghai, China; [4]promed Cancer Centers-shanghai, Promed Cancer Centers, Shanghai, China; [5]ruijin Hospital, Comprehensive Breast Health Center, Shanghai, China*

Background: Programmed death-1 (PD-1), a coinhibitory checkpoint receptor, is mainly expressed on functionally 'exhausted' $CD8^+$ T cells, dampening the host antitumour immune response. We evaluated the ratio between effective and regulatory T cells (Tregs), and PD-1 expression as prognostic factors for breast cancer patients.
Material and Methods: A series of 218 newly diagnosed invasive breast cancer patients who had undergone primary surgery at Ruijin Hospital between 2004 and 2008 were identified. The influence of $CD8^+$ cytotoxic T lymphocytes (CTLs), $FOXP3^+$ (Treg cell marker), and $PD\text{-}1^+$ immune cell counts on prognosis was analysed utilising immunohistochemistry.
Results: A total of 208 breast tumours were examined after exclusion of 10 patients with uninformative slides. No correlation between $CD8^+$ cells and clinicopathologic variables were demonstrated, while both $PD\text{-}1^+$ immune cells and $FOXP3^+$ Tregs counts were significantly associated with unfavourable prognostic factors. In univariate analysis, high tumour infiltrating $PD\text{-}1^+$ cell counts were correlated with significantly shorter overall survival (OS) (p = 0.004, log rank = 9.55), with a hazard ratio of 3.29 (95% CI, 1.48–7.32). However, multivariate analysis showed PD-1 expression not to be independently associated with OS (HR = 2.37; 95% CI, 0.99–5.65; p = 0.051).
Conclusions: Tumour progression was seen with higher PD-1 expression on previously functional immune cells and more aggressive cancers harboured increased Tregs. Our results suggest a prognostic value of the $PD\text{-}1^+$ immune cell population in breast cancer patients. Targeting the PD-1 pathway as well as depletion of Tregs may be a feasible approach to treat patients with breast cancer.

Protein biomarker signature for risk classification of hormone receptor positive breast cancer identified by reverse phase protein array based tumor profiling

J. Sonntag[1], C. Bender[1], S. Aulmann[2], S. Von der Heyde[3], B. Burwinkel[4], S. Wiemann[1], T. Beißbarth[3], H.P. Sinn[2], A. Schneeweiss[5], U. Korf[1]. *[1]German Cancer Research Center, Molecular Genome Analysis, Heidelberg, Germany; [2]University of Heidelberg, Department of Pathology, Heidelberg, Germany; [3]University Medical Center Göttingen, Department of Medical Statistics, Göttingen, Germany; [4]University of Heidelberg, Department of Gynecology and Obstetrics, Heidelberg, Germany; [5]University of Heidelberg, National Center for Tumor Diseases, Heidelberg, Germany*

Background: Around 70% of breast cancer cases belong to the luminal intrinsic molecular subtype, characterized by hormone receptor overexpression. This subtype can be further divided into luminal A and luminal B, which is commonly used as surrogate for good and bad prognosis, respectively. The classification is crucial for therapy decision as patients of the luminal B subtype are at higher risk of recurrence and require chemo-endocrine therapy, contrasting low risk patients who do not benefit from chemotherapy. However, accurate definition of low and high risk luminal breast cancer has remained a challenge so far. Thus, the objective of this study was the identification of a robust protein biomarker signature to facilitate the risk classification of luminal breast cancer.
Materials and Methods: Reverse phase protein arrays (RPPA) were applied to quantify over 120 breast cancer relevant target proteins of hormone receptor positive breast cancer tumor samples. Subsequently, we used a novel bioinformatics workflow combining a bootstrap approach with three different classification methods for biomarker selection. To validate our RPPA derived results we have applied Western blot, immunohistochemistry, and mRNA profiling.
Results: Our results confirm that markers for cell proliferation are prominent factors to distinguish between low and high risk tumors with Ki-67, TOP2A, and PCNA appearing among the top hits. However, NDKA, RPS6, and caveolin-1 were selected as prime candidates. Comparably to Ki-67, NDKA and RPS6 were expressed at an elevated level in high risk tumors whereas caveolin-1 was observed to be downregulated.
Conclusions: We have identified a protein biomarker signature (consisting of caveolin-1, NDKA, RPS6, and Ki-67) using RPPA based tumor profiling with the potential to facilitate the risk of recurrence classification in luminal breast cancer. In addition, we present RPPA as promising experimental platform for the identification of biomarkers in clinical samples.

1011 POSTER

Generation of a potent uPAR-antagonist by forced-proximity engineering of the receptor binding domains of urokinase and vitronectin

S. Gandhi[1], N. Sidenius[1]. *[1]IFOM IEO Campus, Cell Matrix Signalling, Milan, Italy*

Background: Extensive in vitro, in vivo and clinical evidence suggest that urokinase-type plasminogen activator receptor (uPAR) plays important functions in wide range of pathological processes including tumor growth, invasion and metastasis, inflammatory diseases and viral infections. Drugs interfering effectively with uPAR-function may therefore provide novel therapeutical regimens in a variety of pathological conditions. We here describe the conception, construction and validation of a novel type of inhibitor of the uPAR.
Material and Methods: *a)* Inspection of the crystal structure of the ternary complex between uPAR, the aminoterminal fragment of urokinase-type plasminogen activator uPA (growth factor-like domain, GFD) and the somatomedin B domain (SMB) of vitronectin (VN) reveals that the peptide backbone of uPA and VN are closely located. In particular Lys48 in uPA and Pro42 in VN are only distant 18Å. Connecting residues 1−48 of uPA (i.e. GFD) and 1−42 of VN (i.e. SMB) to a common scaffold, via their C-termini, is thus predicted to generate a chimera. To join GFD and SMB onto a common scaffold the constant region (Fc) of human IgG was chosen to form stable dimers (named uPAR-lock).
b) To evaluate the activity of uPAR-lock in inhibiting uPAR-signalling in live cells we quantified cell adhesion to VN coated wells by impedance measurements using a real-time cell analyser.
Results: *a)* Potent uPAR inhibitor was generated by forced proximity engineering. The uPAR binding domains of uPA and VN are natural and specific inhibitors of uPA and VN binding to uPAR and resulted in uPAR-lock.
b) uPAR-lock is a potent inhibitor of uPAR function. Addition of uPA induced a rapid and strong increase in the adhesion of 293/uPAR cells. Importantly, the treatment with uPAR-lock completely abrogates the increase in 293/uPAR cell adhesion induced by uPA addition. These data clearly showing that uPAR-lock is a potent and specific inhibitor of uPA induced, uPAR mediated, cell adhesion to VN.
Conclusions: The generated inhibitor (uPAR-lock) is a hetero-bivalent uPAR-ligand containing the receptor binding domains of the extracellular protease uPA and the Extracellular matrix protein VN positioned in close proximity on a common scaffold. Binding of uPAR-lock to uPAR results in a complex where the binding sites for both uPA and VN are occupied contemporarily and efficiently, thus blocking both the proteolytic and signalling activities of the receptor.

1012 POSTER

Increased body mass index shortens telomeres through elevated C-reactive protein

S. Bojesen[1], L. Rode[1], M. Weischer[1], B.G. Nordestgaard[1]. *[1]Herlev Hospital, Clinical Biochemistry, Copenhagen, Denmark*

Rationale: Obesity is associated with decreasing telomere length (TL). The cause of this association is unknown.
Objectives: By measuring leukocyte TL, body mass index (BMI) and C-reactive protein (CRP) in 45069 individuals, we tested the hypothesis that increased BMI causes TL shortening, and that low-grade inflammation contributes through elevated CRP. Using the three obesity-associated polymorphisms rs9939609, rs17782313, and rs6548238, and the CRP promoter polymorphism rs3091244 in instrumental variable analyses, we estimated the causal associations between BMI and TL and between CRP and TL.
Findings: In multivariable adjusted observational analyses, TL decreased with 5 base pairs (bp) (95% confidence interval −7; −3) per unit increase in BMI, and further adjustment for CRP attenuated this association to −2 bp (−4; 0.1). In accordance, instrumental variable analysis showed a causal non-significant TL shortening of 6 bp (−37; 25) per unit increase in BMI. Furthermore, in observational analyses TL decreased with 10 bp (−17; −3) for a doubling in CRP, supported by the instrumental variable analyses showing a causal decrease of 66 bp (−124; −7).
Conclusions: The association between increasing BMI and decreasing TL may be causal, and possibly mediated through elevated CRP: elevated CRP *per se* is a causal determinant of TL shortening.

1013 POSTER

Pooled analysis of two phase III studies provides prognostic indicators for clinical out-come after catumaxomab treatment for malignant ascites

C. Bokemeyer[1], M.M. Heiss[2], F. Lordick[3], S.L. Parsons[4], P. Wimberger[5], H. Friccius-Quecke[6]. *[1]University Medical Center Hamburg Eppendorf, Hamburg, Germany; [2]University of Witten-Herdecke, Cologne-Merheim Medical Center, Cologne, Germany; [3]University Cancer Center Leipzig, Leipzig, Germany; [4]Nottingham University Hospitals NHS Trust, Surgery, Nottingham, United Kingdom; [5]Technical University Dresden, UniUniversity Cancer Center Dresden, Dresden, Germany; [6]Fresenius Biotech GmbH, Munich, Germany*

Background: For identification of factors with potential impact on efficacy of catumaxomab (CATU) in patients (pts) with malignant ascites data from two phase III studies (IP-REM-AC-01 and CASIMAS) were used for a meta-analysis.
Materials and Methods: All randomized pts of both studies were included: 389 pts treated with CATU plus paracentesis and 88 control pts (paracentesis only). Efficacy parameters were overall survival (OS), puncture-free survival (PuFS) and time to first puncture (TTPu). Karnofsky Index (KI), total serum protein (protein), presence/absence of distant metastases (metastases) and number of prior chemotherapies (prior CTX) at inclusion were analysed as potential prognostic factors for the treatment effect of CATU.
Results: Pts treated with CATU showed a significant prolongation of PuFS (44 vs 11 d, $p < 0.0001$), TTPu (88 vs 13 d, $p < 0.0001$) and OS (88 vs 68 d, $p = 0.007$) compared to control.
CATU treated pts with a KI of 80–100 at inclusion had a significantly better OS and improved PuFS compared to those with a KI of 60−79 (120 vs 57 d, $p < 0.001$ and 55 vs 27 d, $p < 0.001$, respectively). TTPu was not improved (88 vs 96 d, $p = 0.186$). Linear Cox regression of KI as a co-variable showed a significantly positive impact of high KI on CATU efficacy for OS (HR 0.97, $p < 0.001$) and PuFS (HR 0.98, $p < 0.001$) but not for TTPu (HR 0.99, $p = 0.054$).
Cox regression analysis of the presence of distant metastases and low (< normal) total serum protein on CATU efficacy showed a negative impact on

OS (metastases: HR 1.43; p < 0.001; protein: HR 1.39, p = 0.002), PuFS (metastases: HR 1.37, p = 0.003; protein: HR 1.45, p < 0.001) and TTPu (metastases: HR 1.28, p = 0.069; protein: HR 1.41, p = 0.011).
Median number of prior CTX was 3. Pts with >3 prior CTX had a reduced treatment effect of CATU compared to those with 1 or 3 prior CTX. Overall, significant treatment effects on ascites (PuFS and TTPu) were observed in all subgroups for all factors; however, significant effects on OS were only found in pts with KI 80–100, with no distant metastases, with ⩾ normal total serum protein and with 3 prior CTX.
Conclusion: Karnofsky Index, distant metastases, total serum protein and number of prior CTX at screening were identified as factors having a significant impact on OS in CATU-treated pts and better prognostic pts compared to controls. In contrast, the effect of CATU on ascites control was observed in all subgroups irrespective of whether the pts were in the good or poor prognostic group.

1014 POSTER

A new IDH1/2 PCR assay for one-step detection of 12 IDH1 and IDH2 mutations in glioma

H. Girardi[1], F. Monville[1], C. Poggionovo[1], A. Catteau[2], M. Giry[3], J. Voos[4], R.B. Jenkins[4], K. Mokhtari[5], H. Peyro-Saint-Paul[2], C. Giannini[4]. *[1]Qiagen Marseille, R&D, Marseille, France; [2]Qiagen Marseille, Medical Affairs, Marseille, France; [3]Groupe Hospitalier Pitie Salpetriere, Institut Cerveau et Moelle, Paris, France; [4]Mayo Clinic, Laboratory Medicine and Pathology, Rochester MN, USA; [5]Groupe Hospitalier Pitie Salpetriere, Neuropathology, Paris, France*

Background: Isocitrate dehydrogenase (IDH) mutation status is a strong diagnostic and prognostic marker in glioma which will probably be introduced in the WHO classification system. Current screening for IDH mutations is performed with an IHC assay specific for IDH1 R132H, the most frequent mutation; subsequent sequencing is recommended when IHC is negative or equivocal. A qPCR assay was designed to detect in one single step, IDH1R132H and 11 rare IDH1/2 mutations in FFPE samples. This study describes development, analytical performance and validation of this new assay.
Material and Methods: PCR Clamping was used to detect IDH1 R132H and 11 additional mutations (5 IDH1 R132, 1 IDH1 R100, 5 IDH2 R172). ARMS was combined to selectively identify IDH1 R132H/R132C and IDH2 R172K. Limit of detection (LOD) (minimum % mutant DNA detected in a WT DNA background) was determined using five low positive samples per mutation (n = 5x30 measurements/mutation). FFPE glioma samples (n = 170) were retrospectively collected from 3 independent sources. The assay was validated on samples meeting assay requirements (<10 yrs, $\geqslant$50 mm^2, $\geqslant$40% tumor cells) comparing PCR IDH status to IHC (mIDH1 R132H) and bidirectional sequencing. Additionally, to better document minor mutations, synthetic samples for the 11 minor mutations (30% and 45% mut DNA in WT DNA) were tested.
Results: Assay sensitivity varied across mutations with LOD <5% for 11/12 mutations (mean=3.3%). From the first 120 clinical samples analyzed, 103 were <10 yrs (48/103 glioblastomas). IDH status was successfully obtained by PCR for these 103 samples. All IHC positive cases were concordantly identified as R132H by PCR (n = 45). One R132H case detected by PCR was negative by IHC (negative concordance 98%). PCR additionally detected 9 rare mutations (8 IDH1, 1 IDH2). Moreover, the kit produced 100% correct results on the synthetic samples with rare mutations.
Conclusions: The one-step IDH1/2 PCR assay showed a 100% technical success rate and is more sensitive than published references for bidirectional sequencing. Positive concordance with IHC detection for IDH1 R132H was 100%. Complete validation results including sequencing data (to be presented at the meeting) will further document the value of this new assay to screen in one step for 12 IDH12 mutations.

1015 POSTER

Plasma testosterone in the general population, cancer prognosis and cancer risk

D. Orsted[1], B.G.N. Nordestgaard[2], S.E.B. Bojesen[2]. *[1]Herlev University Hospital, Herlev, Denmark; [2]Herlev University Hospital, Clinical Biochemistry, Herlev, Denmark*

Background: Testosterone is an important anabolic hormone in humans and, i*n vitro*, testosterone stimulates growth of lung and colon cancer cells. We tested the hypothesis that increased plasma testosterone associates with increased risk of cancer and with increased risk of early death after cancer in the general population.
Material and Methods: Plasma testosterone was measured in 8771 20−94 year old men and women who participated in a prospective study of the general population. Participants were included in 1981−83 and followed for up to 30 years.
Results: During follow-up, 1140 men and 809 women developed cancer. For risk of early death after cancer and after adjustment for age at diagnosis, tumour stage at diagnosis, and time since blood-sampling, the hazard ratios in men were 1.30 (95% confidence interval 1.03–1.65) for the 2nd quintile, 1.31 (1.02–1.67) for the 3rd quintile, 1.52 (1.19–1.93) for the 4th quintile, and 1.52 (1.20–1.91) for the 5th quintile, versus the 1st quintile. In women, corresponding hazard ratios were 1.09 (0.81–1.46), 1.17 (0.86–1.59), 1.03 (0.76–1.39), and 1.80 (1.32–2.46). For risk of any cancer for a doubling in testosterone levels, multifactorially adjusted hazard ratios were 1.07 (0.98–1.18) in men and 1.06 (0.93–1.22) in women. For both men and women, a doubling of testosterone levels was not associated with risk of any individual cancer type.
Conclusions: In this prospective study of 8771 men and women from the general population followed for up to 30 years, increased testosterone levels were associated with a 30−80% increased risk of early death after cancer, but with unchanged risk of incident cancer.
No conflict of interest.

1016 POSTER

Expression of cancer stem cell (CSC) markers in primary tumors (PT) and matched lymph node metastases (LNM) in breast cancer patients

A. Zaczek[1], N. Bednarz-Knoll[2], A. Markiewicz[1], P. Nastaly[2], B. Seroczynska[3], J. Skokowski[4], J. Szade[5], M. Welnicka-Jaskiewicz[6], J. Jassem[6]. *[1]Intercollegiate Faculty of Biotechnology Medical University of Gdansk, Department of Medical Biotechnology, Gdansk, Poland; [2]University Medical Center Hamburg-Eppendorf, Department of Tumor Biology, Hamburg, Germany; [3]Medical University of Gdansk, Bank of Frozen Tissues and Genetic Specimen, Gdansk, Poland; [4]Medical University of Gdansk, Department of Surgical Oncology, Gdansk, Poland; [5]Medical University of Gdansk, Department of Pathomorphology, Gdansk, Poland; [6]Medical University of Gdansk, Department of Oncology and Radiotherapy, Gdansk, Poland*

Background: Breast cancer is characterized by high intra-tumor heterogeneity, with multiple cell populations differing in metastatic potential. CSCs, representing a minor subset of cells, play a critical role in breast cancer initiation, progression, metastasis and drug resistance. However, their status in LNM remains unclear. We evaluated in PT and in matched LNM protein levels of CSC markers: CD44 and ALDH1, and epithelial–mesenchymal transition (EMT) markers: E-cadherin and vimentin. The results were correlated with clinicopathological data, overall (OS) and disease-free survival (DFS).
Material and Methods: We examined formalin-fixed paraffin-embedded samples from PT and matched LNM from 42 stage II−III breast cancer patients. Protein expression was measured by immunohistochemistry on tissue microarrays. For CD44 and ALDH1 staining intensity (scored as: 0-negative, 1-weak, 2-intermediate, 3-strong) and percentage of positively stained cells (0–100%) were multiplied to count the expression score. For E-cadherin and vimentin $\geqslant$10% of stained cells defined a positive result. Results were considered concordant if PT and LNM were both positive or both negative. Concordance was measured by Cohen's kappa coefficient (κ), with κ value equal 1 indicating perfect agreement. DFS and OS were compared using F-Cox test. Hazard ratios (HRs) with 95% confidence intervals (95% CI) were computed using Cox regression analysis.
Results: Median expression score of CD44 was significantly higher in LNM compared to PT (p = 0.04). Status of ALDH1 and CD44 between PT and LNM was discordant in 16/42 (38%) and 7/27 (26%) of cases, respectively (κ=0.24 and κ=0.5), with only negative-to-positive conversion for CD44. Status of E-cadherin was fully concordant (κ=1), and of vimentin has changed in 7% (3/40, κ=0.63). CD44 positive status correlated with vimentin expression (p = 0.03). Increased expression of CD44 in LNM was strongly associated with shorter OS (HR 8.4, 95% CI 1.04–67.6, p = 0.001) and DFS (HR 9.6, 95% CI 1.2–76.7, p = 0.0005), whereas its expression in PT had no prognostic impact. Status of ALDH1 and vimentin in both PT and LNM did not correlate with OS and DFS.
Conclusions: Compared to PT, LNM are enriched in cells with CSC markers, suggesting that phenotype of these aggressive cell subpopulations might easier be captured in LNM than in PT. High level of CD44 in LNM confers worse prognosis, confirming the correlation of CSC-phenotype with aggressive disease behavior.
No conflict of interest.

1017 POSTER

HER3 expression in primary colorectal cancer and corresponding lymph node metastases

F. Ledel[1], K. Ohrling[2], M. Hallström[2], P. Ragnhammar[2], D. Edler[1].
[1]*Karolinska Insitutet, Colorectal Surgery, Solna Stockholm, Sweden;*
[2]*Karolinska Insitutet, Oncology and Pathology, Solna Stockholm, Sweden*

Background: To evaluate the prognostic value of the epidermal growth factor receptor HER3 and to elucidate heterogeneity of HER3 expression in primary colorectal cancer (CRC) and corresponding lymph node metastases.
Material and Methods: HER3 expression was analyzed immunohistochemically (IHC) in primary tumors and in corresponding lymph node metastases from 236 patients with stage II and III CRC. In 58 primary tumors, fluorescence in situ hybridization (FISH) detection was performed.
Results: HER3 was detected at high frequency in the cellmembrane. Seventy per cent of the primary tumors were categorized with high HER3 expression compared to 75% in the lymph nodes metastases. HER3 expression in the primary tumor was an independent prognostic factor for overall survival in the entire group of patients ($p = 0.026$) and in the subgroup of patients with colon cancer stage II ($p = 0.030$). A high HER3 expression in the primary tumor was associated with worse clinical outcome. The expression of HER3 was homogenous within the tumor ($p < 0.0001$) and correlated with the HER3 expression in corresponding lymph node metastases ($p < 0.0001$). No gene amplification with respect to HER3 was seen in primary tumors using FISH analysis.
Conclusion: High HER3 expression was found in about 70% of the primary CRC tumors and corresponding lymph node metastases. HER3 expression in the tumor was an independent prognostic factor where a high HER3 expression was associated with worse clinical outcome. There was correlation in HER3 expression between primary tumors and corresponding lymph node metastases.
No conflict of interest.

1018 POSTER

Can we accurately report PTEN status in advanced colorectal cancer?

T. Price[1], C. Hocking[2], V. Broadbridge[2], J. Wrin[3], A.R. Townsend[2], N. Tebbutt[4], J. Cooper[5], A. Ruszkiewicz[6], C. Lee[7], J. Hardingham[3]. [1]*The Queen Elizabeth Hospital and University of Adelaide, Medical Oncology Department, Adelaide, Australia;* [2]*The Queen Elizabeth Hospital, Medical Oncology Department, Adelaide, Australia;* [3]*The Queen Elizabeth Hospital, Haematology and Oncology Unit, Adelaide, Australia;* [4]*Austin Health, Medical Oncology, Melbourne, Australia;* [5]*The Queen Elizabeth Hospital, Pathology, Adelaide, Australia;* [6]*SA Pathology, Pathology, Adelaide, Australia;* [7]*University of Sydney, NHMRC Trials Unit, Sydney, Australia*

Background: The tumour suppressor gene PTEN is considered to have a potential role as a biomarker for anti-EGFR therapy in CRC, although results are inconsistent and there is debate as to the optimal method of reporting low PTEN expression/loss of function. Immunohistochemistry (IHC) is frequently used, although other methods have also been reported (Fluorescence in situ hybridisation and mutation status). PTEN status also appears to vary between primary and secondary tumour samples, further complicating interpretation of the data. Our group has used the Taqman® copy number assay (CNA) previously and here we report results of a subgroup of patients from the AGITG/MAX trial PTEN analysis exploring the concordance between pathologists assessment of PTEN IHC expression, and the relationship of Taqman CNA result and IHC.
Methods: Genomic DNA was extracted from FFPE tissue sections. The Taqman PTEN CNA was performed using 5 ng DNA in quadruplicate PCR. The results are calculated as a ratio relative to a 2-copy control using the 2-ΔΔCt method (Rotorgene software), and multiplied by 2 to give the copy number. Loss of PTEN was defined as $\leqslant$1.5 copies, no loss was >1.5 copies. IHC was performed on 60 tissue arrays and then assessed by two blinded Pathologists. Scoring was 0, 1+, 2+, 3+ for PTEN IHC expression. The two pathologists were compared directly for an IHC concordance rate, and then the scores were grouped and majority score used for IHC v Taqman CNA.
Results: Tissue arrays were analysed for PTEN staining by IHC. 95% of tissue arrays were from the primary CRC. Three were found to have no residual tissue present on the array. 18 of 57 (31.6%) had a score of zero, ie loss of PTEN expression based on IHC. Concordance of IHC PTEN loss (0 v 1+, 2+, 3+) was 63% (36/57) when comparing two pathologists. Using majority score for IHC from the two pathologists, for the 18 specimens with IHC loss of expression, 12 (66.7%) had copy number loss by Taqman. Furthermore the rate of IHC PTEN loss was 44% of those with copy number loss (12/27). There was no evidence that PTEN loss in this small subset measured by low copy number or IHC negativity was prognostic for RR, PFS or OS.
Conclusion: PTEN loss based on IHC is not directly associated with PTEN copy number loss, suggesting that there are other mechanisms such as mutation or promoter methylation, leading to loss of IHC expression. Conversely loss of just 1 PTEN allele may still allow compensatory up-regulation of PTEN to normal levels. This supports the concept that various mechanisms may lead ultimately to loss of PTEN expression. PTEN assessment by IHC alone however remains unreliable based on the lack of concordance between pathologists and robust validation will be required before routine use.
No conflict of interest.

1019 POSTER

The protective role of the vagus nerve in cancer

M. De Couck[1], J.L. Van Laethem[2], R. Maréchal[2], J. De Grève[3], Y. Gidron[1]. [1]*AZ-VUB, Medicine, Brussel, Belgium;* [2]*Erasme Universitary Hospital Université Libre de Bruxelles, Gastroenterology, Brussel, Belgium;* [3]*Oncological Center UZ Brussels, Medical Oncology, Brussel, Belgium*

Background: The evolution of tumors is multifactorial and complex. Recent research shows however, that not only do microenvironmental factors play pivotal roles in carcinogenesis, but so does the autonomic nervous system. The vagus nerve is thought to have protective roles in cancer since it reduces inflammation, oxidative stress and sympathetic activity. Vagotomized tumor-bearing animals show greater metastasis, and in contrast, activating the vagus nerve by a medication was found to reduce tumors and their metastases. In a series of retrospective studies we conducted, higher heart rate variability (HRV), a non-invasive index of vagal nerve activity, was found to predict reduced tumor burden and longer survival times, independent of important confounders including stage and treatment. Furthermore, finding modifiable prognostic factors paves the way for new treatments, which is crucial in advanced pancreatic cancer.
Methods: A 'historical prospective' study in N = 272 patients with advanced pancreatic cancer was performed. HRV was obtained retroactively from ECGs near diagnosis, and some other confounders such as age and treatments were obtained from the medical charts. Levels of C-reactive protein (CRP) were also measured as an inflammatory marker. Overall survival and survival date were obtained from medical charts and the national registry.
Results: In a Cox regression, higher initial HRV (>20 msec) significantly predicted lower risk of death, independent of confounders including age and cancer treatments. This relationship was mediated (explained) by CRP levels. Importantly, in patients who lived only one month or less from diagnosis, HRV was unrelated to CRP, while in patients surviving longer, HRV was significantly inversely related to CRP ($r = -0.20$, $p < 0.05$), suggesting that neuroimmuno-modulation let patients survive longer. Finally, chemotherapy doses increased overall survival only when vagal nerve activity was low, while patients with high vagal nerve activity survived longer, even without chemotherapy.
Conclusion: These results support vagal nerve protection in a fatal cancer, and propose that the mechanism may involve neuroimmunomodulation. Vagal nerve activity may also determine in whom certain treatments are effective and necessary.
No conflict of interest.

1020 POSTER

Prognostic value of Tubedown-100 in patients with breast cancer

W. Jiang[1], W. Jia[2], S.Q. Jia[3], L. Ye[1], R.E. Mansel[1]. [1]*Cardiff University, School of Medicine, Cardiff, United Kingdom;* [2]*Chaoyang Hospital Capital Medical University, Department of Neurosurgery, Beijing, China;* [3]*Inner Mongolia Medical University, Department of Surgery, Hothot, China*

Background: Tubedown-100, also known as NAA15 and NARG1, is a large protein initially found to express at high level in testis tissues and proliferative neuronal tissues. It has been found to be expressed in certain cancer cells including thyroid cancer and lymphoma cells. Although Tubedown-100 has been indicated in the regulation of apoptosis, its biological role in cells including cancer cells remains unknown. It clinical implication in cancer is not known. In the present study, we aimed to investigate the pattern of expression of this molecule in human breast cancer and the potential prognostic value in the patients.
Materials and Methods: The levels of Tubedown-100 gene transcripts were determined using quantitative transcript analysis and PCR analysis. Human breast cancer cell lines MCF-7 and MDA MB-231 were used. Anti- Tubedown-100 transgenes were constructed and used to regulate the expression of Tubedown-100 in breast cancer cells. (cell growth and apoptosis were evaluated on the cells with differential expression of Tubedown-100) A cohort of human breast cancer tissues (n = 127) were

tested for the levels of Tubedown-100 gene transcript. Patient's clinical, pathological and outcome results were analysed against the levels of Tubedown-100.
Results: MCF-7 and MDA MB-231 cells expressed Tubedown-100 gene transcripts. Knockdown of Tubedown-100 gene in both cells resulted in cells with significantly increased growth rate and motile and adhesive to matrix (P<0.001). The Tubedown-100 knockdown cells did not have a significant difference in apoptosis compared with control cells. Levels of Tubedown-100 transcript were significantly lower in tumours from patients with a predicted poor prognosis compared with those with good prognosis (p = 0.038), although there were no significant links with tumour grade. Perhaps the most interesting observation is that levels in patients who developed distant metastasis and who died of breast cancer related complications had significantly lower levels than those who remained disease free (p = 0.016 and p = 0.022, respectively). This is reflected a significantly shorter overall survival time in patients with low levels of Tubedown-100 than those with high level.
Conclusions: It is concluded that Tubedown-100 is aberrantly expressed in patients with breast cancer and the levels are linked with the prognosis of the patients. Tubedown-100 thus is a potential prognostic indicator in patients with breast cancer.
No conflict of interest.

1021 POSTER

Expression of aquaporin 5 and its polymorphism predicts survival in patients with early breast cancer

Y. Chae[1], S. Lee[1], J. Kim[1], B. Kang[1], Y. Lee[1], J. Jung[2], H. Park[2], J. Park[3]. *[1]Kyungpook National University Medical Center, Oncology/Hematology, Daegu, South Korea; [2]Kyungpook National University Medical Center, Surgery, Daegu, South Korea; [3]Kyungpook National University Medical Center, Pathology, Daegu, South Korea*

Background: Our previous study showed the association of aquaporin 5 (AQP5) up-regulation with cancer proliferation and migration in hormone-responsive breast cancer cell lines and with unfavorable prognosis in patients with breast cancer. Accordingly, we analyzed the prognostic impact of AQP5 expression and polymorphisms in a large number of patients with early breast cancer (EBC).
Materials and Methods: AQP5 expression was investigated based on the immunohistochemistry of tissue microarray specimens from 609 EBC patients who underwent surgery between 2003 and 2008. We scored the staining intensity (IS) and percentage of positive tumor cells (PC). The genomic DNA was extracted from paraffin-embedded tumor-free tissue and then genotyped for 3 polymorphisms (rs3736309, rs1964676, and rs74091167) using the Sequenom Mass array system.
Results: Among the 3 polymorphisms, AQP5 overexpression (IS + PC $\geqslant$6) was correlated with AQP5 rs74091167 GG genotype. AQP5 overexpression and AQP5 rs74091167 was significantly associated with disease-free survival (DFS; P <0.001 and P = 0.021, respectively). Moreover, a multivariate survival analysis revealed that AQP5 overexpression and the GG genotype of AQP5 rs74091167 were significantly associated with DFS (HR = 2.026, 95% CI 1.058–3.881, P = 0.030; HR = 0.377, 95% CI 0.179–0.793, P = 0.010, respectively), which was prominent in patients with an ER/PgR-positive tumor.
Conclusions: Consistent with our previous study of breast cancer cell lines, AQP5 expression and AQP5 rs74091167 variant can be considered as a prognostic marker in patients with EBC after curative surgery. In the future, functional relevance of this variant needs to be clarified.

1022 POSTER

Significance of S100A7 and S100A4 expression as a prognostic biomarker for oral squamous cell carcinoma

K. Dey[1], K.B.N. Prashanth[1], D. Subhasis[1], R. Shashi[1], P. Ipsita[1], D. Goutam[1], P. Aditya[1], P. Sheetal[1], R. Jaygopal[2], M. Mahitosh[1]. *[1]Indian Institute of Technology, School of Medical Science and Technology, Kharagpur, India; [2]Dr Rafi Ahmed Dental College and Hospital, Department of Pathology, Kolkata, India*

Oral cancer is a leading cause of cancer death worldwide. The goal of cancer-screening program is to detect tumors at early stage, enough that treatment is likely to be successful. Moreover, the screening tool must be sufficiently noninvasive and inexpensive to allow widespread applicability. A substance secreted by tumor tissue, not secreted by non-tumor tissue, and easily and cheaply detectable in saliva, serum or urine is, therefore, an ideal biomarker because the cancer is detected specifically and non-invasively. The aim of the study was to investigate the expression pattern of calcium- binding proteins S100A7 and S100A4 for patients with oral squamous cell carcinoma. The S100 Calcium binding protein family consists of at least 25 different types of low molecular weight proteins (9−13 kDa), which are characterized by two calcium-binding sites of the EF-hand type conformation and located on a cluster on human chromosome 1q21. Psoriasin (S100A7) is a member of the S100 gene family in the early stages of tumor genesis S100A7 is highly expressed in ductal carcinoma *in-situ*, but S100A7 is often up regulated in adjacent invasive carcinoma.S100A7 is thus also associated with altered and abnormal pathways of epithelial cell differentiation. The prognostic significance of S100A4 as potential biomarker for oral Cancer. The nuclear S100A4 in TNM (Tumor Node Metastasis) stage indicates the proper early diagnosis in the OSCC.S100A4 promotes metastasis and is involved in several steps of the metastatic cascade, including cell motility, invasion and angiogenesis. Disruption of calcium signaling pathways has been implicated as a central mechanism in tumor genesis and specifically in the process of invasion and metastasis The protein biomarker expression in the OSCC human tissue specimens and matching normal oral tissues from 20 patients were examined. Expression of the protein and mRNA were analyzed by Western blot, RT PCR and IFC/IHC in the human oral cancer tissue comparison with adjacent normal tissue Increased expression at mRNA level was observed in OSCC samples by quantitative real-time RT-PCR.Moreover, significantly increased mRNA ratios between malignant and normal samples were observed. From this we can predict that over expression of S100A7 and S100A4 that epithelial cells undergoing abnormal differentiation and tumor genesis, this could be the potential early detection bio-marker to prevent cancer progression and will show new direction in early stage cancer treatment.
No conflict of interest.

1023 POSTER

CRNDE (a novel marker of poor prognosis in patients with cancer) encodes the CRNDEP protein, a component of stress granules

L. Szafron[1], A. Balcerak[2], E.A. Grzybowska[2], A. Felisiak-Golabek[1], J. Kupryjanczyk[1]. *[1]Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Department of Pathology, Warsaw, Poland; [2]Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Department of Molecular and Translational Oncology, Warsaw, Poland*

Background: The *CRNDE* gene, currently known as non-protein coding, has been found to negatively affect prognosis in patients with colorectal and ovarian carcinomas when overexpressed in cancer at mRNA level. Identification of a protein product encoded by this gene may be important due to its potential role in cancer prognosis and prospective usage in ovarian cancer screening.
Material and Methods: The study was performed on RNA samples isolated from normal endometrium, ovarian cancer and HeLa cells. 5' RACE/3' RACE techniques and reverse transcription PCR followed by nested PCR were employed to identify complete splice variants of the *CRNDE* gene. Next, based on bioinformatics analyses, the most promising open reading frame (ORF) was chosen and cloned into five expression vectors. These vectors were used to elicit overexpression of the hypothetical peptide in bacteria (pQE30, pET201) and HeLa cells (pCDNA3.1(+)). They were also utilised in cellular localisation studies under a fluorescence microscope (pEGFP-N1, pDsRed Monomer-C1). In addition, a polyclonal antibody against the peptide was developed in rabbits. It was used in western blot hybridisation and immunohistochemical experiments.
Results: The 5' RACE and 3' RACE experiments revealed two different splice variants of *CRNDE*. Additional PCR experiments, inspired by the results of other research teams, proved the existence of several other splice variants of *CRNDE*. Some of them seemed to be tissue-specific, but the variant recognised here as protein-coding was ubiquitous. This shortened variant encodes the CRNDEP peptide, consisting of 84 amino acids. This peptide localises to stress granules in HeLa cells, and its upregulation stimulates the formation of these granules. Given these results and the outcome of bioinformatics analyses, CRNDEP seems to exhibit oxidase activity, thus enhancing risk of oxidative stress when overexpressed. The presence of CRNDEP in the variety of human tissues was confirmed by our team with the use of immunohistochemical methods. The existence of a protein product encoded by the *CRNDE* gene has never been reported before in the literature.
Conclusions: *CRNDE* emerges as a protein-coding gene. The product of this gene, the CRNDEP peptide, was identified herein as a component of stress granules, and its overexpression seems to stimulate the formation of these granules.
No conflict of interest.

1024 POSTER

The CRNDE, VAV2 and CEBPA genes as new negative prognostic factors in ovarian cancer patients

L. Szafron[1], A. Balcerak[2], E.A. Grzybowska[2], T. Rubel[3], J. Kupryjanczyk[1]. *[1]Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Department of Pathology, Warsaw, Poland; [2]Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Department of Molecular and Translational Oncology, Warsaw, Poland; [3]Warsaw University of Technology, The Institute of Radioelectronics, Warsaw, Poland*

Background: Ovarian cancer is the leading cause of death from gynaecological malignancies. Mortality in this disease is exceptionally high due to the absence of specific symptoms at early phases and the lack of good screening methods. The majority of patients are diagnosed at late stages, characterised by poor prognosis. Identification of new molecular prognostic markers, potential targets of molecular therapy, may facilitate the fight against this neoplasm.
Material and Methods: The genes examined in this study were selected based on the results of preceding gene expression microarrays. The prognostic value of their expression at mRNA level was evaluated in ovarian cancer patients treated with either cisplatin and cyclophosphamide (the PC regimen, N = 32) or taxanes and cisplatin (the TP regimen, N = 74). *HGPRT* was chosen experimentally as a reference gene. In qPCR reactions, inventoried TaqMan assays (Life Technologies) were used, except for the *CRNDE* gene, expression of which was evaluated with two personally designed TaqMan assays, specific to two different splice variants. The amount of genomic DNA contamination was assessed and taken into account if necessary (i.e., for *CEBPA*, an intronless gene). The results were analysed statistically using univariate and multivariate Cox proportional hazards models.
Results: Elevated mRNA expression of *CRNDE* (two different splice variants), *VAV2* and *CEBPA* genes negatively influenced prognosis by significantly increasing risk of death and/or recurrence. For *CEBPA*, this association was mainly observed in a group of patients treated with PC. The clinical significance of *VAV2* overexpression seemed to be related to the TP treatment, though a negative impact of upregulation was also visible in the group of all patients analysed. Overexpression of *CRNDE* negatively affected prognosis without clear discrimination between the chemotherapies administered. In addition, some clinical associations of *CRNDE* seemed to depend on TP53 accumulation status.
Conclusions: Considering the Real-Time qPCR results, the *CRNDE*, *VAV2* and *CEBPA* genes emerged as novel cancer-promoting factors and potential molecular markers in ovarian cancer patients. The clinical meaning of their protein products should be further evaluated in a bigger, well characterised group of tumours through immunohistochemical staining.
No conflict of interest.

1025 POSTER

Characteristics of the relation between epithelial–mesenchymal transition and proliferative activity in breast carcinomas

A.A. Brilliant[1], Y.M. Zasadkevich[1], S.V. Sazonov[1]. *[1]Institute of Medical Cell Technologies, Laboratory of Pathology, Ekaterinburg, Russian Federation*

Background: Metastases in distant sites are the leading cause of death from breast cancer. One of the most important features of this process is epithelial–mesenchymal transition (EMT), the key marker of which is vimentin − a protein of intermediate filaments of cytoskeleton. EMT is a final stage of tumour dedifferentiation and is started by a row of signalling mechanisms responsible for adhesion and proliferation of tumour cells. The aim of the research was to study interplay between the level of proliferation of breast carcinoma tissue, detected by a proliferative index Ki-67, and realisation of EMT.
Material and Methods: 129 cases of breast carcinoma were studied. Vimentin in the tumour cells was detected by monoclonal antibodies Monoclonal Mouse Anti-Swine Vimentin (DAKO, Denmark). For detection of the cell proliferation index antibodies Mouse Anti-Human KI-67 Antigen (DAKO, Denmark) were used. Immunohistochemical tests were made in autostainer 'DAKO' (Denmark) with the use of Dako Wash Buffer, visualisation system Dako EnVision+Dual Link System-HRP, chromogen Dako Liquid DAB+ Substrate Chromogen System (DAKO, Denmark). Test evaluation was made with the microscope 'Zeiss Ymager M' (Germany). A criterion of positive expression of vimentin in the tumour cells was presence of strong cytoplasmic staining. Proliferative activity of the investigated tumour was evaluated by the percentage ratio between the stained nuclei of breast carcinoma cells and the unstained ones.
Results: A weak positive correlation between vimentin expression and Ki-67 level was found ($r = 0.39$; $p < 0.05$). Due to heterogeneity of the group of analysed carcinomas all the cases were divided into immunohistochemical subtypes: luminal A subtype − 39 cases (30.2%), luminal B (Her2-) subtype − 36 cases (27.9%), luminal B (Her2+) subtype − 15 cases (11.6%), Her-2 subtype − 15 cases (11.6%), basal-like subtype − 24 cases (18.6%). We found a strong positive correlation between proliferative activity of a tumour and vimentin expression in Her-2 positive and basal-like subtypes ($r = 0.85$; $p < 0.05$; $r = 0.87$; $p < 0.05$ respectively). A weak negative correlation was found for cases from luminal A subtype ($r = -0.38$; $p < 0.05$). For other subtypes a fairly significant correlation between studied parameters was not found.
Conclusions: EMT mainly occurs in breast carcinomas with a high level of proliferation that reflects on the correlation between the presence of the vimentin expression and a high level of Ki-67, distinctive for basal-like and Her-2+ subtypes, associated with poor prognosis and a high risk of distant metastases development.
No conflict of interest.

1026 POSTER

Prognostic significance of heme oxygenase-1, S100A4 and syndecan-1 expression in primary non-muscle invasive bladder cancers

J. Park[1], J.H. Kim[2]. *[1]Eulji University Hospital Eulji University College of Medicine, Urology, Daejeon, South Korea; [2]Eulji University Hospital Eulji University College of Medicine, Pathology, Daejeon, South Korea*

Background: The prognosis of non-muscle invasive bladder cancer (NMIBC) is variable and significant proportions of patients undergo tumor recurrence and progression despite clinically complete transurethral resection. We have examined whether altered protein expression for three potential biomarkers, which are associated with different BC carcinogenesis pathway and have been studied by limited number of studies, could predict tumor recurrence and progression in patients with primary NMIBC.
Materials and Methods: The study included 109 patients who were diagnosed with primary NMIBC after clinically complete transurethral resection between 2000 and 2008 at our institute. After extensive and critical literature review regarding prognostic molecular markers based on immunohistochemistry and cDNA microarray in NMIBC, three molecular markers including heme oxygenase (HO-1), S100A4 and syndecan-1 (SYND1) were selected. Protein expression was analyzed by immunohistochemistry, and the immunoreactivity for each biomarker was evaluated using a semi-quantitative scoring system for both the intensity of the stain and the percentage of positive neoplastic cells. Survival analysis was performed using Kaplan–Meier curves and Cox regression to determine the effect of each marker on recurrence-free survival (RFS) and progression-free survival (PFS).
Results: The altered expressions for each marker were noted in 36 patients (33.0%) for HO-1, 40 (36.7%) for S100A4 and 69 (63.3%) for SYND1, respectively. Abnormal expressions of HO-1 and S100A4 were significantly correlated with higher T stage and grade, whereas SYND1 alteration was significantly with lower T stage and grade (all $p < 0.001$). On multivariate analysis including clinicopathological parameters and biomarkers, the three biomarkers were significant predictors for RFS while HO-1 and S100A4 were significant predictors for PFS. A combination analysis of three markers showed that patients with multiple ($\geqslant 2$) marker alteration was associated with significantly lower 5-year RFS (43.0%) and PFS (64.0%) rates than patients with none or single marker alteration (RFS: 78.1%, $p = 0.003$; PFS: 97.0%, $p < 0.001$). In protein-protein interaction analysis using BisoGenet, there were large protein network among the three markers.
Conclusions: Our findings indicate that immunohistochemical analysis for HO-1, S100A4 and SYND1 may be useful in predicting tumor recurrence and progression, thus planning treatment strategies in NMIBC.

1027 POSTER

Role of C-reactive protein in advanced cancer prognostication

S. Shrotriya[1], D. Walsh[1], N. Bennani-Baiti[1], A. Aktas[1], B. Estfan[1]. *[1]Cleveland Clinic Taussig Cancer Institute, The Harry R. Horvitz Center for Palliative Medicine, Cleveland, USA*

Background: CRP, a non-specific marker of inflammation may help cancer prognostication. CRP is secreted by liver due to interleukin-1 (IL-1), IL-6 and tumor necrosis factor (TNF). It has been linked to shorter survival in some cancers. We examined associations between CRP levels and prognosis in solid tumors.
Material and Methods: Retrospective study of electronic medical records (EMR). Multiple CRP levels at a tertiary cancer center reviewed (2006–2011). Hematological cancer diagnoses excluded. Survival defined from the date with highest CRP to date of death. CRP reported as median (25^{th}, 75^{th} percentile). CRP reference range 0−10 mg/L.
Results: N = 6809 with solid tumors identified. 56% males. 83% Caucasian, 15% African American. Common cancers − genitourinary (GU) 29%, breast

14%, gastrointestinal (GI) 14%, lung 7%. Highest CRP for GI, GU, lung, breast = 8 (2, 15); 6 (2, 15); 3 (1, 8); 2 (1, 5) respectively. Median survival (months) = 13 (8, 30); 18 (11, 33); 16 (8, 27) and 25 (15, 41) respectively.
Conclusions: 1. Higher median CRP in GI, GU, lung and breast cancers.
2. Higher CRP associated with shorter prognosis across primary sites (even within reference range).
3. Inverse relationship between absolute CRP values and survival.
4. High CRP, an adverse prognostic indicator in most solid tumors.
No conflict of interest.

1028 POSTER

Atypical spitzoid melanocytic tumors versus spitzoid melanoma: Diagnostic and prognostic assessment by FISH analysis

G. Tragni[1], B. Valeri[1], E. De Paoli[1], M.G. Facciorusso[1], A. Testi[1], F. Crippa[2], A. Maurichi[2], R. Patuzzo[2], R. Ruggeri[2], M. Santinami[2]. *[1]Fondazione IRCCS Istituto Nazionale Tumori, Pathology, Milan, Italy; [2]Fondazione IRCCS Istituto Nazionale Tumori, Sarcoma-Melanoma Unit, Milan, Italy*

Background: The aim of our study was to evaluate whether molecular alterations detected by Fluorescence In Situ Hybridization (FISH) could be helpful in differentiating Atypical Melanocytic Spitzoid Tumors (AST) from Spitzoid Melanoma (SM) and performing risk assessment particularly for AST in order to a correct management of the patients.
Material and Methods: The study included 61 AST and 32 SM retrived from the files of the Department of Pathology-Istituto Nazionale Tumori-Milan from January 2010 up to March 2013. All cases were reviewed by two expert pathologists and analyzed by FISH technique using the 4-probe multicolour FISH DNA kit (Visys/Abbott Molecular®) targeting RREB1 (6p25), MYB (6q23), CCND1 (11q13) and CEP6. Sentinel lymph node biopsy (SLNB) was performed in 8 AST and 24 SM.
Results: Positive FISH result was found in 27 of 61 AST (44.6%) and 20 of 32 SM (62.5%). Gain of both CCND1 and RREB1 was the most common molecular alteration in AST (23%) and SM (75%). In AST series 4 (50%) out of 8 patients had metastatic involvement of sentinel node, 3 of them with positive FISH result. In SM series 7 (29%) out of 24 patients had metastatic involvement of sentinel node, 4 of them with positive FISH result. Furthermore molecular analysis of nonmetastasizing cases show that 1 of 4 AST (25%) and 10 of 17 SM (58.8%) had also positive FISH result. All patients affected by AST or SM with positive SLNB were alive with no evidence of disease at last follow-up.
Conclusions: Our study shows that FISH analysis is not really helpful in differential diagnosis of AST versus SM because we found positive FISH result in both lesions (AST 44.6% versus SM 62.5%) with the same molecular alteration (CCND1 and RREB1) as the most common. Furthermore we cannot use it as prognostic tool because of positive FISH result in both metastasizing and not metastasizing AST and SM. To validate the utility of FISH analysis for the differential diagnosis and risk assessment of AST versus SM a larger sample of cases of both series with prolonged follow-up need to be evaluated and tested by a broader spectrum of FISH probes.
No conflict of interest.

1029 POSTER

Evidence of cathepsin K (CTSK) in the aggressive development and invasion of pituitary adenomas

W. Jia[1], A.J. Sanders[2], W. Jiang[2]. *[1]Beijing Tiantan Hospital affiliated to Capital Medical University, Beijing, China; [2]Cardiff University-Capital Medical University Joint Centre for Biomedical Research Cardiff University School of Medicine Heath Park Cardiff UK, Metastasis and Angiogenesis Research Group Department of Surgery, Cardiff, United Kingdom*

Background: CTSK, cathepsin K, is a member of cysteine proteinases and has been found to be highly expressed in muscle and skeletal tissues. It has been indicated in the degradation of extracellular matrix and in particular protein component of bone matrix and that CTSK knockout mice has abnormalities in bone development and functions and resulted in increased fragility of bones. Pituitary adenomas are mostly benign with or without active endocrine functions. Located in the fossa of sphenoid bone, sella turcica, one of the key features of the pituitary adenomas is the invasion and destruction of the surrounding bones in the sella fossa. However, biological and molecular events involved in the destruction of sella fossa remains unclear. In the present study, we investigated expression of CTSK in pituitary adenomas with particular reference to invasion and destruction of sella fossa.
Materials and Methods: Pituitary adenomas were freshly collected immediately after surgery. Histological, radiological and biochemical analyses were carried out to provide clinical classification (Knosp's method) and to establish the endocrine status of the tumours. Expression of CTSK in pituitary tumours was determined using quantitative gene transcript analysis and analysed against tumour grade, invasion, Knosp grade, endocrine nature. Statistical analyses were conducted using Mann-Whitney U test and Kruskall-Walis method.
Results: Pituitary tumours which had invaded sphenoid sinus had a higher level of CTSK compare with those without invasion (median 14.8 vs 25.7). Likewise, using the Knosp classification, Stage 3 and 4 tumours which had signs of invasion showed high levels of CTSK than Knosp 0, 1 and 2 tumours (medians 25.7 vs 14.8). These links were independent of the size of tumours. It was interesting to observe that TSH-, gonadotrophin- and ACTH-secreting tumours had high levels of CTSK than endocrine-inactive tumours (70.1, 53.9 and 46.2 vs 20.9 respectively) and tumours secreting PRL and GH had lower levels (3.02 and 4.0 respectively). Finally, it was noteworthy that pituitary tumours with internal haemorrhage had lower levels of CTSK than those without haemorrhage (25.70 vs 4.0, $p < 0.05$), suggesting that CTSK is an unlikely candidate for this clinical condition.
Conclusions: It is concluded that Cathepsin K, an proteinase commonly involved in the regulation of bone absorption and bone pathology is over-expressed in pituitary adenomas which have aggressive pattern toward its surrounding bone tissues. This provides new direction in the understanding of the biology of pituitary tumours and their progression.

Targeting hypoxia to enhance the anti-tumour effect of a stereotactic radiation schedule

M.R. Horsman[1]. *[1]Aarhus University Hospital, Experimental Clinical Oncology, Aarhus C, Denmark*

Background: Hypoxia in tumours is well known to reduce the efficacy of radiation therapy. Recent studies suggest that such hypoxia may play a more significant role when radiation is given as large doses/fraction. The aim of this study was to use clinically relevant approaches for eliminating hypoxia to see if they could improve tumour response to a stereotactic radiation schedule.
Material and Methods: A C3H mammary carcinoma grown in the right rear foot of female CDF1 mice was used in all experiments. Treatments were performed in restrained non-anaesthetised animals when tumours had reached 200 mm^3 in size. Tumours were locally irradiated (230 kV x-rays) with 3 x 15 Gy (each fraction given with an interval of 2−3 days over a one week period). Hypoxic modification was achieved by intraperitoneally (i.p.) injecting the radiation sensitizer nimorazole (200 mg/kg), combining the oxygen modifiers nicotinamide (120 mg/kg; i.p.) and carbogen (95% O_2 + 5% CO_2) breathing, using the hypoxic cytotoxin hyperthermia (41.5^{O}C; 1-hour), or injecting the vascular disrupting agent OXi4503 (10 mg/kg; i.p.). Three days after the final irradiation the tumours were subjected to a clamped top-up dose which involved giving graded radiation doses with the tumour bearing leg clamped for 5 minutes before and during irradiation. The percentage of mice in each treatment group showing local tumour control 90 days after irradiating was recorded and the TCD50 values (radiation dose to control 50% of tumours) estimated from the clamped top-up radiation dose response curves. A Chi-squared test ($p < 0.05$) was used to determine significant differences between the TCD50 values.
Results: The clamped top-up TCD50 value (with 95% confidence intervals) following 3 x 15 Gy was 30 Gy (23−38). This was significantly reduced to 6 Gy (3−10) when nicotinamide (injected 20 minutes prior to irradiation) and carbogen breathing (starting 5 minutes before radiation and continued during each radiation period) were combined; to 9 Gy (5−17) by heating tumours 4-hours after each radiation treatment; and 12 Gy (8−19) if OXi4503 was injected 1 hour after each irradiation. The value obtained when nimorazole was injected 30 minutes prior to irradiation is currently under analysis.
Conclusions: Targeting hypoxia is a very effective method for improving the efficacy of radiation given in a stereotactic schedule. This enhancement also seemed to be relatively independent of the hypoxic modifier used.

EGFR-amplification correlates with response to combined treatment of fractionated irradiation and EGFR-inhibition in HNSCC tumour xenografts

K. Gurtner[1], C. Thurow[1], A. Yaromina[1], W. Eicheler[1], M. Baumann[1], M. Krause[1]. [1]*Medical Faculty and University Hospital Carl Gustav Carus Technische Universität Dresden, Department of Radiation Oncology and OncoRay − National Center for Radiation Research in Oncology, Dresden, Germany*

Background: With the aim to identify potential biomarkers for the improvement of local tumour control by simultaneous EGFR inhibition during fractionated irradiation, 10 different HNSCC tumour xenografts are evaluated for local tumour control after irradiation with or without EGFR inhibition, while simultaneously investigating factors that might influence the response. Results of the first 5 tumour models are already published (Gurtner et al., Radiother Oncol 2011 (99):323–330) and revealed a correlation between EGFR-amplification (EGFR-CEP-7 ratio) and response to combined treatment of irradiation and EGFR-Inhibition with cetuximab. Here we present an update of the data on a total of 8 tumour models and a comparison of EGFR gene amplified versus non-amplified tumours.
Material and Methods: For evaluation of local tumour control dose 50% (TCD_{50}) 120 days after treatment tumours were treated with fractionated irradiation (RT) (30f/6 weeks) alone or combined with application of the monoclonal EGFR-antibody cetuximab (1 mg, weekly, i.p.). For tumour growth delay and relative tumor volume cetuximab was applied alone (once d0 or 4x d0, d2, d5, d7). Results were compared with molecular data on fluorescense-in situ-hybridisation (FISH) and immunohistochemistry.
Results: A significant improvement of local tumour control could be observed for the combined treatment of RT and cetuximab compared to RT alone in all 3 tumours harbouring an EGFR gene amplification. The enhancement ratios for the TCD_{50} after irradiation alone versus irradiation plus cetuximab were 2.0 (CAL-33), >40 (UT-SCC-14) and >44 (UT-SCC-8). In only 2 of the 5 tumour models without EGFR gene amplification local tumour control was improved by simultaneous Cetuximab application.
Conclusion: EGFR gene amplification appears as a promising biomarker for prediction of the improvement of local tumour control by combined fractionated irradiation and Cetuximab treatment. However, using this biomarker alone would result in some false-negative predictions, as also the group of non-amplified tumours contains some responder models. Thus, further biomarker evaluation is warranted to improve the validity especially in the latter subgroup of tumours.

Myeloid cells as a novel determinant of hypoxic radioresponse in colorectal cancer cells through L-arginine turnover

M. De Ridder[1], W. Leonard[1], I. Dufait[1], F. Steenbeke[1], H. Jiang[1], K. Law[1], D. Van den Berge[1], V. Verovski[1], G. Storme[1]. [1]*UZ Brussel, Radiotherapy, Brussel, Belgium*

Introduction: Tumor-associated myeloid cells may undergo antitumor M1 or protumor M2 polarization linked to the alternative L-arginine turnover through inducible nitric oxide synthase (iNOS) and arginase-1 (ARG) respectively. The former pathway is known to result in production of nitric oxide (NO), a potent inhibitor of mitochondrial respiration. This study explored the ability of M1 versus M2 macrophages to affect radioresponse of colorectal cancer (CRC) cells in a model of metabolic hypoxia, and screened the iNOS/ARG signature of mouse and human tumor-associated myeloid cells.
Material and Methods: Mouse peritoneal macrophages were polarized to M1 and M2 types by exposure to IFN-γ/LPS or IL-4 respectively, and profiled by RT-PCR. CRC cells and macrophages were placed in a tissue-mimetic co-culture system (TMCS), wherein metabolic hypoxia was induced under limited oxygen diffusion. Oxygen depletion was assessed by fluorescence, and hypoxic radioresponse to 0−12 Gy by colony formation assay. ARG+ myeloid cells were phenotyped by FACS in colon CT26 mouse tumors and in 10 rectal cancer patients.
Results: M1 stimuli increased in macrophages the mRNA levels of iNOS, IL-6, IL-12α and IL-12β by 49700, 220, 260 and 740-fold respectively, and NO/nitrite output above 40 μM. M2 macrophages showed the up-regulation of ARG, Ym1, Fizz1 and CCL17 by 20, 499, 118 and 72-fold respectively, and no iNOS activation. In the TMCS, M2 macrophages significantly contributed to oxygen consumption and hypoxic radioprotection in CRC cells up to 2.5-fold, as compared with aerobic cells. Contrasting, M1 macrophages were able to uniformly restore impaired radioresponse of mouse CT26 and human DLD-1, HT29, HCT116, and SW480 CRC cells through NO-induced arrest of oxygen consumption resulting in oxygen sparing. The radiosensitizing effect was entirely attributed to iNOS+ macrophages since all CRC cell lines failed to activate the iNOS/NO pathway in the presence of M1 stimuli. In CT26 tumor-bearing mice, the myeloid $CD11b^+Gr\text{-}1^+$ subset underwent M2-type polarization marked by ARG activation. In cancer patients, whole blood CD15+ granulocytes displayed ARG overexpression and accelerated L-arginine turnover (up to 3-times), as compared with healthy donors.
Conclusions: CRC is associated with the predominant expansion of ARG+ myeloid cells that feature radioprotective properties and compete for L-arginine, thereby compromising the radiosensitizing potential of iNOS+ myeloid cells.

A validated score predicting short survival (death within 30 days) after palliative radiotherapy: Better health economics and less overtreatment

K. Angelo[1], J. Norum[2], A. Dalhaug[3], A. Pawinski[4], G. Aandahl[4], E. Haukland[4], K. Engljaehringer[4], C. Nieder[4]. [1]*University of Tromsø, Tromsø, Norway;* [2]*University of Tromsø, Department of Oncology, Tromsø, Norway;* [3]*University of Tromsø, Faculty of Health Sciences, Tromsø, Norway;* [4]*Nordland Hospital, Department of Oncology and Palliative Medicine, Bodø, Norway*

Background: Radiotherapy (RT) might palliate symptoms from incurable cancer. Its use should be tailored to prognosis and avoided in the terminal phase of disease. Survival prediction is challenging and recent reports have disclosed overutilization of RT during the final 30 days of life. Decision aids predicting short survival might help to avoid overtreatment.
Material and Methods: Uni- and multivariate analyses of factors predicting use of RT during the final 30 days of life for all palliative RT courses (metastatic or non-metastatic) administered at Nordland Hospital between 20.06.2007 (opening of radiation oncology unit) and 31.12.2009. Development of a predictive model by recursive partitioning analysis (RPA) and independent validation of its performance in patients treated during 2010 and 2011.
Results: We analysed 579 palliative RT courses given in the time period 2007–2009. Of these, 25 (4%) remained incomplete (typically because of clinical deterioration). Median survival was 6.3 months. In 53 cases (9%) RT was administered in the final 30 days of life. In univariate analysis, 19 factors were significantly associated with this endpoint. Multivariate analysis confirmed performance status (PS), primary tumour type, liver metastases, known disease progression outside the actual RT volume(s), steroid use, opioid analgesic use, serum haemoglobin, c-reactive protein and albumin levels as independent predictors for use of RT in the final 30 days of life. RPA resulted in a model consisting of 6 parameters (low haemoglobin, opioid analgesic use, ECOG PS 3−4, known progressive disease, steroid use, lung (small or non-small cell) or bladder cancer), which correctly identified 75% of RT courses administered during the final 30 days of life. Maximum survival of patients fulfilling all criteria was 69 days. Death within 40 days occurred in 83%. In the independent validation data set (2010–2011) these figures were 74% (30 days), 84% (40 days) and 100% (92 days).
Conclusions: Assigning the right patient to the right palliative approach is challenging. Based on our results, we suggest that patients with lung or bladder cancer with ECOG PS 3−4, low haemoglobin, progressive disease outside the actual RT volume, and on steroids and opioids are at high risk of dying shortly after initiation of RT. Our model facilitates decision making (best supportive care versus RT) and is the first decision aid specifically addressing RT in the final 30 days of life.

Reduction of heart dose during left breast cancer radiotherapy: comparison between respiratory gating RT and IMRT

G.R. D' Agostino[1], B. Diletto[1], A. Martino[1], G. De Dilectis[1], F. Catucci[1], L. Nardone[1], D. Pasini[1], V. Valentini[1], G. Mantini[1]. [1]*Catholic University of the Sacred Heart, Radiation Oncology, Roma, Italy*

Background: Breast conserving surgery and post-operative whole breast radiotherapy (RT) have proved to reduce local recurrence and improve survival of early stage breast cancer patients. It has also been demonstrated that long-term survivors have a significantly higher risk of cardiac death as a consequence of heart irradiation during left breast tangential RT. Novel technologies, such as prospective respiratory gating RT (PGRT) and intensity modulated radiotherapy (IMRT), provide a chance to reduce heart doses. This study compares the cardiac dose delivered by a standard 3D conformal tangential radiotherapy (CRT) to that delivered by PGRT or a 5 fields-IMRT.

Material and Methods: Patients with early left breast cancer, referred for adjuvant radiotherapy to our Institution, were enrolled in this study. For each patient, two simulation CT-scans were acquired: the first during free breathing and the second on prospective gating during deep inspiration breath-hold. The scans were monitored by the Varian RPM^{TM} respiratory gating system. For each patient, three treatment plans were performed: a 3D-CRT plan and an IMRT plan, based each on the free-breathing scan, and a PGRT plan based on the deep inspiration breath-hold scan. Mean heart dose (MHD), heart V_{25} and mean dose to the controlateral breast were evaluated. Dose-volume histograms were compared by the Friedman test.
Results: 44 patients were enrolled. Median age was 52 years (range 34−76), the mean breathing period was 4.3s (range 2–12.9), and the mean 4DCT scanning time was 12.5 s (range 10–16.5). Overall patients' compliance to respiratory gating technique was good. The median MHD was 3 Gy (range 1.22–7.38) in the CRT plans, 1.9 Gy (range 0.50–3.60) in the PGRT plans and 4.13 Gy (1.12−8.5) in IMRT plans ($p < 0.001$). The mean heart V_{25} was 1.06% (range 0−9.7), 0% (range 0−2.7) and 0.1% (range 0–5.82) for CRT, PGRT and IMRT plans, respectively ($p < 0.001$). Mean and maximum doses to the controlateral breast was 0.79 Gy (range 0.02−2) and 6.97 Gy (range 0.25–13.8) for the PGRT plans, and 1.98 Gy (0.05–5.38) and 9.39 Gy (range 3.73–20.57) for the IMRT plans ($p < 0.001$).
Conclusions: In this study the prospective gating tangential RT to left breast proved to offer the better dose sparing of heart, with also a lower irradiation of the controlateral breast.

Present and future radiation therapy infrastructure in Europe: a wake up call to cut the mustard?

N.R. Datta[1], S. Khan[1], A. Meister[1], E. Puric[1], G. Lutters[1], E. Rabe[1], S. Bodis[1]. *[1]Kantonsspital Aarau, Radiation Oncology, Aarau, Switzerland*

Background: Radiation therapy (RT) is required in 50% of newly diagnosed cancer patients and 25% of those previously irradiated. The present status of teletherapy (TRT) units in 33 countries of Europe was recently published. To further look into a complete RT scenario with TRT and brachytherapy (BRT) units and manpower − radiation oncologist (RO), medical physicist (MP) and radiotherapy technologist (RTT) as exists today and projected needs till 2020, a comprehensive analysis for European countries was carried out.
Material and Methods: Data for 40 European countries, whose individual cancer incidences, equipments and manpower were available in the databases of GLOBOCAN and DIRAC were analysed. Norms recommended by IAEA and ESTRO-QUARTS were used to ascertain the adequacy of RT facility for each country.
Results: The combined outcome of these countries is summarized in the table.

Parameter	Total	Range (min to max)
Cancer incidence[2]	3,377,743	1,378 to 493,853
RT needed	2,111,089	861 to 308,658
TRT listed[3]	3,638	2, 529
TRT required	4,691	2, 686
Deficit in TRT	1,053	−283 to 59
BRT listed[3]	700	0 to 94
BRT required	1,055	1 to 154
Deficit in BRT	355	−95 to 7
RO listed[3]	7,399	2 to 1,218
RO required	7,037	3 to 1,029
Deficit in RO	Nil	−501 to 488
MP listed[3]	3,823	2 to 744
MP required	5,278	2 to 722
Deficit in MP	1455	−504 to 46
RTT listed[3]	13,213	4 to 4,241
RTT required	14,074	6 to 2,058
Deficit in RTT	860	−1,728 to 2,809

[2] http://globocan.iarc.fr

[3] http://www-naweb.iaea.org/nahu/dirac/default.asp

Additional number of TRT units, BRT units, RO, MP and RTT required by 2020 are 1661, 492, 550, 2138, and 2685 respectively.
Conclusions: None of the 40 countries have presently an all inclusive recommended number of RT units and manpower. While in some, the deficiencies are marginal, in others, a gross lack or imbalance of either manpower or treatment units or both were detected. This could lead to long RT waiting list, inadequate implementation of specialized RT techniques like IMRT, possibility of compromise on quality of RT and in some cases to even resort to 'fill in the RT waiting list' by chemotherapy. All these could seriously affect the treatment outcomes and nullify the efforts of early detection and treatment. Thus, in view of the imminent rise in cancer incidence during the next decade and the projected needs, adequate steps are highly desirable at individual country level or jointly to provide optimal RT access to all patients.

VARIAN AWARD: Prediction of normal tissue morbidity in radiotherapy of prostate cancer using motion-inclusive dose distributions

M. Thor[1], L. Bentzen[2], L.B. Hysing[3], C. Ekanger[3], S.I. Helle[3], A. Karlsdóttir[3], L.P. Muren[1]. *[1]Aarhus University Hospital, Departments of Medical Physics and Oncology, Aarhus, Denmark; [2]Aarhus University Hospital, Department of Oncology, Aarhus, Denmark; [3]Haukeland University Hospital, Department of Oncology and Medical Physics, Bergen, Norway*

Background: In radiotherapy (RT) of prostate cancer the key organs at risk (ORs) − the rectum and the bladder − display considerable motion, which may influence the dose/volume parameters predicting for morbidity. In this study we compare motion-inclusive doses to planned doses for the rectum and the bladder and explore their associations with prospectively recorded morbidity.
Material and Methods: This study included 38 prostate cancer patients treated with hypo-fractionated image-guided intensity-modulated RT that had an average of nine (7−10) repeat CT scans acquired during treatment. These scans were registered to the respective treatment planning CT (pCT), based on rigid registration (translations) on intra-prostatic fiducial gold markers, followed by a new dose calculation on the repeat CT geometry. One motion-inclusive dose distribution was assessed for each patient and structure (rectum, rectum wall, bladder and bladder wall) by averaging over the, on average nine, motion-inclusive dose-volume histograms. The pCT volumes, the treatment course averaged volumes as well as the planned and motion-inclusive dose distributions were associated with acute and late morbidity (morbidity cut-off: $\geqslant$ Grade 2) using logistic regression.
Results: Acute rectal morbidity (observed in 11 (29%) patients) was significantly (p£0.05) associated with smaller treatment course averaged rectal volumes (population median: 75 vs. 94 cm^{-3}). Furthermore the motion-inclusive rectal wall volume receiving doses close to the prescription dose (2 Gy-equivalent dose of 76 Gy (a/b=3 Gy)) was also significantly associated with this morbidity end-point.
Conclusions: To the best of our knowledge, this study is the first to show that motion-inclusive DVH parameters are better predictors than DVH parameters based on the 'static' planning CT along. Both findings of the study are plausible − smaller rectal volumes are likely to be related to a more stable portion of this organ being located in the high-dose volume high and a high-dose relation with morbidity is in agreement with the QUANTEC study − increasing the credibility of the findings despite the modest patient number. This study indicates that the deviations between planned and delivered dose/volume parameters − caused by internal organ motion − should be accounted for to improve the ability to predict morbidity following RT.

ACCURAY AWARD: Targeting radiation resistance in p53 mutant tumours

A. Abraham[1], G. Hamilton[1], E. O'Neill[1]. *[1]Gray Institute for Radiation Oncology and Biology, Department of Oncology University of Oxford, Oxford, United Kingdom*

Background: Increasing our understanding of how resistance to treatment occurs, helps us develop more efficient and personalised therapeutic regimes for cancer patients. Through molecular dissection of events that drive tumour initiation and progression, we have uncovered a functional connection between the most frequent oncogenic mutations that are likely to contribute to therapeutic resistance in 30% of all human tumours. Mutations activating the 'AKT/PI3K' signalling pathway and inactivation of

the '*TP53*' tumour suppressor gene are common mechanisms that cancer cells require to proliferate and escape pre-programmed cell death. Tumours employ many strategies to inactivate p53; however sequence mutations that result in mutant p53 protein (p53mut) are most often observed. p53mut tumours not only fail to respond to DNA damaging therapy, but are also described to promote therapeutic resistance by dominant negative suppression of p53 dependent promoter activity. We find that in combination these events lead to therapeutic resistance that is reversible by the AKT clinical candidate, MK-2206 and the PI3K inhibitor PI-103.
Methods: Using a combination of *in vivo* and *in vitro* techniques we have tracked the molecular mechanism for AKT mediated resistance to treatment in solid tumours. This has helped us to simultaneously derive potential biomarkers that could highlight where the greatest efficacy may be achieved in clinical practise.
Results: We demonstrate that AKT inhibition promotes reduced levels of p53mut in tumour cells via a novel regulation of the 'tumour suppressor' p14ARF and promotes re-engagement of cell cycle arrest, senescence and increased sensitivity to ionising radiation in both *in vivo* and *in vitro* systems. We also show that PI3K/AKT inhibitors- and as proof of concept, the clinical candidate AKT inhibitor, MK-2206, and PI3K inhibitor, PI-103, are effective in treatment of mice with therapeutically resistant tumours with elevated AKT and carrying p53mut.
Conclusions: We show that targeting the PI3K/AKT pathway sensitise xenografts carrying p53 mutations to DNA damaging therapy. We have also been identifying potential molecular markers to select the cohort of patient most likely to benefit best from this treatment.

CBCT-based internal gross tumor volume definition for radiotherapy of of non-small-cell lung cancer: Comparison with target volumes based on three-dimensional CT and four-dimensional CT

F. Li[1], J. Li[1], Q. Shao[1], Y. Zhang[1], T. Fan[1], M. Xu[1], H. Qi[1]. [1]*Shandong Cancer Hospital and Institute, Department of Radiation Oncology, Jinan, China*

Background: To evaluate the amount of respiration information included in CBCT and investigate the use of CBCT c-ombined with 3DCT and 4DCT in the definition of target volumes.
Materials and Methods: Thirty-first patients with NSCLC sequentially underwent 3DCT and 4DCT simulation scans of the thorax during free breathing. A 3D conformal treatment plan was created based on 3DCT. The first CBCT was performed and registered to the planning CT using the bony anatomy registration. All contours were performed by a radiation oncologist using the same contouring protocol. GTV-3D and GTV-50 were contoured based on 3DCT and end-expiration phase (50% phase) of 4DCT. Internal GTVs (IGTV-MIP and IGTV-CBCT) were contoured based on maximum intensity projection (MIP) of 4DCT and CBCT. The differences in the position, size, and degree of inclusion (DI) of different volumes were compared.
Results: The mean size ratio of GTV-3D, GTV-50, IGTV-MIP to IGTV-CBCT were 0.77 ± 0.18, 0.84 ± 0.2, 1.1 ± 0.26 respectively for tumors in the upper lobe and 0.67 ± 0.11, 0.65 ± 0.18, 1.17 ± 0.27 respectively for tumors in the middle and lower lobe. The motion vector showed a significant correlation to the ratio of GTV-50 to IGTV-CBCT ($r = -0.45$, $p = 0.012$) for all the patients. DIs of GTV-3D, GTV-50, IGTV-MIP in IGTV-CBCT were 0.65 ± 0.27, 0.65 ± 0.2 and 0.62 ± 0.2, while DIs of IGTV-CBCT in GTV-3D, GTV-50, IGTV-MIP were 0.47 ± 0.2, 0.49 ± 0.2 and 0.67 ± 0.19 respectively.
Conclusion: The tumor motion included in CBCT is significantly larger than 3DCT and end-expiration phase of 4DCT, but less than 4DCT MIP. CBCT can include the respiration motion information well compared to 4DCT MIP. The use of 3DCT registered to CBCT, or 4DCT registered to CBCT based on bony anatomy in radiotherapy may result in a severe target miss, which should be focused on when we perform adaptive radiotherapy and rectify treatment planning.

1059 POSTER

Comparison of internal target volumes defined on three-dimensional CT, four-dimensional CT and cone-beam CT images of non-small-cell lung cancer

F. Li[1], J. Li[1], Y. Zhang[1], J. Xing[1], D. Shang[1], N. Yu[1]. [1]*Shandong Cancer Hospital and Institute, Department of Radiation Oncology, Jinan, China*

Background: To compare positional and volumetric differences of internal target volumes defined on three-dimensional CT (3DCT), four-dimensional CT (4DCT) and cone-beam CT (CBCT) images of non-small-cell lung cancer.
Materials and Methods: Thirty-first patients with NSCLC sequentially underwent 3DCT and 4DCT simulation scans of the thorax during free breathing. A 3D conformal treatment plan was created based on 3DCT. The first CBCT was performed and registered to the planning CT using the bony anatomy registration. All contours were performed by a radiation oncologist using the same contouring protocol. GTVs were contoured based on 3DCT, maximum intensity projection (MIP) of 4DCT and CBCT. CTV3D, ITVMIP and ITVCBCT were defined with a 7 mm margin accounting for microscopic disease. ITV10 mm and ITV5 mm were defined based on CTV3D. ITV10 mm with a 5 mm margin in LR, AP directions and 10 mm in CC direction; ITV5 mm with an isotropic internal margin (IM) of 5 mm. The differences in the position, size, Dice's similarity coefficient (DSC) and inclusion relation of different volumes were compared.
Results: The median size ratio of ITV10 mm, ITV5 mm, ITVMIP to ITVCBCT were 2.33, 1.88, 1.03 respectively for tumors in the upper lobe and 2.13, 1.76, 1.1 respectively for tumors in the middle-lower lobe. The median DSC of ITV10 mm, ITV5 mm, ITVMIP and ITVCBCT were 0.6, 0.66 and 0.83 for all patients. The median percentage of ITVCBCT not included in ITV10 mm, ITV5 mm, ITVMIP were 0.1%, 1.63% and 15.21% respectively, while the median percentage of ITV10 mm, ITV5 mm, ITVMIP not included in ITVCBCT were 57.08%, 48.89%, 20.04%. The median percentage of ITVCBCT not included in ITV5 mm were 1.24% for tumors in the upper lobe and 5.8% for tumors in the middle-lower lobe ($p = 0.404$).
Conclusion: The individual ITV derived from 4DCT can't encompass the ITV from CBCT effectively, and using 4DCT ITV in radiotherapy may result in a target miss. The ITVs derived from 3DCT with istropic margins can encompass the CBCT ITV, but the size of 3DCT ITVs was far greater than the CBCT ITV. It is feasible to generate the 3DCT ITV with an isotropic IM of 5 mm for tumors in the middle-lower lobe.
No conflict of interest.

1060 POSTER

A correlation study on target displacement and its influencing factors of primary thoracic esophageal cancer during radiotherapy based on repeated four-dimensional CT scan

J.Z. Wang[1], J.B. Li[1], W. Wang[1], H.P. Qi[1], Z.F. Ma[1], Y.J. Zhang[1], T.Y. Fan[1], Q. Shao[1], M. Xu[1]. [1]*Shandong Cancer Hospital & Institute, Department of Radiation Oncology, Jinan, China*

Background: To investigate the correlation between the motion of gross tumor volume(GTV)and the tumor volume, length, the largest diameter of lesion in CT image with enhanced four dimensional computed tomography (4DCT) scanning during fractionated radiotherapy.
