Material and Methods: Thirty-two patients with thoracic segment esophageal carcinoma were divided into upper (9 patients), middle (14 patients) and distal (9 patients) esophageal tumors, enhanced 4DCT were performed after every ten fractions. The gross tumor volume (GTV) were delineated by the same radiotherapist on each of the 10 4DCT phase, the displacements in left-right (LR), anterior-posterior (AP), senior-inferiors (SI) directions and three-dimensional vector were calculated, the tumor length and the largest diameter of lesion were also calculated. Then, investigate the correlation between the motion of GTV and the tumor volume, length, the largest diameter of lesion for every fraction.
Results: The correlation were not significantly between the motion of GTV and the tumor volume for the first positioning, the tenth fraction and the thirtieth fraction; but the correlation was significantly to the distal segment for the twentieth fraction in the LR direction ($r = 0.731$,$P = 0.040$). The correlation were not significantly between the motion of GTV and the tumor length for the first positioning, the tenth fraction and the thirtieth fraction; but the correlation was significantly to the upper and distal segment for the twentieth fraction in the SI direction($r = 0.714$,$p = 0.031$;$r = 0.646$,$p = 0.044$), the correlation was also significantly to the distal segment for the twentieth fraction in the LR direction($r = 0.765$,$p = 0.027$). The correlation were significantly between the motion of GTV and the largest diameter of lesion to all patients for the first positioning in LR, SI and three-dimensional vector ($r = 0.373$,$p = 0.036$;$r = 0.377$,$p = 0.033$;$r = 0.415$,$p = 0.018$), but the correlation were not significantly for the tenth fraction, the twentieth and the thirtieth fraction.

Conclusion:s There have an correlation between the primary tumor displacements and the tumor volume, length and the largest diameter of lesion during the radiotherapy, but the appearance of time and the degree of correlation were different.

1061 POSTER

Research of primary thoracic esophageal tumor volume variance during radiotherapy based on reduplicated four-dimensional CT scan

J.Z. Wang[1], J.B. Li[1], W. Wang[1], H.P. Qi[1], Z.F. Ma[1], Y.J. Zhang[1], T.Y. Fan[1], Q. Shao[1], M. Xu[1]. [1]*Shandong Cancer Hospital & Institute, Department of Radiation Oncology, Jinan, China*

Background: To investigate the volume variation of primary thoracic esophagus carcinoma with enhanced four dimensional computed tomography (4DCT) scanning during fractionated radiotherapy.
Material and Methods: Thirty-two patients with thoracic segment esophageal carcinoma were divided into upper (9 patients), middle (14 patients) and distal (9 patients) esophageal tumors, enhanced 4DCT were performed after every ten fractions. The gross tumor volume (GTV) were delineated by the same radiotherapist on each of the 10 4DCT phase, $IGTV_{MIP}$ was the contour delineated from the maximum intensity projection (MIP), all 10 GTVs were combined to form $IGTV_{10}$, GTV_{mean} was the average of all 10 phases of each GTV.
Results: The majority of the GTV_{mean}, $IGTV_{MIP}$ and $IGTV_{10}$ were decreased with increasing fractions during radiotherapy based on repeated 4DCT scanning, but the volume change was different in different positions or different fractions. GTV_{mean} increased by 4.20–39.42% (1.31–7.44 cm^3) at the tenth fraction for 21.87% (7/32) patients, and the differences were significant ($t = -4.753$, $P = 0.003$). Except the upper esophageal tumors, statistical significance were existed in GTV_{mean}, $IGTV_{MIP}$ and $IGTV_{10}$ for all patients between the twentieth fraction and the first positioning (all $P<0.05$).
Conclusions: Repeated 4DCT scanning could not only observed the volume variance of primary tumor GTV without motion information, but also observed IGTV volume change. For primary middle and distal esophageal cancer, the best time to reset position should be selected at twentieth fraction when the primary tumor target volume changed significantly, and it was preferable to guide target correction and planning modification.
No conflict of interest.

1062 POSTER

Radionuclide therapy in cancer patients with bone metastases

M. Yaneva[1]. [1]*University Hospital "Sv.Georgi", Radiotherapy and Nuclear Medicine, Plovdiv, Bulgaria*

Aim: We submit our experience in the application of radionuclides for therapy of bone metastases of cancer patients with different foci of appearance of the cancer process: breast cancer, prostate cancer, lung cancer and others.
Material and Method: In 167 patients with bone metastases we used 32-P in 71 patients and 89-Sr in 96 patients. 93 are women and 74 are men; 90 women are with cancer of the breast, 52- with prostate cancer, 24 are with lung cancer and 1 with renal cell carcinoma. All patients are observed for side effects when an application of a radiopharmaceutical is done-32-P per os and 89-Sr intravenous, as well as for the changes of haemoglobin, leucocyte and thrombocyte count.
Results: One months after the radionuclide therapy we observed a significant reduction of the leucocyte and thrombocyte count in the group accepted 32-P ($t = 3.83$, $p < 0.05$; $t = 5.29$, $p < 0.001$). For the group, where 89-Sr is applied we did not calculate statistically significant decrease of the tested indicators mentioned above. At the same time the basic reason for which the radionuclides are applied- pain, decreases in intensity and patients return to their normal activity.This is more typical for patients with cancer of the breast and prostate cancer.
Discussion: The serious symptom 'pain' is influenced by the not so high applied activity of 2 mCi of 32-P speaks in favour of the use of this radiophar-maceutic, although there is a resistance among authors of its application with regard to myelosuppression. According to our observations it is light, the blood indicators restore quickly even without special therapy and patients can take the advantage of this additional method to overcome pain syndrome. The intravenous applicaton of 89-Sr in activity of 4 mCi also influences pain in a very good way, but the price per patient is high and all patients wait for an reimbursement from the health insurance. This is a significant factor for wider use. The use of 32-P is cheaper but the delivery stopped and for the moment we can use only 89-Sr.
Conclusion: The application of 32-P and 89-Sr is additional possibility for the treatment of pain due to bone metastases of cancer patients- easy and effective especially for those that are not treated effectively after local irradiation. The myelosuppressive effect is not statistically significant and both isotopes can be used successfully in the treatment of pain in cancer patients.
No conflict of interest.

1063 POSTER

Influence of radiotherapy on frequency of sister chromatid exchange, micronuclei and binuclear cells in breast cancer patients

M. Koc[1], N. Turaclar[2], H. Yurdakul[3], Y. Tezcan[1], H. Vurallar[2]. [1]*Necmettin Erbakan University Meram Medical School, Radiation Oncology, Konya, Turkey;* [2]*Selcuk University, Konya, Turkey;* [3]*Genetikon Lab, Konya, Turkey*

Purpose: Sister chromatid exchange (SCE) is a mutual segment exchange which occurs between two chromatids of sister chromosome that does not change the structure of the chromosome morphologically. Micronucleus (MN) is round objects stemming from nucleus and located in cytoplasm outside the main nucleus. Few studies have previously analyzed the effect of chemotherapy or radiotherapy on SCE or MN frequencies in breast cancer patients. The aim of this study was to evaluate any cytogenetic change in SCE, MN and binuclear cell (BNC) of peripheral blood lymphocytes in breast cancer patients treated with postoperative radiation therapy (RT).
Material and Methods: Frequency of the SCE, MN and BNC were examined in 22 breast cancer patients received RT and 10 healthy individuals. All parameters were measured before (RT-a), at the completion of (RT-b) and three months after the completion of (RT-c) RT. Median patient age was 47.5 (range: 29−58), and 13 (59%) were pre-menopausal, 9 (41%) were post-menopausal. Median RT dose was 50 Gy (range: 50−66). Eighteen (82%) patients received chemotherapy in addition to radiotherapy.
Results: A significant difference emerged in SCE ($p = 0.008$) and MN ($p = 0.004$) between RT-a and control groups. No statistical difference observed in BNC frequencies in breast cancer patients compared to control group.
Compared to the control group there was a significant increase in SCE frequencies in RT-b ($p = 0.008$) and RT-c ($p = 0.005$). There was also a significant increase in SCE frequencies in RT-b ($p = 0.001$) and RT-c ($p = 0.001$) values compared to RT-a measurements. There was not any statistically significant difference in the SCE frequencies between RT-b and RT-c measurements.
The frequencies of MN were also significantly higher in RT-b ($p = 0.005$) and RT-c ($p = 0.005$) than in control group. The MN frequencies were significantly increased in the RT-b compared to RT-a ($p = 0.001$). However, there was not any statistically significant difference in MN frequency between RT-a and RT-c measurements. MN levels decreased to pre-RT levels three months after completion of treatment.
No significant difference in BNC was observed between control group and any study group values.
MN decreased significantly at RT-c compared to RT-b ($p = 0.001$). No statistically significant difference was observed in MN frequencies between RT-a and RT-c (Table).
Conclusion: Increasing MN and SCE frequencies following radiotherapy is an expected situation. Decrease in MN frequency at 3-month after the completion of RT suggests that expected repair continues. Persistent SCE at the same period suggests that recovery in SCE has not completed yet and a longer period of time is needed.
No conflict of interest.

1064 POSTER

Unilobar transarterial radioembolization versus portal vein embolization for induction of contralateral liver hypertrophy in patients with secondary liver malignancies − a matched-pair analysis

B. Garlipp[1], M. Seidensticker[2], T. De Baere[3], R. Damm[2], R. Irmscher[2], P. Stuebs[1], F. Meyer[1], J. Ricke[2], H. Lippert[1]. [1]*Universitätsklinikum Magdeburg, Allgemein- Viszeral- und Gefäßchirurgie, Magdeburg, Germany;* [2]*Universitätsklinikum Magdeburg, Radiologie und Nuklearmedizin, Magdeburg, Germany;* [3]*Institut de cancérologie Gustave Roussy, Departement d'imagerie − Imagerie thérapeutique, Villejuif, France*

Background: Selected patients with liver malignancies can be cured by surgical resection. In case of a small-sized future liver remnant (FLR), portal vein embolization (PVE) of the tumour-bearing liver is used to induce hypertrophy of the contralateral lobe but leaves the tumour untreated and may even stimulate tumour growth. Unilobar transarterial radioembolization using Y90-labelled resin microspheres (RE) treats the tumour in the embolized lobe, reducing the risk of tumour progression, and has also been demonstrated to produce hypertrophy of the contralateral lobe. However, contralateral hypertrophy induction with these two modalities has never been compared directly. We performed a matched-pair analysis to compare the capacity for contralateral hypertrophy induction of PVE vs. RE.

Methods: Patients with secondary liver malignancies limited to the right lobe who were treated by right-lobar PVE (n = 141) or RE (n = 35) were matched according to the following criteria known to have an impact on liver regeneration following PVE: (i) Baseline FLR/Total liver volume ratio, (ii) prior platinum-containing chemotherapy, (iii) inclusion of liver segment 4 in the treatment, and (iv) baseline platelet count.The relative change in FLR volume from baseline to follow-up 4−6 weeks after treatment was calculated and compared between treatment groups using a one-way ANOVA.
Results: 21 fully matched pairs of patients were identified. After matching, minor differences between the PVE and RE groups were still seen in the interval between treatment and follow-up imaging, embolized liver volume, body weight, prevalence of colorectal cancer as the primary cancer site, and number of prior chemotherapy lines; however, covariate testing revealed none of these factors to have an impact on relative volume change in the contralateral liver lobe, indicating that the criteria used for matching resulted in two well comparable cohorts of PVE and RE patients. Baseline and post-treatment FLR volume as well as relative change in FLR volume before/after treatment are shown in table. The increase in FLR volume from baseline to follow-up was significant with both modalities but PVE produced significantly more FLR volume gain than RE (68.7 vs. 34.2%, p < 0.001). None of the RE patients demonstrated tumor progression in the embolized lobe at follow-up imaging.

	RE		PVE		
	Mean	SD	Mean	SD	
FLR baseline (mL)	246.1	115.6	287.1	84.3	
FLR post treatment (mL)	317.8	141.1	474.9	143.5	
Change from baseline (%)	+34.2	28.6	+68.7	39.0	<0.001
p(change from baseline within treatment)	<0.001		<0.001		

Conclusions: Our study shows for the first time that unilateral RE is inferior to PVE in terms of contralateral hypertrophy induction. However, contralateral hypertrophy induced by RE is substantial and RE minimizes the risk of tumour progression in the treated lobe, possibly making it a suitable modality for selected patients who need preoperative FLR hypertrophy induction and whose liver tumours are at risk of becoming locally unresectable in case of progression.

1065 POSTER

Predictive nomogram for heterotopic ossification following radiation prophylaxis of traumatic acetabular fractures

W.F. Mourad[1], T. Nabhani[1], S. Packianathan[1], R.A. Shourbaji[1], R.L. Jennelle[1], M.R. Kanakamedala[1], J.K. Ma[1], C.C. Yang[1], P.N. Mobit[1], S. Vijayakumar[1]. *[1]University of Mississippi Medial Center, Radiation Oncology, Jackson, USA*

Purpose: To report clinically predictive model for heterotopic ossification (HO) in patients (pts) who have undergone surgical repair and radiation (RT) prophylaxis after traumatic acetabular fracture (TAF).
Methods: Between 1995 and 2010, 737 pts were eligible to our study. All underwent surgery followed by prophylactic post-operative RT after TAF. All pts received a single fraction of 7 Gy within 72 hours from surgery, prescribed to mid-plan without bone shielding. The data collected on each patient (24 categories in all) included: age, gender, race/ethnicity, body mass index (BMI), type of injury, time between injury and surgery, time between surgery and RT, use of indomethacin, NSAIDs, and narcotic, hip fracture, Brooker grade, etc.
Results: A logistic regression model was constructed and internally validated with bootstrapping techniques. Statistically significant predictors for HO were age, BMI, narcotic use, time interval between surgery and RT, and bilateral vs. unilateral acetabular fracture. The parameters in the final model were: age (coefficient=0.0211, standard deviation (SD)=0.0069, p = 0.0021), BMI (coefficient=0.0766, SD=0.0180, p < 0.0001), surgery to RT in days (coefficient = 0.1379, SD = 0.0968, p = 0.1546), bilateral vs. unilateral fracture (coefficient = −0.8683, SD = 0.3381, p = 0.0102), narcotic use (coefficient=0.7078, SD=0.2354, p = 0.0026). The area under the 'receiver operating characteristic' curve (AUC) for the predicted probability of HO was 0.731 (95% CI 0.70–0.76). The model calibrated well and demonstrated adequate discriminative ability.
Conclusion: This predictive nomogram provides a precise algorithm to predict the risk of HO. Prophylactic RT is an effective modality for HO prevention, however, patients' age should be wisely considered because of scattered RT dose to the reproductive organs (ovaries and testicles) and the risk of RT induced malignancies.

1066 POSTER

Combination of topotecan and chronomodulated radiotherapy for treatment of xenografted human nasopharyngeal carcinoma

J. Wu[1], L. Yang[1], Y. Zhang[1], X. Chen[1], J. Fan[1], P. Ren[1]. *[1]The Affiliated Hospital of Luzhou Medical College, Department of Oncology, Luzhou, China*

Background: Nasopharyngeal carcinoma (NPC) is a malignant disease of the head/neck region and radiotherapy is the predominant treatment strategy. Here we reported a novel therapeutic strategy by combination of topotecan (TPT) and chronomodulated radiotherapy for NPC.
Materials and Methods: After a uniform biological rhythm was built through a light/dark cycle (LD 12:12). A xenografted NPC model was established by subcutaneous injection of poorly differentiated human NPC cells (CNE-2) to BALB/c (nu/nu) nude mice. Then the mice were separately administrated with: TPT (10 mg/kg), radiotherapy (RT), and TPT+RT, the anti-tumor effect was evaluated by analysis of tumor re-growth delay, the expressions of pimonidazole hydrochloride (HP-1), phosphorylated H2AX (γ-H2AX), DNA-topoisomerase I (Top I), cell cycle and apoptotic at 3, 9, 15, 21HALO (HALO means hours after light onset). The tumor-loaded mice without any treatment were used as the control.
Results: All therapeutic protocols showed the obvious tumor growth delay compared to the control at the same time point. In which, TPT+RT had the best tumor inhibitory effect and existed a remarkable increase in γ-H2AX expression and decrease in HP-1. For four time points, TPT+RT group at 15HALO showed the best inhibitory effect on tumor re-growth. The results revealed tumor hypoxia and DNA damage response varied in a time-dependent manner. The expression of Top I also showed obvious circadian rhythms with higher level at 15HALO and lower at 3HALO. Flow cytometry also appeared same trend of an increased apoptosis index and decreased proportion of S-phase cells (P<0.05).
Conclusions: Our study confirmed that combination of TPT and chronomodulated radiotherapy could enhance the radiosensitivity of xenografted NPC. TPT+RT group at 15HALO had the best therapeutic effect. The chronomodulated radiosensitization mechanisms of TPT might be related to many factors: tumor hypoxic state, cell cycle and apoptosis, DNA damage and the circadian rhythm of Top I.

Treatment of glomus tumours with fractionated stereotactic radiation therapy and tomotherapy

M. Lopez-Valcarcel[1], R.M. Magallon[2], M.I. Garcia-Berrocal[2], F.J. Valcarcel[2], I. Zapata[2], P. Tavera[2], A. De la Torre[2]. *[1]Hospital Puerta De Hierro, Majadahonda Madrid, Spain; [2]Hospital Puerta De Hierro, Radiotherapy, Majadahonda Madrid, Spain*

Background: Glomus are uncommon benign tumours. Treatment options are resection and radiotherapy. These tumours usually were treated using conventional RT 3D with 10−15 mm margins. Technical innovation allows to cover target volume with narrow margins. Since 2002 in our institution we use fractionated stereotactic radiation therapy (FSRT) in these tumours.
We analyze local control, clinical response and toxicity in patients treated with new techniques.
Methods and Materials: Between March 2002 and January 2013, 16 glomus were treated. 13 patients with FSRT and 3 with tomotherapy. Median follow-up was 31 months (range: 6−66.5).
Median age was 60 years (range: 46−81). 12 women and 4 men. Most common symptoms were tinnitus (13 patients) and injury lower cranial nerves (9 patients). Location: 87.5% jugular and tympanic. 93.8% unilateral. 43.8 % had surgical resection previously. Median glomus size was 30 mm (range: 10−70) and median target volume was 21.3 cc (range 6.37–464.2).
Median margins added to the gross tumour volume (GTV) to generate planning target volume (PTV) was 3 mm (range 2−10). The median total dose was 50.4 Gy (1.8 Gy per fraction) at 95% PTV coverage.
Median conformity index in FSRT was 1.2 (range: 1.18–1.47).
Results: No patients developed exacerbated symptoms or new neurological complications.
50% improved tinnitus and hearing.
No cases of clinical or radiological progression were identified.
63.7% of tumours were stable and 37.3% showed size reduction.
Conclusion: FSRT and tomotherapy are effective and safe therapies for patients with glomus. High local control rates associated with very low incidence of side effects were achieved. This treatment may be used in many patients as an alternative to surgical resection.
No conflict of interest.

1068 POSTER

Hypersensitivity of cancer cells derived from human thyroid, cervical and breast carcinomas to triptolide and its combination with radiation

V. Kudryavtsev[1], A.V. Demidkina[2], V.A. Mosina[2], A.E. Kabakov[2]. [1]*Medical Radiology Research Center, Obninsk, Russian Federation;* [2]*Medical Radiology Research Center, Department of Radiation Biochemistry, Obninsk, Russian Federation*

Background: Many human carcinomas are highly resistant to chemotherapy and radiotherapy; therefore, development of approaches to better therapeutic targeting such tumors is of paramount importance. In the present work, we examined the effects of triptolide (a diterpenoid triepoxide from the Chinese herb *Tripterygium wilfordii* exhibiting anticancer activity), as a mono-agent or in combination with gamma-radiation, on human carcinoma cells of different origin.
Materials and Methods: Three tumor cell lines (1) FRO (derived from human anaplastic thyroid carcinoma), (2) HeLa (derived from human cervical carcinoma) and (3) MCF-7 (derived from human breast carcinoma) were here studied. In the comparative experiments, human normal (non-tumor) epithelium cell lines 293 and HBL-100 were used as well. The cell death/survival was assessed in MTT-test, annexin-V staining and clonogenic assays. The expression of certain cell survival- and apoptosis-related proteins was explored by serial immunoblotting.
Results: We have established that the above three carcinoma cell lines are extremely sensitive to very low (0.5−5 nM) concentrations of triptolide and its combinations with low doses (2−5 Gy) of irradiation. This hypersensitivity was usually manifested in the suppressed cell proliferation, massive apoptotic cell death and sharply (100–10000-fold) impaired clonogenicity following the (co)treatment. As for the molecular basis of such enhanced cytotoxicity, the simultaneous inhibition of NF-kappaB- and Akt-mediated cytoprotective pathways in the cancer cells treated with triptolide seems to promote apoptosis that may be aggravated by such an apoptotic stimulus as radiation exposure. Besides, the known ability of triptolide to inhibit the HSF1-dependent expression of cytoprotective heat shock proteins (e.g. Hsp70 and Hsp27) may also help to kill the cancer cells treated with the drug. Importantly, when the above normal (non-tumor) cells were (co)treated by the same way, they exhibited the significantly less sensitivity as compared with the carcinoma cells.
Conclusions: The present findings allow us to hope that clinically achievable and tolerable concentrations of triptolide in the organism of patients will exert therapeutic effects upon carcinoma tumors and/or improve the outcome of anticancer radiotherapy.
No conflict of interest.

1069 POSTER

Quantitative evaluation of online correction shifts between bone and soft tissue matching for gated and non-gated stereotactic body radiation therapy (SBRT) treatments

A. Kennedy[1], C.M. Marshall[1], K. Corr[1], L. Rock[1], A. Mihai[1]. [1]*Beacon Hospital, Radiotherapy Physics, Dublin, Ireland*

Purpose: To compare the use of setup marks on skin versus setup marks on immobilization device for patient positioning for SBRT. To determine the magnitude and frequency of online correction shifts between bone and soft tissue.
Methods: A retrospective study of two hundred and seven fractions of lung SBRT treatments was performed, of which one hundred and three were non-gated (group I) and one hundred and four were gated treatments (group II).
The first part of the study compared cone beam computed tomography (CBCT) localization using bone landmarks with reference to setup marks either on the patient or the immobilization device (BodyFix) in the anterior-posterior (AP), left-right (LR) and superior-inferior (SI) directions. The second part of the study evaluated if fluoroscopic localisation for moving tumours was influenced by change in tumour motion, baseline tumour position or if the internal target volume (ITV) created from treatment planning 4DCT was appropriate. Analysis of total tumour excursion was performed using CBCT for each fraction.
Results: The first part of the study demonstrated that the setup marks on the localization device yielded lower magnitude shifts in the AP and SI directions when using CBCT guided bone matching. Initial results show that 12% of gated treatments and 24% of non-gated treatments required soft tissue matching. Analysis of Group I and II showed that the ITV created from the initial 4DCT motion was adequate. The majority of soft-tissue moves were due to a change in baseline position of the tumour. An analysis of individual patients whose tumour motion was outside the norm (3 mm) will be presented. Data table 1 shows the number of total fractions and number of soft tissue shifts for gated and non gated treatments.

Table 1. The number of fractions of gated and non gated treatments where soft tissue shifts were performed. The number of shifts outside 0.3 cm is also presented.

	# Fractions	Ant	post	Sup	inf	Right	left
Gated	104	2	3	3	4	1	6
Soft tissue >0.3 cm		0	3	0	1	0	4
Non Gated	103	10	6	10	5	9	3
Soft tissue >0.3 cm		6	0	2	3	0	1

Conclusion: Based on this analysis, setup marks are placed on the immobilization (BodyFix) device for all SBRT treatments in our department. Our current motion analysis method has proven to be sufficient for creating ITVs. From our experience we have found that in most cases there may be no difference between online CBCT bone matching and soft tissue. However, the use of soft tissue verification and tumour motion using fluoroscopy is recommended on a daily basis.
No conflict of interest.

1070 POSTER

Comparison of target definition by 4DCT and 3DCT, the addition of asymmetric margins, or the addition of traditional margins for esophageal cancer

W. Wei[1], L.I. Jianbin[1], X.U. Min[1], S.H.A.O. Qian[1], F.A.N. Tingyong[1]. [1]*Shandong Tumour Hospital, Department of Radiation Oncology, Jinan Shandong, China*

Background: To investigate the 4DCT based planning target volume (PTV) definition compared to conventional PTV definition and PTV definition using asymmetrical margins for thoracic primary esophageal cancer.
Materials and Methods: Forty-three patients with esophageal cancer underwent 3DCT and 4DCT simulation scans during free breathing. The motion of primary tumors located in the proximal (group A), mid- (group B), and distal (group C) thoracic esophagus were obtained from the 4DCT scans. PTV3D was defined on 3DCT using the tumor motion measured based on 4DCT; PTVconv was defined on 3DCT using a 1.0 cm margin to CTV; PTV4D was defined as the union of the target volume contoured on the 10 phases of 4DCT images. PTV centroid position, volumetric differences and dice similarity coefficient (DSC) were evaluated.
Results: The median centroid shifts between PTV3D and PTV4D, PTVconv and PTV4D in the three dimensional directions were all less than 0.3 cm for the three groups. The median size ratio of PTV4D to PTV3D was 0.80, 0.88, 0.71 for group A, B and C, and for PTV4D to PTVconv was 0.67, 0.73, 0.76 respectively ($\chi 2 = -3.18, -2.98, -3.06$; $P = 0.001, 0.003, 0.002$). The DSC were 0.87, 0.90, 0.81 between PTV4D and PTV3D, with 0.80, 0.84, 0.83 between the PTV4D and PTVconv ($\chi 2 = -3.18, -2.98, -3.06$; $P = 0.001, 0.003, 0.002$). The difference between degree of inclusion of PTV4D in PTV3D and PTV4D in PTVconv was all less than 2%. Compared with PTVconv, PTV3D decreased 11.81% and 11.86% of irradiated normal tissue in group A and B respectively, but increased 2.93% for group C.
Conclusions: For proximal and mid- esophageal cancer, 3DCT-based PTV using asymmetrical margins provides a good coverage of PTV4D, meanwhile for distal esophageal cancer, 3DCT-based PTV using conventional margins provides an ideal conformity with PTV4D.
No conflict of interest.

1071 POSTER

Diffusion-weighted magnetic resonance imaging in radiotherapy: Do not forget about geometric distortion

T. Leroy[1], B. Renard[2], L. Ceugnart[2], L. Lemaitre[3], R. Lopes[4], A. Beauguitte[5], E. Lartigau[1], D. Pasquier[1]. [1]*Centre Oscar Lambret University of Lille-Nord de France, Academic Radiotherapy Department, Lille, France;* [2]*Centre Oscar Lambret, Department of Radiology, Lille, France;* [3]*CHRU de Lille, Nephrological and Urological Radiology Department, Lille, France;* [4]*University of Lille Nord de France and Lille University Hospital, Clinical Imaging Platform IMPRT, Lille, France;* [5]*Clinique Radiologique du Pont St Vaast, Department of Radiology, Douai, France*

Background: Due to its high soft tissue contrast, MRI is commonly used in radiotherapy. Higher field strengths give higher signal-to-noise ratios and thus improved tissue contrast. Diffusion-weighted (DW) MRI enables measurement of the apparent diffusion coefficient (ADC) of the water in the field of view (FOV). Low ADCs are associated with higher cell densities and malignancy so DW MRI could improve tumour delineation. The most frequently used DW MRI technique comprises a single-shot, spin-echo

echo-planar imaging sequence. However, echo-planar images suffer from geometrical image distortions due to the relatively long gradient echo train. In theory, the incidence of these distortions increases as the field strength rises.
Material and Methods: We investigated two 3-T systems (a GE Discovery MR 750® and a Philips Achieva®) and two 1.5-T MRI systems (a Philips Intera® and a GE Signa HD®) with phased array coils. Distortion was assessed for a morphologic turbo spin-echo (TSE) T2-weighted sequence (contiguous axial slice thickness: 5 mm; matrix: 512x512; FOV: 30 cm) and DW sequences using different diffusion weightings (B values of 600, 1000 and 2000 sec/mm^2; matrix: 256x256; FOV: 30 cm). Acquisition characteristics with the phased array coil were the same for all MRI systems and distortion was measured on each ADC map. The geometric distortion was measured using a cylindrical MRI 3D Geometry Phantom® filled with an aqueous solution (dimensions: 21 x 22 x 23 cm; hole spacing: 1.5 cm; hole diameter: 0.3 cm; 196, 196 and 140 holes in the x, y and z plates, respectively). The deviation between the markers' theoretical and measured positions yielded the distortion as a function of distance to the center of the FOV. The results were compared in the Student's t-test and the threshold for statistical significance was set to $p < 0.05$. The statistical analysis was performed with SPSS software.
Results: For the two 1.5 T MRI scanners, the median ($\pm$ standard deviation (SD)) distortions on TSE T2 images were 1.2$\pm$0.3 mm, 2.4$\pm$5.2 mm and 3.2$\pm$5.4 mm at 35, 70 and 100 mm from the center of the FOV, respectively. These values were respectively 1.8$\pm$1.1 mm, 2.9$\pm$5.1 mm and 6.1$\pm$5.5 mm in ADC B600 images and 1.6$\pm$0.4 mm, 4.3$\pm$5.3 mm and 8.4$\pm$5.4 mm in ADC B1000 images.
For the two 3 T MRI scanners, the median$\pm$SD distortions on TSE T2 images were 0.2$\pm$0.1 mm, 0.7$\pm$6.7 mm and 0.9$\pm$7.2 mm at 35, 70 and 100 mm from the center of the FOV, respectively. These values were respectively 4.2$\pm$3.7 mm, 20.1$\pm$7.6 mm and 31.2$\pm$5 mm in ADC B600 images and 1.9$\pm$2.8 mm, 18.1$\pm$4.5 mm and 25$\pm$4.3 mm in ADC B1000 images. Distortion was significantly greater in 3 T scanners than in 1.5 T MRI scanners ($p < 0.01$) for DW images but not for T2 sequences. The B2000, B1000 and B600 distortions were all significantly different ($p < 0.01$).
Conclusion: Distortion is much greater in DW MRI than in morphological MRI and must be carefully assessed and corrected before it can be integrated into radiotherapy planning. The development of higher gradients and/or readout-segmented echo-planar imaging is probably a promising approach.

1072 POSTER

A preliminary study of bone marrow metabolic response after pelvic radiation on 18F-FDG PET-CT: Correlation with hematologic toxicity

S. Jo[1], H.K. Shim[2]. [1]*Inje University Haeundae Paik Hospital, Radiation Oncology, Busan, South Korea;* [2]*Inje University Haeundae Paik Hospital, Nuclear Medicine, Busan, South Korea*

Background: The relationship between metabolic decrease and radiation dose in irradiation field has not been revealed. The aim of this study is to evaluate the impact of pelvic radiation on bone marrow (BM) metabolic response using 18F-fluorodeoxyglucose positron emission tomography (18F-FDG-PET) and hematologic toxicity according to metabolic change.
Material and Methods: We analyzed 19 gynecologic patients treated radiotherapy with or without chemotherapy. The patients underwent baseline 18F-FDG-PET before treatment, immediate and delayed 18F-FDG-PET after treatment. Pelvic bone marrow (BM) was defined as the region extending from the iliac crests to the ischial tuberosity. On the 18F-FDG-PET, the 0.8 cm $\times$ 0.8 cm sized round region of interest (ROI) was drawn in each 10, 20, 30, and $\geqslant$40 Gy (V10, V20, V30, and V40, respectively) irradiated volume, and in the control (the first lumbar spine (L1)). Each ROI was divided by that of the liver for metabolic correction. The correlation between BM metabolic change of each dose regions, BM dose-volume metrics and hematologic nadirs (hemoglobin (Hb), white blood cell (WBC), platelet (PLT), and absolute neutrophil count (ANC)) were evaluated.
Results: The median age was 66 years old. All the patients were uterine cervical cancer except two (endometrial cancer, uterine leiomyosarcoma). The median radiation dose to pelvis was 45 Gy (range, 19.8 Gy-60.4 Gy). In comparison with pre-treatment 18F-FDG-PET, the metabolic change in the immediate 18F-FDG-PET was 29.54%, 33.43%, 36.60%, 37.41% and in the delayed 18F-FDG-PET was 31.04%, 41.73%, 44.38%, 27.71% (V10, V20, V30, V40, respectively). The metabolism of the L1 was not affected according to the hematologic change. The relationship between interval metabolic changes of V10−40 on the immediate, delayed 18F-FDG-PET and radiation dose were significant according to the linear regression model (immediate t=4.992, p<0.005, delayed t=2.167, p = 0.034). Percent hematologic changes were 15.49%, 50.96%, 39.77%, 45.21% (Hb, WBC, PLT, and ANC, respectively). Hematologic changes were not correlated with immediate and delayed metabolic response significantly.
Conclusions: The metabolic change of pelvic BM after radiotherapy was linearly correlated with irradiated dose, however, was not connected with hematologic alteration.
No conflict of interest.

1073 POSTER

Assessment of esophageal tumor motion and impact uncertainties using four-dimensional computed tomography

W. Wei[1], L.I. Jianbin[1], Z. Yingjie[1], X.I.N.G. Jun[1], Q.I. Huanpeng[1]. [1]*Shandong Tumour Hospital, Department of Radiation Oncology, Jinan Shandong, China*

Background: To access the three-dimensional motion caused by respiration and its influencing factors for radiotherapy of the thoracic primary esophageal cancer.
Methods: Sixty-five patients with esophageal cancer underwent 3DCT and 4DCT simulation scans during free breathing. The amplitude was calculated as the maximum difference between any of the 10 phases. The distance between the GTV upper/lower edges and the interesting target (carina, lower edge of aortic, the apes of the doms of the diaphragms) were measured. The motion of different thoracic groups was measured.
Results: The centroid motion of GTV were (0.15$\pm$0.10) cm, (0.12$\pm$0.15) cm, (0.34$\pm$0.15)cm in lateral(LR), anteroposterior (AP) and superioinferior (SI) directions, respectively. There were no relationship between GTV motion and patient gender, age and body mass index(BMI)($p > 0.05$). Tumor in the lower thorax had a lager displacement in LR and AP directions than tumor in the upper and mid- thorax($p = 0.036$, 0.014). Squamous carcinoma exhibited smaller motion than adenocarcinoma in all the three dimensional directions. A significant difference between the motion of the tumors with different length, and no significant difference was found in the motion of these locations in the absence or presence of the enlarged nodes. There is a negative correlation between the GTV movement and the distance between the GTV upper/lower edges and carina.
Conclusions: The greatest motion was seen in the SI direction for the thoracic esophageal cancer during free breathing. Appropriate site-specific internal target volume expansion should be consulted the tumor location and histologic type, and correlated with the distance between the GTV upper/lower edges and carina. The recommend margins might be applicable to patients with or without involved nodes.
No conflict of interest.

1074 POSTER

Comparison of the thoracic esophagus position and volume between quiet end-inspiration and end-expiration three dimensional CT assisted with active breathing control and corresponding phases in four dimensional CT

H. Qi[1], J. Li[2], C. Liang[2], Z. Ma[2], Y. Zhang[2], W.E.I. Wang[2], J.U.N. Xing[2]. [1]*Shandong Cancer Hospital, Jinan Shandong, China;* [2]*Shandong Cancer Hospital, Department of Radiation Oncology, Jinan Shandong, China*

Background: To compare the position, volume and matching index (MI) of the thoracic esophagus between quiet end-inspiration and end-expiration three dimensional CT (3DCT) assisted with active breathing control (ABC) and the corresponding phases in four dimensional CT (4DCT).
Material and Methods: Eleven patients with peripheral lung cancer underwent 4DCT simulation scan and 3DCT simulation scans in end-inspiratory hold (CT_{EIH}) and end-expiratory hold (CT_{EEH}) in succession. The 4DCT images from each respiratory cycle were sorted into 10 phases: the 0% phase was defined as end-inspiratory phase (CT_0), while the 50% phase was defined as end-expiratory phase (CT_{50}). The proximal, mid- and distal thoracic esophaguses were delineated separately on CT_0, CT_{50}, CT_{EIH} and CT_{EEH} images.
Results: In the X direction, the displacement differences of the proximal, mid- and distal thoracic esophaguses between CT_0 and CT_{EIH} were (−0.02$\pm$0.16)cm, (0.06$\pm$0.26)cm and (0.10$\pm$0.33)cm respectively, and in the Y direction, that were (0.04$\pm$0.24)cm, (0.04$\pm$0.12)cm and (0.08$\pm$0.15)cm respectively, and the displacement differences of the same direction were not statistically significant (all $P > 0.05$). In the X direction, the displacement differences of the proximal, mid- and distal thoracic esophaguses between CT_{50} and CT_{EEH} were (−0.02$\pm$0.24)cm, (0.12$\pm$0.37)cm and (0.26$\pm$0.33)cm respectively, and in the Y direction, that were (0.03$\pm$0.21)cm, (0.04$\pm$0.17)cm and (0.14$\pm$0.18)cm respectively, and the displacement differences of X and Y directions of proximal and mid-thoracic esophaguses between CT_{50} and CT_{EEH} were not statistically significant (all $P > 0.05$), while that of distal thoracic esophaguses between CT_{50} and CT_{EEH} were both statistically significant (both $P<0.05$). The volumes of the proximal, mid- and distal thoracic esophaguses were all

larger in CT_0 and CT_{50} than in CT_{EIH} and CT_{EEH}, but the differences between them were found both not statistically significant ($P > 0.05$). The MIs of the volumes of the proximal, mid- and distal thoracic esophaguses between CT_0 and CT_{EIH} were (0.50 ± 0.17), (0.50 ± 0.19) and (0.56 ± 0.08), and that between CT_{50} and CT_{EEH} were (0.50 ± 0.16), (0.47 ± 0.14) and (0.51 ± 0.15). The MI of each segment esophagus between CT_0 and CT_{EIH} was larger than that between CT_{50} and CT_{EEH} ($P > 0.05$).
Conclusions: The influence of breathing modes to the centroid positions of the proximal, mid-thoracic normal esophaguses were not significant. But there were spatial mismatches for any segment esophagus between two breathing modes.
No conflict of interest.

1075 POSTER

Low dose pre-irradiation and radio-adaptive response detected by MTT in HT29 and MRC5 cell lines

I. Djan[1], G. Bogdanovic[2], S. Solajic[2], M. Djan[3], M. Erak[1]. *[1]Institute of Oncology, Department of Radiotherapy, Sremska Kamenica, Serbia; [2]Institute of Oncology, Department of Experimental Oncology, Sremska Kamenica, Serbia; [3]University of Novi Sad Faculty of Sciences, Department of Biology and Ecology, Novi Sad, Serbia*

Background: The effects of radio-adaptive response is the main interest of many studies. Adaptive response can lead to hypersensitivity or radioresistance. Both phenomena play important role in radiotherapy. The aim of this research was to examine the effects of low-dose pre-irradiation followed by two different irradiation regimes on metabolic activity in two cell lines: HT29 human colorectal adenocarcinoma and fetal fibroblasts MRC5 cell lines.
Material and Methods: The cell lines were pre-irradiated with 0.03 Gy, 0.05 Gy and 0.07 Gy and the control cell lines were not pre-irradiated. Both, control and pre-irradiated cells were irradiated two hours after priming dose and specially designed hyper- and hypofractionation regimes were applied. For the hyperfractionation the calculated doses were 1.3 Gy twice per day, with four hours period between daily fractions during four consecutive days. For the hypofractionation the calculated doses were 4.6 Gy on the first and fourth day, once per day, in order to obtain same overall treatment time as in hyperfractionation regime. The determined irradiation doses were estimated as biological equivalent (BED) to four-day treatment with 2 Gy fraction. Cell survival was tested by MTT. STATISTICA 10.0 software was applied in data processing.
Results: In hyperfractionation regime the low-dose of 0.05 Gy led to a significantly induced radioresistance in MRC5 cells compared with non pre-irradiated control. Low doses of 0.03 Gy and 0.07 Gy significantly increased radioresistance in HT29 cell line compared with non pre-irradiated control and pre-irradiation dose of 0.05 Gy. Statistically significant decrease of metabolic activity in HT29, after 0.05 Gy priming dose was observed, compared with 0.03 Gy and 0.07 Gy priming doses. In hypofractionation regime after priming dose of 0.05 Gy, as in hyperfractionation regime, statistically significant increase of cell metabolic activity in MRC5 cells was observed. In HT29 cells 0.05 Gy and 0.07 Gy priming doses led to a significance decrease of metabolic activity compred with irradiated control.
Conclusions: In both regimes, the priming dose of 0.05 Gy followed by challenging dose after two hours, led to decrease of metabolic activity in human colorectal cancer cells, and at the same time had significant radioresistance effect on the metabolic activity of human fetal lung fibroblasts. These results represent promising effect of applied low-dose pre-irradiation followed by different irradiation regimes afterwards.

Emodin enhances growth suppression of human hepatoma cells by irradiation via enhancement of apoptosis and inhibition of cyclin D1

S. Hwang[1], J.S. Kim[1], J.W. Im[1], S.M. Lee[1], C.W. Choi[1], G.M. Yang[1]. *[1]Dongnam Institue of Radiological & Medical Sciences, Gastrointestinal Cancer Center, Busan, South Korea*

Background: The application of radiotherapy of hepatocellular carcinoma (HCC) is limited due to radioresistance in tumor and radiotoxicity in nontumorous liver. Therefore, study for radioresistance mechanism and improvement of killing effect of irradiation by therapeutic insult such as radiosensitizer etc. Emodin (1,3,8-trihydroxy-6-methylanthraquinone), a family of plant derived polyphenol has been proven to have anticancer properities. There is limited data about role of emodin as radiosensitizer in human hepatoma cell line. In this study, we examined the followings: (i) whether emodin attenuated radioresitance of hepatoma cell line, (ii) what was the mechanism of radiosensitization.
Material and Methods: Methods: Two human HCC cell lines were used in this study: HepG2, and Hep3B. They were exposed to four different manners; none (control), irradiation (10 Gy, one fraction), emodin (10 μM), and irradiation combined with emodin. Cells were then subjected to MTT assay (3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide, a yellow tetrazole) and immunoblotting in 24 hours and 72 hours after exposure.
Results: The growth suppression of two cell lines was significantly more enhanced compared to control group in the same order as followings; combination group, emodin, and irradiation. Treatment with irradiation combined with emodin resulted in maximal upregulation of apoptotic signaling such as poly (ADP-ribose) polymerase (PARP) and caspase-9 and downregulation of proliferation signaling such as cyclin D1.
Conclusions: Emodin enhances the activity of irradiation in tumor growth suppression of human hepatoma cells via enhancement of PARP, caspase-9 and inhibition of cyclin D1. Therefore, our findings may provide new insights into understanding the pharamacological mechanism of emodin as radiosensitizer in HCC and may aid in the design of new therapeutic strategies for the radioresistant HCC.
No conflict of interest.

1077 POSTER

Endocrinological late effects after radiotherapy

M. Seland[1], H. Holte[2], T. Bjøro[3], T. Schreiner[4], J. Bollerslev[4], J.H. Loge[5], T. Furre[6], C.E. Kiserud[1]. *[1]Oslo University Hospital, National Resource Center for Late Effects − Division of Surgery and Cancer Medicine, Oslo, Norway; [2]Oslo University Hospital, Dept of Oncology − Division of Surgery and Cancer Medicine, Oslo, Norway; [3]Oslo University Hospital, Dept of Medical Biochemistry, Oslo, Norway; [4]Oslo University Hospital, Dept of Endocrinology, Oslo, Norway; [5]Oslo University Hospital/University of Oslo, National Resource Center for Late Effects − Division of Surgery and Cancer Medicine/Dept of Behavioural Sciences, Oslo, Norway; [6]Oslo University Hospital, Dept of Physics − Division of Surgery and Cancer Medicine, Oslo, Norway*

Background: Treatment for cancer might lead to hormonal dysfunctions. Aims of this cross-sectional study were to assess the prevalence of disturbances in four hormonal axes: Hypothalamic-pituitary (HP) − thyroid axis, HP-adrenal axis, HP-gonadal axis and Growth hormone (GH), and to analyze associations between disturbances and patient- and treatment-related variables. Here we report frequency of abnormal values for all axes and analyze variables related to the thyroid- and GH axes.
Material and Methods: Eligible patients aged $\geqslant$15 years at diagnosis were treated for lymphoma, plasmacytoma, multiple myeloma or carcinoma of the epipharynx region by radiotherapy to the head and neck region or total body irradiation, with or without chemotherapy, from 1980–2006. For each axis the hormonal function was dichotomized as normal or impaired according to reference values at the laboratory. Treatment data was obtained from the patient records, and the radiation dose to the pituitary and thyroid gland was estimated. Comparisons were performed by chi-square and t-tests with $p < 0.05$ considered statistically significant (two-sided).
Results: A total of 84 males and 57 females treated for lymphoma (HL=20, NHL=103), multiple myeloma (n = 5), plasmacytoma (n = 3) and carcinoma (n = 10) were included. Observation time was 15.8 (6.4) years, age at diagnosis was 43.4 (15.1) years and at age survey 59.2 (12.9) years (mean, SD). Forty-nine (37%) survivors had biochemical hypothyroidism, 35 (25%) had abnormal GH- and/or IGF-1 values and 2 had abnormal values in the adrenal axis. Forty (48%) men had impaired gonadal function and 10 (18%) women had premature menopause (<42 years).
Survivors with hypothyroidism had received a significantly higher dose to the thyroid gland and had significantly longer observation time than those with normal thyroid function [mean 29.8 Gy (SD 16.5) vs 12.9 Gy (SD 15.8) $p < 0.001$, mean 18.3 years (SD 6.2) vs 14.1 years (SD 6.2), $p < 0.001$]. Survivors with abnormal levels in the GH-axis had received a non-significant higher radiation dose to the pituitary gland [mean 16.9 Gy (SD 18.3) vs mean 12.4 Gy (SD 11.9) ($p = 0.19$)]. There were no significant associations between gender and age at survey and abnormal levels in the GH axis and/or the thyroid axis.
Conclusions: Abnormal hormone values are frequent after radiotherapy to the head and neck region and should be measured in follow up. The clinical impact of failure in the GH axis needs further examinations.
No conflict of interest.

1078 POSTER

Do we need adaptive radiotherapy in head and neck cancer to decrease xerostomia?

J. Castelli[1], A. Simon[2], O. Henry[1], E. Chajon[1], M. Nassef[2], G. Louvel[1], G. Cazoulat[2], F. Jegoux[3], B. Laguerre[1], R. De Crevoisier[1]. *[1]Centre Eugène Marquis, Rennes, France; [2]LTSI, INSERM 1099, Rennes, France; [3]CHU Pontchaillou, ORL, Rennes, France*

Background: Significant morphologic variations can be observed during the course of locally advanced head and neck cancer (HNC). The purposes of this study were:
– to estimate the difference between the planned dose and the actual delivered cumulative dose in the parotids (PG),
– to assess the benefit of a weekly replanning to spare the PGs.
Material and Methods: 11 patients (pts) with locally advanced HNC received IMRT to a total dose of 70 Gy. Each pt had one initial planning CT (CT0) and a weekly CT (wCT) during the treatment. The anatomical structures were manually segmented on each CT. The dose distribution corresponding to the pretreatment planning was calculated on each wCT. A new IMRT planning was also generated on each wCT, in order to spare the PGs at least as they were spared at the pretreatment planning. Each weekly dose distribution was reported on the CT0 by elastic registration. Two kinds of cumulative dose were therefore calculated on the CT0: one corresponding to the actual delivered dose and the other one to the weekly re-planned dose. The cumulative doses (with or without replanning) were compared with the planned dose for the PGs. The risk of xerostomia was estimated by the NTCP model (n = 1, m=0.4, TD50=39.9).
Results: The volume of the PGs decreased of an average of 33% [10−69 %] during the treatment. The average Dice score for the parotid registration was 0.93 (0.88–0.95). The dose in the PGs was increased in 62.5% of the PGs, by comparing the planned dose with the actual delivered dose. This increase was observed in 50% of the homo-lateral PG and 75% of the contra-lateral PGs. An increase of more than 3 Gy of the mean PG dose was observed in 31 % of PGs (up to 10 Gy for 1 PG),observed in 50% of pts and corresponding to an absolute average increase risk of xerostomia of 13% [6−24%]. A weekly replanning allows reducing the mean PGs dose at least at the same dose than at the pretreatment plan for more than 80% of the pts ($D_{mean\ Replan}$ = 31.3 Gy, $D_{mean\ initial}$ = 32.5 Gy, p = 0.013). Moreover, the doses in the CTV and PTV were not statistically different between the pre-treatment planning and the weekly re-planning.
Conclusion: A weekly re-planning can benefit significantly to one third of the PGs (and 50% of the pts), leading to decrease the absolute risk of xerostomia of at least 13%. An ongoing randomized IMRT trial comparing one planning to a weekly planning aims demonstrating the benefit on this adaptive radiotherapy strategy.
No conflict of interest.

1079 POSTER

Nodal PTV margin validation for head-and-neck cancer patients (HNC) treated with image-guided tomotherapy: Need of adaptive re planning?

I. Dell'Oca[1], C. Fiorino[2], R. Raso[2], F. Zerbetto[1], M.L. Belli[2], A. Chiara[1], G.M. Cattaneo[2], L. Gianolli[3], R. Calandrino[2], N. Di Muzio[1]. *[1]San Raffaele Scientific Institute, Radiotherapy, Milan, Italy; [2]San Raffaele Scientific Institute, Medical Physics, Milan, Italy; [3]San Raffaele Scientific Institute, Nuclear Medicine, Milan, Italy*

Background: Changes in dimension, shape and position of positive lymphnodes (PLs) in patients treated with image-guided RT for HNC may lead to dangerous geographical misses, especially in the case of concomitant boosting of PET PLs. Aim of this study was to assess the entity of the problem and to check if the margin (5 mm) used in our simultaneous-integrated-boost (SIB) approach with Helical Tomotherapy (HT) is appropriate.
Material and Methods: Thirty-seven HNC N2/N3 patients (pts) treated with SIB HT (delivering 54, 66 and 69 Gy in 30 fr on PTV(N), PTV($T+N^+$) and PTV of the PET-positive $T+N^+$) were considered. Regarding PLs position: 33, 7 and 2 PLs were respectively in levels II, III and V. For each patient, MVCTs taken at fr 1, 5, 10, 15, 20, 25 and 30 were matched with the planning kVCT (pl_kVCT) on bone anatomy (averaged on the treated volume). Three experts contoured 42 PLs of 30 pts on the pl_kVCT and all MVCTs (7 patients were excluded because PLs were not visible on MVCT). Intra-observer variability was assessed by blind re-delineation of 16 PLs. Volumes were normalized to fraction 1 MVCT and time-trend in volume change was assessed by Spearman's test. PLs displacement was assessed by the center of mass (CM) shift with respect to the 1st MVCT. For each PL, the % fraction of the union (UN) of all PL positions over the whole treatment that was missed by the clinical PTV (pl_kVCT PL contour+5 mm) was assessed. For pts with some missing, larger margins were tested to find UN coverage >99%.
Results: PLs were sufficiently well visible on MVCT: an acceptable intra-observer variability confirmed this impression (median DICE: 0.805±0.134). 27/42 PLs showed an average volume reduction of 70% (range: 27−94%), with significant time trend (median Spearman ρ = −0.93; range −0.78÷-1.00; p < 0.05).
Larger 3D average CM shifts on the whole population were observed in the 2nd part of the treatment toward the midline (medial shift in the 1st and 2nd part: 0.1 vs 1.6 mm, Wilcoxon test p < 0.001). Only 7/42 PLs of 7/30 pts needed margins >5 mm: respectively 6 and 7 mm for n = 2; 8, 9 and 12 mm for n = 1.
Conclusions: Results show a significant, although small, residual error in the localization of PLs during IGRT for HNC. 64% PLs show a significant shrinkage. A margin of 5 mm covers all possible positions of PLs in about 80% of pts, extending to 93−97% with a margin of 8−9 mm. Interestingly, the shrinkage seems to counterbalance the shift of PLs due to deformations, more pronounced in the last fractions. Seeing these results, adaptive re-planning aiming to avoid to miss PLs should not be recommended (excepting very selected pts) also in the case of PET PLs boost.
No conflict of interest.

Evaluation of EPID based transit dosimetry on the implementation of In-vivo dosimetry and a step forward for dose guided adaptive radiation therapy

D. Wilson[1], A. Sankar[2], J. Warnock[1], L. Goodall[1]. *[1]Edinburgh Cancer Centre, Radiation Oncology, Edinburgh, United Kingdom; [2]Edinburgh Cancer Centre, Oncology Physics, Edinburgh, United Kingdom*

Background: The common practice of In-vivo dosimetry using point detectors were very successful with conformal treatment techniques but could not be extended its usage effectively for modulated treatment techniques. To address the need for an efficient in-vivo dosimetry system for the modulated treatments, Edinburgh Cancer Centre collaborated with Math Resolutions, U.S.A, to develop a 'transit dosimetry' solution using Electronic portal imaging device [EPID] based data acquisition. The algorithm used in 'Dosimetry Check' software was extended to support transit dosimetry and was extensively tested. Further studies were performed to integrate cone beam CT based dose calculations using transit dosimetry.
Material and Methods: 6MV and 10MV clinical photon beams delivered from Varian Accelerators (Clinac 21EX, Novalis − Tx and Silhouette) and amorphous silicon based EPID [aSi 1000] systems mounted on these accelerators were used in this study. For conformal and fixed gantry dmlc based modulated techniques, transit images were acquired in 'integrated' acquisition mode and for volumetric modulated [RapidArc] deliveries, 'continuous' acquisition mode is used. All the patient treatments were planned using Eclipse [Varian, U.S.A] treatment planning system. Cone beam images were taken only for RapidArc treatment deliveries using Varian On-board Imager system [Ver.15].
The transit dose calculations were initially tested using beam deliveries on water equivalent slabs and compared with 0.6cc ion chamber based measurements. Reproducibility and sensitivity of the transit dosimetry process was tested using fixed gantry dynamic MLC based modulated deliveries on an anthropomorphic thoracic phantom.
Results: The water equivalent phantom based verifications agreed within +/− 3% with the treatment planning system and the ion chamber measured values. The reproducibility study using the anthropomorphic phantom resulted within the standard deviation of +/− 0.005%. The sensitivity study with a known manual shift of the phantom by 5.0 cm shift resulted 7% dose deviation.
The agreement of transit dosimetry based dose estimations at the isocentre for 325 clinical patients so far collected from different clinical sites treated with conformal techniques agreed with the treatment planning results within a mean value of +/− 4.0%. Larger deviations of the order of +/− 10% were observed from Ca. Breast treatments especially if the mono-isocentric technique is used. For H&N and Prostate RapidArc deliveries, the results were of similar magnitude with the independent verifications using ArcCheck diode array system [Sun Nuclear, U.S.A].
Conclusions: EPID based transit dosimetry using 'Dosimetry Check' software can be reliably used for in-vivo dosimetry purposes for all co-planar treatment techniques. The reliability of the cone beam based calculation highly depends on the reproducibility of the Hounsfield units and the registration process.
No conflict of interest.

Long-term risk of ischemic heart disease following Hodgkin lymphoma treatment

F.A. Van Nimwegen[1], M. Schaapveld[1], A.D.G. Krol[2], C.M.P. Janus[3], D. Cutter[4], S. Darby[5], B.M.P. Aleman[6], F.E. Van Leeuwen[1]. *[1]Netherlands Cancer Institute, Epidemiology, Amsterdam, Netherlands; [2]Leiden University Medical Center, Radiotherapy, Leiden, Netherlands; [3]Erasmus MC − Daniel den Hoed Cancer Center, Radiotherapy, Rotterdam, Netherlands; [4]Oxford University Hospitals NHS Trust, Oxford Cancer Center, Oxford, United Kingdom; [5]University of Oxford, Clinical Trial Service Unit, Oxford, United Kingdom; [6]Netherlands Cancer Institute, Radiotherapy, Amsterdam, Netherlands*

Background: Hodgkin lymphoma (HL) is the prototype of a curable malignancy. However, treatment causes excess cardiovascular morbidity and mortality in long-term survivors. The objective of this study is to identify risk factors for ischemic heart disease (IHD), defined as myocardial infarction (MI) and angina pectoris (AP) (⩾grade 2 CTCAE4.0). We quantified separate and joint effects of radiation dose to the heart, anthracycline dose, other chemotherapeutic agents, lifestyle factors and established cardiovascular risk factors.
Methods: A nested case-control study was conducted in a cohort of 2201 5-year HL survivors who were treated in the Netherlands between 1965 and 1995. Cases with IHD were matched to controls with HL who did not develop IHD (ratio 1:2 at least) on sex, age, date of HL diagnosis and duration of follow-up. Detailed treatment information was collected from medical records. Radiation dose to the heart was based on the prescribed mediastinal dose reported in the radiotherapy charts. Conditional logistic regression was used for analyses.
Results: 180 cases with IHD were identified from the cohort and matched with 499 controls. Mediastinal radiotherapy (usually performed using parallel opposed fields) was associated with an increased risk of IHD (OR: 3.0, 95% CI: 1.7−5.4). A dose-response relationship was identified (OR per 10 Gy: 1.2, $p = 0.004$). As compared to patients who did not receive mediastinal irradiation, we observed increased risks of IHD for patients who received 20−34 Gy (OR: 2.1, 95% CI: 0.97–4.63), 35−39 Gy (OR: 2.0, 95% CI: 1.10–3.51) or ⩾40 Gy on the mediastinum (OR: 3.6, 95% CI: 1.94–6.77) ($p < 0.001$), after adjusting for smoking at HL diagnosis and the presence of cardiovascular risk factors at cut-off (Diabetes Mellitus type II, hypertension, hypercholesterolemia) or obesity at diagnosis or at cut-off. No associations or interactions were found with (anthracycline-containing) chemotherapy.
Conclusions: Mediastinal irradiation is associated with a dose-dependent increased risk of IHD in patients treated for Hodgkin lymphoma.
No conflict of interest.

1082 POSTER

Multidisciplinary management of small cell cancer of non-pulmonary origin

R. Allison[1], S.A. Salenius[2], A. Hnatov[3], C. Ballenger[3], S. Finkelstein[4], C. Mantz[5], E. Fernandez[5], D. Dosoretz[5]. *[1]21st Century Oncology, Greenville, USA; [2]21st Century Oncology, Research, Fort Myers, USA; [3]21st Century Oncology, Radiation Oncology, Greenville, USA; [4]21st Century Oncology, Radiation Oncology, Scottsdale, USA; [5]21st Century Oncology, Radiation Oncology, Fort Myers, USA*

Background: While small cell lung cancer is managed by chemotherapy generally followed by consolidative radiation therapy, management of a non-pulmonary primary is less clear. In contrast to pulmonary small cell, aggressive surgery for these primaries is often employed. We analysed treatment technique and outcome in a large cohort of these patients to better define the role of surgery, radiation and chemotherapy.
Materials and Methods: An IRB approved chart review of all primary small cell cancers of non-pulmonary origin returned 60 (65% male, mean age 67 years) histologically confirmed cases. A total of 52 were pure small cell and the remainder were mixed with adenocarcinoma (n = 3), transitional cell carcinoma (n = 2), sarcomatoid (n = 2) and squamous cell (n = 1). Primary tumour location was head and neck (n = 20), bladder (n = 8), rectum (n = 7), prostate (n = 6), cervix (n = 5), vagina (n = 4), oesophagus (n = 4) and 1 case each from: anus, axilla, breast, ovary, trachea and inguinal. Treatment varied by anatomic site, with 31 (52%) patients undergoing definitive surgery, 51 (85%) undergoing chemotherapy, and 100% undergoing radiation therapy to the primary and regional nodes. External beam radiation therapy (XRT) was intensity modulated or 3D in almost all cases with 20 (33%) also undergoing image guided radiation therapy. The mean XRT dose to the primary was 52.4 Gray.
Results: Treatment was well tolerated. Late morbidity (grade 1/2) included 3 cases of xerostomia and 1 case each of stricture, cystitis, urinary frequency and anal incontinence. Local control was maintained in the majority of patients. Failure was most commonly distant (bones, liver, brain) with only one patient developing lung metastasis. Only 30% of patients are alive at last follow-up. Univariate analysis of local control and survival revealed that chemotherapy ($p = 0.01$) and male gender ($p = 0.007$) were statistically significant variables. Type of surgery and extent of surgery (definitive versus biopsy) did not impact outcome.
Conclusions: Small cell cancer of non-pulmonary origin is aggressive with high rates of systemic spread and poor 5 year outcome. The major treatment factor impacting survival remains chemotherapy. The addition of radiation to chemotherapy allows for control of the primary tumour. The role of surgery is limited as no benefit to survival or local control was seen. Responders may undergo consolidative XRT to the primary site. Consideration for central nervous system prophylaxis by radiation is also suggested by these data, as this is a common site of failure.
No conflict of interest.

1083 POSTER

Patterns of tumor response after stereotactic radiosurgery for vestibular schwannoma

R. Kabarriti[1], W.F. Mourad[1], D. Molinares Mejía[1], J. Glanzman[1], S. Patel[1], L. Hong[1], J. Fox[1], P. LaSala[2], S. Kalnicki[1], M.K. Garg[1]. *[1]Montefiore Medical Center, Radiation Oncology, New York, USA; [2]Montefiore Medical Center, Neurosurgery, New York, USA*

Background: Stereotactic radiosurgery (SRS) is commonly used for the treatment of vestibular schwannoma. In this study, we evaluate the control rates and MRI changes after treatment with Linac based SRS.
Material and Methods: 27 consecutive patients treated with 12 to 14 Gy using LINAC based SRS at a single institution from 2007–2013 were analyzed. Baseline and post-treatment tumor volumes were assessed on T1 weighted contrast enhanced magnetic resonance imaging. Local control and changes in tumor volume were calculated.
Results: Median follow up time was 35.6 months (range 1.5–61.9) and median treatment tumor volume was 1.1 cc (range: 0.1−8.7 cc). Sixty three, 33, and 4% of patients had reduction, stable, and progression in the tumor volume at their last post treatment MRI, respectively. Median SRS treatment dose was 12 Gy (range: 8−14) treated to 100% of the PTV. Median Dmin was 99.6% (range: 60.9–100), and median Dmax was 124.2% (range: 108.7–148.5%). Median number of beams was 12 (range: 8−15). 42% developed an early transient increase in their post treatment tumor volume occurring 3 to 7 months after SRS. Additionally, 19% had late transient increase in their post treatment volumes occurring 26−37 months post SRS. 7% had both an early and late transient increase in their tumor volumes. Tumor volume, treatment dose, and Dmax did not correlate with MRI changes.
Conclusions: Early and late transient increases in tumor volume occur in a significant number of patients with vestibular schwannoma treated with SRS. It is important to continue to monitor these patients with follow up imaging to avoid mistaking them for treatment failures.
No conflict of interest.

1084 POSTER

Plasmon-induced photothermal effects of gold nanoparticles on human permanent cell line T-24

L. Yossifova[1], E. Gardeva[1], R. Toshkova[1], M. Alexandrov[1], N. Nedyalkov[2], P. Atanasov[2]. *[1]Institute of Experimental Morphology Pathology and Anthropology With Museum, Pathology, Sofia, Bulgaria; [2]Academician Emil Djankov Institute of Electronics, Micro and Nano Photonics, Sofia, Bulgaria*

Background: Gold nanoparticles (GNPs) have been extensively used in various biomedical applications due to their advantageous biocompatibility, excellent optical scattering and photothermal properties, high chemical, photo- and thermal stability in comparison with most of molecular absorbers. The plasmon resonance for gold nanoparticles (GNPs) is at ~520 nm. The aim of the present investigation was to elucidate the effect of spherical GNPs with diameter 40nm combined with laser irradiation on permanent human tumor cell line T-24 (transitional cell bladder carcinoma).
Materials and Methods: The permanent tumor cell line T-24 was cultured in DMEM, supplemented with 10% FCS, at standard conditions. The samples were irradiated with Nd-YAG laser system, at λ=532 nm, pulse duration τ p= 15 ns and repetition rate 1 Hz. Laser pulses with energies of 20.5 J, 21.5 J, 22.5 J and 23.5 J for 5 s and 10 s were used. The potential anti-tumor effect in vitro of GNPs and laser treatment on T-24 cells were studied by MTT assay. Apoptotic changes in cell morphology were investigated with Annexin V/Propidium iodide (PI) and DAPI staining.
Results: Cells treated with GNPs or laser irradiation alone showed no significant difference from the control. Significant inhibition of tumor cell growth was detected in samples, pre-treated with GNPs and laser

beam with energy 20.5 J for 5 and 10 s (76.19±5.81 and 71.29±7.01 respectively). Similar results were obtained after irradiation with energy 21.5 J for 5 s (71.07±7.06).
Induction of apoptosis in treated with GNPs and irradiated cells was studied using Annexin V-FITC/PI and DAPI staining. Well defined morphological features of apoptosis were observed in order to interpret the results from MTT cytotoxicity assay. The results were statistically significant.
Conclusions: Based on the results obtained the combination of GNPs 40 nm and laser treatment with different characteristics of the laser beam and time of influence resulted in localized heating and causing irreversible thermal cellular destruction. This approach could have potential application in clinical practice and in experimental models in vivo for local treatment of tumors.
This work was supported by the European Social Fund and Republic of Bulgaria, Operational Programme 'Human Resources Development' 2007–2013 framework, Grant BG051PO001-3.3.06-0048 from 04.10.2012.
No conflict of interest.

1085 POSTER

When pain restricts symptomatic radiotherapy procedure

L. Diaz Gomez[1], L. Gutierrez Bayard[1], M.C. Salas Buzon[1], L. De Ingunza Barón[1], E. Gonzalez Calvo[1], V. Diaz Diaz[1], I. Villanego Beltran[1], E. Munive Alvarez[1]. [1]*Hospital Puerta Del Mar, Unidad Clinica de Gestion Atención Integral al Cancer, Cadiz, Spain*

Background: Irradiation treatment of various cancer processes in order to achieve symptomatic relief in the shortest time and with the least toxicity to maintain or increase the quality of life of patients. The ionizing radiation is a proven therapy for the treatment of pain due to bone metastases. The pain relief is achieved in 70−80% of patients using different fractionation schemes and total dose, occurs in 2−3 days, up to 2−4 weeks. However, what do we do when the pain suffered by these patients limits the tolerance requirements for the preparation and administration of radiotherapy? The aim of this study was to evaluate the efficiency of oral transmucosal fentanyl citrate (OTFC) as an analgesic for a highly specific subgroup of cancer patients.
Material and Methods: We analyzed the influence of predictable procedural breakthrough pain (set up, mobilization, treatment administration) in candidates for symptomatic radiotherapy and control pain with the use of oral transmucosal fentanyl citrate. From January 2007 to March 2013 we retrospectively reviewed 1995 patients indicating analgesic purposes radiotherapy, patients who didn't tolerate set up requirements and treatment time for breakthrough pain, and changes in use of OTFC.
Results: Between 2007–2009 the 11.63% (111) of patients requiring radiotherapy for analgesia (954), received OTFC before receiving radiotherapy, a 27.02% (30) who indicated OTFC not tolerated not set up. Between 2010 to March 2013, after evaluation the reasons for not proceeding tolerance of palliative radiotherapy, 24.68% (257) of these patients received OTFC (out of 1041 cases), all patients tolerated the procedure set up radiotherapy. The average score premedication with OTFC with procedural breakthrough pain according to VAS was 7.5 (range 5−10). The average score after use of OTFC was 1.8 (range 1−3). The 47% required a dose of 200 mg, 23% 400 μg, 600 μg 22%, and 8% 800 μg. No patients colds undesirable effects related to the use of OTFC.
Conclusions: We can recommend the ideal analgesic OTFC as its speed and safety for the treatment of breakthrough pain in Radiation Oncology procedural. It is easy and convenient administration of short duration, allowing tolerance and administration of radiation therapy. It is important consider predictable pain control but limiting. Give the patient independence, which they can take, even if you are away from home.

1086 POSTER

Adjuvant hypofractionated radiation therapy for breast cancer: Long term results in a cohort of 80 Cases treated at the Department of Radiation Oncology of CHUOran

A. Boukerche[1], A. Yahia[2], R. Madouri[1], A.F. Dali-Youcef[1]. [1]*CHUOran/Faculty of Medicine − University of Oran, Radiation Oncology, Oran, Algeria;* [2]*CHUOran, Radiation Oncology, Oran, Algeria*

Background: To evaluate the incidence of local recurrence (LR) and locoregional recurrence (LRR) and the toxicity results (acute and late) in a group of patients with breast cancer treated with a hypofractionated schedule of adjuvant radiotherapy after surgery.
Patients and Methods: From January to December 1998, 80 patients underwent radiotherapy treatment (telecobaltotherapy) after conservative (6%) and radical (94%) surgery at our department. The dose delivered was 36 Gy (3 Gy daily fraction). The boost dose was 15 Gy (3 Gy daily fraction) in conservative surgery. To score toxicity, we used the RTOG criteria (acute) and SOMA-LENT scale (late).
Results: With a median follow-up of 77 months (9 to 113 months), 7 patients had locoregional recurrences. The 8-year actuarial rates for local recurrence (LR) and LRR were 5.4% (±2.6%) and 9.5% (±3.4%), respectively. The 8-year overall survival rate was 74.3% (±8.1%). 72 patients (90%) were tolerated this hypofractionated schedule (grade 0). We found that 14 patients had grade ⩾ II late toxicity (17.5%). No patients developed grade IV late toxicity. On univariate analysis, the grade of SBR was influenced the LR and LRR ($p = 0.023$). The tumor size ($p = 0.038$), lymph node status ($p = 0.039$) and hormone receptor status ($p = 0.0001$) were influenced the OS. On multivariate analysis, we found that tumors classified T3−4 ($p = 0.028$; HR 3.999) and hormone receptor status ($p = 0.001$; HR 14.16) were independent factors on the OS.
Conclusion: This hypfractionated RT scheme is perfectly realizable (acceptable results in terms of local control and toxicity). It permitted a short course of treatment (<3 weeks), allowing a larger number of patients to be treated per year, with a reduction in cost to the health system. However, an important number of patients and a longer follow-up are necessary to better appreciate the efficacy and the cosmetic outcome of this scheme.
No conflict of interest.

1087 POSTER

Radiotherapy and prolongation of overall treatment time: a single center case report

G. Moro[1]. [1]*Ospedale Degli Infermi, Radiotherapy, Biella, Italy*

Background: The prescribed total radiation dose should be administered within a specific time; however, in clinical practice, unplanned treatment interruptions are inevitable for many reasons. This fact can have a detrimental effect on the tumour local control and patient's outcome. In this report we evaluate, in a single institution, the difference between the planned and the registered overall treatment time (OTT) of a different tumour sites, due to unplanned interruptions for various reasons.
Material and Methods: A total of 3936 patients (pts) were treated between 1990 and 2010 for breast, prostate, lung, head and neck (H&N) and pelvic malignancies with radical or adjuvant intent. Palliative or symptomatic treatments were excluded. Overall there were 1032 males and 2904 females with a mean age of 66 years. For all patients [treated with single fraction (F) of 1.8 to 2 Gy administered five times per week] we registered the total radiation dose, the number of fractions and the treatment's duration (in days); than for each group we evaluated the difference between the mean planned overall treatment time (number of fractions/5 multiplied for seven days of a week) and the mean duration of the treatment.
Results: The table shows the differences (in days) between mean planned and registered overall treatment time stratified by different tumour sites; the gap represents about 10% of planned OTT for all of the groups. Causes of prolongation of OTT could be various (holydays, machine breakdowns, toxicity and others), but we can't identify them in our computerized record. Moreover this case report don't correlate the prolongation of OTT with the therapeutic outcome.

Site	Pts	Gender (M/F)	Total dose	Dose/F (Gy)	Number of Fs	OTT (days) planned	OTT(days) observed	Difference (days)
Breast								
no boost	902	0/902	50 Gy	2	25	35	39	**4**
+ boost	1597	0/1597	60 Gy	2	30	42	47	**5**
Pelvis	219	67/152	45 Gy	1.8	25	35	38	**3**
Prostate	184	184/0	76 Gy	2	38	53	58	**5**
Lung	76	66/10	61.2 Gy	1.8	34	48	51	**3**
H&N								
no CT	741	494/247	58.7 Gy (mean)	1.8−2	31	43	46.5	**3.5**
+ CT	217	145/72	63.7 Gy (mean)	1.8−2	33.5	47	50	**3**

Conclusions: This is a simple picture of an unselected case report of patients treated at a single institution. Our results shows a moderate gap between planned and observed OTT. Efforts should be done to minimize the unforeseen prolongation of the overall treatment time through different methods for compensation (weekend treatments, increase number of daily fractions, increased dose per fraction, delivering extra fractions). In our centre, according with a codified internal protocol, we add a fraction on Saturday if unplanned break caused by machine breakdowns exceeds two consecutive days; we generally don't operate a compensation if the prolongation of the treatment is due to other causes (e.g. holydays, toxicity). If the break has occurred late in the schedule, we sometimes deliver one or more extra fractions.
No conflict of interest.

1088 POSTER

The impact of intensity modulated radiotherapy on skin dose for deep sited tumours

H. Abouelenein[1], E. Attalla[2], H. Ammar[2], I. Eldesoky[2], M. Farouk[2], S. Shoer[2]. *[1]Children's Cancer Hospital Egypt, Cairo, Egypt; [2]Children's Cancer Hospital Egypt, Radiotherapy, Cairo, Egypt*

Abstract: Background: The purpose of this study was to investigate the impact of IMRT on surface doses for brain, abdomen and pelvis deep located tumours treated with 6 MV photon and to evaluate the skin dose calculation accuracy of the XIO, 4.04 treatment planning system.
Materials: More investigations for the influences of IMRT on skin doses will increase its applications for many treatment sites. Measuring skin doses in real treatment situations will reduce the uncertainty of skin dose prediction. In this work a paediatric human phantom was covered by a layer of 1 mm bolus at three treatment sites and thermolumencent dosimeter TLD chips were inserted into the bolus at each treatment site before CT scan. Two different treatment plans (3-DCRT and IMRT) for each treatment sites were performed on XIO, 4.04 treatment planning system using superposition algorism.
Results: The results showed that the surface doses for 3DCRT were higher than the surface doses in IMRT by 1.6%, 2.5% and 3.2% for brain, abdomen and pelvis sites respectively. The results showed that there were good agreement between measured and calculated surface doses, where the calculated surface dose were 15.5% for brain tumour calculated with 3DCRT whereas the measured surface dose were 12.1%. For abdomen site the calculated surface dose for IMRT treatment plan was 16.5% whereas the measured surface dose was 12.6%.
Conclusions: The skin dose in IMRT for deep sited tumours is lower than in 3DCRT which is another advantage for the IMRT. The TLD readings showed that the difference between the calculated and measured point dose is negligible. The Superposition calculation algorism of the XIO, 4.04 treatment planning system modelled the superficial dose well.
No conflict of interest.

1089 POSTER

Development of pretreatment 'truly' patient-specific quality assurance procedure for stereotactic body radiotherapy using volumetric modulated arc radiotherapy

S. Tachiiri[1], K. Tanaka[2], K. Tanaka[2], M. Yanagawa[2], T. Kosuga[2], Y. Onishi[2], A. Miyai[2], S. Otsu[1]. *[1]Kyoto City Hospital, Radiation Oncology, Kyoto, Japan; [2]Kyoto City Hospital, Radiation Technology, Kyoto, Japan*

Background: In stereotactic body radiotherapy (SBRT) using volumetric modulated arc therapy (VMAT), pretreatment patient-specific quality assurance (QA) is essential. But radiochromic films suitable for larger doses (10−25 Gy) than conventional fraction dose (~2 Gy) are hardly available now. In some institutions, VMAT-SBRT verification with radiochromic film have been performed by rescaling dose prescribed to be inside the optimal dose range from the calibration curve (c.g. ~2 Gy). This is not patient-specific QA. We have developed a new patient-specific QA procedure for VMAT-SBRT patient pretreatment verification.
Materials: Co-planar VMAT plans (one arc VMAT plans, the total dose 55 Gy in five fractions) were created in five patients, who have been already treated using breath-holding conventional seven non-coplanar static SBRT (55 Gy in five fractions). We constructed a script to export VMAT plan from Pinnacle^3 (Philips Medical Systems, Best, The Netherlands) and to divide it into three partial arcs VMAT plans and then to import the divided three arcs plan into Pinnacle^3. We compared digitally reconstructed radiographs (DRRs) of all control points, 2D/3D dose distribution and DVH parameters of targets and organs at risk (OARs) of original plans and divided plans. And then we performed gamma analysis on both plan with the DD-System (R-TEC. Inc., Tokyo, Japan) using 1 mm/1% with a dose threshold of 5%. We moreover divided the divided plans into three plans with one partial arc VMAT in Pinnacle^3 and performed patient-specific QA measurements for each partial arc plans as routinely performed in conventional fraction dose (e.g. 2 Gy).
Results: All original plans and divided plans are completely coincided on DRRs of all control points, 2D/3D dose distribution and DVH parameters of targets and OARs. Gamma analysis showed original plans and revised plans are perfectly matched. In all five patients, gamma evaluation of three plans with one partial arc VMAT plans showed more than 95 % of passing rate using 3 %/3 mm criteria.
Conclusions: New pretreatment 'truly' patient-specific QA procedure was developed using a script in Pinnacle^3. New procedure enables us true QA for VMAT-SBRT patient plans using the same procedures as ones in VMAT plan using conventional fraction doses.
No conflict of interest.

1090 POSTER

Quality improvement project streamlines workflow performance and results in improved access to cancer care

H. Lomas IV[1], N. Bennion[2], K. Spencer[2], M. Richardson[2], M. Diggs[3], L. Miller[3], B. Bowden[3], J. Sheehan[4], R. Kersh[5]. *[1]Virginia Commonwealth University/Riverside Regional Medical Center, Radiation Oncology, Richmond VA/Newport News VA, USA; [2]Riverside Regional Medical Center, Radiosurgery Center, Newport News VA, USA; [3]Riverside Regional Medical Center, Radiosurgery Center, Newport news VA, USA; [4]University of Virginia, Neurosurgery, Charlottesville VA, USA; [5]University of Virginia/Riverside Regional Medical Center, Radiation Oncology, Charlottesville VA/Newport News VA, USA*

Objectives: Our Team performed a work-flow performance quality improvement project in our Radiosurgery Center. Our primary endpoint was to decrease the mean time between initial consult and first radiosurgery treatment. Our goal was to determine our current performance level and then implement a systematic performance quality improvement process to streamline workflow through the center, which in turn would result in improved access to care, patient satisfaction, and clinical outcomes without compromising patient safety.
Methods: We retrospectively reviewed our workflow performance for 248 patients treated in 2010 using 15 metrics to evaluate delays in the workflow and identify variables we could modify to improve performance. We assigned times to each metric as a benchmark. Time limits were assigned to each step in the process. Our evaluation resulted in a goal of 23 days between consult and treatment. In 2011−12, we prospectively evaluated 539 patients using the above metrics to evaluate the effect of our interventions.
Results: In 2010, the Radiosurgery Center treated 248 patients; mean time between consultation and treatment was 36 days. Access to dedicated CT Simulation time was a cause for delay and for 2011 we increased dedicated slot times which reduced our mean time between consultation and start by 4.52 days to 31.48 days with 245 patients treated. We determined the largest barrier to care was insurance carrier approval. To improve the insurance approval process, our Radiation Oncologists developed site specific templates which provided specific carrier approval requirements depending on the type of radiosurgical intervention. Contouring of target volumes and treatment planning times were rigorously monitored and timelines were enforced for each step to prevent treatment planning delays. In 2012 we treated 294 patients and our mean time between consult and initial treatment dropped to 22.92 days, this was an 8.56 day improvement over 2011, and a 13 day improvement over 2010, while patient volume in the center increased by over 17%, between 2011 and 2012. Patient safety was monitored throughout the process to ensure there was no compromise in patient treatment from changes in the process.
Conclusion: This research demonstrates that proactive interventions can result in a significant reduction in time between consult and initial treatment. Improved access provides more agility within our center while allowing for scheduling flexibility to triage more acute lesions with expedited start times. Protected treatment planning time has been demonstrated to decrease the potential for errors in treatment plans while ensuring adequate quality assurance and plan review prior to treatment. This model is a low-cost high-yield example of the quality improvement process which could easily be adapted to fit many practice models and yield significant improvement in the delivery and access of safe patient care.
No conflict of interest.

1091 POSTER

Deliberated errors caused by shifts in an ionization chamber bidimensional array. How far can we get without realizing?

A. Seguro Fernandez[1], A. Ureña Llinares[1], E. Angulo Pain[1], L.J. Ramos Caballero[1], I. Castro Ramirez[1], L.A. Quiñones Rodriguez[1], R. Mora Melendez[1], M.A. Iborra Oquendo[1]. *[1]Hospital Puerta del Mar, UGC Radiofisica y SPR, Cadiz, Spain*

Background: One of the issues we have to take into account about bidimensional ionization chamber arrays for IMRT pre-verification is the low spatial resolution and sample frequency. In this study we analyze PTW 2DARRAYSeven29® (2DARRAY) which consists of 729 ionization chambers with a center to center distance of 1 cm and a volume of 0.125 cm^3.
Our goal in this study is to find a pattern between systematic misalignments and the values of the gamma index criteria for IMRT verification. We also hope to determine if a spatial resolution of 1 cm is small enough to detect misalignments less or equal *to* 5 mm.
Materials and Methods: We carried out several deliberated shifts (±1 mm, ±3 mm and ±5 mm) in three orthogonal directions (head-feet, left-right and

up-down) on 2DARRAY placed inside PTW Octavius® Phantom (Octavius). Both of them were irradiated in a Siemens Oncor Impression® 6MV Linear Accelerator equipped with a 160 multileaf collimator. Previously, a real prostate plan was transferred on to 2DARRAY and Octavius CT and it was computed by Pinnacle® v9.2 Treatment Planning System without any shift, providing us with a reference dose map and a reference central chamber dose. We also measured the dose at the isocenter for 5x5, 10x10 and 20x20 cm^2 fields to check the constancy of the dose along the whole study. Finally, we compared the doses at the 2DARRAY central chamber and reference map doses computed by TPS to those measured in each shift using the 2DARRAY. The comparison between the reference dose map computed by TPS and 2DARRAY measured planar doses was performed by PTW Verisoft® Software drawing on a gamma index (3 mm, 3%, local dose).
Results: There is an agreement between the TPS reference dose in the central chamber and those obtained by 2DARRAY whatever the shift performed. In all cases the differences were less than 2.5%. However, we obtained unacceptable values for gamma index when shifts were greater than 1 mm. For 1 mm shifts, the drop in the gamma index was from 100% to 98.8%, the mean gamma index for 3 mm shifts was 81.1% and for 5 mm it was 70.4%.
Conclusions: Misalignments greater than 1 mm can be detected by map dose measured by 2DARRAY when using a gamma index criteria (3%, 3 mm, local dose) but no useful information is provided by dose at the 2DARRAY central chamber as we have a tolerance level of 3%. On the other hand, these results could be achieved once we had planned and verified about 30 prostate cases and the values of the gamma index were always approximate 100%.
No conflict of interest.

1092 POSTER

An approach to individualized tolerance level of patient-specific QA depending on treatment planning using dosimetric metrics

J.I. Kim[1], J.M. Park[1], H.G. Wu[1], C.H. Choi[2], J.G. Lee[3], J.I. Park[3], S.J. Ye[4]. *[1]Seoul National University Hospital, Radiation Oncology, Seoul, South Korea; [2]VHS Medical Center, Radiation Oncology, Seoul, South Korea; [3]Seoul National University, Biomedical Radiation Sciences, Seoul, South Korea; [4]Seoul National University, Transdisciplinary Studies, Seoul, South Korea*

Background: The aim of this study is to compare and evaluate the individualized tolerance levels of patient-specific DQA depending on the delivery techniques (IMRT vs VMAT) and treatment sites using a variety of dosimetric tools.
Material and Methods: Dosimetric QA (DQA) measurements were performed with (1) a point dose by an ion chamber, (2) 2D dose distribution by radiochromic film (EBT2) for an axial plane and an ion chamber array (Matrixx®) for a coronal plane, and (3) 3D dose distribution by a head-mounted ionchamber array (COMPASS®). The two criteria (2 mm/2% and 3 mm/3%) were used to analyze the gamma passing rate of 2D and 3D dose distributions. Several statistics were applied to analysis the normality of each group (IMRT, VMAT, Prostate, and H&N), significance between the comparisons (IMRT vs VMAT and Prostate vs H&N), and correlation between dosimetric tools. The concept of confidence limit was applied to approach to the tolerance levels.

Measurement		2D (Matrixx)	2D (Film)	3D w/Body	3D w/PTV
Point dose	*r*-value	−0.33	0.17	0.35	−0.32
	p-value	<0.05	0.29	<0.05	<0.05
	N	40	40	40	40
2D (Matrixx)	*r*-value		−0.11	−0.02	0.42
	p-value		0.49	0.89	<0.05
	N		40	40	40
2D (Film)	*r*-value			0.17	0.31
	p-value			0.30	0.05
	N			40	40
3D w/ Body	*r*-value				0.02
	p-value				0.90
	N				40

Results: The difference between IMRT and VMAT showed in the point dose, axial plane dose, coronal plane dose and 3D volume dose measurements. The difference between prostate and H&N showed in the axial plane dose, coronal plane dose, and 3D volume dose measurements. There was no the correlation between the dosimetric tools as shown in table.
Conclusions: 3D volumetric verification is required to assess the dose discrepancy in VMAT and the multi-institutional study is required to have confidence in the implementation of individualized tolerance level based on the approach and results in this study.
No conflict of interest.

1093 POSTER

Quality assurance in IMRT: A comparison between two-dimensional ionization chamber array and film dosimetry

A. Seguro Fernandez[1], A. Ureña Llinares[1], L.J. Ramos Caballero[1], I. Castro Ramirez[1], L.A. Quiñones Rodriguez[1], R. Mora Melendez[1], E. Angulo Pain[1], M.A. Iborra Oquendo[1]. *[1]Hospital Puerta del Mar, Medical Physics, Cadiz, Spain*

Background: Two dimensional ionization chamber arrays are an easy-handling and fast real-time method for pre-treatment verification in IMRT. However, spatial resolution can be an issue because the sample frequency in the Fourier domain must be at least 0.2 mm^{-1} (5 mm in coordinate space) when using 1 cm^2 beamlets. Commercial devices provide smaller resolutions PTW 2DARRAY Seven29® (2DARRAY): 0.1 mm^{-1}, Scanditronix Wellhofer IMRT Matrixx®: 0.13 mm^{-1} and Sun Nuclear Mapcheck2®: 0.14 mm^{-1}). Together with Merge 27® software, a 5 mm shift for 2DARRAY in orthogonal directions can provide a 5 mm spatial resolution map dose. Although this is not a good settlement as it triples the time for verification. The aim of this study is to check if 2DARRAY has a good gamma index agreement to Film dosimetry using Gafchromic® EBT2 when IMRT Step and shoot beamlets have a minimum area of 4 cm^2.
Materials and Methods: All the measurements were performed in a Siemens Oncor Impression® 6 MV Linear Accelerator that was equipped with a Multileaf Collimator of 160 leaves whose width was 5 mm at the isocenter. Planar doses were computed by Pinnacle v9.2 Treatment Planning System (TPS) and measured planar doses were carried out in Octavius® Phantom both for films and 2DARRAY. Also, computed doses at isocenter from the TPS were compared to measured doses using a PTW 31003 Semiflex® Chamber for film verification and the central ionization chamber from 2DARRAY.
The comparison between planar doses was made using gamma index (3 mm, 3%, local dose) for Head and Neck and Prostate cancer cases. We used FILM QA PRO® and PTW Verisoft® software for these purposes.
Results: In all prostate cases (N = 32) we obtained a gamma index higher than 95% for 2DARRAY or film verifications when comparing to the TPS planar doses. For head and neck cases (N = 13) we achieved a gamma index higher than 91% for all cases for film dosimetry and even better results for 2DARRAY verification as the results were never less than 95%. For dose at the isocenter the difference between TPS and semiflex® chamber or central chamber from 2DARRAY was never higher than 3% for both sets of cases.
Conclusions: PTW 2DARRAYSeven29® has proved to be a reliable and accurate method for IMRT pre-treatment verifications compared to film dosimetry and has the great advantage of real-time measurements for quality assurance purposes.
No conflict of interest.

Impact of inhomogeneous tissue on IMRT QA for MatriXX

Y. Yin[1]. *[1]Shandong Cancer Hospital, Jinan Shandong, China*

Purpose: By applying self-made inhomogeneous phantom to MatriXX, a group of IMRT plans were delivered, to observe the impact on test results on different measuring condition.
Method: Two foam planks were made to simulate the low density tissue, e.g lung tissue, in the size of (40×40×3)cm, identical to virtual water. Three measurement condition using MatriXX were arranged: A. virtual water only (8 cm top and 5 cm bottom); B. one foam plank was used plus 5 cm virtual water on its top, and 5 cm virtual water on MatriXX bottom; C. two planks were used on the top and at the bottom of MatriXX, with 5 cm and 2 cm virtual water planks wrapped. The sizes in B and C condition were same to A. CT scanning images for three conditions were obtained and transmitted to TPS. QA plans were generated to the scanning images respectively. The original plans were 10 esophageal cancer IMRT plans. The QA plans were calculated in CMS xio-release 4.62, using superposition algorithm, and then delivered to Elekta Synergy. Each plan was measured in different condition, and the gamma passing rate was obtained.
Results: There was no significant difference (P<0.05) among the three measuring condition. The results, i.e gamma passing rate, in B (98.78±1.34)% and C (98.71±1.16)% were as good as in A (98.49±1.10)%.

Conclusion: The results showed that there is no difference in MatriXX measurement, no matter what phantom is used. However, more measurements should be needed to make it confirmed.
No conflict of interest.

1095 POSTER

Multi-dimensional patient-specific plan QA on IMRT and RapidArc techniques

J. Chen[1]. [1]*Shandong Tumour Hospital, Jinan Shandong, China*

Background: The aim was to distinguish the differences between IMRT and RapidArc delivery, through comparison of plan QA results in three modalities.
Materials: 20 cases with NPC were enrolled. Based on the simulation CT images and targets, IMRT and RapidArc plans were both generated for every case in Eclipse v8.6. The plans, after approved, were converted into QA plans, using virtual water as phantom. 1. A cylindric ion chamber (PTW 0.125cc) was applied to point dose QA. The selected point was set to iso-center. 2. MatriXX (IBA v1.76) was applied to plane QA. The plane through iso-center was the measurement plane. 3. COMPASS system (IBA v2.0) was applied to volumetric QA. Each QA plan was delivered to Varian Trilogy to be measured. For point measurement, the QA result was the ratio of measurement to planning. For plane and volumetric measurement, the QA results were gamma passing rate with the criteria of 3%&3 mm. The paired *t*-test was used as statistical analysis.
Results: Point QA: the average result was (96.83±0.84)% for IMRT and (97.03±0.46)% for RapidArc, $P = 0.275$.
Plane QA: the gamma passing rate on average was (97.59±0.61) for IMRT and (97.98±0.36)% for RapidArc, $P = 0.055$.
Volumetric QA: the gamma passing rate on average was (96.70±0.81) for IMRT and (97.03±0.83)% for RapidArc, $P = 0.068$.
Conclusion: Although the differences among three QA modalities were not significant, it's found that almost RapidArc plan measurement results were better than IMRT's. The study indicated that RapidArc technique could be as good and safe as IMRT in plan delivery.
No conflict of interest.

1096 POSTER

Dosimetric shield evaluation with tungsten sheet in 4, 6, and 9 MeV electron beams

T. Fujimoto[1], H. Monzen[2], S. Yano[1], T. Okada[1], M. Nakata[1], T. Takakura[1], M. Sasaki[3], J. Kuwahara[1], K. Higashimura[1], M. Hiraoka[2]. [1]*Kyoto University Hospital, Clinical Radiology Service Division, Kyoto, Japan;* [2]*Kyoto University Graduate School of Medicine, Radiation Oncology and Image-applied Therapy, Kyoto, Japan;* [3]*Tokyo University Hospital, Radiology, Tokyo, Japan*

Purpose: In electron radiotherapy, shielding material is required for attenuate beam and scatter. A newly introduced shielding material, *Tungsten functional paper* (TFP), has been expected as much useful device which is lead-free, light, flexible and easily processed containing very tiny tungsten powders as much as 80 percent by weight. The purpose of this study is to investigate the dosimetric changes due to TFP shielding for electron beams.
Method and Materials: TFP (thickness 0−15 mm) was placed on water or water equivalent phantom. Percentage depth ionization and transmission were measured by 4, 6, and 9 MeV electron beams with 10×10 and 20×20 cm^2 field size. Off-center ratio was also measured using the film at depth of dmax under the similar condition. Then, beam profiles, transmission with two shielding materials, TFP and Lead, were evaluated.

Table 1. TFP thickness required for 95% and 98% reduction.

Depth	Attenuation	TFP thickness required (mm)					
Energy (MeV)		4		6		9	
Field size (cm^2)		10×10	20×20	10×10	20×20	10×10	20×20
0.0 cm	95%	5.56	5.63	10.57	10.74	15.61*	15.65*
	98%	5.87	6.09	11.86	11.93	16.20*	16.18*
0.5 cm	95%	4.31	4.30	8.88	8.94	15.06*	15.20*
	98%	5.11	5.08	11.14	11.34	15.91*	16.02*
1.5 cm	95%	0.98	0.98	5.67	5.70	11.49	11.99
	98%	1.33	1.34	7.63	7.91	15.12*	15.55*
3.0 cm	95%	–	–	–	–	4.99	5.49
	98%	–	–	0.66	0.77	8.63	11.47

*Estimation value by linear interpolation with transmission curve.

Results: TFP thickness required for 95 % and 98 % reduction is shown Table 1. The reduction of 95% by use of TFP at 0.5 cm depth were 4, 9, and 15 mm with 4, 6, and 9 MeV electron beams, respectively. Beam profile of TFP intended to increase dose at the field edge that might be influenced by thickness. The energy of 4, 6 MeV were not problem in the clinical situation since the transmission under shielding were less than 2%.
Conclusions: This study shows the characteristic of new radiation-shield-material (TFP) was evaluated by using the electron beams. It has several unique features and is highly expected to be useful for radiation protection for the electron beam.
Conflict of interest: *Other substantive relationships: Device (Tungsten functional paper) used in this study was provided by TOPPAN PRINTING CO., LTD, Tokyo, Japan.*

1097 POSTER

Dosimetric comparison of postoperative whole pelvic lymph node intensity-modulated radiotherapy for cervical cancer patients with multiple pelvic lymph node metastases

T. Liu[1], X. Lin[1]. [1]*Shandong Tumour Hospital, Jinan Shandong, China*

Background: To study the dosimetric difference among RapidArc (RA) and intensity-modulated radiotherapy (IMRT) plans applying different energy x-ray for whole pelvic lymph node irradiation.
Material and Methods: Ten cases of cervical cancer who underwent radical surgery and demonstrated multiple pelvic lymph node metastases were treated with radiotherapy. Three plans were generated for each case: 7-field IMRT, one-arc RapidArc (RA1 = 358º)and two-arc RapidArc (RA2 = 716º). For each plan, 6 MV and 15 MV X-ray were applied respectively. The dosimetric differences were compared among different plans.
Results: All plans could meet the clinical requirement. The CI, HI and EVI of IMRT and RA2 were better than RA1 with significantly difference ($p < 0.05$), while the differences between IMRT and RA2 were not significant. There were no significant differences were found in irradiation dose of organs at risk except for small bowel V40 (IMRT < RA2).
Conclusions: Compared to IMRT, there were no significant dosimetric benefits were found except treatment time and monitor unit in radiotherapy for whole pelvic lymph node applying RaidArc. Additionally, the 6MV photons may be the prudent choice.
No conflict of interest.

1098 POSTER

Dosimetric test of collapsed cone convolution superposition algorithm in a heterogeneous media

L.F. Oliveira e Silva[1], T.F. Mangueira[2], J.R. Dias[3], S.R. Avelino[1]. [1]*Hospital Universitário de Brasília, Radiotherapy, Brasilia, Brazil;* [2]*Universidade de Brasília, Radiotherapy, Brasilia, Brazil;* [3]*Instituto de Radioterapia de Taguatinga, Radiotherapy, Brasilia, Brazil*

Background: The Collapsed Cone Convolution Superposition (CCCS) algorithm is used for dose calculation and intrinsically considers the effects of patient heterogeneities. The purpose of this study is to evaluate the accuracy of Prowess 5.0 (Prowess Inc., Concord, Ca) TPS dose calculations using CCCS algorithm in a heterogeneous phantom.
Material and Methods: Dose calculations of Prowess 5.0 TPS using the CCCS algorithm were compared against measured data. Measurements were performed with ionization chamber (0.057 cm^3) and EBT2 radiochromic films. The films were calibrated in 10 points between 0 and 320 cGy and scanned in Epson Expression 1000 XL scanner. Two different phantoms were used in the measurements and both were imaged using CT scanner for TPS dose calculation at corresponding detector locations. Both phantoms are composed of an 8.6 cm depth cork slab between two 7 cm depth solid water slabs. Each phantom has a rounded shape volume (≈95.5 cm^3) made of wax inside the cork. One wax volume is split at central plane for film placement and the other is made with the ionization chamber build up cap at volume's center. The irradiations were carried out with 6 MV Primus Siemens linear accelerator (Siemens Medical Solutions, Concord, Ca) photon beam with 20x20 cm^2 field size, 90 cm SSD and 200 MU. Three field profiles were acquired with film dosimetry in the crossplane direction: 1) at 7 cm depth (in solid water/cork transition); 2) at the central plane of wax volume; and 3) at 15.6 cm depth (in cork/solid water transition). Further, absolute dosimetry with ionization chamber was performed at two positions: 1) inside the wax volume with the build up cap; and 2) at 16.6 cm depth, inside a solid water ion chamber slot (1 cm deeper than cork slab).
Results: The field profiles did not present dose differences higher than 2% or 2 mm DTA. Inside the wax volume, the dose calculated was 2.6% higher than the measured dose, and in deeper position was 4.5% higher.
Conclusions: The field profiles relative dosimetry presented acceptable agreement with TPS calculation. The absolute measured doses showed

that collapsed convolution superposition algorithm can overestimate dose (up to 4.5%) in a heterogeneous media. Further study is necessary for CCCS algorithm clinical implementation.

MicroRNA-regulated pathways of radiotherapy sensitivity and resistance in breast cancer

M. Pajic[1], P.H. Graham[2], E.K.A. Millar[1], S.A. O'Toole[1], T.J. Molloy[1].
[1]The Kinghorn Cancer Centre/Garvan Institute of Medical Research, Cancer Resarch, Sydney, Australia; [2]St George Hospital, Cancer Care Centre, Sydney, Australia

Background: Radiotherapy is an important component of primary, adjuvant, and palliative treatment for many types of solid tumour. Because of this, innate or acquired resistance is a major clinical problem. These issues are compounded by the fact that effective biomarkers that can identify this subset of resistant tumours or can otherwise accurately target radiotherapy to those patients who would most benefit from it have yet to be discovered. We previously identified 3 microRNAs (miRs) able to regulate genes associated with key mechanisms of the cellular response to radiotherapy, and which could trigger resistance or sensitivity to clinically-relevant doses of radiation in breast cancer cells *in vitro*. We aimed in the current study to characterise these miRs.
Materials and Methods: Bioinformatics analyses were used to identify putative gene targets of each miR of interest. Target binding was confirmed by luciferase assay, QPCR analyses, and Western blotting. Knockdown of several targets themselves also triggered significant sensitivity or resistance to radiation in breast cancer cells *in vitro*. Four key targets, NEK1, PLK2, SKP2, and RAG1 were further tested as biomarkers predictive of relapse following radiotherapy in two independent early-stage breast cancer patient cohorts.
Results: Microarray gene expression profiling of miR mimic-transfected MCF7 cells together with miR binding sequence prediction algorithms were used to identify putative miR targets. Mimics were confirmed to bind to specific 3′ UTR sequences of several key genes, including those associated with DNA repair, cell cycle control, and reactive oxygen species defence, resulting in their downregulation at both the mRNA and protein level. For radiotherapy-sensitizing mimics this also had functional significance, with impaired DNA repair and increased sensitivity to both radiation and DNA damaging chemotherapy agents. Several miR targets were also effective biomarkers − the expression of miR targets NEK1, PLK2, SKP2, and RAG1 were significantly correlated to relapse-free survival in 435 early-stage breast cancer patients.
Conclusion: The expression of several genes important to the cellular response to radiation are miRNA-regulated, which suggests that the dysregulation of these miRs could lead to resistance to radiotherapy in patients. Furthermore, several of these genes correlate to survival in radiotherapy-treated patients, and could be used to guide treatment in the clinic.
No conflict of interest.

Identification of compounds modifying radiation-therapy using a 3D-microtissue technology

I. Hoefig[1], C. Thirion[2], J. Kelm[3], M.J. Atkinson[1], N. Anastasov[1].
[1]Helmholtz Zentrum Muenchen, Institute for Radiation Biology, Munich, Germany; [2]Sirion Biotech GmbH, Munich, Germany; [3]InSphero AG, Schlieren, Switzerland

Background: The two key issues in chemo- and radiation therapy is the development of tumor resistance as well as toxic effects on normal tissue. In this sense new strategies are required to increase efficacy of radiation to improve the therapeutic impact and reduce toxicological side effects**.** Material and Methods: The performance of 3D cell culture systems over classical 2D culture systems has been shown to provide a closer representation of tissue-level biology. This has led to the rapid adoption of 3D systems for both drug discovery and toxicology. InSphero has developed a highly reproducible hanging drop technology able to generate monotypic cell spheroids called microtissues in a 96-well format.
Results: The innovative 3D-microtissue plate technology has been adapted for analysis of the cellular response of radioresistant T47D breast cancer and FaDu head and neck cancer cells to combined radio-chemotherapy (RCTx). We have validated the model by comparing the treatment of microtissues with 10 different chemotherapeutic compounds, each tested alone and in combination with an acute 2 Gy radiation exposure. The cancer cells were stably transduced with GFP-lentiviral vector enabling faster high throughput quantification of 3D microtissue growth assessment using an Operetta working Software and detection system 'Harmony 3.0' (PerkinElmer, USA). We studied the ability of RCTx to modify 3D-microtissue growth 3, 6 and 10 days after treatment. Results for five compounds (Actinomycin D, Staurosporine, Docetaxel, Doxorubicin and Vinblastine) showed that the IC50 values were improved by the addition of the single 2 Gy radiation dose, indicating that they are capable of inducing a radiosensitation effect on radioresistant breast cancer cells. Panels of commercial secondary functional assays were adapted to the 3D-microtissue high throughput assay. Cellular viability and cytotoxicity were measured directly in microtissues using the CellTiter-Glo Reagent (Promega, USA). Apoptosis was measured using an ELISA based M30-Apoptosense assay (TECOmedical AG, Switzerland).
Conclusions: These results confirm that the assay operated with the 3D-microtissue model system is able to detect compounds that modulate tumor cell survival after irradiation.
No conflict of interest.

1101 POSTER

Identification of the mechanisms of radiosensitization by human papillomavirus (HPV) in head and neck cancer cell lines

V. Bol[1], F. Masquelier[1], B. Mohktar[1], V. Grégoire[1]. *[1]University Catholique De Louvain, Irec-miro (Molecular Imaging Radiotherapy and Oncology), Brussels, Belgium*

Background: Several clinical studies have shown that HPV+ head and neck squamous cell carcinomas (HNSCC) present a more favorable outcome and greater response to radiotherapy. Although there are some data supporting the hypothesis that HPV-related tumors have a better survival due to a higher sensitivity to radiation therapy, it is difficult to conclude that the improved clinical outcome of HPV-related HNSCC is only attributable to intrinsic radiosensitivity of the HPV+ cells. As an hypothesis, it is postulated that a complex interaction concurs between intrinsic mechanisms of radio-response and the tumor micro-environment including cells of the immune system stimulated by the presence of HPV. The objectives are to identify the mechanisms of radiosensitization by HPV and to investigate whether irradiated HPV+ cells exhibit an increased immunogenic cell death signal.
Material and Methods: We determined radiosensitivity by clonogenic survival of two HPV+ HNSCC cell lines (UPCI-SCC-154 & UPCI-SCC90) compared to two HPV− (SCC61 & SQD9). Cell cycle distribution and G2/M checkpoint were assessed by flow cytometry. DNA damage repair was evaluated by gamma-H2Ax assay. In addition, apoptosis was investigated in the four cell lines together with immunogenic cell death signal, through membrane exposure of calreticulin.
Results: The surviving fraction at 2 Gy (SF2) for the two HPV+ cell lines was 0.13 and 0.15 for UPCI-SCC-90 and UPCI-SCC-154, respectively while SF2 for SQD9 was 0.49 and 0.16 for SCC-61 a head and neck squamous cell line known to be radiosensitive. Cell cycle distribution indicated a block in G2/M 24 h after irradiation for the HPV+ cell lines not observed in the HPV− cells. In HPV+ cells, gH2Ax kinetics after a single dose of 5 Gy correlated the SF2 data with a slower clearance of gH2Ax for HPV+ cells, compared to HPV− cells. At 24 h after irradiation, less than 5% of cells in all groups were apoptotic, but further time points still need to be analysed. Finally, calreticulin membrane translocation as a measure of immunogenic death signal after irradiation was detected in HPV+ but not in HPV− cell lines, before and 24 h after irradiation.
Conclusions: These results confirm the increased radiosensitivity of HPV+ cells although at this point further investigation is needed to elucidate what are the mechanisms implicated. However, detection of calreticuline translocation as a marker of immunogenic death signal in HPV+ cells opens an interesting hypothesis.
No conflict of interest.

1102 POSTER

Antitumor effect induced by combination of radiation with a novel HSP70 inhibitor pifithrin-mu on human prostate cancer

K. Sekihara[1], N. Harashima[2], Y. Tamaki[1], Y. Hieda[1], N. Uchida[3], T. Inomata[1], M. Harada[2]. *[1]Shimane University Faculty of Medicine, Department of Radiation Oncology, Izumo, Japan; [2]Shimane University Faculty of Medicine, Department of Immunology, Izumo, Japan; [3]Tottori Prefectural Central Hospital, Department of Radiation Oncology, Tottori, Japan*

Background: Heat shock proteins (HSPs) are constitutively expressed in many cancers, and various types of stress increase their expression. HSPs are thought to make cancer cells resistant to anti-cancer therapy, with HSP70 playing a central role in the resistance. Recently, pifithrin-μ (PFT-μ) has been revealed as a new HSP70 inhibitor. In this study, we investigated the antitumor effects of the combination therapy of radiation with PFT-μ on

human prostate cancer cell lines and attempted to elucidate the underlying mechanisms.
Material and Methods: Three human prostate cancer cell lines (LNCaP, PC-3, and DU145) and a human normal prostate epithelial cell line (PrEC) were used. HSP70 expression in the cancer cells was examined by immunoblot. HSP70 was knocked down with siRNA. Cell viability was evaluated using a WST-8 assay. Clonogenic capacity of cancer cells was determined using a colony formation assay. Cell proliferation was examined by flow cytometry after labeling with carboxyfluorescein succinimidyl ester (CFSE).
Results: Knockdown of HSP70 significantly decreased the viability and the colony-forming capacity of all three prostate cell lines, suggesting a crucial role of HSP70 in the survival of cancer cells. The combination of low-dose radiation (2 Gy) and low-dose PFT-μ (3 μM) significantly decreased the viability and the colony-forming capacity of three prostate cancer cell lines compared with either treatment alone. Importantly, this combination effect was not observed on PrEC cells. In addition, CFSE assay revealed that the combined therapy decreased proliferation of cancer cells, suggesting the induction of growth arrest.
Conclusions: These data indicate that the combination therapy with radiation and PFT-μ can decrease the growth of human prostate cancer cells, and that PFT-μ is a promising reagent to enhance the antitumor effect of radiation.
No conflict of interest.

1103 POSTER

In vitro prediction of radiation sensitivity in patients treated with external beam radiation therapy

S.W. Wilcox[1], J. Maneerat[2], I. Radford[2], M.J. McKay[3]. *[1]North Coast Cancer Institute, Radiation Oncology, Port Macquarie, Australia; [2]Peter MacCallum Cancer Centre, Radiation Oncology, Melbourne, Australia; [3]North Coast Cancer Institute, Radiation Oncology, Lismore, Australia*

Background: Understanding the basis of clinical radiosensitivity (RS) is considered by many to be a key goal of radiation research. Numerous cellular and molecular assays have been applied to cells from RS cancer patients in an attempt to predict which patients may suffer excessive RS reactions. In this study, a correlation between transformed lymphoblasts and clinical response was investigated using the limiting dilution assay (LDA) in cell lines from clinically RS individuals with seven tumour varieties, compared with controls.
Material and Methods: Lymphoblasts from 29 cancer patients (19 RS patients, 10 controls) who had or had not experienced severe normal tissue reactions, and one ataxia telangiectasia positive control cell line, were exposed to graded doses of gamma-radiation *in vitro* and cell survival assessed via LDA. RS cell lines were created from patients who had RTOG Grade 2 (n = 1), Grade 3 (n = 12) or Grade 4 (n = 3) skin reactions. Cell survival was expressed as the surviving fraction at 2 Gy (SF_2), and data fitted with non-linear regression analysis.
Results: SF_2 ranged from 0.0245–0.3894, with variability in cell survival evident both among and within individuals, with a coefficient of variation of 31% overall. A non-significant trend was seen between acute or consequential late reaction cell lines and LCL radiosensitivity ($p = 0.10$ and $p = 0.08$ respectively). Two RS outliers were detected in the assay corresponding clinically to Grade 3 late breast fibrosis, and Grade 4 osteoradionecrosis of the jaw and odynophagia in a patient treated for head and neck cancer.
Conclusions: The presence of cell survival heterogeneity and a number of patients demonstrating *in vitro* sensitivity but normal clinical response, among other reasons, may limit the usefulness of this assay for predictive purposes. However, two radiosensitive outliers were observed in the present study which may yield insight into the genetic basis of RS, for example by utilizing deep DNA sequencing.
No conflict of interest.

1104 POSTER

Ionizing radiation of esophageal carcinomas leads to alterations of the hyaluronan matrix and stroma mediated cell death of tumor cells in vitro

A. Schütze[1], K. Röck[1], R.U. Jänicke[2], J.W. Fischer[1]. *[1]Universitätsklinikum Düsseldorf, Institut für Pharmakologie und Klinische Pharmakologie, Düsseldorf, Germany; [2]Universitätsklinikum Düsseldorf, Klinik und Poliklinik für Strahlentherapie und Radioonkologie, Düsseldorf, Germany*

Background: Radiotherapy is commonly used in the management of esophageal carcinomas (OSC). Hyaluronan (HA), a major carbohydrate constituent of the extracellular matrix, forms a complex, biologically active matrix with its binding partners (e.g. versican). This network plays an important role in tumor–stroma interactions. However, little is known about the response of the HA-matrix to radiation.
Material and Methods: To investigate changes of the HA-matrix induced by ionizing radiation, mono-cultures of OSC and fibroblasts were irradiated with 10 Gy. The HA matrix was analysed by qRT-PCR, ELSA and immunocytochemistry. Cell cycle was investigated by FACS. Cells were observed by time lapse microscopy. Cell death was measured by visual analysis. The results were confirmed by PARP and Annexin-V analysis. The role of ROS in matrix changes was assessed by the ROS inhibitor N-acetylcysteine (NAC).
Results: Mono-cultures of OSCs and fibroblasts show an altered expression of HA-matrix related genes. The main HA-synthase (HAS)-isoform of OSCs, HAS3, was up-regulated (2.02 ± 0.25 fold of control), whereas the main isoform in fibroblasts, HAS2, was reduced (0.21 ± 0.02 fold of control). Versican mRNA is induced in fibroblasts (1.64 ± 0.08 fold of control), however not changed in OSCs. HA quantification by ELSA showed no differences in irradiated cells, although structural changes evident by the formation of HA-cables were observed in irradiated OSCs. Immunocytochemistry confirmed the increase of versican in irradiated fibroblast. To evaluate functional consequences of the altered HA-matrix in the tumor–stroma interaction, fibroblasts were seeded on OSCs 24 h after irradiation. A significantly increased amount of dead OSCs was observed in co-culture with irradiated fibroblasts compared co-culture with mock-irradiated fibroblasts (36.72 ± 9.68 fold of control). This effect could be abolished by pre-incubation of fibroblasts with NAC. PARP western blots and flow cytometry confirmed the microscopic results.
Conclusions: In conclusion, ionizing radiation leads to stromal cell mediated, ROS dependent, cell death of tumor cells. These effects might be associated with changes of the HA-matrix. In particular, versican has been shown to exhibit pleiotropic effects concerning cell death. Therefore, it might protect stromal cells while driving tumor cells into apoptosis. This effect will be subject to further investigations, thereby possibly leading to new innovative strategies in tumor chemoradiotherapy.
No conflict of interest.

1105 POSTER

Relationship between the quantity of serum reactive oxygen metabolites and skin toxicity grade in the irradiated rat model

T. Nomiya[1], T. Kaneko[2], J. Goto[2], M. Harada[2], H. Akamatsu[1], I. Ota[2], T. Kamada[1], K. Nemoto[2]. *[1]National Institute of Radiological Sciences, Radiation Oncology, Chiba, Japan; [2]Yamagata University Hospital, Radiation Oncology, Yamagata, Japan*

Background: Adverse effects of radiation are one of the major problems for the patients undergoing radiotherapy. It is known that radiation causes damage by producing free radicals or oxidative stress. The aim of this study was to analyze relationship between oxidative stress and reactions to radiation in vivo using rats.
Materials and Methods: 4 MeV Electron beams were irradiated to the skin of the right leg of 6-week-old female Wistar rats. Serum ROMs were quantified with d-ROMs test using blood collecting from caudal vein.
Serum ROMs (reactive oxygen metabolites) were quantified with d-ROMs test instead of directly measuring free radicals, which have extremely short life-time.

1. Rats were divided into 3 groups according to irradiated dose (0 Gy [control], 2 Gy/fraction, 30 Gy/fr.), and then time course of serum ROMs of each group was quantified using blood sample at certain intervals.
2. In another experiment, rats were divided into 4 groups according to irradiated dose (0 Gy [control], 30 Gy/fr., 50 Gy/fr., 70 Gy/fr.). Serum ROMs and skin reactions were examined at certain intervals. Skin reactions to radiation (inflammation, erosion, ulcer, necrosis, etc.) were graded according to the grading system.

Results:

1. In the analysis of time-course of measured serum ROMs, there was a significant difference among the 3 groups (0 Gy, 2 Gy, 30 Gy), and measured serum ROMs were higher in the 2 Gy group than other groups ($p = 0.018$, repeated-measure ANOVA). At 3 days after irradiation, the serum ROMs of 2 Gy-group were significantly higher than those of the other groups (0 Gy vs. 2 Gy: $p = 0.034$, 2 Gy vs. 30 Gy: $p = 0.028$).
2. There were significant differences among 4 groups in the time-course of skin grade in each group ($p < 0.001$), the skin grades were high in the order of 70 Gy-group, 50 Gy-group, 30 Gy-group (and control-group). In the analysis of time-course of measured serum ROMs, there were significant differences among the 4 groups. Measured serum ROMs of 70 Gy-group and 50 Gy-group were significantly higher than that of 30 Gy-group and control-group. The peak of serum ROMs and appearance of skin toxicity were emerged around the same time.

Conclusion: Increasing the amount of serum ROMs by irradiation has been shown. Moreover, it has been shown that an increase in serum ROMs and occurrence time of the skin reactions to radiation were almost concurrent. Measuring serum ROMs may be useful for predicting radiation damage.

Inhibition of tumor growth and metastasis in mice by pulsed low-dose (<0.5 Gy) X-ray irradiation

M.A. Buldakov[1], I.A. Klimov[1], L.U. Larkovich[2], O.P. Kutenkov[3], N.V. Litviakov[1], M.A. Bolshakov[3], N.V. Cherdyntseva[1], V.V. Rostov[3]. *[1]Cancer Research Institute SB RAMS, Molecular Oncology and Immunology, Tomsk, Russian Federation; [2]Tomsk State University, Department of Physiology, Tomsk, Russian Federation; [3]Institute of High-Current Electronic SB RAS, Physical Electronics Department, Tomsk, Russian Federation*

Background: Main radiotherapy problem of cancer treatment is side-effect as a result of high dose of radiation. All of the modern apparatus for cancer therapy are not enough efficient when low-doses applying. It related with the biological sensitivity and reaction of tumor cells on radiation. Biological effects could be increased by using pulse-modulated radiation. It could allowed to significantly decrease radiation dose with saving antitumor efficacy. The source of low-dose repetitively pulsed X-ray radiation was first developed and created at the Institute of high-current electronics (Russia).
Material and Methods: 'Sinus-150' as a generator of pulse periodic X-ray was applied. A high-voltage pulse had a half-height duration of 4 ns and amplitude of 260 kV. The calculated photon energy spectrum had a maximum at 90 keV, and most of the quantum flux was the 60–200 keV range. Dose per pulse was 0.3 mR, absorbed dose were 0.12; 0.2 and 0.5 Gy for 2-time irradiation (day 6 and 9). Solid-type of Lewis lung carcinoma was prepared by intramuscularly transplantation of 3×10^6 cells into the hind limb of C57BL/6 female mice. Tumor volumes were measured with calipers and a volume calculated (L+W+W/2). The metastases of the lung were counted using a stereoscopic microscope.
Results: Low-dose pulsed X-ray inhibits growth of Lewis lung carcinoma cells at all experimental groups. Irradiation with absorbed dose 0.12 Gy affects 69% of tumor inhibition, 0.2 Gy – 56% and 0.5 Gy up to 46% compare to control group. Inhibition of metastasis growth (by square of colonies) was highest in group 0.5 Gy (72%) and lowest at 0.2 Gy absorbed dose (58%). Applying 0.12 Gy produced 68% decreasing of metastatic colonies square. Same time, index inhibition of metastasis (by number of colonies) was highest both in groups irradiated with 0.12 and 0.5 Gy (84−85%) and only 67% observed in group with absorbed dose 0.2 Gy.
Conclusions: Pulse regime increase antitumor efficacy of low dose X-ray up to 50−70% and antimetastatic action up to 60−80%. Similar effects of non-pulsed X-ray achieved when the absorbed dose exceed 10−20 Gy.
No conflict of interest.

X radiation effects on small cell lung cancer and non-small lung cancer − an in vitro study

F. Mendes[1], R. Silva[2], A.M. Abrantes[2], A.C. Gonçalves[3], M. Laranjo[2], P. César[4], J. Casalta-Lopes[4], P. Soares[4], A.B. Sarmento-Ribeiro[3], M.F. Botelho[2]. *[1]Clinical Analysis and Public Department, Coimbra Health School, Coimbra, Portugal; [2]Biophysics Unit − IBILI, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [3]Applied Molecular Biology and Hematology Group, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [4]Radiotherapy Service, Hospital and University Center of Coimbra, Coimbra, Portugal*

Background: Lung Cancer (LC) is one of the most diagnosed cancers, with higher mortality in men and among women is the fourth most commonly diagnosed and the second with highest mortality rate. This cancer is associated with smoking, which is the cause of about 80% in men and 50% in women worldwide. Radiation therapy may be used in all stages of LC, enabling better the disease site control, as well as the reduction of metastatization, however, tumor radioresistance is often a barrier to therapeutic effectiveness. The aim of this study was to assess the effects of ionizing radiation (X-rays) in three LC cell lines, two of non-small cell lung cancer (NSCLC) (H1299 and A549 cells) and one of small cell lung cancer (SCLC) (H69 cells), namely in cell proliferation and viability.
Materials and Methods: To attain the purposed objectives we submitted the 3 LC cells to X irradiation (0.5, 15 and 30 Gy**)** and used spectrophotometry, clonogenic assays and flow cytometry after 48 hours, to analyze the effect on cell proliferation, viability and death, and also to evaluated the effect on cell cycle.
Results: X-rays induces a decrease in cell proliferation and viability in a dose, time and cell line dependent manner, inducing cell death preferentially by apoptosis. These anti-proliferative and cytotoxic effects are in agreement with the observed cell cycle arrest. However, our results show that A549 and H69 cells are more sensitive to cell death induced by radiation, being the H1299 cells more resistant. These results may be related with differences in the p53 expression or stress oxidative response and could contribute to radiotherapy failure in this type of cancer.
Conclusion: Our preliminary results suggest that X-rays leads to a decrease in LC cells viability inducing cell death mainly by initial apoptosis. However, the sensibility and/or resistance to radiation may be dependent on molecular LC characteristics which could influence the response to radiotherapy and consequently treatment success.
No conflict of interest.

Prognostic value of the nodal ratio and Ki-67 expression in breast cancer patients treated with postmastectomy radiotherapy

T.R. Koo[1], K.Y. Eom[1], E.Y. Kang[2], Y.J. Kim[2], S.W. Kim[2], J.H. Kim[2], J.S. Kim[1], I.A. Kim[2]. *[1]Seoul National University College of Medicine, Department of Radiation Oncology, Seoul, Korea; [2]Seoul National University Bundang Hospital, Breast Care Center, Seongnam, Korea*

Background: This study was performed to evaluate the prognostic or predictive factors in breast cancer patients having postmastectomy radiotherapy (PMRT).
Material and Methods: A total of 113 patients received PMRT between 2003 and 2009: 61 patients underwent preoperative systemic therapy, and 52 patients received postoperative systemic therapy. Baseline molecular parameters were evaluated by immunohistochemical analysis, using biopsy specimens (preoperative systemic therapy group) or surgical specimens (postoperative systemic therapy group).
Results: The median follow up time was 72.3 (34.0–109.4) months for surviving patients. The median number of excised lymph nodes was 22 (1−55), and the median nodal ratio (NR) was 0.19 (range, 0−1). Higher NR had association with worse disease-free survival (DFS; relative risk (RR), 3.589; $p = 0.003$), and overall survival (OS; RR, 3.444; $p = 0.019$). Higher baseline Ki-67 was associated with poor locoregional progression-free survival (LRPFS; RR, 2.944; $p = 0.041$), DFS (RR, 3.274; $p = 0.002$), and OS (RR, 3.133; $p = 0.015$). Patients were classified into three subgroups: low risk (NR $\leqslant$0.2 and baseline Ki-67 $\leqslant$20%; n = 34), intermediate risk (NR >0.2 or baseline Ki-67 >20%; n = 63), and high risk (NR >0.2 and baseline Ki-67 >20%; n = 16). At the time of analysis, all the low risk group patients survived. Comparing the high and the low risk group patients, there was a significant difference in LRPFS ($p = 0.040$) and DFS ($p < 0.001$). Between the intermediate and the low risk group, significant difference was observed in DFS ($p = 0.022$), while not in LRPFS ($p = 0.204$).
Conclusions: In breast cancer patients having PMRT, higher NR and baseline Ki-67 were associated with worse outcomes. A prognostic model using these two factors can discern the patients with poor prognosis regardless the setting of systemic therapy, preoperative or postoperative.
No conflict of interest.

1109 POSTER

Spinal cord tolerance dose in fractionated stereotactic body radiation therapy for spinal metastases − can biologic equivalent dose according to linear quadratic model be applied?

S. Lee[1], K. Sung[1], J. Choi[1], S. Lee[1], K. Lee[1]. *[1]Gilhospital Gachon Medical University, Radiation Oncology, Inchon, South Korea*

Background: Stereotactic body radiation therapy (SBRT) has been increasingly adopted to treat spinal metastases with its merit of rapid dose fall off near spinal cord. The authors hypothesized that irradiated dose to spinal cord is low (<6 Gy) enough to adopt the linear-quadratic (LQ) model in biological effective dose (BED) calculation with modern SBRT technique. This study is to verify this hypothesis, and report clinical outcome in patients with spinal metastases treated by fractionated SBRT.
Material and Methods: Between January 2010 and March 2012, 44 cases of spinal metastases in 33 patients were treated with Novalis Tx® at Gachon University Gil Medical Center. Spinal cord was contoured starting from 6 mm above the superior of the planning target volume(PTV) to 6 mm below the inferior of the PTV. Spinal cord itself was always excluded from PTV. Prescription doses to PTV ranged from 26−44 Gy in 4−6 fractions. The most common prescription dose was 40 Gy in 5 fractions.
Results: The rapid dose fall off from PTV resulted in much decreased dose to spinal cord. The maximum irradiated dose to spinal cord per fraction varied from 2.8 to 5.5 Gy (average, 4.3 Gy) depending on each PTV shape and fraction size. The maximum dose to spinal cord were 12.1–33.2 Gy (20.5 Gy) which were equivalent to 15.0–62.4 Gy2/2 (2 Gy per fraction with α/β ratio of 2, EQD2/2) (32.9 Gy2/2) according to LQ model. The average maximum dose to spinal cord was 54.8% of prescription dose to PTV. The average dose to the 10% spinal cord volume was 14.3 Gy (18.5 Gy2/2). The mean follow-up period was 9.8 months (0.3–37.4 months). No patient developed radiation-induced myelopathy or other neurologic deficit. During follow-up period, radiological local control rate and pain control rate were 80.1% and 90.9%, respectively. There were 3 compression fractures at 2, 3 and 4 months after treatment, respectively.

Conclusions: The dose to spinal cord was low enough to apply LQ model when spinal cord dose was constrained to 55% of prescription. The clinical outcome until now supports its validity without any radiation-induced myelopathy.
No conflict of interest.

1110 POSTER

Stereotactic body radiotherapy for spinal metastases using CyberKnife

H. Park[1], H.J. Kim[1], A.R. Chang[1]. *[1]Soonchunhyan University Hospital, Department of Radiation Oncology and CyberKnife Center, Seoul, Korea*

Background: To evaluate local control and pain and quality of life improvement for spinal metastases, with and without prior irradiation, treated with Stereotactic Body Radiotherapy (SBRT) using CyberKnife.
Material and Methods: Between August 2008 and December 2011, 47 lesions in 30 patients were treated with SBRT for spinal metastases. Twelve lesions (25.5%) were given re-irradiation for recurrence after prior radiotherapy. Patients were treated with a median dose of 27 Gy (range, 18−33 Gy) in a median of three fractions (range, 1−5) by CyberKnife Xsight™ Spine tracking system. The median target volume of 47 spinal metastatic lesions was 28.28 cm^3 (range, 0.9–301.45 cm^3). Radiation was prescribed to the 73−83% isodose line that encompassed at least 90 % of the tumor volume except one re-cyberknife case. SBRT dose was calculated with linear-quadratic model and normalized to a 2-Gy equivalent dose (nBED, α/β=2 Gy for spinal cord, α/β=10 Gy for tumor). Doses to a point within the spinal cord that received the maximum dose (Pmax) were checked. Local failure was defined as progression by imaging and/or clinically or the case that other therapy was given such as surgery or re-irradiation. Pain relief was assessed by Revised Oswestry Disability Index (ODI) Questionnaire before and 3 months after completion of SBRT. The median follow-up period was 6.3 months (range, 1.2–26.4 months).
Results: The local progression-free survival (LPFS) rate at 12 months was 84.7%, and 4 out of 47 (8.5%) tumors have progressed radiologically. Two of 4 treatment failure occurred in re-irradiated tumors, which received 21 Gy in 3 fractions, and their time to local progression was short (3.2 and 3.8 months). The median spinal cord Pmax nBED was 51.1 Gy2/2 (range, 3.4–75.1) in retreatment and 62.6 Gy2/2 (range, 3.2–84.9) in initial treatment. No neuropathy or myelopathy was observed during follow-up periods. No one suffered from spinal compression fracture. All patients experienced pain relief with SBRT. The ODI score dropped significantly from 51.5 to 18.4 on an average.
Conclusions: SBRT using CyberKnife is a safe and effective modality to achieve local control. SBRT offers significant pain relief in spinal metastases and maintenance of quality of life even after previous radiotherapy.
No conflict of interest.

1111 POSTER

Partial breast irradiation margins with two deep-inspiratory breath-hold techniques

F. Bartlett[1], E. Donovan[2], R. Colgan[2], H. McNair[1], K. Carr[1], I. Locke[1], P. Evans[3], J. Haviland[4], J. Yarnold[5], A. Kirby[1]. *[1]Royal Marsden NHS Foundation Trust, Academic Radiotherapy, Sutton, United Kingdom; [2]Royal Marsden NHS Foundation Trust and Institute of Cancer Research, Joint Department of Physics, Sutton, United Kingdom; [3]University of Surrey, Centre for Vision Speech and Signal Processing Faculty of Engineering and Physical Sciences, Guildford, United Kingdom; [4]Institute of Cancer Research, Clinical Trials and Statistics Unit (ICR-CTSU), Sutton, United Kingdom; [5]Royal Marsden NHS Foundation Trust and Institute of Cancer Research, Academic Radiotherapy Unit, Sutton, United Kingdom*

Background: Partial external beam breast irradiation (PBI) is being investigated in a number of ongoing phase III trials (IMPORT LOW, NSABP B-39, RAPID) and it is hoped that this technique will, in selected patients, reduce normal tissue doses whilst maintaining local control rates. Deep-inspiratory breath-hold with the active breathing coordinator™ (ABC_DIBH) significantly reduces the volume of heart irradiated, and voluntary deep-inspiratory breath-hold (v_DIBH) significantly reduces median heart and LAD volumes receiving >50% of the prescription dose. These dosimetric savings are projected to equate to a 10-fold reduction in cardiac deaths. Combining PBI with DIBH would be expected to reduce normal tissue doses yet further, however, data is lacking on suitable PBI margins to account for setup error and organ motion with DIBH. This study aimed to estimate appropriate CTV-PTV margins for using DIBH in combination with PBI.
Material and Methods: The UK HeartSpare Study (Stage IA) compared v_DIBH with ABC_DIBH in terms of positional reproducibility and normal tissue sparing. Patients were randomised to receive one technique for fractions 1−7 and the second technique for fractions 8−15 (40 Gy/15 fractions total). Cone-beam CT (CBCT) images were acquired for 6/15 fractions and matched to planning-CT data. Using clip-based matches, population systematic (Σ) and random errors (σ) were estimated. By applying the margin recipe proposed by van Herk (2.5 Σ + 0.7 σ), appropriate CTV-PTV margins were estimated for both DIBH techniques.
Results: Twenty-three patients were recruited between February and August 2012. Twenty-two patients underwent CBCTs and clip-based matches were possible in 18 (4 patients underwent mastectomy). In all, 126 CBCTs were analysed and uncorrected data was used. Σ for v_DIBH were 2.4 mm (right-left (R-L)), 3.6 (superior-inferior (S-I)), 3.0 mm (anterior-posterior (A-P)) and σ were 2.3 mm (R-L), 2.7 mm (S-I) and 2.7 mm (A-P). Σ for ABC_DIBH were 3.2 mm (R-L), 2.9 (S-I), 2.7 mm (A-P) and σ were 2.3 mm (R-L), 3.4 mm (S-I) and 3.5 mm (A-P). Estimated CTV-PTV margins for v_DIBH were 8 mm (R-L), 11 mm (S-I) and 9 mm (A-P) and for ABC_DIBH were 10 mm (R-L), 10 mm (S-I) and 9 mm (A-P).
Conclusions: Using either DIBH technique, a minimum uniform CTV-PTV margin of 10 mm is suggested for PBI.
No conflict of interest.

Accelerated partial breast irradiation (APBI) with tomotherapy HI-ART on 85 patients treated at San Giovanni-Addolorata Hospital Rome: Preliminary report

U. De Paula[2], R. Muni[1]. *[1]Complesso Ospedaliero San Giovanni-Addolorata, Breast Unit, Rome, Italy; [2]Complesso Ospedaliero San Giovanni-Addolorata, Radiation Oncology, Rome, Italy*

Background: Partial Breast Irradiation (PBI) after conservative breast surgery is a novel radiation technique for the tumor bed area where the most frequent local recurrences occur. The smaller irradiated volume allows a higher dose fractionation with shorter overall treatment time (APBI) and reduced total dose to the breast as well as nearby structures. It was recently reported that exposure of the heart to ionizing radiation during whole breast irradiation (WBRT) increases the subsequent rate of ischemic heart disease and the increase is proportional to the mean dose to the heart.
Material and Methods: At the Breast Unit of our Hospital, since April 2011 we have enrolled 85 women in a phase II study on APBI, using a highly conformal external beam approach with Tomotherapy HI ART linac. Inclusion criteria were: age $\geqslant$50 years, unicentric and unifocal tumors smaller than 3 cm diameter, negative surgical margins without an extensive intraductal component (EIC) and lympho-vascular invasion (LVI). Patients received a total dose 38.5 Gy in 3.85 Gy fractions daily per 2 weeks. The clinical target volume (CTV) was the tumor bed and the close area defined by surgical markers. The primary end points of the study are local control and acute and late toxicity. Secondary end points are survival, cosmetic outcome, QoL and patient compliance.
Results: We present a preliminary report in terms of local control, toxicities, cosmetic outcome, QoL and patient compliance. In all cases the treatment was well tolerated and no acute or subacute side effects (according RTOG scale no toxicity > grade 1). Physical examination at 3−6−12 months and bilateral mammogram, US, MRI at 1 year, were performed on all women after radiotherapy. With a median follow-up of 10.5 months (range 3−22), there were no ipsilateral breast tumors and no loco-regional recurrences. The overall average of the mean doses to the whole heart was 0.9 Gy: much lower than that reported in cases of standard WBRT (>4.9 Gy).
Conclusions: The growing evidence obtained from phase I−II studies supports the use of APBI for selected early stage breast cancer. In our experience patients with tumor-related cautionary features will benefit from careful selection and a highly conformal external beam approach with Tomotherapy HI ART linac can significantly decrease the mean dose to the whole heart by at least 1/5 with respect to WBRT. These preliminary results need to be confirmed by longer-term follow-up data.
No conflict of interest.

1113 POSTER

Application of IMRT technique in treatment of malignant gliomas: Assessment of treatment tolerance

A. Mucha-Malecka[1], K. Kisielewicz[1], K. Malecki[1], A. Sladowska[1], B. Glinski[1]. *[1]Center of Ocology, Head and Neck Oncology, Krakow, Poland*

Background: Assessment of tolerance of combined modality therapy of patients with malignant gliomas irradiated using IMRT technique. We compared dose distribution in IMRT and conformal 3D treatment plans.
Materials and Methods: Between 2009 and 2012 in the Oncology Center in Krakow 50 patients with malignant gliomas received combined modality treatment. Mean age was 53 years (range 24−70 years). All patients were in good performance status (WHO 0−1). There were 38 patients with glioblastoma multiforme and 12 with anaplastic astrycytoma.

38 patients underwent complete resection and 12 partial resection. Patient were irradiated using IMRT technique with a total dose of 60 Gy in 30 fractions. All patients concurrently received temozolamide in the dose of 75 mg/m^2. In all patients we performed additional plans using 3D conformal radiotherapy (3D-CRT) techniques and compared with IMRT plans. The 3D-CRT plans were prepared using 3−4 fields and IMRT plans consisted of 7−8 fields. The primary objective was to treat the planning target volume and to minimize the dose to organs at risk (OAR). Volumetric analysis, target coverage and conformity of prescribed doses were used in plan comparison.
Results: Treatment tolerance was vary good in all patients. Only 12 patients needed steroids during treatment. Adjustment of the dose distribution to the target volume was improved and the critical structures were better spared in the IMRT plans than in 3D-CRT plans. For all patients the mean dose and the maximum dose to OAR were significantly reduced in IMRT plans. With respect to target volume, IMRT technique reduced the maximum dose while increasing the minimum dose, resulting in improved conformity. In same patients with tumors located very close to OAR it was impossible to give 60 Gy for target volume with 3D-CRT technique because of not acceptable doses in OAR.
Conclusions: The IMRT technique combined with concurrent temozolamide is well tolerated and offers significant advantages comparing to 3D-CRT. Application of IMRT allows dose reduction at OAR without compromising target coverage.
No conflict of interest.

1114 POSTER

Feasibility of simultaneous integrated boost by helical tomotherapy in whole-pelvis radiation for prostate cancer: From a standpoint of acute toxicity

S. You[1], C.G. Lee[2]. *[1]Yonsei University Wonju College of Medicine, Radiation Oncology, Wonju, South Korea; [2]Yonsei University College of Medicine, Radiation Oncology, Seoul, South Korea*

Background: The validity of simultaneous integrated boost (SIB) by helical tomotherapy (TOMO) was assessed in terms of acute intestinal and urinary toxicity by comparing with 3-dimensional conformal radiotherapy (3DCRT) in the cases of whole-pelvis radiotherapy (WPRT) for prostate cancer.
Material and Methods: Thirty-eight consecutive patients who underwent curative WPRT were retrospectively reviewed. The pathologic diagnoses for all patients were adenocarcinoma, and median age was 68 years (range, 50−79 years). Twelve patients (31.6%) were treated by TOMO SIB method. A local boost for the prostate circumferential area was added to WPRT sequentially for 3DCRT and concomitantly for TOMO SIB. The median prostate dose was 64.8 Gy (range, 59.4 to 75.6 Gy) for 3DCRT and 66.6 Gy (range, 66.0 to 75.0 Gy) for TOMO SIB. The WPRT dose was 45.0 Gy (range, 41.4 to 45.0) for 3DCRT and 51.0 Gy (range, 50.4 to 54.0 Gy) for TOMO SIB. Acute toxicities were assessed according to RTOG criteria.
Results: The ratio of Grade 2 or higher acute intestinal toxicity was lower in the TOMO SIB group ($p = 0.008$). When intestinal toxicity was analyzed separately for rectum and bowel except rectum (BXR), TOMO SIB showed no significant difference in rectal toxicity ($p = 0.191$) with borderline superiority only in BXR toxicity ($p = 0.047$). The proportion of acute urinary toxicity of Grade 2 or higher was 55.3% (21 patients) with no significant difference in the proportion between the two groups ($p = 0.796$). On dosimetric analysis for the rectum, the mean dose ($p < 0.001$), dose delivered to 80% of the rectum (D80) ($p < 0.001$), V15 Gy ($p = 0.001$), V25 Gy ($p < 0.001$), V40 Gy ($p < 0.001$), and V45 Gy ($p = 0.029$) were higher in 3DCRT. For the bladder, dose delivered to 80% of the bladder (D80) ($p < 0.001$), V25 Gy ($p < 0.001$), V40 Gy ($p < 0.001$), and V45 Gy ($p < 0.001$) were higher in 3DCRT. For BXR, overall dosimetric data did not show significant difference between TOMO SIB and 3DCRT except maximum dose ($p < 0.001$).
Conclusions: Acceptable acute intestinal toxicity results by TOMO SIB should be verified with more detailed anatomic categorization such as rectum and BXR. TOMO SIB could not reduce acute urinary toxicity because of the inevitable high prostatic urethral dose exposure. Current dosimetry system did not reflect acute toxicities directly at the time of full dose WPRT, especially in urinary toxicity assessment. Proper dosimetric guidelines need to be determined in TOMO SIB.
No conflict of interest.

1115 POSTER

Is there a role for IMRT in bilateral breast cancer? Dosimetric comparison of IMRT and standard 3D conformal radiation therapy

A. Seguro Fernandez[1], L. Diaz Gomez[2], A. Ureña Llinares[1], E. Gonzalez Calvo[2], L.J. Ramos Caballero[1], V. Diaz Diaz[2], I. Villanego Beltran[2], M.A. Iborra Oquendo[1], M.C. Salas Buzon[2]. *[1]Hospital Puerta Del Mar, UGC Radiofisica y SPR, Cádiz, Spain; [2]Hospital Puerta Del Mar, Unidad de Gestion Clínica Atención Integral al Cancer, Cádiz, Spain*

Background: The incidence of bilateral breast cancer is increasing due to improved diagnosis test and methods of screening. In addition, recent trials have shown the benefit of regional nodal irradiation. The aim of our study is to demonstrate if there is dosimetric benefit in women diagnosed with bilateral breast cancer that undergoing bilateral breast and regional nodal irradiation comparing standard 3D conformal radiation therapy 3DCRT) versus IMRT technique after breast conserving surgery.
Material and Methods: Volumes were delineated on 6 patients. The 3DCRT technique involved bilateral tangential fields for breast and two oblique, one anterior and one posterior, to the supraclavicular fossa. IMRT technique involved several multifield coplanar inverse planning. The prescription dose was 50 Gy in 25 fractions. Dose- volume histograms, dose homogeneity and dose to OAR were evaluated.
Results: See Table 1.

	V95 (%)		D99-D1 (%)		Mean dose (Gy)		V20 Gy (%)		V30 Gy (%)	
	IMRT	3D	IMRT	3D	IMRT	3D	IMRT	3D	IMRT	3D
Breast	96	96.6	(92.7–107.1)	(92.5–108.2)						
Supra	96.4	97.8	(91.7–106.4)	(91.1–107.5)						
R-Lung					15.8	18.3	25.7	35.3		
L-Lung					15.7	18.3	25.3	35.8		
R+L							25.5	32.5		
Heart					12.3	9.9			2.3	11.3

IMRT was superior to 3DCRT with improvements in reducing the volume of heart and lung in the high dose region (V30 and V20 respectively) and achieving lower mean lung dose (IMRT: 15.8 Gy versus 3DCRT: 18.3 Gy), although for some patients we would find within the limits of tolerance for lungs with both techniques. This can be explained due to larger gaps between inner parts of both breasts.
However, there were no significant improvements covering the planning target volume. Both techniques are adequate with good coverage in the V95 with no differences in PTV dose homogeneity.
Conclusions: IMRT provided reduction in the high dose heart volume without differences for improvements in coverage. We recommend this technique for cases with breasts showing a big concavity which embraces the heart and there is a high probability of superimposed beams on the skin in the gap between inner parts of both breasts.
No conflict of interest.

Impact of 6DOF robotic couch in high volume radiotherapy centre, surveying geometrical, dosimetric, management parameters

S. Chiesa[1], L. Placidi[2], G.C. Mattiucci[1], L. Azario[2], M. Ferro[1], B. Fionda[1], F. Miccichè[1], A.R. Alitto[1], V. Valentini[1], M. Balducci[1]. *[1]Catholic University "A. Gemelli" Hospital, Radiotherapy Oncology Department, Roma, Italy; [2]Catholic University "A. Gemelli" Hospital, Medical Physics Department, Roma, Italy*

Background: To investigate the impact of Protura 6 degree of freedom (DOF) Robotic Patient Positioning System (CIVCO Medical Solution) in high volume radiotherapy centre, surveying geometrical, dosimetric, management and parameters.
Material and Methods: We enrolled patients with pelvic, brain and head and neck cancer treated by 3D-CRT, RapidArc, IMRT and SRT radiotherapy.
A daily CBCT was acquired before dose delivery. The translational and rotational displacements obtained by 3D automatch were applied on the Protura Robotic Couch to obtain a more accurate alignment. The initial treatment plan was copied to a translated CT (TPt) and a rototranslated CT (TPtr) according by MIM 5.5.2 software according to the collected displacements.
Finally the daily dose volume histogram (DVH) was calculated for both the treatment plans and the dosimetric parameters were compared.
Results: From October 2012 to April 2013, we enrolled 23 patients: 8 affected by prostate cancer treated by RapidArc, 11 by brain cancer treated by RapidArc or 3D-CRT or SRT, 3 by H&N cancer, treated with IMRT.

The mean (±SD) interfraction displacement in vertical, lateral, longitudinal direction and the mean (±SD) interfraction rotations (Pitch, Roll and Yaw) were reported in the table 1.
Regarding prostate displacement, 85% of the translational shifts were <5 mm and 6% of the rotation were >2º. H&N translational shift smaller than 5 mm were 94% while 9% of the rotational shift were bigger than 2º. For brain and SBRT brain displacement, the translational shift <5 mm were 94% and 96% respectively, the rotational displacement >2º were 9% in both the group.
No correlation was observed between the magnitude of translational and rotational shifts.
The mean time for all treatment procedures take just one minute more respect to conventional IGRT without displacement correction by 6DOF robotic couch. The applied protocol is anyway no time consuming and it does not required any extension of staff.
Preliminary linear correlations were observed in a selected subgroup of prostate patients, between shifts and dosimetric parameters differences (PTt vs PTtr): yaw rotation with the V20 femoral heads and pitch rotation with V50 rectum.
Conclusion: Our preliminary results underline the feasibility of IGRT workflow with Protura system in daily clinical practice and in standard patient care. The data show the relevance of the translational and rotational errors and their dosimetric effect analysis is ongoing.
No conflict of interest.

Table 1. mean (±SD) interfraction translational and rotational patient setup error

Location	Translational error (mm)			Rotational error (º)		
	x axis (Lat)	y axis (Lng)	z axis (Vrt)	Pitch	Roll	Yaw
Prostate (n = 223)	0.5±3.8	−1.8±4.4	−1.8±4.1	−0.4±1.1	−0.2±1.1	−0.1±0.7
Brain (n = 164)	1.2±2.6	0.5±3.4	−1.2±1.8	−0.2±1.2	0.7±1.2	0.9±1.0
H&N (n = 24)	0.8±2.8	0.5±3.1	0.7±2.8	−0.3±0.7	0.95±1.2	0.1±0.5
SBRT brain (n = 17)	0.7±3.7	−1.2±3.4	−1.2±2.3	−0.5±1.0	−0.1±1.2	0.9±1.3

The role of stereotactic body radiation therapy for hepatocellular carcinoma refractory or unsuitable for other therapeutic modalities

S. Hwang[1], J.S. Kim[1], J.W. Im[1], S.M. Lee[1], S.B. Ahn[1], E.K. Ji[1], C.W. Choi[1], G.M. Yang[1]. *[1]Dongnam Institue of Radiological & Medical Sciences, Gastrointestinal Cancer Center, Busan, South Korea*

Background: The aim of this study was to evaluate safety and efficacy of stereotactic body radiotherapy (SBRT) for the naive or salvage treatment of inoperable hepatocellular carcinoma (HCC) were unsuitable for other therapies.
Methods: The authors reviewed the medical records of 30 patients that were treated by SBRT in our institution when they had HCC without another standard treatment option or complete response of loco-regional therapy between August 2010 and November 2013. All patients SBRT dosages (24−60 Gy from two to five fractions) were administered according to tumor volume. Survival, response, and toxicities were evaluated. Response evaluation was performed according to modified Response Evaluation Criteria for Solid Tumors.
Results: Twenty-five patients had Child-Pugh class A disease, 5 patients had class B disease. Eleven patients had macrovascular invasion (7 portal vein thrombosis, 2 hepatic vein thrombosis, 2 both venous thrombosis), 2 patients had bile duct invasion. The median greatest tumor dimenstion was 32.5 mm (range, 10–170 mm). The median survival was 9.5 months (range 4−28 months) and the median progression-free survival was 6 months (range 1−19 months). Twenty-five patients (83.3%) achieved complete response within 6 months after complete SBRT, 2 patients (6.7%) had a partial response, 3 patients had stable disease, and 1 patients had progression disease. Infield local recurrence was observed in 3 patients, and outfield failure was 13 patients. Three patients (10%) experienced grade 3 gastrointestinal toxicity, 1 patients (3.3%) experienced grade 4 gastric ulcer perforation, and 4 patients (13.3%) experienced pneumonitis.
Conclusions: This study suggests that SBRT can be effective and safe modality that achieves promising rates of local control in inoperable HCC, even with vascular invasion. A further well controlled, large scaled study to reduce gastrointestinal and pulmonary toxicity is recommended.
No conflict of interest.

1118 POSTER

A comparison study utilizing portable bladder scanner versus cone beam computed tomography (CBCT) to measure bladder volumes in post-prostatectomy patients having radiotherapy

K. Ung[1], R. White[1], M. Mathlum[1], V. Mak[2], R. Lynch[1]. *[1]Andrew Love Cancer Centre, Radiation Oncology, Geelong Victoria, Australia; [2]Deakin University, School of Information Technology, Victoria, Australia*

Background: In post-prostatectomy radiotherapy to the prostatic bed, consistent bladder volume is essential to minimize the amount of small bowel within the radiotherapy fields and to maintain the position of the treatment target volume. We assessed the differences between bladder volume readings from a portable bladder scanner (BS-V) and those obtained from planning CT (CT-V) or cone-beam CTs (CBCT-V). Inter-fraction bladder volume variation was also determined.
Material and Methods: BS-Vs were recorded in the treatment position pre- and post-planning CT or CBCT. The percentage difference between the readings using the two imaging modalities, standard deviations, and 95% confidence intervals were determined. Data was analyzed for the whole patient cohort and separately for the older BladderScan™ BVI3000 and newer BVI9400 model. Inter-fraction bladder volume variation was evaluated by determining the percentage differences between the CT-V with CBCT-V. Treatment duration incorporating the BS and CBCTs were determined.
Results: Fourteen patients were enrolled into this study, producing 133 datasets for analysis. BS-Vs were taken using the BVI9400 in four patients (43 datasets). The mean BS-V and CT-V or CBCT-V was 253.2 mls and 199 cm^3, respectively. The mean percentage difference between the two modalities was 19.7% (SD 42.2; 95% CI 12.4 to 26.9). BVI9400 model (n = 43) produced more consistent readings with a mean percentage difference of −6.2% (SD 27.8; 95% CI −14.7 to −2.4%). The mean percentage difference between CT-V and CBCT-V was 31.3% (range −48%- 199.4%). Treatment duration from time of first BS reading to CBCT was on average 12 minutes (range 6−27).
Conclusions: The BS produces bladder volume readings of an average of 19.7% difference from those CT-V or CBCT-V and can potentially be used to screen for large inter-fraction bladder volume variations in radiotherapy to prostatic bed. The observed inter-fraction bladder volume variation suggests the need to improve bladder consistency. Incorporating the BS into practice is feasible.

Verification of mechanical accuracy of new irradiation technique with simultaneous gantry and ring rotation

S. Sato[1], Y. Miyabe[1], K. Takahashi[2], M. Nakamura[1], Y. Ishihara[1], M. Yamada[1], S. Kaneko[1], T. Mizowaki[1], H. Monzen[1], M. Hiraoka[1]. *[1]Kyoto University Graduate School of Medicine, Department of Radiation Oncology and Image-Applied Therapy, Kyoto, Japan; [2]Mitsubishi Heavy Industries LTD., Advanced Mechanical Systems Department, Hiroshima, Japan*

Background: Vero4DRT (MHI-TM2000) is a unique image-guided radiotherapy system consisting of an O-ring gantry that is designed to rotate ±185º around the patient (gantry rotation) and ±60º around its vertical axis (ring rotation). This system can realize a new irradiation technique called Dynamic WaveArc (DWA) which employs continuous and simultaneous gantry and ring motion during dose delivery. The purpose of this study is to verify the mechanical accuracy of DWA irradiation.
Material and Methods: (1) Verification of irradiation accuracy during ring rotation. Beam outputs during ring rotation (rotation range were −30º − +10º and −10º − +30º for clockwise (CW) and counter clockwise (CCW) directions) were measured using a farmer type ionization chamber and cylindrical phantom, and compared to the output at static irradiation. At the same time, the mechanical accuracy was assessed by analyzing linac log files. The ring position error (E_R) and accumulated MU error (E_{MU}) at each time were evaluated as the differences between planned and actual values recorded in the log files.
(2) Mechanical verification of DWA irradiation by log file analysis. Some test pattern irradiations with different ring rotational range (±5º, 10º, 15º, 30º), direction (CW, CCW), and speed (1.0, 2.0, 3.0 deg/s) were examined. In all test plan, gantry were rotated from 270º to 90º (CW direction). The E_R, E_{MU}, and gantry position error (E_G) at each time were evaluated by the log files.
Results: (1) Beam output variation with ring rotation was less than 0.2% on the basis of the output value with static irradiation. E_R and E_{MU} were less than 0.03º, 1.1 MU, respectively.
(2) E_R, E_{MU}, and E_G were less than 0.11º,3.4 MU, and 0.13º, respectively. Although each mechanical motion were stopped momentarily (for about 0.5

sec) in the turning point of gantry and ring speed, the beam irradiation was continued with low dose rate (nearly 100 MU/min) in the actual treatment machine. Therefore, maximum E_{MU} were occurred in the suspended time. These differences were compensated in about 2 seconds after that time. Except these time, E_{MU} were less than 1.5 MU.
Conclusions: As an initial experiment, we have demonstrated that Vero4DRT has sufficient mechanical accuracy and beam output constancy during gantry and ring rotation. A more quantitative evaluation of irradiation accuracy, treatment planning and dose distribution are needed to apply this new irradiation technique in clinical settings.

Development and evaluation of a system based on 3D printer to create IMRT compensator blocks

S.R. Avelino[1], L.F. Oliveira e Silva[1], C.J. Miosso[2]. [1]*Hospital Universitário de Brasília, Radiotherapy, Brasilia, Brazil;* [2]*Universidade de Brasília, Biomedical Engineering, Brasilia, Brazil*

Background: In this study a system based on 3D printer was developed and evaluated to manufacture IMRT compensator blocks from a fluency map. This alternative method doesn't use milling machines.
Material and Methods: A fluency map of a prostate case planned with Jaws-Only IMRT (Prowess Panther®, v.5.01) was selected from our clinical database. An algorithm was developed to convert an image file into a STL file (used by 3D printers). The gray levels of the intensity map were converted into a STL file representing a mold thicknesses. The mold was printed by a 3D printer (Z Corp®, model 310). It was made with a thermal resistant powder. Then it was filled with *cerrobend* alloy. After solidification time, the mold was removed and the final IMRT block was achieved. The algorithm considered previously data acquired about linear attenuation coefficient and beam hardening factor of the *cerrobend* alloy. In order to evaluate the block, dosimetric tests were performed in 3 planes of a phantom (depths: 2.5, 6.5 and 15.5 cm) using a matrix with 729 ionization chambers (PTW®, 2D Array). Phantom/detector CTs were used to generate reference dose distributions of the selected beam (intensity map) predicted by a Jaws-Only IMRT algorithm. The gamma-index function (3%, 3 mm) was used for dose distribution evaluation. The Monitor Units (MU) were defined carrying out measurements of absolute dose using a thimble ionization chamber in a homogeneous dose region. It was used the MU that provided a dose closer than that predicted by TPS. Further, absolute doses were measured in 7 depths for 2 regions of the IMRT block. The block thicknesses of these regions were 0 and 1.5 cm.
Results: The mold printing and the manufacturing of the IMRT block took 4 h. The MU used was 10% less than that reported by the same Jaws-Only IMRT plan. The MU used was 60 (dose deviation of 0.66%). The measurements using a matrix of detectors provided 81, 99 and 91% of the assessed points approved for the depths of 2.5, 6.5 and 15.5 cm respectively. The absolute doses measurements presented dose deviations up to 1.8% for all depths and both regions.
Conclusions: The 3D printers can be effectively used to manufacture IMRT compensator blocks. The advantages to this approach are: it can be fully conducted inside a radiotherapy facility; 3D printers are easier to operate. The results suggest lower cost and production time. Further investigations are in progress to permit the clinical use.

Dosimetric relevance in prostate cancer of 6 degree of freedom patient correction with Protura Robotic Couch System

L. Placidi[1], S. Chiesa[2], L. Azario[1], G.C. Mattiucci[2], G.R. D'Agostino[2], G. Mantini[2], V. Frascino[2], A.R. Alitto[2], V. Valentini[2], M. Balducci[2]. [1]*Catholic University "A. Gemelli" Hospital, Medical Physics Department, Roma, Italy;* [2]*Catholic University "A. Gemelli" Hospital, Radiotherapy Oncology Department, Roma, Italy*

Background: To investigate the magnitude and the dosimetric relevance of translational and rotational errors on IGRT prostate RapidArc using Protura 6 degree of freedom (DOF) Robotic Patient Positioning System (CIVCO Medical Solution).
Material and Methods: We enrolled patients with cT3aN0M0 low risk for nodal involvement prostate cancer, treated with RapidArc simultaneous integrated boost. PTV2 was obtained adding margins of 0.7 cm to seminal vesicle base (CTV2), while PTV1 adding to prostate (CTV1) a margin of 0.7 cm in all directions and 1.2 cm as lower margin. A daily CBCT was acquired before dose delivery. The translational and rotational displacements obtained by 3D automatch were applied on the Protura Robotic Couch to obtain a more accurate alignment. The initial treatment plan was copied to a translated CT (TPt) and a rototranslated CT (TPtr) according by MIM 5.5.2 software according to the collected displacements. Finally the daily dose volume histogram (DVH) was calculated for both the treatment plans and the dosimetric parameters were compared.
Results: From October 2012 to April 2013, we enrolled 8 patients with a median age of 76 yrs (range 72−77). We performed 223 CBCT studies, 223 TPt and 223 TPtr. The mean (±SD) interfraction displacement in vertical, lateral and longitudinal direction was-1.8±4.1 mm, 0.5±3.8 mm and −1.8±4.4 mm respectively, with 85% of the shifts <5 mm. The mean (±SD) interfraction rotations were: Pitch= −0.4±1.1º, Roll = −0.2±1.1º and Yaw = −0.1±0.7º, with 6% of the rotations >2º. No correlation was observed between the magnitude of translational and rotational shifts. Dosimetric evaluation is ongoing and nowadays it was carried out on 4/8 patients We observed two linear correlations between yaw rotation and the V20 femoral heads and pitch rotation with V50 rectum. Regarding prostate target coverage, V95% and V105%, no significant difference between the TPt and TPtr was observed.
Conclusion: Our preliminary data show the relevance of rotational shift in prostate patients. The preliminary dosimetric data underlines that the used PTV margins are such as to compensate all translational and rotational shifts detected before treatment. Dosimetric effects evaluation of PTV reduction margins, useful to promote dose escalation studies, is ongoing.

1122 POSTER

Stereotactic Body Radiotherapy (SBRT): Are we improving? Trends from a single Brazilian institution

F.Y. Moraes[1], L.A. Bonifacio[1], G.N. Marta[1], S.A. Hanna[1], H.A. Carvalho[1], F.F. Arruda[1], G.S.M. Siqueria[1], S.F.M. Correa[1], J.L.F. Silva[1], C.E.C.V. Abreu[1]. [1]*Sirio Libanes Hospital, Radiation Oncology, São Paulo, Brazil*

Background: The possibility of delivering radiation in a single high dose or with short radiation courses of high doses/fraction is very attractive. Though, the use of SBRT for curative or palliative purposes is becoming very popular besides the fact that the technology needed for such treatment is not yet worldwide available. The objective of this study was to make a profile of the indications of SBRT in the institution.
Materials and Methods: Data of patients' registers from May/2007 (first treated patient) to February/2013 were retrospectively collected. We extracted data on patients' characteristics (demographics), treatment sites, data processing, fractionation, dose and technique. Two independent researchers performed data collection.
Results: 74 patients, 47 (63.5%) men, with histologically proven primary or metastatic tumors (clinical/radiographic or by biopsy) were treated. The median age was 73 years (31−96 years). Ten (13.5%) patients were treated from 2007 to 2009 (period 1), and 64 (86.5%) from 2010 to 2013 (period 2). The most usual treated site was lung, comprising 51/74 (70%) lesions (39 primary and 12 metastatic tumors). In period 1, all 10 treated patients had primary lung tumors. In period 2, there was still a predominance of lung tumors 41/64 (64.1%). In addition, 17 (26.5%) bone tumors (4 primary and 13 metastatic), 5 (7.9%) liver metastases and 1 (1.5%) primary prostate cancer was also treated. One to five fractions from 7 Gy to 24 Gy with total doses ranging from 12 to 60 Gy were delivered. Single doses were mostly used for bone tumors, and lung and hepatic lesions were treated with 3 or 5 fractions. Prescription ranged from 78 to 85% isodose. The equivalent dose to 2 Gy fractions (EQD2) was calculated for evaluation of the different fractionation schemes. Three-dimensional (3D) conformal technique was the most widely used (81%), followed by volumetric arc therapy (VMAT) (15%) and intensity modulated radiotherapy (IMRT) (4%). In period 1, only 3D techniques was used, and in period 2, 78.2% of patients were treated with 3D, 15.6% with DA, and 6.2% with IMRT. In all cases, prescription and plan analysis was based on already published protocols (RTOG and others) on the respective disease site, and 74% of the plans respected absolutely all the required dosimetric criteria of the protocols; the others were approved with minor deviations.
Conclusion: In this private institution, there has been an increase in the use of SBRT along the years. A progressive indication for different tumor sites, as well as an evolution of the treatment technique was observed. All treatments were based in already published and well-established protocols.
No conflict of interest.

1123 POSTER

Is what you move what you get? A phantom study of surrounding tissue importance in delineation of moving targets

M.N. Duma[1], K.J. Borm[1], J. Berndt[1], J.J. Wilkens[1], M. Oechsner[1].
[1]*Klinikum rechts der Isar, Department of Radiation Oncology, München, Germany*

Purpose: To evaluate the relevance of surrounding tissues for contouring of moving targets in tissue specific phantoms.
Material and Methods: The xy-table (SunNuclear®) was combined with a self-developed equipment. This equipment enabled programable motion in 3 dimensions of a 3.4l PMMA box. A water filled table tennis ball simulated the tumor. The ball was placed centrally in PMMA box, surrounded by three different materials: corkboards to simulate lung tissue (lung phantom − LunPh), animal fat to simulate fatty soft tissue (fatty tissue phantom − FatPh) and water with contrast medium with hounsfield units (HU) adapted to simulate liver tissue (liver phantom − LivPh). Slow planning 3D-CT (Somatom Emotion, Siemens Medical Solutions®) were aquired with and without phantom movements (period 3s). Linear motions in y direction (cranio caudal) with amplitudes of 5 and 10 mm, respectively and complex motions with simultaneous amplitudes in x, y and z directions (2.5, 10, 2.5 mm, period 3 s) were performed. Additionally, patients' tumour trajectory were reconstructed using the center of mass motion of GTVs delineated in the 10 phases of 4D-CT scans. These movements were simulated with each phantom. The ball volume was contoured using the Eclipse 10 planning system (Varian Medical systems®) in optimal window settings The contoured ball volumes were compared with the mathematically calculated ball volumes.
Results: The relative differences between contoured and calculated volumes are presented in the table. The volume of the ball without movement was overestimated in LunPh and FatPh and underestimated in the LivPh. As compared to the real volume, the volume of the moving target was underestimated in all phantoms. Further, significant differences were found between the three phantoms.

Table: Relative difference between contoured and calculated ball volume

Motion amplitude	Relative difference [%]		
	LunPh	FatPh	LivPh
0	111.9	112.4	96.4
y 5 mm	94.4	97.4	69.6
y 10 mm	91.2	90.8	70.3
x 2.5 mm, y 10 mm, z 2.5 mm	89.7	91.5	82.7
Patients (average ± standard deviation)	93.7±7.0	91.9±2.8	71.5±5.4

Conclusion: Our results showed relevant differences between real target volumes and contoured target volumes if the target is surrounded by different tissues. This could have an impact on the gross tumor volume and internal target volume delineation, and needs to be critically considered when delineating target volumes at different anatomical sites.
No conflict of interest.

Quantitative study of 18F-fluorodeoxyglucose and 18F-fluorothymidine PET characteristics in esophageal squamous cell carcinoma staging

C. Ma[1]. [1]*Shandong Tumour Hospital, Radiation Oncology Physics, Jinan Shandong, China*

Objective: PET has become the key investigative tool with its expanding role in esophageal carcinoma diagnosis, staging and assessing or predicting response to therapy. Until recently, early detection and surgery are the hope of cure for patient with esophageal carcinoma. In addition, precise pretherapeutic staging is crucial in choosing best available therapy for esophageal carcinoma patient. The aim of this study was to quantitatively evaluate the value of diagnostic information provided by both ^{18}F-FDG and ^{18}F-FLT PET and quantitatively investigated whether ^{18}F-FLT PET had a better performance compared with ^{18}F-FDG PET in esophageal squamous cell carcinoma (ESCC) staging and delineation.
Materials and Methods: 26 patients with newly diagnosed ESCC and underwent pretreatment ^{18}F-FDG and ^{18}F-FLT PET were included in this study. The indices such as the standardized uptake value (SUV), gross tumor length and extracted texture parameters between ^{18}F-FDG and ^{18}F-FLT PET were compared, respectively. Moreover, the indices' relationship between ^{18}F-FDG and ^{18}F-FLT PET mentioned above, were analyzed using Spearman's correlation coefficient and Paired T-test. Subsequently all patients received esophagectomy and the extracted PET indices' capability in ESCC pathological staging were assessed by Kruskal-Wallis test and Mann-Whitney test. In addition, tumor delineation length on ^{18}F-FDG (SUV threshold 2.5) and ^{18}F-FLT (SUV threshold 1.4) PET were validated by pathologic gross tumor length.
Results: ^{18}F-FDG highly correlated with ^{18}F-FLT possessing a high correlation coefficient value r approximate 0.8 and $p < 0.001$ in SUVmax or SUVmean. ^{18}F-FDG uptake was significantly higher than ^{18}F-FLT with respect to average SUVmax(^{18}F-FDG: 11.48, ^{18}F-FLT: 6.07) or average SUVmean (^{18}F-FDG: 6.09, ^{18}F-FLT: 3.80), with Paired T-test result $p < 0.001$. In terms of texture parameters' relationship Entropy and Correlation (two derived texture parameters) showed statistically significant difference. Both of ^{18}F-FDG and ^{18}F-FLT PET SUV, some of texture parameters,gross tumor length and shape feature showed statistically significant difference with respect to their feasibility in ESCC staging. The mean±standard deviation pathologic longitudinal tumor length was 5.52±2.56 cm and delineation length for ^{18}F-FDG and ^{18}F-FLT were 5.60±2.32 cm and 5.49±2.43 cm, respectively.
Conclusion: The ^{18}F-FDG and ^{18}F-FLT PET scans have their own advantages in ESCC staging and tumors were well identified as the nonphysiologic distribution of radiotracers intensity typically higher than normal tissues on either PET scans. Delineation on the two types of PET with proper threshold can both provide accuracy estimation of pathologic tumor length. Those different indices extracted from PET scans can be potentially employed to differentiate AJCC and TNM in ESCC stage.
No conflict of interest.

1125 POSTER

Comparative study of the position and/or volume of diaphragm dome, lung and heart between quiet end-inspiration and end-expiration three dimensional CT assisted with active breathing control and corresponding phases in four dimensional CT

H. Qi[1], J. Li[2], Q.I.A.N. Shao[2], M.I.N. Xu[2], T. Fan[2], Z. Ma[2]. [1]*Shandong Cancer Hospital, Jinan Shandong, China;* [2]*Shandong Cancer Hospital, Department of Radiation Oncology, Jinan Shandong, China*

Background: To compare the position and/or volume of diaphragm dome, lung and heart between quiet end-inspiration and end-expiration three dimensional CT (3DCT) assisted with active breathing control (ABC) and the corresponding phases in four dimensional CT (4DCT).
Material and Methods: Eighteen patients with peripheral lung cancer underwent 4DCT simulation scan during free breathing and 3D-CT simulation scans in end-inspiratory hold (CT_{EIH}) and end-expiratory hold (CT_{EEH}) in succession. The 4DCT images from each respiratory cycle were sorted into 10 phases: the 0% phase was defined as end-inspiratory phase (CT_0), while the 50% phase was defined as end-expiratory phase (CT_{50}). The left and right lungs, heart and both diaphragm domes were delineated separately on CT_0, CT_{50}, CT_{EIH} and CT_{EEH} images.
Results: In the cranio-caudal direction, between CT_{EIH} and CT_{EEH}, CT_0 and CT_{50}, the mean displacement differences of both diaphragm domes were not larger than 1.5 mm and were not statistically significant (P = 0.228, 0.106). Between CT_{EIH} and CT_0, CT_{EEH} and CT_{50}, the centroid position differences of two lungs and heart were found all statistically significant (P = 0.001–0.047) in the cranio-caudal direction, and not statistically significant (P = 0.128–0.798) in the radial directions. The volumes of two lungs were both larger in CT_{EIH} and CT_{EEH} than in CT_0 and CT_{50}, and the differences between them were found both statistically significant (P = 0.000–0.041); while the volume of heart was larger in CT_0 and CT_{50} than in CT_{EIH} and CT_{EEH}, but the differences between them were found both not statistically significant (P = 0.054, 0.085).
Conclusions: Compared with quiet end-inspiration and end-expiration 3DCT assisted with ABC, in the corresponding limited phases of 4DCT, the centroid positions of lungs and heart had obvious hysteresis in the cranio-caudal direction, and the volumes of lungs were obviously larger in the former than in the latter, while the volumes of heart were smaller in the former than in the latter. From the point of view to protect lung and heart, when other conditions were same, gated radiotherapy in quiet end inspiration was better basing on ABC than basing on 4DCT.

1126 POSTER

Impact of anatomic changes and treatment parameters on simulated dose to lung tumors in a patient cohort with sequential 4D-CTs

R. Brevet[1], D. Richter[1], C. Graeff[1], C. Bert[2], M. Durante[1]. *[1]GSI, Biophysics, Darmstadt, Germany; [2]Universitätsklinikum, Medizinische Strahlenphysik, Erlangen, Germany*

Background: The physical and biological properties of scanned carbon ion beam therapy potentially permit more conformal irradiation than photons. Range sensitivity and interplay renders treatment of moving tumors complex. Purpose of this study is to investigate adaptive treatment of lung cancer in a sequential 4DCT planning study.
Materials and Methods: For 7 NSCLC lung tumor patients from MDACC (The University of Texas MD Anderson Cancer Center), a total of 55 weekly 4DCT datasets were available. Reference phases of each subsequent CT were registered rigidly (based on bony anatomy or the complete CT) to mimic patient setup. Motion phases of each 4DCT were registered non-rigidly. Gating plans were simulated using the GSI treatment planning system TRiP4D, including 4D-dose reconstructions. For each calculation, the target point was set as the center of the CTV in reference phase. The impact on dose coverage (V95) of variations in focus size and length of the gating window was analyzed. Three beam foci (6, 10 and 15 mm) and three gating windows (11.9%, 30% and 50% of the amplitude) were investigated. To assess the need of margins, these initial simulations were performed without a CTV-PTV extension.
Results: The largest effects on dose coverage were caused by anatomic variations such as tumor shrinkage but also different patient positioning with deformed soft tissue. For three patients, such variations reduced V95 below 75% for all studied parameter combinations.
A larger beam focus and a shorter gating window increased the homogeneity of the dose, but not sufficiently to compensate the anatomic changes. The worst configuration of longest gating window and smaller focus yielded a mean V95 value of 79.7% (from 51.3% to 96.3%) while the best configuration of shortest gating window and largest focus yielded V95 = 91.2% (71.0% to 99.7%).
Conclusions: Dose coverage deteriorated due to anatomic changes as well as patient setup. Gating window and beam focus size could partially recover 4D-dose coverage, but adaptive treatment schemes appear necessary. CTV-PTV margins will most likely cover patient setup uncertainties and will be included as a next step.
No conflict of interest.

1127 POSTER

External beam radiotherapy target volumes for cervical cancer: A multi-institutional study assessing contouring variability on magnetic resonance imaging (MRI) and computer tomography (CT)

J. Veera[1], S.K. Vinod[1], L.C. Holloway[2], N. Borok[3], M. Dimigen[3], E. Pogson[4], K. Lim[5]. *[1]Ingham Institute, Collaboration for Cancer Outcomes Research and Evaluation (CCORE), Sydney NSW, Australia; [2]Liverpool Hospital, Cancer Therapy Centre, Sydney NSW, Australia; [3]Liverpool Hospital, Radiology Department, Sydney NSW, Australia; [4]University of Wollongong, Medical physics, Wollongong NSW, Australia; [5]Liverpool Hospital, Radiation Oncology Department, Sydney NSW, Australia*

Background: Accurate delineation of target volumes for external beam radiotherapy is a crucial step in radiation treatment, but can be associated with considerable uncertainty and variability. The aim of this study was to compare target volume delineation on MRI vs CT and to compare Simultaneous Truth and Performance Level Estimation (STAPLE) generated contours with expert clinician contours.
Material and Methods: Nine expert clinicians from five tertiary centres across Australia participated. Each clinician independently contoured target volumes on a CT and a T2 weighted 3T MRI dataset for a cervical cancer patient. Gross tumour volume (GTV), uterus, cervix, vagina and parametrium were each delineated using RTOG consensus guidelines and the individual volumes were combined into a clinical target volume 'CTV'. To evaluate inter-observer agreement the kappa co-efficient was calculated for each structure, and the dice similarity co-efficient (DSC) was used to compare individual clinician contours for each structure to both a clinician determined consensus contour and the STAPLE contour.
Results: The GTV_{staple} volume for MRI was 2.5 times smaller than the CT volume (17.1 cm^3 vs. 43.1 cm^3) and there was less inter-observer variation when contouring the GTV on MRI compared to CT, with a kappa coefficient (corrected for chance) of 0.70 for MRI and 0.52 for CT. The MRI contours for the uterus and CTV demonstrated substantial agreement between clinicians with kappa coefficients 0.64 and 0.68 respectively. The remaining contours completed on MRI showed moderate agreement with kappa coefficient of 0.41 for cervix, 0.43 for vagina and 0.56 for parametrium. The cervix contours on CT only showed slight agreement with a kappa coefficient of 0.31. The remaining structures on CT (uterus, vagina, parametrium and GTV) demonstrated moderate or substantial agreement. The MRI GTV_{staple} contour demonstrated a high concordance with the clinician determined consensus contour with a DSC of 0.77. The MRI $uterus_{staple}$, $parametrium_{staple}$ and CTV_{staple} contours all exhibited a good concordance with the clinician determined consensus contour with DSCs of 0.74, 0.69 and 0.80 respectively.
Conclusions: GTV delineation on MRI resulted in a smaller GTV and reduced inter-observer variability compared to CT. STAPLE contours on MRI demonstrated a high level of agreement with expert clinician consensus contours for GTV, uterus, parametrium and CTV.

Dosimetric comparison of four different irradiation techniques to treat mediastinum in Hodgkin Disease (HD) and lung cancer (LC) patients (pt): Three dimensional conformal radiation therapy (3D-CRT), intensity modulated radiation therapy (IMRT), volumetric modulated arc therapy (VMAT) and helical tomotherapy (HT)

S. Magrini[1], M. Buglione[1], S. Pedretti[1], A. Polonini[1], P. Borghetti[1], L. Triggiani[1], L. Donadoni[1], F. Barbera[1], M. Maddalo[1], L. Spiazzi[2]. *[1]Brescia University, University Department of Radiation Oncology, Brescia, Italy; [2]Spedali Civili, Medical Physics, Brescia, Italy*

Aims: To compare PTV coverage and OAR dose distribution in the treatment of mediastinum in HD and LC pt, treated with 30 Gy and 50 Gy using 3DCRT, IMRT, VMAT, HT.
Methods and Materials: 10 HD and 9 LC pt were treated with 3D-CRT. 2 experimental plans were calculated for each technique and patient: 1 optimized for PTV coverage, 1 for lung dose reduction. IMRT static fields(f) plans were evaluated with a 5 and 8f combination. In LC pt, for HT plans optimized for the reduction of lung doses, 2 plans were calculated (collimation width 1 cm /2.5 cm); 9 and 10 plans were calculated for each pt. Optimal PTV coverage required D95 and D98 >95% of prescribed dose; lungs constraints were V20 <20% and V5<50%. PTV and OAR doses were directly compared. The best experimental plan was compared with that used to treat the pt. Differences were considered significant if $p < 0.01$ (T-student).
Results: Results are presented in the tables. LC: a statistical direct correlation was shown between 'PTV length/lung length' ratio (PLLLR) and lungs V5 for 3D-CRT, IMRT with 8f and VMAT plans and an inverse correlation between PLLLR and PTV D95 for HT plans.
Conclusion: For HD the dose distributions obtained with HT seem to be better than with the other techniques, with a high target coverage and a reduction of high doses to lungs and spinal cord. For LC IMRT with 8f is the best technique to obtain the goals of the optimization. VMAT can be used when the PLLLR is low. HT doesn't allow to maintain an acceptable PTV coverage if the ratio is high. Clinical correlates needed to evaluate impact on practice of the findings.
No conflict of interest.

Study of usefulness of megavoltage computed tomography for electron beam treatment planning for conjunctival MALT − lymphoma

J. Lee[1], J.H. Kim[1], R.H. Park[1], J.W. Yoon[1], J.H. Cho[1], J.I. Lee[1]. [1]*Yonsei University Health System, Radiation Oncology, Seoul, South Korea*

Background: The Kilo-voltage Computed Tomography (KVCT) has been used for electron beam treatment planning for conjunctival MALT − lymphoma; however, its lens shielding generates metal artifact, leading to inaccurate treatment planning. This study assessed the usefulness of treatment planning using the Mega-voltage Computed Tomography (MVCT) images without metal artifact.
Material and Methods: The Image Value-to-Density Table (IVDT) of KVCT and the IVDT of MVCT was calculated by using the Cheese Phantom® and then the density values calculated from the above process was input in the Pinnacle®. As establishing the treatment planning and measuring the projection result with the EBT3 Film® using the Elekta Infinity™, the $10\times10\,cm^2$ electron cone with 6-MeV and 9-MeV electron beam was used at 300 MU and the Source-Skin Distance (SSD) was set to 100 cm.
First, the treatment planning of KVCT was matched to that of MVCT using the IVDT to measure the consistency.
Second, the error of treatment planning of KVCT caused by metal artifact (generated by lens shielding) was compared with that of MVCT caused under the same conditions.
Third, the treatment planning with the above settings was executed for the MVCT image (with lens shielding) matched using the IVDT and the electron beam was projected to the EBT3 Film® (with lens shielding) with the same conditions. The acquired MVCT result and EBT3 Film® result were analyzed using Axial PDD, D_{max} beam profile, and R_{50} beam profile.
Results: First, for the γ − index between the KVCT and the MVCT matched using IVDT, the γ value has not exceeded 1 at 3%/3 mm and 2%/2 mm.
Second, the radiation difference between the KVCT and the MVCT with the lens shielding was calculated as about 74%.
And third, after analyzing the level of radiation projected to the MVCT image for treatment planning and to the EBT3 film, the γ value has not exceeded 1 at 3%/3 mm for 6-MeV and 9-MeV. However, for 6-MeV at 2%/2 mm, 6.34% of axial PDD and beam profiles of D_{max} and R_{50} were 3.48% and 4.21%, respectively, and for 9-MeV at 2%/2 mm, 10.68% of axial PDD and beam profiles of D_{max} and R_{50} were 3.85% and 6.23%, respectively.
Conclusion: This study assessed the error rate of treatment planning, caused by metal artifact, between the KVCT and the MVCT.
As shown in the study, metal artifact was generated at the MVCT, too. However, as comparing to the result of EBT3 Film®, the error rate was lower than 3%, within the clinically-allowable range.
The result showed that the MVCT could get images which allowed establishment of an accurate treatment planning without being affected by metal artifact. It will be a new solution to improve the weak point of KVCT, inaccurate electron beam treatment planning for conjunctival MALT − lymphoma.
No conflict of interest.

Evaluation of dose distribution using positioning CT in IMRT for prostate cancer

A. Terahara[1], N. Saotome[1], K. Miyamoto[1]. [1]*Toho University Medical Center Omori Hospital, Radiology, Tokyo, Japan*

Background: In room cone beam CT (CBCT) is a popular modality for reducing setup errors nowadays, however, CT numbers of CBCT is not reliable enough for the dose calculation by treatment planning system (TPS). We analyzed dose distribution using conventional diagnostic CT image that was obtained for checking the patient position just before the treatment.
Material and Methods: The dose distributions for 8 patients with prostate cancer were evaluated. IMRT was done by step and shoot technique with 7 fields. The CTV included prostate and proximal seminal vesicle, and the PTV margin was 5 to 7 mm in the posterior direction, and 10 mm in other directions. The prescribed dose was 72 Gy at D50 of the PTV. We daily used Linac graphy to check setup errors and also used CT image that was acquired in the separate CT room weekly. Patients were transported to the treatment room in the fixation device after CT scanning and underwent radiotherapy. After the CT image dataset for verifying the isocenter was transferred to TPS (Xio), the target volumes and organs at risk (OARs) were contoured by the same physician in the same manner as done on planning CT image. The IMRT plan was imported as a QA plan, and dose calculation and evaluation of dose for contours were performed.
Results: The dose evaluation could be done with total of 41 CT datasets, 1 to 8 (median of 6) times for each patient. For the CTV, the mean EUD was 2.00 Gy, ranged from 1.97 to 2.03 Gy and D98 was more than 1.92 Gy except for one CT. For the PTV, the mean EUD was 1.93 Gy (range, 1.31–2.01 Gy) and D98 was more than 1.9 Gy only in two CT, which implied the presence of low dose area in the PTV. Regarding OARs, the dose constraint was not satisfied only in one CT for the rectum because of large rectal volume, and in four for the bladder by reason of small bladder volume.
Conclusions: It was verified that the dose for the CTV was sufficient mostly without exceeding dose constraint for the OARs and the PTV margin used in this study was considered to be appropriate.
No conflict of interest.

1131 POSTER

First experience with rotational IMRT with a Siemens accelerator ARTISTE®

U. Spahn[1], F.J. Prott[1]. [1]*RNS Gemeinschaftspraxis, Strahlentherapie, Wiesbaden, Germany*

Introduction: In our departement, since February 2012 a Siemens accelerator ARTISTE ® is in clinical use. The dose rate with flattened beam is 300MU/min for 6MV photons respectively 500MU/min for 15MV photons. Simultaneaously with the start of patient treatment at this accelerator also IMRT with the step&shoot method was established in our department. Although Siemens quit the business in radiation therapy, we got the opportunity to test the already developed method of rotational IMRT (mARC®) at our accelerator. In this investigation, both methods of IMRT will be compared according treatment time, monitor units and plan quality.
Material and Method: In this new variation of rotational IMRT, the dose is delivered during a continuous rotation of the gantry in bursts over short gantry angels with static leaf positions. Between these dose bursts, the MLC leaves are moving rapidly in order to form the next field segment.
For IMRT treatment planning a direct aperture optimization algorithm DAO (Panther® DAO, Prowess Inc.) is used. The planning of the rotational IMRT is done with the proarc option of the Panther treatment planning system.
In a retrospective study, this new technique will be compared with the step&shoot IMRT used for treatment. For both methods the same dose prescription to the target volumes and the same dose limits for organs at risk is used. The IMRT techniques are compared regarding the nessescary monitor units (MU), the treatment time, target coverage (TC), conformity index (CI) and conformity number (CN).

	MU/Gy	Treatment time [s]	TC	CI	CN
Prostate					
Step&Shoot	212.6±10.3	283.0±22.3	0.91±0.03	0.84±0.07	0.88±0.33
mARC	222.0±20.9	217.3±18.4	0.94±0.03	0.92±0.70	0.99±0.34
difference [%]	+ 4.4	−23.0%	+ 3.6	+ 9.6	+ 12.7
p	0.22 (n.s.)	0.0000013	0.11 (n.s.)	0.09 (n.s.)	0.58 (n.s.)
Head & Neck					
Step&Shoot	185.5±15.5	386.8±33.8	0.921± 0.03	0.884±0.02	0.814±0.03
mARC	169.6±10.6	306.4±24.5	0.957±0.11	0.887± 0.02	0.849±0.02
difference [%]	−8.5	−20.8	+3.8	+0.3	+4.2
p	0.103 (n.s.)	0.0032	0.036	0.85 (n.s.)	0.061 (n.s.)

Results: The first results for patientes treated for prostate cancer indicate a slight increase (+4.4%) in monitor units (212.6±10 MU/Gy for Step&Shoot

IMRT compared to 222±21 MU for the mARC-technique) while the treatment time is reduced significantly by 23% (283±22sec (Step&Shoot) vs 217±18sec (mARC)).
For head&neck cases, with the mARC-technique a reduction of monitor units and treatment time could be observed. The monitor units could be reduced by 8.5% from 185.5±16 MU/Gy (Step&Shoot) to 169.6±11 MU/Gy (mARC). The mean treatment time of 306±25sec with the mARC method has been reduced by 20% compared to a mean treatment time if 387±34sec in case of step&shoot IMRT.
In all cases, the plan quality according to TC, CI and CN could be improved slightly with the mARC techniqe.
Conclusion: In comparison to Step&Shoot IMRT, the mARC technique shows comparable or improved dose distributions with a significant reduction in treatment time even for an accelerator with flattening filter. A further reduction of treatment time might be expected in case of flattening filter free beams with a higher dose rate.
No conflict of interest.

Monitoring of pulmonary tumors in computed tomography: Thresholds for volume-based response assessments and target lesions selection

H. Beaumont[1], S. Souchet[1], J.M. Labatte[2], A. Iannessi[3], D. Wormanns[4]. *[1]MEDIAN Technologies, Sophia Antipolis, France; [2]Universite Angers, Mathematics, Angers, France; [3]Centre Antoine Lacassagne, Radiology, Nice, France; [4]ELK Berlin Chest Hospital, Radiology, Berlin, Germany*

Background: The change in lung tumor volume is an emerging imaging biomarker that is expected to be more sensitive to disease evolution than Longest Axial Diameter (LAD). Several aspects of volume-based response assessment are still under investigation. One aspect to be clarified is the magnitude of significant volume changes that allows classifying response as Progressive Disease (PD), Partial Response (PR) and Stable Disease (SD). A second aspect is the selection of target lesions usually restricted to 'Measurable' lesions (ML). So far, no precise definition of volume measurability is available despite its probable impact on the response performance. This study proposes a solution for volume-based response assessments that provides, thresholds for volume-based response of ML and a method for automatic identification of ML.
Material and Method: Our study relies on data published by the Quantitative Imaging Biomarker Alliance (QIBA) which reports an inter reader (IR) Limits of Agreement (LoA) of repeated ML assessments of +/−30%. Considering a standard deviation of measurement as 15%, we used Geary Hinkley (GH) transformation to model response thresholds with a 5% Type I error. We used Training (Tr) and Testing (Te) datasets of respectively 99 and 100 pulmonary lesions. Tr and Te data were segmented twice by two imaging scientists (IS) and two expert radiologists (ER). 79 image-based lesion features, such as statistics of intensities and morphology, were computed from segmentations. We labelled all data as 'Non Measurable Lesions' (NML) when repeated measurements exceeded the LoA. We used labels and computed features to train a Support Vector Machine (SVM) classification system. Sensibility (Se) and Specificity (Sp) at detecting ML have been computed.
Results: With 95% confidence, our model gives response thresholds for volume as: 35% reduction reports for PR, 55% increase for PD and SD otherwise. Our Tr and Te datasets disclose 27.3% and 27% of NML respectively. Performance in classifying ML was Se=91.3%; Sp=48.2%.
Conclusions: We provide response thresholds and validate an approach to detect ML. In documenting these two aspects we make the volume a usable biomarker applicable to lung tumors in CT imaging. However, these aspects of the biomarker cover only metrological considerations, and should be validated by clinical investigations.
No conflict of interest.

Characteristics of lung cancer diagnosed with low dose chest CT

S.H. Choi[1], C.H. Lee[2], S.J. Kang[1]. *[1]Seoul National University Hospital Gangnam Center, Internal Medicine, Seoul, South Korea; [2]Seoul National University Hospital, Radiology, Seoul, South Korea*

Background: Role of chest CT in early diagnosis of lung cancer is controversial between benefits revealed by recent NLST study showing mortality reduction in high risk gruop and harms of overdiagnosis and radiation hazards. The clinical characteristics of lung cancer detected on CT screening is not well known in general population. This study aimed to find clinical characteristics of lung cancers with screening chest.
Material and Methods: This study included 15,615 Korean adults who received low dose chest CT(LDCT) screening in voluntary health checkup program in Healthcare system gangnam center from October 2003 to June 2010. Patients of lung cancer diagnosed on CT screening were reviewed retrospectively about clinical parameters such as sex, smoking et al and final pathology and stage of lung cancers.
Results: 35 lung cancer patients occured. Lung cancer detection rates were 0.22%(crude annual incidence rate 61.0/100,000/year). Male and female ratio was 6:4. 18 of 35 lung cancers occurred in high-risk groups(>20 pack-year smoking) and 17 in low risk groups(ex-smokers and non-smokers). 76% of lung cancers showed less than 3 cm tumor size(<1 cm − 30%, <2 cm −22%, <3 cm − 24%).
The comparison of clinical characteristics with Korean national cancer registry showed that features of lung cancers detected in CT screening showed less advanced stage(stage I 60.6% vs 17.5%), more frequent histology of adenocarcinoma(68.6% vs 36.1%) and relatively higher rates in non-smokers and females than general population.
Of 35 patients with lung cancer, VATS segmentectomy or VATS lobectomy was performed in 10 patients and lobectomy in 16. 4 patients underwent chemotherapy and 5 patients was managed with supportive therapy because of advanced stage or old age. 2 patients died despite of treatment and other patients survived during followup. Adenocarcinoma including BAC histology was more prevalent and most of patients could be treated in early stage.
Conclusion: Lung cancers detected in CT screening had somewhat different clinical characteristics such as less advanced stage and higher frequency of adenocarcinoma from general population. LDCT screening may be useful in diagnosis of lung cancer in early, operable stage.
No conflict of interest.

Comparison of moving target delineation using slow 3D-CT, CBCT and MVCT: A phantom study

M. Oechsner[1], K. Borm[1], J. Berndt[1], J.J. Wilkens[1], M.N. Duma[1]. *[1]Klinikum Rechts der Isar der TU-München, Klinik für Strahlentherapie, Muenchen, Germany*

Background: To assess whether different motion patterns have an impact on delineation of a moving target in a lung phantom using planning CTs (slow 3D-CT) and IGRT-CTs (Conebeam-CT [CBCT], Megavoltage-CT [MVCT]).
Material and Methods: A commercial xy-table (SunNuclear®) was combined with a self-made installation wich enables programable motion of a box in 3 dimensions. The box was filled with corkboards and a water-filled table tennis ball to simulate a tumour inside the lung. Using this phantom, slow 3D-CT (Somatom Emotion, Siemens Medical Solutions®), CBCT (Clinac DHX, Varian Medical Systems®) and MVCT image series (Tomotherapy, Accuray Inc.®) were acquired during phantom movement. Different motion patterns were performed: linear motion in x or y direction with amplitudes of 5 and 10 mm, each with periods of 3 and 5 s. Additionally, a linear motion with amplitudes in x, y and z directions (2.5, 10, 2.5 mm, periode 5 s) and a patient tumour trajectory was applied. The latter was constructed using the center of mass motion of GTVs delineated in a 4D-CT scan.
The ball volume was contoured in all image series (Eclipse 10, Varian Medical systems®) using a lung window setting of 200 HU to −1000 HU. The contoured ball volumes were compared with the mathematically calculated ball volumes.

Table: Relative difference between contoured and calculated ball volume

Motion amplitude	slow 3D-CT		CBCT		MVCT	
	period 3 s	period 5 s	period 3 s	period 5 s	period 3 s	period 5 s
0	11.9	11.9	2.4	2.4	21.5	21.5
x 5 mm	−0.5	−8.5	−8.1	−18.0	−30.2	−14.5
x 10 mm	−6.0	−18.4	−10.9	−19.1	−63.5	−43.9
y 5 mm	−5.6	−7.4	−4.6	−8.3	−8.0	−13.4
y 10 mm	−9.2	−18.8	−7.5	−11.4	−10.9	−25.2

Results: The relative differences between contoured and calculated volumes are presented in the table. The static ball volume was overestimated in all imaging methods. Ball motion resulted in underestimation of the contoured volumes. The volume decreases as the motion amplitude increases. In the slow 3D-CT and CBCT smaller differences were determined for motion period of 3 s than for 5 s. For CBCT and MVCT

ball motion in y direction resulted in smaller deviations than motion in x direction. The largest underestimation of volumes was found for MVCT. Complex motion patterns resulted also in underestimated volumes (−4% to −29%).
Conclusion: Due to movement, contoured volumes were underestimated for all imaging methods. Depending on the applied technique, motion amplitude, direction and period have different impact on target delineation which has to be considered in clinical assessments.
No conflict of interest.

Evaluation of a cloud-based local read paradigm for imaging evaluations in oncology clinical trials

N. Aragane[1], N. Kobayashi[1], E. Bonnard[2], C. Charbonnier[3], J. Yamamichi[4], H. Mizobe[4], S. Kimura[1]. [1]*Saga University, Internal Medicine, Saga, Japan;* [2]*NICE University Hospital, Radiology Department, Nice, France;* [3]*MEDIAN Technologies, Radiology Department, Nice, France;* [4]*Canon Inc, Global Healthcare IT Project, Tokyo, Japan*

Background: Imaging evaluation in oncology heavily depends on human readers performances. In clinical trials, regulatory authorities have been recommending an Independent Central Review (ICR) with several readers to mitigate potential biases resulting from variance between investigator sites. Based on recent publications promoting site based evaluation as imaging endpoint, they currently investigate an alternative to ICR. The goal of this study is to evaluate a cloud-based paradigm implementing software solutions and services that standardize the imaging evaluations among international investigator sites.
Material and Methods: 10 patients, who received chemotherapy for lung cancer and for which chest CT scans were available at 3 different time points, were retrospectively selected. CT scans were evaluated according to the RECIST 1.1 criteria by two oncologists (Saga University) and one radiologist (Nice University Hospital) independently, through web software solutions (MEDIAN Technologies). Such solutions were hosted by the data center (Canon IT Solutions, Japan) and used by readers and data managers (CANON and MEDIAN Technologies) for de-identification, quality control and centralization of the images and their evaluations. The study compared evaluations between readers and analyzed the reasons for discordances.
Results: Readers with different medical training and education, working at distant locations were able to reliably perform radiological evaluations from the same cloud system. The cloud quality control service detected2 non-conformances in applying RECIST 1.1 and had the readers changed their evaluations, resolving discrepancies. Between the oncologists and the radiologist, a discordance rate of 35 % (14/40 evaluations) was observed when considering RECIST overall response (CR, PR, SD, PD) at all time points.
The main reason for discordance in RECIST overall response was a difference in the selection of the target lesions (50%, 7/14). Those discordances represented 78% (7/9) in the group where target selection was different.
Conclusions: The study shows the feasibility of imaging evaluation based on cloud services for clinical studies involving multiple international sites. Centralization of data made possible the on-going monitoring of evaluations through specialized services reducing variability among sites. Analysis of discordances between readers identified areas of improvement for cloud-based services such as consensus process for target selection at baseline evaluation to reduce discrepancies.

Hepatic blood flow using CT perfusion as a prognostic imaging biomarker for esophageal squamous cell carcinoma

T. Fujishiro[1], K. Shuto[2], T. Kono[1], H. Matsubara[1]. [1]*Graduate School of Medicine Chiba University, Department of Frontier Surgery, Chiba, Japan;* [2]*Teikyo University Medical Center, Department of Surgery, Chiba, Japan*

Background: According to the previous reports, preoperative evaluation of hepatic blood flow by diagnostic imaging such as ultrasound and scintigraphy could identify patients of malignancy with high risk of recurrence. CT perfusion (CTP) is a noninvasive, functional imaging which can quantify a perfusion of the target organ, by an analysis of the time-density curve of the injected contrast material. The purpose of this research is to evaluate the change of hepatic blood flow measured by preoperative CTP and identify the high-risk group of postoperative recurrence in patients with esophageal squamous cell carcinoma.
Material and Methods: Forty-five consecutive patients with esophageal squamous cell carcinoma treated with surgical resection at Chiba University Hospital from Jun 2010 to December 2012 were enrolled in this study. Radical subesophagectomy with field lymphadenectomy was performed. Prior to surgery, hepatic CTP images were obtained using a 320-row area detector CT with a 0.5-mm slice thickness. Data was analyzed by perfusion software (Body Perfusion; Toshiba, Tokyo, Japan), based on the dual input maximum slope method. Perfusion parameters, arterial blood flow (AF: ml/min/100g tissue), portal blood flow (PF: ml/min/100g tissue) and %AF (AF/AF+PF x100), were measured by placing region of interest in the abdominal aorta, in the portal vein, in the right hepatic lobe and spleen excluding vessels. We compared the perfusion parameters with pathological Stage (TNM classification of UICC) and postoperative course.
Results: The following factors, which might have influence to a hemodynamics, had no significant correlation with the hepatic perfusion parameters; age, sex, systolic blood pressure, body surface area, hematocrit, serum asparate aminotransferase (AST) and estimated glomerular filtration rate (eGFR). In the comparison of the mean values of the parameters for each stage, there was no significant difference. The postoperative recurrence has observed in 8. The types of recurrence were as follows: hematogenous metastases 9, lymph node 6 and peritoneum 2 (duplication was included). %AF of recurrent cases was significantly higher than that of without recurrence (24.8 vs. 15.9, $P = 0.0027$). The predictive value of recurrence have a sensitivity of 87.5% and a specificity of 88.9%, by setting a cut-off %AF value (%AF=20) from Receiver Operating Characteristic analysis. If divided into two groups, high %AF group ($\geqslant$20) and low %AF (<20), the relapse free survival rate of low %AF group was significantly better than that of high group ($P<0.0001$). Multivariate analysis using the Cox proportional hazards model showed that preoperative high %AF was an independent risk factor of recurrence (Hazard ratio: 26.1, P value: 0.0029).
Conclusions: Hepatic CTP is a non-invasive modality and a valid functioning tool to predict postoperative recurrence of esophageal squamous cell carcinoma, furthermore its potentiality, as an imaging biomarker, has been suggested.
No conflict of interest.

1155 POSTER

A novel approach for cancer risk reduction associated serial CT scanning in pediatric hydrocephalus

R. Ferguson[1], J.S. Williams[1], M.C. Vang[1], R. Geertman[2], M.J. Mhanna[3], S. Reed[1], M.S. Rzeszotarski[4]. [1]*MetroHealth Medical Center, Radiology, Cleveland, USA;* [2]*MetroHealth Medical Center, Neurosurgery, Cleveland, USA;* [3]*MetroHealth Medical Center, Pediatrics, Cleveland, USA;* [4]*MetroHealth Medical Center, Radiology/Physics, Cleveland, USA*

Background: Pediatric patients with acute hydrocephalus are frequently subjected to serial CT studies to confirm ventricular shunt patency. It is not uncommon for patients to receive up to 12 CT scans/year resulting in substantially increased lifetime cancer risk. This feasibility study investigates the ability to accurately measure ventricle size as CT dose is reduced far below the child-size CT protocols routinely employed in pediatric imaging. By narrowing the diagnostic goal to a determination of ventricle size, rather than exclusion of all possible pathology within the scan region, the radiation dose can be greatly reduced.
Materials and Methods: Initial studies were performed using phantom materials with CT Hounsfield units matched for brain and CSF. These images were acquired at various kVp, mAs, slice thickness using axial and helical acquisitions. The data was processed using a variety of reconstruction kernels and several post-processing and volume rendering algorithms to modulate image smoothing.
In addition, three fresh cadaver heads were imaged using a wide range of CT protocol parameters, varying kVp, mAs, axial versus helical, and reconstruction kernels to maximize the dataset for analysis. Raw and reconstructed data was saved for post-processing using 3D workstations as well as image processing toolkits provided in commercial image analysis software.
Results: Ventricular dimensions were estimated using both 3D volume rendered and 2D image analysis algorithms. Concordance of measurements between the maximum dose and reduced dose datasets was analysed and confirmed as was the lack of significant interobserver variability between three experienced neuroradiologists.
The range of CTDI from the maximum dose protocol to the minimum dose protocol was greater than two orders of magnitude. In spite of this extreme dose reduction, ventricular dimensions could still be accurately measured despite a 100X dose reduction.
Conclusions: Radiation exposure from serial CT scans results in an increased risk of malignancy later in life and is particularly significant in young patients. CT scanning required to exclude acute obstructive hydrocephalus related to shunt malfunction may result in radiation exposure levels known to significantly increase cancer risk in pediatric patients. A method to reduce dose by more than 2 orders of magnitude associated with

serial CT scanning in suspected shunt malfunction has been developed that can reliably exclude acute hydrocephalus in a vulnerable pediatric population. This strategy to maximally reduce dose while maintaining accurate identification of key image parameters to reliably resolve a specific clinical question can reduce cancer risk while ensuring appropriate patient management.

1156 POSTER

Predictive value of optimal morphologic response to first-line chemotherapy in patients with colorectal liver metastases

A. Hosokawa[1], T. Ando[1], H. Yoshita[1], N. Horikawa[2], K. Yabushita[2], H. Kawabe[3], G. Tomizawa[3], H. Kato[3], T. Kashii[4], T. Sugiyama[1].
[1]University of Toyama, Department of Gastroenterology and Hematology, Toyama, Japan; [2]Takaoka City Hospital, Department of Surgery, Takaoka, Japan; [3]University of Toyama, Department of Radiology, Toyama, Japan; [4]University of Toyama, Department of Medical Oncology, Toyama, Japan

Background: It was reported that morphologic response to preoperative chemotherapy was an independent prognostic factor in patients who underwent hepatic resection of colorectal liver metastases (CLM). The aim of this study was to evaluate the predictive value of morphologic response to first-line chemotherapy in patients with CLM.
Methods: We assessed 41 patients with CLM who received fluorouracil-based chemotherapy with or without bevacizumab as first-line chemotherapy at two institutions between April 2006 and June 2012. All patients underwent enhanced computed tomography (CT) at the start of chemotherapy and then every 2−3 months. Three blinded radiologists evaluated CT images and classified as optimal, incomplete or none response according to the morphologic criteria (Chun YS, et al. JAMA 302: 2338−44, 2009). Response to systemic chemotherapy was also evaluated according to RECIST. Progression-free survival (PFS) was calculated with the Kaplan–Meier method and statistical differences with survival curves were determined by the log-rank test. Predictive factors associated with PFS were identified in multivariate analysis.
Results: Patients characteristics were as follows: median age=67 years (range 52−80); Male: female=29:12; PS 0:1:2:3=24:13:3:1. Thirty two patients had synchronous liver metastases and 9 had metachronous liver metastases. Five patients had solitary liver lesions and 36 had multiple liver lesions. Twenty three patients (54%) received chemotherapy with bevacizumab, while 18 patients (46%) received chemotherapy without bevacizumab. Optimal morphologic response was observed in 11 patients (48%) treated with bevacizumab and, in 5 patients (28%) treated without bevacizumab. Eight patients (20%) underwent hepatic resection after chemotherapy. The median follow-up period was 31.3 months. The median PFS was 12.7 months for patients with optical morphologic response and 8.1 months in those with incomplete/none morphologic response ($p = 0.0026$). On multivariate analysis, PS and morphologic response were significant independent predictors of PFS. Morphologic response was superior to RECIST for prediction of PFS.
Conclusions: Optimal morphologic response was significantly associated with PFS in patients with CLM who were treated with fluorouracil-based chemotherapy as first-line chemotherapy. Chemotherapy with bevacizumab tends to have a higher optimal morphologic response than chemotherapy without bevacizumab.

The value of chest CT for prediction of breast tumor size: Comparison with pathology measurement

E.Y. Kim[1], Y.S. Kim[2], I. Park[2], H.K. Ahn[2], E.K. Cho[2]. *[1]Gachon University Gil Hospital, Radiology, Incheon, South Korea; [2]Gachon University Gil Hospital, Internal Medicine, Incheon, South Korea*

Background: To date, no data are available on the use of chest CT for prediction of breast tumor size in patients with breast cancer, although the CT examinations are increasing in practice. The purpose of this study is to evaluate the value of chest CT for prediction of breast tumor size using the pathology measurement as the reference standard.
Materials and Methods: We retrospectively analyzed the tumor size on the preoperative chest CT for 295 patients with surgically proven unifocal, invasive carcinoma. The maximal diameter of tumor on chest CT and pathologic result were compared by linear regression and Spearman's rho correlation coefficient. Concordance between CT and pathology was defined as a difference $\leqslant 0.5$ mm. Sub-groups analysis was also performed by tumor size (<2 cm and $\geqslant 2$ cm), and histologic grades.
Results: CT and pathology tumor size showed positive correlation (Pathology tumor size = 1.092 × CT tumor size − 1.013, Spearman's rho correlation coefficient = 0.84, P <0.001). Most of the tumors (n = 232, 78.6%) showed concordance in the size on chest CT and pathology, and 42 of tumors (14.2%) showed underestimation (average underestimation of CT = 12 mm) and 21 of tumors (7.1%) showed overestimation on CT (average overestimation of CT = 10 mm) compared with that of pathology. No significant difference was found in the sub-group analysis by tumor size and the histological subtypes.
Conclusion: CT tumor size positively correlates with pathology size in the breast cancer patients. Most of the tumors show difference less than 5 mm in the size on chest CT and pathology. The tumor size and histological subtype is no significant indicator for prediction of tumor size on CT.
No conflict of interest.

1158 POSTER

Geographical analysis of hypoxic subvolumes in locally advanced head and neck tumours during primary chemoradiotherapy in serial 18-F-MISO-PET imaging

M.I. Bittner[1], N. Wiedenmann[1], S. Bucher[1], M. Mix[2], W.A. Weber[3], A.L. Grosu[1]. *[1]University Medical Center Freiburg, Department of Radiation Oncology, Freiburg, Germany; [2]University Medical Center Freiburg, Department of Nuclear Medicine, Freiburg, Germany; [3]Memorial Sloan-Kettering Cancer Center, Molecular Imaging and Therapy Services, New York, USA*

Background: Hypoxic subvolumes (HV) in head and neck tumours are associated with worse prognosis and outcome, attributed to increased chemo- and radioresistance. Tumour hypoxia can be visualized using PET imaging. 18-Fluoro-Misonidazole (F-MISO) was the first tracer clinically validated and established. The incorporation of biological information into radiotherapy planning can personalize radiotherapy (e.g. by dose painting).
Material and Methods: In a pilot project, 16 patients with locally advanced head and neck tumours underwent 3 consecutive F-MISO-PET scans (weeks 0, 2, 5) before and during primary chemoradiotherapy (70 Gy, Cisplatin) in addition to FDG-PET, CT and MRI (week 0). Tumour localisations included oral cavity (n = 1), oropharnynx (n = 7), hypopharynx (n = 5) and larynx (n = 3). Normalised standardized-uptake-values (SUV) were generated for all patients (index SUVmax Tumour/SUVmax Muscle) on the F-MISO-PET scans. The size, localisation and overlap of the HV between the F-MISO-PET scans were analysed. Volume delineation was done using a semi-automatic algorithm: A sphere containing normal tissue contralateral to the tumour site was defined for all patients and scans. A 1.5-fold increase over the spheres' mean SUV yielded the threshold for the HV for each scan and patient. Analyses were carried out with BrainLAB iplan.
Results: For an index of 1.5, quantitative evaluation showed tumour hypoxia in week 0 in 16/16, in week 2 in 5/14 and in week 5 in 0/11 patients. The mean tumour volume − as defined on FDG-PET and validated with CT and MRI − was 28 cm^3, the mean HV initially 28 % with a decrease to 15 % after 2 weeks. HV completely resolved in the majority of patients. Mean HV overlap between the first and second scans was 55 % of the HV on the first scan, indicating a relatively high proportion of initial hypoxia persisting at the same localisation in later scans. Similarly, the majority of the later HV have already been hypoxic before (mean overlap 72 % of the HV on the second scan). Descriptive analyses showed both stationary and dynamic components in those patients with persisting hypoxia (decreased or increased).
Conclusions: Tumour hypoxia decreased or regressed in a majority of patients; however, HV showed a geographically relatively stable conformation in those patients with persistent hypoxia. This might make an inclusion into radiation treatment planning possible.
No conflict of interest.

1159 POSTER

Visualization of solid tumors and metastasis using an uPAR specific NIR fluorescent-labeled antibody

M.C. Boonstra[1], P.B.A.A. Van Driel[2], A.P. Mazar[3], F.W.B. Van Leeuwen[2], D.M. Van Willigen[1], P.J.K. Kuppen[1], J.V. Frangioni[4], C.J.H. Van de Velde[1], A.L. Vahrmeijer[1], C.F.M. Sier[1]. *[1]Leiden University Medical Center, Surgery, Leiden, Netherlands; [2]Leiden University Medical Center, Radiology, Leiden, Netherlands; [3]Chemistry of Life Processes Institute and Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Evanston, USA; [4]Beth Israel Deaconess Medical Center, Medicine, Boston, USA*

Real-time near-infrared (NIR) fluorescent imaging is a novel technique used to intraoperatively visualize tumor cells. For this purpose NIR light-emitting fluorophores are conjugated to tumor protein-specific tracers. One potential target for tracing tumors is the urokinase plasminogen activator receptor (uPAR). uPAR plays an important role in the development of cancer, tumor invasion, angiogenesis and metastasis. Over-expression of uPAR is found on the majority of human carcinomas, in cancer as well as stromal cells.

This study investigates the potential of an uPAR-specific NIR fluorescent antibody for the *in vivo* identification of tumor cells.
The NIR fluorophore MSAP-ZW800−1 was conjugated to a humanized monoclonal uPAR specific antibody and an isotype IgG control. The conjugation and binding capacity of both compounds were validated *in vitro* using photospectrometry and plate-assay analyses on tumor cells. Athymic mice were subcutaneously injected with human colon adenocarcinoma HT-29 cells or orthotopicly in the tongue with OSC-19 cells, a metastasizing human squamous cell carcinoma. After establishment of the tumors, 1 nmol of either uPAR-specific or control IgG were injected intravenously (IV). At sequential time points up-to 120 h after injection images were obtained with the PEARL Impulse small animal imager and the intraoperative FLARE™ imaging system. A dose-range study was performed with doses of 150 μg (1 nmol), 100 μg, or 50 μg per mouse. *Ex vivo* fluorescence imaging and histology was performed to demonstrate distribution of the compounds and tumor specificity.
In vivo, the tumors were clearly fluorescently delineated, with the highest tumor-to-background ratios (TBR) at 72 hours after injection of 3.6±0.4 in the HT-29 model and 2.3±0.1 in the OSC-19 model respectively (n = 3). The control compound showed a mean TBR of 1.8±0.2 in the HT-29 model and 1.1±0.2 in the OSC-19 model, whereas injection of the fluorophore alone showed a mean TBR of 0.8 ±0.1 in both animal models. Unexpected fluorescent spots were found in the cervical region of the OSC-19 tumor-specific compound group, which histologically turned out to be cervical lymph node metastases. Two-way repeated measurements ANOVA analysis showed significant differences between the tumor-specific compound and control groups in the HT-29 model at all time points later than 24 hours ($p < 0.01$) and for the OSC-19 model at every time point from the start ($p < 0.01$). *Ex vivo* evaluation showed a tumor-specific signal in both the OSC-19 primary tumors and lymph node metastases. No significant differences were found among the dose groups, indicating the potential of this anti-uPAR compound to be used in the lower micro-dose range.
In conclusion, this study describes a new tumor-specific fluorescent probe, targeting uPAR, which provides visualization of solid tumors including their metastases in real time using a NIR fluorescence imaging system.

1160 POSTER

Non-invasive monitoring of pharmacodynamics and -kinetics of a death receptor 5 antibody: Induction of apoptosis depends on treatment schedule

T. Weber[1], T. Poeschinger[1], S. Galbán[2], A. Rehemtulla[2], W. Scheuer[1]. *[1]Roche Diagnostics GmbH, Pharma Research and Early Development Discovery Oncology, Penzberg, Germany; [2]University of Michigan, Department of Radiation Oncology & Center for Molecular Imaging, Ann Arbor, USA*

Background: Using fluorescence- and bioluminescence-imaging, the pharmacodynamics and tumor saturation kinetics of a Death Receptor 5 antibody (anti-DR5) was examined to optimize treatment schedules of a combination therapy with Doxorubicin (DOX).
Material and Methods: Split-luciferase based bioluminescence imaging allowed us to monitoring apoptosis non-invasively in living mice. A human glioblastoma cell line stably transfected with the split-luciferase apoptosis reporter was applied to screen various chemotherapeutics and anti-DR5 on their ability to induce apoptosis in cells *in vitro* as well as *in vivo*. Fluorescence labeled anti-DR5 was injected i.v. and tumor saturation kinetics was monitored.
Results: We found that DOX treatment *in vitro* led to significant apoptosis induction within 48 hours and to a 2.3-fold increased anti-DR5 binding to the cell surface in contrast to Cisplatin and 5-FU treatment. Induction of apoptosis by treatment with anti-DR5 was dose- and time-dependent (both *in vitro* and *in vivo*). Simultaneous visualization of fluorescence labeled anti-DR5 in tumor tissue and apoptosis revealed maximal apoptosis induction immediately after the compound had reached tumor site. Regarding combination therapy of anti-DR5 and DOX, we found that the sequential application of DOX before anti-DR5 resulted in synergistically enhanced apoptosis reporter activity. In striking contrast, anti-DR5 given before DOX did not lead to increased apoptosis induction.
Conclusions: We suggest that DOX-induced recruitment of DR5 to the cell surface impacts the enhanced apoptotic effect which can be longitudinally monitored by apoptosis imaging. This study demonstrates that the combination of apoptosis and antibody accumulation imaging is an excellent method for optimizing dosing and treatment schedules in preclinical cancer models.

1161 POSTER

The hybrid tracer ICG-99mTc-nanocolloid aids surgical visualization of the sentinel node in different basins

G. KleinJan[1], N.S. Van den Berg[1], O.R. Brouwer[2], H.M. Mathéron[2], S. Horenblas[3], W.M.C. Klop[4], O. Nieweg[5], B. Van der Hiel[2], R.A. Valdés Olmos[2], F.W.B. Van Leeuwen[1]. *[1]Leiden University Medical Center, Radiology, Leiden, Netherlands; [2]Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Nuclear Medicine, Amsterdam, Netherlands; [3]Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Urology, Amsterdam, Netherlands; [4]Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Head and Neck Surgery & Oncology, Amsterdam, Netherlands; [5]Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Surgery, Amsterdam, Netherlands*

Background: Conventionally a combination of radiocolloid and blue dye is used for sentinel node (SN) biopsy. The radiocolloid allows preoperative lymphoscintigraphy and SPECT/CT for SN mapping, and intraoperatively its gamma rays can be traced to guide the surgeon to the SN. An intraoperative injection with blue dye prior to the start of the procedure is then used to enable optical lymphatic ducts and SN identification. Recently we introduced the hybrid, radioactive and fluorescent, tracer indocyanine green (ICG)-99mTc-nanocolloid. With this tracer, one single injection enables preoperative SN mapping and intraoperative radio- and fluorescence guidance to the SN. In this study we compared SN identification via the fluorescence component of the hybrid tracer to SN identification using blue dye in different drainage basins.
Materials and Methods: One-hundred-ninety-six patients were included in the study: 77 patients with melanoma and 119 patients with squamous cell carcinoma of the penis or vulva. The hybrid tracer was injected surrounding the lesion/scar 3−27 hours prior to surgery. The SNs were then preoperatively identified using lymphoscintigraphy and SPECT/CT imaging. Prior to the start of the operation vital blue dye was injected. The SNs were intraoperatively traced using a gamma ray detection probe and a portable gamma camera. In addition, SNs were visualized via fluorescence imaging and/or blue dye detection.
Results: Intraoperatively, a total 342 basins was explored from which a total of 609 SNs were excised. In the 43 neck-basins a total of 68 SNs were excised with 33% of these SNs being blue and 97% being fluorescent. In the 247 inguinal basins (461 SNs), 54% of the SNs was blue whilst 92% was fluorescent. Eigthy-one percent of the SNs located in the 44 axillary basins was blue while 92% was fluorescent. Three SNs were located in other basins namely the elbow (n = 1) and supraclavicular (n = 2); here 20% of the SNs was stained blue vs. 100% being fluorescent. Aberrant drainage to the periscapular region was found in 4 patients, to 4 basins with a total of 4 SNs. Drainage to one prepubic SN was found in a patient with penile carcinoma. Of these abberant draining 5 SNs only 1 SN was blue whereas they were all fluorescent.
Discussion: For all nodal basins studied significantly ($p < 0.001$) more fluorescent SNs (average 93%) than blue stained SNs (average 54%) were visualized and removed. This was especially true for the neck. The fluorescence feature of the hybrid tracer might, therefore, provide a valuable alternative for optical SN identification in the operating room.

89Zr-cetuximab imaging in advanced colorectal cancer patients: A feasibility study

C.W. Menke-van der Houven van Oordt[1], M. Huisman[2], C. Roth[1], D.J. Vugts[2], R.C. Schuit[2], A. Clement[1], R. Boellaard[2], O.S. Hoekstra[2], G.A.M.S. Van Dongen[2], H.M.W. Verheul[1]. *[1]VU Medical Center, Medical Oncology, Amsterdam, Netherlands; [2]VU Medical Center, Radiology and Nuclear Medicine, Amsterdam, Netherlands*

Systemic treatment for advanced, wild type K-RAS colorectal cancer (wtK-RAS CRC) includes Epidermal Growth Factor Receptor (EGFR)-inhibition with anti-EGFR antibodies like cetuximab. Only 40% of patients with wtK-RAS CRC do benefit from this treatment, while the others are intrinsically resistant. Potential causes of resistance include aberrations in the EGFR-signaling cascade and/or differential pharmacokinetics of anti-EGFR-antibodies in patients. We hypothesize that high EGFR-expression in normal tissues, such as in normal liver, may lead to insufficient availability of anti-EGFR-antibodies to effectively target tumor lesions and thereby may be responsible for resistance.
To study our hypothesis, we first investigated whether accumulation of cetuximab can be detected in tumor lesions of patients with wtK-RAS CRC by PET-imaging with radiolabeled cetuximab (^{89}Zr-cetuximab).
Six patients with histopathologically confirmed advanced wtK-RAS CRC who were candidates for monotherapy with cetuximab, were included in this feasibility study upon their consent. Based on a 40% clinical benefit

rate of cetuximab we hypothesized that 40% of patients would show ^{89}Zr-cetuximab tumor uptake. This hypothesis would be correctly accepted if uptake would be present in $\geqslant$1 and $\leqslant$7 of 10 patients (power >90%, type I error <5%). ^{89}Zr-cetuximab PET-imaging was performed at the start of treatment with cetuximab. ^{89}Zr-labelled cetuximab (10 mg, 37MBq) was injected within 2 hours after the first dose of cold cetuximab (500 mg/m^2) on day 1. PET scans were performed on days 1, 2, 3, 4 and 7. While high liver uptake of ^{89}Zr-cetuximab was found in all patients, specific uptake of ^{89}Zr-cetuximab was detected in non-hepatic metastases of 3 patients during subsequent scans (standard uptake values between 3 and 8.5 on day 7). In the other 3 patients, no specific ^{89}Zr-cetuximab uptake was detected in non-hepatic metastases. Detailed imaging results will be shown at the meeting. The patients did not experience any toxicity related to ^{89}Zr-cetuximab; only known adverse events to cetuximab were observed, none exceeding grade 2. We conclude that PET imaging with ^{89}Zr-cetuximab for determination of tumor uptake in non-hepatic lesions is feasible. Based on these results, we initiated a clinical trial in which we will investigate the correlation between tumor uptake and tumor response by ^{89}Zr-cetuximab PET-imaging of non-hepatic lesions. Our goal is to guide treatment decisions for the individual patient with wtK-RAS CRC using a non-invasive, patient-friendly imaging strategy.

No conflict of interest.

Segmentation of subsequent FMISO-PET before and during radiochemotherapy: Experts versus swarm intelligence

R. Haase[1], R. Perrin[2], K. Zöphel[3], H.J. Böhme[4], N. Abolmaali[5].
[1]Oncoray, Biological and Molecular Imaging Group, Dresden, Germany; [2]Oncoray, High Precision Radiotherapy Group, Dresden, Germany; [3]University Hospital C.C.G. TU Dresden, Clinic and Policlinic for Nuclear Medicine, Dresden, Germany; [4]HTW Dresden, Faculty of Computer Science/Mathematics, Dresden, Germany; [5]University Hospital C.C.G. TU Dresden, Institute and Policlinic for Radiology, Dresden, Germany

Background: Researchers in the field of imaging diagnostics for oncology increasingly incorporate new PET tracers such as [18F]fluoromisonidazole (FMISO) for hypoxia localisation in clinical trials to determine its prognostic potential. However, reproducibility of FMISO-PET measurements is part of controversy. To determine the stability of contours derived from subsequent FMISO PET imaging, we compared manually-outlined target object definitions and automatically-created contours.
Material and Methods: As part of a prognostic trial on head and neck cancer, 35 patients were imaged using FMISO-PET before and after the first week of combined radiochemotherapy. Three experts outlined FMISO-positive objects related to the primary tumor in the PET data sets. The analogously applied automatic routine is based on swarm intelligence. The algorithm utilizes virtual ants that move in the PET image stack and accumulate inside potential target objects.
Comparison of manually- and automatically-created contours was performed using the Jaccard-Index for determination of the degree of contour overlap. The comparison included expert-versus-expert analysis on both single FMISO-PET scans to estimate inter-observer-similarity, inter-scan-comparison to determine intra-observer- and intra-algorithm-similarity and algorithm-versus-expert comparison to estimate the reliability of automatic contours.
Results: In 25 of the 35 data sets, all experts consistently outlined objects which were further analysed. The Jaccard-Index was JI_{EvE}=45% and JI_{iE}=36% for inter- and intra-observer-similarity, respectively. Automatically-generated contours matched to the manually-created contours with JI_{AvE}=45%, which was a similar measurement as inter-observer-similarity. However, automatic contours matched by JI_{iA}=53% between both scans.
Conclusions: Automatically delineated contours matched to manually-created contours to a degree as the latter matched to each other. However, the similarity of contours between both scans was significantly increased using automatic delineation. The fact that intra-observer-similarity between the scans was decreased may partly be explained by changes of the tumour microenvironment during the first week of therapy between both PET scans.

1164 POSTER

Diffusion-weighted imaging in the follow-up of patients after primary surgical and non-surgical treatment for rectal cancer

L.A. Heijnen[1], D.M.J. Lambregts[2], M.J. Lahaye[2], M.H. Martens[1], B.E. Heidemann[2], M. Maas[2], G.L. Beets[3], R.G.H. Beets-Tan[2]. *[1]Maastricht University Medical Centre, Radiology/Surgery, Maastricht, Netherlands; [2]Maastricht University Medical Centre, Radiology, Maastricht, Netherlands; [3]Maastricht University Medical Centre, Surgery, Maastricht, Netherlands*

Background: Accurate detection of recurrent disease after primary rectal cancer treatment is crucial to allow for curative salvage surgery. Standard imaging is known to experience difficulties in differentiating between post-treatment effects (inflammation and fibrotic scar tissue) and recurrent disease. Diffusion-weighted MRI (DWI) is a technique that analyses differences in tissue cellular density to differentiate between hypercellular (tumour) and low or normocellular tissues (fibrosis and inflammation). Aim of this study was to evaluate the value of DWI in the follow-up of patients after primary surgical or non-surgical treatment for rectal cancer.
Material and Methods: The study group (n = 117) consisted of 36 patients who had previously undergone rectal cancer treatment, consisting of either standard surgical resection with or without neoadjuvant (chemo-)radiotherapy (n = 36), a local transanal excision (n = 40, of which 15 after chemoradiotherapy) or a non-operative 'wait-and-see'-policy (n = 41). During clinical follow-up (FU) patients underwent on or more FU-MRIs (1.5T) including DWI (highest b-value b1000), as part of routine FU or because of a suspected local recurrence after surgery. Two readers in consensus evaluated each MRI and scored the b1000 DWI-images as 'no high signal', 'high signal suspected of recurrence' or 'not adequately assessable due to artefacts'.
Results: Patients underwent a mean number of 3 FU-scans (range 1−11) with a mean FU-time of 44 months (4–144). 27/117 patients developed a local recurrence, of which 23 (85%) were accurately detected on DWI. The other 90 patients (without recurrence) together underwent a total of 261 FU scans, of which 194 (74%) remained consistently true negative (no high signal) on DWI. 57 DWI-scans (19%) could not adequately be assessed due to artefacts. 14 DWI-scans were false positive (mainly at the first FU-scan after surgery/local excision), of which 50% again normalised during further FU.
Conclusion: DWI is a useful tool in the follow-up of patients after primary rectal cancer treatment. False positives may occur immediately after surgery, but the DWI signal normalises again during follow-up.

Superparamagnetic iron oxide nanoparticles (SPIONs) modified with epidermal growth factor (EGF) or heat shock protein Hsp70 for targeting the brain tumor

M. Shevtsov[1], L. Yakovleva[2], B. Nikolaev[2], A. Dobrodumov[3], Y. Marchenko[2], K. Onokhin[1], I. Guzhova[1], M. Martynova[4], O. Bystrova[4], B. Margulis[1]. *[1]Institute of Cytology of the Russian Academy of Sciences (RAS), Laboratory of Cell Protection Mechanisms, Saint-Petersburg, Russian Federation; [2]Research Institute of Highly Pure Biopreparations, Laboratory of Medical Nanotechnology, Saint-Petersburg, Russian Federation; [3]Institute of Macromolecular Compounds of the Russian Academy of Sciences (RAS), Analytical Department, Saint-Petersburg, Russian Federation; [4]Institute of Cytology of the Russian Academy of Sciences (RAS), Laboratory of Morphology, Saint-Petersburg, Russian Federation*

Background: Superparamagnetic iron oxide nanoparticles (SPIONs) due to their high magnetic moment have the ability to function as theranostic agents. They could be used both as contrast agents for MRI, and as delivery vehicles for anti-cancer agents and thermotherapy. In series of *in vitro* and *in vivo* experiments we analyzed brain tumor targeting with magnetic nanoparticles conjugated with epidermal growth factor (EGF) or heat shock protein Hsp70.
Material and Methods: Human recombinant Hsp70, EGF were produced by genetic engineering. SPIONs modified by EGF, Hsp70 were characterized by spectrophotometry, ELISA assays, atomic-force microscopy and NMR. Proton magnetic relaxation times T_2 were measured with the help of the NMR-spectrometer (CXP-300, Bruker) in magnetic field of 7.1 T. The *in vitro* binding and uptake of SPIONs, Hsp70-SPIONs and EGF-SPIONs conjugates were assessed on the C6 glioma cells culture by confocal and electron microscopy. The *in vivo* traffic was analyzed in the model of intracranial C6 glioma. MR images (gradient echo (FLASH), T_1- and T_2-weighted, multi-sc and multi-echo (MSME T_2-map) of rat glioma were obtained by Bruker Avance II NMR spectrometer 11 T.
Results: SPIONs measured relaxivity corresponded to properties of negative contrast agents with a hypointensive change of resonance signal

in MR imaging. According to *in vitro* studies SPIONs were incorporated into C6 cells mostly by endocytosis pathway. Intriguingly, the conjugation of protein Hsp70 or EGF to the SPIONs increased the internalization of nanoparticles as was demonstrated by confocal microscopy (by the receptor-mediated endocytosis: EGFR for EGF-SPIONs, CD40 for Hsp70-SPIONs). *In vivo* studies confirmed the tumor targeting ability of modified SPIONs. I.v. injected nanoparticles accumulated inside C6 glioma tumor with a significant decrease of signal on T2-weighted images. Confocal microscopy images confirmed the Hsp70-SPIONs or EGF-SPIONs accumulation within the tumor cells cytoplasm.
Conclusions: Modified SPIONs application represents a promising approach for the targeted therapy and imaging of malignant tumors. SPIONs conjugated with heat shock protein Hsp70 or EGF increased the uptake of nanoparticles by glioma cells and, what is more important, − provided the selectivity of tumor targeting in *in vivo* conditions. The proposed technology based on magnetic nanoparticles exhibits the high diagnostic potential and could be further transferred to the thermotherapy of brain tumors.

1166 POSTER

Diffusion-weighted magnetic resonance imaging at 3.0-T versus fluorine 18 fluorodeoxyglucose positron emission tomography/computed tomography for detection of pulmonary malignant tumors

J. Zhang[1], L.B. Cui[2], X. Tang[3], Y. Zhang[1], H.N. Yang[1], L.Z. Chen[1], X.L. Ren[1], J.R. Shi[1], H. Yin[3]. *[1]Department of Respiratory Medicine, Fourth Military Medical University, Xi'an, China; [2]Division of Graduate, Fourth Military Medical University, Xi'an, China; [3]Department of Radiology, Fourth Military Medical University, Xi'an, China*

Background: Emerging evidences suggest that diffusion-weighted magnetic resonance imaging (DW MRI) at 1.5-T could be useful for tumor detection, together with N and M staging in patients with lung cancer, especially non-small cell lung cancer (NSCLC), in place of fluorine 18 fluorodeoxyglucose positron emission tomography/computed tomography (FDG PET/CT) most recently. This investigation prospectively examined whether DW MRI at 3.0-T might be as useful as FDG PET/CT for detection of pulmonary malignant tumors.
Material and Methods: This study was approved by the institutional review board, and written informed consent was obtained from all patients. DW MRI and FDG PET/CT were performed before therapy in 113 patients with pulmonary nodules, including lung cancer, lung metastases, and benign lesions, diagnosed by pathological examination. Mean apparent diffusion coefficient (ADC), maximal standardized uptake value (SUV_{max}), and five-point visual scoring were assessed. Immunohistochemical staining for Ki-67 was performed in 36 patients with lung cancer, and Ki-67 score was evaluated. Receiver operating characteristic (ROC) curve analysis was used to determine feasible threshold values. Diagnostic capabilities for detection of pulmonary malignant tumors were compared with the McNemar test on a per-patient basis, and correlation between malignant degree of lung cancer and ADC or SUV_{max} was analyzed by Spearman rank test.
Results: As for diagnostic capability, area under ROC curve (A_z) for ADC (0.91) were significantly higher than that for SUV_{max} (0.78, P <0.05), and A_z value for DW MRI (0.94) were not significantly different from that for FDG PET/CT (0.92, P >0.05). For quantitative assessment, specificity and accuracy of ADC (91.7%, 92.9%) proved to be significantly higher than those of SUV_{max} (66.7%, 77.9%, P <0.05), although sensitivity of ADC (93.5%) was not significantly different from that of SUV_{max} (83.1%, P >0.05). When feasible threshold values were used to assess qualitatively, sensitivity, specificity, and accuracy of DW MRI (96.1%, 83.3%, 92.0%) were also not significantly different from that of FDG PET/CT (88.3%, 83.3%, 86.7%, P >0.05). Significant correlation was found between Ki-67 score and ADC (Spearman coefficient r = −0.66, P <0.05), as well as ADC and SUV_{max} (r = −0.37, P <0.05). On the contrary, Spearman coefficient was −0.11 between Ki-67 score and SUV_{max} (P >0.05).
Conclusions: Quantitative and qualitative assessments for detection of pulmonary malignant tumors obtained with DW MRI at 3.0-T are as useful as, even superior to, those obtained with FDG PET/CT. Furthermore, another significant outcome of this study was that ADC in DW MRI at 3.0-T can also play a role in prediction for malignant degree of lung cancer in particular, but SUV_{max} did not in FDG PET/CT.
No conflict of interest.

1167 POSTER

Associations between BRCA mutation status, pathologic findings, and MR imaging features in patients with breast cancer who have high risk factors for mutation

J.M. Noh[1], D.H. Choi[1], B.K. Han[2], S.J. Rhee[2], E.Y. Cho[3], S.J. Huh[1], W. Park[1], H. Park[1], S.J. Nam[4], J.E. Lee[4]. *[1]Samsung Medical Center Sungkyunkwan University School of Medicine, Radiation Oncology, Seoul, Korea; [2]Samsung Medical Center Sungkyunkwan University School of Medicine, Radiology, Seoul, Korea; [3]Samsung Medical Center Sungkyunkwan University School of Medicine, Pathology, Seoul, Korea; [4]Samsung Medical Center Sungkyunkwan University School of Medicine, Surgery, Seoul, Korea*

Background: We investigated the relationship between BRCA mutation, pathologic findings, and magnetic resonance imaging (MRI) findings in patients with breast cancer who had risk factors for the mutation.
Materials and Methods: Genetic testing for BRCA mutation was performed in 275 breast cancer patients with at least one risk factor for the mutation. Using the Breast Imaging Reporting and Data System MR lexicon, morphologic and kinetic features on MRI were reviewed for 230 tumors in 209 of these patients. The relationship between BRCA mutation, pathologic findings, and MRI findings was examined by chi-square or Fisher's exact tests. Disease recurrence was also estimated.
Results: BRCA mutation was detected in 48 (23.0%) patients; BRCA1, 21 (10.0%); BRCA2, 25 (12.0%). Two (1.0%) patients had mutations in both genes. Tumors in patients with BRCA1 mutations more frequently showed a high nuclear grade (p = 0.0041) and triple-negative (TN) phenotype (p <0.0001). On MRI, the tumors were seen as mass types in 182 (79.1%) of 230 lesions and non-mass types in 48 (20.9%) cases. Among the MRI features, rim enhancement was significantly associated with molecular subtypes based on immunohistochemistry (p <0.0001) and nuclear grade (p = 0.0387) in multiple logistic regression. Rim enhancement on MRI, along with advanced pathologic T stage, was associated with increased disease recurrence (p = 0.0023) in multivariate analysis. However, the proportion of mass types and non-mass types and the distribution of morphologic shape, margin, internal enhancement, or kinetic features on MRI were not different according to BRCA mutation status.
Conclusion: In patients with high-risk breast cancer, BRCA1 mutation was associated with aggressive pathologic characteristics and TN phenotype. However, direct association between BRCA mutations and MRI features was not observed. Rim enhancement was frequently seen on MRI in high grade tumors and in TN phenotype, and a significant predictor of increased early recurrence of disease.
No conflict of interest.

1168 POSTER

Preoperative assessment of gastrointestinal stromal tumors using diffusion-weighted magnetic resonance imaging

K. Narushima[1], K. Shuto[2], S. Imanishi[1], T. Kono[1], G. Ohira[1], T. Toma[1], H. Gunji[1], T. Tochigi[1], T. Hanaoka[1], H. Matsubara[1]. *[1]Graduate School of Medicine Chiba University, Frontier Surgery, Chiba, Japan; [2]Teikyo University Medical Center, Surgery, Chiba, Japan*

Background: In Gastrointestinalstromal tumors (GIST), surgical indication is an important problem, and the malignant evaluation is indispensable. In recently modified Flecher risk classification and UICC-TNM are made, and it was shown for the risk evaluation that mitosis count and the tumor size are index. The establishment of clinical diagnostics count is a problem.
Method and Materials: Fifty-three patients who underwent surgical resection were enrolled (esophagus 1, stomach 39, small bowel 7, Cecum 1 and rectum 5; mean size 4.3 cm, range 1.4−21 cm). Prior to surgery, Diffusion-weighted Magnetic Resonance imaging was performed by SENSE-STIR-EPI TR/TE 10000/75 ms, 4 mm, b=0, 1000 sec/mm2. Apparent diffusion coefficient Minimum value (ADCmin) of the tumor was measured Histological diagnosis was made by immunohistological staining of c-kit and CD34. Risk groups were estimated by assessing tumor size and mitosis per 50 HPFs based on modified Flecher risk classification and UICC-TNM. We evaluated the relationship between ADCmin and risk groups, Stage.
Results: There was a correlation of ADCmin between tumor size (R = −0.43, P = 0.001). There was a correlation of ADCmin between mitosis (R = −0.41, P = 0.003). ADCmin of very low-risk group was 1.39 +/− 0.26, low-risk 1.23 +/− 0.29, intermediate-risk 1.29 +/− 0.18 and high-risk 0.80 +/− 0.23. ADCmin of high-risk group was higher than that of other groups with a statistical difference (P = 0.001). The cut-off ADCmin level of 0.8 revealed 76.9% sensitivity and 97.5% specificity and 90.9% positive predictive value and 92.9% negative predictive value and 92.5% accuracy in predicting high-risk group. ADCmin of Stage I group was 1.28 +/− 0.29, Stage II 1.20 +/− 0.18 and Stage III/IV 0.75 +/− 0.23. ADCmin of Stage

III/IV group was higher than that of other groups with a statistical difference (P = 0.001).
Conclusion: Diffusion-weighted MRI may enable to discriminate high-risk group from other groups with high accuracy and to discriminate high-risk group from others with high specificity. It may become one of the valid clinical modalities for evaluating risk group of GIST.
No conflict of interest.

1169 POSTER

Diagnostic performance of the combination of multi detector-row computed tomography and fluorodeoxyglucose-positron emission tomography and diffusion-weighted magnetic resonance imaging for preoperative esophageal squamous cancer lymph node

T. Hanaoka[1], K. Shuto[2], T. Tochigi[1], K. Hujishiro[1], K. Narushima[1], T. Kono[1], H. Matsubara[1]. *[1]Graduate School of Medicine Chiba University, Department of Frontier Surgery, Chiba, Japan; [2]Teikyou University Medical Center, Department of Surgery, Chiba, Japan*

Background: Lymph node diagnosis is important in determining the course of treatment of esophageal cancer. Lymph node metastasis of esophageal cancer currently is done by multi detector-row computed tomography (MDCT) mainly, it is made in the size and morphological evaluation to identify the lymph nodes. MDCT is superior in resolution, but is poor in qualitative diagnosis. fluorodeoxyglucose-positron emission tomography (FDG-PET) and diffusion-weighted magnetic resonance imaging (DWI) is superior to qualitative diagnosis, utility as a diagnostic aid in the lymph nodes of esophageal cancer is not being considered.
We use MDCT and DWI and FDG-PET to the lymph nodes preoperative diagnosis. We examined the usefulness of DWI and FDG-PET in the diagnosis.
Material and Methods: 47 cases of esophageal squamous cell carcinoma resection with no preoperative treatment. 2813 lymph nodes were dissected, it was identified in the CT 252(9.0%). The meta diagnosed with a case in which diameter more than 10 mm and ratio of the major axis and single size 0.7 or more are met. Further, diagnosis of metastasis even if it meets rim enchancement. Line of SUV value was set to 3.0 and Line of ADC value was set to 1.5 than the data in the normal tissue and abnormal tissue of esophageal cancer. Line of ADC was possible to distinguish 100% non-metastatic lymph nodes allow the diffusion suppression and metastatic lymph nodes that allow the diffusion suppression in DWI.
Result: Sensitivity 19.1% positive predictive value 69.2% correct diagnosis rate 83.3% in the CT diagnosis. Sensitivity decreases to 12.8% by the addition of PET to CT diagnosis, PPV was increased to 100%, overall accuracy rate was increased to 83.7%. By adding a DWI in CT diagnosis sensitivity is next to 48.9%, PPV is next 100%, overall accuracy rate became 90.2%. DWI was increased the sensitivity significantly.
Conclusions: Combination of the PET is not lead to increase overall accuracy rate, but it is suitable to maintain a high PPV.
Combination of DWI increased sensitivity and overall accuracy, and improve the diagnostic performance of the lymph nodes.
No conflict of interest.

1170 POSTER

Diffusion weighted magnetic resonance imaging for assessing the early response to chemoradiotherapy for advanced esophageal squamous cell carcinoma

T. Hanaoka[1], K. Shuto[2], S. Imanishi[3], T. Kono[3], H. Matsubara[3]. *[1]Graduate School of Medicine Chiba University, Department of Frontier Surgery, Chiba, Japan; [2]Teikyo University Medical Center, Department of Surgery, Chiba, Japan; [3]Graduate School of Medicine Chiba University, Department of Frontier Surgery, Chiba, Japan*

Background: Predicting the outcome at an early stage of chemoradiotherapy (CRT) for advanced esophageal squamous cell carcinoma (eSCC) can prevent the exposure of the patient to ineffective and unnecessary toxicity. Identifying the patients of which treatment is effective could increase the probability of surgical resection and finally improve the prognosis of locally advanced eSCC. The aim of this study was to investigate the utility of the apparent diffusion coefficient (ADC) value in Diffusion Weighted Magnetic Resonance Imaging (DWMRI) for prediction and early detection of treatment response in advanced eSCC.
Materials and Methods: Twenty-seven consecutive patients with primary cT4 eSCC who underwent CRT were retrospectively evaluated. Patients received accelerated radiotherapy. Chemotherapy was performed with 5FU and CDDP. CRT response was assessed at the end of a 40 Gy the clinical response of the primary tumor was discriminated as follows: CR; disappearance of tumor, PR; at least a 30% decrease, PD; at least a 20% increase, SD; not CR, PR nor PD. CR and PR were estimated as responders. Responder patients underwent operation. Meanwhile, non-responder patients underwent definitive CRT until the 60 Gy. DWMRI was performed before CRT, after 20 Gy and after 40 Gy. We measured tumor ADCs (x 10^{-3} mm^2/s) and compared with the therapeutic effect between responders and non-responders.
Results: The ADC value of 20 Gy was significantly higher in responders in comparison to non-responders (1.13 vs. 0.93; P = 0.005). Cut-off ADC value was set at 1.00 by Receiver Operating Characteristic analysis. The ADC predicted the responders with a sensitivity, positive predictive value(PPV), and accuracy of 79%, 73%, and 74%, respectively. The increase rate of the ADC at the period of 20 Gy (ADC20) was also significantly higher in the responders in comparison to the non-responders (35.4% vs. 1.5% P = 0.0007). An ADC cut-off value for ADC20 of 15% predicted the responders with a sensitivity, PPV, and accuracy of 71%, 100%, and 85%, respectively. At the time of 20 Gy, eleven patients were less than cut-off level both of ADC and ADC (Group A). Ten patients of Group A were non-responders. Sixteen patients were more than cut-off level either ADC or ADC (Group B). Thirteen patients of Group B were responders.
Conclusion: DWMRI is a non-invasive functional modality for eSCC. It may predict early response after CRT and also available to estimate outcome after the treatment.
No conflict of interest.

1171 POSTER

Detection of liver tumors by indocyanine green fluorescence: Results and perspectives

J. Ferrario[1], A. Peloso[1], M.C. Canepa[1], L. Briani[1], L. Barbieri[1], B. Maiga[1], S. Delfanti[1], T. Dominioni[1], J. Viganò[1], M. Maestri[1]. *[1]Fondazione IRCCS Policlinico S. Matteo, Surgery, Pavia, Italy*

Introduction: The gold standard to treat liver metastases from colorectal cancer is a parenchymal resection that achieves a R0 result at final pathology. This is a major determinant for a prolonged disease free survival. However the current imaging techniques can face a limit of resolution. Possibly one could find an intraoperative staging worse that expected from the preoperative workup. Recently Indocyanine green fluorescence has been proposed to improve the intraoperative staging of liver tumors in synergy with IOUS.
Material and Methods: 30 patients with colorectal metastases were enrolled. Each had a i.v. bolus of ICG (0.5 mg pro kg of body weight) 24 hrs before surgery. ICG fluorescence, which accumulates around neoplastic lesions as a result of defected biliary clearance, was detected intraoperatively with a specifically near-infrared camera system (PDE-PhotoDynamicEye). We recorded the total number of lesions detected by PDE-ICG, intraoperative ultrasound (IOUS) and preoperative computed tomography (CT).
Results: The combined use of PDE-ICG and IOUS revealed 30% more nodules than IOUS alone and 40% more than preoperative CT. While the detection was quite similar for nodules >3 mm, PDE-IOUS was significantly superior for nodules <3 mm.
Conclusions: The chase for radical liver surgery requires imaging techniques that effectively detect all the tumor deposits. PDE-IOUS detection could foster our ability to find and remove undiscovered liver nodules. Probably we should recognize that current imaging still has limits. New technologies will probably modify our approach to liver resections.
No conflict of interest.

1172 POSTER

Evaluation of malignancy for esophageal cancer by dynamic FDG-PET

T. Tochigi[1], K. Shuto[1], T. Kono[1], S. Okazumi[1], H. Matsubara[1]. *[1]Graduate School of Medicine Chiba University, Frontier Surgery, Chiba, Japan*

Background: One of the basic characteristics of cancer includes heterogeneity. The heterogeneity of the tumor tissue is thought to have influence to the sensitivity such as an anticancer agent or the radiation and is thought one of the treatment-resistant causes. In late years a cancer stem cell hypothesis is advocated, and the biological malignancy evaluation of cancer by the molecular biologic technique attracts attention. It is the present conditions that there are few reports about the heterogeneity of the tumor tissue. We analyze heterogeneity in the glucose metabolism of the esophageal cancer by applying a fractal dimensional analysis using Dynamic FDG-PET (dPET). The fractal dimension is a parameter of heterogeneity and it is used for brain blood flow evaluations by the SPECT, for example.
Methods and Materials: Our evaluation study included 30 patients of esophageal cancer. dPET studies were performed after intravenous injection of 370 MBq ^{18}F-FDGfor 60 min. All patients were examined with

a 23-frame protocol (10 frames of 1 min, 5 frames of 2 min, and 8 frames of 5 min). The evaluation of the dynamic PET was performed using the software package PMod (PMod Ltd.,Zurich, Switzerland). Fractal dimension (FD) was calculated for the time-activity-data in each individual voxel of a VOI (volume of interest, consists of several regions of interest (ROI) over the target area). We compared SUVmax with FD and examined a change of FD in before and after preoperative adjuvant therapy, and an association of clinical progress.
Results: FD has a stronger correlation in a clinical progression than SUVmax; by the comparison between a clinical depth of tumor invasion (cT) and FD, $r^2 = 0.603$ whereas $r^2 = 0.5733$ SUVmax, and by the comparison between a clinical stage of tumor (cStage) and FD, $r^2 = 0.5929$ whereas $r^2 = 0.5694$ SUVmax. When we compared a rate of decline of FD before and after treatment in preoperation, in the case with the rate of decline of FD more than 10 the effect was grade 2 or 3 in postoperative pathology, in the rate of decline of FD is less than 10 the grade was 1. It was confirmed pathologically that the rate of decline of FD reflected an effect of the treatment more exactly than that of SUV in preoperation.
Conclusions: FD is a useful parameter for indicating heterogeneity of tumor, and clinically it is thought that FD is feasible for a preoperative curative effect judgment. It becomes the new parameter for the SUV.
No conflict of interest.

1173 POSTER

Optical coherence tomography (OCT) in pigmented lesions

R. Wessels[1], D.M. De Bruin[2], G.N. Relyveld[3], D.J. Faber[4], A.D. Vincent[5], J. Sanders[6], T.G. Van Leeuwen[4], T.J.M. Ruers[1]. *[1]Netherlands Cancer Institute, Department of Surgery, Amsterdam, Netherlands; [2]Academic Medical Center, Biomedical Engineering and Physics and Department of Urology, Amsterdam, Netherlands; [3]Netherlands Cancer Institute, Department of Dermatology, Amsterdam, Netherlands; [4]Academic Medical Center, Biomedical Engineering and Physics, Amsterdam, Netherlands; [5]Netherlands Cancer Institute, Department of Biometrics, Amsterdam, Netherlands; [6]Netherlands Cancer Institute, Department of Pathology, Amsterdam, Netherlands*

Background: Cutaneous malignant melanomas are diagnosed worldwide in about 200,000 patients per year. To reduce mortality, early diagnosis is important. Optical coherence tomography (OCT) measures backscattered light like ultrasound measures backscattered sound waves. The backscattered light versus the depth is described by the attenuation coefficient (μ_{oct}). We hypothesize that OCT images of benign nevi will differ qualitatively and quantitatively from malignant melanomas, enabling the dermatologist real time, non-invasive measurement of suspicious lesions.
Material and Methods: Forty lesions from thirty-three consecutive patients were imaged with OCT. Directly after data acquisition, excision was performed. Images were studied with attention to morphological details. Epidermal layer thickness was measured and values of μ_{oct} were extracted from 200 OCT images of pigmented lesions.
Result: Morphologically, absence of the lower border of the lesion was characteristic for melanoma ($p = 0.02$). Also, the attenuation coefficient (μ_{oct}) was different between benign and malignant lesions ($p = 0.02$). There were no differences in epidermal layer thickness of benign lesions and malignant melanoma.
Conclusion: This study shows that quantitative analysis of OCT images in pigmented skin lesions gives valuable additional information about lesions characteristics. When using the attenuation coefficient, it becomes possible to distinguish between benign lesions and malignant melanoma.
No conflict of interest.

1174 POSTER

Optical coherence tomography (OCT) in neoplasia of the penis

R. Wessels[1], D.M. De Bruin[2], D.J. Faber[3], S. Horenblas[4], B.W.G. Van Rhijn[4], A.D. Vincent[5], T.G. Van Leeuwen[3], T.J.M. Ruers[6]. *[1]Netherlands Cancer Institute, Department of Surgery, Amsterdam, Netherlands; [2]Academic Medical Center, Biomedical Engineering and Physics, Department of Urology; [3]Academic Medical Center, Biomedical Engineering and Physics, Amsterdam, Netherlands; [4]Netherlands Cancer Institute, Department of Urology, Amsterdam, Netherlands; [5]Netherlands Cancer Institute, Department of Biometrics, Amsterdam, Netherlands; [6]Netherlands Cancer Institute − University Twente, Department of Surgery- MIRA Institute, Amsterdam Twente, Netherlands*

Introduction: Optical coherence tomography (OCT) measures backscattered light like ultrasound measures backscattered sound waves. With OCT, non-invasive micro-scale resolution volumetric *in vivo* image datasets of (pre)malignant lesions of the penis are obtained, closely resembling histopathology. Moreover, the OCT-signal can be quantified, using the attenuation coefficient (μ_{oct}). This quantitative parameter, μ_{oct}, may vary along different histological types of tissue. We hypothesize that qualitative and quantitative measurements of penile skin with OCT can differentiate between benign and (pre)malignant tissue.
Material and Methods: OCT-imaging was performed at the outpatient clinic of the NKI-AvL. All OCT- images were conducted in vivo and were analyzed afterwards. Directly after imaging, a punch biopsy was performed. One investigator, blinded for pathology, performed the qualitative analysis as well as the quantitative analysis. Qualitative analysis consisted of epidermal layer thickness measurements and determination of visible lower border of the lesions, quantitative analysis comprised of determination of the μ_{oct} of the suspicious lesions. All results were grouped according to histopathology reports.
Results: OCT images of 18 penile lesions of 18 patients were analyzed. Qualitative analysis showed a statistically significant difference ($p = 0.047$) between benign and (pre)malignant lesions with regard to the visibility of the lower border of the lesions. Also, epidermal layer thickness was significantly different between benign and (pre)malignant tissue ($p = 0.001$). Quantitative analysis showed an attenuation coefficient (μ_{oct}) of benign and (pre)malignant lesions of 2.47 mm^{-1} (SE 0.52 mm^{-1}) and 5.23 mm^{-1} (SE 0.32 mm^{-1}) respectively ($p < 0.001$).
Conclusion: OCT imaging and quantitative analysis of suspicious penile lesions has the ability to differentiate benign penile lesions from (pre)malignant penile lesions.
No conflict of interest.

1175 POSTER

Optical coherence tomography in vulvar squamous cell carcinoma

R. Wessels[1], M. Van Beurden[2], D.M. De Bruin[3], D.J. Faber[4], A.D. Vincent[5], J. Sanders[6], T.G. Van Leeuwen[4], T.J.M. Ruers[7]. *[1]Netherlands Cancer Institute, Department of Surgery, Amsterdam, Netherlands; [2]Netherlands Cancer Institute, Department of Gynaecology, Amsterdam, Netherlands; [3]Academic Medical Center, Biomedical Engineering and Physics, Department of Urology; [4]Academic Medical Center, Biomedical Engineering and Physics, Amsterdam, Netherlands; [5]Netherlands Cancer Institute, Department of Biometrics, Amsterdam, Netherlands; [6]Netherlands Cancer Institute, Department of Pathology, Amsterdam, Netherlands; [7]Netherlands Cancer Institute − University Twente, Department of Surgery- MIRA Institute, Amsterdam, Netherlands*

Objective: Vulvar squamous cell carcinoma (VSCC) is the fourth most common gynaecological type of cancer with an incidence of approximately 2−3 per 100,000 women. VSCC arises from, and occasionally next to, premalignant lesions called vulvar intraepithelial neoplasia (VIN). VIN and VSCC are diagnosed through painful and invasive punch biopsy.
Optical coherence tomography (OCT) is a non invasive optical imaging technique that measures backscattered light like ultrasound measures backscattered sound waves. OCT has the potential to reduce the number of biopsies by performing an optical tissue diagnosis. We hypothesize that: a) specific qualitative features in the OCT images will differ between normal vulvar skin, VIN and VSCC, b) thickness of the epidermal layer of the skin, measured in the OCT-images, is different for normal, VIN and VSCC tissue, c) quantitative measurements of the OCT image, such as the attenuation coefficient (μ_{oct}), can differentiate between VIN, VSCC and normal vulvar tissue.
Material and Methods: Eighteen consecutive patients diagnosed with VSCC were included. Tumour and surrounding tissues were imaged with OCT. Directly after data acquisition, biopsies for histopathological correlation were taken. Thereafter, wide local excision or (partial) vulvectomy was performed. In the OCT-images specific features were sought, that could differentiate between the different tissue types In addition, epidermal layer thickness was measured and values of μ_{oct} were extracted from the OCT data. For both methods, statistical analysis was performed using mixed effects regression analysis.
Results: Qualitative analysis of OCT images showed an evident epidermal layer and a clear basement membrane layer in normal vulvar skin, while these layers could not be observed in VIN and VSCC ($p < 0.0001$).
OCT images showed a significant difference in epidermal layer thickness between normal vulvar tissue and VIN or VSCC ($p < 0.0001$) where no difference was found between VIN and VSCC. When looking at μ_{OCT}, a statistically significant difference between normal skin and VIN ($p = 0.001$) was found as well as between normal vulvar skin and VSCC ($p < 0.0001$). There was no difference between the μ_{OCT} of VIN and VSCC ($p = 0.68$).
Conclusion: This study demonstrates that OCT may be a helpful technique for non invasive tissue diagnosis of vulver malignancies.
No conflict of interest.

Pitfalls with the independent audit method of PFS endpoint trials with central imaging

O. Bohnsack[1], A. Schmid[2], L. Chen[2], B. Chandler[2]. [1]*Parexel International GmbH, Berlin, Germany;* [2]*Parexel International GmbH, Billerica, USA*

ODAC (Oncologic Drug Advisory Committee) discussed the pros and cons of implementing subpopulation audit methods of sites' assessments in oncology trials with PFS endpoints. Instead of a complete Blinded Independent Central Review (BICR) of the entire study population only a few selected cases should undergo BICR.
The discussion is about two potential methods introduced by Dodd et al., 2008, 2011 and Amit et al., 2011. In these papers the authors attempt to reduce the risk of informative censoring, optimize trial conduct and reduce associated cost.
Both authors describe novel and interesting methods to be used. Based on logistical and even more so statistical complexities inherent in both these methods in their current form neither will achieve any of the proposed goals of reducing cost, complexity, time and data censoring challenges.
This paper challenges the proposed processes and provides detailed explanations to introduced obstacles logistically, timewise, statistically, operationally. Either method increases the complexity of conducting Oncology trials. The study duration can not be shorter but rather longer in most study designs. The statistical impact of any such discrepancy between Local Evaluations (LE) and BICR are not foreseeable and not at all defined. Operationally, any sponsor and imaging CRO together need to invent new and abandon well established and industry-accepted processes. This will increase the risk, complexity and as such any chance for errors.
Based on experience and daily practice this paper gives examples why the proposed audit methods of PFS endpoints with central imaging are not feasible for Oncology trials and rather put patients, sponsors and study data at risk.
No conflict of interest.

1177 POSTER

3D SPECT/CT-based navigation to the sentinel node in the groin

N.S. Van den Berg[1], G.H. KleinJan[1], O.R. Brouwer[2], H.M. Mathéron[2], S. Horenblas[3], H.G. Van der Poel[3], R.A. Valdés Olmos[2], F.W.B. Van Leeuwen[1]. [1]*Leiden University Medical Center, Radiology, Leiden, Netherlands;* [2]*The Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Nuclear Medicine, Amsterdam, Netherlands;* [3]*The Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Urology, Amsterdam, Netherlands*

Background: To further improve the accuracy with which a sentinel node can be detected, the Declipse® SPECT-system (SurgicEye, Munich, Germany) was introduced. This navigation system can incorporate preoperatively acquired SPECT/CT information. By projecting this dataset onto the patient, it enables intraoperative mixed-reality-based navigation to the area of interest (e.g. the sentinel node). This study evaluated the accuracy of the navigation during open- and laparoscopic sentinel node biopsy in urological malignancies.
Materials and Methods: Following tracer injection in penile carcinoma (n = 10) patients, who were scheduled for sentinel node biopsy, preoperative SPECT/CT was performed with a reference target fixed on the patient. For the penile carcinoma patients the reference target was placed on the pubic bone. The location of the reference target was then marked with indelible ink. Prior ot the start of the operation a sterile ReT was repositioned on the patient. A second reference target was positioned on the gamma probe as such allowing the surgeon to navigate the tip of the gamma probe to the sentinel node. Navigation was provided in mixed-reality, in 3D, based on the preoperatively acquired SPECT/CT imaging. The accuracy of the navigation approach was determined in relation to the location pointed out by the conventional gamma probe (coronal plane). The depth measured on the axial CT slices (distance skin surface − sentinel node; sagittal plane) was compared to the depth measured with the navigation system.
Results: In the 10 penile cancer patients, compared to the results obtained with the conventional approach, the average error of navigation was 5.0 mm and 5.3 mm in the coronal and sagital plane, respectively. During exploration, the inaccuracy of navigation could be overcome by both gamma tracing and fluorescence imaging of the sentinel node.
Conclusion: 3D SPECT/CT mixed-reality-based navigation allowed the identification of the sentinel node and has the potential to more accurately guide the surgeon to the area of interest.
No conflict of interest.

1178 POSTER

Quantification of baseline [18]F-FDG PET images predicts treatment response and progression free survival in Hodgkin's lymphoma

B.P. Taylor[1], M. Siddique[1], S.F. Barrington[2], N.G. Mikhaeel[3], G.J.R. Cook[2]. [1]*King's College London, Imaging Sciences, London, United Kingdom;* [2]*King's College London/Guy's & St Thomas' NHS Foundation Trust, Nuclear Medicine/Imaging Sciences, London, United Kingdom;* [3]*Guy's & St Thomas' NHS Foundation Trust, Clinical Oncology, London, United Kingdom*

Background: Efforts to tailor treatments to individual prognosis are important in Hodgkin's Lymphoma (HL) which has a relatively good prognosis but a high chance of developing late treatment effects. Interim PET has shown prognostic value in HL but baseline PET has not yet been extensively studied. In solid tumours the heterogeneity of ^{18}F-FDG uptake as measured by image heterogeneity analysis has been associated with treatment response and survival.
We investigated whether similar predictive and prognostic value exists in the baseline pre-treatment ^{18}F-FDG images.
Material and Methods: 55 consecutive patients with stage II−IV disease were retrospectively analysed (median FU 34 months), defining the nodal mass with the highest SUV on the baseline scan. Interval and end-of-chemotherapy responses were classified according the Deauville Score (Responders = Deauville 1, 2 & 3; Non-responders = Deauville 4 & 5); Overall treatment response was assessed using the Deauville Score combined with clinical evaluation. In-house software was used to measure Standard Uptake Value (SUV) parameters alongside 1st and 2nd order heterogeneity features.
Results: SUVmean, max and peak from the baseline ^{18}F-FDG PET image predicted the end of chemotherapy and overall treatment response ($p \leqslant 0.01$), as well as progression free survival (SUVmax $p = 0.016$, SUVpeak $p = 0.028$). 1st order parameters from region of interest (ROI) analysis similarly predicted end of chemotherapy Deauville response and overall treatment response ($p \leqslant 0.05$).
The 2nd order heterogeneity parameters measured on the baseline PET image using grey-level co-occurrence matrices (GLCM) and grey-level run length (GLRL) analyses predicted the Deauville response of the early interval PET ($p = 0.01$–0.05).
Conclusions: Baseline ^{18}F-FDG PET SUV and other 1st order parameters predict end of chemotherapy Deauville response, overall treatment response and PFS. GLCM and GLRL 2nd order heterogeneity measures of the baseline PET image predicts early response to chemotherapy.
No conflict of interest.

1179 POSTER

Preoperative assessment of gastrointestinal stromal tumors using positron emission tomography

K. Narushima[1], S. Okazumi[2], K. Shuto[3], T. Kono[1], G. Ohira[1], T. Toma[1], H. Gunji[1], T. Tochigi[1], T. Fujishiro[1], H. Matsubara[1]. [1]*Graduate School of Medicine Chiba University, Frontier Surgery, Chiba, Japan;* [2]*Toho University Medical Center, Surgery, Chiba, Japan;* [3]*Teikyo University Medical Center, Surgery, Chiba, Japan*

Background: In Gastrointestinalstromal tumors (GIST), surgical indication is an important problem, and the malignant evaluation is indispensable. In recently modified Flecher risk classification and UICC-TNM are made, and it was shown for the risk evaluation that mitosis count and the tumor size are index. The establishment of clinical diagnostics count is a problem.
Method and Materials: Eighty-seven patients who underwent surgical resection were enrolled (esophagus 5, stomach 66, small bowel 8, Cecum 2 and rectum 6; mean size 5.0 cm, range 2.0−30 cm). Prior to surgery, PET imaging was performed after injection of 370MBq of F18-DG tracer. Standardized uptake value (SUV) of the tumor was measured for evaluation. Histological diagnosis was made by immunohistological staining of c-kit and CD34. Risk groups were estimated by assessing tumor size and mitosis per 50 HPFs based on modified Flecher risk classification and UICC-TNM. We evaluated the relationship between SUV and risk groups, Stage.
Results: There was a correlation of SUV between tumor size (R=0.41, P = 0.0007). There was a correlation of SUV between mitosis (R=0.52, P = 0.0000002). SUV of very low-risk group was 4.0 +/− 2.1, low-risk 3.6 +/− 1.6, intermediate-risk 3.5 +/− 2.0 and high-risk 8.9 +/− 5.4. SUV level of high-risk group was higher than that of other groups with a statistical difference (P = 0.000001). The cut-off SUV level of 5.5 revealed 76.0% sensitivity and 87.5% specificity and 73.1% positive predictive value and 90.2% negative predictive value and 85.1% accuracy in predicting high-risk group. SUV of Stage I group was 3.5 +/− 1.6, Stage II 4.3 +/− 2.3 and

Stage III/IV 10.1 +/− 5.0. SUV level of Stage III/IV group was higher than that of other groups with a statistical difference (P = 0.000001).
Conclusion: FDG PET may enable to discriminate high-risk group from other groups with high accuracy and to discriminate high-risk group from others with high specificity. It may become one of the valid clinical modalities for evaluating risk group of GIST.
No conflict of interest.

1180 POSTER

Utility of PET scan for early diagnosis of bleomycin induced pneumonitis in Hodgkin's Lymphoma

S. Mittal[1], M. Sengar[1], V. Rangarajan[2], N. Purandare[2], S. Tandon[3], U. Dangi[1], N. Tandon[1], H. Menon[1]. *[1]Tata Memorial Hospital, Medical Oncology, Mumbai, India; [2]Tata Memorial Hospital, Nuclear Medicine, Mumbai, India; [3]Tata Memorial Hospital, Internal Medicine, Mumbai, India*

Background: Bleomycin induced pneumonitis (BIP) is an inflammatory process occurring with use of Bleomycin. This is an idiosyncratic response which is debilitating, potentially irreversible and at times ending in fatality (up to 27%). Currently, signs & symptoms, pulmonary function tests (PFT), carbon monoxide diffusion capacity (DLCO) and high resolution computed tomography (HRCT) are used to diagnose BIP. Unfortunately these reveal only manifest BIP. Positron emission tomography (PET), has shown promise to detect early inflammatory changes, a key feature of early BIP. We prospectively explored the abilty of PET scan to detect early BIP and compared it with standard existing modalities such as DLCO and HRCT in our patients with Hodgkin's Lymphoma (HL).
Methods: This was a prospective observational single centre study wherein, newly diagnosed HL treated with the ABVD regimen from November 2011 to July 2012 was included. After baseline staging evaluation, ABVD was instituted. All were monitored every two cycles for any form of BIP, assessed clinically, by PFT, DLCO and PET scan with HRCT chest. If none occurred they were followed up until completion of treatment. Data was analyzed using SPSS v 16.0.
Results: 75 patients were enrolled in the study and 59 were evaluable for final analysis. 49% had advanced stage, 12% were smokers and 8% had history of tuberculosis. 25 (40%) had features suggestive of BIP based on any one or combination of tests. 11/25 showed PET positivity but 14/25 were negative on PET while showing clinical or PFT findings indicative of BIP. 7/25 and 9/25 were positive only on PET and DLCO respectively but were asymptomatic for BIP. 5/25 were clinically symptomatic for BIP and correlated with DLCO but were negative on PET. Only 2/25 was both positive by PET and PFT combined but remained asymptomatic. 2/25 patients had all three parameters indicative of BIP. 34 patients remained negative.
Conclusions: Our study showed PET scan to be sensitive in detecting early BIP but did not directly correlate with standard testing and clinical suspicion. It however provides a platform for exploring its utility for detecting early BIP.
No conflict of interest.

Table 1. Bleomycin induced pneumonitis in 25 patients

1181 POSTER

Role of the maximal standardized uptake value on fluorine 18 fluorodeoxyglucose positron emission tomography /computed tomography for predicting malignancy grade of operable breast cancer

T. Kadoya[1], K. Aogi[2], S. Kiyoto[2], E. Akimoto[1], A. Emi[1], H. Shigematsu[1], N. Masumoto[1], Y. Sugawara[3], M. Okada[1]. *[1]Hiroshima University Hospital, Surgical Oncology, Hiroshima city, Japan; [2]Shikoku Cancer Center, Breast Surgery, Matsuyama city, Japan; [3]Shikoku Cancer Center, Radiation Therapy, Matsuyama city, Japan*

Background: [18F]-fluorodeoxyglucose (FDG) positron emission tomography (PET)/computed tomography (CT) is potentially useful not only in examining and assessing metastasis but also in predicting prognosis of recurrent breast cancer and measuring treatment effects.
Material and Methods: Stage I−III breast cancer patients who underwent preoperative FDG-PET/CT and who were able to undergo radical surgery at the Hiroshima University Department of Breast Surgery and the Shikoku Cancer Center between January 2006 and December 2011, were included in this study (median follow up period:26.5 months). The maximal standardized uptake value (SUVmax) were assessed for predicting disease free survival (DFS). For the evaluation of relationship between SUVmax values and prognostic factors such as hormone receptors, human epidermal growth factor receptor 2 (HER2), nuclear grade, lymph node metastasis and tumor size, statistical analyses were performed using Student t test and log-rank test, and p values of less than 0.05 were considered to indicate statistically significant differences.
Results: Clinical Stage included were I (n = 194, 56.4%), II (n = 134, 39.0%) and III (n = 16, 4.7%). Tumors with estrogen receptor (ER) positive were 292 (84.9%) and negative were 52 (15.1%). All patients were divided into two groups according to cut-off SUVmax established on the basis of receiver operating characteristic (ROC) analysis ($\leqslant$3.0 vs >3.0, AUC=0.713). There was a significant difference in DFS between two groups (p = 0.001) and, hormone receptor, HER2, nuclear grade, lymph node metastasis were found strong relation to SUVmax values. SUVmax and ER status were predictive factors with multivariable analysis using cox proportional hazard regression model (p = 0.033 and p = 0.004, respectively). Furthermore patients were categorized in 3 subtypes including luminal (ER+, HER2−, n = 260), HER2 (ER− or ER+, HER2+, n = 47), and triple-negative type (ER−, HER2−, n = 37), and average SUVmax in each subtype were 3.24$\pm$2.64 in luminal, 5.01$\pm$3.60 in HER2, 4.99$\pm$4.57 in triple-negative type.
Conclusions: Our results suggest that SUVmax on preoperative FDG PET/CT have a predictive value for high-grade malignancy and prognosis in clinical Stage I−III breast cancer and it might be necessary to determine the cut-off points for each subtype for use in determining the course of treatment.
No conflict of interest.

Subtype	n (total 344)	SUVmax (average$\pm$SD)	Recurrence (total 17)
Luminal	260	3.24$\pm$2.64	6
HER2	47	5.01$\pm$3.60	5
Triple-negative	37	4.99$\pm$4.57	6

Nuclear medicine in the study of multidrug resistance in hepatocellular carcinoma: Studies with 18F-FDG and 99mTC-MIBI

A.F. Brito[1], M. Mendes[2], M. Ribeiro[3], A.M. Abrantes[1], J. Casalta-Lopes[1], A.C. Gonçalves[4], A.B. Sarmento-Ribeiro[4], J.G. Tralhão[5], M.F. Botelho[1]. *[1]Biophysics Unit − IBILI, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [2]Physics Department, Faculty of Science and Technology of University of Coimbra, Coimbra, Portugal; [3]Life Sciences Department, Faculty of Science and Technology of University of Coimbra, Coimbra, Portugal; [4]Applied Molecular Biology and Hematology Group, Faculty of Medicine of University of Coimbra, Coimbra, Portugal; [5]Surgical Department − Surgery A, Coimbra University Hospitals, Coimbra, Portugal*

Background: Hepatocellular carcinoma (HCC) is known to be resistant to chemotherapy, which is due in part to overexpression of multidrug resistance proteins (MDR). A method to evaluate the function of these proteins involves the measure of radiolabeled substrate ^{99m}Tc-MIBI uptake. Studies have demonstrated that ^{18}F-FDG uptake is associated with MDR proteins expression in HCC. Other studies have demonstrated that ^{18}F-FDG uptake by HCC is associated with p53 expression since tumors with lower expression or mutated expression of this protein has a higher uptake of this tracer. This study aims evaluate the uptake and retention of ^{18}F-FDG and ^{99m}Tc-MIBI in three human HCC cell lines and to correlate them with the expression of three MDR proteins and with p53 expression.
Methods: Cell lines used were HepG2 (wp53), HuH7 (mp53) and Hep3B2.1−7 (p53null). Uptake and retention studies with ^{18}F-FDG or ^{99m}Tc-MIBI were performed. Cells grown were evaluated in low glucose medium (5mM) and in high glucose medium (25mM) in order to verify the influence of the glucose on ^{18}F-FDG and ^{99m}Tc-MIBI uptake and retention. Pgp, MRP1 and LRP proteins were determined by flow cytometry. To evaluate MDR modulation, retention studies were performed in the presence of verapamil (Pgp inhibitor) prior to incubation with ^{18}F-FDG or ^{99m}Tc-MIBI.

Results: For all cell lines used, ^{18}F-FDG and ^{99m}Tc-MIBI uptake and retention were higher when cells grown on low glucose medium. For both media formulations Hep3B2.1−7 cell line has higher uptake and retention of ^{18}F-FDG and ^{99m}Tc-MIBI. HepG2 cell line has a lower uptake and retention and a higher expression of MRP1. Through modulation studies with cells incubation with verapamil, a considerable increase of ^{18}F-FDG and ^{99m}Tc-MIBI retention in all cell lines were obtained.
Conclusions: It is concluded that medium glucose concentration influences the uptake and retention of both radiopharmaceuticals. There is an inverse relationship between MRP1 expressions and uptake and retention of ^{99m}Tc-MIBI and ^{18}F-FDG. Through modulation studies it was found that Pgp has an active role on MDR in HCC. Uptake and retention profiles for the two radiopharmaceuticals are similar, showing that the ^{18}F-FDG can be used to study the MDR proteins function in HCC cells, being an alternative to ^{99m}Tc-MIBI. We also conclude that p53 expression influences ^{18}F-FDG uptake once Hep3B2.1−7 and HuH7 cell lines have higher uptake than HepG2.
No conflict of interest.

1183 POSTER

The effect of respiratory motion of diaphragm on positron emission tomography/computed tomography for patients with clinical stage IA lung adenocarcinoma

T. Yoshiya[1], Y. Miyata[1], T. Mimae[1], Y. Ibuki[1], H. Nakayama[2], S. Okumura[3], M. Yoshimura[4], M. Okada[5]. *[1]Hiroshima University, Surgical Oncology, Hioshima, Japan; [2]Kanagawa Cancer Center, Thoracic Surgery, Yokohama, Japan; [3]Cancer Institute Hospital, Thoracic Surgery, Tokyo, Japan; [4]Hyogo Cancer Center, Radiology and Thoracic Surgery, Akashi, Japan; [5]Hiroshima University, Surgical Oncology, Hiroshima, Japan*

Objectives: F-18-fluorodeoxyglucose positron emission tomography/computed tomography (PET/CT) is reported to be a surrogate marker of tumor malignancy grade in lung adenocarcinoma. However, respiratory motion of diaphragm resulted in reducing the measured maximal standardized uptake value (max SUV) on PET/CT of tumors, especially localized in the lower zone of lung. The purpose of this study is to compare the diagnostic significance of max SUV to predict tumor malignancy and prognosis between upper zone (UZ, containing segment 1, 2, 3 and 6) and lower zone (LZ, containing segment 4, 5, 7, 8, 9 and 10) in patients with early stage lung adenocarcinoma.
Methods: 608 consecutive patients with clinical stage IA lung adenocarcinoma who had undergone preoperative PET/CT were enrolled in this study. Tumor location (UZ, n = 383; LZ, n = 225) and surgical results were retrospectively analyzed for all patients.
Results: Although there were no significant differences between UZ and LZ patients in terms of sex, age, whole tumor size, solid component size, lymphatic invasion (ly), vascular invasion (v), pleural invasion (pl) and lymph nodes metastasis (n), max SUV in UZ is significantly higher than that in LZ (2.4±2.4 VS 2.0±1.8, respectively, p = 0.013). All receiver operating characteristics area under the curve of max SUV for predicting ly, v, pl, n, and high-grade malignancy (ly, v, pl or n) were larger for UZ tumor than those for LZ tumor. Moreover cut-off values of maxSUV for predicting pathological malignancy (ly, v, pl, and n) in UZ and LZ were 2.4 vs 1.9, 2.5 vs 1.9, 2.3 vs 1.9, and 2.8 vs 1.6, respectively. The predictability of all outcomes on the basis of maxSUV in UZ seemed to be better than that in LZ and cut-off values in UZ tended to be higher than that in LZ.
Conclusion: MaxSUV of tumors in LZ may be affected by the respiratory motion of diaphragm and apparently become lower than those which reflects a real malignant potential of tumors. Deep-inspiration breath-hold PET/CT could resolve this problem in order to precisely evaluate the malignant grade of tumors and to select appropriate surgical procedures.

Characterization and analysis of tumorous 18F FDG-avidity in deaths due to differentiated thyroid cancer

D.H.Y. Shen[1], L.F. Lin[1], C.H. Hou[1], C.Y. Cheng[1]. *[1]Tri-Service General Hospitall National Defense Medical Center, PET & Nuclear Medicine, Taipei City, Taiwan*

One of the major roles of ^{18}F Fluorodeoxyglucose (FDG) PET in managing differentiated thyroid cancer (DTC) is to detect the non-iodine avid or dedifferentiated tumors and therefore, the FDG avidity is regarded as a poor prognostic indicator. In this study we attempt to characterize and analyze the FDG PET findings in patients dying due to advanced DTC.
Material and Methods: Our institutional cancer registry has maintained a record of all patients with malignancies seen at our hospital since 1983. The registry was searched for cases with diagnosis of thyroid cancers and also to determine if the death cause is thyroid cancer-related. A total of 290 such patients were known to be expired during the follow-up and 67.9% (197/290) were ascribed to die from thyroid cancer after exclusion of non-cancer related deaths (N = 60) or dying due to other known (N = 21) or unknown (N = 12) malignancies. We further review the cases ever assessed by FDG PET within 2 years before their death and categorized the patterns and FDG avidity of tumors on PET. The lesional FDG avidity of each case was measured from the most dominant ones and presented as maximal standardized uptake value (SUVmax).
Result: Totally 38 cases of FDG PET were analyzed and 26 of them showed extensive FDG-avid metastatic lesions including: lung (N = 17), bone (N = 9), liver (N = 3), brains (N = 2), neck and mediastinal lymph nodes (N = 11) and other soft tissues (N = 6). There were 8 cases with only loco-regional tumor with FDG uptake at neck region. The SUVmax of bony lesions were significantly higher than the others whereas the pulmonary and cervical lesional FDG-avidity could vary greatly, 1.1 to 8.4 (lung), 1.3 to 7.2. However, there were four cases showing none of obvious FDG-avid lesion demonstrated on the PET.
Conclusion: As FDG PET begins to gain its role in assessing advanced DTC and our observation of FDG-avid metastasis pattern as well as tumor FDG uptake of different tumor sites in these DTC patients with imminent death might raise more clinical interests in related investigation.

Predictive outcome assessment of extravasation injuries by use of indocyanine green video angiography

W. Haslik[1], U. Pluschnig[2], G.G. Steger[2], C.C. Zielinski[2], K. Schrögendorfer[1], M. Frey[1], R. Bartsch[2], R.M. Mader[2]. *[1]Comprehensive Cancer Center of the Medical University of Vienna, Dept. of Surgery, Vienna, Austria; [2]Comprehensive Cancer Center of the Medical University of Vienna, Dept. of Medicine I, Vienna, Austria*

Background: Extravasation of cytotoxic drugs constitutes a serious complication of cancer treatment. So far, a reliable method for early and predictive assessment of tissue damage is still missing. In this study, we evaluated superficial blood flow as assessed by indocyanine green (ICG) angiography in the affected extravasation area as a possible prognostic parameter. Aim of the study was to discriminate between sufficiency of conservative treatment versus the need for later surgical intervention.
Material and Methods: 29 patients were evaluated by ICG angiography after extravasation of vesicant or highly irritant cytotoxic drugs administered by peripheral i.v. infusion. To this aim, 0.2 mg/kg ICG (Pulsion Medical Systems, Germany), tricarbocyanine dye that binds quantitatively to plasma proteins, were injected i.v. to the contralateral extremity. Perfusion index and maximum pixel intensity of the defined regions of interest were individually calculated after recording by dynamic laser-fluorescence-videography (IC-VIEW®).
Results: The perfusion index at the site of extravasation differed significantly between patients (n = 22) with reversible tissue damage and thus healing under conservative management versus those (n = 7) who needed surgical intervention due to the development of necrosis (p = 0.0001). In patients benefiting from conservative management, the perfusion index was significantly higher in the central extravasation area denoting hyperaemia, when compared with the peripheral area (p = 0.0001).
Conclusions: In this cohort of 29 patients, ICG angiography as indicator of superficial local perfusion within the extravasation area of i.v. cytotoxic drugs was of prognostic value for tissue damage. ICG angiography could thus be used for the early identification of patients at risk discriminating between the appropriateness of conservative or surgical measures in the management of extravasation of cytotoxic drugs.

Early esophageal squamous cell cancer by high-barium esophagography using flat panel X-ray detector in comparison with histological findings

T. Tochigi[1], K. Shuto[1], H. Staito[1], T. Kono[1], H. Matsubara[1]. *[1]Graduate School of Medicine Chiba University, Frontier Surgery, Chiba, Japan*

Background: In Japan Esophageal squamous cell cancer (eSCC) has been increasing and 5-year survival rate has prolonged in recent years due to standard operation, subtotal esophagectomy with thoraco-abdominal radical lymphadenectomy. Also endoscopic submucosal dissection (ESD) for superficial cancer has become not rare treatment. Because curative operation for eSCC is one of the high invasive surgical treatments of gastro-intestinal diseases, the therapeutic indications for surgery or ESD should be assessed precisely. The aim of this study is to evaluate the depth of tumor

invasion of superficial esophageal cancer by high-barium esophagography (HBE) using flat panel X-ray detector(FPD) and to compare X-ray findings with histological results.
Methods and Materials: 146 lesions of 132 consecutive patients of superficial eSCC in 2007–2012 who underwent esophagectomy or ESD were included. Histological tumor depth was classified into three groups; A (pT1a-EP/pT1a-LPM): carcinoma in situ/invades lamina propria, B (pT1a-MM/pSM1): invades muscularis mucosae/upper 1/3 in submucosa, C (pSM2/pSM3): invades middle 1/3 submucosa or extended to under 1/3. Group A: N = 68, Group B: N = 42, Group C: N = 36. HBE was performed with double-contrast method with 200–230w/v% of bariumsulfate using FPD by three experienced gastroenterologists. X-ray findings were evaluated by morphological findings as follows: longitudinal fold, aggregated nodularity, degree of the depression, roughness, double line in the lateral image, deformation and compliance of wall.
In early period (2007–2010, N = 101 lesions) we compared these X-ray findings with histological results postoperatively, and established new X-ray criteria according to these findings. The accuracy rate was re-evaluated according to the new criteria. In latter period (2011–2012, N = 48 lesions) we examined the criteria prospectively.
Results: The detectability of superficial cancer was 97.0%. **In early period** we scored on each X-ray findings from 0 to 6 point, and by the total number of points, we divided to three clinical groups; 0−5 points was group 'a' (cT1a-EP/cT1a-LPM), 6−12 points was 'b' (cT1a-MM/cSM1), and 13−21 was 'c' (cSM2/cSM3). We establishednew criteria retrospectively, and its accuracy rate was 81.2%. Then in latter period, we tried the new criteria prospectively, the accuracy rate was 79.2%.
Conclusions: HBE with FPD may enable to assess the depth of superficial eSCC in detail. These morphological findings are valid features to discriminate between T1a and T1b of superficial eSCC lesions. This study is clinically available for appropriate selection of the treatment, surgery for T1a cancer or endoscopic resection for T1b cancer.

Prognostic factors of ductal carcinoma in situ in association with mammographic characteristics

I. Papapanagiotou[1], K. Chatoupis[2], E. Likaki[2], V. Kalles[1], M. Matiatou[1], D. Koulocheri[1], P. Liakou[1], A. Pazaiti[1], A. Nonni[3], G. Zografos[1]. *[1]Ippokrateion General Hospital, Breast Unit 1st Surgery DepartmentUniversity of Athens, Athens, Greece; [2]Asklepieion Voulas General Hospital, Radiology Department, Athens, Greece; [3]University of Athens, Department of Pathology, Athens, Greece*

Background: The aim of this study is to examine the correlation between mammographic characteristics of Ductal Carcinoma In Situ (DCIS) and tumor Grade, Estrogen(ER)/Progesterone Receptors(PR) expression and amplification of the oncogene HER2/neu respectively.
Material and Methods: During 2012, 145 women with microcalcifications in their mammogram, classified as BIRADS$\geqslant$4, underwent Vacuum Assisted Breast Biopsy(VABB) with the use of radiofrequency device(Breast Lesion Excision System).
Histology identified 92 Ductal Carcinomas In Situ, which were classified as high, intermediate or low nuclear grade, as positive(+) or negative(−) for immunohistochemical (IHC) expression of ER and PR receptors and as low(1+), intermediate(2+) or high(3+) HER2/neu protein expression, respectively.
We studied the biopsy results and we evaluated the former prognostic histological parameters in association with the mammogrpahic pattern of microcalcifications.
Results: From 92 DCIS, 35 were evaluated as high, 31 as intermediate and 26 as low nuclear grade respectively. The expression of ER and PR was positive in 77% of DCIS, and HER2 overexpression was observed in 72% of the tissue samples. Casting/linear calcifications were present in 54% of high grade DCIS, in 25% of intermediate grade and in 21% of low grade respectively. Casting/linear and granular/irregular calcifications were also present in 92% of DCIS with intermediate and high HER2 expression. No correlation was established between morphologic characteristics of calcifications and ER/PR receptors status.
Conclusions: Mammographic manifestation of casting/linear and/or granular/irregular calcifications in a biopsy confirmed DCIS, might be associated with poor prognosis, since it seems to correlate with high tumor Grade and intermediate and high HER2 expression.
No conflict of interest.

1188 POSTER

Microinvasive ductal carcinoma in situ: mammographic features and pathologic findings

K. Chatoupis[1], I. Papapanagiotou[2], E. Likaki[1], V. Kalles[2], D. Koulocheri[2], P. Liakou[2], G. Georgiou[2], A. Pazaiti[2], A. Nonni[3], G. Zografos[2]. *[1]Asklepieion Voulas General Hospital, Radiology Department, Athens, Greece; [2]Ippokrateion General Hospital, Breast Unit 1st Surgery Department, University of Athens; [3]University of Athens, Department of Pathology, Athens, Greece*

Background: The aim of our study was to evaluate the mammographic and pathologic findings of microinvasive Ductal Carcinoma In Situ.
Material and Methods: Our study sample consists of 15 patients who underwent Vacuum Assisted Breast Biopsy(VABB) with the use of radiofrequency device(Breast Lesion Excision System) for excision of suspicious non palpable mammographic lesions, presenting as microcalcifications. These 15 patients were diagnosed with microinvasive Ductal Carcinoma In Situ. We retrospectively evaluated the BIRADS classification, the tumor size and nuclear grade as well as the biological pattern of the tumors.
Results: The mammographic lesions, as interpreted in our Breast Unit, by two separate radiologists, were classified as BIRADS 4b in 8 cases and BIRADS 4c in 7. The mean tumor size was 7.95 mm(range 4−15 mm). Based on the pathologic report, 4 carcinomas were non-high grade while 11 were high grade. Furthermore, 10 out of 15 tumors were ER(+), 9 out of 15 were PR(+) and 10 were Her2(+).
Conclusions: The presence of suspicious for malignancy microcalcifications (classified as BIRADS 4b and 4c) might be indicative of microinvasive Ductal Carcinoma In Situ. Such tumors often present with an aggressive phenotype, as indicated from their high nuclear grade and the increased rate of Her2 positiveness.
No conflict of interest.

1189 POSTER

About techniques to choose the right anti-cancer agents and determine the proper dosage

S. Kosuge[1], T. Matsumoto[1]. *[1]Matsumoto Living Cell Research Laboratory, Tokyo, Japan*

Background: Various anti-cancer drugs have been developed. Suitable agent and dose for each patient should differ. I announce that we have developed a way to achieve that goal.
Material and Methods: *New-Matsumoto method*:
1. Using the MH method, living blood cells are taken from a patient, and divided into two layers, upper and lower (i.e., ULRBC(U) and LLRBC(L): hereinafter referred to as 'U' and 'L'). Then, each layer of blood cells is put into 3 ml of RPMI-1640 solution and cultured at 37degrees in a 5%-CO_2 incubator.
2. Assuming that the entire amount of daily dosage of drug administered to the patient (α) is absorbed in 5L of blood, the absorbed amount of drug in 3 ml of blood (X) is calculated as follows: X:3=α:5000, i.e. X=3$\times\alpha$/5000.
3. The calculated amount of drug (X) is added to 3 ml of saline, solution and fully mingled together.
4. The solution, which the drug is dissolved, is sterilized by filtering twice in a clean bench.
5. The sterilized solution is put into U and L, and cultured at 37degrees in a 5%-CO_2 incubator.
6. They are monitored with an inverted scanning microscope, and recorded on photos and VTRs.
7. U and L which the drug-dissolved solution is not added to are used as the control groups.

Judgment method: The most appropriate medicine is that alteration and deformation of blood cells is less, also life span of the cell is increased, compared with the control without the addition of drug.
Results:
1. The conventional dose is overdose in most cases. 1/3 is a proper equivalent in many medications.
2. Inappropriate drug will be easily clear.

Conclusions: This method is very beneficial to the patient and should be used widely from now on.
No conflict of interest.

1190 POSTER

Implementation of hybrid PET/MRI for target volume delineation in stereotactic body radiotherapy of liver tumors

M.N. Duma[1], H.M. Specht[1], N. Andratschke[2], K. Schiller[1], M. Molls[1], M. Schwaiger[3], M. Essler[3]. *[1]Klinikum rechts der Isar − Technische Universität München, Klinik und Poliklinik für Strahlentherapie und Radiologische Onkologie, München, Germany; [2]Universität Rostock, Klinik und Poliklinik für Strahlentherapie und Radiologische Onkologie, Rostock, Germany; [3]Klinikum rechts der Isar − Technische Universität München, Nuklearmedizinische Klinik und Poliklinik, München, Germany*

Background: Stereotactic treatment of liver metastases is a treatment option for patients not eligible for surgical resection. PET/MRI could be a helpful tool to improve target volume delineation. The aim of this report is to assess whether hybrid (^{18}F)FDG PET/MRI is feasible for stereotactic treatment planning and whether the implementation of this new imaging modality into the daily routine wokflow is effective.
Material and Methods: Patients diagnosed with liver metastases or recurrent primary tumor of the liver, who were not eligible for surgical resection, were referred to stereotactic body radiation by a multidisciplinary tumor board. Prior to the start of stereotactic treatment all patients were imaged in the same session on a hybrid 3-Tesla MRI with an integrated PET scanner as well as a on a conventional PET/CT-scanner. For stereotactic treatment planning, patients were positioned using a vacuum couch and scanned with a conventional slow CT as well as a respiratory gated 4-D CT. Images were then transferred to a commercial treatment planning system and a rigid co-registration was performed. Gross target volume (GTV) was delineated in PET-CT(GTV_{PETCT}), slow planning CT (GTV_{CT}), SUV corrected PET(GTV_{PET}) and T2-weighted MRT (GTV_{MRT}). Liver Volume was delineated in PET-CT($Liver_{PETCT}$), slow planning CT ($Liver_{CT}$), respiratory gated CT at maximum expiration(GTV_{4-D}) and MRI (GTV_{MRI}).
Results: There was a good reproducibility concerning liver volume delineated on PET/CT compared to PET/MRI, with the volume delineated on MRT being slightly smaller ($Liver_{MRT}$/$LiverPET_{CT}$ = 93.0% $\pm$ 5.5%). The best correlation was seen between liver volume delineated on PET/CT and respiratory gated 4-D CT ($Liver_{4-D}$/$Liver_{PETCT}$ = 97.8% $\pm$ 3.6%). The average GTV_{CT} was 84.2 ml, GTV_{PETCT} 82.6 ml, GTV_{PET} 108.8 ml and GTV_{MRT}.75.8 ml. Volumes delineated in PET were in average 32.8% larger than volumes delineated on contrast enhanced CT.
Conclusions: Combining MRI and FDG-PET imaging using a hybrid PET/MRI scanner lead to increased patient comfort by acquiring both modalities at a single appointment. First experiences demonstrated a good reproducibility of target volume delineation. Further studies will be performed to test whether the precision of target volume delineation might be increased by using PET/MRI images.

Simultaneous cone beam CT scans captured during prostate radiotherapy; image quality and the effect of arc delivery time

P.D. Dickinson[1], C.J. Boylan[1], J. Stratford[1], J. Malik[1], C. Rowbottom[1], C. Faivre-Finn[1], A. Choudhury[1]. *[1]Christie NHS Foundation Trust, Clinical Oncology, Manchester, United Kingdom*

Background: Cone beam CT (CBCT) images can be acquired during delivery of VMAT rotational radiotherapy. We assessed the quality of simultaneous CBCTs captured during prostate radiotherapy and studied the effects of arc delivery time on image quality.
Methods: Fifty patients with localised prostate cancer were treated with radical VMAT radiotherapy. Treatment was delivered using a single 8 or 10 MV arc on an Elekta linear accelerator fitted with a Synergy CBCT system. Standard and simultaneous CBCT's were captured on fractions 1, 6, 11 and 16. The simultaneous CBCT data was reconstructed and image quality was improved using in-house software. The quality of the CBCT images was assessed using a previously validated scoring tool. The scoring clinician was blinded to whether the scan was a standard or simultaneous CBCT.
Results: 392 CBCT scans were performed on 49 patients who completed radical radiotherapy. 74 simultaneous CBCT scans were performed with a mean arc delivery time of 120 seconds during which 688 CBCT frames were acquired (slow simultaneous CBCT). Following a software upgrade the subsequent 122 simultaneous CBCTs were obtained with a mean arc delivery time of 83 seconds during which 502 CBCT frames were acquired (fast simultaneous CBCT).
All standard CBCTs and 101 (52%) simultaneous CBCTs were deemed to be clinically useful. Further results are given in table 1.
The image quality from fast simultaneous CBCT was significantly worse than image quality from slow simultaneous CBCT (chi squared test, $p < 0.001$).
Conclusion: Simultaneous CBCT scanning can produce images which are clinically useful. Prostate CBCTs are affected by bowel gas and patient habitus. Simultaneous CBCTs are also affected by scatter from the MV beam. Reducing the arc delivery time and the number of CBCT frames acquired by approximately one-third reduces the quality of simultaneous CBCTs.
Further development and refinement of simultaneous CBCT scanning is warranted. Future reductions in arc delivery times may have to be limited if the use of simultaneous CBCT scanning becomes standard practice.
No conflict of interest.

Table 1. The quality of cone beam CT scans (CBCTs) according to method of acquisition and arc delivery time.

	Standard CBCT	Slow simultaneous CBCT	Fast simultaneous CBCT
Low quality CBCT (Not clinically useful)	0	12 (16%)	83 (58%)
Intermediate quality CBCT (Clinically useful)	86 (44%)	62 (84%)	39 (32%)
Good quality CBCT (Clinically useful)	110 (56%)	0	0

1192 POSTER

Visualization of the left anterior descending coronary artery on computed tomographic images used for breast radiotherapy planning

Y. Kirova[1], S. Vennarini[1], C. Aristei[2], C.E. De Almeida[3], N. Fournier-Bidoz[1], A. Fourquet[1]. *[1]Institut Curie, Radiotherapy Department, Paris, France; [2]University of Perugia, Department of Radiation Oncology, Perugia, Italy; [3]UERJ, Laboratorio de Ciencias Radiologicas, Rio de Janeiro, Brazil*

Background: The purpose of this study was to assess the visualization of the left anterior descending coronary artery (LAD) on CT images that were used for breast radiation treatment planning.
Material and Methods: Twenty-five breast cancer patients (including 11 left breast tumors) had radiation treatment. The delineation of the LAD artery was achieved by one radiologist and one radiation oncologist independently on 2 sets of images for each patient: one set was a pre-operative CT scan using intravenous contrast media (IV) to determine the primary gross tumor volume (GTV) and the second set was a post-operative CT scan used for treatment planning. A Student's paired t-test was used to compare the number of CT slices in which the LAD was visible for each patient in the 2 series by each observer. Interpolations and extrapolations of the LAD volume were performed for the left-sided cases using a published heart atlas. Doses to the interpolated LAD structure and the heart were reported for the group of left-sided cancer patients.
Results: There was a non-significant difference between the results with and without IV ($p = 0.34$ for the radiologist; $p = 0.90$ for the radiation oncologist). The visible LAD corresponded to a 30% portion (range 12−47%) of the interpolated structure. The maximum dose to the left artery as measured by D2% varied widely, from 2.7 Gy to 41.7 Gy, in the group of patients with left breast tumors. The largest values (>25 Gy) corresponded to those patients in whom the LAD distal extremity lay inside the breast fields.
Conclusions: With the current planning CT protocol, only one-third of the LAD could objectively be visualized. Contrast-enhanced imaging used for GTV delineation before the breast surgery did not improve the visualization of the artery. The large range of doses to the LAD artery reported in the literature may be partially due to imaging artifacts and consequently to variations in the delineation. This study has revealed the lack of consistency that may be encountered when contouring heart vessels, thereby questioning the reliability of dose reporting.

Validation of biomarkers to predict PFS with DCE-US in 539 patients treated with different anti-angiogenic drugs: analysis of sub-groups

N. Lassau[1], M. Kind[2], V. Vilgrain[3], J. Lacroix[4], S. Taieb[5], R. Aziza[6], A. Sarran[7], O. Lucidarme[8], A. Luciani[9], S. Koscielny[10]. *[1]Institut Gustave Roussy, Département d'Imagerie, Villejuif, France; [2]Institut bergonié, Imaging Department, Bordeaux, France; [3]Hopital Beaujon, Imaging Department, Clichy, France; [4]centre Antoine Baclesse, Imaging Department, Caen, France; [5]Centre Oscar Lambret, Imaging Department, Lille, France; [6]Centre Claudius Regaud, Imaging Department, Toulouse, France; [7]Centre Paoli Calmettes, Imaging Department, Marseille, France; [8]Hopital Pitié Salpétriere, Imaging Department, Paris, France; [9]CHU Créteil, Imaging Department, Créteil, France; [10]Institut Gustave Roussy, Biostatistic Department, Villejuif, France*

Background: The prospective multicentre French National Program for the Evaluation of DCE-US has studied the technique in different tumor types and anti-angiogenic treatments.

The aim was identify perfusion parameters to predict tumor response to different anti-angiogenic treatments.
Methods: DCE-US was performed at baseline and at 4 time-points (Day 7, 15, 30, 60). At each examination, we quantified 7 DCE-US parameters. We also estimated the variation between baseline and each post-baseline time-point. The main endpoint was freedom from progression assessed according to RECIST. We first selected the best parameters: for each parameter and each time point, we studied the trend between the parameter value and freedom from progression. After, the best cut-points were searched through a grid search. The best single cut-point was that with the lowest P-value for progression free survival. We performed analyses according to the treatment and type of tumor, looking for the groups of patients that contribute the most to the heterogeneity.
Results: A total of 1968 DCE-US were performed in 539 patients. The median follow-up was 1.65 year. The mean transit time (MTT) was the only significant parameter at day 7 (P = 0.002). The best cut-point to predict tumor progression was 12 seconds (P = 0.02), a MTT >12s being of good prognosis. Variations from baseline were significant at day 30 for several parameters. The area under the curve (AUC) was the parameter with the lowest P-value (P = 0.00004); Patient with a decrease of more than 40 % had a better prognosis. The groups defined accordingly were different for both FFP (P = 0.009) and OS (0.03).
The analyses according to treatment suggested heterogeneity. We performed a separate analysis for RCC treated with Sunitinib: the best cutoff for AUC at 30 days was 0.1, corresponding to a decrease of 90%. A total of 122 patients treated with Bevacizumab were analysed: 61 Metastatic colon cancer and 61 breast cancer. The median follow-up was 1.65 year. The MTT was the only significant parameter at day 7 (P = 0.002). PFS was significantly different according to MTT < or >12S for 122 patients (<0.05), breast cancers (P<0.05) and Colon cancers (P<0.001).
Conclusion: DCE-US is the first functional imaging technique that validated predictors of tumor progression in a large multicentric cohort. This study confirms the potential of DCE-US as imaging biomarker to monitor different anti-angiogenic treatments in different type of tumors.

Isolation of stem cells and production of extracellular matrix powder from fat tissue for tissue engineering: in vivo and in vitro tests

S. Sadighi[1], A.H. Tavacoli[2], A. Khoshzaban[3], N. Dadashpoor[4], Z. Sobhani[5], K. Hoseini[5]. *[1]Cancer Institute, Tehran, Iran; [2]Tissue Bank and Transplantation Center, Medicine, Tehran, Iran; [3]Tissue Bank and Transplantation Center, Biomaterial, Tehran, Iran; [4]Azad University, Tissue Engineering, Tehran, Iran; [5]Tissue Bank and Transplantation Center, Medicine, Tehran, Iran*

Objectives: Due to easy accessibility and large amounts, adipose tissue could provide ideal source of stem cells. The aim of this study is to isolate stem cells and produce natural matrix from human fat tissue and then examine the growth potential of stem cells on that natural scaffold with in vivo and in vitro tests.
Material and Methods: Adipose tissue is obtained on sterile conditions from waste materials of liposuction in plastic surgery clinic of Tehran. Stem cells are isolated, examined by flow-cytometry, cultured on DMEM plate with or without acellular matrix powder (natural scaffold). In order to provide appropriate scaffold, we use physical, chemical and enzymatic digestion of abdominopelvic fat. To proof decellurisation and structure of the scaffold, hematoxylin and eosin and immunochemistry staining is used. We compare the proliferation, adhesion and differentiation potential of cultured stem cells as well as transplantation of that as graft on the subcutaneous tissue on the back of immunosupressed rats.
Results: The mesenchymal nature of the stem cells was confirmed by expression of CD90, CD105, CD166, and lack of expression of haematopoietic markers of CD34, CD31, and CD45. IHC markers showed heavy staining for collagen IV and no staining for vimentin, laminin, or S100. Assessment of stained stem cells by electron-microscopy and live cell counting examination showed increased proliferation and adhesion of adipose stem cells after adding scaffold to medium for one week (in vitro test). After six weeks of animal phase of study, increased graft size, surface vascularisation, more differentiation of stem cells, neovascularisation, and penetration of host cells to the graft and less necrosis or fibrosis were seen with microscopic examination of stained scaffold contained grafts in comparison to stem cells alone (in vitro test).
Conclusion: Our study shows that our produced human decelluralised fat scaffold provided a suitable environment to increase proliferation, differentiation, adhesion and migration of stem cells. This product should be checked in clinical setting for tissue repair.

KRAS, BRAF and TP53 deep-sequencing for colorectal carcinoma patient diagnostics

M. Rechsteiner[1], A. Von Teichman[1], J.H. Rüschoff[1], N. Fankhauser[2], B. Pestalozzi[3], P. Schraml[1], A. Weber[1], P. Wild[1], D. Zimmermann[1], H. Moch[1]. *[1]University Hospital Zurich, Surgical Pathology, Zurich, Switzerland; [2]ETHZ, Department of Cell Biology, Zurich, Switzerland; [3]University Hospital Zurich, Department of Oncology, Zurich, Switzerland*

Background: In colorectal carcinoma, *KRAS* and *BRAF* mutations have emerged as predictors of resistance to anti-EGFR antibody treatment and worse patient outcome, respectively. In this study, we aimed to establish a high-throughput deep-sequencing workflow based on 454 pyrosequencing technology to cope with the increasing demand for sequence information at medical institutions.
Material and Methods: A cohort of 81 patients with known *KRAS* mutation status detected by Sanger sequencing was chosen for deep-sequencing. The workflow allowed us to analyze seven amplicons (1 *BRAF*, 2 *KRAS*, 4 *TP53* exons) of nine patients in parallel in one deep-sequencing run.
Results: Target amplification and variant calling demonstrated reproducible results with input DNA derived from FFPE tissue ranging from 0.4 to 50 ng using different targets and multiplex identifiers (MIDs). Equimolar pooling of each amplicon in a deep-sequencing run was necessary to counterbalance differences in patient's tissue quality. Five *BRAF* and 49 *TP53* mutations with functional consequences were detected. The lowest mutation frequency detected in a patients tumor population was 5% in *TP53* exon 5. This low frequency mutation was successfully verified in a 2nd PCR and deep-sequencing run.
Conclusion: Our workflow allows to process 315 targets a week and provides the quality, flexibility, and speed needed to be integrated as standard procedure for mutational analysis in diagnostics.

1202 POSTER

An interactive web portal for patient empowerment in cancer survivorship

W. Kuijpers[1], W.G. Groen[1], H.S.A. Oldenburg[2], M.W.J.M. Wouters[2], N.K. Aaronson[1], W.H. Van Harten[1]. *[1]Netherlands Cancer Institute, Psychosocial Research and Epidemiology, Amsterdam, Netherlands; [2]Netherlands Cancer Institute, Surgery, Amsterdam, Netherlands*

Background: Interactive web portals are an effective tool to enhance patient empowerment, but they are still uncommon in oncology. In the Netherlands Cancer Institute we are developing such a portal for breast and lung cancer survivors. The aim of this abstract is to report on the developmental phase of this project.
Material and Methods: We determined the portal requirements based on a literature review and on focus group discussions. We used 3 electronic databases to identify relevant literature on interactive, web-based interventions for various chronic diseases, and used available guidelines for cancer survivorship care to evaluate the relevance of these interventions for the oncology setting. We held focus groups with cancer survivors and health care professionals to better identify the desired features of a web portal from the perspective of these stakeholders.
Results: The literature review indicated that although the content, duration and frequency of interventions varied considerably, features commonly used included education, self-monitoring, feedback, self-management training, individualized exercise, and communication with either health care providers or patients. These elements were evaluated as appropriate to fulfil recommendations for survivorship care. The analysis of the focus group transcripts indicated that breast and lung cancer survivors were primarily interested in those features of a web-base portal that could fulfil their information needs: a survivorship care plan, access to their medical record, and an overview of their medical appointments. Health care professionals considered telemonitoring, patient-reported outcomes plus related feedback and a rehabilitation program as the most useful elements of such a portal. Cancer survivors and health care providers agreed on the potential value of a survivorship care plan and on the possible risks of a patient forum, but were less in agreement with regard to access to medical records and e-consultation (survivors were positive).
Conclusions: Based on our literature study and focus group discussions we were able to formulate requirements for an interactive web portal to empower breast and lung cancer survivors: information provision by means of a survivorship care plan and interactivity by providing feedback on patient- reported outcomes (on, for example, quality of life and physical

activity behaviour). These features will be transformed into prototypes of the web-based portal and will be evaluated. We will present screenshots, algorithms for automated feedback, and additional patient and professional views on late draft versions of the portal. The final version of the web portal will be implemented and evaluated.
No conflict of interest.

ARRACT − a real-time randomisation application for clinical trials

N.K. Mejer[1], D.L. Nielsen[1], B. Christiansen[1], L. Sengeloev[2], P. Skovby[3]. *[1]Herlev University Hospital, Clinical Research Unit, Herlev, Denmark; [2]Herlev University Hospital, Department of Oncology, Herlev, Denmark; [3]ComVis, Copenhagen, Denmark*

Introduction: In investigator-initiated trials there is a need for affordable and adequate tools to randomise patients.
Relational database technology and internet-based connectivity offer resources to facilitate development of efficient randomisation procedures.
At Department of Oncology, Herlev University Hospital, we have developed a web application – ARRACT. The system covers the following aspect of the randomisation process:
- **Various Algorithms:** Range based n-factors stratified balanced randomisation and permuted block randomisation.
- **Patient Randomisation:** Enables randomisation of patients.
- **Monitoring and Management of data:** Enables on-going data management and monitoring in step by step visual logging.
- **Administration:** Allows overall system oversight, configuration, and reporting by administrators.
- **Test Environment:** Allows simulations on existing treatments with fixed factors and levels and performs generic multiple n-trials simulations.
- **Integration:** Use of web services to integrate with clinical remote data entry system (OpenClinica) − Under development.

Materials and Methods: Commercial and Open Source randomisation systems were investigated as well as relevant literature to establish the minimum requirements in respect of the systems functionality and security.
A data model for the system was designed and a database was created in Microsoft SQL server 2005. The web application was programed in Visual Studio 2010.
As part of the implementation plan we tested:
- IQ – Installation Qualification
- OQ – Operational Qualification
- PQ – Performance Qualification
- Site Standard Operational Procedure (SSOP)

Results: We have conducted several simulation with the system especially the Stratified Balanced Allocation Method: A test study was setup and simulated 1000 times with satisfactory results in respect of imbalance.
At least two clinical trials are awaiting the final implementation.
Discussion: Many investigators are still forced to use inadequate methods such as 'envelope method' for randomisation in their trials.
An option might be to turn to the Open Source programs available. Currently, however, we have not found any Open Source programs suitable for our needs.
To succeed in developing and implementing systems one needs: adequate resources, funding, an implementation plan and a skilled staff.
The final aim is to use ARRACT for all investigator-initiated randomised studies.
No conflict of interest.

1204 POSTER

National online portal for registration of chemotherapy side effects

J. Due[1], A. Juul[1], P.M. Vestlev[1]. *[1]Roskilde Amtssygehus, Clinical Oncology, Roskilde, Denmark*

Background: The department of oncology at Roskilde Hospital has a large outpatient ward for patients treated for CRC, Breast cancer, lung cancer and ovarian cancer. At the clinical research unit we wanted to capture data regarding the side effects of chemotherapy. Currently we register the side effects of chemotherapy by contacting the patients and register data in a pre-printed paper template. This can be biased as no current instructions currently are available on how to interview the patient.
The best sources of information about how patients experience their side effects are the patients themselves, so it seemed as an obvious choice to get patients to register themselves It has been shown that easy access to relevant information regarding disease improves patient empowerment. Studies also indicate that the better the patients handle the adverse reactions to chemotherapy, the more they are able to complete a course of treatment as planned.
Aim: The first aim was to create an online portal that could provide patients with better access to relevant guidance and accurate information about side effects in real time. By providing the patients with relevant information in due time they will increase their empowerment to act and comply with the treatment.
The second aim was the development of a database based on all the registrations done by the patients for further research and developmental projects.
Methods: We created an online portal for patients to record their side effects. This portal is part of a national project for patient based registration of data and observations linked to their chronic diseases. Roskilde is pilot site for cancer treatments.
Each side effect reported is graded according to CTCAE standards, and users get practical advice on how to act precisely to what they are experiencing. In addition, patients will be able to get a visual overview of the development of their own side effects, and compare with other patients receiving similar treatments.
Result: Patients have increased their abilities to manage their cancer treatment and compliance and are more likely to respond to the side effects accordingly and therefore more likely to complete their treatment as planned.
Conclusion: The portal and the database enable us to capture side effects for all treatments currently given to patients at our department, potentially the whole country. As this is the first time an attempt to capture this much data is made in Denmark, it will hopefully facilitate research within oncology.
No conflict of interest.

1205 POSTER

Evaluation of the metastatic potential of human tumor cells by means of 3D culture on silicon microstructures

M. Danova[1], I. Scovassi[2], F. Aredia[2], N. Panini[3], M. Torchio[1], G. Barillaro[4], S. Surdo[4], F. Carpignano[5], G. Silva[5], S. Merlo[5]. *[1]Internal Medicine and Medical Oncology, Medicine, Vigevano, Italy; [2]Istituto di Genetica Molecolare IGM-C.N.R., IGM-C.N.R. Pavia, Pavia, Italy; [3]Istituto di Ricerche Farmacologiche "Mario Negri" Milano, "Mario Negri", Milano, Italy; [4]Università di Pisa, Ingegneria dell'informazione, Pisa, Italy; [5]Università di Pavia, Ingegneria Industriale e dell'Informazione, Pavia, Italy*

Background: − The ability of cancer cells to spread and give rise to a secondary tumor is dependent of their physical interactions with microenvironment. Tumor cells must undergo elastic deformations and aberrant activation of the epithelial–mesenchymal transition (EMT). A better understanding of the role of cell mechanical properties will provide new insights in cancer progression and identification of new prognostic biomarkers and therapeutic targets. We investigate cell plasticity as an indicator of the tumor cell behaviour, strongly related to the metastatic potential.
Methods: − Silicon micromachined structures (SmS) were exploited as 3D microincubators (Carpignano F, PLOS ONE, 2012) able to host tumor cells. The 3D microstructure consists in periodic arrays of silicon walls separated by empty gaps, fabricated by electrochemical micromachining of a small silicon dice. After incubation, samples were washed, fixed overnight in 10% formalin and stained for fluorescence microscopy analysis. Experiments were performed in triplicate with human cell lines, with high (A375, MDA-MB-231, RPMI-7951) or low (MCF-7, CAPAN-1) metastatic potential. The K562 leukaemia cells were utilized as control.
Results: − Fluorescence microscopy analysis of the SmS populated by cells evidenced: a) cells with low metastatic potential are largely unable to grow on the SmS surface; only few of them can survive on top of the walls. Their nuclei showed a round shape typical of cell growing on flat surfaces; b) cells with high metastatic potential can grow on the SmS thanks to their ability to colonize the deep, narrow gaps between the silicon walls. These cells showed stretched nuclei aligned along the wall direction, proving that are deep inside the extremely limited empty spaces of the SmS.
Conclusions: − Data indicate that mechanical stiffness grades the metastatic potential (Swaminatan V, Cancer Res, 2011); on these basis, the less stiffed cytoskeleton/membrane of the cells grown inside the SmS can be related to their bio-mechanical ability to undergo dynamic changes in EMT. Applied to the study of circulating tumor cells (CTCs), the SmS could provide rapid and significant insights into functional readouts of EMT-oriented CTC subpopulations characterized by different levels of aggressiveness. Thus, SmS could be implemented in a lab-on-microchip clinically applicable to predict the metastatic potential. Work was partially supp. by Fondazione Cariplo, grant nº 2011–0308.

1206 POSTER

Preclinical antitumor activity of a nanoparticulate SN38-polymeric micelle formulation in mouse xenograft models

H. Tseng[1], S. Chou[2], C. Wang[2], Y. Chang[2], C. Hsueh[2], M. Lu[2], S. Wang[3], Y. Hsu[2]. [1]*Industrial Technology Research Institute, Hsin-chu, Taiwan;* [2]*Industrial Technology Research Institute, Biomedical Technology and Device Research Laboratories, Hsin-chu, Taiwan;* [3]*Industrial Technology Research Institute, Material and Chemical Research Laboratories, Hsin-chu, Taiwan*

Background: Irinotecan (CPT-11) functions as a prodrug which is converted into SN38 (active metabolite of CPT-11) in liver or tumor tissues through carboxylesterases. In general, only 2−8% of CPT-11 can be converted into SN38 and to considerable patient-to-patient variability. Although SN38 is very effective against various human cancer cells, its extreme hydrophobicity also prevents the clinical use. In the current study, we demonstrated that SN38 was able to be efficiently incorporated into polymeric micelles (PM) fabricated using the synthesized block copolymers.
Material and Methods: Fifteen human cancer cell lines were testing and treated with CPT11, SN38, and SN38-PM respectively, and the cell viability was determined by MTT assay. The in vivo pharmacodynamics efficacy was performed in BALB/c nude mice. NCI-H460 (human large cell lung cancer) and RPMI-2650 (human nasal septum squamous cell carcinoma) were subcutaneously (sc.) implanted into mice and to develop xenografts tumor models.
Results: Compared with the IC_{50} of cytotoxicity concentration, SN38 and SN38-PM were 217-fold activity than CPT-11 in NCI-H460 cell and 1200-fold more potent than CPT-11 in RPMI-2650 cell. In NCI-H460 xenograft model, SN38-PM was administered to mice at doses of 20 mg/kg (iv., twice week) for three weeks, the tumor inhibition rate (TIR) was 87% at day 37. In contrast, for mice given CPT-11 at the dose of 50 mg/kg, 80% of TIR was achieved at the same time. In tumor growth delay (TGD), the mean tumor volume reaching to 1000 mm^3 was as compared with control group. The TGD of SN38-PM (iv., 20 mg/kg, twice week) were 28 days. In sc. xenograft of RPMI2650 tumor models, SN38-PM at doses of 20 mg/kg and 30 mg/kg (iv., twice week) for five doses, the TIR were 95% and 99% at day 40. On the other hand, treatment with CPT-11 at the dose of 20 mg/kg and 50 mg/kg, the TIR of RPMI2650 tumor were 54% and 80% respectively.
Conclusions: We have successfully developed a PM formulations that can efficiently incorporate with SN38 and markedly increase the solubility. Furthermore, SN38-PM exhibited significantly pronounced anti-tumor activities against both NCI-H460 and RPMI-2650 xenografts. These results suggest that SN38-PM has the potential to become a modality of anticancer treatments.

Diffuse reflectance spectroscopy (DRS) for identification of breast cancer in lumpectomy specimen

L.L. De Boer[1], B.G. Molenkamp[1], J. Wesseling[1], B.H.W. Hendriks[2], T.M. Bydlon[2], T.J.M. Ruers[3]. [1]*Dutch Cancer Institute − Antoni van Leeuwenhoek Hospital, Department of Surgery, Amsterdam, Netherlands;* [2]*Philips Research, Department of Minimally Invasive Healthcare, Eindhoven, Netherlands;* [3]*Dutch Cancer Institute − Antoni van Leeuwenhoek Hospital Department of Surgery Amsterdam Netherlands, MIRA Institute University Twente, Enschede, Netherlands*

Background: Breast-conserving surgery (BCS) is an effective treatment provided adequate surgical margins can be obtained. Irradicality is a risk factor for an adverse clinical outcome. Even in highly specialized cancer centers often over 10% of BCS patients are left with a positive resection margin after initial surgery. Here we investigate whether DRS based on altered spectroscopic properties in malignant tissue can provide guidance in differentiating benign from malignant tissue.
Materials and Methods: The lamellae of 15 lumpectomy specimens were measured at the pathology department. Using an optical probe, spectra between 400 and 1600nm of macroscopically malignant, benign and borderline tissue were obtained. At each measurement location three optical spectra were acquired as well as histology. By fitting the spectra with a mathematical model fat and water content was registered.
Results: On the fifteen ex-vivo lumpectomy specimen a total of 95 locations were measured. Of these locations 56 were benign and 39 were malignant tissue. Comparing the shape of the tumor spectra with the benign spectra clear differences were seen, especially in the 1000–1200nm wavelength region where fat and water are the dominant absorbers. By calculating fat and water ratios for all 95 locations (Fat/Water >1 for benign and Fat/Water <1 for malignant tissue) malignant tissue can be distinguished from benign tissue with a sensitivity of 97% and a specificity of 92%. Based on this ratio not all of the locations were classified correctly in three patients. When these specimens were evaluated individually, in two of the three specimens all measurement locations were classified correctly when the cut-off of the ratio was shifted to a lower value. In a clinical setting where each patient is their own control and DRS spectra of suspicious tissue is compared to benign spectra of the individual patient even better results are to be expected.
Conclusions: DRS was able to distinguish benign tissue from malignant tissue based on fat and water content. This makes it a promising tool for the future.

Transcatheter oily chemoembolisation (TOCE) in the treatment of patients with locally advanced adenocarcinoma of the stomach: First experience

A. Polikarpov[1], S. Dolgikh[2], P. Tarazov[1], V. Polysalov[2]. [1]*Russian Research Centre for Radiology and Surgical Technologies, Interventional Radiology, Saint Petersburg, Russian Federation;* [2]*Russian Research Centre for Radiology and Surgical Technologies, Surgery, Saint Petersburg, Russian Federation*

Purpose: To study the first results of new treatment for local advanced unresectable gastric cancer.
Materials and Methods: We performed 26 TOCEs in 18 pts with histologically proven adenocarcinoma of the stomach (T_{3-4}, N_{1-2}, M_{0-X}). TOCE of branches of the left gastric (LGA, n = 17), gastroduodenal (GDA, n = 5) and right gastric (n = 4) supplying the tumour was made using bolus injection of 5−10 mg mitomycin C (n = 14) or 40–100 mg irinotecan (n = 12) emulsified in 3−10 ml lipidiol. In 5 cases, when selective catheterisation of feeding arteries was impossible, we used redistribution embolisation of the right gastroepiploic and right gastric arteries with steel coils. Every TOCE was added with celiac arterial infusion of oxaliplatin, docetaxel, 5FU, gemcitabin in different combinations. The follow-up included clinical exemenation, repeat biopsy, CT and PET. In 8 pts, TOCEs was repeated with 1- mo interval.
Results: There were no treatment-related complications. The post-embolisation syndrome included mild upper abdominal pain and nausea; these symptoms disappeared within 1 day of symptomatic therapy.
After first TOCE partial tumour response was seen in 9 (50 %), stabilisation in 6 (33%), and progression in 3 (17%) pts. All 9 responders became resectable and were operated (R0 resection). Of them, 7 are alive 2−40 (mean 17.4) mo, 2 pts died in 7 and 26 mo from disseminated tumour progression. The 1-, 2- and 3 yr survival was 66%, 33 % and 33 % respectively.
At present three non-operated pts are alive during 2, 5 and 21 mo. Mean survival of 6 pts who died was 9.9 ± 2.3 mo.
Conclusion: TOCE of gastric arteries is a well-tolerated procedure that causes partial tumour response and promising down-staging effect in 50% patients with advanced unrespectable adenocarcinoma of the stomach.
No conflict of interest.

Spanish radiotherapy department experience with volumetric modulated arc therapy (VMAT)

E. Lopez[1], A. Lazo[1], G. Arregui[2], A. Serradilla[1], D. Rivas[1], A. Sacchetti[1], M.I. Nuñez[3]. [1]*ONCOSUR Granada, Radiation Oncology, Granada, Spain;* [2]*ONCOSUR Granada, Physics, Granada, Spain;* [3]*Granada University, Radiology and Physical Medicine, Granada, Spain*

Introduction: Technology in Radiation Oncology is rapidly expanding. The Volumetric Modulated Arc Therapy (VMAT) designed by Elekta® is a more efficient way to administer Intensity Modulated Radiation Therapy (IMRT). This study reports the experience of a Spanish Radiotherapy Department by using this technique in several pathologies.
Patients and Methods: Between January 2010 and March 2013, we have analysed the experience in 171 consecutive radical radiotherapy treatments in 142 patients with 114 VMAT (66.67%) and57 IMRT step-and-shoot (33.33%).
All cases were planned with VMAT and Step-and-Shoot IMRT and dosimetric distributions have been compared and selected individually.
The proportion of cases that had been prescribed with each technique (VMAT/IMRT) regarding tumour localization was analysed by the application of a c2 independence test (1) = 19.00; $p < 0.001$.
To find difference between the techniques in terms of time, and monitor units (MU) per dose units we applied a multivariate analysis of covariance (MANCOVA).
Results: The most frequently treated pathologies were:
Prostate 49: 38 VMAT and 11 IMRT c2 (1) = 14.88; $p < 0.001$
Lung 20: 13 VMAT and 7 IMRT

Brain metastases 24: 15 VMAT y 9 IMRT
Head and Neck 22: 8 VMAT y 14 IMRT
Abdominal tumours 18: 15 VMAT y 3 IMRT c2 (1) = 8; $p < 0.01$.
Bone 7: 3 VMAT y 4 IMRT
Mean time (minutes per Gy) of treatment with VMAT = 1.92 (0.83) vs. IMRT Step and Shoot = 2.85 (1.17)
Mean Monitor Units per Gy (MU/Gy) with VMAT = 18.16 (10.61) vs. IMRT Step and Shoot = 25.34 (32.55)
Significant differences in time/Gy between the techniques were found F(1, 93 = 10.44; $p = 0.02$; h2 $p = 0.02$). Nevertheless, there were not significant differences in MU/Gy.
Conclusions: In all cases the dosimetric quality of the VMAT was similar to the IMRT Step-and-Shoot but the treatment time was shortened considerably.
In our series, VMAT is a more efficient therapeutic option in prostate and abdominal tumours, specifically in treatment time.
MU is not statistically different between both techniques in our series.
No conflict of interest.

1210 POSTER

Frameless stereotactic radiosurgery for brain metastases using image guided radiotherapy (IGRT)

E. Lopez[1], A. Lazo[1], G. Arregui[2], A. Serradilla[1], D. Rivas[1], A. Sacchetti[1], M.I. Nuñez[3]. *[1]ONCOSUR Granada, Radiation Oncology, Granada, Spain; [2]ONCOSUR Granada, Physics, Granada, Spain; [3]Granada University, Radiology and Physical Medicine, Granada, Spain*

Introduction: Stereotactic radiosurgery (SRS) has become increasingly used for treatment of brain metastases. A non-invasive mask system plus Image Guided Radiotherapy (IGRT) is a very attractive and comfortable alternative for patients (Elekta® system).
Objective: To assess the clinical outcomes of frameless radiosurgery combined with IGRT for brain metastases.
Patients and Methods: In ONCOSUR and CROASA between January 2010 and December 2012 we have treated 16 patients (50% female) with 45 brain metastases and mean age of 53.63 years (33−68). A total of 21 treatments have been performed. Our GTV margin was of 2−3 mm.
We have evaluated clinical, therapeutic data and acute toxicity.
Results: Primary tumours were 7 breasts, 3 melanomas, 5 lungs, and 1 esophagus.
Only 6 patients were also treated with whole brain radiotherapy (WBRT).
The radiotherapy techniques used were: 15 Volume Modulated Arc Therapy (VMAT); 1 Intense Modulated Therapy Step and Shoot (IMRT S-S); 1 Dynamic Arc Therapy (DART); and 4 3D Conformal Radiotherapy (3DCRT).
The hypofractionated schemes that we used more often were: 6 Gy x 6 fractions (fx) (4 cases) and 10 Gy x 3 fx (6 cases). All patients received 2 fx per week.
A variable positioning accuracy of 1−4 mm has been reported for frameless stereotactic systems. In our series, IGRT repositioning mean accuracy was: X = 0.18 mm (0.01–0.44); Y = 0.23 mm (0.06–0.66); and Z = 0.20 mm (0.01–0.40).
Acute side effects were not detected.
With a mean follow-up of 10.35 months (2−30), 6 patients are alive, and 10 are dead. The causes of death were progression in: brain: 2 patients (no WBRT); lung: 3 patients; liver: 1 patient; unknown: 3 patients and general deterioration: 1 patient.
Conclusions: Frameless SRS is an effective and comfortable treatment in the management of brain metastases.
Non-invasive mask fixation system plus IGRT is associated with a high repositioning accuracy with no errors up to 3 mm.
No conflict of interest.

1211 POSTER

Establishing a clinical trial support system using open source software

Y. Aoyagi[1], H. Hasegawa[1], T. Sudo[1], K. Tobayama[1], K. Furuya[1], A. Sato[1]. *[1]National Cancer Center, Exploratory Oncology Research & Clinical Trial Center, Chiba, Japan*

Background: To conduct an effective clinical study, reliable screening of the study candidates and information sharing of the study is important. IT technologies resolve these problems effectively. Specific software purchase or a service provider contract is needed but it is sometime difficult for academic institute due to the maintenance load and cost issues. As such, we have established a clinical study support system using an open source software (OSS) to meet the objective of solving the above issues.
Material and Methods: The system is based on Netcommons, an open source content management system (CMS), adding two implementations which are the eligibility check upon registration for subjects and information offering and sharing functions. Regarding the eligibility check function, we implemented mandatory and range check functions and examined measures to avoid non-qualified subjects registrations. Also implemented the interface which transfers the user information and registration details considering data coordination with other systems.
Results: The system operation started in our hospital server since 2011 and is now used as a registration system for multi institutions' trials on the Cloud server. The system is mainly operated for registration of the subjects for Phase 1 trial and early development of devices, and has been used in 7 trials registering 90 subjects. Recently, the information sharing functions utilizing CMS is also being used. The coordination with EDC developed by our hospital has also been implemented using data transfer interface.
Conclusions: In our hospital, the effective trial operation has become possible with the advanced IT introduction in subject registrations and information sharing. The rapid implementation of necessary functions for each clinical study is the strength of CMS allowing various allocations of information transfers and file sharing functions. Also, as the software that consists the system is OSS, modifications are possible with the introduced institutions. This indicates the possibility of the user community to come up with new ideas for improved functions and its actual implementations in the future. As such, with the wide use of the system, reasonable costs for clinical studies are expected by offering efficient clinical studies using IT technology in Academia.
No conflict of interest.

1212 POSTER

Does an automated self check-in process improve the quality and patient satisfaction associated with chemotherapy administration?

S. Singh[1], M.E. Trudeau[1], D. Montazeralghaem[1], B. De Mendonca[2], K. Beattie[1], P. Sousa[1], M.C. Cheung[3]. *[1]Sunnybrook Odette Cancer Centre, Medical Oncology, Toronto, Canada; [2]Sunnybrook Odette Cancer Centre, Quality Improvement, Toronto, Canada; [3]Sunnybrook Odette Cancer Centre, Hematology, Toronto, Canada*

Background: The Odette Cancer Centre (OCC) is the sixth largest cancer institution in North America and currently manages over 24,000 chemotherapy patient visits per year (and over 100 chemotherapy patients per day). We initiated an automated kiosk system whereby patients can 'actively' self-identify for check-in to the chemotherapy unit.
Materials and Methods: From January 1 to May 1, 2012, consecutive patients receiving >2 cycles of chemotherapy were randomly assigned to either radio-frequency identification (RFID) or barcode technologies to facilitate self check-in and time-in-motion studies. In parallel, the former manual check-in system (guided by OCC staff) continued for all patients. The primary outcome was the proportion of patients with more 3 or more scheduled appointments who used the self-check system at lest 3 times (compliance). Patient satisfaction was attained with a baseline and post-study survey instrument.
Results: The study accrued 81 patients (43 patients using RFID and 38 patients using barcode technology). Mean age was 59 (range 20 to 81 years). Sixty-four individuals completed baseline survey instruments at the time of analysis. Mean age of patients was 56 (range 21−81). The majority of patients at baseline had regular access to a computer (87.5%) and used the internet at least >1 hour/day (50%). With implementation of the study, 24 of 81 patients (29%) have used the kiosk only once. Of individuals with multiple scheduled chemotherapy appointments (at least 3), 50% assigned to the RFID group and 52.6% assigned to the barcode group used the kiosk at least 3 times ($p = 0.827$; Fisher's exact test). Thirty-eight patients completed patient satisfaction surveys; 95% found the system easy to use. More than half (53%) indicated the self check-in process would have positive effects on their overall cancer care, although only a third (34%) indicated that the efficiency of their care improved.
Conclusions: An automated check-in process is feasible for a diverse population of patients receiving chemotherapy. Multiple uses of the kiosk technology suggest appropriate uptake and retention of the technology. Continued use of the system was not different between RFID and barcode technologies. Patient satisfaction was high and indicated a positive contribution to the delivery of cancer care.
No conflict of interest.

Oncolex.org − a web based cancer encyclopedia for health care providers

M. Seiergren[1], H.E. Danielsen[1]. *[1]The Norwegian Radium Hospital Oslo University Hospital, The Institute for Medical Informatics, Oslo, Norway*

www.Oncolex.org is a free, comprehensive online resource for cancer diagnostics, treatment and supportive care. Oncolex contains extensive material for each cancer type including explanatory articles, illustrations,

animations, photos and video footage. As a resource in continual progress, it keeps track of novel procedures and technology transforming the field of cancer diagnostics and treatment.
Background: Few hospitals and medical centers have cancer specialists on site. Oncolex acts as an accessible resource for health care providers worldwide in need of specialized information when treating and informing their cancer patients. Acclaimed medical specialists in Norway and the US would like to share their knowledge, providing up-to date and detailed information on cancer care to health care professionals worldwide.
The accessibility of Oncolex will aid in increasing the quality of patient treatment, which again will ultimately increase cancer survival rates. The content of Oncolex is constantly being revised and reviewed, and as current information becomes available, it occurs on the site.
Content: Oncolex contains theoretical and practical information on the various forms of cancer, as well as descriptions of procedures within diagnostics, prognostics, surgery, drugs, radiation and adjuvant therapy. Details such as surgical instruments used and cell level histological analyses are included. All types of cancer and stages are covered, so health care providers can consult Oncolex when treating a patient with a possible cancerous disease.
Customizable search options are available on the site, and users can filter out specific information such as surgical procedures or radiation therapy.
Surgical treatments have been filmed at the Norwegian Radium Hospital using a custom made camera crane, capturing the details of the operation without disturbing the surgical team or contaminating the operating theatre.
Conclusions: Since 2006 the Norwegian version of Oncolex has been available, and more than a 1000 Norwegian health care providers consult the site on a daily basis (Norway has a total population of 5 million). In 2012 all texts and articles were translated in to English to supply information for a larger audience. More than 100 cancer specialists from the Norwegian Radium Hospital at Oslo University Hospital and MD Anderson Cancer Center in Houston have contributed to the content of Oncolex.
Oncolex aims to become one of the worlds preferred cancer resources online.
No conflict of interest.

Advances in data capture in oncology outpatients with modern mobile technology

S. Thomas[1], D. Walsh[1], A. Aktas[1], S. Shrotriya[1], B. Estfan[1]. [1]*Cleveland Clinic Taussig Cancer Institute, The Harry R Horvitz Center for Palliative Medicine, Cleveland, USA*

Introduction: The HITECH (Health Information Technology for Economic and Clinical Health) Act, enacted as part of the American Recovery and Reinvestment Act of 2009, was implemented to improve health and management of complex conditions like cancer through appropriate technology. Benefits of electronic health records, patient portals etc has been recognized in Oncology. The ease and portability of iPads (© 2013 Apple Inc, Cupertino, California) is attractive for use in outpatients. Compliance with HIPAA privacy is necessary; REDCap (Research Electronic Data Capture; REDCap Software − Version 5.1.3 − © 2013 Vanderbilt University) allows users to build and manage secure online databases.
Objectives: To assess the feasibility and acceptability of an iPad as an electronic self-report symptom assessment instrument in Oncology outpatients.
Methods: Consent obtained from participants. Electronic symptom assessment instrument on iPad given to the participants prior to their first Oncology visit. The instrument with 34 questions (symptoms, quality of life) was adopted from European Palliative Care Cancer Symptom Study. Responses downloaded to REDCap simultaneously. Printed assessment results given to the Oncologist for effective symptom management.
Results: Sample size = 50; Participation rate = 72%; Mean age = 65 yrs; Males = 64%; College education = 53%; Completion rate = 100%; Self-completed = 65%; Mean time to complete = 10 minutes.
Conclusions:
1. Self completion = 65% in an older population group with college education of 53%
2. Secure web-based data collection ensured compliance with patient privacy regulations
3. New technologies may offer practical comprehensive symptom assessment in complex illness

No conflict of interest.

Automating clinical protocol monitoring: A model from developing countries

A. Samir AlFaar[1], R. Nour[1], M. Kamal[1], S. Ezzat[1], M. Sabry Bakry[1]. [1]*Children's Cancer Hospital Egypt, Research, Cairo, Egypt*

Background: Clinical Research is thought to be a luxury science that needs a lot of investment in implementing policies, protocols and building teams for taking care of patients and their close follow up. With aim of building the first autonomous clinical research unit we tried to reduce the number of staff needed for conducting clinical research and ensuring delivery of patients' best care. We will discuss using the mentioned system in the management of Retinoblastoma as model for other diseases conducted at our center.
Material and Methods: We have developed a standardized treatment protocols for Retinoblastoma diagnosis and treatment based on best available evidence. Clinical research specialist (CRS) job was initiated to handle the different processes in protocol development, monitoring and patients' enrollment. Electronic clinical research system was used to capture different protocol data and registering patients on studies. CRS started to extract data from hospital electronic and paper-based medical record system. The Clinical Research System was integrated with Electronic Medical Records (EMR) to automatically import new patients to the hospital cancer registry. Electronic Hospital Cancer Registry was sorted and revised collaboratively between many departments to distinguish tumours histology and topography. Patients with potential retinoblastoma lesions were also filtered by an electronic routine process from hospital EMR and sent weekly in automatic way to the CR who verifies diagnosis and put the patient on follow-up. With every visit or surgical operation the electronic routine process sends the details to be tracked in the patient clinical research profile.
Results: Clinical protocol management office Retinoblastoma service became fail-proof without missing patients with diagnosis. Moreover, All the visits of the patients were tracked in real time. Patients with missing investigations or data for some visits could be tracked promptly for instantaneous resolution of such incidences. Only one CRS job became needed for monitoring the whole process. The net result of this experience was proper patient monitoring for ensuring that best care is delivered to the patient and maximized control of clinical research subjects enrolled on clinical trials.
Conclusions: The above mentioned integration reduced the need for huge investments in complex processes and reduced the staff needed for implementing clinical research in limited resource settings. We believe that this experience can be replicated in other centers where resources could jeopardize the quality of care.
No conflict of interest.

1216 POSTER

The effect of telephone consultation and triage for outpatients with early breast cancer during chemotherapy

E. Noguchi[1], K. Yonemori[1], Y. Ryushima[2], E. Nara[1], M. Kodaira[1], H. Yamamoto[1], M. Yunokawa[1], C. Shimizu[1], K. Tamura[1], Y. Fujiwara[1]. [1]*National Cancer Center Hospital, Breast and Medical Oncology, Tokyo, Japan;* [2]*National Cancer Center Hospital East, Pharmacy, Chiba, Japan*

Background: In recent years, there has been an increase in the number of cancer patients who receive outpatient chemotherapy. In order to detect adverse events early and provide appropriate care to outpatients, we have offered telephone consultation service for outpatients during chemotherapy since May 2011. We assessed the effect of telephone consultation and triage on unplanned hospital visits and admissions.
Material and Methods: Retrospective date was collected for patients with operable breast cancer who received primary systemic chemotherapy in our outpatient chemotherapy clinic. The chemotherapy regimen included anthracycline-containing regimen or anthracycline followed by taxane. Among patients with HER2-positive cancer, trastuzumab was also administered.
Results: Between May 2011 and March 2012, 166 patients were included. The median age was 51 years (range, 27−78), and all of patients were female. 73 patients (44.0%) were treated with anthracycline-containing regimen only, and 93 (56.0%) with anthracycline followed by taxane regimen. 52 patients (32.0%) accessed the telephone consultation service during chemotherapy, and the median number of service usage was 1 (1−30). A total of 139 complaints, frequently reported symptoms were pain (14.4%), fever (11.5%), chemotherapy-induced nausea and vomiting (CINV) (5.8%), and confirmation of dosing instruction for supportive care drugs (6.5%). Approximately three fourth of consultation subjects were concentrated during first 4 cycles of chemotherapy. After consultation, 12 patients were advised to visit the hospital, 2 of whom ended up with

hospitalization. Patients with telephone consultation had lower rate of unplanned hospital visits compared to patients with no consultation (7.2% vs 31.3%; P = 0.06); but trend toward that of unplanned admissions (1.2% vs 7.2%; P=.151). No treatment-related mortality was observed.
Conclusions: The telephone consultation may reduce unplanned hospital visits during outpatient chemotherapy and decreases the burden on busy hospital clinics. Further evaluation to assess safety and patients' satisfaction is needed.
No conflict of interest.

Near-infrared fluorescence sentinel lymph node mapping in breast cancer: A multicenter experience

F.P.R. Verbeek[1], S.L. Troyan[2], J.S.D. Mieog[1], G.J. Liefers[1], C.J.H. Van de Velde[1], A.L. Vahrmeijer[1], J.V. Frangioni[3]. *[1]Leiden University Medical Center, Surgery, Leiden, Netherlands; [2]Dana-Farber/Harvard Cancer Center, Surgery, Boston, USA; [3]Beth Israel Deaconess Medical Center, Medicine and Radiology, Boston, USA*

Background: The sentinel lymph node procedure plays an important role in the diagnosis and treatment of breast cancer. Currently, blue dyes or radiotracers or a combination are used as standard of care. However, these modalities have several disadvantages, including the use of ionizing radiation and tattooing of the breast up till several months after blue dye injection. Near-infrared fluorescence (NIRF) imaging has the potential to improve the sentinel lymph node (SLN) procedure by facilitating percutaneous and intraoperative identification of lymphatic channels and sentinel lymph nodes. Indocyanine green (ICG) is currently the only FDA and EMEA approved NIRF probe that can be used as a lymphatic tracer. Previous studies indicated that a dose of 500 μM ICG is optimal for SLN mapping in breast cancer. The current multicenter study validates these results in a large patient cohort.
Material and Methods: 95 breast cancer patients planned to undergo SLN procedure were included at the Dana-Farber/Harvard Cancer Center (Boston, MA, USA) and the Leiden University Medical Center (Leiden, Netherlands) between July 2010 and January 2013. Patients underwent standard of care SLN procedure with lymphatic mapping using ^{99}Technetium-colloid, and in 33 patients patent blue dye was also injected. In addition, the optimal dose of 500 μM ICG (1.6 mL) was administered directly before surgical draping. For NIRF imaging the Mini-FLARE™ camera system was used, which is capable of displaying real-time NIR signal and visible image simultaneously.
Results: SLN mapping was successful in 94 of 95 patients using NIRF imaging or a combination of both NIRF imaging and radioactive guidance. A total of 175 sentinel lymph nodes (mean: 1.9, range: 1−5) were detected: 96% hot, 98% fluorescent, and 76% blue. In one patient, the SLN was found only by fluorescence imaging. Time between skin incision and detection of SLN was 8±4 minutes and was correlated to BMI (P <0.001). In all patients that were treated with patent blue, the NIRF signal in the SLN was detected through the axillary fat considerably earlier than blue staining. The NIRF signal of the SLN was on average 11.7±6.7 times higher than the surrounding axillary fat tissue. No adverse events related to ICG injection were noted.
Conclusions: This study demonstrates the safe and feasible introduction of NIRF imaging in order to detect the SLN in breast cancer patients with high identification rate using 500 μM ICG and the Mini-FLARE™ camera system.
Conflict of interest: *Ownership: FLARE™ technology is owned by Beth Israel Deaconess Medical Center, a teaching hospital of Harvard Medical School. It has been licensed to the FLARE™ Foundation, a non-profit organization focused on promoting the dissemination of medical imaging technology for research and clinical use. Dr. Frangioni is the founder and chairman of the FLARE™ Foundation. The Beth Israel Deaconess Medical Center will receive royalties for sale of FLARE™ Technology. Dr. Frangioni has elected to surrender post-market royalties to which he would otherwise be entitled as inventor, and has elected to donate pre-market proceeds to the FLARE™ Foundation. Dr. Frangioni has started three for-profit companies, Curadel, Curadel Medical Devices, and Curadel In Vivo Diagnostics, which may someday be non-exclusive sub-licensees of FLARE™ technology.*

1251 POSTER

Intraoperative ultrasound guided lumpectomy versus mammographically needle localization for breast cancer patients after neoadjuvant treatment

I. Rubio[1], A. Esgueva[1], R. Salvador[2], M. Espinosa-Bravo[1]. *[1]Vall D'Hebrón University Hospital, Breast Surgical Oncology Unit, Barcelona, Spain; [2]Vall D'Hebrón University Hospital, Breast Imaging Radiology, Barcelona, Spain*

Background: The use of intraoperative ultrasound (IOUS) to localize and guide breast cancer tumors excision has advantages over other techniques. It has been reported to improve negative margins and to reduce the resection of large excision volumes of breast. However, the use of IOUS has not been explored after neoadjuvant treatments (NAC). We aimed to compare IOUS guided surgery with needle localization (NL) guided surgery in breast cancer patients after neoadjuvant chemotherapy.
Material and Methods: In this study, patients with T1−3 and N0−2 who underwent NAC and where considered for breast conservative surgery after treatment were included in the study between July 2008 and April 2011. All patients had a clip placed at the beginning of systemic treatments for tumor localization after NAC. IOUS guided surgery was used in patients with a visible clip or tumor under ultrasound. If the clip was not visible under US, a NL guided surgery was performed.
Results: A total of 84 patients were included. IOUS was performed in 37 (44%) and in 47 (56%) a NL was performed. Mean age in IOUS was 59 years (range, 33−83) and in the NL was 52 years (range, 27−88), (p = 0.8). Tumoral volume at diagnosis measured by mammogram was 31.7 cc^3 in the IOUS group and 37.1 cc^3 in the NL group (p = 0.54). There were no statistically differences in the lumpectomy volume between groups (p = 0.84). Thirty-two patients (39%) had no tumor on the lumpectomy or microscopic foci of invasive tumor after NAC (11 patients in the IOUS and 21 patients in the NL group). When considering this group with better response to NAC, lumpectomy volume was smaller in the IOUS group 24.5 [SD 14] vs 41 [20] cc^3; p = 0.02. Tumor free margins were obtained in 95% with IOUS and in 94% in the NL group (p = 0.7).
There were no differences in rates of recurrences between groups with a median follow-up of 42 months (range, 24−57).
Conclusions: Compared to NL guided surgery, IOUS surgery lowers the volume of resection in patients with complete pathologic response or minimal microscopic disease after NAC. IOUS reduces the resection of healthy tissue without compromising margins and local recurrences. Breast conservative surgery can easily be achieved with IOUS guided lumpectomy in patients with good response after NAC.
No conflict of interest.

The SentiMag Study: Sentinel node biopsy with superparamagnetic iron oxide (SPIO) vs. radioisotope

M. Thill[1], A. Kurylcio[2], R. Blechmann[3], V. Van Haasteren[1], B. Grosse[1], G. Berclaz[4], W. Polkowski[2], N. Hauser[5]. *[1]Agaplesion Markus Hospital, Clinic for Gynaecology and Obstetrics Certified Breast Centre, Frankfurt, Germany; [2]Medical University of Lublin, Department of Surgical Oncology, Lublin, Poland; [3]Kantonsspital Baden, Interdisciplinary Breast Centre, Baden, Switzerland; [4]Engeriedspital Lindenhofgruppe Bern, Breast Centre Bern, Bern, Switzerland; [5]Kantonsspitaln Baden, Interdisciplinary Breast Centre, Baden, Switzerland*

Background: The SentiMag study compares the 'gold standard' ^{99m}Tc with a new technique, which employs superparamagnetic iron oxide particles (SPIO) for localisation of sentinel lymph nodes. Aim of this study is to investigate the potential equivalency of the SentiMag® technique in comparison to the gold standard of sentinel lymph node biopsy (SLNB).
Materials and Methods: In a prospective, multicentre and multinational 2-arm study, 150 patients with histologically verified breast carcinoma are examined. For comparison, SLNs are marked initially with radioisotope following a 1- or 2-day protocol. Additionally, SPIO (Sienna+®) is injected at least 20 minutes before SLNB into the subareolar interstitial tissue, followed by 5 minutes massage. SLN-detection is carried out using a magnetometer (SentiMag®) and a gamma probe. Preparation and excision of lymph nodes is conducted using both techniques in a parallel manner. All lymph nodes marked with either tracer are excised.
Results: Interim analysis of 96 patients resulted in a detection rate concordance per patient of 98% (94/96). An average of 1.9 (radioisotope) and 2.0 (SPIO) lymph nodes were collected per patient. Nodal detection rate was 92% (173/188) for the radioisotope vs. 99% (185/188) for the SPIO tracer with magnetometer detection. The proportion of pathologically positive lymph nodes was 21/173 (12%) vs. 22/185 (12%). All pathologically positive lymph nodes detected with the conventional technique (radioisotope) were also detected with the new technique (SentiMag®).

Conclusions: The SentiMag® provides an easy technique which can be rapidly implemented into daily routine. Due to the simple handling, preoperative efforts can be reduced to a minimum. If further and consistent results prove its efficacy, this technique may ultimately replace the standard of care.
No conflict of interest.

1253 POSTER

Laparoscopic near-infrared fluorescence imaging of hepatic uveal melanoma metastases using indocyanine green: A technical note

Q.R.J.G. Tummers[1], F.P.R. Verbeek[1], B.E. Schaafsma[1], M.C. Boonstra[1], A.E. Braat[1], C.I.M. Baeten[1], C.J.H. Van de Velde[1], A.L. Vahrmeijer[1]. [1]*Leiden University Medical Center, Department of Surgery, Leiden, Netherlands*

Background: Uveal melanoma is the most common primary intraocular tumor in adults and up to 50% of patients will develop liver metastases. Complete surgical resection of these metastases can improve 5-year survival, but only a few patients are eligible for a radical surgical treatment. Therefore, it is of great importance to select and treat these patients carefully, to prevent unnecessary laparotomies. Near-infrared fluorescence (NIRF) imaging using indocyanine green (ICG) is a promising technique to assist in the intraoperative identification of liver metastases in real time. However, all published cases concerning intraoperative detection of liver metastases using NIRF and ICG were performed in open procedures. A laparoscopic operation is preferable for patients with liver metastases from uveal melanoma, due to the high risk of multiple small metastases. The aim of this study was to introduce a novel, high definition, NIRF laparoscope during minimal invasive surgery for intraoperative identification of uveal melanoma liver metastases and to provide guidance during resection.
Methods: Two patients previously treated for uveal melanoma, both pre-operatively diagnosed with one solitary liver metastasis are presented. Patients received 10 mg indocyanine green (ICG) intravenously 24 hours before surgery (optimal timing based on a dose-finding study performed in 16 patients with colorectal liver metastases and an open imaging system). A high definition NIR fluorescence laparoscope (Karl Storz, Germany) was used to detect malignant liver lesions. After resection, ex-vivo imaging and fluorescence microscopy was performed for histological validation.
Results: In both patients, laparoscopic NIRF imaging using ICG successfully identified uveal melanoma liver metastases. A clear fluorescent rim around the tumor was observed. In patient 1, seven additional lesions in both left and right liver lobe, not seen with computer tomography (CT), were identified by inspection and NIR fluorescence imaging. In patient 2, one additional lesion, not identified by CT, magnetic resonance imaging, laparoscopic ultrasonography and inspection, was seen with NIR fluorescence imaging. Importantly, NIR fluorescence imaging provided guidance during resection of these metastases. A clear fluorescent rim around the metastases was seen with fluorescence microscopy.
Conclusions: This study describes the successful use of laparoscopic identification and resection of uveal melanoma liver metastases using NIR fluorescence imaging and ICG. This procedure is minimal invasive, and should be used as complementary to conventional techniques for the detection and resection of liver metastases.
No conflict of interest.

1254 POSTER

Liver metastases in close contact to supra-hepatic veins ablated under vascular exclusion

S. Evrard[1], V. Brouste[2], P. McKelvie-Sebileau[2], G. Desolneux[1]. [1]*Institut Bergonié, Digestive Tumours Unit, Bordeaux, France;* [2]*Institut Bergonié, Department of Biostatistics, Bordeaux, France*

Background: Liver metastases (LM) in close contact to suprahepatic veins (SHV) is a frequent cause of unresectability. Radical approach involving hepatic vein resection have been published using demanding grafting techniques for reconstruction. Otherwise experimental data have shown high resistance of SHV to heat. Intraoperative radiofrequency ablation (IRFA) with vascular exclusion (VE) may be a useful approach.
Material and Methods: Out of 358 patients operated for LM, 22 with LM close to a SHV treated by IRFA under VE with at least one year of follow-up were included in this retrospective study. Complications and outcomes are reported.
Results: There were 9 females and 13 males with median ASA of 2 (range: 1−3). All patients received IRFA with VE, combined or not with a parenchymal resection. One patient received two IRFA with VE. One patient received a 2-stage procedure. Median age was 67.5 years [range: 38−80]. Eighteen (81.8%) patients had a primary colorectal tumour and all except four received neoadjuvant chemotherapy.
Median number of metastases was 4.5 [range: 1−12]. They were bilateral for 17 patients. Median size of ablated lesions was 2 cm [range: 1−5.5]. Seven complications occurred (4 Grade IVa), and no mortality. At 4 months, no recurrence of ablated lesions was detected. Median overall survival for colorectal patients was 40 months 95% CI [17.5–not reached]. The OS at 2 years was 72.2%, 95% CI [45.6–87.4].
Conclusions: Resection of the metastasis only leaving clear margins is not so much a technical concern, but an oncological one, representing potential under-treatment. Indeed this resection is at high risk of leaving at least microscopic tumoral residue on the vessel's wall (R1 resection) increasing the risk of recurrence. To resect the lesion plus the vessel *en-bloc* is a good oncological solution, but this presents real technical difficulties for reconstruction. Despite some publications originating from transplant liver surgeons, resection of SHV followed by different grafting reconstructions has not gained widespread acceptance and cannot be advocated as a routine procedure. IRFA plus VE for LM in close contact to a SHV is a safe and effective technique which can extend the applications of liver metastases surgery.
No conflict of interest.

1255 POSTER

Extended indications for skin sparing mastectomy and immediate breast reconstruction without compromising oncological safety

M. Espinosa -Bravo[1], T. Ramos[2], V. Marco[3], A. Guinot[1], M. Ramos[2], I.T. Rubio[4]. [1]*Vall D'Hebrón University Hospital, Universitat Autònoma de Barcelona, Breast Surgical Unit;* [2]*Hospital Universitario, Breast Surgical Unit, Salamanca, Spain;* [3]*Hospital Quirón de Barcelona, Department of Pathology, Barcelona, Spain;* [4]*Vall D'Hebrón University Hospital, Universitat Autònoma de Barcelona, Breast Surgical Unit*

Background: Skin sparing mastectomy (SSM) and immediate breast reconstruction (IBR) is the treatment of choice for early breast cancer patients who need or desire a mastectomy. Considering SSM and IBR in patients after neoadjuvant chemotherapy (NAC) or after breast conservative recurrences is more controversial. The aim of this study was to evaluate the oncological safety and risk of complications in this group of patients.
Material and Methods: Outcomes from a multicentric prospectively maintained database of patients undergoing SSM and IBR from 2001 to 2011 were reviewed.
Results: SSM and IBR were performed on 261 breasts in 235 patients. Eleven (4.2%) patients underwent bilateral prophylactic SSM for high risk or mutation carrier, 7 (2.7%) patients underwent contralateral elective SSM at the same time of the breast cancer mastectomy, 22 (8.4%) patients were for local recurrences after breast conservative treatment (BCT) and 221 (84.7%) patients for a diagnosis of breast cancer who need or desire a mastectomy, including 15 patients (6%) who had received NAC. Tumor characteristic included 49 breasts (20%) with ductal carcinoma in situ, 167 breast (70%) with invasive ductal carcinoma, and 25 breasts (10%) with invasive lobular carcinoma. Pathological stage was 0 in 43 (16.5%) patients, I in 77 (29.5%) patients, II in 105 (40%) patients and III in 21 (8%).
IBR were performed with autologous tissue-latissimus dorsi (LD) in 3 (1%) patients, LD + implant in 76 (29%), and implants only in 182 (70%) patients. 45 (19%) patients had post mastectomy radiotherapy (RT) (15 with LD + implant and 30 with implants).
Complications after surgery were more frequent with autologous tissue than implants (27% vs 14%) $p = 0.013$, and this was not influenced by the pathological tumor stage ($p = 0.8$), NAC ($p = 0.6$) or RT ($p = 0.7$). Complications included 13 cases (5%) with partial skin flap necrosis and 15 with hematoma (5.7%). There was no delay in starting adjuvant treatment in any group.
Locoregional recurrence rate was 5.5%, 8 patients developed recurrence in the skin, 4 patients in the locoregional lymph nodes and one in the pectoral muscle; after median follow-up of 46 months (range 5–135). The 5-year disease free survival and 5-year overall survival was 88% and 96%, respectively.
Conclusion: Based on this study, SSM with IBR is an oncologically safe treatment regardless of tumor stage or neoadjuvant chemotherapy. Local recurrences are low and similar to conventional mastectomies series.
No conflict of interest.

1256 POSTER

Modified gastroesophageal anastomosis in proximal gastrectomy

I. Shchepotin[1], A. Lukashenko[1], O. Kolesnik[1], D. Rozumiy[1], A. Burlaka[1], U. Gukov[1]. [1]*National Cancer Institute in Ukraine, Abdominal Oncology, Kyiv, Ukraine*

Background: Radical proximal gastrectomy is remaining to be a widely applied operative method, especially for gastric cancer, that involves mucosa and submucosa layer of the stomach wall. Postgastrectomy syndromes after proximal gastrectomy are still more or less unavoidable.

That is why, the selecting an ideal alimentary canal reconstructive pattern to elevate the quality of life has become more critical.
Methods: Three hundred twenty-four patients with upper third gastric and gastroesophageal cancers were admitted consecutively with curative intent in a clinic of National Cancer Institute of Ukraine, between May 2007 and May 2012. All patients were randomized in three groups by type of gastroesofageal anastomosis use during proximal gastrectomy (stapler anastomosis (SA), hand-sutured anastomosis by Ivor Lewis (HSA) or modified antireflux hand-sutured anastomosis (MAHSA)).
Results: Endoscopic control at 1 year follow-up of SA group showed reflux esophagitis with the following distributions: 40.6%, 30.2% and 13.2%; the same control in HSA group show 17.3%, 13.5 % and 8.6% for grade A, B and C respectively (according to Los Angeles Classification of Esophagitis). In contrast endoscopic control of MAHSA group showed reflux disease grade A and B only in 14.1% and 1.7% respectively.
The evaluation scores measured by the EORTC QOL gastric cancer-specific questionnaire (QLQ-25) for eating solid, liquid food and enjoying of meals were better in group MAHSA than in SA group patients: 2.1 ± 0.1; 1.3 ± 0.1 and 1.1 ± 0.05 vs 2.4 ± 0.2; 1.7 ± 0.2; 1.8 ± 0.2 respectively. The evaluation scores for acid indigestion or heartburn and acid or bile coming into mouth in main group MAHSA were 1.2 ± 0.08; 1.2 ± 0.08 whereas in groups HSA and SA they were 1.8 ± 0.1; 1.8 ± 0.2 and 2.2 ± 0.2; 1.8 ± 0.1 respectively ($p < 0.05$).
Conclusions: Our data showed that the presented modified method of esophagogastric anastomosis forming is a safe, easy to implement and effective in preventing the development of reflux after PGE for cancer of the upper third of the stomach.
No conflict of interest.

1257 POSTER

Oncoplastic breast-conserving surgery using latissimus dorsi miniflap

H. Fakhry[1], H. Hamza[1], B. Ahmed[1], K. Abdelazeem[1], M. Mostafa[1], G. Amira[2], A. Elyamany[3], S. Shehata[4]. *[1]South Egypt Cancer Institute Assiut University, Surgical Oncology Department, Assiut, Egypt; [2]National Cancer Institute Cairo University, Surgical Oncology Department, Cairo, Egypt; [3]South Egypt Cancer Institute Assiut University, Medical Oncology Department, Assiut, Egypt; [4]Assiut University Hospital Assiut University, Medical Oncology Department, Assiut, Egypt*

Background: Breast-conserving surgery plus radiotherapy is firmly established as a good and safe option for most women with early breast cancer. Cosmoses after Breast-conserving surgery depend on two main factors; the site of the lesion and the breast volume excised in relation to total breast volume. Latissimus dorsi miniflap is one of the various autologous tissue reconstructions that can replenish loss of more than 25% of breast volume. The aim of our study is to evaluate the aesthetic outcome and complications of breast reconstruction using latissimus dorsi miniflap augmentation after wide local excision of the tumor combined with axillary lymph node dissection.
Patients and Methods: From January 2008 till January 2010 twenty eight patients with breast cancer were carefully selected from out-patient clinic of surgical oncology department, South Egypt Cancer Institute and underwent conservative breast surgery in the form of wide local excision with safety margin with immediate reconstruction using latissimus dorsi miniflap either by muscle only or musculocutaneous flap. Neoadjuvant chemotherapy was given in some patients to reduce the tumor size and after surgery; all cases received eligible adjuvant therapy. The aesthetic results were assessed independently by the patients and two surgeons. The aesthetic results have been ranked into three categories by the surgeons: good, satisfactory and fair and satisfaction of patients has been classified into three levels: deeply satisfied, satisfied and poorly satisfied. Follow-up of the patients ranging from 24 to 48 months (median 28 months) was done.
Results: Most of the patients (71.4%) were having T2 tumor, while (14.3%) of the patients had T1 tumor and (14.3%) had T3 tumor. Neoadjuvant chemotherapy was given for 14 patients with overall response rate about 76.7%. Wide local excision with safety margin with immediate reconstruction using latissimus dorsi mini-flap was done. Seventeen patients had reconstruction with muscle only, while 11 patients had reconstruction by musculocutaneous flap. A deeply satisfying cosmetic result was achieved in (82.1%) and none of them subsequently required mastectomy. After median follow up of 28 month, the progression free survival was 92.9% and the over all survival was 96.4%. No local recurrence was recorded.
Conclusion: Breast augmentation with autologous tissue comes into play by reducing the resultant deformity when the breast volume excised is significant. The Latissimus dorsi miniflap is the mainstay of oncoplastic breast surgery after partial mastectomy and it has low donor site morbidity, deep patient satisfaction with low and temporary postradiation effects.
No conflict of interest.

1258 POSTER

Oncoplastic surgery as an indispensible technique in breast conserving surgery

A. Stanislawek[1], K. Solowiej[2], S. Lukasiewicz[2], M. Zajac[2], M. Rzaca[3]. *[1]Centrum Onkologii Ziemi Lubelskiej, Chair of Social Health Care, Lublin, Poland; [2]Centrum Onkologii Ziemi Lubelskiej, Departmeny of Surgical Oncology, Lublin, Poland; [3]Medical University, Department of Oncology, Lublin, Poland*

Background: In breast cancer surgery more and more weight is lent to the cosmetic effects of operations whose aim is to decrease the psychic trauma of female patients and minimize mutilation resulting from the surgical treatment. The recent fundamental achievements in breast cancer surgery include the increasing use of breast conserving surgery, performing of breast reconstruction operations in such cases when breast conserving surgery is impossible and resignation from the excision of all the axillary lymph nodes in favour of sentinel node biopsy. This direction of changes in the treatment methods has begun to appear in Poland as well. Oncoplastic surgery is a new element of the therapy. It is the connection of classic oncological surgery associated with tumour resection with plastic surgery procedures. The essence of oncoplastic surgery is supplementing of the defect after tumour excision with healthy surrounding tissues. It is especially important in the case of an unfavourable proportion of a tumour size to the breast size, when a considerable tissue defect causes a negative cosmetic effect.
The aim of the study was to examine whether oncoplastic surgery has significantly increased the percentage of patients undergoing breast conserving surgery.
Material and Methods: 1468 patients with breast cancer were operated in the Oncological Surgery Department in 2010–2011. There were performed 648 simple amputations with sentinel node biopsy /SNB/, or axillary lymph node dissection /ALND/. Breast conserving surgery with SNB or ALND was conducted in 820 cases, including 58 oncoplastic operations. There was performed the translocation of breast tissues to suplement the defect after tumour excision with a margin in 45 patients, and subcutaneous amputation with a simultaneous prosthetic restoration was conducted in 13 patients.
Results: After introduction of oncoplastic surgery increase in the use of BCT techniques compared to simple mastectomy reached approximately 9%.
Conclusions: Oncoplastic surgery significantly increases the possibility of performing breast conserving surgery and thus constitute an indispensible technique which is a must for oncological surgeons specializing in breast cancer treatment. The survey of female patients' satisfaction revealed a high level of satisfaction from the aesthetic effects − 87%.
No conflict of interest.

Strategy for synchronous and multiple liver metastasis

S. Osada[1], H. Imai[1], Y. Sasaki[1], K. Yoshida[1]. *[1]Gifu University School of Medicine, Surgical Oncology, Gifu, Japan*

Background: Surgical indications for resection of synchronous metastasis from colorectal cancer (CRC) and the optimal timing of hepatectomy are still controversial and widely debated.
Patients: Synchronous and multiple metastatic liver tumours were detected in 57 since May 2005. Our treatment policy has been to perform hepatectomy first, if the resection can be done with no limit on size and number of tumours. However, if curative resection is not, chemotherapy is begun first and timing for the possibility of a radical operation is planned immediately. In 37 patients whose tumours were located only in the liver, primary tumour resection was performed first in 16 patients, and after tumour-decreasing by chemotherapy, operation was performed in 7 patients. In 20 patients in whom chemotherapy was performed first, after controlling the distant metastasis, hepatectomy was performed in 3 patients, and staged hepatectomy was performed in 10 patients.
Results: 1) Recurrence was detected after hepatectomy in 75.0% of simultaneous resection cases and in 70.0% of staged cases. In the recurrence cases, early detection (within 6 months) after tumour resection occurred in 58.3% of the simultaneous and 14.2% of the staged. 2) No differences in results of pre- and postoperative liver function tests were found, and duration of hepatectomy and blood loss were also similar. 3) Median survival time (MST) and 2-year survival rate were significantly better in the hepatic resection cases than in the non-operated cases. There was no significant difference in MST or 2-year survival rate between simultaneous and staged cases. 4) In 10 staged cases, length of chemotherapy had no effect on pre- or postoperative liver function test results, and survival curves.

Conclusion: The present data show that neoadjuvant chemotherapy does not increase the risk of postoperative complications or the surgical difficulties of hepatectomy for colorectal metastases.
No conflict of interest.

Randomized control trial for non-palpable breast lesions: Comparing radio-guided occult lesion localization (ROLL) vs. wire guided lesion localization (WGLL)

C. Duarte[1], F. Bastidas[1], A. De los Reyes[1], M.C. Martinez[1], G. Hurtado[1], M.C. Gomez[1], R. Sanchez[1], J. Manrique[1]. *[1]Instituto Nacional de Cancerologia, Bogotá, Colombia*

Background: Non-palpable breast lesions have been localized using a variety of methodologies. Wire guided lesion localization (WGLL) has been employed for many years with successful outcomes. Recently, with the development of radio-pharmaceutical agents, radio-guided occult lesion localization (ROLL) has been implemented in actual worldwide practice. We conducted a study intended to determine the most effective method to localize and excise these non-palpable lesions in our countries biggest neoplastic referral center.
Material and Methods: A randomized control trial was designed and conducted in the National Cancer Institute of Colombia located in Bogota, from March 2006 to June 2011. We included 129 patients of which 64 (49.6%) were allocated to the ROLL group and 65 to the WGLL (51.4%). The intention was to compare effective lesion localization in these two groups of patients with lesions at risk evaluated by mammography or ultrasonography that previously had non-diagnosis percutaneous biopsy.
Results: In our study ROLL technique demonstrated a statistically significantly better median of centricity of the lesion (ROLL= 11.7; WGL = 15.4 p = 0.038). No differences were found for other variables studied between the two groups regarding the demographical characteristics, the surgical specimen, need of widening margins, surgical complications, difficulty of procedure and patient/surgeon satisfaction.
Conclusions: Using the ROLL technique is as equally as effective as WGLL in identifying the non-palpable lesions of the breast. In our study the ROLL technique demonstrated a better centricity of the lesions leading us to conclude that this technique could be applied as routine in localizing non-palpable breast lesions in centers of expertise.
No conflict of interest.

1261 POSTER

Lymphatic mapping and sentinel lymph node biopsy in an in-vivo porcine model using a novel magnetic technique

B. Anninga[1], M. Ahmed[1], J.J. Pouw[2], R.M. Fratila[2], B. Ten Haken[2], D. Westbroek[1], S.E. Pinder[1], M. Douek[1]. *[1]King's College London, Research Oncology, London, United Kingdom; [2]University of Twente, MIRA-Institute for Biomedical Technology and Technical Medicine, Enschede, Netherlands*

Background and Objective: A novel magnetic technique for sentinel lymph node biopsy (SLNB) was developed and is currently being evaluated in an international multicentre trial (SentiMag). In this European collaborative project, we evaluated the optimal dose of magnetic tracer required for performing sentinel lymph node biopsy (SLNB). We also quantified the iron content of nodes and correlated this with readings with handheld magnetometer readings.
Materials and Methods: Local ethics approval was obtained (IR-CAD Ethical Committee, Strasbourg, France). SLNB was performed in anaesthetized pigs (Strasbourg, France) following the subcutaneous administration (deep to the third nipple in the inguinal mammary glands) of magnetic tracer (Sienna+, Endomagnetics Ltd) using a magnetometer (SentiMag, Endomagnetics Ltd.) to localize and excise groin lymph nodes. Procedures were undertaken bilaterally and using a range of different concentrations of magnetic tracer injected (0.1−2.0 ml). First hot spot measurements were performed within minutes post injection. Second hot spot measurements and SLN dissection were performed four hours post injection. Further ex-vivo counts were obtained with the handheld magnetometer. In addition, total quantity of iron in the SLNs was estimated using quantitative magnetometry (University of Twente, the Netherlands). High field ex-vivo MRI (14.1 T) and histological examination (H&E and Perl's staining) was undertaken to demonstrate the intra-nodal presence and distribution of magnetic dye.
Results: The magnetic dye drained from injection site to SLNs in the groin area in all cases. A total of 31 SLNB procedures (16 pigs) were successfully undertaken and 76 nodes (74 sentinel; 2 non-sentinel) were retrieved. Magnetic dye was proven to be present in the SLNs when measured with quantitative magnetometry, on MRI and on histological examination.
Conclusion: SLNB with the magnetic technique is feasible after subcutaneous injection of magnetic tracer, with all doses used. This magnetic tracer is ideally suited for SLNB.
No conflict of interest.

Adding imaging to the clinical picture improves BRONJ case adjudication and staging classification: Results of the "MISSION" study

A. Bedogni[1], V. Fusco[2], M. Scoletta[3], G. Saia[4], G. Colella[5], G. Favia[6], A. Agrillo[7], G. Oteri[8], L. Ottolenghi[9], G. Campisi[10]. *[1]Azienda Ospedaliera Universitaria Integrata, Department of Surgery, Verona, Italy; [2]Azienda Ospedaliera di Alessandria, Department of Oncology and Hematology, Alessandria, Italy; [3]University Hospital S.G. Battista, Department of Biomedical Science and Human Oncology, Turin, Italy; [4]University Hospital of Padua, Department of Medical and Surgical Specialties, Padua, Italy; [5]Second University of Naples, Department of Head and Neck Pathology, Naples, Italy; [6]University Hospital of Bari, Department of Dentistry, Bari, Italy; [7]Sapienza University, Department of Maxillo-Facial Surgery, Rome, Italy; [8]University Hospital of Messina, Department of Odontostomatology, Messina, Italy; [9]Sapienza University, Department of Odontostomatological and Maxillofacial Sciences, Rome, Italy; [10]University Hospital P. Giaccone, Department of Surgical and Oncological Sciences, Palermo, Italy*

Background: Osteonecrosis of the jaw (BRONJ) is an adverse event of bisphosphonate therapy, which can significantly affect the quality of life of patients. Osteonecrosis of the jaw vary widely among studies and remain unclear. Recent data suggest that a defective definition and staging classification, based only on evidence of necrotic jawbone exposure, purulent discharge and pain could represent the main culprit of current under-diagnosis and inconsistent results of treatment.
Material and Methods: The Multicentre study on phenotype, defInition and claSSification of osteonecrosIs of the jaws associated with bisphosphONates (MISSION) was designed to investigate a well characterised large cohort of individuals diagnosed with BRONJ so to test their clinical and radiological phenotype against staging system of the American Association of Oral and Maxillofacial Surgeons (AAOMS), which relies on clinical data alone. The extent of jawbone involvement at computed tomography (CT) was measured based on the density of bone (osteosclerosis). Two patterns were analysed: focal sclerosis against diffuse sclerosis, with the former showing exclusive involvement of the alveolar bone process.

Thirteen European centres (the Institutions here represented plus UCL Eastman Dental Institute of London, Hospital 'S. Anna' of Como and the University of Pisa) contributed to MISSION collecting detailed clinical data of 799 individuals, the largest osteonecrosis cohort ever reported.
The main outcome measure was the proportion of individuals within the cohort who escape the standard AAOMS stage classification when CT is added to describe the extent of bone disease.
The local ethical Committee of each contributing Center approved the study protocol.
Results: Testing the present cohort against AAOMS staging system led to the adjudication of a total of 192 individuals (24.0%) as having non-exposed BRONJ (stage 0), and 605 with exposed BRONJ (stage 1 =72; stage 2 = 405; Stage 3 = 130). When bone disease extent as measured on CT was tested against each AAOMS stage, 57% of Stage 0 patients had already diffuse bone disease to the jaw despite the absence of frank bone exposure. In addition, more than half of AAOMS stage 1 patients had diffuse disease at CT, while 1/3 of AAOMS Stage 2 (35.1%) patients had focal disease at CT. Instead, inclusion of CT signs of bone involvement did not change distribution of AAOMS Stage 3 patients.
Conclusions: We have shown that clinical adjudication of ONJ patients based on current AOOMS staging system would potentially translate into underdiagnosis of stage 0 patients and defective treatment allocation for the entire population. The addition of imaging to the clinical picture of ONJ may become paramount in the future to anticipate diagnosis, categorize patients more consistently and offer successful treatments.

1263 POSTER

Evaluation of surgical outcomes in conventional endoscopic thyroidectomy compared with single incision endoscopic thyroidectomy through the axillary approach for papillary thyroid carcinoma

J. Lee[1], J.M. Baek[1], K.Y. Sung[1]. [1]*The Catholic University, Surgery, Gyeonggi-Do, South Korea*

Background: Minimally invasive thyroidectomy has been researched extensively, and even now, the operative technique for this procedure is being further developed through research. Endoscopic thyroidectomy is performed by many techniques, using the axillary, breast, and anterior chest approaches. We have introduced single incision endoscopic thyroidectomy (SIET) as an alternative method for conventional endoscopic thyroidectomy (CET). The purpose of this study is to compare the surgical outcomes of CET and SIET for papillary thyroid microcarcinoma.
Material and Methods: This study included 118 patients with thyroid microcarcinoma who underwent CET and SIET through the axillary approach from Oct 2002 through June 2012. The surgical outcomes were retrospectively analyzed. The assessment included the size of tumor, operation time, complications, length of hospital stay, postoperative pain, and patient satisfaction.
Results: There was no conversion to conventional open thyroidectomy. The mean age of the patients was 42.3±7.6 years for CET and 38.0±9.0 years for SIET ($p = 0.551$). The mean size of the tumor were 0.5±0.23 cm in CET and 0.56±0.297 cm in SIET ($p = 0.051$). The operation time for SIET was not greater than that for CET (138.4±36.9 min vs. 128.3±36.55 min, $p = 0.794$). Postoperative pain was scored using the Visual Analog Scale (VAS). Postoperative pain was lesser in SIET than in CET (VAS 1: 4.7±1.7 vs. 3.7±1.2, $p < 0.001$; VAS 7: 2.6±1.9 vs. 2.0±1.4, $p < 0.04$). Cosmetic satisfaction was evaluated using a numeric system that ranged from 1 (extremely satisfactory) to 4 (not satisfied at all). Postoperative cosmesis appeared to have no difference between both groups (1.43±0.55 vs. 1.3±0.49, $p = 0.058$).
Conclusions: Endoscopic thyroidectomy is safe and feasible using both CET and SIET. However, SIET results in less postoperative pain with no increase in operation time. Although SIET has not been evaluated in a prospective clinical trial or large study, our results suggest that SIET reduces the postoperative pain by reducing the invasiveness of the procedure.

1264 POSTER

A prospective study of surgical decompression and spinal reconstruction in vertebral metastases

M. Wong[1], H. Lau[1], A. Kaye[1]. [1]*Royal Melbourne Hospital, Department of Neurosugery, Melbourne Victoria, Australia*

Background: The present prospective study aims to investigate the role of surgical decompression and spinal reconstruction in vertebral metastases.
Material and Methods: Patients with vertebral metastases were enrolled. Surgical approaches include laminectomy or laminectomy plus corpectomy. Pedicle screws stabilization was performed in all cases. Corpectomies and stabilization were performed via a single stage posterolateral approach. Expandable titanium cages were used to reconstruct spinal column after corpectomy. All patients were followed up until death.
Results: 21 patients (11 males, 10 females) with a mean age of 58 years were enrolled. 12 patients had a history of cancer, whereas vertebral metastases were first presentation of cancer in 9 patients. There were 3 cases in cervical spine, 14 in thoracic and 4 in lumbar spine. The most common primary cancers were lung, breast, colorectal and renal. Laminectomy and stabilization were performed in 3 cases, and corpectomy and cage reconstruction were performed in 18 cases. No peri-operative death or major complication was encountered. All patients were discharged to home or rehabilitation after surgery. Visual analog scale (VAS) pain score was significantly reduced from 8.8 to 3.2. In patients who had non-surgical treatment of vertebral metastasis, VAS decreased significantly from 8.3 to 3.1. There was no neurological deterioration after surgery. In patients with pre-operative neurological deficits, most patients (10/12) improved after surgery. Cobb angles were significantly reduced from 15 to 10 degree, and vertebral height was significantly increased from 28 to 34 mm after surgery. Mean survival was 5.3 months.
Conclusions: Surgical decompression and spinal reconstruction appeared to be safe in patients with vertebral metastases. Surgery reduced pain in patients with vertebral metastases, and likely to be more effective than non-surgical treatments alone. Surgery improved neurological deficit and spinal deformity.

Diagnostic accuracy of preoperative CT scan and 18F-FDG PET/CT in patients with peritoneal carcinomatosis undergoing hyperthermic intraperitoneal chemotherapy (HIPEC) following cytoreductive surgery

E.M. Pasqual[1], S. Bacchetti[1], S. Bertozzi[1], A. Londero[2], S.M.M. Basso[3], D.A. Santeufemia[4], S. Tumolo[4], G. Lo Re[4], F. Lumachi[5]. [1]*S. Maria della Misericordia Hospital, Department of Surgery, Udine, Italy;* [2]*S. Maria della Misericordia Hospital, Gynecologic & Obstetric Clinic, Udine, Italy;* [3]*S. Maria degli Angeli Hospital, Surgery 1, Pordenone, Italy;* [4]*S. Maria degli Angeli Hospital, Medical Oncology, Pordenone, Italy;* [5]*University of Padua School of Medicine, Department of Surgery Oncology & Gastroenterology, Padova, Italy*

Background: The peritoneum is a preferred site of metastasis from several primary malignancies, and peritoneal carcinomatosis (PC) is one of the most significant negative prognostic indicators in patients with metastatic disease. A survival benefit has been observed for patients with PC from colorectal, ovarian, and gastric carcinomas treated by cytoreductive surgery (CRS) followed by intraoperative hyperthermic intraperitoneal chemotherapy (HIPEC). In patients undergoing this treatment modality, the strongest determinant of outcome is the residual tumor extension after CRS. Unfortunately, PC can be difficult to diagnose preoperatively by imaging studies. The aim of our study was to evaluate the role of 18F-2-deoxy-fluoro-D-glucose positron emission tomography/computed tomography (PET/CT) scanning in detecting the presence and the extent of PC in patients with various malignancies.
Patients and Methods: A group of 47 patients (median age 61.4±11.5 years) with advanced or recurrent cancers (colorectal=26, ovarian=21, gastric=8, pseudomyxoma peritonei=3) scheduled for CRS and HIPEC underwent preoperative CT-scan and PET/CT. The results were expressed as sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy. The negative (NLR) and positive (PLR) likelihood ratio were also obtained. The receiver operator characteristic (ROC) curves were drawn, and areas under the curve (AUC) were measured. The 95% confidence interval (95% CI) was also calculated, when appropriate. The results of CT scan and PET/CT were compared with the final surgical findings.
Results: The sensitivity, specificity, PPV, NPV, accuracy were 91%, 33%, 93%, 29% and 69% for CT-scan, and 82%, 67%, 95%, 33% and 71% for PET/CT, respectively. NLR and PLR were 0.27 (95% CI 0.07–1.09) and 1.37 (95% CI 0.76–2.44), while the AUC was 62 and 74 for CT-scan and PET/CT, respectively (p=NS).
Conclusions: In patients with PC undergoing surgery both PET/CT and CT showed low sensitivity, and thus they seem not to be a reliable tool in view of treatment planning. Our study demonstrates that PET/CT does not add substantially to CT scanning in the detection of this disease.

1266 POSTER

Surgical management for gallbladder cancer

A. Simsek[1], T. Ozer[2], N. Zeybek[1], N. Ersoz[1], A. Gunal[3], Y. Peker[1], S. Cetiner[1]. [1]*Gulhane Military Medical Academy, General Surgery, Etlik Ankara, Turkey;* [2]*Gulhane Military Medical Academy, Gastrointestinal Surgery, Etlik Ankara, Turkey;* [3]*Gulhane Military Medical Academy, Pathology, Etlik Ankara, Turkey*

The effect of radical resection in gallbladder cancer(GC) is still area of debate. Gallbladder carcinoma is rare and associated with dismal outcomes. Radical surgery is the only curative treatment and options for adjuvant therapy remain limited. Gallbladder cancer is a highly lethal disease. It is an aggressive disease with extremely poor outcome after surgical treatment and a poor prognosis. This study aimed to determine the factors influencing outcome of treatment in patients with gallbladder carcinoma and to identify the patients who might benefit from radical surgery and adjuvant therapy.
A retrospective analysis was conducted of 57 patients with the gallbladder carcinoma and the results of surgical treatment of patients with pathologically confirmed gallbladder cancer were identified. There were 57 cases (43 females, 14 males) with a mean age of 58 (range 36−84) years, treated surgically between 1995–2012.
57 patients were assessable for this study. Simple cholecystectomy was the only procedure performed in 44 of T2 and 4 of T3 cases. Radical cholecystectomy was performed as the primary procedure for 5 of the T2 and T3 cases in each. Palliative by-pass procedure or exploration was performed in 4 patients with unresectable tumours. Adenocarcinoma was the most frequent histological type and squamous cell carcinoma in 15 percent. The three-year survival rate was 70%(40 cases) and five-year survival rate was 30%(17 cases).
Favourable survival rate can be achieved after curative resection, even for selected patients with advanced disease. Adjuvant therapy may improve the survival of patients with gallbladder carcinoma. Gallbladder cancer continues to carry a poor prognosis. Very few patients underwent aggressive surgery. En bloc resection and lymphadenectomy may have stage-specific effects on survival. The only consistent curative therapy for gallbladder cancer is surgical resection. A subset of patients with peripancreatic positive nodes or invasion of adjacent organs seems to benefit from a synchronous pancreaticoduodenectomy. Radiotherapy and chemotherapy have not been found effective as an adjuvant or palliative therapy in gallbladder cancer. Because flat infiltrating gallbladder cancer and cancer with cholecystitis and numerous stones are difficult to diagnose preoperatively, we recommend taking frozen sections from patients who are of advanced age, have a long history of stones, or have a thickened gallbladder wall.

Ruptured hepatocellular carcinoma in cirrhotic patients: Treatment options and survival outcome

G. Christodoulidis[1], D. Dimas[2], F. Constantinidis[3]. [1]*University Hospital of Larisa, Gen Surg Dep, Larisa, Greece;* [2]*General Hospital ELPIS, Gen Surg Dep, Athens, Greece;* [3]*General Hospital Sismanogleio, Radiology, Athens, Greece*

Background: Spontaneous rupture of hepatocellular carcinoma (HCC) is reported to be 3−15% of cases, with an increased incidence in Asian countries. It is considered the third leading cause of hepatocellular carcinoma-related death, after tumour progression and liver failure.
Materials and Methods: We retrospectively analysed data of 12 patients with ruptured HCC who were surgically or conservatively treated and evaluated the treatment modalities, the complications and the survival outcome.
Results: All the patients had histologic evidence of underlying cirrhosis. The median age of the patients was 65 years. There was a male predominance. Eight of these patients were hemodynamically unstable at presentation. Five patients had multifocal disease. Transcatheter arterial chemoembolisation was performed in 5 patients and 7 patients were subjected to emergency surgery. Patients with cirrhosis who received transcatheter arterial chemoembolisation had a median survival rate of 32 days. The patients who subjected to hepatectomy had higher survival rates 28.5% at 1 year.
Conclusion: The treatment of ruptured HCC should be individualised for each patient. Even though transcatheter arterial chemoembolisation is a promising treatment option still surgery is associated with better survival.
No conflict of interest.

1268 POSTER

Laparoscopic surgery of pancreatic endocrine tumors: Is there a benefit?

M. Soloviy[1]. [1]*Lviv National University of Medicine, Surgery, Lviv, Ukraine*

Background: Although minimally invasive surgery is widely adopted for the treatment of many surgical diseases, results of laparoscopic procedures for pancreatic endocrine tumors (PET) are published only in small series. Objective of the study was to reveal and estimate the benefits of laparoscopic resection of PET and to compare it with the open approach by reviewing the available data.
Methods: Medline search for the words laparoscopic resection and pancreatic endocrine tumors was performed. 52 relevant papers were identified and studied from 2000 till 2012.
Results: Four non-randomized studies compared laparoscopic and open approach for resection of PET comprising totally 384 patients − 81 laparoscopic and 303 open. There were no cases of postoperative mortality. Mean operative time was estimated in three studies where there has been a significant difference ($p < 0.5$) in favor of open technique (121 min. vs 92 min) in one study, in favor of laparoscopic technique in the other study (188 min. vs 305 min.) and with no difference in the third study. Mean hospital stay was estimated in four studies, where it reached a significant difference ($p < 0.05$) in one study in favor of laparoscopic group (11 days vs. 14 days). Rate of postoperative pancreatic fistula was significantly higher in open group in two studies reaching up to 100% in comparison to only 14.2% in laparoscopic groups ($p < 0.05$).
Conclusion: Laparoscopic resection of PET is at least as feasible and safe as open surgery with possible benefits in terms of operative time, length of stay and rate of pancreatic fistula.

1269 POSTER

Experience with the implant of vascular access devices by medical oncologist in a non-surgical scenery

D. Rodriguez Rubi[1], L. Ruiz[1], L. Sanchez[1], W. Li[1], Q. Perez[1], C. Alvarez[1], M. Solis[1], L. Faez[1], E. Esteban[1]. [1]*Hospital Univ. Central de Asturias (HUCA) and Instituto Univ. de Oncología del P, Medical Oncology, Oviedo − Asturias, Spain*

Background: Totally implantable central venous catheters are widely used in the management of patients (pts) with malignant diseases in order to facilitate drug delivery for the new therapeutic protocols. These are based on continuous administration and higher doses of chemotherapeutic agents with relative phlebitis problems and supportive treatment. Staff of our department, specially trained on the routinely implant of central venous accesses were in charge of the procedure. The technique was carried out under local anaesthetic in a special location of day hospital or in hospitalization environment, under strict aseptic measures without fluoroscopic control.
Material and Methods: From Sep 94 to March 2013, 1240 devices (port-a-cath systems [PS]) were implanted in 1212 pts, with age 50.5 yr (14−81) (mean, range), and K.I. 70% (50–100), female 738/male 474. Venous access: right interior jugular 715, left subclavian 245, right subclavian 252, left interior jugular 28. A thorax X-ray was performed after each procedure and in 168 pts prophylactic antibiotics were given.
Results: The venous access remained implanted a median of 438 days (1- +2210). Complications occurred in 195 placements (16%): Infections 87 (7%); deep venous thrombosis 50 (4%) Left placements 26, right placements 24; obstruction 7 (0.6%); malpositioned 25 (2%); fractures/migration 21 (1.7%); pneumothorax 4 (0.32%); local skin necrosis 7 (0.6%). Five hundred and twenty devices were removed, 347 (28%) after completing planned therapy and 173 (14%) due to complications [Infections (92), migration (22), malposition (12), venous thrombosis (26), obstruction (11) and skin necrosis (10)].
Conclusions: The best access route in order to avoid complications seems to be the right internal jugular vein. Our results are comparable with those obtained when the venous access is placed in the operating room, under fluoroscopic control and prophylactic antibiotics are administrated. This procedure, on top of being more comfortable for the patients is more affordable for the public health system.

1270 POSTER

Needle oophoropexy: A new simple technique for ovarian transposition prior to pelvic irradiation

Z. Gad[1], W. Gareer[1], H. Gareer[1]. [1]*NCI, Surgical Oncology, Cairo, Egypt*

Background: Irradiation of the pelvis in the treatment of cancers will result in ovarian failure unless the ovaries are shielded adequately. To protect

the ovaries, an oophoropexy may be performed. Our aim was to evaluate the feasibility, morbidity, and efficacy of laparoscopic ovarian transposition using a simple percutaneous needle technique.
Material and Methods: Fifteen patients (ten with rectal cancer and five with Hodgkin's disease) underwent the new laparoscopic oophoropexy technique. Laparoscopic releasing of the ovary was performed by cutting the utero-ovarian ligament followed by placing the ovaries on the anterior abdominal wall. A percutaneous straight needle was introduced through a 2-mm skin incision at the site of fixation. Repositioning of the ovaries was done on an outpatient basis without the need for readmission to the operating theatre.
Results: The technique was effective, reliable, and simple with no morbidities. Repositioning was performed simply in the outpatient clinic. At follow-up, 11 patients had evidence of ovarian function.
Conclusion: Percutaneous needle transposition of the ovaries is a simple, effective, reliable, and easy-to-perform technique. It has short learning curve and can be done by less experienced laparoscopic surgeons.

1271 POSTER

From simple to complicated: The first 400 consecutive cases of oncologic robotic surgery

O. Sgarbura[1], C. Blajut[1], V. Tomulescu[1], I. Popescu[1]. *[1]Fundeni Clinical Institute, General Surgery and Liver Transplanation, Bucharest, Romania*

Background: During the recent years, robotic surgery has known a tremendous growth although it is still not as widespread in general surgery as it was expected. However, the robot has changed the preferred approach even in oncologic surgery, in the centers that own the device. The aim of the present study is to globally assess the use of the robot for general oncology cases and to establish major indications.
Material and Methods: The first 400 consecutive cases of oncologic robotic surgery performed in our center were analyzed. The cases span on almost five years since the 1st of January 2008 until the 3rd of December 2012. Data was prospectively assembled in a Robotic Surgery Registry. Personal, clinical and surgical variables were recorded and analyzed using parametric and non-parametric tests under SPSS 16.0 software (SPSS Inc., Chicago IL, USA) for Windows. A p-value <0.05 was considered significant.
Results: In the study group there were 164 males (41%) and 236 females (59%) with an average age of 57 years (±12.53). The operations were performed by three main surgeons in stable surgical teams, with 30% of the cases performed in 2012. Indications included primary neoplasms, relapses and metastases of all major abdominal organs and some thoracic organs (thymus and esophagus). Only 17 patients needed thoracic surgery. 243 cases (60.8%) were pelvic surgery cases (gynecological cancers, rectal cancers, pelvic invasions or recurrences). In time, surgeons showed a stronger preference for pelvic robotic surgery compared to other indications ($p = 0.007$). A surgical complexity score showed a mild increase of the procedures' complexity in time and a correlation with the operative time ($p < 0.05$). Whilst pelvectomies where approached from the first year of experience, major hepatectomies and major pancreatic surgery were only addressed after an experience of 200 cases. There were only 11 conversions (2.8%) and 104 (26%) various Clavien-grade postoperative complications. The pathologic reports were satisfactory. Survival data was not available for all patients.
Conclusions: Robotic surgery in oncologic indications is feasible and safe. Pelvic cancers and pelvic recurrences are one of the most interesting indications due to a combination of factors favoring robotics: a narrow working space, complex procedures and difficult operating positions.
No conflict of interest.

Efficacy and safety of NEPA, a fixed-dose combination of netupitant and palonosetron, in preventing chemotherapy-induced nausea and vomiting (CINV) in patients receiving moderately emetogenic chemotherapy (MEC)

M. Aapro[1], G. Rossi[2], G. Rizzi[3], M.E. Borroni[4], V. Lorusso[5], M. Karthaus[6], S. Grunberg[7]. *[1]Clinique de Genolier, Oncology, Genolier, Switzerland; [2]Helsinn Healthcare S.A., Clinical Operations, Lugano, Switzerland; [3]Helsinn Healthcare S.A., Statistics & Data Management, Lugano, Switzerland; [4]Helsinn Healthcare S.A., Corporate Clinical Development, Lugano, Switzerland; [5]National Cancer Institute Giovanni Paolo II, Oncology, Bari, Italy; [6]Klinikum Neuperlach and Harlaching, Hematology & Oncology Staedt, Munich, Germany; [7]Fletcher Allen Health Care, Oncology, Burlington, USA*

Background: Targeting multiple molecular pathways is important for maximizing control of CINV. This is supported by antiemetic guidelines which recommend agents that target different pathways involved in emesis. NEPA is a fixed-dose combination of netupitant (NETU), a highly-selective NK_1 receptor antagonist (RA) and palonosetron (PALO), a pharmacologically and clinically distinct 5-HT_3 RA, that targets dual antiemetic pathways.
Materials and Methods: This multinational, randomized, double-blind, parallel group study (NETU-08−18; NCT01339260) evaluated the efficacy and safety of a single oral dose of NEPA (NETU 300 mg + PALO 0.50 mg) versus a single oral 0.50 mg dose of PALO in chemotherapy-naive patients receiving anthracycline-based chemotherapy. All patients also received oral dexamethasone (DEX) on Day 1 (12 mg in the NEPA arm and 20 mg in the PALO arm). The primary efficacy endpoint was complete response (CR: no emesis, no rescue medication) during the delayed (25–120 h) phase. Secondary efficacy endpoints included complete protection (CR plus no significant nausea), no emesis, and no significant nausea. Safety was assessed through reporting of adverse events, ECGs and cardiac troponin levels.
Results: 1455 patients were randomized. Treatment groups had comparable baseline characteristics with the overall population being predominantly female (98%) and white (80%), with a mean age of 54 years.
NEPA was superior to PALO for the primary CR endpoint as well as secondary efficacy endpoints during the delayed and overall phases following chemotherapy.

	Overall (0–120 h) % Patients	
	NEPA (N = 724)	PALO (N = 725)
Complete response	74.3*	66.6
Complete protection	63.8*	57.9
No emesis	79.8*	72.1
No significant nausea	74.6*	69.1

*p-value <0.05.

The type, frequency, and severity of AEs were comparable between groups. Most frequently reported treatment-related adverse events (TRAEs) for NEPA included headache (3.3%) and constipation (2.1%). The majority of adverse events were mild/moderate intensity and there were very few (0.7%) severe TRAEs for NEPA-treated patients. There was no evidence of any cardiac safety concerns for either NEPA or PALO.
Conclusions: NEPA is superior to PALO in preventing CINV following MEC. As a fixed-dose antiemetic drug combination it offers guideline-based prophylaxis with a convenient, single-day dose.
This study was sponsored by Helsinn Healthcare, S.A.

1301 POSTER DISCUSSION

Improved control of nausea and vomiting (CINV) with a fixed-dose combination of netupitant and palonosetron (NEPA) following highly emetogenic chemotherapy (HEC): Results from a pivotal study

R. Gralla[1], G. Rossi[2], G. Rizzi[3], M. Palmas[4], A. Alyasova[5], I. Drobner[6], P. Hesketh[7]. [1]*Albert Einstein College of Medicine, Oncology, Bronx, USA;* [2]*Helsinn Healthcare S.A., Clinical Operations, Lugano, Switzerland;* [3]*Helsinn Healthcare S.A., Statistics & Data Management, Lugano, Switzerland;* [4]*Helsinn Healthcare S.A., Corporate Clinical Development, Lugano, Switzerland;* [5]*Federal State Institution Privolzhsky District Medical Center under the Federal Medical-Biological Agency of Russia, Oncology, Nizhny Novgorod, Russian Federation;* [6]*Regional Oncology Center, Oncology, Khmelnytsky, Ukraine;* [7]*Lahey Hospital & Medical Center, Oncology, Burlington, USA*

Background: Further progress in preventing CINV will require the introduction of novel agents with improved efficacy for nausea as well as vomiting. NEPA is a fixed-dose combination of netupitant (NETU), a new NK_1 receptor antagonist (RA) and palonosetron (PALO), a pharmacologically and clinically distinct 5-HT_3 RA.
Materials and Methods: This randomized, double-blind, parallel group study (NETU-07−07) in 694 chemotherapy-naive patients undergoing cisplatin-based HEC compared 3 oral doses of NEPA (100 mg, 200 mg and 300 mg NETU + 0.5 mg PALO) with oral PALO 0.50 mg, all given on day 1. A standard IV ondansetron (OND) 32 mg + 3-day aprepitant (APR) regimen was also included as an exploratory arm. All patients received oral dexamethasone (DEX) days 1−4. The primary efficacy endpoint was complete response (CR: no emesis, no rescue medication) during the overall (0–120 h) phase.
Results: Treatment groups were comparable: male (57%), median age 55. Most frequent cancers were respiratory (27%) and head & neck (21%). Median cisplatin dose: 75 mg/m^2.
All NEPA doses met the primary endpoint of superior overall CR rates compared with PALO (87.4%, 87.6%, 89.6% for $NEPA_{100}$, $NEPA_{200}$, and $NEPA_{300}$, respectively vs 76.5% PALO) with the highest NEPA dose studied ($NEPA_{300}$) showing an incremental benefit over lower NEPA doses for all efficacy endpoints. $NEPA_{300}$ was also more effective than PALO for all secondary efficacy endpoints: no emesis, no significant nausea and complete protection (CR plus no significant nausea) rates during the acute, delayed and overall phases.

	Overall (0–120 h) % Patients		
	$NEPA_{300}$ (N = 135)	APR+OND* (N = 134)	PALO (N = 136)
No emesis	91.1	87.3	76.5
No significant nausea	89.6	85.8	79.4
Complete protection	83.0	78.4	69.9

*Exploratory arm.

The type, frequency, and severity of AEs and % of patients who developed ECG changes were comparable between groups.
Conclusions: NEPA, a convenient single-day oral combination targeting dual antiemetic pathways, is superior to PALO for preventing CINV. $NEPA_{300}$ was more effective than PALO for all efficacy endpoints including nausea control following HEC. All NEPA doses were well tolerated with a similar safety profile to PALO and APR.
This study was sponsored by Helsinn Healthcare, S.A.
Conflict of interest: *Advisory board: Gralla: Helsinn Healthcare Hesketh: Helsinn Healthcare. Other substantive relationships: Rossi, Rizzi, and Palmas: Employed by Helsinn Healthcare*

1302 POSTER DISCUSSION

Prevention of chemotherapy-induced nausea and vomiting (CINV) over repeated chemotherapy cycles: Results of a phase 3 trial of NEPA, a fixed oral dose combination of netupitant and palonosetron

R.J. Gralla[1], S.M. Bosnjak[2], C. Balser[3], G. Rizzi[4], M.E. Borroni[5], G. Rossi[6], K. Jordan[7]. [1]*Albert Einstein College of Medicine, Oncology, Bronx, USA;* [2]*Institute for Oncology and Radiology of Serbia, Oncology, Belgrade, Serbia;* [3]*OnkoNet Marburg GmbH, Oncology, Marburg, Germany;* [4]*Helsinn Healthcare S.A., Statistics & Data Management, Lugano, Switzerland;* [5]*Helsinn Healthcare S.A., Corporate Clinical Development, Lugano, Switzerland;* [6]*Helsinn Healthcare S.A., Clinical Operations, Lugano, Switzerland;* [7]*University of Halle, Oncology, Halle, Germany*

Background: Safe, effective and convenient antiemetic regimens that preserve benefit over repeated chemotherapy (CT) cycles are key for enhanced cancer treatment. This study tested a single oral dose of a fixed combination, NEPA (netupitant (NETU), a highly selective NK_1 receptor antagonist (RA) and palonosetron (PALO), a pharmacologically distinct 5-HT_3 RA) over up to 6 CT cycles. Recent trials have demonstrated the safety and efficacy of NEPA in a single cycle of highly (HEC) or moderately (MEC) emetic CT. Therefore, this study (NETU-10−29; NCT01376297) was intended to assess the safety and describe the efficacy of NEPA over multiple cycles of HEC and MEC. Major efforts were made in this study to retain patients (pts) on trial as many multi-cycle antiemetic studies are of questionable validity due to high patient drop out.
Materials and Methods: This multinational, randomized, double-blind, active-controlled, parallel group study assessed the safety and efficacy of a single oral dose of NEPA (NETU 300 mg + PALO 0.50 mg) given only on day 1 of repeated cycles of HEC or MEC with oral dexamethasone (DEX) [days 1−4 (HEC) or day 1 (MEC)]. A 3-day regimen with oral aprepitant (APR) + PALO + DEX was included as a control in an unbalanced 3:1 (NEPA:APR) randomization. Safety was assessed primarily by adverse events; efficacy by complete response (CR: no emesis, no rescue medication).
Results: 413 pts were randomized with 309 (NEPA) and 103 (APR) included in the efficacy analysis. Groups were comparable with: male (50%), mean age 57, 24% HEC, 76% MEC. Percent of all patients remaining on study (balanced among groups) and overall CR rates by cycle are in the table:

Cycle #	% Pts remaining on study	% CR	
		NEPA+DEX	APR+PALO+DEX
1	100%	81%	76%
2	92%	86%	81%
3	85%	91%	87%
4	76%	90%	88%
5	52%	92%	86%
6	41%	91%	86%

The type/frequency of AEs were comparable for both groups. The most frequent patient-reported treatment-related AEs (TRAEs) for NEPA included constipation (3.6%) and headache (1.0%); there was no indication of increasing TRAEs over multiple cycles. The majority of TRAEs were mild or moderate; few were serious (1.3% NEPA, 0% APR).
Conclusions: With 75% of patients completing 4 CT cycles, it can be concluded that NEPA, a convenient single-dose oral antiemetic targeting dual pathways, was well tolerated and highly effective over multiple cycles of HEC/MEC.

1303 POSTER DISCUSSION

A randomized phase III trial of palonosetron plus dexamethasone (day 1) versus palonosetron plus dexamethasone (day 1−3) in the prevention of nausea and vomiting induced by moderately emetogenic chemotherapy, not including a combination of anthracycline plus cyclophosphamide

K. Sasaki[1], K. Okita[2], S. Yuki[3], Y. Takahashi[4], M. Abe[5], K. Hatanaka[6], H. Isobe[7], S. Sogabe[8], K. Oba[9], Y. Komatsu[10]. [1]*Otaru Ekisaikai Hospital, Surgery, Otaru, Japan;* [2]*Sapporo Medical University Hospital, Surgery, Sapporo, Japan;* [3]*Hokkaido University Hospital, Gastroenterology, Sapporo, Japan;* [4]*Hokkaido Cancer Center, Gastroenterology, Sapporo, Japan;* [5]*Sapporo-Kosei General Hospital, Medical Oncology, Sapporo, Japan;* [6]*Hakodate Municipal Hospital, Gastroenterology, Hakodate, Japan;* [7]*KKR Sapporo Medical Center, Clinical Oncology, Sapporo, Japan;* [8]*Kushiro Rosai Hospital, Internal Medicine, Kushiro, Japan;* [9]*Hokkaido University Hospital, Translational Research and Clinical Trial Center, Sapporo, Japan;* [10]*Hokkaido University Hospital, Cancer Center, Sapporo, Japan*

Background: The objective of this trial was to evaluate the efficacy of palonosetron plus dexamethasone (day 1) single administration for the prevention of chemotherapy induced nausea and vomiting (CINV) in patents receiving moderately emetogenic chemotherapy, not including a combination of anthracycline plus cyclophosphamide (non-AC MEC).
Methods: This trial was conducted as a multi-center, randomized non-inferiority phase III trial. Patients who received non-AC MEC as the first line chemotherapy were randomized by minimization for palonosetron (0.75 mg, IV) plus dexamethasone (9.9 mg, IV) administered before that

chemotherapy (PALO + DEX day1 arm) and PALO + DEX day1 plus day2−3 dexamethasone (8 mg, IV or PO) (PALO + DEX day1−3 arm).
Primary endpoint was complete response (CR; no emesis and no rescue antiemetics) during the overall 5-day study period. The difference of CR rate in overall between two arms and 95% confidence interval (95% CI) were calculated by logistic regression model which includes chemotherapy, sex and age as covariates. Non-inferiority margin was estimated as 15%, and the degree of lower limit of 95% CI in the difference of CR rate in overall was verified whether it include less than 15%.
Results: From April 2011 to March 2013, 305 patients who received non-AC MEC were randomized. Oxaliplatin-containing regimen was the most common non-AC MEC regimen (72.8%), followed by irinotecan-containing regimen (13.4%), carboplatin-containing regimen (12.1%), and other regimens (1.7%). Overall CR rate was 68.2% in PALO+DEX day1 arm (n = 151) and 64.7% in PALO+DEX day1−3 arm (n = 154). PALO+DEX day1 was non-inferior to PALO+DEX day1−3 (difference 3.6%, 95% CI, −6.6% to 13.9%; $p = 0.0002$). There were no differences between two arms on CR rate in acute and delayed phase (Table).

	CR (%)		
	Overall: 0–120 h	Acute: 0−24 h	Delayed: 24–120 h
PALO+DEX day 1	68.2	95.3	68.9
PALO+DEX day 1−3	64.7	94.7	66.0

Conclusions: This is the first report of the study that demonstrated the prevention of CINV induced by non-AC MEC. PALO+DEX day1 was non-inferior to the standard regimen: PALO+DEX day1−3 for the prevention of CINV induced by non-AC MEC. In conclusion, the administration of dexamethasone on day2 and 3 can be omitted in the prevention of CINV for patents receiving non-AC MEC.
No conflict of interest.

1304 POSTER DISCUSSION

Skeletal-related events in patients with solid tumors receiving denosumab or zoledronic acid by baseline pain status: Results from three phase 3 trials

R. Von Moos[1], A. Stopeck[2], K. Fizazi[3], C. Cleeland[4], J.E. Brown[5], S. Oudard[6], L. Costa[7], H. Wang[8], A. Braun[9]. *[1]Kantonsspital Graubünden, Chur, Switzerland; [2]University of Arizona, Arizona Cancer Center, Tucson, USA; [3]University of Paris Sud, Institut Gustave Roussy, Paris, France; [4]University of Texas M.D. Anderson Cancer Center, Division of Internal Medicine, Houston, USA; [5]St James's University Hospital, Cancer Research UK Clinical Centre, Leeds, United Kingdom; [6]Université Paris Descartes, Hôpital Européen Georges Pompidou, Paris, France; [7]Hospital de Santa Maria, Instituto de Medicina Molecular, Lisboa, Portugal; [8]Amgen Inc., Global Biostatistical Science, Thousand Oaks, USA; [9]Amgen Inc., Global Development, Thousand Oaks, USA*

Background: Pain is often a consequence of bone metastases in patients with solid tumors, and may precede skeletal-related events (SREs) (Saad, et al, J Urol 2010). Previous integrated results from three phase 3 trials demonstrated superiority of denosumab compared with zoledronic acid (ZA) for preventing SREs in patients with breast, prostate, or other solid tumors. Here, we asked if it was possible to identify patients who would benefit, or not benefit, from bone-targeted treatment on the basis of clinical pain symptoms at baseline.
Materials and Methods: Patients with solid tumors and bone metastases including breast and prostate cancers and other solid tumors received either SC denosumab 120 mg and IV placebo (n = 2775) or IV ZA 4 mg (adjusted for renal function) and SC placebo Q4W (n = 2768) in the double-blinded treatment phase. Time to first on-study SRE and to first and subsequent SRE were evaluated in patients with no/mild pain or moderate/severe pain at baseline as measured by the Brief Pain Inventory − Short Form (BPI-SF).
Results: Among patients with no/mild pain at baseline, 828 (31%) patients had experienced an SRE at the time of primary analysis compared with 1000 (40%) among those with moderate/severe pain at baseline. Denosumab significantly delayed time to first SRE compared with ZA in patients with no/mild baseline pain (HR = 0.84 [95% CI: 0.73, 0.96]; p = 0.01) and in patients with moderate/severe baseline pain (HR = 0.83 [95% CI: 0.73, 0.94]; p = 0.003). The time to first and subsequent SREs was similarly significantly delayed compared with ZA in the no/mild baseline pain group (RR = 0.81 [95% CI: 0.70, 0.92]; p = 0.002) and in the moderate/severe baseline pain group (RR = 0.82 [95% CI: 0.73, 0.93]; p = 0.001).
Conclusions: In a combined analysis of three phase 3 trials of patients with solid tumors and bone metastases, the presence of pain at baseline was not a reliable predictor of response to bone-targeted therapy. In this analysis, denosumab significantly delayed time to first and multiple SREs compared with ZA. This difference in treatment effect was similar in magnitude regardless of patients' pain status at baseline.

1305 POSTER DISCUSSION

Risk factors for developing osteonecrosis of the jaw (ONJ) in patients receiving denosumab or zoledronic acid for bone metastases: Results from three phase 3 trials

J. Brown[1], F. Saad[2], A. Stopeck[3], K. Fizazi[4], D. Henry[5], I. Diel[6], R. De Boer[7], H. Wang[8], A. Braun[9]. *[1]St James's University Hospital, Cancer Research UK Clinical Centre, Leeds, United Kingdom; [2]Université de Montréal, Centre hospitalier de l'Université de Montréal, Montreal, Canada; [3]University of Arizona, Arizona Cancer Center, Tucson, USA; [4]University of Paris Sud, Institut Gustave Roussy, Paris, France; [5]Pennsylvania Hospital, Joan Karnell Cancer Center, Philadelphia, USA; [6]Center for Comprehensive Gynecology, Institute for Gynecologic Oncology, Mannheim, Germany; [7]Royal Melbourne Hospital, Department of Medical Oncology, Parkville, Australia; [8]Amgen Inc., Global Biostatistical Science, Thousand Oaks, USA; [9]Amgen Inc., Global Development, Thousand Oaks, USA*

Background: The use of antiresorptive therapies such as denosumab or zoledronic acid (ZA) for patients with metastatic bone disease reduces the risk of skeletal-related events (SREs) but is associated with a risk of osteonecrosis of the jaw (ONJ). Here we report risk factors for the development of ONJ for the blinded treatment phase of three phase 3 clinical trials comparing the two agents for reduction of SREs.
Materials and Methods: Patients (n = 5677) with bone metastases from solid tumors or multiple myeloma received either SC denosumab 120 mg and IV placebo or IV ZA 4 mg (adjusted for renal function) and SC placebo Q4W in the double-blinded treatment phase of each trial. Study exclusion criteria included prior/current ONJ or osteomyelitis of the jaw, planned invasive dental procedure, or non-healed oral or dental surgery. Patients who received $\geqslant$1 active dose during the blinded treatment phase were included in this analysis for up to 44.5 months of denosumab exposure and 41.3 months of ZA exposure. Oral assessments were conducted at baseline and every 6 months thereafter by the investigator or other qualified examiner. Potential ONJ events were independently adjudicated by a blinded committee of experts.
Results: In combined data from three phase 3 trials, 63 patients in the denosumab group and 44 patients in the zoledronic acid group had adjudicated positive events of ONJ. Most patients who developed ONJ had recognized oral risk factors, among which tooth extractions were the most frequent (Table). Additional risk factors for ONJ, including concurrent chemotherapy, anti-angiogenesis medications, corticosteroid treatment, and their impact on clinical outcome, will be presented.

Table: Risk factors for developing adjudicated positive events of ONJ in three phase 3 trials

Risk factor	n (%)	
	Denosumab (n = 63)	ZA (n = 44)
History of tooth extraction, poor oral hygiene, and/or use of dental appliance	54 (85.7)	38 (86.4)
Tooth extraction	37 (58.7)	30 (68.2)

Conclusions: In combined data from three trials comparing denosumab with zoledronic acid, development of ONJ was associated with recognized risk factors encompassing oral factors. Trials sponsored by Amgen, Inc. ClinicalTrials.gov registration numbers NCT00321464, NCT00321620, NCT00330759.

1306 POSTER DISCUSSION

Effect of skeletal-related events on pain interference in patients with solid tumors and bone metastases

R. Von Moos[1], L. Fallowfield[2], C. Cleeland[3], D. Patrick[4], J.J. Body[5], J.E. Brown[6], G. Marx[7], Y. Zhou[8], A. Balakumaran[9], Y.I. Qian[10]. *[1]Kantonsspital Graubünden, Medical Oncology, Chur, Switzerland; [2]University of Sussex, Sussex Health Outcomes Research & Education in Cancer (SHORE-C), Brighton, United Kingdom; [3]University of Texas, M.D. Anderson Cancer Center, Houston, USA; [4]University of Washington, Department of Health Services, Seattle, USA; [5]Université Libre de Bruxelles, CHU Brugmann, Brussels, Belgium; [6]University of Leeds, Cancer Research UK Clinical Centre, Leeds, United Kingdom; [7]Sydney Adventist Hospital, Medical Oncology, Wahroonga, Australia; [8]Amgen Inc., Global Biostatistical Science, Thousand Oaks, USA; [9]Amgen Inc., Clinical Development, Thousand Oaks, USA; [10]Amgen Inc., Global Health Economics, Thousand Oaks, USA*

Background: Patients with metastatic bone disease who experience a skeletal-related event (SRE; including pathological fracture [PF], surgery [SB] or radiotherapy to bone [RB], or spinal cord compression [SCC]) often have increased pain. Using data from patients with solid tumors enrolled in three identically designed phase 3 trials, we evaluated how pain interferes with the emotional well-being (affect) and physical function (activity) of these patients.
Materials and Methods: In these completed phase 3, double-blind, double-dummy, placebo-controlled trials, patients were randomized (1:1) to receive denosumab (120 mg SC) or zoledronic acid (4 mg IV, adjusted for renal function) every 4 weeks (ClinicalTrials.gov NCT00321464, NCT00321620, and NCT00330759; sponsor Amgen Inc.). Data from patients with solid tumors in the 2 treatment arms (n = 5543) were pooled for this post-hoc analysis. Pain interference (overall, emotional, and physical) was assessed using the Brief Pain Inventory (BPI)-Short Form (0: no interference to 10: interferes completely) at baseline and each study visit. The impact of 1st on-study SREs, starting 28 days before the SRE, was assessed using a stratified Cox proportional hazards model adjusting for SREs as time-dependent covariates.
Results: On-study SREs were reported for 1925 patients (923 PF; 829 RB, 119 SCC, 54 SB). PF, RB, and SCC were associated with significantly greater risk of pain interference overall; the impact of SB was also greater, but not significantly so (Table). Results were similar for pain interference with emotional well-being. All SRE types were associated with significantly greater risk of pain interference with physical function.

Table: Effect of 1st on-study SREs on time to ⩾2-point increase from baseline in pain interference score*

Pain interference	PF	RB	SCC	SB
Overall (n = 4911)				
HR (95% CI)	1.30 (1.13, 1.51)	2.29 (1.98, 2.66)	2.60 (1.84, 3.68)	1.70 (0.97, 2.98)
P-value	0.0004	<0.0001	<0.0001	0.06
Emotional well-being (n = 4819)				
HR (95% CI)	1.27 (1.10, 1.46)	2.44 (2.12, 2.80)	2.02 (1.41, 2.91)	1.28 (0.73, 2.23)
P-value	0.0012	<0.0001	0.0001	0.39
Physical function (n = 4535)				
HR (95% CI)	1.40 (1.21, 1.62)	2.29 (1.96, 2.67)	2.42 (1.69, 3.46)	2.14 (1.20, 3.81)
P-value	<0.0001	<0.0001	<0.0001	0.01

*Includes patients with baseline BPI score ⩽8.

Conclusions: In general, pain interference was increased in patients who experienced on-study SREs. Effective treatments that prevent SREs may reduce pain interference with patients' emotional well-being and physical function.

1307 POSTER DISCUSSION

Difficulties in meeting accrual and obtaining adequate follow up in palliative trials: Results from an intergroup randomized trial of single vs multiple fractions (Fx) for re-irradiation (RE-RT) of painful bone metastases (PBM): NCIC CTG SC.20

Y. Van der Linden[1], R. Wong[2], D. Roos[3], W. Hartsell[4], P. Hoskin[5], J. Wu[6], M. Brundage[7], R.M. Meyer[8], B.E. Chen[8], E. Chow[9]. *[1]Leiden University Medical Center, Clinical Oncology, Leiden, Netherlands; [2]Princess Margaret Hospital, Radiation Oncology, Toronto, Canada; [3]Royal Adelaide Hospital, Radiation Oncology, Adelaide, Australia; [4]Good Samaritan Cancer Care Center, Radiation Oncology, Downers Grove, USA; [5]Mount Vernon Hospital Cancer Centre, Radiation Oncology, Mount Vernon, United Kingdom; [6]Tom Baker Cancer Centre, Radiation Oncology, Calgary, Canada; [7]Queen's University, Radiation Oncology, Kingston, Canada; [8]NCIC, Clinical Trials Group, Kingston, Canada; [9]Odette Cancer Centre, Radiation Oncology, Toronto, Canada*

Background: The optimal RE-RT dose and fractionation schedule for PBM is uncertain.
Methods: Patients (pts) with PBM after previous radiation (RT) to the same site were stratified by previous Fx schedule and pain response and randomized to 8 Gy in 1 Fx or 20 Gy in 5 Fx. The primary endpoint was overall response rate (RR) at 2 months using the International Consensus schema (Chow 2002) which combines Brief Pain Inventory worst pain score and opioid analgesic use. We tested if 8 Gy was non-inferior (NI), analyzed by intention to treat (ITT) and a per-protocol (PP) sensitivity analysis excluding those who were ineligible, inevaluable or received non-allocated therapy. Sample size was calculated using an expected RR of 70% with 20 Gy and a NI margin of 10% (i.e. upper boundary of 1-sided 95% CI for the RR difference). Patients reported adverse events (AEs) by questionnaire on Day 14.
Results: Between 01/2004 and 06/2012, we enrolled 850 pts from 9 countries. The median age was 65 years old, 59% were male, The Karnofsky performance status was 50 or more in all pts and 17% had no response to prior RT. The median follow-up was 12.2 months (range 0.03 to 15.6 months). The median survival was 8 months with no differences detected between arms (HR = 0.96; P = 0.67). Most common cancers were prostate (27%), breast (26%) and lung (22%). Before the 2 month assessment, 98 (11%) pts died. By ITT, the 2-month RR was available in 66% (557/850) and was 119/425 (28%) with 8 Gy and 136/425 (32%) with 20 Gy (P = 0.2); the upper boundary of the 95% CI for RR difference = 9.2% and is less than the pre-specified NI margin. By PP analysis, 2-month RR was available in 521 and was 117/258 (45.3%) with 8 Gy and 135/263 (51.3%) with 20 Gy (P = 0.17); the upper boundary of the 95% CI for RR difference = 13.2%, which exceeds 10% non-inferiority boundary. Among the 263 pts with a response at month two, 36 had pain progression (16 with 8 Gy and 20 with 20 Gy); the HR for freedom from progression (20 Gy vs. 8 Gy) among these pts was 1.05 (95% CI: 0.55 to 2.04). Day 14 AEs differing by treatment were: lack of appetite (P = 0.01), vomiting (P = 0.001), diarrhea (P = 0.02) and skin reddening (P = 0.002); all were worse with 20 Gy.
Conclusions: In pts with PBM receiving RE-RT, the 2-month RR obtained with 8 Gy is non-inferior to 20 Gy when assessed by ITT but findings were not robust to a PP sensitivity analysis. When choosing between options tested, trade-offs exist between pain response and acute toxicity.
No conflict of interest.

1308 POSTER DISCUSSION

Efficacy and safety of anamorelin HCl in NSCLC patients: Results from a randomized, double-blind, placebo-controlled, multicenter phase II study

J. Temel[1], S. Bondarde[2], M. Jain[3], S. Allen[4], W. Mann[4]. *[1]Massachusetts General Hospital, Hematology/Oncology, Boston, USA; [2]Shatabdi Super Specialty Hospital, Nashik, Maharashtra, India; [3]Ruby Hall Clinic, Xylem Clinical Research Pvt Ltd, Pune, India; [4]Helsinn Therapeutics (U.S.) Inc., Research & Development, Bridgewater, USA*

Background: Cancer cachexia is a multifactorial syndrome, characterized by decreased body weight (BW) and muscle mass/strength, and associated with worsened morbidity/survival. Anamorelin HCl (ANA), an orally active

ghrelin receptor agonist with orexigenic and anabolic activity, is in development for treating non-small cell lung cancer (NSCLC)-associated anorexia/cachexia.
Materials and Methods: We conducted an international, randomized, double-blind, multicenter Phase II trial to evaluate the effect of ANA on BW and handgrip strength (HGS) (NCT00622193; sponsored by Helsinn). Safety endpoints included adverse event (AE) profile and overall survival; secondary endpoints included IGFBP-3 and Quality of Life (MDASI). Patients with Stage IIIB or IV NSCLC, ECOG performance score $\leqslant 1$, and candidates for treatment with carboplatin/paclitaxel ($\pm$ bevacizumab) were eligible. Patients were randomized 1:1:1 to receive either 50 mg ANA, 100 mg ANA, or placebo (PL) once daily for 12 weeks.
Results: 226 patients were randomized and treated (N = 76 for 50 mg ANA; N = 73 for 100 mg ANA; N = 77 for PL), and 215 patients with at least 1 post-baseline efficacy assessment comprised the Modified Intent-To-Treat (MITT) population for efficacy analysis. A beneficial effect on weight was observed as early as 1 week after ANA treatment. Over 12 weeks, the 100 mg ANA group gained an average of 0.14 kg in BW from baseline, compared to mean losses of 0.3 kg and 1.32 kg for the 50 mg and PL groups, respectively (mean treatment difference between 100 mg ANA and PL was 1.47 kg; $p = 0.0005$). For HGS, the mean treatment difference between 100 mg ANA and PL was 0.58 kg, but was not statistically significant. ANA was safe and well-tolerated in this study, and AEs of anorexia, nausea, and fatigue were reported in fewer ANA-treated than PL-treated patients. There was no statistically significant effect on long-term overall survival in the 50 mg or 100 mg ANA groups compared with PL. ANA also increased IGFBP-3, a marker of drug activity ($p < 0.0001$ for both treatments vs placebo). MDASI total and domain scores improved in the 100 mg ANA group, but were not statistically significant.
Conclusions: ANA significantly increased BW, had a neutral effect on survival, and showed an overall favorable safety/tolerability profile. Directional improvements in HGS and QoL were also observed. These data support further investigation of ANA for treating NSCLC anorexia/cachexia.
Conflict of interest: *Corporate-sponsored research: J. Temel, S. Bondarde, and M. Jain received funding from Helsinn to conduct this study. Other substantive relationships: S. Allen and W. Mann are employees of Helsinn, which funded this study.*

1309 POSTER DISCUSSION

Do methylprednisolone 32 mg provide pain relief, improve fatigue and appetite in cancer patients using opioids? A randomized, controlled trial

O. Paulsen[1], S. Kaasa[2], N. Aass[3], P. Klepstad[4]. [1]*Telemark Hospital Trust, Palliative Care Unit, Skien, Norway;* [2]*Norwegian University of Science and Technology, European Palliative Research Centre (PRC), Trondheim, Norway;* [3]*University of Oslo, Faculty of Medicine, Oslo, Norway;* [4]*Norwegian University of Science and Technology, Department of Circulation and Medical Imaging, Trondheim, Norway*

Background: Corticosteroids (CS) are used as co-analgesics in cancer pain patients. In a systematic review we concluded that CS may have a moderate analgesic effect in cancer pain, but with 'very low' level of evidence. Therefore, this randomized study was conducted to compare the analgesic efficacy of CS to placebo. Secondary aims were to evaluate the effects in analgesic consumption, patient satisfaction, fatigue and appetite.
Material and Methods: Adult cancer patients with average pain last 24 hours $\geqslant 4$ (NRS 0−10) despite ongoing opioid treatment were recruited from five palliative centres in Norway. After randomization, the patients received methylprednisolone 16 mg twice daily or placebo for seven days in a double-blind design. Primary outcome was average pain intensity on day seven (NRS 0−10); secondary outcomes were analgesic consumption (oral morphine equivalents (OME)), overall satisfaction (NRS 0−10), fatigue, and appetite (EORTC QLQ-C30 (0–100)). Sample size estimation required 22 patients in each group to show a clinical significant difference of 1.5 (NRS 0−10) with a $p < 0.05$ and a power of 0.90.
Results: A total of 592 patients were screened from April 2008 to January 2012. Fifty patients were recruited, 47 completed the study. Forty seven patients had metastatic cancer disease; mean Karnofsky index was 66 (0–100), and mean analgesic consumption 218 mg OME. On day seven there were no differences in average pain intensity (CS: 3.6, (CI: 2.8−4.4); placebo 3.7 (3.0−4.4)) or in change in opioid consumption (day seven versus baseline: CS 1.19 (1.00–1.38); placebo 1.20 (0.90–1.51)). CS improved both fatigue (CS: −17 (−27 − −6); placebo 3 (−5−11) ($p < 0.01$)), and appetite (CS: − 24 (−38 − −11); placebo 2 (−8−11) ($p < 0.01$)). Overall satisfaction was 5.4 (4.1−6.7) in the CS versus 2.0 (0.7−3.3) in the placebo group ($p < 0.01$).
Conclusions: Methylprednisolone 32 mg daily did not improve pain or decrease analgesic consumption in cancer patients with advanced disease using opioids. The patients treated with CS reported better treatment satisfaction and clinically significant improvement in fatigue and appetite compared to the placebo group.
Funding: Telemark Hospital Trust

1310 POSTER DISCUSSION

Health-related quality of life in small-cell lung cancer: a systematic review on reporting of methodological and clinical issues in randomized controlled trials

E. Zikos[1], I. Ghislain[1], D.E. Ediebah[1], C. Quinten[2], J. Van Meerbeeck[3], R. Stupp[4], M. Koller[5], H. Flechtner[6], M.A.G. Sprangers[7], A. Bottomley[1]. [1]*EORTC, Quality of Life, Brussels, Belgium;* [2]*European Centre for Disease Prevention and Control, Surveillance and Response Support Department, Stockholm, Sweden;* [3]*Antwerp University Hospital, Multidisciplinary Oncology Centre Antwerp (MOCA) Thoracic Oncology, Edegem, Belgium;* [4]*University of Lausanne Hospital, (CHUV), Lausanne, Switzerland;* [5]*University Hospital Regensburg, Center for Clinical Studies, Regensburg, Germany;* [6]*University of Magdeburg, Child and Adolescent Psychiatry and Psychotherapy, Magdeburg, Germany;* [7]*Academic Medical Center, Department of Medical Psychology, Amsterdam, Netherlands*

Purpose Small-cell lung cancer (SCLC) represents approximately 15% of all lung cancers and increasingly health-related quality of life (HRQOL) of SCLC is evaluated in randomized controlled trials (RCTs). The objective was to evaluate the adequacy of HRQOL methodology reporting in SCLC RCTs and its possible impact on clinical decision making.
Material and Methods: A MEDLINE systematic review was performed in RCTs. Eligible RCTs implemented patient-reported HRQOL assessments and oncology treatments for adult SCLC patients. Included studies were published in English between January 1991 and December 2012, with sample size $\geqslant 100$ and patient age $\geqslant 18$.
Results: Thirty RCTs out of seventy-nine studies were classified as eligible, involving over 10,000 patients. HRQOL was a secondary endpoint in 29 RCTs of which 53% reported no significant difference in overall survival (OS). A benefit of HRQOL was reported in 85% of the positive-outcome trials, and in 44% of the negative-outcome trials. Significant improvements in HRQOL were seen when standard platinum-based regimens were compared with: a) irinotecan and carboblatin, b) ifosfamine, carboplatin, etoposide and vincristine. A priori hypothesis on the expected overall HRQOL outcome was defined in 27% of the RCTs. Baseline HRQOL assessment was stated as mandatory in 14% of the RCTs. Tests of statistical significance were applied in 90% of the RCTs and missing data were discussed in detail in 30% of the trials.
Conclusions: While the overall reporting of HRQOL was of acceptable standards, some improvement in reporting RCTs could be encouraged. HRQOL assessment in SCLC RCTs clearly provides major added information in studies where no OS difference is found, but more importantly provides valuable information for these treatments where better HRQOL was associated with OS benefit.
No conflict of interest.

1311 POSTER DISCUSSION

Understanding quality of dying in a hospital

F.E. Witkamp[1], A. Van der Heide[2], C.C.D. Van der Rijt[3], L. Van Zuylen[3]. [1]*ErasmusMC, Medical Oncology and Public Health, Rotterdam, Netherlands;* [2]*ErasmusMC, Public Health, Rotterdam, Netherlands;* [3]*ErasmusMC Cancer Institute, Medical Oncology, Rotterdam, Netherlands*

Background: Quality of dying (QOD) is a multi-dimensional concept that includes physical, psychosocial and existential experiences, life closure, death preparation, circumstances of death, and experiences of care. We studied how relatives of cancer patients who had died in a hospital experienced QOD regarding these dimensions.
Material and Methods: Between June 2009 and February 2011 each adult cancer death at non-IC units in a university hospital was followed by an invitation to relatives, sent 10−13 weeks later, to answer a questionnaire. Relatives were asked to rate QOD overall on a 0−10 numeric rating scale; furthermore, they valuated their experiences in the different domains of QOD on verbal scales, which were merged into 2 answer categories before analysis. Data were analyzed with students' t-tests and linear regression analysis.
Results: In the study period, 259 cancer patients died; of 246 patients (95%) relatives could be traced, and 123 participated (50%). Of patients, 60% was male, mean age was 65 years (sd 13), and mean duration of final hospital stay was 12 days (sd 14). The mean score for QOD 6.3 (sd 2.8). QOD scores were higher when the final stay had been longer and relatives were younger. Adjusted for these characteristics, QOD scores were associated with almost all domains, but most strongly with experiences of care. In this domain the most important variables were

those related to participation in decision making (R^2 0.17) and to outcomes of care (R^2 0.21). QOD scores were higher when relatives were satisfied about patient's and relative's involvement in decisions on medical treatment (Mean QOD 6.8 vs 5.4 and 6.8 vs 5.2); when relatives had been informed of the imminence of death (6.7 vs 5.3); when they judged physician's efforts to relieve suffering, and nursing care as sufficient (6.8 vs 4.0 and 6.7 vs 4.0); and when the patient had primarily been approached as a person (7.0 vs 4.9).
Conclusions: On average, relatives rate QOD in hospital was moderately good. Experiences of care are more important in explaining variance in QOD scores than physical, psychosocial, or existential experiences, or circumstances of death. Therefore, improvements in end of life care can be achieved by clinical staff through being present, providing information, listening, and shared decision making.

Background: OnCoBOS is an ongoing, national, prospective, multicentre, observational study of the use of biosimilar epoetin alfa (Binocrit®) for the treatment of chemotherapy-induced anaemia (CIA). Here we present an evaluation of haemoglobin (Hb) outcomes in 444 patients treated (2000 scheduled) in France.
Patients and Methods: We analysed 444 cancer patients with CIA treated with biosimilar epoetin alfa in 75 centres in France. Data were collected at treatment start and 3−4 weeks (W3−4) and 12 weeks (W12) later. Hb outcomes assessed included the proportion of patients achieving a Hb increase of $\geqslant$1 and $\geqslant$2 g/dL, and the mean Hb change from baseline in the subsets of patients with a baseline Hb $\leqslant$9 and 9.1−10 g/dL.
Results: Median (range) age was 67 (18−93) years and 59.3% of subjects were male. Mean±SD Karnofsky score was 77.9±13.2. 77.5% of patients had solid tumours, including lung (22.1%), breast (13.4%), and colorectal cancer (12.8%), mainly stage 3 or 4 (59.3%); and 22.5% had haematological malignancies including non-Hodgkins lymphoma (55.0%) and multiple myeloma (24.0%), again mainly stage 3 or 4 (77.7%). Overall, 64% of patients had metastatic disease. Mean±SD Hb at biosimilar epoetin alfa initiation was 9.6±0.9 g/dL. Mean±SD biosimilar epoetin alfa starting dose was 32793±5147IU/week; the dose at W12 was 32605±6359IU/week. At W3−4 11.9% of patients received intravenous iron. Mean±SD Hb increased to 10.6±1.4 g/dL at W3−4 and 11.2±1.5 g/dL at W12 ($p < 0.001$ vs baseline). In patients with a baseline Hb $\leqslant$9 and 9.1−10 g/dL, the mean Hb change from baseline at W12 was 2.1 and 1.4 g/dL, respectively. 74.8% of patients achieved a Hb increase $\geqslant$1 g/dL during the study, and 47.8% achieved a Hb increase $\geqslant$2 g/dL. 81.3% of patients were able to continue their chemotherapy without delays or dose reduction. Only three patients experienced an adverse drug reaction, none of which were serious.
Conclusions: These data indicate the real-life clinical effectiveness and safety of managing CIA with biosimilar epoetin alfa (Binocrit®). The results reflect the ability to safely correct anaemia and maintain Hb, in line with current recommendations, using a weekly dose regimen. In agreement with European recommendations, treatment with an erythropoiesis-stimulating agent was not restricted to patients with metastatic disease.

1313 POSTER

Prospective observational study on chemotherapy-induced nausea and vomiting (CINV) for cancer patients who were to receive moderately and highly emetogenic chemotherapy (MEC and HEC) and primary care medical staffs' perception on CINV by the CINV Study Group of Japan

K. Tamura[1], K. Aiba[2], T. Saeki[3], Y. Nakanishi[4], T. Kamura[5], H. Baba[6], K. Yoshida[7], N. Yamamoto[8], Y. Kitagawa[9], Y. Maehara[10]. *[1]Fukuoka University School of Medicine, Internal Medicine, Fukuoka, Japan; [2]Jikei University School of Medicine, Internal Medicine, Tokyo, Japan; [3]Saitama Medical University, Saitama International Medical Center, Hidaka, Japan; [4]Kyushu University, Institute of Diseases of the Chest, Fukuoka, Japan; [5]Kurume University, Obstetrics and Gynecology, Kurume, Japan; [6]Kumamoto University, Gastroenterological Surgery, Kumamoto, Japan; [7]Gifu University, Surgical Oncology, Gifu, Japan; [8]Wakayama Medical University, Internal Medicine, Wakayama, Japan; [9]Keio University, Surgery, Tokyo, Japan; [10]Kyushu University, Surgery and Science, Fukuoka, Japan*

Background: There has been no nationwide survey on CINV and validation of the guideline made in Japan after introduction of NK-1 receptor antagonist to the market. The aim of the study is to investigate occurrence of CINV in cancer patients (pts) who are to receive chemotherapy for the first time, and primary care medical staffs' perception on CINV for their pts.
Methods: A nationwide survey on CINV was conducted by the CINV Study Group of Japan. 108 institutions participated in the study which was approved by the review board. The written consent was obtained from the pts. A 7-day diary for CINV was provided to the pts prior to MEC and HEC to record daily occurrence and severity of CINV and an amount of food intake. Acute and delayed CINV was defined as nausea and vomiting which developed within or after 24 hours after the start of chemotherapy, respectively. The medical staffs also filled out questionnaires to estimate their pts' CINV.
Results: A total of 2068 pts were registered from April 2011 to December 2012. The number of pts' diary paired with their staffs' report was 1925 after pts received HEC or MEC. Underlying diseases were gastrointestinal (651 pts), lung (429 pts) and breast cancer (433 pts), and gynecological (215 pts) and hematological malignancy (197 pts). There were 883 males with a median age of 65 (range: 19−87) and 1042 females with a median age of 59 (range: 21−87). MEC was given to 710 pts as was HEC to 1215 pts. Acute vomiting was noted in 13 pts with MEC as was in 66 pts with HEC, while delayed vomiting was experienced in 88 pts with MEC and 101 pts with HEC, respectively. Acute nausea was experienced in 49 pts with MEC and in 250 pts with HEC, while was noted delayed nausea in 278 pts with MEC and in 542 pts with HEC, respectively. Combination of 3 antiemetics was given along the guideline to 81% of the pts with CDDP-based regimen and 64% of those with non-CDDP regimen of HEC. The staff estimated that the incidence of acute CINV was 58% and that of delayed CINV was 80% of the pts when pts of HEC and MEC were combined.
Conclusions: Chemotherapy-induced vomiting was well controlled, but delayed nausea remained to be high in both HEC and MEC, and needs further investigation. Non-CDDP regimen of HEC had a high incidence of developing acute CINV, indicating that other treatment modality should be studied. Surprisingly medical staffs overestimated the incidence of CINV suggesting that antiemetic treatment for CINV given to the pts was quite appropriate by the fact that 2/3 to 4/5 of the pts with HEC had received a combination of 3 antiemetics recommended by the Japanese guideline.
No conflict of interest.

The efficacy of palonosetron compared with granisetron in preventing chemotherapy-induced nausea and vomiting: A randomized study

S. Kilickap[1], T. Kacan[1], N. Akgul Babacan[1]. [1]*Cumhuriyet University, Medical Oncology, sivas, Turkey*

Background: Chemotherapy-induced nausea and vomiting (CINV) are among the most problematic symptoms for patients (pts) with cancer. 5-HT_3 receptor antagonists such as palonosetron (PAL) and granisetron (GRA) are the current standard of care for the prevention of acute CINV. This study aims to assess the efficacy and safety of PAL versus GRA in pts treated with chemotherapy.
Material and Methods: Eligible pts were randomized to receive iv PAL 0.25 mg (GrpA) or GRA 3 mg (GrpB), 30 minutes before theinitiation of chemotherapy on day 1. All pts were also given dexamethasone iv 8 mg before PAL or GRA. Aprepitant was used for pts who received highly emetogenic chemotherapy. The primary efficacy endpoint was to determine the complete response rate (CRR) for acute and delayed emesis. The secondary endpoints were to identify the safety of both medicine and the rescue medication rate. This study was approved by the institutional Research Ethics Board.
Results: A total of 177 pts were assessed in this study.Eightysix pts (45% female) were in the GrpA and 91 pts (41% female) were in the GrpB study arms. The mean age was similar between the two groups (54±12 vs. 56±11; p = 0.245). Gender distribution, the use of cisplatin and the use of a highly emetogenic protocol were indifferent between the groups. For acute emesis, CRR was 73% in the GrpA and 74% in the GrpBgroup (p = 0.492). The rate of rescue medication was similar between the two groups (22% for GrpA and 19% for GrpB; p = 0.706). The most common side effects were diarrhea, constipation, dizziness, headache and fatigue. The frequencies of these side effects were similar between the two groups (p < 0.05 for each variable). In the sub-group analyses that were performed for patients who received cisplatinum and a highly emetogenic chemotherapy regimen, the rates of acute and delayed emesis as well as the rescue medication rates were not different between the two groups (p = 0.136 and p = 0.341, respectively).
Conclusion: Both PAL and GRA have provided similar CRR for patients with CINV in acute and delayed emesis. Moreover, both PAL and GRA could safely be used and they demonstrated similar side-effect profiles, either.
No conflict of interest.

1315 POSTER

Risk factors for severe complications during febrile neutropenic episodes in patients with solid tumors

R. Martins[1], H.C. Cecotti[2], L.C. Pierrotti[3], E. Abdala[3], P.M. Hoff[1], G. Castro[1]. [1]*Instituto do Cancer do Estado de São Paulo, Clinical Oncology, São Paulo, Brazil;* [2]*Hospital das Clinicas FMUSP, Internal Medicine, São Paulo, Brazil;* [3]*Instituto do Cancer do Estado de São Paulo, Infectious Diseases, São Paulo, Brazil*

Background: Febrile neutropenia (FN) is a frequent complication during chemotherapy in solid tumors, and to identify those patients (pts) with higher risk of developing severe complications during FN episodes is important. Here we aimed to characterize those risk factors for severe complications during FN episodes in pts with solid tumors, admitted for intravenous antibiotics.
Material and Methods: It is a retrospective study of all consecutive pts admitted with FN between May/2008 and May/2012. Eligibility criteria included: age ⩾16 y, the diagnosis of FN (documented axillary temperature greater than 37.8ºC, and neutrophil count <500/mm^3 or expected to fall below 500/mm^3) as an adverse event of chemotherapy for a solid tumor. Potentially life-threatening complications during FN episodes were collected and univariate and multivariate logistic regression analyses were performed to assess the relationships between risk factors and these complications.
Results: 333 FN episodes in 295 pts with solid tumors were studied. Median age was 57 y (16−88), 150 female (51%). Most frequent primary sites included: breast (15%), lung (14%), bone/soft tissues (13%), colorectal (10%), stomach (9%), head & neck (8%) and testis (5%). 31 pts (10%) presented more than 1 FN episode. No GCSF primary prophylaxis was prescribed in 282 pts (85%). At admission, median neutrophil count was 690/mm^3, and the median MASCC score was 19 (7−26). Infection sites were identified as pulmonary (19%), urinary tract (11%), abdominal (10%), bloodstream (8%) and soft tissues (8%), and regarding etiology, Gram-negative bacilli could be isolated in 56 (16%) and Gram-positive cocci in 26 FN episodes (8%). All pts were admitted with a median duration of hospital stay of 10 d (0–106 d). Overall, a severe complication as a consequence of FN was detected in 248 episodes (74%), being hypotension (47%), ICU admission (35%), renal failure (30%), respiratory failure (19%) and altered mental state (17%) the most common (>10%), and 46 pts died (14%). A univariate analysis revealed age ⩾60 y (OR 3.1, 95% CI 1.8−5.5, p 0.0001), controlled cancer (OR 0.5, 95% CI 0.3−0.9, p 0.01), previous COPD (OR 4.5, 95% CI 1.7–11.5, p 0.0016), presence of symptoms (OR 2.2, 95% CI 1.3−3.7, p 0.0063) or dehydration (OR 4.6, 95% CI 2.6−8.3, p < 0.0001) and regular or bad general condition (OR 3.3, 95% CI 1.9−5.7, p < 0.0001) as risk factors for complications. On multivariate analysis, only dehydration (OR 4.1, 95% CI 2.2−7.5, p < 0.0001), previous COPD (OR 3.7, 95% CI 1.3–11.0, p 0.0171) and age ⩾60 y (OR 2.5, 95% CI 1.4−4.6, p 0.0027) were associated with severe complications. The multivariate model correctly classified 75% of all FN episodes as complicated.
Conclusions: Severe complications were common during febrile neutropenic episodes in pts with solid tumors. COPD, age ⩾60 yo and dehydration represent clinically significant risk factors for severe complications in FN pts.
No conflict of interest.

1316 POSTER

Anamorelin's effect on bone mass: beyond the expected outcomes in non-small cell lung (NSCLC) cancer cachexia

M. Lu[1], S.M. Zabbatino[2], J.M. Garcia[3], E.M. Duus[1], J. Friend[1]. [1]*Helsinn Therapeutics (U.S.) Inc, Research & Development, Bridgewater, USA;* [2]*Medpace, Imagepace, Cincinnati, USA;* [3]*Baylor College of Medicine/MEDVAMC, Houston, USA*

Background: Cachexia is a serious complication of cancer, characterized by decreased body weight and muscle mass/strength, and associated with poor survival. Another consequence of cancer is bone loss (a form of secondary osteoporosis), a major risk factor for fractures. Previously, we reported a Phase II study where anamorelin (ANA), an investigational ghrelin receptor agonist with orexigenic and anabolic activity, significantly increased lean body mass (LBM) and functional performance over 12 weeks. Beyond these cachexia-focused endpoints, we present here post-hoc analysis on bone mass (BM), which support additional benefits of ANA in cancer patients.
Materials and Methods: 82 patients with advanced cancers, ECOG performance score ⩽2 and weight loss ⩾5% within 6 months were enrolled in a Phase II trial (NCT00219817/NCT00267358) sponsored by Helsinn. Patients received placebo (PL, N = 36) or 50 mg anamorelin (ANA, N = 38) once daily for 12 weeks. Body composition (BM, LBM, fat mass and total body mass) by dual-energy X-ray absorptiometry and plasma inflammatory cytokines (CRP, IL-6 and TNF-α) were measured at baseline, 4, 8 and 12 weeks.
Results: At baseline, BM was comparable between groups. Over 12 weeks of treatment, BM continuously decreased in PL patients, while BM loss stopped at Week 4 in ANA patients and then stabilized. At Week 12, mean BM loss from baseline was statistically significantly greater in the PL vs. ANA patients (−0.05±0.103 kg vs. −0.02±0.09 kg, respectively; p = 0.0176). Inflammatory cytokines are important in bone remodeling and cachexia, and ghrelin has been shown to have anti-inflammatory properties. Accordingly, temporal decreases (~45% for CRP and IL-6 and ~25% for TNF-α at Week 12) were noted in ANA- compared to PL-treated patients. While not statistically significant, this generally uniform pattern of a directional decrease in ANA-treated patients was not noted in PL-treated patients.
Conclusions: Decreased BM with bone fractures are major medical concerns for cancer patients. In this study, 50 mg ANA treatment for 12 weeks significantly prevented the loss of BM compared to PL patients; trending decreases in pro-inflammatory cytokines after ANA administration may also be related to maintaining BM and improving cachexia-related endpoints. Since interventions to increase bone content typically require 1 year of exposure, a longer treatment duration may be needed to confirm these observations and could result in bigger increases in BM.
Conflict of interest: *Corporate-sponsored research: J.M. Garcia received funding from Helsinn to conduct this study and is a consultant for Helsinn and Aeterna Zentaris Inc. 1317 POSTER

Short post-infusion scalp cooling time still prevents docetaxel-induced alopecia

C.J.G. Van den Hurk[1], M.M.C. Komen[2], J.W.R. Nortier[3], S.H. Goey[4], W.P.M. Breed[5]. *[1]Comprehensive Cancer Centre South, Reserach, Eindhoven, Netherlands; [2]Medical Centre Alkmaar, Oncology, Alkmaar, Netherlands; [3]Leiden University Medical Centre, Medical Oncology, Leiden, Netherlands; [4]Twee Steden Hospital, Oncology, Tilburg, Netherlands; [5]Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands*

Background: Chemotherapy-induced alopecia (CIA) is a common side effect and its pathobiology remains unravelled (Paus et al. Lancet Oncol 2013). Scalp cooling is practiced to reduce CIA, but optimum post-infusion cooling times (PICT) are unknown. Our previous study showed an unchanged and excellent prevention of CIA during 3-weekly docetaxel chemotherapy after a reduction of PICT from 90 to 45 minutes (vd Hurk et al. Support Care Cancer 2012).
Material and Methods: The objective of this prospective multicentre trial (SCALP3, number NTR1856) was to compare the proportion of hair loss between patients who were randomised between PICTs of 45 or 20 minutes and who received docetaxel (75 or 100 mg/m^2). Secondary outcomes were wig and head cover use, pattern of hair loss, quality of the remaining hairs and tolerance of scalp cooling. Multivariate analyses will be performed to identify patient and chemotherapy characteristics associated with the result, including age, type of hair, liver function, infusion times and previous chemotherapy. Scalp cooling was performed using the Paxman system.
Results: Patient inclusion has been finalised (n = 130), 57% of the patients were men, 11 patients will be excluded from analyses. Proportions of hair loss are not known yet, but preliminary results show that a 45 minutes PICT resulted in 79% of the patients (n = 53) not requiring a wig or head cover, versus 73% in the 20 minutes PICT group (n = 44). Data collection is ongoing for 22 patients in both treatment arms. During the conference final results will be presented, including associated characteristics.
Conclusion: Scalp cooling prevents docetaxel-induced hair loss, even when the PICT is shortened to 20 minutes. Therefore the PICT seems not to be determined by the half life time of the cytotoxic agent. It cannot be excluded that shorter PICTs positively contribute to the efflux of cytotoxic agents from the hair follicle cells into the blood stream, thereby questioning any PICT. The shorter PICT is a major advantage in time investment for patients but also for logistics at day care units. Scalp cooling should be offered on a routine basis when docetaxel monotherapy is given, also in men. The proportion wig use after 45 minutes PICT is in accordance with our previous trial.
Knowledge on the influence of scalp cooling time and the reached temperature on the results will possibly be obtained more accurate and quicker with a new research model in which the patient is her or his own control. This work was supported by Sanofi Aventis.
No conflict of interest.

1318 POSTER

Impact of a two-drug combination regimen for cancer-related cachexia on nutritional, anabolic/metabolic, physical activity, anti-infammatory and quality of life variables

C. Madeddu[1], A. Maccio'[1], M. Dessi'[1], G. Antoni[1], R. Serpe[1], L. Orgiano[1], E. Lai[1], I. Omoto[1], G. Mantovani[1]. *[1]University of Cagliari, Department of Medical Oncology, Cagliari, Italy*

Background: Cancer progression is characterised by loss of lean body mass (LBM), inflammatory status, metabolic derangements and poor quality of life (QL) which result in cancer-related anorexia/cachexia syndrome (CACS). The aim of the present study was to test the safety and efficacy of a combination treatment (including nutraceuticals, i.e. quercetin, alpha lipoic acid and curcumin) with carnitine + celecoxib for the treatment of CACS. Primary efficacy endpoints were: increase of LBM, resting energy expenditure (REE) and improvement of QL, particularly fatigue. The following were assessed as secondary endpoints: physical performance (tested by grip strength and 6-min walk test, 6MWT), appetite, chronic inflammatory variables (IL-6 and CRP), Performance Status (PS) and Glasgow prognostic score (GPS).
Patients and Methods: Outpatients with advanced cancer at different sites with CACS (i.e. loss of body weight >5% of the pre-illness (or ideal) weight in the last 3 months) received L-carnitine 4 g/day plus Celecoxib 300 mg/day plus nutraceuticals /antioxidants, i.e., quercetin 300 mg/day, lipoic acid 300 mg/day, carbocysteine 2.7 g/day, curcumin 2 g/day (i.e.400 mg/day of active curcuminoids extract (Meriva, Indena, Milan, Italy). Treatment duration was 4 months.
Results: From June 2011 to October 2012, 80 patients with advanced cancer (all stage IV) at different sites were enrolled: 70 completed the treatment and were evaluable (mean age 65±9.6, range 32−82 years). Ten patients did not complete the treatment for death due to disease progression. Results showed a significant increase of LBM and a significant improvement of QL (by EORTC-QLQ-C30), and particularly fatigue (by MFSI-SF). Moreover, an improvement of physical performance assessed by 6MWT as well as a decrease of inflammatory parameters (IL-6 and CRP), ECOG PS and GPS was observed. The treatment was very well tolerated (no grade 3−4 toxicities occurred) and no patient discontinued the treatment due to severe adverse events.
Conclusions: The results of the present study showed that a combined treatment with anti-inflammatory, anabolic/metabolic agents plus antioxidants was able to improve the main nutritional, metabolic and physical activity variables as well as QL of cachectic cancer patients with an optimal safety and cost-benefit profile, so that it may be suggested in the clinical practice as treatment for CACS.
No conflict of interest.

1319 POSTER

A phase II/III, randomized, double-blind, placebo controlled study to investigate the efficacy of a probiotic VSL#3®, on chemotherapy-induced diarrhoea in cancer patients receiving fluoropyrimidines and or irinotecan (interim analysis)

A. Sharma[1], S.P. Chaudhary[1], V. Sreenivas[2], S. Prakash[3], V. Raina[4], N.K. Shukla[5]. *[1]Inst Rotary Cancer Hospitalall India Institute of Medical Sciences, Medical Oncology, Delhi, India; [2]Alll India Institute of Medical Sciences, Biostatics, Delhi, India; [3]Alll India Institute of Medical Sciences, Human Nutrition, Delhi, India; [4]Institute Rotary Cancer Hospitalall India Institute of Medical Sciences, Medical Oncology, Delhi, India; [5]Institute Rotary Cancer Hospitalall India Institute of Medical Sciences, Surgical Oncology, Delhi, India*

Background: Chemotherapy induced diarrhoea (CID) is a common side-effect and its treatment is non-specific. VSL#3 a safe supplemental product has shown to be effective in prevention of radiation-induced diarrhoea. Primary end point of this study is to see effect of study medication (VSL#3) or placebo on grade III or IV diarrhoea.
Material and Methods: This Phase II/III double blind placebo controlled study was approved by Institute Ethics Committee and all subjects signed informed consent prior to enrolment. 121 evaluable patients in each arm are needed to demonstrate reduction in grade III or IV CID from 30% in placebo to 15% in study group with 80% power and α value of 0.05. The trial medications were in the form of a sachet for oral use.
VSL#3: It contains 900 billion viable, lyophilized bacteria, 4 strains of *Lactobacillus*, 3 strains of *Bifidobacterium* and 1 strain of *Streptococcus thermophilus.*
Placebo: Identical sachets containing cornstarch. The daily dose is 1 sachet bid. Eligible subjects received either sachets for atleast 14 days before starting chemotherapy and continued till two weeks after the end of cycle 3. CTCAE 3.0 was used for assessment of diarrhoea. We also randomly collected serum (for VEGF, clusterin) and stool (for calprotectin) sample before and at the end of study from subset of study subjects.
Results: Interim results for primary end point are presented after evaluation of 202 subjects without unblinding. Ten patients (10.42%) in group1 and 4 (3.8%) in group 2 developed grade III or IV diarrhoea (p = 0.07). Biomarkers data given in table 1 clearly shows that levels either increased or remained same in group 2 compared to significant reductions in group 1 at the end of treatment.
Conclusion: Interim analysis suggests that incidence of grade III and IV diarrhoea in two groups is significantly lesser than expected and possibly because of this difference between the 2 groups is not evident. However, the biomarkers analysis suggests that levels of biomarkers reduced significantly during treatment in one of the groups (group =1).

1320 POSTER

Use of erythropoiesis-stimulating agents and comparison of different products for the treatment of chemotherapy-induced anaemia (CIA)

A. Rodriguez Garzotto[1], S. Cortijo Cascajares[1], C. Pernaut Sanchez[1], I. Otero Blas[1], G. Ruiz Ares[1], G. Ruiz Ares[1], F.J. Rebollo Laserna[2], H. Cortés Funes[2]. *[1]Hospital 12 de Octubre, Medical Oncology Department, Madrid, Spain; [2]Sandoz, Medical Department, Madrid, Spain*

Background: It is unclear if the most recent recommendations for more conservative use of ESAs to treat CIA are reflected in real-world clinical practice. In addition, there is a paucity of data on the relative effectiveness of biosimilar ESAs and other available ESAs in this setting.
Patients and Methods: This was a retrospective, single-centre audit of the treatment of CIA with ESAs at the largest oncology centre in Spain, and included patients treated by multiple physicians. It included a total of 284 patients with mostly solid tumours, treated with Binocrit® 40,000 IU QW (n = 116) or 30,000 IU QW (n = 14), darbepoetin alfa 500 μg Q3W (n = 99), darbepoetin alfa 300 μg Q2W (n = 2), darbepoetin alfa 150 μg QW (n = 45), or epoetin beta 30,000 IU QW (n = 8).
Results: Overall, the most common tumour types were NSCLC (30%), breast (12%), ovarian (6%) and bladder (5%). 27% of patients received ESA treatment for 4 weeks, and 42% received >4 weeks' treatment. The mean overall haemoglobin (Hb) at start of ESA treatment was 9.3 g/dL; 19% of patients had Hb <8.5 g/dL at the start of treatment, and 42% had Hb <9 g/dL. The mean overall Hb level at the end of treatment was 10.8 g/dL; 54% of patients had Hb in the range 10−12 g/dL, and 68% achieved a Hb >10 g/dL. Comparisons were performed of Hb outcomes according to the different ESA treatments given to patients. There were no significant differences ($p > 0.05$) between the groups in terms of Hb levels at the start of ESA treatment, Hb levels achieved at the end of ESA treatment, and the highest Hb level achieved on ESA treatment. No drug-related adverse events were recorded.

ESA	Mean treatment duration (weeks)	Mean Hb at start of treatment (g/dL)	Mean maximum Hb achieved (g/dL)
Darbepoetin 150 μg QW	4.98	9.0	11.2
Darbepoetin 300 μg Q2W	4.50	9.4	10.6
Darbepoetin 500 μg Q3W	4.68	9.3	10.7
Epoetin beta	6.50	9.6	11.3
Binocrit 30,000 IU	4.57	9.1	10.4
Binocrit 40,000 IU	4.20	9.3	10.7

Conclusions: The use of ESAs in our centre could be described as conservative and safe, and reflects the most recent ESA label change and recommendations for more moderated ESA use in patients with CIA (i.e. use the lowest possible dose and duration of treatment necessary to avoid transfusions). Our data indicate that Hb outcomes are similar for the different ESA products in a real-world clinical practice setting.
No conflict of interest.

1321 POSTER

Nutritional assessment: Who should report and how?

A. Aktas[1], D. Walsh[1], M. Fischer[2], B. Hullihen[1], E. Schleckman[1], C. Upshaw[1]. *[1]Cleveland Clinic Taussig Cancer Institute, Harry R Horvitz Center for Palliative Medicine and Supportive Oncology, Cleveland, USA; [2]Cleveland Clinic Digestive Disease Institute, Section of Nutrition, Cleveland, USA*

Background: Malnutrition is common but likely under-diagnosed and adversely affects quality of life and survival. Recognition will improve care and facilitate timely and appropriate nutritional interventions. Local and national diagnostic criteria have been imprecise. Standardized guidelines have been developed to standardize a reliable nutrition assessment tool to identify and grade severity of malnutrition. We aimed 1) to identify prevalence and severity of malnutrition among inpatients who consulted a Registered Dietitian (RD) 2) to compare Nutrition Therapy assessments (NTA) and physician Electronic Medical Records (EMR) notes for diagnosis and severity of malnutrition.
Material and Methods: This study was a quality improvement project. Data included consecutive nutrition therapy assessments in 2009 made by a Registered Dietitian. RD used a standard assessment tool with 6 criteria to assess nutritional status; unintentional weight loss, BMI, visual muscle wasting, nutrient intake, wounds, and laboratory values e.g., pre-albumin, albumin, and transferrin. ⩾2 criteria had to be present for malnutrition. Weight loss (WL) was: moderate if 1−2% WL in 1 week, 5% in 1 month, 7.5% in 3 months, or 10% in 6 months; severe if >2% WL in 1 week, >5% in 1 month, >7.5% in 3 months, or >10% in 6 months. Physician notes were reviewed as to whether malnutrition was reported and/or graded.
Results: 213 NTA were reviewed for 116 patients. Median age 65 years (range 19−94); 57% male; 84% cancer diagnosis. Most common cancers were gastrointestinal 26%, genitourinary 26%, and respiratory 16%. 78% had metastatic disease. 147 (69%) NTA were eligible for RD assessment. Most often requested by physician/physician assistant (51%), dietetic technician (21%), or nurse (18%). Of the 147 NTA, most 99 (67%) identified malnutrition per RD; 55% of them had moderate/severe malnutrition. Malnutrition was usually noted by unintentional WL (59%), low nutrient intake (58%), and low serum albumin (54%). WL was severe in 68%. 60% of physician notes did not document nutritional status; 28% reported moderate/severe malnutrition.
Conclusions:
1. Clinically important (moderate/severe) malnutrition was highly prevalent (42%).
2. Weight loss, albumin level, nutrient intake were the most common malnutrition criteria used by RD.
3. Most physician notes did not formally document malnutrition.

No conflict of interest.

1322 POSTER

Oral nutritional support can shorten the duration of parenteral hydration in end-of-life cancer patients: A randomized exploratory trial

H. Ishiki[1], S. Iwase[2], Y. Gyoda[3], Y. Kanai[4], K. Ariyoshi[5], T. Miyaji[6], Y. Tahara[6], T. Kawaguchi[7], T. Yamaguchi[5]. *[1]National Cancer Center Hospital East, Division of Head and Neck Medical Oncology, Kashiwa Chiba, Japan; [2]The University of Tokyo The Institute of Medical Science, Department of Palliative Medicine, Tokyo, Japan; [3]Genki Healthcare Corporation, Department of Home Palliative Care, Tokyo, Japan; [4]The University of Tokyo, Department of Palliative Medicine, Tokyo, Japan; [5]Tohoku University Graduate School of Medicine, Division of Biostatistics, Miyagi, Japan; [6]The University of Tokyo, Interfaculty Initiative in Information Studies, Tokyo, Japan; [7]Tokyo University of Pharmacy and Life Sciences, Department of Practical Pharmacy, Tokyo, Japan*

Background: Varied symptoms such as anorexia and vomiting reduce oral intake in end-of-life cancer patients. Thus, nutritional support or artificial hydration needs to be initiated in clinical practice. However, these procedures jeopardize patients' quality of life (QoL). The amino acid jelly Inner Power® (IP) does not contain any fat and is easy to drink owing to its taste and semisolid form, proving useful for exhausted people. We conducted a randomised trial to compare the efficacies of IP and a liquid enteral nutrient Ensure Liquid® (EL) in terminally ill cancer patients.
Material and Methods: We randomly assigned patients to 3 arms. We started nutritional support for patients when their oral intake decreased to less than 10% of the normal amount. Patients received nutritional support in 3 arms as per their intakes: EL, supported by EL; IP, supported by IP; and EL+IP, support with EL followed by IP. When the amount of oral intake decreased despite nutritional support, patients received parenteral hydration (500–1000 ml/day). This regimen was continued until patients' death. We recorded the duration of nutritional support, the duration of parenteral hydration, and the amount of oral intake. Primary endpoint was drip infusion in vein (DIV)-free survival, which is defined as the duration from the initiation of nutritional support to the administration of parenteral hydration. Secondary endpoints included overall survival, the duration of parenteral hydration, the duration of nutritional support, adverse events, and QoL.
Results: Twenty-seven patients were enrolled in the study, of which 21 were included in intention-to-treat analysis (EL:IP:EL+IP, 8:5:8). Median age of the subjects was 69 years. Primary tumor sites were the lung (n = 6), hepatobiliary (n = 5), breast (n = 4), colorectal (n = 3), head and neck (n = 2), and cervix (n = 1). There was a significant difference between the 3 arms with regard to DIV-free survival (EL, IP, and EL+IP time was 0.5, 6.0, and 4.5 days, respectively; $P = 0.050$). Overall survival was 7, 9, and 8 days in the EL, IP, and EL+IP arms, respectively. The IP arm showed better QoL scores for fatigue and global health and low occurrence rates of adverse event in nausea.
Conclusions: IP can shorten the duration of parenteral hydration in terminally ill cancer patients and does not affect their survival.
No conflict of interest.

1323 POSTER

Transdermal fentanyl vs oral oxycodone+naloxone prolonged release: Efficacy in pain control for stage IV cancer patients

A. Prudente[1], S. Pepe[1], G. Della Vittoria Scarpati[1], C. Fusciello[1], G. Di Giulio[1], V. Faiola[1], D. Napoli[1], S. Cigolari[1], B. Serio[2], R. Guarrasi[1].
[1]Ospedali Riuniti San Giovanni, Oncology Unit, Salerno, Italy; [2]Ospedali Riuniti San Giovanni, Ematology Unit, Salerno, Italy

Background: The Breakthrough cancer Pain (BTcP) is a transitory exacerbation of pain that occurs on a background of otherwise stable pain in an oncologic patient receiving chronic opioid therapy. The management of BTcP episodes require on-demand opioid (e.g., immediate-release morphine or rapid-onset fentanyl) in addition to the baseline (regular) opioid therapy. The aim of this study is to assess the pain control in metastatic cancer patients receiving either transdermal fentanyl or oxycodone+naloxone prolonged release tablets, through the evaluation of the frequency of BTcP episodes in these patients.
Methods: An observational study to assess the frequency of BTcP episodes in patients with metastatic disease receiving either transdermal fentanyl (25 mcg/h every 72 hours) or oral oxycodone+naloxone prolonged release tablets (30 mg/die). Rapid onset fentanyl (buccal or nasal at equidoses) were provided as rescue medication for Breakthrough pain. Patients were asked to record when they took additional medication for incident pain.
Results: Baseline characteristics = N patients: 132; men: 60%; mean age: 61.05 years; ECOG 1: 70%. Main location of the primary tumor: breast (44%), lung (25%), colon/rectum (17%), head and neck (14%). 60 patients were treated with transdermal fentanyl 25 mcg/h (45%), 72 with oxycodone+naloxone prolonged release tablets 30 mcg/die (55%). In the fentanyl group, patients used more on-demand opioid than the oxycodone+naloxone group (54% vs 42%; $p = 0.0005$) and a sizeable proportion of patients required upward titration of opioids (47% required at least one fentanyl dose change and 27% at least one oxycodone+naloxone dose change; $p < 0.05$).
Conclusions: Clinical practice confirms significant improvement in preventing BTcP episodes in metastatic disease with oral oxycodone+naloxone compared to trandermal fentanyl. Furthermore, we observed that the efficacy of the patch is shorter than 72 hours (in a range between 4 h − 60 h) and that in some clinical occurrences (e.g., hyperhidrosis, altered thermoregulation) transdermal opioids are less effective than oral formulations.

Current emesis patterns of chemotherapy and antiemetic treatments in Western Europe

C. Ricarte Iniesta[1], C. Anger[2]. *[1]IMS Health, Client Service Oncology, Puteaux, France; [2]IMS Health, Client Service Oncology, London, United Kingdom*

Background: Cytotoxic treatments and supportive care to prevent chemotherapy-induced nausea and vomiting (CINV) vary across key cancers and countries in Western Europe, which may influence patient outcomes. This study describes the latest use of chemotherapies and antiemetic regimens in clinical practice across five countries.
Methods: For this study IMS Oncology Analyzer™ (OA) was used, a patient database collected through a quarterly physician panel survey. OA reports on patient case history information related to the treatment of patients across all cancer types. The most recent data (January-December 2012) in France, Germany, Italy, Spain and UK was used.
Results: From a total sample of 58,619, 37,444 patients were identified as being treated with chemotherapy. Among them, 22,145 (59.1%) received an antiemetic. 73.5% of patients were ⩾56 y. Overall, patients were mainly diagnosed with Colorectal (14.9%), Breast (11.7%) and Non-hogdkin lymphoma (NHL) (11.6%). 36.7% of patients received high-emetogenic chemotherapy (HEC), 41.2% moderate-emetogenic chemotherapy (MEC) and 21.5% low/minimal-emetogenic chemotherapy (LEC) −0.6% not specified-.
In HEC, 71% of chemotherapies contained a platinum compound. The antiemetic treatment used the most was Ondan±Dex (30.9%) and 25% of HEC patients received Aprepitant. HEC were mainly used in Non-small cell lung cancer (22.1%) and Breast (17.3%). In MEC, 19% of chemotherapies contained an anthracycline and cyclophosphamide. The main antiemetic treatment was still Ondan±Dex (28.6%) and only 5.4% of patients received Aprepitant. MEC were mainly used in Colorectal (30%) and NHL (23.9%). In LEC, 19% of chemotherapies contained a taxane. Only 1.3% of patients received Aprepitant. The anti-emetic treatment used the most was Dex (14.9%). LEC were mainly used in Multiple Myeloma (20.8%) and Pancreas (17.5%).
Focusing on Breast cancer, HEC and MEC were mainly used in Stage II and III (75.1% and 59.6% respectively), whereas LEC were mainly used in Stage IV (61.9%).
Conclusions: Nearly 60% patients treated with chemotherapy received a treatment for CINV in Western Europe. Over 75% of patients received a HEC or MEC. Emetogenic level of chemotherapies used depend on the tumor types but also on the stage of the disease; aggressive chemotherapies can be used mainly in early stages as in Breast cancer. Usage of setrons and aprepitant differ also across countries, key cancers and types of chemotherapy.
Ondan: ondansetron, Dex: dexamethasone

1325 POSTER

Comparison of CKD-EPI, MDRD and Cockcroft-Gault to estimate baseline renal function in patients with head & neck and thoracic cancers

T.B. Castria[1], R.C. Bitton[1], A.A. Amaral[2], J.G. Lollo[2], V.T. Costa e Silva[3], E. Burdmann[3], P.M. Hoff[1], G. Castro Jr.[1]. *[1]Instituto do Câncer do Estado de São Paulo, Medical Oncology, São Paulo/SP, Brazil; [2]Faculdade de Medicina da Universidade de São Paulo, Medicine, São Paulo/SP, Brazil; [3]Faculdade de Medicina da Universidade de São Paulo, Nephrology, São Paulo/SP, Brazil*

Background: Estimation of renal function is essential in patients (pts) treated with cisplatin (DDP). We aimed to compare the estimated glomerular filtration rate (eGFR) according to different methods and also to verify the incidence of acute renal failure (ARF) after DDP in pts diagnosed with head & neck and thoracic cancers.
Materials and Methods: Uniinstitutional, retrospective and exploratory study. All pts were >18 y, diagnosed with head & neck or thoracic cancer, and were treated with DDP, at least for one cycle. DDP was administered in NS 500 mL in 60 min, following NS 1000 mL, KCl 25 mEq, $MgSO_4$ 100 mg and manitol 20 g. Baseline eGFR was calculated using Cockcroft-Gault (CG), Modification of Diet in Renal Disease (MDRD) and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations. ARF was defined as elevation of serum creatinine ⩾0.3 md/dL, or more than 50%.
Results: 157 pts were included: median age 58 y (26−78), 68% male. Lung (61%), larynx (13%), oral cavity (8%) and oropharynx (8%) were the most common primary sites. Median weight was 60 kg (36–107), and BMI 22.7 kg/m^2 (13.2–39.3). First DDP cycle was administered to all 157 pts, the second to 154 pts, the third to 127 pts and 91 pts received the fourth one. Median DDP dose was 80 mg/m^2 for all cycles. Median baseline serum creatinine was 0.75 mg/dL (0.46–1.76) and it increased to 0.78 (0.40–1.51, p = 0.044, t-test), 0.80 (0.42–1.68; p = 0.005) and 0.77 (0.41–1.69, p = 0.075) after each DDP dose. At baseline, median eGFR (ml/min/1.73 m^2) was 86 (34–175)(CG), 107 (44–226)(MDRD) and 100 (45–145)(CKD-EPI). Considering normal eGFR as >90(CG), >125 (MDRD) and >100 (CKD-EPI), according to ROC analysis, the agreement between MDRD and CG was fair (k=0.291) and between MDRD and CKD-EPI was moderate (k=0.553). Bland-Altman analysis revealed that CG overestimates eGFR in comparison to MDRD (+19) and to CKD-EPI (+11). Overall, the incidence of ARF was low: 9 pts (6%), 11 pts (8%) and 1 pt (1%) after first, second and third cycles, respectively.
Conclusions: In comparison to MDRD, both CG and CKD-EPI overestimate eGFR, and the agreement between these equations is not good. CG should be used with caution as the reference eGFR in these pts.
No conflict of interest.

A probability/risk matrix of febrile neutropenia to select patients for G-CSF primary prophylaxis

A. Ramchandani Vaswani[1], L. Faez[2], M. Selvi Miralles[3], M. Antonio-Rebollo[4], C. Font Puig[3], J. Espinosa Arranz[5], M. Biosca[6], E. Vicente Rubio[7], P. Jiménez Fonseca[2], A. Carmona-Bayonas[8].
[1]Hospital Universitario Insular de Gran Canaria, Oncología, Las Palmas de Gran Canaria, Spain; [2]Hospital Central de Asturias, Oncología, Oviedo, Spain; [3]Hospital Clinic, Oncología, Barcelona, Spain; [4]ICO-Duran i Reynals, Oncología, Barcelona, Spain; [5]Hospital General de Ciudad Real, Oncología, Ciudad Real, Spain; [6]Hospital Vall d'Hebron, Oncología, Barcelona, Spain; [7]Hospital Universitario Insular de Gran Canaria, Oncología, Barcelona, Spain; [8]Hospital Universitario Morales Meseguer, Oncología, Murcia, Spain

Introduction: Current guidelines suggest a risk threshold of 20% for G-CSF primary prophylaxis (PP) in patients with solid tumors. Individual factors that increase the risk of FN are considered when chemotherapy

yields a medium rate of FN (10−20%). This recommendation does not address the qualitative impact of FN. A probability/risk matrix could improve the prevention of severe episodes.
Patients: An ambispective study of cases with solid cancer and FN was carried out in 15 Spanish hospitals between 2006–2013. The risk factors (RF) that were available before chemotherapy initiation were used to create a vulnerability index (VI): low risk (0 RF), medium risk (1−2 RF) and high risk (⩾3 RF). We classified the cases on a 3x3 table, according to the probability of FN (<10%, 10−20%, >20%) and the VI.
Results: We reviewed 734 cases of FN. We found 207 complications (28.5%) and 27 deaths (3.7%). The independent baseline predictors of complications were COPD (OR 2), cardiovascular disease (OR 2.4), ECOG PS ⩾2 (OR 2.6) and palliative setting (OR 1.4). Rates of complications and deaths according to the VI and the predicted myelotoxicity are shown in Table 1. Of note, the use of G-CSF PP increased in parallel to the expected myelotoxicity of the regimen: 6%, 21% and 61% ($p < 0.0001$), but not in relation to the VI.
Conclusions: This study identified risk factors for severe neutropenic complications and mortality before chemotherapy initiation, with potential implications for prevention. It remains a priority to classify the patients on basis of the likelihood of FN and their individual vulnerabilities.
No conflict of interest.

Table 1. Complications and deaths

VI % FN	Low risk	Medium risk	High risk	n	p-value
Complications					
<10%	4/20 (20%)	35/97 (36%)	13/17 (76%)	134	<0.0001
10−20%	27/165 (16%)	65/239 (27%)	34/50 (68%)	454	<0.0001
>20%	14/84 (17%)	13/53 (25%)	2/3 (67%)	140	0.1
Deaths					
<10%	0/20	4/97 (4%)	6/17 (35%)	134	0.006
10−20%	1/165 (1%)	10/239 (4%)	3/50 (6%)	454	0.01
>20%	0/84	1/53 (2%)	2/3 (67%)	140	0.08

1327 POSTER

Effect of food and age on the pharmacokinetics of NEPA (a fixed-dose combination of netupitant and palonosetron) in healthy volunteers

S. Calcagnile[1], C. Lanzarotti[1], M. Gutacker[1], V. Jakob-Rodamer[2], K.P. Kammerer[3]. [1]*Helsinn Healthcare SA, Research and Development, Lugano, Switzerland;* [2]*CRS Clinical Research Services Mannheim GmbH, Bioanalytics, Grünstadt, Germany;* [3]*CRS Clinical Research Services Mannheim GmbH, Early Phase 1/2a, Mannheim, Germany*

Background: The incidence of cancer is highest among the elderly and chemotherapy-induced nausea and vomiting has an adverse impact on their quality of life and compliance with therapy. NEPA, an oral fixed-dose combination of netupitant, a new NK_1 receptor antagonist (RA), and palonosetron, a pharmacologically distinct 5-HT_3RA, targets dual antiemetic pathways with a single-dose administration. This trial assessed the effect of food and age on the pharmacokinetics (PK) of NEPA.
Material and Methods: This was an open-label, randomized, two-way, cross-over trial (EudraCT 2010–020436−20). NEPA (300 mg netupitant + 0.5 mg palonosetron) was administered to healthy volunteers (⩽45 years) after an overnight fast of ⩾10 hours (fasted condition), or following a high-fat breakfast (fed condition). Cross-over took place after 28 days. A parallel group of healthy volunteers (⩾65 years) received NEPA in the fasted state. PK parameters of netupitant and palonosetron were calculated in the fasted and fed condition, as well as in elderly and younger volunteers in the fasted condition. Safety and tolerability were evaluated.
Results: 24 adult (22−45 years) and 12 elderly (66−79 years) volunteers were enrolled in the study. Food had no effect on the PK of palonosetron. In the fed state, netupitant maximum plasma concentration and overall plasma exposure increased by 18% and 16%, respectively, compared with the fasted condition (C_{max}: 635.0 vs. 539.3 μg/L and AUC_{inf}: 21271 vs. 18344 h*μg/L, respectively). This increase in netupitant exposure is not considered clinically relevant. Compared to younger, elderly volunteers showed an increased exposure to netupitant [C_{max}: 36% (735.4 vs. 539.3 μg/L); AUC_{inf}: 25% (22913 vs. 18344 h*μg/L)] and to palonosetron [C_{max}: 10% (839.5 vs. 760.1ng/L); AUC_{inf}: 37% (44414 vs. 32445 h*ng/L)], which was not considered clinically relevant. All reported treatment-emergent adverse events (TEAEs) were of mild and moderate intensity. TEAEs were more frequent in elderly volunteers (91.7%), as well as in the fed vs. fasted condition (47.8% vs. 34.8%). Overall, most common TEAEs were constipation (47%) and headache (33%). No deaths and no serious adverse events occurred during the study.
Conclusion: The changes in the PK profile of NEPA are not considered clinically relevant and, consequently, dose adjustments are not expected with regards to food and age. Overall, NEPA was safe and well tolerated.

1328 POSTER

Prevalence of iron deficiency in severe anemia for cancer patients visiting the emergency unit for acute onset symptoms

S. Antoun[1], A. Tahar-Alibay[1], S. DeBotton[2], V. Concas[3], L. Duvillie[3], M. DiPalma[1], M. Merad-Taoufik[1]. [1]*Institut Gustave Roussy, Ambulatory Care, Villejuif, France;* [2]*Institut Gustave Roussy, Cancer Medicine, Villejuif, France;* [3]*Vifor France, Research and Development, Paris, France*

Background: Anemia in cancer is a common biological abnormality and etiological research is often not conducted. Iron deficiency is rarely explored. The objective is to determine the prevalence of absolute (A) or functional (F) iron deficiency (ID) in severe anemia for cancer patients.
Materiel and Methods: All cancer patients who visited the emergency unit for acute symptoms were included prospectively during 3 months if hemoglobine level was <10 g/dl. Three groups were defined using serum ferritin (SF (ng/ml) and transferrin saturation (TSAT): Absolute ID: TSAT<20% and SF<30; status unknown for ID (UID) (functional ID): TSAT<20% and SF>30 ng/ml and a group without ID (WID): TSAT >20%.
Results: Severe anemia was observed for 85 patients; 5% of the patients had AID. Asthenia and dyspnea were reported in 76% and 62% of the patients, respectively. A gastrointestinal localization was found for only 50% of the patients with AID. Anemia had another cause than ID in 19%. ID status was difficult to define for 76.5% of the patients (CS<20%, SF>30). For 66% of the patients in UID, inflammatory syndrome (C reactive protein >60 mg/l) might explain the functional ID, but for the remaining patients (34%), there are probably other explanations for the TSAT less <20%.
Conclusions: Absolute ID was rarely observed in cancer patients visiting for acute onset symptoms. There are more than 3/4 of the patients with an ID status difficult to determine and the reticulocytosis response after an iron supplementation could be of help for diagnosis and understanding the underlying mechanisms.
No conflict of interest.

1329 POSTER

Factors associated with mortality rates of patients with advanced cancer admitted to a specialized intensive care unit

G.M. Bariani[1], T.B. Castria[1], A.M. Andrade[1], L.D. Faria[1], D.F. Silva[1], M.I. Braghiroli[1], V.C. Miranda[1], A.B. Fêde[1], L. Hajjar[2], R. Riechelmann[1]. [1]*Instituto do Cancer do Estado de São Paulo, Clinical Oncology, São Paulo, Brazil;* [2]*Instituto do Cancer do Estado de São Paulo, Intensive Care Unit, São Paulo, Brazil*

Background: Cancer patients often need intensive care to recover from drug- related toxicities, infections or other clinical complications. Proper selection of cancer patients who could benefit from such care would spare resources and avoid overtreatment of patients with poor prognosis. We aim to evaluate the prognostic factors associated with mortality rates of these patients during hospitalization in an Intensive Care Unit (ICU) and within 30 days after hospital discharge.
Material and Methods: All cancer patients with advanced solid tumors admitted in an ICU of a comprehensive cancer center were retrospectively evaluated in a 6-month period. We extracted the following data from the last medical visit before hospital admission: tumor type, performance status (PS), body mass index (BMI), renal and liver function, hemoglobin, cancer treatment, and number of days from the last cancer therapy. Results of laboratory tests at ICU admission were also collected. A multivariable logistic regression model was performed to evaluate potential predictors of mortality during hospitalization and after 30 days from hospital discharge. Variables were considered statistically significant if two-sided *P* values <0.05.
Results: From May 2012 to Oct 2012, 627 patients were admitted to ICU and 338 were eligible. Median age was 60.0 years; 257 (76.0%) were metastatic. Gastrointestinal was the most common primary site (30.2%). Half of patients had a poor PS (ECOG⩾2) and 16.6% were malnourished (BMI⩽18.5). Any degree of renal and liver impairment was found in 33.8% and 7.1% of patients, respectively. One-fourth (20.4%) had received two or more lines of therapies against cancer. The mortality rate was 38.8% during ICU period and 59.2% when considering the whole hospitalization. Of the 132 discharged patients, the 30-day mortality rate was 21.2%.

The multivariable analysis demonstrated that hypoalbuminemia (OR=3.93; 95%IC: 1.58–9.79) and high levels of arterial lactate (OR=1.84; 95%IC: 1.03–3.30) collected at ICU admission were significantly related to death during hospitalization.
Conclusions: In this large retrospective analysis, the mortality rate of patients with advanced cancer admitted to a specialized ICU is high, what shows the poor prognosis of these patients. Hypoalbuminemia and high level of arterial lactate at ICU admission were associated with death during hospital recovery. The indication of ICU to cancer patients should be carefully discussed.
No conflict of interest.

1330 POSTER

Chemotherapy-induced neutropenia and febrile neutropenia during chemotherapy for gynaecologic malignancy

Y. Hashiguchi[1], T. Fukuda[1], T. Ichimura[1], Y. Matsumoto[1], T. Yasui[1], T. Sumi[1]. *[1]Graduate School of Medicine Osaka City University, Obstetrics and Gynaecology, Osaka, Japan*

Background: Chemotherapy-induced neutropenia seemed to be a relevant problem in clinical practice. Febrile neutropenia (FN) seemed to be one of medical emergency in cancer treatment. In this study, we investigated chemotherapy-induced neutropenia recently performed in patients with gynaecologic malignancy.
Methods: Between January 2009 and December 2011, we examined our reported chemotherapy-induced neutropenia using the Common Terminology Criteria for Adverse Events (CTCAE) v.4.0. We analysed the incidence and clinical features of chemotherapy-induced neutropenia (grade4: absolute neutrophil count <500 /μL) and febrile neutropenia in patients with gynaecologic malignancy.
Results: During this period we administered over 1614 infusions (29 regimens) to 291 patients with gynecologic malignancy. Median age was 60 years (24−84). Neutropenia occurred in 147 (50.5%) patients over 378 (23.4%) chemotherapy cycles. Febrile neutropenia occurred in 20 (6.9%) patients over 25 (1.5%) cycles. FN occurred after cycle 1 in 14 (56%) cycles. Mean duration of neutropenia and fever was 3.6 (1−12) and 3.4 (1−9) days respectively. The source of fever was unexplained by exam or cultures in 15 (60.0%) cycles. 5 patients (25%) had bowel resection history. There were two neutropenic-related death cases. Neutropenia was associated with elderly age (over age 70) ($p < 0.0001$), less than five previous chemotherapy cycle ($p = 0.02$), disseminated disease ($p = 0.03$), platinum-based regimens ($p < 0.0001$), taxan-containing regimens ($p < 0.0001$) and combined therapy ($p < 0.0001$). Febrile neutropenia was associated with poor performance status ($p < 0.0001$), no previous chemotherapy ($p < 0.05$), disseminated disease ($p < 0.0001$) and distant metastatic disease ($p = 0.03$). Both neutropenia and febrile neutropenia were not related with bone marrow metastases or previous radiotherapy.
Conclusions: By estimating risk factor of febrile neutropenia such as performance status and progression of disease, safe management of chemotherapy-induced neutropenia may be possible in patients with gynaecologic malignancy.
No conflict of interest.

1331 POSTER

Evaluating the impact of a new oncology consultant ward round

V. Navani[1], D. Bloomfield[1], G. Rosie[1]. *[1]Royal Sussex County Hospital, Sussex Cancer Centre, Brighton, United Kingdom*

Background: Regular consultant ward rounds have been shown to reduce length of stay and improve discharge planning for patients. The Royal College of Physicians advises regular morning consultant led ward rounds for medical patients. Balancing the competing demands of outpatient activity and inpatient oncology specialist care has been difficult in our hospital. Previously there was no timetabled consultant ward round for oncology inpatients at our hospital. Inpatients were managed primarily by oncology specialist trainees, qualified in internal medicine, with ad-hoc review by their named consultant. A regular consultant ward round was introduced for the first time on the 7/1/13. Each consultant was timetabled to give a twice weekly morning ward round, on a rolling rota. Whilst based on the ward they provided cover for all inpatients, regardless of tumour site.
Materials and Methods: To evaluate this intervention, a retrospective case note analysis was undertaken. This included all patients admitted under oncology for the two months preceding and succeeding the new ward round. For each patient the admission date, time to first consultant review, number of consultant reviews, time to discharge after consultant review and discharge date was identified. A staff survey also took place before and after the new consultant ward round. Statistical analysis was performed using Mann-Whitney U or Chi-Squared tests.
Results: 85 patient episodes meeting the inclusion criteria were under the care of oncology between 7/11/12 and 7/3/13. Case notes were available for 63 episodes (74%). The average length of stay significantly decreased from 11 days to 3.5 days ($p < 0.05$). The time to discharge after first consultant review also significantly decreased from 6 days to 2 days ($p < 0.05$). The number of consultant reviews and time to first consultant review remained unchanged (p= not significant). The percentage of patients receiving a consultant review increased, from 54.3% to 71.4%, though this was not statistically significant. However it is likely such a large increase is clinically significant. Medical and nursing staff satisfaction assessed by an online questionnaire and free text survey also improved following the new ward round.
Conclusion: This study suggests that a regular consultant ward round improves length of stay for patients, possibly through more patients having a consultant review and by expediting treatment and discharge decisions after such a review. Further robust work is needed to establish exactly how this is achieved and how best to make the new ward round a permanent feature logistically.

Randomized trial to explore indisetron tablets for preventing chemotherapy-induced nausea and vomiting (CINV)/acute-onset diarrhea induced by IRIS/FOLFIRI: An exploratory trial -HGCSG0704-

M. Dazai[1], H. Fukushima[2], T. Sasaki[3], T. Miyagishima[1], I. Iwanaga[4], M. Kudo[5], K. Hatanaka[6], K. Kato[7], M. Tateyama[8], Y. Komatsu[2]. *[1]Kushiro Rosai Hospital, Internal Medicine, Kushiro, Japan; [2]Hokkaido University Hospital, Cancer Center, Sapporo, Japan; [3]Hokkaido University Hospital, Gastroenterology and Hepatology, Sapporo, Japan; [4]Japanese Red Cross Kitami Hospital, Gastroenterology, Kitami, Japan; [5]Sapporo Hokuyu Hospital, Gastroenterology, Sapporo, Japan; [6]Hakodate Municipal Hospital, Gastroenterology, Hakodate, Japan; [7]Iwamizawa Municipal General Hospital, Gastroenterology, Iwamizawa, Japan; [8]Tomakomai Nisshou Hospital, Internal Medicine, Tomakomai, Japan*

Background: Indisetron is a serotonin (5-hydroxytryptamine type 3: 5-HT_3) receptor antagonist that also antagonizes 5-hydroxytryptamine type 4 receptors. Indisetron tablets showed the non-inferiority to ondansetron tablets in terms of efficacy for preventing chemotherapy-induced nausea and vomiting (CINV). Preclinical data administered with irinotecan showed indisetron significantly reduced the stool frequency in mice and inhibited the colonic peristalsis in dogs. We designed a pilot study compared the efficacy and tolerability of indisetron for irinotecan-induced diarrhea, nausea, and vomiting with granisetron.
Material and Method: This study was a pilot, multicenter, randomized, open-label, comparative trial (HGCSG0704). Advanced colorectal cancer patients treated with FOLFIRI or IRIS (Irinotecan + S-1) with or without bevacizumab were enrolled in this study. Treatment: Arm A: indisetron tablets po day1. Arm B: granisetron iv day 1. The primary endpoints were the incidence of acute-onset diarrhea and complete protection from vomiting. Secondary endpoints were complete protection from nausea, rate of no rescue therapy and tolerability. Nausea, vomiting and other adverse events (AE) were evaluated using Common Terminology Criteria for Adverse Events, version 3.0.
Results: Between May 2008 and July 2012, 33 patients (pts) were randomized. The study was closed prematurely due to poor accrual. Arm A: 16 pts, arm B 17 pts. Median age A: 68 yrs (55−76), B: 66 yrs (47−78): ECOG PS 0/1: A: 12/4, B: 14/ 3pts. There was no significant difference of the incidence of acute-onset diarrhea between both groups (18.8% [95% CI −0.2–39.5] in A vs 35.3% [95% CI 10.7–59.9] in B, $p = 0.44$). The proportion of pts with complete protection from vomiting was 87.5% in A and 88.2% in B (p=1.00). Similarly, complete protection from nausea and rate of no rescue therapy did not have a significant difference (50.0% in A and 41.2% in B, $p = 0.73$). Severe AE as nausea and vomiting were also similar between two groups. No severe AE induced by 5-HT3 receptor antagonist were observed in both groups.
Conclusions: Although indisetron showed effective and feasible results for preventing CINV induced by regimen containing irinotecan, the proportion of acute-onset diarrhea induced by irinotecan had not improved in indisetron group. Because there were small numbers in this study, the significant difference was not recognized. However, Group A tends to be a low incidence of the diarrhea. Therefore, it may be necessary to prove it in the clinical trial with the larger number.

Results of ultrasonic stimulation in oncological patients with leucopenia

D.A. Pulatov[1], G.A. Avezmuratova[1], A.A. Asrarov[2], S.R. Abdiganieva[1], J.M. Ibragimov[1], D.A. Abdurakhmanov[1]. [1]*National Oncological Research Centre, Chemotherapy, Tashkent, Uzbekistan;* [2]*National Oncological Research Centre, E.C.Hemo-Immuno Correction, Tashkent, Uzbekistan*

The purpose of the study: Studying the role and assessment of efficiency of ultrasonic stimulation of spleen in oncological patients during chemotherapy complicated with leucopenia.
Objectives: Evaluate the effectiveness of ultrasonic stimulation of spleen in patients with leucopenia receiving polychemotherapy. Suggest indications and terms of ultrasonic stimulation of spleen in leucopenia.
Materials and Methods: The study included 113 patients with a diagnosis of a malignant tumor, complicated by leucopenia receiving specialized treatment in chemotherapy department of National Cancer Research Center in 2010–2011. From the total enrolled patients 24 (21%)- patients were diagnosed breast cancer, 26 (23%)- ovarian cancer, 13 (11.5%)- cervical cancer, 8 (7%)- brain tumors, 7 (6%) − non-Hodgkin's lymphoma. All patients before the beginning of next course or during chemotherapy had complication in the form of reduction in the total number of leukocytes. Indicators of leucocytes ranged from 1.8 to 3.2 and averaged $2.4 \pm 0.03 \times 10?/l$. To activate the production of white blood cells used ultrasonic stimulation of the spleen (USS) 1−2 times per day, 3−6 procedures without the use of corrective and immunostimulatory drugs. Ultrasonic stimulation of the spleen was prescribed in case of reducing the number of leucocytes below $3.0 \times 10?/l$. The effectiveness of treatment was assessed after the third procedure.
Results: In the study of peripheral blood on the third day after the start of the USS were detected increase in the number of white blood cells from 4.5 to $6.0 \times 10?/l$ and up to $11 \times 10?/l$ after treatment ($p < 0.05$). After the stimulation of the spleen in the period from 1 to 6 days 113 (100%) patients had recovery of white blood cells that allowed for a special anti-cancer treatment.
Conclusions: The study shows the usefulness and actuality of the method for further study of the ultrasonic stimulation at leucopenia in oncological patients receiving chemotherapy.
This method can be recommended as an effective and economically unhindered method for stimulating leucopoiesis.

Qualitative assessment of dysgeusia in early breast cancer patients undergoing anthracycline or taxane-based standard chemotherapies

H. Tsujimura[1], M. Yamada[2], E. Asako[3], Y. Kodama[4], T. Sato[4], Y. Nabeya[5], H. Nagase[6], A. Nakagawara[6]. [1]*Chiba Cancer Center, Division of Clinical Oncology, Chiba, Japan;* [2]*Chiba Cancer Center, Department of Nursing, Chiba, Japan;* [3]*Chiba Cancer Center, Department of Pharmacy, Chiba, Japan;* [4]*Kikkoman Corporation, Research and Development Division, Noda, Japan;* [5]*Chiba Cancer Center, Division of Gastroenterological Surgery, Chiba, Japan;* [6]*Chiba Cancer Center, Research Institute, Chiba, Japan*

Background: Taste alternations (TAs) during chemotherapy are common and significant complaints of cancer patients potentially leading to poor compliance, malnutrition and decreased quality of life. Although chemotherapy regimens with different toxicity profiles may vary in their impact on TAs, research on this topic has not extensively examined. Therefore, the standard prevention and treatment have not been established. Here we conduct a prospective study to assess not only the prevalence but also the quality of TAs in chemotherapy-naive patients receiving 2 distinct worldwide standard therapies.
Patients and Methods: Japanese female patients with early breast cancer who undergo 4 cycles of FEC (5-fluorouracil, epirubicin and cyclophosphamide) or TC (docetaxel and cyclophosphamide) regimen as adjuvant setting were prospectively enrolled. Patients completed a daily questionnaire, which measures dysgeusia and related adverse effects by using CTCAE criteria. In addition, alternations of 5 basic tastes were qualitatively monitored with 5-category scales consisting of very strong (+2), strong (+1), normal (0), weak (−1) and very weak (−2). These data were collected from 24 and 18 patients who received FEC and TC, respectively.
Results: (1) To assess the sequential alteration of dysgeusia, 21 days of single cycle were separated to 5 short periods; day 1−2, 3−5, 6−8, 9−14 and 15 or later. The frequency of grade 2 dysgeusia in each period was 29%, 25%, 29%, 21%, 8% and 38%, 44%, 56%, 56%, 25% in 1st and 4th cycle of FEC, respectively. On the other hand, TC showed 0%, 44%, 50%, 33%, 0% and 17%, 50%, 58%, 42%, 8% in the same setting. These results suggest that the onset of TAs induced by FEC is prompt and the symptoms prolong with accumulation. In contrast, the adverse symptoms caused by TC may appear more frequent but transient.
(2) The character of TAs developed clearly until 2nd cycle of both regimens. The average score of 5 basic tastes (salty/sweet/umami/sour/bitter) in the 2nd cycle of FEC and TC were 0.48/0.38/−0.43/0.29/0.33 and −0.41/−0.35/−0.59/−0.35/−0.12, respectively. These results support the idea that each taste sensations except umami are emphasized during FEC, while they are potentially diminishing during TC.
Conclusions: This study demonstrates that the features of TAs may differ definitively between anthracyclin-based FEC and taxane-based TC regimen. Further research has yet to be required focusing on individualized management strategies for TAs depending on the type of chemotherapy.

1335 POSTER

Palonosetron plus dexamethasone for the prevention of nausea and vomiting in patients with locally advanced head-neck squamous cell cancer (HNSCC) treated with radiotherapy plus concomitant administration of cisplatin

A. Rozzi[1], C. Nardoni[1], M. Corona[1], P.T. Falbo[1], M.S. Gasparro[1], G. Lanzetta[1]. [1]*Istituto Neurotraumatologico, Clinical Oncology Unit, Grottaferrata, Italy*

Background: Nausea and vomiting still represent relevant issues in patients treated with cisplatin (>50 mg/mq): an unsatisfactory emetic control could negatively affect the patients' compliance with potential detrimental effects in terms of treatment's efficacy. In this study we have evaluated the efficacy of single dose IV palonosetron (0.25 mg) plus dexamethasone (8 mg IV day 1 plus 8 mg PO dd.2−3) in patients with locally-advanced HNSCC treated with standard fractionation radiotherapy (total dose from 66 to 70 Gy) plus concomitant administration of cisplatin 100 mg/m^2 every 21 days.
Material and Methods: From March 2010 to January 2013 we consecutively recruited 43 pts with locally advanced HNSCC. Main characteristics of pts were as follows: M:F 34:9, median age 62.3 yrs (range 54−73 yrs), median ECOG PS 1 (range 0−1). 10 pts (23%) were still alcohol consumers. Primary end points were: Complete Response (CR: no vomiting and no rescue therapy) and Complete Control (CC: CR and no more than mild nausea). These endpoints were evaluated during the acute (0−24 h), the delayed (25–168 h) and overall (0–168 h) phases. A safety evaluation of this antiemetic protocol was also planned.
Results: All recruited patients were evaluated for efficacy and safety. During the acute phase, CR and CC were reported in 84% and 81% of patients, respectively; 86% and 81% of patients achieved CR and CC during the delayed phase; in the overall phase, 81% and 79% of patients experienced CR and CC, respectively. This antiemetic regimen was really well tolerated: 12 pts (28%) experienced G1−2 constipation easily managed by the administration of common laxatives; in 3 pts (7%) was reported G1 headache.
Conclusions: In this study the combination of palonosetron and dexamethasone has proven to be effective and safe to prevent chemotherapy-induced nausea and vomiting in patients with locally-advanced HNSCC treated with radiotherapy plus concomitant cisplatin 100 mg/m^2 administered every three weeks.

1336 POSTER

The efficacy of low dose transdermal fentanyl in opioid-naive cancer patients with moderate and severe pain

H. Song[1], M. Kang[1], J. Kang[1], S. Oh[2], I. Hwang[3], S. Lee[4], W. Kim[5], K. Park[5]. [1]*Gyeongsang Naiotnal University Hospital, Internal Medicine, Jinju, South Korea;* [2]*College of Medicine Dong-A University, Internal Medicine, Busan, South Korea;* [3]*College of Medicine Chung-Ang University, Internal Medicine, Seoul, South Korea;* [4]*College of Medicine Dankook University, Internal Medicine, Cheonan, South Korea;* [5]*Sungkyunkwan University Samsung Medical Center, Internal Medicine, Seoul, South Korea*

Background: Little was known about the efficacy of low doses of transdermal fentanyl patch(TDF) in opioid naive patients with moderate to severe cancer pain.
Methods: The study was conducted open-label, prospective design from April 2007 to February 2009 in seven tertiary cancer hospitals and 98 patients were enrolled. TDF was started with low dose formulation(12.5 μg/h) and adjusted according to clinical situation. Pain intensity, used TDF doses, adverse events were monitoring over 4 weeks. Data were analyzed by intent-to-treatment(ITT) principle.
Results: Of 98 enrolled patients, sixty-four(65%) patients completed the study. The median pain intensity decreased from 6.0 to 3.0

(p<0.0001) at the follow-up visit. The efficacy of low dose TDF on pain relief was consistently maintained after considering various variables such as sex(p<0.0001), age(p<0.0001), metastasis(p=0003), previous treatment(p<0.0001) and regardless of baseline pain intensity(p<0.0001). The decrease of pain intensity were significantly larger in severe group than in moderate group(mean±SD; 5.10±2.48 vs 2.48±1.56, p<0.0001). There were no differences between two intensity groups in the TDF dose (27.8 μg/h vs 24.8 μg/h, p = 0.423) and mean time (7.5 days vs 7.9 days, p = 0.740) for pain control.
Conclusion: Low dose TDF was effective treatment in cancer pain patients with moderate to severe intensity. Future randomized trials on efficacy of TDF in severe pain and/or optimal starting dose are warranted.
No conflict of interest.

1337 POSTER

Suppression of bone resorption by denosumab is better measured with CTX than with alkaline phosphatase

F. Geurs[1], S. Tuyls[2], B. Vandendriessche[2], K. Debraekeleer[2]. [1]*St. Mariaziekenhuis, Halle, Belgium;* [2]*St. Mariaziekenhuis, Medical Oncology, Halle, Belgium*

Aim: Study design. This was a single centre study to determine the efficacy of a single injection of denosumab in 20 patients with solid tumors, to expand this experience to serum CTX and in other common metastatic tumors. The study ran from 1.6. 2012 to 1.11.2012.
Patients: Patients with radiological evidence of lytic or mixed bone metastases were enrolled into the study as well as patients with a bone isotope scan confirming diffuse bone metastases (N = 20).
Methods: On the morning of dosing, patients received a s.c. injections of 120 mg denosumab. Chemotherapy within 21 days following denosumab treatment, was allowed.
Patients were followed for at least 7 to 28 days; blood samples for alkaline phosphatase and serum CTX were scheduled on days 1, 2, 3, and 4, and then weeks 1, 2, 3. The data were recorded whenever the patient accepted this exam.
Results: The results from this study show that denosumab, a monoclonal antibody with high affinity and specificity to inhibit osteoclasts, was effective in decreasing bone resorption rapidly and for a sustained period of time in patients with all tumor types metastatic to bone. Bone resorption suppression was extensive based on changes from baseline in the measured biochemical markers, notably serum CTX. Normalisation of this bone resorption markers occurred within 4 to 21 days following single s.c. dose of denosumab in 18 out of 19 patients. Bone-specific alkaline phosphatase levels were only mildly and lately suppressed, confirming that denosumab does not have a direct effect to inhibit osteoblasts.
Conclusions:
1. The effect of denosumab can be easily followed by measuring serum CTX and the use of alkaline phosphatase can no longer be uphold.
2. CTX decreased with denosumab even in zoledronic acid pretreated patients.

No conflict of interest.

1338 POSTER

Predicting adverse outcomes after cisplatin administration in head & neck and thoracic cancer

R.C. Bitton[1], T.B. Castria[1], A.A. Amaral[2], J.G. Lollo[2], V.T. Costa e Silva[3], E. Budmann[3], P.M. Hoff[1], G. Castro Jr.[1]. [1]*Instituto do Cancer do Estado de São Paulo, Clinical Oncology, São Paulo, Brazil;* [2]*Faculdade de Medicina da Universidade de São Paulo, Medicine, São Paulo, Brazil;* [3]*Faculdade de Medicina da Universidade de São Paulo, Nephrology, São Paulo, Brazil*

Background: Renal failure after cisplatin(DDP)-based chemotherapy is a harmful adverse event. Although different equations are used to estimate glomerular filtration rate (eGFR), there is no evidence supporting superiority of one over another in cancer patients (pts). We compared three equations: Cockroft-Gault (CG), Modification of diet in renal disease (MDRD) and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) in a population of cancer pts, after one cycle of DDP. We aimed to investigate if a decrease in eGFR using these equations could predict negative endpoints: death, dialysis or acute kidney failure (ARF).
Materials and Methods: Uniinstitutional, retrospective and exploratory study. All pts were >18 y, diagnosed with head & neck or thoracic cancers, and were treated with DDP, at least for one cycle. Acute renal failure (ARF) was defined as elevation of serum creatinine ⩾0.3 mg/dL, or more than 50%. We defined treatment-related deaths if they occurred in the first 28 days after DDP exposure.
Results: 157 pts were analysed. First DDP cycle was administered to all pts, the second to 154 pts, the third to 127 pts, and 91 pts received the fourth one. Median DDP dose was 80 mg/m^2 for all cycles. At baseline, median eGFR (ml/min/1.73m^2) was 86 (34–175)(CG), 107 (44–226)(MDRD) and 100 (45–145)(CKD-EPI). After first DDP administration, according to ROC analysis, cutoff values of eGFR reductions were calculated as follows (ml/min/1.73m^2): 10 (CG; sensitivity 78%, specificity 72%, AUC 0.816, 95% CI 0.74–0.88, p = 0.0001), 8 (CKD-EPI; 72%, 76%, 0.75, 0.67–0.82, 0.0003)and 20 (78%, 89%, 0.83, 0.76–0.90, 0.0001), respectively. No differences regarding ROC curves in detecting the studied outcomes were seen: CG vs. CKD-EPI (p = 0.971), CG vs. MDRD (p = 0.529) and CKD-EPI vs. MDRD (p = 0.556). Overall, 4 treatment-related deaths were observed and 14 pts developed ARF. Decreased renal function estimated by any of the studied equations was able to predict negative outcomes, with OR 9.0(CG, 95% CI 2.8–29.2, p < 0.0001), OR 33.0(MDRD, 95% CI 9.3–116.3, p < 0.0001) and OR 8.45 (CKD-EPI, 95% CI 2.8–25.6, p < 0.0001).
Conclusions: Decrease in renal function estimated by all three equations (CG, CKD-EPI and MDRD) seemed to predict negative outcomes (ARF, dialysis and 28-day mortality) after one cycle of DDP-based chemotherapy in patients with head & neck and thoracic cancers.
No conflict of interest.

1339 POSTER

Pneumocystis jiverocii infection during chemotherapy in solid cancer patients

H. Kim[1], S.Y. Lee[1], Y.J. Choi[1], J.S. Kim[1], S.T. Kim[1], K.H. Park[1], S.W. Shin[1], Y.H. Kim[1]. [1]*Korea University Anam Hospital, Hemato-oncology, Seoul, Korea*

Background: Pneumocystis pneumonia (PCP) is an opportunistic infection caused by the ascomycetous fungus Pneumocystis jiroveci. Pneumocystis pneumonia (PCP) is common in patients with HIV infection but may also occur in patients with other causes of immunodeficiency, including hematologic and solid malignancies. Although solid tumors carry a lower risk of PCP than do hematologic malignancies, the incidence of PCP in solid tumor patients is increasing. Many studies on the risk factors of PCP in this patient group have been conducted. However, few data have been reported exploring PCP during systemic chemotherapy in solid cancer patients.
Material and Methods: We retrospectively analyzed 24 HIV-negative patients diagnosed with PCP between April 2005 and February 2013 during systemic chemotherapy for solid tumors.
Results: The median age at the time of diagnosis of PCP was 63.7 years (range 46−82) and the majority of patients (81.9%) did not have comorbidities. In terms of purpose of chemotherapy, 23 patients (95.8%) received chemotherapy for locally advanced or metastatic/recurrent disease and 1 (4.2%) had adjuvant chemotherapy after curative resection. Of 23 patients, 7 (29.2%) had non-small cell lung cancer and 4 (16.7%) breast cancer. All patients had a median of 2 metastatic lesions (range 0−4). The most common site of metastasis was brain. At the time of diagnosis, 6 patients (25.0%) were receiving first-line chemotherapy and 11 (45.8%) more than third-line chemotherapy. The proloned use of steroids was found on 17 patients(70.8%). The mean white blood cell, platelet and albumin level was 5,736, 1,205×10^3/uL and 3.1 mg/dl, respectively. The mean pressure of O_2 measured by arterial blood gas analysis was 51.3 mmHg. On analysis for disease evaluation at the time nearest to diagnosis of PCP infection, only 5 patients (20.8%) revealed tumor response to chemotherapy. After the diagnosis of PCP infection, most patients(21/24, 87.5) were treated with sulfamethoxazole and trimethoprim accompanied with steroid. Almost half of the patients (13/24, 54.2) experienced failure of therapy for PCP leading to death.
Conclusion: We reported PCP infection during systemic chemotherapy in solid cancer patients. Patients may have a relatively poor tumor response to chemotherapy at the time nearest to diagnosis of PCP infection. A prospective or matched controlled trial is needed to confirm this finding.
No conflict of interest.

1340 POSTER

Hair preservation results of scalp cooling in >3000 patients − The Dutch Scalp Cooling Registry

C.J.G. Van den Hurk[1], L.V. Van de Poll-Franse[1], M.M.C. Komen[2], J.W.R. Nortier[3], J.M.G. Van Riel[4], V. Derleyn[5], J. Van den Bosch[6], J.W.W. Coebergh[1], W.P.M. Breed[1]. [1]*Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands;* [2]*Medical Centre Alkmaar, Oncology, Alkmaar, Netherlands;* [3]*Leiden University Medical Centre, Clinical Oncology, Leiden, Netherlands;* [4]*St Elisabeth Hospital, Oncology, Tilburg, Netherlands;* [5]*Elkerliek Hospital, Oncology, Helmond, Netherlands;* [6]*A. Schweitzer Hospital, Oncology, Dordrecht, Netherlands*

Background: Chemotherapy-induced alopecia (CIA) is a frequently occurring side effect of cancer treatment. Scalp cooling can prevent CIA

and is practiced in more than 70 out of 100 Dutch hospitals. Here the results of the Dutch Scalp Cooling Registry from 2006 and onwards are presented. The main objective is to study the proportion of patients with satisfactory hair preservation after scalp cooling for each currently used chemotherapy schedule. Wetting the hair before scalp cooling is of particular interest, because it is applied in several Dutch hospitals. It has been shown to lower the scalp skin temperature, but it might be an extra burden for the patient and it is unknown whether it affects the result.
Methods: Patients who received scalp cooling with Paxman cooling devices in 55 Dutch hospitals participated in our prospective registry. Scalp cooling was performed from 30 minutes before the chemotherapy infusion until 90 minutes after stopping the infusion. Nurses registered information on type, dose and infusion time of chemotherapy. Patients completed questionnaires on the result of scalp cooling and reported age, gender, type of hair, hair length and quantity, chemical manipulation (dyeing, waving, colouring), wetting the hair before scalp cooling, and previous chemotherapy. Logistic regression analysis will be used to examine all above mentioned factors that might be associated with the scalp cooling result. The main outcome is whether a patient wore a wig or head cover.
Results: From 2006, more than 3000 scalp cooled patients have been included in the Registry. During the conference scalp cooling results will be presented for the currently used main types and doses of chemotherapy. Furthermore, associated factors will be discussed.
Conclusions: This study is by far the largest in the literature about scalp cooling. Our Registry is invaluable for informing patients and medical professionals about the scalp cooling result they may expect for a particular type and dose of chemotherapy. Besides, studying associated factors will ultimately lead to a more patient-tailored approach. The Registry also adds to improving the results by evaluating scalp cooling methods between hospitals.
No conflict of interest.

1341 POSTER

Familiarity, opinions, experiences and knowledge about scalp cooling − a Dutch survey among breast cancer patients and oncological professionals

M. Peerbooms[1], W.P.M. Breed[1], C.J.G. Van den Hurk[1]. [1]*Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands*

Background: Scalp cooling is applied to reduce chemotherapy-induced alopecia (CIA). The aim of this study was to investigate patients' familiarity and opinions and oncological professionals' attitude and knowledge about scalp cooling in the Netherlands.
Methods: (Ex)breast cancer patients, nurses and medical oncologists (MDs) from scalp cooling and non-scalp cooling hospitals were asked to fill out questionnaires.
Results: The questionnaires of 177 breast cancer patients, 49 nurses and 100 MDs were eligible for analysis. In scalp cooling hospitals, the majority of MDs (80%, n = 52) and nurses (81%, n = 30) were satisfied with the results, as were patients who had scalp cooling (61%, n = 52). In these hospitals, 41% of the MDs and 63% of the nurses perceived their level of knowledge insufficient to inform patients about the effectiveness and safety of scalp cooling. The most important reason of MDs to not apply scalp cooling was doubt about effectiveness and safety. Severe problems in implementing scalp cooling were reported by three professionals. Scalp cooling had been offered to a minority of eligible patients, especially men had been excluded. Patients were often unfamiliar with scalp cooling before breast cancer diagnosis. Twenty out of 51 scalp cooled patients (39%) reported an insufficient result and most of them (72%) reported CIA to be moderately or very bothersome. With an expected chance for hair preservation of 35%, 36% of the patients would like to use scalp cooling in case of future chemotherapy treatment, which was 54% at a success rate of 50%.
Conclusions: Much room for improvement has been shown for both patients' familiarity and oncological professionals' knowledge about scalp cooling, which will apply for other countries too. Sharing knowledge about results and safety of scalp cooling and patients' experiences with CIA will improve patient counseling and availability of scalp cooling. The results of this survey have led to the development of a national standard on chemotherapy-induced alopecia and scalp cooling.
This study was supported by the Dutch Pink Ribbon Foundation.

Feasibility and acceptability of an interactive mobile phone application for early detection of patient reported symptom distress in prostate cancer

K. Sundberg[1], A. Langius[1], K. Blomberg[2], A.K. Isaksson[2], Y. Wengström[1]. [1]*Karolinska Institutet, Neurobiology Caring Sciences and Society, Huddinge, Sweden;* [2]*Örebro University, Hälsoakademin, Örebro, Sweden*

Introduction: For immediate and continuous dialogue between patients and caregivers new approaches in modern technology are encouraged today. In cooperation with a Swedish health management company, we developed an interactive mobile phone application for the assessment of symptom distress, evidence-based self-care advice and an alerting function of severe symptoms with instant access to professionals in real time. By using this technique patients can communicate symptoms with instant support while cared for out-side hospital but at the same time reassured that their condition is monitored by the professionals. The objective of this study was to evaluate the feasibility and acceptability of the application for patients with prostate cancer during radiotherapy and for the involved health care staff.
Material and Methods: Evidence-based symptoms and related self-care advices were implemented in the application after literature review and interviews with patients and health care professionals. Nine patients diagnosed with prostate cancer undergoing radiotherapy treatment were recruited to test the application for two weeks. The patients reported in the electronic symptom questionnaire daily. After the two weeks they were interviewed about their experience. Nurses directly involved in the care and treatment of the participating patients were interviewed at the end of study.
Results: Overall, patients and nurses reported positive experiences of using the mobile phone system. The patients considered the application helpful and easy to use although there were some suggestions for further development of the electronic questionnaire. Most of the patients had read the self-care advice and found them useful. The alerting system was activated in several cases; the nurses found it useful to identify and manage problematic symptoms early and the patients felt safe and well cared for. Some of the nurses considered the monitoring system time-consuming and made suggestions for improvement.
Conclusions: Both patients and nurses could see the potential for using the mobile application in clinical practice. The system enables the involvement of the patients and the alerts showed problematic symptoms promoting timely interventions. The results support further development and testing of the system in full-scale.

Complementary and integrative medicine improved quality of life, depression, anxiety and fatigue levels in cancer patients on active oncology treatment

G. Bar Sela[1], S. Danos[2], B. Visel[2]. [1]*Rambam Health Care Campus − Bruce Rappaport Faculty of Medicine, Haifa, Israel;* [2]*Rambam Health Care Campus − Bruce Rappaport Faculty of Medicine, Oncology, Haifa, Israel*

Background: Complementary/integrative medicine (CIM) is being integrated more frequently in conventional clinical and academic institutions as part of the treatment of cancer patients. The influence of those therapies on quality of life (QoL), depression, anxiety and fatigue on the short- and long-term was tested prospectively in this study.
Patients and Methods: CIM treatments are given as part of the service at Rambam Health Care Campus, Haifa, Israel, for oncology patients. According to a 'waiting list', patients were referred to six weekly treatments of one of the therapies: art therapy, music therapy, Reiki, Shiatsu, guided imagery, healing, cranio-sacral therapy or oil anointing. Hospital Anxiety and Depression Scale (HADS) and the Brief Fatigue Inventory (BFI) were completed every two weeks and QoL-EORTC-Q30 questionnaire every six weeks during the treatment sessions and six weeks after the end of treatment.
Results: Over a two-year period, 162 patients entered the study and 135 completed therapies sessions. There were 86% women, 60% on chemotherapy and 24% on radiotherapy treatments. Global QoL ($p < 0.001$) and parameters on the functioning scale and symptoms scale of EORTC-Q30 questionnaire showed significant improvement, which was also seen in median scores of BFI from 4.57 to 3.76 ($p < 0.001$), HADS-Anxiety from 8.27 to 6.83 ($p < 0.001$), and HADS-Depression from 7.12 to 6.16 ($p < 0.001$) after 12 weeks. Main improvement was during the treatments and for six weeks after. No significant difference was seen in use of opioids, anxiety-depression medication, steroids or epo-treatment, and haemoglobin levels were maintained without significant change.
Conclusion: A short intervention of CIM therapies improved QoL of cancer patients. The improvement lasted even six weeks following treatments.
No conflict of interest.

1344 POSTER

Polyprenol in cancer cachexia management

I. Kuznecovs[1], S. Kuznecovs[1]. *[1]Preventive Medicine Research Society, Cancer Research Laboratory, Riga, Latvia*

Background: Many patients with advanced cancer undergo a wasting syndrome associated with cancer cachexia. Patients with cachexia generally have a short survival time, respond poorly to palliative chemotherapy and immunotherapy. A number of cytokines (TNF-apha, IL-1,IL-6, interferon-gamma) and proteolysis-inducing factor (PIF) have been proposed as mediators of the cachectic process. Dolichyl Phosphate (Dol-P) plays an essential role in cytokine synthesis and protein processing. The present study was carried out to present evidence that Dol-P is rate limiting factor in pathogenesis of cachexia using a 'urinary dolichol test' and polyprenol (PP) supplement in nutrition.
Methods: Urinary dolichol (Dol) concentrations were studied in 64 patients with cachexia with good performance status and life expectancy >1 to 2 months, treated with megestrol acetate >480 mg/day (group 1), 48 patients with poor performance status and short life expectancy, treated with prednisolone 50 mg/day (group 2). Nutrition of 30 and 25 patients in both groups contained PP 2 mg/day. Samples were taken from fresh urine and assayed by HPLC. Radioimmunoassay was used to measure cytokins and PIF.
Results: Mean urinary Dol concentration in patients from group 1 (45.9±4.8 mkg/mmol) as well as in group 2 (62.3±9.5erbfts;mkg/mmol) was significantly higher ($p < 0.001$) than that observed in patients without weight loss (19.8±2.2 mkg/mmol). Urinary Dol increase was shown to be correlated with weight loss in cachexia: 2 mkg/mmol = 1 kg. PP in nutrition caused a significant fall in production of IL-1in group 1 (from mean 74.8 pg/ml to 26.3 pg/ml, $p < 0.001$) and a fall in the proportion of patients excreting PIF (from 90% to 27%, $p < 0.001$).
Conclusions: Dol concentration in urine of cancer patients with cachexia is dictated by performance status and life expectancy. Dol-P dependent disorders in cachexia are established as a possible step in mechanism of weight loss in advanced cancer and as a new target for therapy and nutrition. Modulating effect of Dol-P substitute polyprenol on IL-1and PIF opens up possibilities for cachexia management.

1345 POSTER

Does wetting hair during scalp cooling decrease scalp skin temperature?

I. Muhanna[1], M.W. Dercksen[2], J.P. Dieleman[3], C.J.G. Van den Hurk[4], W.P.M. Breed[4]. *[1]Maastricht University, Faculty of Health Medicine and Life Sciences, Maastricht, Netherlands; [2]Máxima Medical Centre, Oncology, Eindhoven, Netherlands; [3]Máxima Medical Centre, Epidemiology, Eindhoven, Netherlands; [4]Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands*

Background: Hair is frequently wetted before scalp cooling in order to improve its effect. Whether this actually improves the prevention of chemotherapy-induced alopecia (CIA) remains to be seen. If wetting improves scalp cooling results a lower scalp skin temperature may be expected. We have investigated whether scalp skin temperature was reduced by wetting the hair.
Material and Methods: Experiments were performed on 29 healthy subjects with a Paxman cooling device. Scalp skin temperatures were measured with thermocouples. To document tolerance a graded scale has been used; zero in case of no discomfort at all and 10 for feeling very uncomfortable. As theoretically wetting of one side may cause a lower temperature of the other side, scalp cooling was also performed without wetting. The scalp was first cooled with dry hair. After a warming up period of 30 minutes to normalize the scalp skin temperature, the cooling procedure was repeated, whereby only one half of the scalp was wetted.
Results: Lower scalp skin temperatures were observed on the wetted side compared to the dry side. The initial great differences between the scalp skin temperature of the dry and the wet side decreased. After 30 minutes this difference was 4.5ºC,(95% C.I. 3.8−5.1, $p < 0.001$). The inter-individual differences in scalp skin temperatures after 30 minutes were considerable, both in dry (range 13.9 −26.9ºC) as in wet hair (range 0.3 −20.8ºC). Only for a short period, till about 15 minutes after the start of scalp cooling, the feeling of discomfort was considerable higher when the hair was wetted.
Conclusions: This is the first study, as far as we know, that demonstrates that wetting of hair before scalp cooling actually results in lower scalp skin temperatures. This substantial lower scalp skin temperature may be relevant to the prevention of CIA as there are indications that a number of scalp cooled patients do not obtain the required scalp skin temperature to prevent CIA. The initial increased feeling of discomfort caused by wetting will be no problem if hair wetting leads to less CIA.
Scalp skin temperature is substantially decreased if hair is wetted before scalp cooling. Wetting hair lowers scalp skin temperatures more rapidly which may lead to shorter pre-infusion cooling times. Further research is needed to determine if wetting leads to less CIA.
No conflict of interest.

1346 POSTER

Skeletal muscle density predicts prognosis in metastatic uterine sarcomas: an observational pilot study

S. Rajpar[1], J. Hadoux[1], G. Malouf[1], A. Rey[2], P. Pautier[1], S. Antoun[3]. *[1]Institut Gustave Roussy, Medicine, Villejuif Cedex, France; [2]Institut Gustave Roussy, Statistic, Villejuif Cedex, France; [3]Institut Gustave Roussy, Ambulatory, Villejuif Cedex, France*

Background: Several studies have shown that skeletal muscle mass, skeletal muscle density and adipose tissue are linked to progression free survival (PFS) and overall survival (OS) in lung and gastro intestinal cancer. Because prognostic factors are not well defined in metastatic uterine sarcomas (MUS), another approach is required. Our aim was to analyze whether body composition parameters have a prognostic role in MUS.
Materials and Methods: Adipose tissue, skeletal muscle mass and skeletal muscle density (SMD) were assessed with computed tomography imaging by measuring cross-sectional areas of the tissues and mean muscle Hounsfield Units (HU). High level of HU reflects high SMD and high quality of muscle. As there is no defined threshold for SMD, we chose the one that had the best sensitivity: 29.5 HU. The population was dichotomized in two groups according to this value. OS and PFS were estimated using Kaplan–Meier method and compared with the log-rank test.
Results: In the 79 patients, median age was 56 years (range: 32−74). Histology: leiomyosarcoma (n = 53), undiffenciated sarcoma (n = 16), endometrial stromal sarcoma (n = 4), unknown (n = 6). OS was correlated with SMD: the median OS in the 24 patients with high SMD (5 years) was twice that in the 55 patients with low SMD (2.4 years) ($p = 0.04$). At 2 years OS was 58% (95% CI: 45%-70%) versus 81% (95% CI: 61%-93%) respectively for low and high SMD. Despite a trend for a better PFS for the group with a high level of SMD, the difference was not statistically significant. No associations between OS or PFS and adipose tissue or muscle mass were found.
Conclusion: High muscle density is associated with improved outcome in metastatic uterine sarcoma and could be part of a prognosis scores based on body composition parameters enhancing metastatic uterine sarcomas management. This hypothesis has to be confirmed in a prospective way.
No conflict of interest.

1347 POSTER

Palliative chemotherapy in patients with malignant bowel obstruction

D.Q. Muniz[1], M.P. Mak[1], R.C. Bitton[1], T.K. Takahashi[1], D.F. Saragiotto[1], E. Abdo[1], J. Sabbaga[1], P.M. Hoff[1]. *[1]Instituto do Câncer do Estado de São Paulo, Medical Oncology, São Paulo/SP, Brazil*

Background: Malignant bowel obstruction (MBO) is a frequent complication of gastrointestinal (GI) and gynecological cancers. It is often associated with advanced stages of disease and high tumor burden, and hence a marker of poor prognosis. It is unknown whether palliative chemotherapy (CT) can alter this unfavorable scenario.
Material and Methods: Retrospective, single institution analysis of 36 patients' chart data, hospitalized at the Instituto do Cancer do Estado de São Paulo (ICESP) from 2009 to 2013 due to MBO. All patients (pts) were not candidates for surgical intervention and were submitted to palliative CT. Primary objective was median survival after CT, estimated by Kaplan–Meier method. Secondary objectives were relief and failure rates of obstruction after CT, and toxicities associated with CT. Possible prognostic factors were analyzed by log-rank.
Results: Pts median age was 53 years (22−71). They were mostly females (67%), ECOG-PS >2 (94%), with gastrointestinal primaries (69%) and without previous systemic treatment (64%). Anemia was frequent (median hemoglobin 10.8 mg/dL, 5.3–15.6) as well as malnutrition (mean albumin 3 g/dL, 1.8−4.3). Normal bowel function after CT was achieved in 23 pts (64%) (median 13 days, 3−39), however 30% recurred MBO within one month (mo). Median overall survival was 1.97 months. About one third (36%) of pts experienced grades 3 or 4 toxicity. On univariate analysis the only factor associated with better outcome was reversal of MBO (5.8 vs. 1.2 mo, p 0.001). There was no correlation of serum albumin, creatinine, hemoglobin or ECOG with prognosis.
Conclusions: In this mostly treatment naive population no apparent clinically significant survival benefit was associated with CT. Its role in the reversal of MBO is unclear, as pts may have recovered normal bowel function with clinical measures alone. When considering palliative CT for pts with MBO, which is associated with other known poor prognostic

markers (such as anemia and malnutrition), patient selection is critical to avoid exposure to unnecessary toxicity and provide better quality of life.
No conflict of interest.

Complementary and integrative medicine therapy for chemotherapy induced peripheral neuropathy in breast cancer patients

I. Ben-Horin[1], I. Kahan[2], S. Lev-Ari[2], L. Ryvo[1], M. Inbar[1], R. Geva[1]. [1]*Tel Aviv Sourasky Medical Center, Oncology Division, Tel Aviv, Israel;* [2]*Tel Aviv Sourasky Medical Center, CIM Center, Tel Aviv, Israel*

Background: Peripheral neuropathy is a known side effect of several chemotherapeutic drugs, mainly paclitaxel. When severe it can lead to significant disability and discontinuation of therapy with the offending drug. Neuropathy can be long lasting and recovery can take months and is often not complete. As patients feel that 'Western' medicine has little to offer as remedy, many turn to different types of complementary and integrative medicine (CIM) thrapies. In an attempt to evaluate CIM's efficacy we assessed the improvement in patients' neuropathy after treatment at our institution's CIM centre.
Methods: Thirty consecutive breast cancer patients files were retrospectively evaluated. Neuropathy was graded before and after treatment and was categorized to grade 1−2 and grade 3−4 according to the treating physician's follow up. Type of neuropathy was also recorded. Additional data gathered included patients' age, disease stage, presence and location of metastasis and chemotherapy used with total doses. All patients were treated with acupuncture on a weekly basis according to the CIM's protocol for neuropathy.
Results: Two patient's records were lacking sufficient information and not included in the analysis. The remaining patients had stage Ia-IV breast cancer with 4 patients (14%) having metastatic disease. Patients were treated with various agents including paclitaxel, docetaxel, doxorubicin, cyclophosphamide, trastuzumab and tamoxifen. Twenty one (75%) patients had grade 1−2 neuropathy and 7 (25%) had grade 3−4 neuropathy. Types of neuropathy included sensory neuropathy in 21 (75%) patients, proprioceptive neuropathy in 7 (25%) patients and unknown in 2 (7%) patients. Symptomatic improvemnt was recorded in 11 (39%) patients, with 82% improving after 3 months and 18% after 6 months from starting acupunture therapy.
Conclusions: Thirty nine percent of the cohort patients demonstrated symptomatic improvement, for either sensory or proprioceptive complaints, after acupuncture therapy. Most responders improved 3 months from starting therapy and while on continued oncological therapy. Shortcomings of this study include its retrospective nature and the heterogeneity of the oncological treatment patients were receiving. However, this high response rate indicate that acupuncture might offer a relief to patients and justifies further studies.
No conflict of interest.

Early treatment discontinuation and switching in 1st line metastatic breast cancer: Impact of symptom burden in a real world sample

M.S. Walker[1], A.S. Masaquel[2], J. Kerr[1], D. Lalla[2], O.D. Abidoye[3], L.S. Schwartzberg[4]. [1]*ACORN Research LLC, Scientific Management, Memphis, USA;* [2]*Genentech Inc., Health Economics & Outcomes Research, San Francisco, USA;* [3]*Genentech Inc., Medical Affairs, San Francisco, USA;* [4]*The West Clinic, Hematology and Medical Oncology, Memphis, USA*

Background: Treatment options in 1st line metastatic breast cancer (MBC) vary and may include chemotherapy, targeted and hormone therapy. Some patients (pts) discontinue or switch therapies, perhaps due to treatment related toxicities. The current study examined the association of symptom burden with early treatment discontinuation or switching (EDS) of 1st line therapy of MBC in real-world settings.
Materials and Methods: Data were abstracted from medical records of pts at 9 community oncology practices. Eligible pts had stage IV MBC with start of 1st line therapy 1/2004 to 6/2012, were $\geqslant$18 years old, and had $\geqslant$1 Patient Care Monitor (PCM) survey, an 86-item survey of cancer-related symptoms, during 1st line. Age, race, HER2 and hormone status, oral and infused agents, dates of diagnosis, treatment, progression, and death were recorded. EDS was defined by direct indication of early stopping in the record, and by treatment duration $\leqslant$6 weeks or regimen change without evidence of disease progression. Cox regression of EDS with time varying covariates was used to examine the impact of 23 separate symptoms, a multivariate (MV) model with multiple symptoms, and an overall composite symptom burden score based on individual symptoms.
Results: 797 pts were included, with mean age of 58.4 years, 62.1% White; with 340 on Chemotherapy (CT), 349 on CT + Targeted therapy (T) and 108 on Hormone therapy only (H). Overall, EDS occurred in 197 (24.7%) pts, with rates highest among CT (27.9%), followed by T (26.1%) and H (11.5%). Cox regression showed that 22 of 23 symptoms each increased the risk of EDS. Across several MV models, 4−6 symptoms were retained, each reflecting distinct symptom clusters (e.g., hair loss, fatigue, numbness/tingling, mouth sores/ulcers, diarrhea). In the composite symptom burden score (median 6; range 0−22) analysis, overall symptom burden was found to be significant (HR = 1.13, $p < 0.0001$), indicating a 13% increased risk of EDS with each additional symptom. Pts with 10+ symptom score had a significantly increased risk of EDS (HR = 4.03, $p < 0.0001$) compared to pts with <5 symptom score. Pts with 15+ symptom score had the highest risk of EDS (HR = 5.12, $p < 0.0001$).
Conclusions: Pts treated with CT or T for 1st line MBC had higher rates of EDS than pts on H. The likelihood of EDS increased as the number of symptoms increased. Additional research is needed to evaluate impact of symptoms on other pt outcomes, including overall survival.
Conflict of interest: *Other substantive relationships: The study was sponsored by Genentech, Inc. A. S. Masaquel, D. Lalla, and O. D. Abidoye are employed by Genentech/Roche and have stock or stock options at Genentech/Roche. L.S. Schwartzberg has received honoraria from Genentech/Roche.*

Patient-proxy agreement of health-related quality of life (HRQOL) measurements in low-grade glioma patients

D.E. Ediebah[1], J.C. Reijneveld[2], M.J.B. Taphoorn[3], C. Coens[1], E. Zikos[1], A. Bottomley[1], M. Klein[2]. [1]*EORTC HQ, Quality of Life Department, Brussels, Belgium;* [2]*VU University Medical Center, Department of Neurology, Amsterdam, Netherlands;* [3]*Medical Center Haaglanden, Department of Neurology, The Hague, Netherlands*

Background: HRQOL has become an important outcome measure in clinical trials of glioma patients. Utilizing patient-by-proxy HRQOL assessment might increase data availability, provided that patient and patient-by-proxy ratings show high levels of concordance, which we aim to investigate in this study. Based on Sneeuw et al (1997), we hypothesized that 1) concordance levels are relatively high in cognitively intact patients, and 2) decrease in cognitively impaired patients, with proxies being more negative on patients' HRQOL.
Material and Methods: We analyzed cross-sectional data on HRQOL of 281 Dutch low-grade glioma (LGG) patients with stable disease who participated in a study comparing cognition and HRQOL after radiotherapy versus no radiotherapy. Proxy rating was assessed via the SF36 and EORTC BN20 in 246 patients. Data on the cognition were collected on a subgroup of 195 patients. The Bland-Altman limit of agreement (LA), mean difference (MD) [proxy minus patient], concordance correlation coefficient (CCC) and the percentage difference (PD, +/− 0, 5, or 10 points) were used to assess patient-proxy agreement. To investigate the effect of cognitive function on agreement we defined patients to be cognitively impaired (n = 66) or cognitively intact (n = 129) based on their neuropsychological performance and investigated the level of agreement via LA and MD.
Results: Patients were more negative in rating their HRQOL than their proxies in general except for the SF36 scale role emotional and social functioning and the BN20 scale future uncertainty, motor dysfunction, headaches, seizures and drowsiness. We found no statistically significant difference in MD except for the SF36 scale general health ($p = 0.03$) and BN20 scale visual disorder ($p = 0.04$). Results from the LA revealed a fairly high agreement between the patient and proxy rating in all HRQOL domains. However, a slightly poorer agreement was observed for the physical component summary (PCS) [LA; −13.63–11.03). The CCC was fairly high overall in all HRQOL domains (ranging from 0.37 to 0.80). The CCC for PCS was (r = 0.69) and mental component summary (MCS) was [r = 0.55]. The percentage of perfect agreement (PD +/− 0 point) ranged from 8.54% (general health) to 76.83% (hair loss). The PD for the PCS and MCS for a +/− 5 points and +/- 10 points was 76.42% and 65.85%, and 93.0% and 87.40%, respectively. The magnitude of the MD in the cognitively intact patient group was overall smaller and agreement by LA higher in the cognitive intact group.
Conclusion: Preliminary results suggest that there was overall a high level of agreement between patient and proxy rating of patient's HRQOL but a larger mean difference was observed in the cognitively impaired patients. Contrary to our hypothesis, patients tended to rate their HRQOL more negatively. Future research will focus on the validity of using complementary HRQOL assessments provided by proxies for patients with declining cognitive functioning.
No conflict of interest.

1351 POSTER

Internal and external validation of a fatigue prognostic score for overall survival (OS)

R. El Aidi[1], O. Marouf[1], A.S. Chimm[1], F. Scotte[2], J. Medioni[2], E. Fabre[2], N. Pecuchet[2], Y. Vano[2], N. Delanoy[2], S. Oudard[2]. *[1]ARTIC Institute, Hopital Européen G. Pompidou. Medical Oncology, Paris, France; [2]Hopital Européen G. Pompidou, Medical Oncology, Paris, France*

Background: Fatigue is an adverse reaction related both to disease and treatment in cancer patients (pts). We previously found (ESMO2012, lecture 15450) that the F score was able to discriminate pts in "Good", "Intermediate" and "Poor" risk groups. We present the results of an internal and external validation of our model.
Methods: Patients included in the PROCHE program between 2008 and 2011 at the HEGP hospital (Paris, France). Pts were contacted before each chemotherapy (CT), and F experienced since the last cycle was collected (patient's reported outcome from CTC-NCI grading: 0=none, 1=mild, 2=moderate, 3=severe, 4=3+long-term condition). Scores were calculated as weighted means of F over the whole CT period and during the 2 and 4 first cycles. OS was calculated from CT initiation to death or censured at last contact. Cox regression covariates: age, tumor localization, disease setting and continuous or categorized Fatigue score. Patients with localized (M0) or metastatic (M+) disease during the study period led to two distinct cohorts: C1 and C0 according to M1 or M0 period considered. A bootstrap internal validation was performed on 1000 samples, followed by an external validation using Kaplan–Meier curves for risks groups.
Results: 1279 pts entered the program, 662 had at least 1 assessment of fatigue. Excluded pts (617) due to lack of survival status did not differ (log-Rank=0.98). Median age=64.9 y, sex-ratio=1.1, more frequent localization (%): lung: 25, breast: 21, urogenital: 21, gynecological: 13, ENT: 12. OS (m, 95% CI) was 27.8 (26.2–29.4). Median follow-up was 26.7m (25.5–27.9). F score was still strongly associated with prognosis after updating data. Model obtained from the initial dataset was internally validated (C-index=0.733, shrinkage=0.957). To evaluate prognostic value, 197 patients among 617 previously excluded were used for external validation. Concordance was very good (Kendall t=0.816, $p < 0.0001$). Predicted F score HR (95% CI): 0.17 (0.09–0.35) and 0.34 (0.21–0.56) for the "Good" and "Intermediate" prognosis groups, respectively; actual HR for the same groups (validation cohort): 0.19 (0.11–0.37) and 0.31 (0.19–0.52).
Conclusion: This study confirmed through internal and external validation the prognostic value of our fatigue score based on patients reported outcomes.
No conflict of interest.

1352 POSTER

Quality of life improves after placement of percutaneous tunneled drainage catheter for refractory ascites in prospective study of patients with end stage cancer

P.C. Robson[1], X. Jia[2], M. Gonen[2], N. Kline[3], B. Thom[4], L.A. Brody[1], K.T. Brown[1], G. Getrajdman[1], M. Kennedy[5], A.M. Covey[1]. *[1]Memorial Sloan-Kettering Cancer Center, Department of Radiology, New-York NY, USA; [2]Memorial Sloan-Kettering Cancer Center, Department of Epidemiology and Biostatistics, New-York NY, USA; [3]Boston Children's Hospital, Nursing Research, Boston MA, USA; [4]Memorial Sloan-Kettering Cancer Center, Survivorship, New-York NY, USA; [5]Memorial Sloan-Kettering Cancer Center, Department of Nursing, New-York NY, USA*

Background: Refractory ascites in the terminal cancer patient causes debilitating symptoms often managed by serial paracenteses. Percutaneous tunneled drainage catheters (PTD) offer the advantage of home management but the impact on quality of life (QoL) has not been described.
Materials and Methods: Adult patients with stage IV or end-stage cancer undergoing PTD placement for refractory ascites were eligible for this prospective study. Subjects completed the EORTC QLQ-30 (EORTC) and McGill Quality of Life (MQoL) instruments prior to the procedure, immediately post procedure (PP) (2−7 days), and 3 weeks PP (+/− 7 days). Patients were interviewed for catheter function at the time of the instrument assessments as well as 2, 4, 6, 8 weeks (wks) and 4 and 6 months PP. Completion rates were defined as total number of completed instruments out of number of subjects surviving. QoL data were scored according to instrument manuals and analyzed using a pattern-mixture model to adjust for informative drop-out.
Results: 50 patients enrolled, 48 were evaluable of which 3 withdrew during follow up. All evaluable patients had a Tenckhoff catheter placed (Cook Inc., Bloomington, IN). Median survival post catheter placement was 1.2 months (95% CI: 1−1.8 months). For all time points, median completion rate among survivors was 88% (range: 65%-100%). Three PTD were removed for infection (26, 101, 170 days PP). Analysis of EORTC demonstrated an improvement in global QoL ($p = 0.04$), functional role ($p = 0.01$), emotional ($p < 0.01$), and cognitive ($p = 0.02$) scales at 1 wk PP. At the same time point significant symptom improvement was seen in reported fatigue ($p = 0.005$), nausea/vomiting ($p = 0.002$), pain ($p = 0.005$), dyspnea ($p = 0.001$), insomnia ($p = 0.001$) and appetite loss ($p = 0.009$). This improvement was sustained at 3 wks for dyspnea ($p = 0.006$), insomnia ($p = 0.002$), and appetite loss ($p = 0.03$). Baseline scores did not effect survival. The MQoL offered similar results with a significant overall QoL improvement at 1 wk ($p < 0.001$) and 3 wks ($p = 0.016$).
Conclusions: QoL and symptoms improved for end-stage patients after placement of a tunneled catheter to relieve refractory ascites. The benefits of placement diminish over time, likely due to progression of disease. This study supports the use of a PTD to palliate the debilitating symptoms associated with refractory ascites.
No conflict of interest.

1353 POSTER

What do patients really mean when they complain of fatigue after treatment? Reliable identification of post cancer fatigue

B. Bennett[1], K. Webber[2], D. Goldstein[2], A. Lloyd[2]. *[1]University of New South Wales, School of Medical Sciences, Randwick New South Wales, Australia; [2]University of New South Wales, NSW Cancer Survivors Centre, Randwick New South Wales, Australia*

Introduction: Fatigue is a ubiquitous symptom. Self-reported fatigue symptoms following cancer diagnosis and treatment are common. A definitive diagnosis of post cancer-related fatigue (PCF) is challenging due to lack of consensus on diagnostic criteria and the diversity of measurement tools currently used to identify the syndrome(predominantly self-report). A semi-structured clinical interview to reliably identify PCF and differentiate co-morbid symptoms (like insomnia or mood disturbance) has been developed.
Methods: Using both qualitative and quantitative methods, a semi-structured clinical interview to identify PCF was developed. Analogous to clinical interview schedules used in sleep medicine or psychiatry, it incorporates published diagnostic criteria for the syndromes of cancer related fatigue (CRF); chronic fatigue syndrome (CFS) and major depression. For validation, the interview was trialled in patients with clinician identified fatigue syndromes: multiple sclerosis ($n = 9$), post infectious and chronic fatigue ($n = 108$) and post cancer fatigue ($n = 30$).
Results: In the interview seven symptom domains were assessed: fatigue; fatigability; neurocognitive difficulties; mood disturbance; sleep problems; pain and other symptoms (e.g. night sweats). Symptom severity − both frequency and intensity − were identified. A diagnostic algorithm was developed to classify the symptom complexes. Sensitivity (sens) and specificity (spec) was determined against specialist-clinician diagnosis and syndrome diagnostic criteria ($n = 128$): CFS (sens 100, spec 83); major depression (100, 72) and PCF (72, 58).
Conclusion: While the interview schedule facilitates the diagnosis of clinically significant fatigue and co-morbid symptoms the lower sensitivity and specificity in those patients reporting fatigue post cancer, in comparison to those in groups diagnosed with CFS or major depression, suggests need for the further refinement of the diagnostic criteria for post cancer fatigue. Potential uses of the interview are in aetiopathological studies (identification of homogenous cases), for clinical management, and monitoring of patients participating in clinical intervention trials.

1354 POSTER

A prospective investigation of nutritional status of ambulatory Irish oncology patients undergoing chemotherapy: prevalence of malnutrition, cachexia, sarcopenia and impact on quality of life

S. Cushen[1], D. Power[2], P. McEneaney[3], P. McLaughlin[3], F. Fitzpatrick[1], A. Ryan[1]. *[1]University College Cork, Food and Nutritional Sciences, Cork, Ireland; [2]Mercy University Hospital, Medical Oncology, Cork, Ireland; [3]Mercy University Hospital, Radiology, Cork, Ireland*

Background: Malnutrition is a significant factor in predicting quality of life (QoL) in oncology patients. Our study describes the general health of Irish cancer patients (pts), including QoL, and determines the prevalence of cachexia, malnutrition, and sarcopenia in ambulatory pts undergoing chemotherapy in a regional cancer centre.
Methods: A prospective cross sectional study of ambulatory adult cancer pts, undergoing chemotherapy at a university teaching hospital was conducted. The risk of malnutrition was examined using the Malnutrition Universal Screening Tool (MUST). QoL was measured using the European Organisation for Research and Treatment of Cancer QoL Questionnaire (EORTC QLQ-C30). In addition, CRP (C-reactive protein) levels were recorded. Cancer cachexia was defined as weight loss (WL) >5% over the

past 6 months or WL >2% in combination with a Body Mass Index (BMI) <20 kg/m^2 or sarcopenia. Skeletal muscle cross-sectional area at L3 was measured on baseline CT scan. Sarcopenia was defined using published cut offs.
Results: 150 pts (96 male) with solid tumours, mean age 64 yrs, were included. 52.7% were overweight/obese (BMI>25 kg/m^2). Frequency of cancer subtypes was recorded: colorectal cancer(35%), upper gastro-intestinal cancer (GI, 31%), and lung cancer (15%) were the most common. Sarcopenia was present in 54% (38% of normal BMI, 40% of overweight groups) with fatigue significantly associated with sarcopenia in males ($p < 0.05$). Sarcopenia and reduced adipose tissue index were significantly associated with adverse QoL ($p < 0.05$) in females but not in males. Overall 73% met the criteria for cachexia, with the highest prevalence of cachexia observed in hepatobillary (86%) and upper GI cancers (79%). Using MUST, 42% of pts were classified as at risk of malnutrition (n = 63) and appetite loss scores were worse in malnourished patients than in non malnourished ($p < 0.05$). WL ($\geqslant$5%) in the previous 6 months was reported by 34%, 45% and 50% of pts with colorectal, lung and upper GI tumours, respectively. Furthermore, WL ($\geqslant$5%) in the previous 6 months was significantly associated with loss of appetite ($p < 0.05$), low fat free mass ($p < 0.05$) and advancing age (65 yrs vs. 61 yrs $p < 0.05$). 55% had a CRP >10 mg/L which was significantly associated with adverse QoL ($p < 0.05$). There was a significant association between cancer type and poor QoL ($p < 0.05$) with upper GI cancers reporting the worst global QoL scores.
Conclusion: Cancer patients undergoing chemotherapy experience weight loss, sarcopenia and a high percentage are cachectic in an inflammatory milieu. Site of primary tumour appears to be associated, at preliminary analysis, with significant weight loss, nutritional risk and QoL. Early nutritional screening is warranted in cancer patients.
No conflict of interest.

1355 POSTER

A prospective analysis of the association between skeletal-related events and quality of life in patients with advanced lung cancer (CSP-HOR13)

T. Yokoyama[1], H. Kunikane[1], N. Katakami[2], I. Yokota[3], Y. Saio[4], K. Shimozuma[5], Y. Ohashi[3], K. Eguchi[6]. [1]*Yokohama Municipal Citizen's Hospital, Yokohama, Japan;* [2]*Institute of Biomedical Research and Innovation Hospital, Kobe, Japan;* [3]*The University of Tokyo, Tokyo, Japan;* [4]*Shizuoka Cancer Cente, Shizuoka, Japan;* [5]*Ritsumeikan University, Kyoto, Japan;* [6]*Teikyo University School of Medicine, Tokyo, Japan*

Background: Bone metastasis (BM) is a frequent complication in patients with advanced lung cancer. We had reported incidence of BM and **skeletal-related events** (SREs) in patients with advanced lung cancer as a prospective study in the previous meeting, while there have still been few reports on the association between SREs and quality of life (QOL). The aim of this study was to investigate prospectively how QOL of patients with advanced lung cancer was affected by SREs.
Material and Methods: The eligibility criteria are newly-diagnosed patients with stage III B or IV lung cancer, whose ages were over 20-years old, and those who had a written informed consent. The patients were closely followed up in every four weeks to see if they developed SREs. QOL questionnaires were conducted at the time of the enrollment, three- and twelve-months later, and one month after the onset of SREs, using QOL scores including EQ-5D, FACT-G and Barthel Index. Then each QOL score was analyzed. Treatment for lung cancer and use of zoledronate were done at the discretion of the investigator. We evaluated QOL of the patients who developed SREs. SREs are defined as pathologic fracture, radiation or surgery to bone lesion, spinal cord compression or hypercalcemia.
Results: 274 patients were enrolled in this study from April 2007 through December 2009 (median age was 68-years old). Small/non small cell = 77/197. Stage IIIB/IV = 73/124, Male/female = 193/81. The median follow-up period was 13.8 months. 78 patients already had BM at the enrollment. Among them, 24 had accompanying SREs and another 12 developed SREs during the follow-up. Among 196 patients without initial BM, 34 developed BM. 16 patients of these 34 developed SREs during the follow-up.
A chronological analysis did not show statistically significant difference in QOL of all patients in whom the QOL evaluation was performed. QOL data were collected in nine patients out of 28 who had SRE during the follow-up. For those nine patients, QOL scores fell by 0.05 in EQ5D, by 9.4 in FACT-G, and by 6.9 in Barthel Index. Statistically, these declines in QOL scores subsequent to SREs were not significant. Analysis on FACT-G by four factors (physical, social/family, emotional, functional), however, showed that the emotional factor decreased by 4.76, which was statistically significant.
Conclusion: QOL of the patients with advanced lung cancer was not proven to have been affected by SREs when measured by EQ5D, FACT-G and Barthel Index. However, the evaluation by each four factor of FACT-G revealed that the statistically-significant decline in the emotional factor after SREs.
Conflict of interest: *Ownership: Yuko Saito is Clinical Trial Head at Novartis pharma K.K.*

1356 POSTER

Be positive, it can help you! The role of positivity on quality of life of cancer patients

G.V. Caprara[1], V. Castellani[1], M. La Torre[2], F. Mazzuca[3], F. Colaiaco[1], V. Pasquali[1], V. Ziparo[2]. [1]*Sapienza University of Rome, Department of Psychology, Rome, Italy;* [2]*Sapienza University of Rome, Dipartimento di Scienze Medico Chirurgiche e Medicina Traslazionale, Rome, Italy;* [3]*Sapienza University of Rome, Dipartimento di Medicina Clinica e Molecolare, Rome, Italy*

Background: Positive beliefs and emotions among people experiencing adversities are crucial to manage the emotional costs associated with negative events. Self-esteem, life satisfaction, and optimism to well-being, all traced to the common factor of Positivity, correspond to pervasive views of experience, highly correlated to each other and commonly associated with various domains of functioning and across the life-span.
The Authors examined the function of positivity and proper management of positive emotions in buffering the progress of illness, the recovery and the quality of life (QoL) in cancer patients.
Material and Methods: 110 patients with pulmonary, colorectal and breast cancer, aged 40−70, have been prospectively enrolled between 2012 and 2013, at the S. Andrea Hospital in Rome. Patients with previous diagnosis of other malignancies and psychiatric disorders were excluded from the analysis. Positivity was assessed by the Positivity scale (Caprara et al., 2012), EORTC QLQ-C30 was used for the QoL and physical functioning evaluation and the Mini-mental adjustment to cancer scale for the patients coping style assessment.
Results: Level of positivity is significantly associated to better QoL ($r=-.26$, $p < 0.01$) and less reported symptoms of worse physical ($r=-.26$, $p < 0.01$), cognitive ($r=-.30$, $p < 0.01$) and emotional functioning ($r=-.25$, $p < 0.01$). Moreover, positivity is related to the implementation of coping strategies focused on good illness management. In particular, patients with medium-high level of positivity tend to cope actively the illness($r=-.32$, $p < 0.01$) and to report less feelings of hopelessness($r=-.36$, $p < 0.01$). Furthermore, hierarchical regression analysis showed the role of positivity in predicting the impairment in physical functioning, after controlling for sex, type of diagnosis and coping strategies. Finally, a significant interaction between sex and positivity was found, showing that males tend to report less impairment in physical functioning than females.
Conclusions: According to previous studies, our results support the hypothesis that psychological characteristics may influence the QoL of cancer patients. In particular, in our sample, the level of positivity is associated to better QoL, less impairment in physical, cognitive and emotional functioning.
Positivity can predict QoL in cancer patients, and can support physicians to promptly identify patients that could need psychological support.
No conflict of interest.

1357 POSTER

Ocular disorders in long-term survivors

A. Di Mari[1], V. Pumo[1], S. Rametta Giuliano[1], M. Iacono[1], E. Lanteri[1], R. Sorce[2], E. Montalto[3], P. Tralongo[3]. [1]*Umberto I Hospital, Medical Oncology Unit, Siracusa, Italy;* [2]*Umberto I Hospital, Ocular Unit, Siracusa, Italy;* [3]*Umberto I Hospital, Medical Oncology Unit, Siracusa, Italy*

Background: To describe the frequency of ocular disorders in long-term cancer survivors ($\geqslant$3 years) observed in Interdisciplinary Units and evaluate the relationship with comorbidities.
Patients and Methods: In 118 consecutive long-term survivors with different cancer type we identified 18 patients, surviving $\geqslant$3 years after primary diagnosis, who reported ocular sequelae. All patients received multimodality treatments, including surgery (n = 17, 14%), conventional chemotherapy (n = 12, 10%), radiotherapy (n = 6, 5%), hormonal therapy (n = 9, 7.6%) and biological treatment (n = 2, 1.69%).
Results: Of 18 patients, 22% (n = 4) were males and 77% (n = 14) females, median age 62.5 (range 35−84 years); of them, 11 were affected of breast cancer, 3 of colorectal cancer, 1 of prostate cancer, 1 of kidney cancer, 1 of testicular cancer, 1 of GIST. 16.6% (n = 3) patients reported diabetes non-insulin-dependent, 33.3% (n = 6) hypertension in medical treatment. In particular, we have seen that 6 patients (33.3%) reported cataract, 7 (38.8%) visual deficit, 2 (11%) myopia, 1 (5.5%) keratoconjunctivitis, 1 (5.5%) retinal detachment and 1 (5.5%) periorbital edema.

Conclusion: The ocular complications may affect the quality of life of these patients and need more attention in clinical practice, especially in consideration of the use of new biological drugs.
No conflict of interest.

1358 POSTER

Efficacy of tapentadol for managing severe pruritus related biological cancer treatments: Multicentric experience

A. Lugini[1], R. Rossi[2], G. Pistillucci[2], V. Sciacca[2], A.A. Ciorra[2], R. Pace[1], A. Rauco[1], V. Capparella[1]. *[1]San Camillo de Lellis Hospital, Medical Oncology Unit, Rieti, Italy; [2]Santa Maria Goretti Hospital, Medical Oncology Unit, Iatina, Italy*

Background: Severe pruritis affects a large proportion of the cancer patients treated with anti-EGFR antibodies and tyrosine-kinase inhibitors. Tapentadol is a centrally acting analgesic with 2 mechanisms of action, μ-opioid receptor agonism and norepinephrine reuptake inhibition. We designed a multicentric study to asses of Tapentadol for the management pruritis induced by biological treatments.
Material and Methods: In this multicentric study we enrolled 30 patients with metastatic solid tumours treated with biological drugs between November 2012 at February 2013. Intensity of itch was evaluated by Visual Analogue Scale (VAS) score. The primary endpoint was change in median VAS score during treatment with biological drugs. All patients were enrolled in the failure of standard therapies for itch. All patients received tapentadol 50 mg cpr bid.
Results: Median VAS was 9.00 at baseline and 1.00 after 3 days of treatment. 25 patients responded to Tapentadol. the only side event was experienced nausea G1 resolved in a week.
Conclusions: Tapentadol showed excellent efficacy in the control of pruritus associated with the use of biological drugs. is not a minor reduction on the quality of life of pain associated with hand–foot syndrome typical of TKI inhibitors.
No conflict of interest.

1359 POSTER

To assess the effect of regular exercise, involvement with art (origami) and group therapy on quality of life, anxiety, depression, patient satisfaction and hope levels in patients with remission who had a variety of cancer diagnoses "quality of life support program (QoLSP)" was developed

D. Arslan[1], H. Bozcuk[1], S. Gunduz[1], A.M. Tatli[1], M. Uysal[2], S. Goksu[1], D. Tural[1], H.S. Coskun[1], B. Savas[1]. *[1]Akdeniz University Faculty of Medicine, Department of Medical Oncology, Antalya, Turkey; [2]Afyon Kocatepe University Ahmet Necdet Sezer Research and Practice Hospital, Department of Medical Oncology, Afyon, Turkey*

Informed consents and demographic information was compiled prior to the onset of study, HOPE, HADS (Hospital anxiety and depression) and EORTC QLQ-C30 (30th question assessing the quality of life) quality of life scales were used at the beginning and at the end of the study. Apart from these scales, program satisfaction and scales evaluating the arm use in breast cancer patients were also used. QoLSP consisted of excercise on Mondays, art therapy (origami) or group therapy on Wednesdays (rotating once a week) and home excercise on Fridays.
A total of 26 patients took part in this study, 23 of whom were female and the remaining 3 were male patients. Twenty patients were diagnosed as breast cancer, 2 patients had cancer of the overy and the remaining four had endometrium, colon, larynx cancer and soft tissue sarcoma.
When the analyses were completed, average hope scores of the patients were 25.6±3.9 and EORTC QLQ-C30 scale 30th question average score was found as 5.1±1.5 before QoLSP. After the QoLSP, average score for the HOPE scale was raised to 29.7±1.9 and EORTC QLQ-C30 scale's 30th question score average was increased to 6.6±0.82. Before QoLSP, HADS anxiety scale score was 8.2±4.7 on the average and HADS depression scale average score was found as 6.4±4.4. After QoLSP HADS anxiety scale score average was decreased to 3.5±3.3 and HADS depression scale score average was down to 2.5±3.2. All differences in scale scores between before and after QoLSP program were considered as statistically significant ($P < 0.001$).
After QoLSP, factors which might have been involved with quality of life were also evaluated. In multivariate analysis, hope score differences were statistically significant when compared with preliminary hope scale ($\beta = -0.89$, $t = 11.21$, $p < 0.001$), which is also true for anxiety score differences when compared with HADS preliminary anxiety scores; and global QoI preliminary scores ($\beta = -0.55$, $t = -3.65$, $p = 0.001$ and $\beta = 0.33$, $t = 2.2$, $p = 0.038$ respectively), depression score differences according to HADS depression scale preliminary results ($\beta = -0.74$, $t = -5.39$, $p < 0.001$), as well as Global QoI score differences according to Global QoI preliminary results ($\beta = -0.88$, $t = -9.22$, $p < 0.001$) were also statistically significant.
In the study population 6 patients had breast sparing surgery + lymph node dissection out of 20 patients who were operated for breast cancer. When assessed arm movement of 3 patients (out of the 6) have been defined as 'much beter', 2 patients' arm movements were 'better' and 1 patient reported 'no change'. Out of 14 patients who had modified radical mastectomy 13 had rated their arm movements as 'much beter' and 1 reported arm movement as 'beter'.
When program satisfaction was assessed via a questionnaire, all of the 26 participants rated themselves as 'highly satisfied'.
QoLSP a multidisciplinary activity, if established in other centers, can have very positive influence on cancer patients' quality of life, anxiety, depression, hope and patient satisfaction by having an active part in diagnosis and treatment.
No conflict of interest.

1360 POSTER

The experience of partners of cancer patients' participation in a phase I study after the patients' death: A retrospective study

S.M.C.H. Langenberg[1], M.E.J.W. Peters[1], W.T.A. Van der Graaf[1], A.N.M. Wymenga[2], J.B. Prins[1], C.M.L. Van Herpen[1]. *[1]Radboud University Nijmegen Medical Center, Medical Oncology, Nijmegen, Netherlands; [2]Medical Spectrum Twente, Medical Oncology, Enschede, Netherlands*

Background: Research data on the impact of patients (pts)' participation in a phase I study on the well-being of their partners after death is scarce. Yet, partners' well-being is essential as it can affect their mental and physical health. This study aimed to explore the experience of partners of deceased pts who participated in a phase I study and investigate their well-being after pts' death.
Patient and Methods: 63/74 (85%) eligible partners of deceased pts participating in a phase I study between 2007 and 2010 agreed to participate. Between 0.5 and 2 years after bereavement, they completed 5 self-assessment questionnaires, the RAND-36 Health Survey (RAND-36), Shortened Fatigue Questionnaire (SFQ), Beck Depression Inventory for Primary Care (BPI-PC), Inventory of Traumatic Grief (ITG) and the Hospital Anxiety and Depression Scale (HADS). Furthermore, they completed a general questionnaire (GQ) about their experience on the participation in a phase I study.
Results: Participants had a mean age of 58 years (range 37−82), 67% was female. 58/63 partners returned the questionnaires. Retrospectively partners reported negative effects on the pts' QoL (14/58), burdensome side effects (21/58) and burdensome increase of visits to the outpatient clinic (16/58). In contrast, 55/58 partners did not regret participation of the pts in a phase I study, where 24/58 partners even reported a positive effect on the pts' QoL. Regarding the impact that the disease and it's treatment have on partners after pts' bereavement, the GQ reports that 8/58 partners experienced a decline in their general health after bereavement compared to the time before the diagnosis. In addition, the RAND-36 showed significantly lower average scores on 2 subscales compared to normative data, namely limitations in social functioning ($p < 0.011$) and mental functioning ($p < 0.004$). Assessment of severe fatigue, depression, complicated grief and distress showed no abnormalities on the SFQ, BPI-PC, ITG and HADS respectively.
Conclusion: Even though one third of the partners reported burdensome consequences and negative effects on the QoL of pts during participation in a phase I study, retrospectively most of the partners did not regret pts' participation in phase I studies. Assessment of the well-being of the partners after pts' death shows, aside from significant differences compared to normative data on social and mental functioning, no abnormalities.
No conflict of interest.

1361 POSTER

Chemobrain in patients participating in clinical trials

D. Trivanovic[1], N. Spasic[2], S. Plestina[3], R. Dobrila-Dintinjana[4], L. Jerin[5], I. Hrstic[5], T. Peharda[2], L. Honovic[6], L. Kocic[1]. *[1]General Hospital Pula, Oncology, Pula, Croatia; [2]General Hospital Pula, Psychiatry, Pula, Croatia; [3]University Hospital Centre, Oncology, Zagreb, Croatia; [4]University Hospital Centre, Oncology, Rijeka, Croatia; [5]General Hospital Pula, Internal Department, Pula, Croatia; [6]General Hospital Pula, Laboratory Department, Pula, Croatia*

Background: The observation that cytotoxic drugs given systemically for non-CNS tumors might have neurotoxic effects on cognitive functioning was made decades ago.The term chemobrain or chemotherapy-induced cognitive impairment is recognized as a common adverse effect of chemotherapy. In the past years, the number of clinical trials has increased rapidly in Croatia and the actual degree of understanding or perceptions of

clinical trial participating is unknown. Aim of this study is to evaluate does patients which signed informed consent to participate in clinical trials (both, academic and sponsored) have different chemobrain status than other.
Methods: Adult cancer patients receiving chemotherapy in General Hospital Pula between January 2010 and December 2012 were included. In experimental arm were 32 adult patients with advanced cancer, ECOG PS 0−3, without CNS involvement which signed clinical trial ICF. In control arm were 92 patients matched for same conditions as experimental arm patients (matched for location, age, stage, gender, ECOG PS, fatigue, anemia, and chemotherapy line.Cognitive impairment was detected using cognitive tests HVLT-R, TMT, and COWA after signed Informed consent form (ICF). After approval of sponsors and conductors of clinical trials, for using some data from trials, patients in both arms were evaluated.
Results: Median age was 63.5 years, 39% were female, and 11% had poor ECOG PS ($\geqslant$2). Patients had advanced solid tumors (Lung: 32%; colorectal: 27%; breast: 15%; other solid tumors: 26%). Average time of follow up and chemotherapy were 14.5 and 6.7 months, respectively. Patients were well balanced between arm in age, gender, overall survival (8.7 months), performance status, locations of tumors, stage, anemia, number of chemotherapy lines, and fatigue (FACIT-F test result). There were less cognitive impairment in term of chemobrain (detected with HVLT-R, TMT, and COWA tests) in experimental arm than in control arm 21.9% and 39.1% of patients, respectively ($p < 0.05$). Also, patients in control arm had trend to be more anemic (21.9% vs 31.5%) but not statistically significant ($p = 0.07$).
Conclusion: This is, to our knowledge, the first evaluation of chemobrain in patients inside and outside of clinical trials. Cognitive impairment could significantlly influence willing to participate in clinical trials independently of clinical trial eligibility criteria. This data provides more light on importance of psycho-oncological estimation of patients affected by cancer.
No conflict of interest.

1362 POSTER

Alternative and complementary treatments in cancer patients

O. Castillo-Fernández[1], Y. Loo[1], A. Cabreja[1], I. Rodríguez[2], N. Novoa[3], J. Del Cid[3], J. Mezquita[4], Y. Pereira[5]. *[1]Instituto Oncologico Nacional, Medical Oncology, Panama, Panama; [2]HOMS, Internal Medicine, Santiago, Dominican Republic; [3]Caja de Seguro Social, Internal Medicine, David, Panama; [4]Instituto Oncológico Nacional, Neurosurgery, Panama, Panama; [5]Instituto Oncológico Nacional, Surgical Oncology, Panama, Panama*

Background: Alternative and Complementaries therapies (CT) are used widely, especially among cancer patients. Insufficient clinical research data exist to indicate whether CT is safe and efficacious. The purpose of this study was to determine the prevalence and the impact of sociodemographic and clinical factors on CT use among cancer patients.
Methods: A cross-sectional survey was conducted in a sample of adults with cancer seeking care at Instituto Oncologico Nacional within a 4-month period. Univariate and multivariate analyses were performed to detect differences between CT users and nonusers.
Results: 421 pts were interviewed. Median age was 57 years. 69% female, 31% male. Breast (34%) and gastrointestinal cancer (14%) were the most frequent tumors. 47% of pts were within the first year of diagnosis. 128 pts (30%) used CT. The most common was herbal remedies (38%). Median use time was 4 months. Factors associated with CT use were female gender ($p = 0.04$), recent diagnosis ($p = 0.001$), higher education level ($p = 0.001$) and income ($p = 0.08$). The main reason for CT use was to assist conventional treatments (45%). 50% of CT users did not informed to their physician about its use. In 43% of cases the use of CT was recommend by friends and family. Multivariate analysis showed that higher education (OR 2.01 95% CI 1.18–3.43) and recent diagnosis (OR 2.03 95% CI 1.26–3.27) were predictive for CT use.
Conclusion: Educational level and recent diagnosis are associated with CT use. Patient and physician communication regarding potential risk and benefit is highly recommended.
No conflict of interest.

1363 POSTER

Decreasing anxiety with welcoming workshops in a radiation oncology unit

L. Diaz Gomez[1], M.D. Polanco[1], A. Ureña[2], E. Jimenez[1], S. Ramirez[1], A. Seguro Fernandez[2], J. Roldan[2], I. Villanego[1], J. Cabral[1]. *[1]Hospital Puerta Del Mar, Unidad Clinica de Gestion Atención Integral al Cancer, Cádiz, Spain; [2]Hospital Puerta Del Mar, Radiofisica y Protección Radiologica, Cádiz, Spain*

Background: In recent years the treatment of cancer has changed as more and more people are treated and the greater number survive the disease. The main goal of cancer treatment is survival, but also the treatment of symptoms and quality of life of patients and their family members also become important. Cancer treatment by radiotherapy is an opportunity to control, improvement or cure of the disease, but also involves facing major challenges that can affect their quality of life and emotional state. In order to improve the emotional care, we have begun work on workshops within the welcoming plan of our unit, where through group techniques and information received as well as the opportunity to resolve doubts and feel heard, we improve the management of anxiety in patients and their families, and therefore, dealing with the treatment and disease.
Material and Method: We choose patients who will receive radiation treatment in our unit as long as they are not palliative, and invite their main caregiver too. After signing the informed consent of the study, are given a first HADS questionnaire (Hospital Anxiety and Depression Scale) and then they assist to the workshop. The first day of radiotherapy answer a second test and the third is answered at the end of radiation therapy. The three test results are compared.
Results: Data shows that at baseline levels of anxiety and depression are very high, and decrease at the beginning and as the treatment goes on. This study demonstrated that the welcoming workshop decreased symptoms of anxiety and depression during radiation therapy, In addition there was a high prevalence of anxiety and depressive symptoms in family caregivers groups, and also was improved.
Conclusions: The emotional state, in particular anxiety, is a variable that should be assessed throughout the entire radiotherapy process as it affects the welfare status of patients and caregivers. The welcoming workshops, as support groups, are affective in treatment of the oncological disease.
No conflict of interest.

1364 POSTER

Symptom clusters and demographic characteristics in advanced cancer

A. Aktas[1], D. Walsh[1], L. Rybicki[2], A. Fitz[1]. *[1]Cleveland Clinic Taussig Cancer Institute, Harry R Horvitz Center for Palliative Medicine and Supportive Oncology, Cleveland, USA; [2]Cleveland Clinic Lerner Research Institute, Department of Quantitative Health Sciences, Cleveland, USA*

Background: Little is known about demographic variations in cancer symptom clusters (SC). Our objective was to determine whether SC are associated with age, gender, race, performance status (PS), or primary cancer site.
Material and Methods: Symptoms from 1000 advanced cancer patients referred to a palliative medicine program were recorded prospectively. Among 922 patients with complete symptom data, hierarchical cluster analysis identified 7 SC. A SC was considered present if the patient had $\geqslant$50% of the symptoms in the cluster. Comparisons were made between patients with and without each cluster using the chi-square test (age <65 vs. $\geqslant$65 years; gender female (F) vs. male (M); race Caucasian (C) vs. African American (AA); 10 primary site groups (PSG), or Wilcoxon rank sum test (ECOG PS 0−4). A p value <0.05 indicated statistical significance.
Results: 83% of patients were C, 52% $\geqslant$65 years, 56% M, and 55% ECOG PS 3−4 Most common PSG were lung (25%), genitourinary (18%), and gastrointestinal (GI) (11%). Fatigue/anorexia-cachexia cluster was associated with race (58% AA vs. 68% C, $p = 0.032$) and PSG (range 47% melanoma to 83% pancreas, $p = 0.012$); Neuropsychological cluster was associated with older age (29% $\geqslant$65 vs. 39% <65, $p < 0.001$) and race (22% AA vs. 36% C, $p = 0.001$). Upper GI cluster was associated with female gender (16% M vs. 22% F, $p = 0.035$) and PSG (range 8% Head & Neck to 32% pancreas, $p = 0.035$). Nausea/vomiting cluster was associated with younger age (35% $\geqslant$65 vs. 43% <65, $p = 0.010$) and female gender (33% M vs. 47% F, $p < 0.001$). Aerodigestive cluster was associated with male gender (36% F vs. 44% M, $p = 0.010$) and PSG (range 24% pancreas to 58% Head & Neck, $p < 0.001$). Debility cluster was associated with race (33% AA vs. 44% C, $p = 0.016$) and poor PS (range 17% PS0 to 54% PS4, $p < 0.001$). Pain cluster was associated with younger age (88% $\geqslant$65 vs. 92% <65, $p = 0.028$).
The table briefly summarizes the associations that are significant at P<0.05.

Cluster	Age	Gender	Race	Performance status	Primary Site
Fatigue/anorexia-Cachexia					+
Neuropsychological	+		+		
Upper GI		+			+
Nausea/vomiting	+	+			
Aerodigestive		+			+
Debility			+	+	
Pain	+				

Conclusions: We identified 7 SC whose prevalence were influenced by age, gender, race, PS, or primary cancer site. This supports the clinical relevance of the cluster concept in palliative and supportive care. Demographic characteristics may warrant different clinical approaches to patient care. Identification of these differences may help develop more effective cancer treatment and management strategies.
No conflict of interest.

1365 POSTER

Denosumab treatment of hypercalcemia of malignancy (HCM) in patients not responding to bisphosphonate therapy

S. Leboulleux[1], M. Hu[2], I. Glezerman[3], R. Gucalp[4], W. Misiorowski[5], A. Jaccard[6], G. Tonini[7], W. Ying[8], A. Braun[9], R. Jain[9]. *[1]Institut Gustave Roussy, Service de Médecine Nucléaire et Cancérologie Endocrinienne, Villejuif, France; [2]University of Texas MD Anderson Cancer Center, Endocrine Neoplasia and Hormonal Disorders, Houston, USA; [3]Memorial Sloan-Kettering Cancer Center and Weill Cornell Medical College, Medicine, New York, USA; [4]Montefiore Medical Center-Bronx, Oncology, New York, USA; [5]Medical Center for Postgraduate Education, Endocrinology Department, Warsaw, Poland; [6]Centre Hospitalier Universitaire de Limoges − Hôpital Dupuytren, Service d'Hématologie et de Thérapie Cellulaire, Limoges, France; [7]Policlinico Universitario Campus Biomedico, Medical Oncology, Rome, Italy; [8]Amgen Inc., Global Biostatistical Science, Thousand Oaks, USA; [9]Amgen Inc., Oncology, Thousand Oaks, USA*

Background: HCM, resulting primarily from tumor-induced bone resorption, is commonly treated with intravenous (IV) bisphosphonate therapy but patients may relapse or not respond. We present results evaluating denosumab for treatment of HCM in patients who remained hypercalcemic despite IV bisphosphonate by bone metastases (BM) or PTHrP status at study baseline (ClinicalTrials.gov NCT00896454; May, 2009; sponsor Amgen Inc.).
Material and Methods: In this single-arm, open-label study, patients with HCM (corrected serum calcium [CSC] >12.5 mg/dL; CTCAE grade $\geqslant$3) despite IV bisphosphonate treatment $\geqslant$7 and $\leqslant$30 days before screening, received subcutaneous denosumab 120 mg on days 1, 8, 15, and 28, then every 4 weeks. The primary endpoint was the proportion of patients with CSC $\leqslant$11.5 mg/dL (CTCAE grade $\leqslant$1) within 10 days of denosumab initiation.
Results: The study enrolled 33 patients (64% men; mean age 60 years; 39% with BM; median PTHrP 4.2 pmol/L). Median baseline CSC was 13.7 mg/dL and median time from last bisphosphonate treatment to enrollment was 17 days. By day 10, 21 patients (64%) reached CSC $\leqslant$11.5 mg/dL, with a total of 23 patients (70%) over the course of the study; estimated median response duration was 104 days. Of patients without BM, 14 of 20 (70%) reached CSC $\leqslant$11.5 mg/dL by day 10 compared with 7 of 13 (54%) with BM. The estimated median time to reach CSC $\leqslant$11.5 mg/dL was 8 days for patients without BM and 11 days for patients with BM. Of patients with PTHrP $\leqslant$4 pmol/L, 10 of 12 (83%) achieved CSC $\leqslant$11.5 mg/dL by day 10 compared with 6 of 12 (50%) with PTHrP >4 pmol/L. The estimated median time to CSC $\leqslant$11.5 mg/dL was 8 days for both the $\leqslant$4 pmol/L and the >4 pmol/L PTHrP groups. The most frequently reported serious adverse event was hypercalcemia (5 patients, 15%). Two patients had isolated episodes of CSC levels $\leqslant$8.0 mg/dL and no patients had CSC <7.0 mg/dL.
Conclusions: Denosumab lowered CSC to CTCAE grade $\leqslant$1 in 64% of patients within 10 days and induced durable responses in patients with HCM not responding to IV bisphosphonate treatment. Denosumab decreased CSC levels in patients independent of BM or PTHrP status. These results suggest that denosumab may offer a new treatment option for HCM in this challenging patient population.

1366 POSTER

Palliative effect of MR guided focused ultrasound (MRgFUS) on patients with bone metastases previously receiving sham treatment

R. Pfeffer[1], R. Catane[1], J. Meyer[2], M. Hurwitz[3], S. Kanaev[4], V. Turkevich[4], D. Iozeffi[5], P. Ghanouni[6], R. Abdah-Bortnyak[7], A. Napoli[8]. *[1]Sheba Medical Center, Oncology, Tel Hashomer, Israel; [2]Fox Chase Cancer Center, Oncology, Philadelphia, USA; [3]Brigham and Women's Hospital, Oncology, Boston, USA; [4]Petrov Institute of Oncology, Oncology, St Petersburg, Russian Federation; [5]Rostov State Research Institute of Oncology, Oncology, Rostov on Don, Russian Federation; [6]Stanford University Medical Center, Oncology, Palo Alto, USA; [7]Rambam Medical Center, Oncology, Haifa, Israel; [8]Sapienza University of Rome, Oncology, Rome, Italy*

Background: Radiation therapy (RT) is the primary treatment for most patients with painful bone metastases. Many patients have persistent or recurrent pain after RT or are not candidates for RT. Magnetic resonance guided focused ultrasound (MRgFUS) combines non-invasive focused ultrasound with MR guidance. We showed in a multi-center phase III trial significantly greater pain relief for patients treated with MRgFUS (67% response) compared to controls receiving sham treatment (21% response). Non responders on the placebo arm were unblinded and offered MRgFUS. We analyse here the response to MRgFUS in these patients who acted as self-control.
Materials and Methods: Patients with a painful bone metastasis amenable to MRgFUS treatment and NRS pain score >4 for whom RT was not considered appropriate (e.g. prior RT to target site) were randomized 3:1 to MRgFUS or sham. Subjects were followed for 3 months. Sham subjects without pain relief after 2 weeks were offered crossover to MRgFUS treatment. Significant pain response was defined as decrease in worst pain NRS score >2 from baseline without increase in pain medication. Quality of life (QOL) including BPI-QOL, and safety were also evaluated.
Results: Blinding of sham subjects was excellent; 94% of MRgFUS and 88% of sham subjects believed they had received MRgFUS treatment. 18 of 28 non-responders on the placebo arm elected to receive MRgFUS therapy. One patient did not complete MRgFUS therapy due to transient pain exacerbation during treatment. There were no other side effects. 13 of 17 treated patients (76%) had significant pain reduction. 15 patients were followed for the 3 month study period, follow up was discontinued for 2 patients after 2 months. One died of disease progression at other sites and one received additional RT. Mean NRS pain score of all 17 patients improved from 7.6 after sham treatment and before MRgFUS treatment to 3.1 at 2 months after treatment and 2.7 three months after treatment. BPI-QOL score improved from a mean of 5.8 before MRgFUS to 3.4 at 2 months and remained stable.
Conclusions: MRgFUS is well tolerated and results in significant durable pain relief, improvement in QOL, and function for patients with metastatic bone pain who are not candidates for RT. This analysis of patients who did not respond to prior sham treatment confirms that pain relief after MRgFUS is not due to placebo effect. MRgFUS should be considered for patients with painful bone metastases when RT is contraindicated.

1367 POSTER

Weight loss in solid tumors: Clinical features and prognostic importance

S. Shrotriya[1], D. Walsh[1], A. Aktas[1], B. Estfan[1], L. Rybicki[1]. *[1]Cleveland Clinic Taussig Cancer Institute, The Harry R. Horvitz Center for Palliative Medicine, Cleveland, USA*

Background: Large cancer databases provide valuable information on weight change and its impact on different clinical parameters. Body weight change in adults with solid tumors examined in outpatients. Objective was to determine if demographics, clinical and biochemical indices predicted weight loss (WL). Examine if WL and related parameters were prognostic for survival.
Material and Methods: Electronic medical records (EMR) for outpatient visits from a tertiary cancer center retrospectively reviewed. Body weight and other clinical parameters on first visit (V1) − within a year post diagnosis − last visit (V2) $\geqslant$3 weeks after V1. WL at V2 from V1 categorized as: $\leqslant$5%, 5.01−10%, >10%. Logistic regression and Cox proportional hazards analysis identified risk factors for WL and prognosis.
Results: N = 5901; Mean age ($\pm$SD): 61$\pm$12 years; 82% were Caucasians; 16% African Americans. Common cancers were genitourinary (GU) 31%; gastrointestinal (GI) 16%; breast 15%; lung 15%; head and neck 6%; brain 5% and others 12%. Metastatic disease in 18%. Bone, brain, lymph nodes − common. 45% had radiotherapy and

41% chemotherapy. Median (min, max) weight, kgs: V1 = 81 (32.0, 223), V2 = 79 (34, 221). Median duration (min, max), days V1→V2: 195 (22, 1080).
Weight loss V1→V2: ⩽5% (73%), 5.01−10% (13%) and >10% (14%). Median change in BMI V1→V2: −0.2 (−19, 13). Median change systolic/diastolic blood pressure (BP) V1→V2: −3 (−99, 80)/−1 (−57, 47). Change in REE V1→V2: −13 (−890, 365). Median survival for 5.01–10.0% WL = 9.4 months, >10.0% = 5.3 months and not observed for ⩽5%.
Conclusions:
1. Majority lost ⩽5% of body weight by V2
2. Head & Neck and GI cancers (primary) − the greatest risk of WL; breast − lowest
3. High BMI predicted greater WL compared to normal or underweight
4. ⩽5% WL had a survival advantage 5.01−10% and >10%
5. WL remained prognostic for survival after adjusting for other prognostic factors

No conflict of interest.

1368 POSTER

Malignancy-related hypercalcemia in the bisphosphonate era

M.F.S. Alves[1], M.P. Mak[1], G.H.M. Piotto[1], T.K. Takahashi[1], R.E.O. Ramos[1], L.G. Fonseca[1], M. Silvino[1], M.S. Mano[1], P.M. Hoff[1], G. Castro Jr.[1]. [1]*Instituto do Câncer do Estado de São Paulo, Clinical Oncology, São Paulo, Brazil*

Background: Malignancy-related hypercalcemia (MRH) is associated with a poor prognosis. With advances in supportive care and cancer treatment, the impact of such occurrence might have diminished. Bisphosphonates (BP) play a role in symptom control but survival gain is unknown. In order to assess the prognostic implication of MRH in a present population, this retrospective analysis was performed.
Methods: Charts of 310 consecutive patients (pts) hospitalized due to symptomatic hypercalcemia in a single tertiary institution were retrospectively reviewed, from 2009 to 2012. All patients had solid tumors and serum ionized calcium (iCa) >5.5 mg/dL or total Ca >10.5 mg/dL. The Kaplan–Meier survival curves, long-rank test and the Cox regression model were used for analysis.
Results: 310 pts were included with a median age 58 y.o., most with diagnosed squamous cell carcinoma (61%) and ECOG-PS >1 (96%). 141 pts (45%) had no previous chemotherapy (no CT) and mean iCa 6.8±0.9 mg/dL. Most frequent primary sites were head and neck (27%), lung (15%), esophagus (10%) and breast (10%). At presentation, 171 pts (55%) had altered mental status (AMS); median Hb 9.7 g/dL (3.9–15.4), C-reactive protein (CRP) 129 mg/L (3–448, NV <5), albumin (alb) 2.9 g/dL (1.6−4.5) and creatinine clearance 66 mL/min (9.7–199). Hypercalcemia episodes ranged from 1−5 (median 1). 245 pts (79%) were treated with pamidronate and 11 (4%) with zoledronic acid. No difference in overall survival was seen between those pts treated or not treated with BP (HR 0.65, p 0.7). Subsequent CT was administered to 99 pts (32%). Median OS was 40 d (95% CI 33−47 d). Pts with ECOG-PS >1, AMS, CRP >30, alb <2.5 or body mass index <18 kg/m^2 had significantly poorer survival. Longer OS was related to treatment-naive pts, subsequent CT and breast primary. On multivariate analysis, subsequent CT led to a survival improvement (HR 0.23, 95% CI 0.14–0.38, p < 0.0001).
Conclusions: MRH implicates a dismal prognosis in pts with solid tumors, despite administration of BP. Even so, pts treated with CT had a better survival, suggesting that appropriate treatment of selected pts can alter the course of this syndrome.
No conflict of interest.

1369 POSTER

Should patients with advanced colorectal cancer and ECOG 3/4 be treated with chemotherapy?

M.A.T. Crosara[1], D.F. Marques[1], A.C. Ferrari[1], M.F.S. Alves[1], A.K. Alex[1], J. Sabbaga[1], P.M. Hoff[1], R.P. Richelmann[1]. [1]*Instituto do Cancer do Estado de São Paulo, Medical Oncology, São Paulo, Brazil*

Background: Patients (pts) with metastatic colorectal cancer (mCRC) and ECOG 0/1 benefit from chemotherapy (CT). However, the impact of CT on the overall survival (OS) of ECOG 3/4 pts remains uncertain, since they are generally excluded from clinical trials.
Material and Methods: We retrospectively analyzed all consecutive mCRC pts who started first line CT at our institution in a 4-year period. The objectives were to compare the OS of pts with ECOG 3/4 who underwent CT with those receiving best supportive care (BSC) only and to compare the outcomes of these pts with those with ECOG ⩽2. Multivariable Cox regression model was used to verify prognostic factors and logistic regression, to identify predictive factors for grade 3/4 toxicity.
Results: From Jun/2008 to Jun/2012, 240 consecutive pts were included: 72 pts had ECOG 2, 54 ECOG 3 and 11 ECOG 4. Among pts treated with CT, the median OS was: 18.4 months for ECOG 0/1, 10.8 months for ECOG 2 and 6.8 months for 3/4. For pts with ECOG 3/4, CT led to a non-significant OS gain (median: 6.8 vs 2.3 months for BSC; p = 0.13). Factors significantly associated with worse OS were right-sided tumors (HR: 2.97; p = 0.005), ECOG 2 (vs ECOG 0/1, HR: 1.67; p = 0.025) and ECOG 3/4 (HR: 2.67; p < 0.0001). The rate of grade ⩾3 toxicities during first cycle did not differ significantly whether ECOG 3/4 pts received or not CT; likely because 40% of them received upfront dose-reduced CT. This was confirmed by multivariable analyses. While 70% of ECOG 3/4 pts were hospitalized during the first cycle, only 19% were admitted due to CT toxicity. This rate was similar across other ECOG groups.
Conclusions: Despite the small sample size, it seems that palliative CT may benefit selected pts with mCRC and poor performance status, without resulting in an increase in the risk of major adverse events when a reduced CT dose is used and pts are closely followed for toxicity. Further research may help to better identify the best candidates for CT.

1370 POSTER

Impact of race on cancer symptom profiles and survival in advanced cancer

A. Aktas[1], D. Walsh[1], L. Rybicki[2], A. Fitz[1]. [1]*Cleveland Clinic Taussig Cancer Institute, Harry R Horvitz Center for Palliative Medicine and Supportive Oncology, Cleveland, USA;* [2]*Cleveland Clinic Lerner Research Institute, Department of Quantitative Health Sciences, Cleveland, USA*

Background: Racial differences have not been investigated in detail in advanced cancer. In this study, we first examined whether race had an influence on cancer symptom prevalence and severity. Secondly, we investigated whether survival differed by race.
Material and Methods: 38 symptoms were assessed in 1000 consecutive advanced cancer patients referred to a palliative medicine program. Moderate/severe symptoms may be more clinically relevant than overall prevalence; hence, they were grouped together and referred to as 'clinically important'. Race was unknown in 30 patients. Age was compared between 167 African-Americans (AA) and 803 Caucasians (C) with the t-test. Gender and primary site groups (PSG) were compared with the Chi-square test. Performance status (PS) and symptom severity was compared with the Wilcoxon rank sum test. Survival after referral was estimated using the Kaplan–Meier method and compared with the log-rank test. A p value ⩽0.05 indicated statistical significance.
Results: Age, gender, PS, and PSG did not differ between AA and C (p⩾0.36). AA had less edema (21% vs. 30%, p = 0.02), depression (27% vs. 44%, p < 0.001), anxiety (14% vs. 26%, p = 0.001), tremors (1% vs. 6%, p = 0.018), anorexia (57% vs. 67%, p = 0.022), and dry mouth (48% vs. 59%, p = 0.01) than C, but more headache (17% vs. 11%, p = 0.035). Severity of 5 symptoms was lower in AA relative to C: edema (p = 0.038), depression (p < 0.001), anxiety (p < 0.001), tremors (p = 0.048), and dry mouth (p = 0.021). AA had more clinically important weight loss (24% vs. 16%, p = 0.024), but less depression (12% vs. 23%, p = 0.002) and anxiety (3% vs. 13%, p = 0.001) than C. AA had longer survival than C (median 2.4 vs. 1.6 months, p = 0.006).
Conclusions: We identified 7 symptoms whose prevalence and/or severity was associated with race. Caucasians had more common and severe edema, depression, depression, anxiety, tremors, and dry mouth. AA had less moderate/severe weight loss. Survival after referral was better among AA than C. Our study demonstrated that it is important and clinically relevant to examine race as a variable of cancer symptom research. This may stimulate research to evaluate racial variability in the provision of supportive and palliative care services for individuals with advanced cancer.
No conflict of interest.

The use of catumaxomab for treatment of malignant ascites in clinical practice: Results of an observational trial

C. Kurbacher[1], J. Sehouli[2], M. Welslau[3], G.F. Tempelhoff[4], J. Kufahl[5], C. Marth[6], H. Oettle[7], B. Schmalfeldt[8], E. Schulze[9], V. Kunzmann[10]. [1]*Medical Centre Bonn-Friedensplatz, Gynecologic Oncology, Bonn, Germany;* [2]*Charité Campus Virchow-Klinikum, Klinik für Frauenheilkunde und Geburtshilfe, Berlin, Germany;* [3]*Praxis Welslau, Aschaffenburg, Germany;* [4]*Klinikum Aschaffenburg, Frauenklinik, Aschaffenburg, Germany;* [5]*Klinikum Deggendorf, Medizinische Klinik II, Deggendorf, Germany;* [6]*Universitätsklinik für Frauenheilkunde, Innsbruck, Austria;* [7]*Onkologische Schwerpunktpraxis, Friedrichshafen, Germany;* [8]*Technische Universität München, Frauenklinik, München, Germany;* [9]*Fresenius Biotech GmbH, München, Germany;* [10]*Medizinische Klinik u. Poliklinik II, University of Würzburg, Würzburg, Germany*

Background: The trifunctional antibody catumaxomab (anti-EpCAM x anti-CD3) is approved in the EU for intraperitoneal (IP) treatment of

malignant ascites (MA) in patients (pts) with EpCAM positive carcinomas. Catumaxomab (CATU) has been investigated in two randomized phase III and several phase I/II trials but there are no data on routine use of CATU. Therefore, a prospective observational study (CARMA, DRKS00000458) started in 2010 investigating the administration of CATU in a total of 160 pts with MA under routine conditions. Participating centers were hospitals and oncologic practices in Germany and Austria. Results of the pre-planned 2nd interim CARMA analysis are reported here.

Patients and Methods: This analysis included 103 pts with MA due to EpCAM positive carcinomas: ovarian, n = 37; gastric, n = 13; breast, n = 13; pancreatic, n = 10; colorectal, n = 6, other, n = 24. Pts were treated with CATU according to the approved posology schedule with 4 increasing IP dosages over up to 20 days. Primary endpoint was puncture-free interval (PFI). Secondary endpoints included safety and overall survival (OS).

Results: The study population was more advanced compared to the phase III studies with regard to distant metastases, performance status, time since first diagnosis of tumor and of MA. Patients were treated in 24 hospitals (73%) and in 9 outpatient facilities (27%). Before treatment, pts suffered from typical MA-related symptoms such as abdominal swelling (77%), pain (56%), dyspnea (27%), anorexia (31%), constipation (14%). 67 pts (65%), received the planned CATU schedule, 36 pts (35%) received <4 infusions. Median PFI was 57 days (d), median OS was 100 d. For the subgroups ovar/non-ovar, a median PFI of 93/41 d and a median OS of 115/72 d was observed. Preliminary results show improved quality of life after CATU therapy. Most frequent adverse events related to CATU were fever (20%), abdominal pain (17%), nausea (14%), vomiting (9%) and diarrhea (6%).

Conclusions: CARMA represents the first systematic evaluation of CATU therapy given for MA under routine conditions. Despite the fact that pts were more advanced than in prior interventional trials, the data demonstrate a clinically relevant benefit of CATU which was particularly pronounced in ovarian cancer pts. Overall, the data confirm the position of CATU treatment in clinical practice including outpatient setting for adequately selected pts with MA. The final CARMA analysis will be performed after including 160 pts.

1372 POSTER

A phase II study of cediranib as palliative treatment in patients with symptomatic malignant ascites or pleural effusion

S.F. Mulder[1], M.J. Boers-Sonderen[1], H.F.M. Van der Heijden[2], K.C.P. Vissers[3], C.J.A. Punt[4], C.M.L. Van Herpen[1]. *[1]Radboud University Nijmegen Medical Centre, Medical Oncology, Nijmegen, Netherlands; [2]Radboud University Nijmegen Medical Centre, Pulmonology, Nijmegen, Netherlands; [3]Radboud University Nijmegen Medical Centre, Anesthesiology Pain and Palliative Medicine, Nijmegen, Netherlands; [4]Academic Medical Centre University of Amsterdam, Medical Oncology, Amsterdam, Netherlands*

Background: Malignant ascites and pleural effusion are challenging clinical problems with a major impact on quality of life. Because malignant effusions are associated with high levels of VEGF we wanted to determine the palliative effect of the oral VEGF TKI cediranib.

Materials and Methods: We conducted an open label, randomized phase II trial (ClinicalTrials.gov nr. NCT01262612). After a baseline paracentesis or thoracentesis (day 0), pts with symptomatic malignant ascites and/or pleural effusion were randomized between immediate treatment with cediranib (ITC) or delayed treatment with cediranib (DTC) on day 29, or after a new puncture was needed. The starting dose of cediranib was 30 mg orally once daily. The primary objective of the study was the puncture free survival (PuncFS), defined as the time from study start (day 1) to the first need for paracentesis or thoracentesis, or time to death, which event occurred first. Secondary objectives of the study were the change in puncture free interval (PuncFI) (defined as the difference between the PuncFS and the PuncFI before start of the study in days) and the tolerability of cediranib. Cediranib was provided by AstraZeneca for this investigator-initiated study.

Results: Twelve pts were enrolled. The median PuncFS was 45 days (range 10–368 days) in the ITC pts and 7 days (range 4−13) in the DTC pts ($P = 0.011$). The PuncFI increased with a median of 31 days in the ITC pts and shortened with a median of 3 days in the DTC pts ($P = 0.015$). Cediranib was well tolerated; the most common observed AEs were fatigue and anorexia. Dose reductions took place in 25% of pts. No bowel perforations were observed, contrary to other studies with intravenous anti-VEGF treatments for ascites. We planned to enroll 32 pts but the study was prematurely discontinued, due to slow accrual and the withdrawal of cediranib for further clinical development by AstraZeneca.

Conclusions: Cediranib increased the PuncFS and PuncFI in pts with malignant ascites or pleural effusion with an acceptable toxicity. This is the first study in which an oral VEGFR TKI showed beneficial palliative effects in pts with malignant ascites or pleural effusion. Although confirmation of these results by a larger prospective placebo-controlled trial would be preferred, the feasibility in terms of patient accrual rate appears low. Our data suggest that an oral anti-VEGFR treatment may be considered as palliative treatment in pts with malignant effusions.

No conflict of interest.

Can megesterol acetate induce thrombosis in oncology patients?

K.N. Pilanci[1], C. Ordu[1], K. Okutur[1], U. Iner Köksal[1], S. Saglam[1], C. Tecimer[1], G. Demir[1]. *[1]Istanbul Bilim University, Medical Oncology, Istanbul, Turkey*

Background: Megestrol acetate (MA) is a white, crystalline solid steroid origin medicine often use for cachexia in oncologic palliative care. Thrombosis is a common problem in oncology patients. There is a question can MA induce thrombosis in oncologic care setting? So, this trial is a retrospective, registry-based analysis to assess the thrombotic process in oncology patients using MA.

Materials and Methods: Data on oncology patients at metastatic stage using MA were obtained from the archives of our center. Outcomes of patients were evaluated if they developed any thrombotic process during the treatment.

Results: Fifty five oncology patients with metastatic disease using MA were analyzed if they developed any venous thrombosis. The median age of the patients was 64 (40−84) years. Most of the patient's diagnostic histopathology consists of lung cancer, gastric cancer, colorectal cancer, and pancreatic cancer. During the mean follow-up of 31.80 months, 34 (61.81%) patients died and 21 (38.18%) patients are still alive. The median time of overall survival (OS) was 19 months (6–180). All patients had been treated with chemotherapy. Cisplatin, taxanes, gemcitabine and 5-fluorouracil had been commonly used agent. Three patients received bevacizumab, one received cetuximab and one patients received everolismus as targeted therapy. Twenty six patients (47.27%) received radiotherapy. MA had been initiated if patient's weight loss was more than 10% on palliative care settings. The mean time of MA use was 8.69 months ($\pm$3.53). Seven thrombotic process have detected after MA use. Three of seven patient's diagnosis were pancreatic cancer. The other four patient's diagnosis were gastric cancer (2), lung cancer and endometrial cancer. Five of seven patients had received platin based chemotherapy. The patients with thrombosis non-significantly had worse OS, comparing without thrombosis ($P = 0.106$).

Conclusion: As a conclusion, in this trial it is revealed that the patients on MA treatment have rarely developed thrombosis. As a general rule, cisplatin based chemotherapy and pancreatic cancer seems to be more related with thrombosis than MS use. More detailed and prospective randomized studies should be planned on MA use in oncologic care.

No conflict of interest.

1374 POSTER

Symptomatic palliation of musculoskeletal metastasis: Efficacy and safety of intra-arterial chemoembolization

J.H. Kim[1], Y.H. Park[2], J.H. Choi[2], J.Y. Lee[2], S.J. Park[2], J.H. Seo[3], D.H. Lee[2]. *[1]Sam Hospital, Integrative Cancer Center Radiology, Anyang, Korea; [2]Sam Hospital, Integrative Cancer Center Medical Oncology, Anyang, Korea; [3]Kyung Hee University Hospital, Medical Oncology, Seoul, Korea*

Background: Metastasis to musculoskeletal tissues is commonly associated with severe or sometimes intractable pain. If it is not sufficiently controlled with standard therapies including chemotherapy, radiotherapy, and opioid analgesics, patients' quality of life (QoL) might be seriously compromised. This study evaluated the efficacy and safety of intraarterial chemoembolization in the palliation of the musculoskeletal metastasis resistant to standard therapies.

Materials and Methods: From 2008 June to 2012 December, intraarterial chemoembolization was tried in total 51 patients with musculoskeletal metastasis. All patients had intractable pain or discomfort unresponsive to medication and/or radiotherapy, compromising patients with serious deterioration of QoL. Correlating clinical symptoms with findings on CT or PET-CT, arterial suppliers to problematic lesions were selected. Cocktail of chemoagents (gemcitabine 200 mg, oxaliplatine 50 mg, adriamycin 10 mg mixed in glycirrhyzinic acid 40 ml) was infused, followed by 15 mg pamidronate in bone metastasis. Embolization with imipenem-induced micro-particles (40−50um) was performed when the lesions were highly vascular and safe for embolotherapy. This treatment was repeated per 4 to

8 weeks according to the patients' response and clinical condition. Changes of bone pain, analgesics consumption, and quality of life were evaluated after treatment.
Results: Technical success was achieved in 45 patients. Six patients underwent just angiography, showing no definite tumour staining in them. In 45 patients, improvement of pain (reduction of numerical pain rating scales, reduction of analgesics consumption) was demonstrated in 31 patients (clinical success 68.9%). Neurological improvement was demonstrated in 2 patients. The pain was not changed in 9 patients, and aggravated in 5 patients. Improvement of quality of life occurred in 28 patients. The time reaching maximum clinical improvement ranged from 1 day to 8 days. Clinical improvement maintained for 2 to 8 weeks. The procedure was well tolerated without significant complications.
Conclusion: Intraarterial chemoembolization is a useful, sometimes like a saviour, modality for the symptomatic palliation of musculoskeletal metastasis uncontrolled with standard therapies. However, personal difference exists in the commencement of palliation and duration of effectiveness. To maintain therapeutic effectiveness, decision for interval of procedure repetition is important.
No conflict of interest.

Initial symptom management of cancer patients, as an outcome of care, in a home palliative care unit in Greece

E. Patiraki[1], S. Katsaragakis[2], H. Avgetidou[2], O.M. Bagiaou[2], A. Hamou[2], C.H. Ikonomou[2], G. Liakopoulos[2], E. Petta[2], A. Tsiatsouli[2], A. Tserkezoglou[2]. *[1]University of Athens, Nursing Faculty, Athens, Greece; [2]Galilee Palliative Care Unit, Galilee Palliative Care Unit, Spata Attica, Greece*

Background: 'Galilee' palliative care service provides home care for adult cancer patients, in a large suburban area of Athens since March 2010. The purpose of the study was to explore symptom management of patients for the first two months of home palliative care.
Material and Methods: A total number of 162 cancer patients received home palliative care from March 2010 to December 2012. Retrospective data collection included: demographic and clinical characteristics and patients' ESAS-r (Edmond Symptom Assessment System Revised) self evaluation of symptoms (Likert type 0−10 scale) at the time of referral to the service (T_0), one month (T_1) and two months later (T_2).
Results: Most of patients were female (53.1%). Their mean age was 67.1 years and ECOG performance status 2.7. The most frequent diagnosis was lung cancer (18.5%) followed by breast (17.3%) and gastrointestinal cancer (17.3%). Most of the patients (46.9%) did not receive any antineoplasmatic treatment and 56.2% were not hospitalized during home care. Health status deterioration (27.5%), unrelieved breathlessness (19.6%) and persisted infection/ fever (15.7%) were the most prevalent reasons for hospital admission. Patients' median length of care was 54.5 days. The majority of patients (70.8%) died and 36.8% and 20.2% of them within the first and the second month respectively after referral to service. Anxiety (T_0 6.2$\pm$3.6, T_1 4.9$\pm$3.8, T_2 5.3$\pm$3.8), depression (T_0 5.9$\pm$3.3, T_1 5.2 $\pm$3.4, T_2 5.3$\pm$3.5), tiredness (T_0 5.1$\pm$3.6, T_1 4.7$\pm$3.3, T_2 4.5$\pm$3.8), and pain (T_0 4.8$\pm$3.4, T_0 4.1$\pm$3.2, T_2 4.3$\pm$3.7) were the most self reported symptoms at referral to the service and the two subsequent months. On the contrary nausea (T_0 1.1$\pm$1.0, T_1 0.8$\pm$0.6, T_2 0.4$\pm$0.1), breathlessness (T_0 1.5$\pm$1.0, T_1 1.0$\pm$0.2, T_2 1.2$\pm$0.5) and drowsiness (T_0 1.8$\pm$1.0, T_1 1.9$\pm$0.3, T_2 2.4$\pm$0.6) were less frequently reported. Overall during the study period, patients' well being improved. Moreover all of their symptoms were alleviated except for drowsiness, but only anxiety and depression at a statistical significant level ($p < 0.050$).
Conclusions: Study results highlight that regardless of the deterioration of patients' health and high rates of death among them, they reported improved well being in a home palliative care program. Further research is needed to specify the relevant involved factors.
No conflict of interest.

1376 POSTER

Four years experience of treatment painful bone metastases with magnetic resonance guided focused ultrasound

V. Turkevich[1], S. Kanaev[1]. *[1]N.N. Petrov Research Institute of Oncology, Nuclear Medicine and Radiation Oncology, Saint Petersburg, Russian Federation*

Background: Magnetic Resonance guided Focused Ultrasound Surgery (MRgFUS) is an innovative technology combining non-invasive deposition of high intensity focused ultrasound energy into a specified target inside the body, with high resolution Magnetic Resonance Imaging (MRI) guidance and real-time thermal feedback. Starting from 2009 up to 2012 our Institute participated in the clinical randomized multi-site study to evaluate safety and efficacy of MRgFUS for palliative treatment of Bone Metastasis. This study was approved by FDA at 18 October 2012.
Material and Methods: 37 patients with painful bone metastases were treated with the ExAblate® system (*InSightec*, Haifa, Israel) at Petrov Research Institute of Oncology, St. Petersburg, Russia. Immediately after procedure patients were examined for any adverse events and after a brief recovery discharged. Patients were followed up on 1 and 3 days, 1 and 2 weeks, 1, 2 and 3 months post treatment. During each visit, treatment safety was evaluated by recording and assessment of device or procedure related adverse events. Effectiveness of palliation was evaluated using the standard pain scale (0-no pain/10-worst pain imaginable) and by monitoring changes in the intake of pain-relieving medications. A reduction of 2 points or more on pain scale was considered a significant response to treatment. 8 patients were male and 29 female. Mean age was 58 years old (19−76). The primary cancers were: 25 breast, 4 stomach, 2 bronchus, 2 bladder, 4 other. Targeted lesions were 14 osteolytic, 8 osteoblastic and 15 mixed. 27 were pelvis metastases, 4 were located in the humerus bone and 6 were located in the ribs.
Results: No significant device or procedure related adverse events were recorded. 4 patients died during the follow-up period due to disease progression, thus 3 months follow-up data includes only results of 33 patients. All patients reported significant improvement in pain with no change in their medication intake. Mean worst pain score at baseline, 1 day, 3 days, 1 week, 2 weeks, 1, 2 and 3 months post-treatment was 6.9, 6.1, 5.1, 3.5, 2.6, 1.8, 1.2 and 0.9.
Conclusions: MRgFUS can provide effective, safe and noninvasive palliative therapy for patients suffering from painful bone metastases. The ability to achieve rapid pain relief after only one treatment session, combined with the high safety profile of the procedure implies that MRgFUS has a significant potential for patients suffering from painful bone metastases.
No conflict of interest.

1377 POSTER

Attitudes and referral patterns of lung cancer specialists in europe to specialized palliative care (SPC) and the practice of early palliative care (EPC)

H. Charalambous[1], A. Pallis[2], B. Hasan[2], M.E.R. O'Brien[3]. *[1]BOC Oncology Center, Department of Medical Oncology, Nicosia, Cyprus; [2]EORTC, Lung Cancer Group, Brussels, Belgium; [3]Royal Marsden Hospital, Medical Oncology, London, United Kingdom*

Purpose: To examine availability of Palliative Care (PC) services as well as referral patterns of European Lung cancer specialists to PC and in particular the timing of this referral.
Methods: All members of the EORTC Lung Cancer Group (LCG) were asked via email to participate in an on-line survey. Three (3) emails were sent.
Results: 50 out of 170 (29.4%) EORTC LCG members replied. Among the respondents there were 24 (48%) medical oncologists, 14 (28%) radiation/clinical oncologists, 11 (22%) pulmonologists and 1 (2%) thoracic surgeon. All but one of respondents (98%) reported that either most of their practice (30%) or a substantial proportion of their practice (68%) involved the care of patients with metastatic/incurable cancer. All but two (2) of respondents (96%) had access to at least one component of PC services. Twenty seven (54%) had access to comprehensive PC services, including hospital based teams and outpatient/community based PC teams and inpatient Hospice services. In terms of referral of metastatic lung cancer patients to PC almost 75% of participants would refer almost all or most of their patients when they were close to death, while 22% or less would refer their patients at earlier stages of disease. Regarding barriers for referral to PC, negative attitudes of patients to PC was cited by 26% of participants, lack of availability of PC services by 20%, lack of expertise of PC physicians by 18%, and only 8% of participants felt that referral to PC signifies abandoning their patients, and that PC specialists interfere or discourage active oncological therapy. Although most of the respondents expressed positive attitudes towards PC, 12−22% had overtly negative attitudes towards PC. Seventy-eight (78%) of participants expressed an interest to participate in a trial of early PC (EPC).
Conclusion: There is good availability of PC services at institutions of members of the EORTC LCG. Most respondents expressed positive attitudes towards PC, however the majority of them referred patients to PC late in the disease trajectory, hence lung cancer specialists in Europe have not adopted the practice of EPC concurrent with active oncological care. Negative attitudes of patients to PC and lack of expertise of PC physicians remain the major barriers, according to Lung Cancer specialists, for referral to PC. The majority of EORTC LCG members would like to participate in a trial of EPC.
No conflict of interest.

1378 POSTER

Availability of informal caregivers for palliative care patients with cancer: Is there a difference between higher- and lower-income settings?

R. Abdel Malek[1], S. Cox[2], M. Bower[2], D. Farag[3], S. Alsirafy[3]. [1]*Cairo University Hospital, Clinical Oncology, Cairo, Egypt;* [2]*Chelsea & Westminster Hospital, Palliative Care Team, London, United Kingdom;* [3]*Cairo University Hospital, Palliative Medicine, Cairo, Egypt*

Background: The modern palliative care movement started in higher-income countries where palliative care models were developed to meet the needs of patients and their families. Although the principles of palliative care are the same, the ideal palliative care models in lower-income countries may be different from that in higher-income ones due to many variables related to culture and resources. Among the factors that need to be considered when developing suitable palliative care models in lower-income settings are the availability of informal caregivers and the degree to which they are involved in the care of palliative care patients. This study was conducted to compare the availability of informal caregivers between a higher-income setting and a lower-income one.
Patients and Methods: We investigated the availability of informal caregivers for 190 palliative care patients with advanced cancer from a higher-income setting in the United Kingdom (UK) and 115 patients from a lower-income setting in Egypt.
Results: Patients in Egypt were significantly younger than patients in UK (mean age 52 vs. 71, respectively; $p < 0.001$) and were more likely to be married (84% vs. 48%, respectively; $p < 0.001$). An informal caregiver was available in 92% of the cases from Egypt compared to 76% of the cases from the UK ($p < 0.001$). While 100% of Egyptian informal caregivers were family caregivers, 10% of those from the UK were non-family caregivers. In the Egyptian setting, 100% of informal caregivers were living with the patient compared to 63% in the UK setting ($p < 0.001$). In total, 92% of Egyptian palliative care patients with cancer had an informal caregiver living with them. In comparison, 48% of palliative care patients with cancer from the UK had an informal caregiver living with them ($p < 0.001$).
Conclusions: The results of this study suggest that there are significant differences between higher-income and lower-income settings regarding the availability and characteristics of informal caregivers for palliative care patients with cancer. The palliative care models developed in higher-income countries may not be 'universally' suitable for lower-income countries. Future research is essential to develop palliative care delivery models suitable for the culture and resources in Egypt and other lower-income settings.
No conflict of interest.

1379 POSTER

Hyponatremia severity among cancer patients and its association with type of cancer and mortality

A. Hassan[1], A. Allam[1], S. Al-Kindi[1], G. Abu Zeinah[1]. [1]*Al Amal Hospital, Palliative Care, Doha, Qatar*

Background: Hyponatremia is common in patients with cancer, and results in clinical symptoms that might increase the burden of the disease. It has been associated with increased mortality and length of hospital stay. The objectives of this study are to investigate the severity distribution of hyponatremia among different malignancies and study its association with mortality at a tertiary cancer center in Qatar.
Material and Methods: This is a retrospective study of all cancer patients admitted or seen at the National Center for Cancer Care and Research in Doha, Qatar between 2008 and 2012. We reviewed electronic medical records for patients and analyzed demographics and clinicopathological reports. Descriptive statistical analysis was used to determine hyponatremia severity distribution among malignancy groups. A model was built through multivariate analyses to investigate the role of hyponatremia in mortality.
Results: A total of 2048 patients were included in this study. Prostate (57.1%), pancreatic (50%), liver (49%), and lung (40.2%) cancers showed the highest frequency of severe hyponatremia, while breast cancer showed the lowest frequency at 23.5%. In the multivariate analyses, patients with moderate-severe hyponatremia (Na <130 mmol/L) were 4.28 times more likely to die than those with normal sodium levels ($p < 0.05$).
Conclusion: The present study shows that hyponatremia is a common electrolyte disturbance among hospitalized patients with cancer diagnosis. The severity of hyponatremia was a statistically significant independent factor associated with higher in-hospital mortality. This is in accordance with the reported literature and emphasizes the importance of early diagnosis and correction of hyponatremia.
No conflict of interest.

1380 POSTER

Palliative care in the last days of cancer patients admitted to Torrecardenas Hospital

V.E. Castellon Rubio[1], J. Carrillo Ramos[1], F.E. Rosillo Fernandez[1], B. Medina Magan[1], P. Reche Molina[1], A. Martinez Guisado[1], A. Fernandez Freire-Leal[1], L.G. Canosa Ruiz[1]. [1]*Hospital Torrecardenas, Oncology Service, Almeria, Spain*

Introduction: The cancer is still an incurable disease, and in the last moments of life aims primarily to avoid the pain and consequently suffering of cancer patients. The objective of this study is to describe the characteristics of patients who died in the ward of Medical Oncology during 2012.
Material and Methods: We retrospectively reviewed all patients who died in our service between January and December 2012, and performed a descriptive analysis of the following variables: sex, age, primary tumor, symptoms that led to the hospitalization, length of hospital stay, presence of refractory symptoms, and if received palliative sedation.
Results: We analyzed 90 patients: 52 were male (57.7%) and 38 women (42.2%) with a median age of 59 years (range 23−89). According to the primary tumor: lung cancer 38.8%, non-colorectal gastrointestinal cancer 21.1%, breast cancer 10%, colorectal cancer and cervical cancer 8.8%, genitourinary 6.6% and soft tissue sarcoma and 5.5%. All patients were in an advanced or terminal stage of their condition, and 49.5% in an agonal phase. The most common symptoms that prompted admission were dyspnea (22.6%), followed by fatigue (18.6%) and uncontrolled pain (15.4%). The median stay was 11 days, but 19 patients (21.1%) died in the first day of admission. Symptoms leading to sedation were: dyspnea (42.7%), pain (26.6%) and delirium (21.8%). Informed consent (IC) was explicit in 9% of the cases, and given prior to the appearance of refractory symptoms and/or agonal phase. In 82% of sedation cases, the IC was given by a representative. Midazolam was the most used drug of choice in 91% of the cases. Up to 75% of sedations required drug changes or combinations.
Conclusions: The tumor with increased mortality was lung cancer followed by gastrointestinal cancer (esophagus, gastric and pancreas). Dyspnea as a symptom and liver failure secondary to tumor progression were the main reasons for admission. The most common refractory symptoms were: dyspnea, pain and dyspnea association with pain or delirium. The therapeutic approach to these patients is complex, since most suffer a variety of symptoms and any complications during hospitalization. In 100% of cases was agreed sedation, being in most cases the conformity with the patient.
No conflict of interest.

1381 POSTER

Exploring knowledge and experience of cancer patients in pain relief − a Greek study

S. Katsaragakis[1], S. Sgourou[2], A. Vardakastani[2], E. Patiraki[2]. [1]*University of Peloponnese, Nursing Faculty, Sparta, Greece;* [2]*University of Athens, Nursing Faculty, Athens, Greece*

Background: The purpose of this study, funded by the University of Athens, was to explore Greek patients' knowledge and experience of cancer pain relief.
Material and Methods: A descriptive correlation research design was used. A sample of 100 cancer patients with pain was interviewed, in a central oncology hospital in Attica area. A demographic and clinical form and the Patient Pain Questionnaire (PPQ-Ferrell BR, 2000, City of Hope) were used for data collection. The PPQ consists of 16 items divided between two subscales. The 'Experience' subscale consists of seven items measuring current pain and pain relief, pain over the last week, expectation of future pain, sense of control over pain and distress related pain. The 'Knowledge' subscale consists of nine items to evaluate knowledge of, and attitudes to, cancer pain and medications. Patients rate their agreement or disagreement on 0−10 rating scales. Higher scores indicate poorer experience of pain, and poorer knowledge and attitudes.
Results: Most patients were female (55.5%), with a mean age 65.0 years. The prevalent diagnosis was lung cancer (20.0%). Median time since cancer diagnosis was 17.5 months and pain onset 6.5 months. More patients were prescribed with mild (45.0%), or strong (41.0%) opioids and only 14% non opioids analgesics. Patients reported a median knowledge about cancer pain management (5.3 ± 1.4) and a median experience of pain (5.3 ± 1.7). Although patients experienced almost severe pain over the past week (6.8 ± 2.3), they reported receiving a great deal of pain relief (3.1 ± 2.8). Patients' knowledge about cancer pain management was positively related with their pain experience (rho=0.22, $p = 0.028$). None of patients' demographic and clinical characteristics was related with patients knowledge and experience about cancer pain ($p > 0.050$). Patients'

analgesic treatment was associated with their pain experience ($z = -2.3$, $p = 0.021$). Patients prescribed with opioids described a poorer pain experience (6.4±2.0), than those prescribed with non-opioids (5.2±1.3). Additionally patients receiving opioids reported more pain over the past week (7.0±2.3 vs 5.5±2.2), present pain (4.0±2.8 vs 2.2±2.2) and more distress (7.6±2.6 vs 6.8±1.6), than those receiving non-opioids.
Conclusions: Although patients were undertreated they described a great deal of pain relief. Most patients held limited knowledge about pain and pain management, and those with poorer knowledge reported worse pain experience.
No conflict of interest.

1382 POSTER

Knowledge and experience in pain management of Greek cancer patients − the family caregivers perceptions

S. Katsaragakis[1], A. Vardakastani[2], S. Sgourou[2], A. Psychogyiou[2], E. Patiraki[2]. [1]*University of Peloponnese, Nursing Faculty, Sparta, Greece;* [2]*University of Athens, Nursing Faculty, Athens, Greece*

Background: The aim of this study, funded by the University of Athens, was to investigate knowledge and experience of family caregivers in patient's cancer pain management.
Material and Methods: Patients with a cancer diagnosis who reported pain, in 'Ag. Anargyroi' Cancer Hospital, were approached for a three month period (January-March 2013) and accepted to name their primary family caregiver. A total of 100 caregivers consented to participate to the study. A demographic form and the Family Pain Questionnaire (FPQ-Ferrell BR, 2000, City of Hope) were administrated. The FPQ is a 16 item ordinal scale that measures the Knowledge and Experience of a family caregiver in managing chronic cancer pain. The FPQ includes 9 items that measure knowledge about pain and 7 items that measure the caregivers experience with patient's pain. Caregivers rate their agreement or disagreement on 0−10 rating scales (0= the most positive outcome, 10= the most negative outcome).
Results: Most caregivers (59.0%) were female with a mean age 52.9 years. The majority of them was patients' wife/ husband (48.0%) with no previous caregiving experience (66.0%), assisted by others (76.0%). Most of caregivers were married (76.0%) with two children (54.0%) having the same residence with the patient (66.0%). The median time of care provision was 13 months. Caregivers reported a median knowledge about cancer pain management (5.7±1.4) and a median patient's experience of pain (6.4±1.3), which were not correlated each other ($rho = -0.15$, $p = 0.146$). Caregivers reported almost severe patient's pain over the past week (6.7±2.4), mild current pain (4.2±2.9) and an inadequate pain relief (7.0±2.4). Caregivers' knowledge in pain management was associated only with patient's age ($r = 0.26$, $p = 0.006$). The caregivers of younger patients had higher score in knowledge subscale. Similarly, higher score in knowledge had those that did not receive assistance from others ($t=2.2$, $p = 0.030$). Caregivers experience with patients' pain was worse for patients receiving opioids analgesic ($z = -2.3$, $p = 0.019$) particularly strong opioids ($z = -2.7$, $p = 0.006$), than those receiving non opioids. Moreover, caregivers reported that patients receiving strong opioids had worse pain experience over the past week ($p < 0.006$) and current pain ($p < 0.018$), than those receiving non opioids or mild opioids.
Conclusions: Family caregivers had a moderate knowledge about cancer pain management and experienced undertreated their patient's pain.
No conflict of interest.

1383 POSTER

Optimal timing of influenza virus vaccination during chemotherapy treatment in adult patients with solid tumours

M. Wumkes[1], A.M.T. Van der Velden[1], M. Los[2], M.B.L. Leys[3], A. Beeker[4], M.R. Nijziel[5], A. Meerveld-Eggink[2], G.F. Rimmelzwaan[6], G.T. Rijkers[7], D.H. Biesma[8]. [1]*Tergooi Ziekenhuizen Hilversum, Internal Medicine, Hilversum, Netherlands;* [2]*St. Antoniusziekenhuis Nieuwegein, Internal Medicine, Nieuwegein, Netherlands;* [3]*Maasstad Ziekenhuis Rotterdam, Internal Medicine, Rotterdam, Netherlands;* [4]*Spaarne Ziekenhuis Hoofddorp, Internal Medicine, Hoofddorp, Netherlands;* [5]*Maxima Medisch Centrum Eindhoven, Internal Medicine, Eindhoven, Netherlands;* [6]*Erasmus Medisch Centrum Rotterdam, Virology, Nieuwegein, Netherlands;* [7]*St. Antoniusziekenhuis Nieuwegein, Medical Microbiology and Immunology, Nieuwegein, Netherlands;* [8]*Universitair Medisch Centrum Utrecht, Internal Medicine, Utrecht, Netherlands*

Background: Higher rates of hospitalisation and mortality are described in oncology patients with influenza virus infection compared to the general population. Yearly influenza vaccination is strongly recommended for patients treated with chemotherapy or other immunosuppressive drugs. The optimal moment to administer the vaccine during a treatment cycle has not been studied extensively.
Patients and Methods: During the influenza season 2011–2012 we conducted a multicenter randomised controlled trial (OFLUVAC, NTR2858, no sponsoring) in the Netherlands. Patients receiving adjuvant chemotherapy for breast or colorectal cancer were randomized between early (day 5 after chemotherapy) and late (day 16 after chemotherapy) vaccination with the influenza virus vaccine (Influvac® 2011/2012, Abbott Biologicals B.V, Weesp, the Netherlands and Vaxigrip® 2011/2012, Sanofi Pasteur MSD, Brussels, Belgium). Influenza virus-specific antibody titres were determined before and 3 and 12 weeks after vaccination by haemagglutination inhibition.
Results: Thirty-eight breast cancer patients (early = 21; late = 17) and 18 colorectal cancer patients (early =8; late = 10) were analysed. In breast cancer patients overall serologic responses were adequate. A statistically significant higher response in patients who received early compared to late vaccination in the chemotherapy cycle was observed. Geometric mean titres post vaccination day 5 versus day 16 were 69.3 versus 27.4 (H3N2), 76.4 versus 17.5 (H1N1) and 34.4 versus 26.0 (B/Brisbane), respectively. In colorectal cancer patients overall serologic responses were adequate, no significant difference was found between early and late vaccination with the influenza virus vaccine. Geometric mean titres post vaccination day 5 versus day 16 were 170.1 versus 192.4 (H3N2), 233.0 versus 280.8 (H1N1) and 62.6 versus 75.9 (B/Brisbane), respectively.
Conclusion: The overall serologic response to the influenza vaccine in patients treated with chemotherapy for breast or colorectal cancer patients is adequate. The optimal timing of vaccination in breast cancer patients is early after receiving chemotherapy ($\leqslant$ day 5). No difference was found between early and late vaccination in colorectal cancer patients.
No conflict of interest.

1384 POSTER

Impact of chemotherapy on activated protein C-dependent thrombin generation − association with venous thromboembolism occurrence

M. Roselli[1], P. Ferroni[2], S. Riondino[2], S. Mariotti[1], A. Laudisi[1], M. Vergati[1], V. Cereda[1], F. Cavaliere[3], R. Palmirotta[2], F. Guadagni[2]. [1]*University of Rome Tor Vergata, Dept. of System Medicine Medical Oncology, Rome, Italy;* [2]*IRCCS San Raffaele Pisana, Department of Advanced Biotechnologies and Bioimaging, Rome, Italy;* [3]*San Giovanni Hospital, Dept. of Surgery, Rome, Italy*

Background: Cancer patients have an increased risk of venous thromboembolism (VTE), which differs among patients, or even in the same patient over the course of cancer natural history. The high VTE rates observed during the first year after diagnosis have been possibly related to the administration of combined anti-cancer therapies. However, the prevalence of coagulation abnormalities or VTE occurrence as a result of different anticancer agents or treatment schemes is largely uncharacterized. Thus, we aimed at analyzing the impact of different anticancer drugs on the pro-thrombotic status of cancer out-patients scheduled for chemotherapy.
Material and Methods: Activated protein C (APC) function (by HemosIL ThromboPath) was prospectively analyzed in 505 cancer out-patients with primary or relapsing solid cancer at the start of a new chemotherapy regimen (6% neoadjuvant, 31% adjuvant and 63% metastatic treatments). Blood was withdrawn in all 505 patients prior to chemotherapy start and before the second cycle. Additional samples were obtained from 51 patients before the start of the third and sixth cycle (elapsed time between cycles: 28d).
Results: APC function was impaired in roughly 27% of all cases at baseline and significantly decreased after one cycle of chemotherapy (mean ThromboPath value: 78.0±11.8 PICI%, $p = 0.0001$). Subgroup analysis of the 51 patients who consented to repeated blood withdrawal showed that APC functionality was progressively impaired during the first 3 months of chemotherapy (82.3±8.9 PICI% at T0 vs. 78.4±12.2 PICI% at T1 vs. 78.7±11.5 PICI% at T3), but reverted to baseline levels by the sixth month (84.9±8.6 PICI% at T6; Friedman's ANOVA among the four study points: $p = 0.008$). Advanced age (>65 y, $p = 0.01$), ECOG-PS ($p = 0.01$), platinum-based ($p = 0.035$) and fluoropyrimidine-based regimens ($p = 0.008$) were independent predictors of impaired APC function during chemotherapy. Multivariate Cox proportional hazards analysis demonstrated that a decline in APC function ($HR = 2.4$; $p = 0.013$) and platinum-based regimens ($HR = 2.2$; $p = 0.042$) were both capable of predicting the occurrence of a first VTE episode during chemotherapy. Indeed, 14% of patients with platinum-associated APC impairment had VTE over a 1 yr follow-up, compared to 3% of patients treated with other regimens and in whom APC function remained stable ($HR = 1.5$; $p = 0.003$).
Conclusions: Use of platinum-based regimens is responsible for induction of an acquired thrombophilic condition in the first three months of therapy and represents a predictor for VTE even after adjustment for other risk

Table 1 (abstract 1386). Congruence scores

	All Pts	Oncology Pts	Haematology Pts	*p**
Pt Risk Score 0−11 (mean±SD)	2.82±1.94	2.81±1.88	2.87±2.15	0.6544

*Significance of difference between oncology and haematology pts.

factors. Monitoring coagulation changes during the first cycle, more than the determination of a single point measurement at baseline, could provide a valid estimate of the associated pro-thrombotic risk and might help to identify patients susceptible of developing VTE during treatment.
This work has been performed within the PhD Programs XXVI and XXVII Ciclo and was partially supported by the Italian Ministry of Health Grant MERIT RBNE08NKH7.
No conflict of interest.

1385 POSTER

Complications and mortality associated with febrile neutropenia in a Spanish multicenter cohort of patients with cancer

L. Faez[1], M.P. Solis[1], A. Ramchandani[2], P. Castaño[3], M. Antonio-Rebollo[4], P.J. Fonseca[1], J. Martínez-García[5], E. Martínez[6], C. Font Puig[7], A. Carmona-Bayonas[3]. *[1]University Central Asturias Hospital, Medical Oncology, Oviedo, Spain; [2]University Insular Gran Canaria Hospital, Medical Oncology, Las Palmas de Gran Canaria, Spain; [3]Universitary Morales Meseguer Hospital, Medical Oncology, Murcia, Spain; [4]ICO-Duran i Reynals, Medical Oncology, Barcelona, Spain; [5]Universitary Virgen de la Arrixaca Hospital, Medical Oncology, Murcia, Spain; [6]Universitary Marqués de Valdecilla Hospital, Medical Oncology, Santander, Spain; [7]Universitary Clinic Barcelona Hospital, Medical Oncology, Barcelona, Spain*

Background: Febrile Neutropenia (FN) is associated with complications, mortality, severe infections and long hospital stays, in a significant number of adult cancer patients. Nevertheless, FN is a heterogeneous disease, and patients are not exposed to the same risk factors.
Patients and Method: An ambispective registry of adult cancer patients with FN from 15 Spanish hospitals was carried out from 2006 to 2013. Cases were clustered according to the primary tumor and the source of infection. Primary outcomes included mortality, complications and hospital stays. Univariate and multivariate analyses were performed to fit these variables to other well-known risk factors.

Table 1. Multivariate Logistic regression analysis: severe complications

Category	OR	95% CI	p-value
Pneumonia	3.4	1.92−6.2	<0.0001
Lower respiratory infection	2	1.21–3.58	0.007
Stomatitis ⩾2	1.9	1.25–3.05	0.003
ECOG PS ⩾2	2.3	1.31–3.56	<0.0001
Cardiovascular disease	2.08	1.22–3.56	0.007
Palliative chemotherapy	1.5	1.03–2.41	0.036
Bacteremia	2	1.23–3.36	0.005
MASCC <21	4.8	2.81–8.31	<0.0001

Results: 734 events were included with 28.5% complications, 3.8% deaths and a mean hospital stay of 7.1±5.8 days. The most frequent tumors were breast (30.3%) and lung (25.2%) cancers, while other tumors occurred at a frequency below 10%. Complications were significantly higher in patients with pancreatobiliar (68.8%) and lung (40.4%) tumors*, while breast cancer had the lowest rate (17.9%)*. Mortality was higher in patients with lung (6.6%), colorectal (10.8%) and ovarian cancer (11.1%)*. Otherwise, the most common infections were fever of unknown origin (FUO) (28.7%), stomatitis (15.2%), enteritis (11.9%) and pneumonia (10.3%). A higher rate of complications was associated with pneumonia (61.8%) and bronchitis (42%)*, whereas coughs and FUO had the lowest rates. Mortality showed a similar trend, highlighting the role of lower respiratory infections, specially pneumonia. These disparities persisted even after adjustment for comorbidities and other risk factors, as shown on Table 1. Otherwise, the rate of bloodstream infections was significantly higher in patients with catheter-related infections (42.9%), urinary infections (31.4%) and cellulitis (25%)*.
*$p < 0.05$ (z-test of proportions with Bonferroni method for multiple comparisons).

Conclusions: This study revealed several risk factors for complications, mortality and longer hospital stay, with potential implications for prevention and treatment, especially in lung cancer and respiratory pneumonia.
No conflict of interest.

1386 POSTER

Congruence to EORTC guidelines of biosimilar filgrastim treatment in patients enrolled in MONITOR-GCSF

H. Ludwig[1], M. Boccadoro[2], M. Aapro[3], P. Gascon[4], C. Bokemeyer[5], M. Turner[6], M. Muenzberg[6], K. Denhaerynck[7], I. Abraham[8], K. MacDonald[7]. *[1]Wilhelminenspital, Medizinische Abteilung mit Onkologie, Wien, Austria; [2]Azienda Ospedaliero Universitaia S. Giovanni Battista di Torino, Dipartimento di Oncologia e Ematologia, Torino, Italy; [3]Clinique de Genolier, Institut Multidisciplinaire d'Oncologie, Genolier, Switzerland; [4]Hospital Clinic de Barcelona, Division of Medical Oncology Department of Hematology-Oncology, Barcelona, Spain; [5]Universitaetsklinikum Hamburg Eppendorf, Oncology, Hamburg, Germany; [6]SANDOZ Biopharmaceuticals, Oncology, Holzkirchen, Germany; [7]Matrix45, Oncology, Tucson AZ, USA; [8]The University of Arizona, Center for Health Outcomes and Pharmacoeconomic Research, Tucson AZ, USA*

Background: The MONITOR-GCSF study is a prospective observational study of practice patterns and outcomes of biosimilar filgrastim (Zarzio®, Sandoz) for prophylaxis of chemo-induced febrile neutropenia (CIN/FN). One study objective is to describe the congruence of individual patients' (pts) biosimilar filgrastim treatment with the 2010 EORTC GCSF guidelines. The goal of this interim analysis is to assess the internal validity of a proposed congruence scoring methodology.
Methods: A methodology for scoring pt-level congruence of actual biosimilar filgrastim treatment with EORTC guidelines was developed (possible range 0−3). Scoring focuses on 4 aspects of therapy: 1) pt risks; 2) primary vs. secondary prophylaxis, 3) day of treatment initiation, 4) persistence. We conducted this interim analysis on 1168 pts enrolled to date (target 1500) from 139 centers in 12 European countries.
Results: In this mainly female (61%) and older (61.6±11.7 y) sample with predominately (79%) solid tumours, 11% of pts were on chemo regimens with <10%, 54% on regimens with 10−20%, and 35% on regimens with >20% FN risk. Table 1 summarizes biosimilar filgrastim congruence scores by tumour type. About half of pts were treated with biosimilar filgrastim (either primary or secondary prophylaxis) as recommended by the guidelines; just over a quarter of pts on chemo with FN risk >20%, or 10−20% FN risk in combination with other pt-related risk factors, did not receive primary prophylaxis as recommended. Half were initiated 24−72 hours after chemo and with few exceptions pts persisted as recommended.
Conclusions: Variability in biosimilar filgrstim (Zarzio®) treatment is captured in the congruence scoring indicating internal validity. Proportionately more oncology pts were initiated within the 24−72 hr time window, explaining also the higher overall congruence scores in these pts. Initiation time for haematology pts may need to be reconsidered. The relationship between EORTC guideline congruence and clinical outcomes will be evaluated at study end.

1387 POSTER

The use of probiotics in people with cancer: A systematic review

M. Redman[1], B. Phillips[2], E. Ward[3]. *[1]Hull York Medical School, York, United Kingdom; [2]York University, Centre for Reviews and Dissemination, York, United Kingdom; [3]Leeds General Infirmary, Paediatric Oncology/Haematology, Leeds, United Kingdom*

Background: Probiotics are living microorganisms that are generally thought of as being beneficial to the recipient. They may be consumed

as dairy drinks and have been shown to be effective in people with acute infectious diarrhoea. Probiotics may have a role in people with cancer, as various cancer treatments often lead to diarrhoea; however, guidance for their use is yet to be determined. People with cancer are often immunocompromised, so it is important to assess for adverse events such as infection, which could potentially be a consequence of deliberate ingestion of living microorganisms.
Materials and Methods: A systematic review was performed to collect, analyse and synthesise all available data on the efficacy and safety of probiotics in people with cancer (PROSPERO registration: CRD42012003454). Randomised control trials (RCTs), identified through screening multiple databases and grey literature, were included. Primary outcomes were the reduction in duration, severity and incidence of antibiotic-associated diarrhoea and chemotherapy-associated diarrhoea, and adverse events, especially probiotic-associated infection. All included studies and data extraction forms were independently reviewed. Where possible, data was combined for meta-analysis by a random effects model, assessing causes of heterogeneity, including differences in strains, dosage and patient characteristics.
Results: Data was extracted from 10 RCTs totalling 1431 participants. There was little strong evidence of difference in mean number of average daily bowel movements between probiotic and control groups of −3.98 stools per day [95% confidence interval (CI)-14.99 to 7.04; p = 0.48]. Liquid stools tended to be less common in the probiotic group [odds ratio (OR)=0.37; 95% CI 0.06 to 2.43; p = 0.30], whereas soft/semi-solid stools possibly occurred more often (OR=2.12; 95% CI 0.49 to 9.18; p = 0.31). The change in enterobacteriaceae count was lower in the probiotic group; mean difference of −1.98 (log10 CFU/g of faeces) (95% CI −2.56 to −1.39; p < 0.00001) compared to the control group. Probiotics seemed to decrease the use of rescue (anti-diarrhoeal) medication (OR=0.63; 95% CI 0.27 to 1.45; p = 0.28). No probiotic-associated infection was identified in any of 1311 patients assessed for adverse events.
Conclusions: There is a potential that probiotics may reduce the severity and frequency of diarrhoea in patients with cancer and may reduce the requirement for anti-diarrhoeal medication, though there is currently insufficient evidence with which to draw conclusions. More studies are needed to assess the true efficacy and safety of probiotics in people with cancer.
No conflict of interest.

1388 POSTER

Neutropenia score as an overall survival (OS) prognosis factor

R. Elaidi[1], A.S. Chimm[1], O. Marouf[1], F. Scotte[2], E. Fabre[2], J. Medioni[2], Y. Vano[2], N. Pecuchet[2], N. Delanoy[2], S. Oudard[2]. *[1]ARTIC Institute, Medical Oncology, Paris, France; [2]Hopital Européen G. Pompidou, Medical Oncology, Paris, France*

Background: Chemotherapy (CT) is a common cause of neutropenia (N). N is a prognostic factor in several studies. Prognostic value of N can be evaluated with global scores calculated over the whole CT period.
Methods: Patients included in the PROCHE program between 2008 and 2011 at the HEGP hospital (Paris, France). PNN levels were assessed at least once before each CT and graded using the CTC-NCI scale: 0: >2000, 1: [2000–1500[, 2: [1500–1000[, 3: [1000–500[, 4: <500. Scores were calculated as weighted mean of grades from 1st cycle to end CT (mean grade per cycle when multiple values). OS was calculated from CT initiation to death or censured at last contact. Cox regression covariates: age, tumor localization, disease setting, neutropenia after 1st cycle, and continuous or categorized PNN score. Patients with localized (M0) or metastatic (M+) disease during the study period led to two distinct cohorts: C1 and C0 according to M1 or M0 period considered. Bootstrap validation was performed using 1000 samples.
Results: Among the 1279 pts who entered the program, data were available for 657 who had at least 1 assessment of PNN. Excluded pts (622) due to lacking or dubious PNN results did not differ (log-Rank=0.98). Median age=63 y, sex-ratio=1, more frequent localization: lung (25%), breast (21%), urogenital (21%), ovary (13%), ENT (12%). 269/388 and 191/466 pts had localized/metastatic disease respectively for C0 and C+. Median cycles received: 4 (IQR=5). Median follow-up time=26.9m. Median PNN (/μl) was 4400 at baseline and 3820 thereafter. Score: 308 pts (47%) and 349 had a score>0 (S+: at least 1 neutropenia) and a score=0 (S0), respectively. 148 (22%) were S+ as soon as the 1st cycle. OS (m, 95% CI) was S+=35.2 (28.5-NR) and S0=17.0 (14.5–21.5). PNN continuous score was an independent predictor of OS: HR(C0)=0.70 (0.56–0.88), HR(C1)=0.72 (0.56–0.91). Categorical PNN score (S+/S0): HR(C0)=0.58 (0.45–0.73), HR(C1)=0.55 (0.43–0.69). The deeper the neutropenia after 1st cycle, the longer the OS. Other independent factors were age, disease setting, ENT and lung tumors. The model was internally validated (C-index=0.732, shrinkage=0.956).
Conclusion: Neutropenia scored over the whole CT period is a strong prognostic factor of OS.
No conflict of interest.

1389 POSTER

Epidemiology, resistance profile and origin of bacteremia in non-neutropenic patients with solid tumor

M. Merad[1], E. Chachaty[2], A. Alibay[3], B. Gachot[2], M. Di Palma[3], S. Antoun[3]. *[1]Gustave Roussy, Villejuif, France; [2]Gustave Roussy, Microbiology, Villejuif, France; [3]Gustave Roussy, Ambulatory Care, Villejuif, France*

Background: In oncology, and especially for solid tumors, the principal studies describe bacteriema in patients with neutropenia, Few microbiological data are available without neutropenia. Furthermore, bacteria resistance in immucompromised patients is increasingly reported.
The aim of this study is to describe the bacteremia occurring in solid tumors and to identify a potential association with other sites of infection.
Materials and Methods: This retrospective study was conducted in patients visiting an emergency oncology department for acute onset symptoms. Urinary, skin and/or sputum samples were analyzed according to clinical symptoms. Central venous catheter infection (CVC) was defined with the differential time to positivity between hub-blood and peripheral-blood cultures.
Results: We reported 290 bacteremia, Gram-positive represented 58%: coagulase-negative staphylococci (CNS) (n = 105), *Staphylococcus aureus* (SA) (n = 38) (one methicillin-resistant), *Streptococcus* sp (n = 36). The majority of gram-negative were Enterobacteria (E) (n = 97) and most of them were *E coli* (n = 62). Only 2 (*E coli*) developed extended spectrum beta-lactamases resistance. Two ore more microorganisms were found in 41 bacteremia.
When CNS, SA and *Candida* sp were isolated it was most often related to CVC, and, 25/98 of E bacteremia were also attributed to a catheter infection.
It is important to highlight that all the bacteremia were associated with another site of infection.
Conclusion: In patients with solid tumors without the context of neutropenia, all the bacteremias are associated with documented sites of infection. Bacteria resistance is the exception (1%), 58% of the bacteremia are Gram-positive microorganisms and catheter infection could be with Enterobacteria microorganisms.
No conflict of interest.

1390 POSTER

Real-world hypertension (HTN) adverse events (AEs), interventions and outcomes in bevacizumab (BV) − treated patients

C. Chen[1], G.P. Hess[1], E. Yu[2], A. Ravelo[2], K. Look[2]. *[1]IMS Health, Plymouth Meeting PA, USA; [2]Genentech, South San Francisco, USA*

Background: HTN is one of the most common AE associated with BV. In clinical trials, the incidence of NCI CTCAE Grade 3 or 4 HTN ranged from 5−18%. Utilizing US clinical practice data, this study aimed to understand the occurrence of HTN AE, interventions and outcomes in cancer patients receiving BV.
Methods: Adult patients with select cancer types including mCRC, NSCLC, mBC, OC and other indications who initiated BV between 2007 and 2011 were identified from the IMS US Oncology Electronic Medical Record database. Patients were followed for 12 months post initial administration of BV for the occurrence of HTN events, defined as either elevated/suboptimal blood pressure (BP) readings, HTN related diagnosis, or use of antihypertensive medications. Post AE interventions, including BV treatment modification and/or HTN treatments, as well as HTN outcomes were evaluated.
Results: Final sample consisted of 3,850 adult cancer patients; median age was 61 years and 62.9% were female. The top four cancer types–mCRC (43.8%), non-squamous NSCLC (26.4%), mBC (23.6%), OC (4.6%)-- accounted for almost all study patients, and most were stage III or IV. Baseline HTN were observed in 37.7% (n = 1,453) of patients; most of them (90.3%, n = 1312) did not have an exacerbation during the 12-month follow-up. Overall, 21.1% (n = 811) of patients had either newly developed HTN (n = 670; 28.0% of patients without baseline HTN) or exacerbated HTN (n = 141; 9.7% of patients with baseline HTN). 54.4% (365/670) of patients with newly developed HTN and 34.8% (n = 49/141) of patients with exacerbated HTN were grade 3 or 4. The majority continued BV post AE; only 9.6% had a BV dose reduction, 3.3% had a dose withheld and 18.9% discontinued BV. HTN medications (new or addition to existing) were prescribed for 58.8% of the AE patients (n = 477); diuretics or ACEI were most commonly prescribed. BV modification and HTN treatments mostly occurred within 2 weeks of each other (92.5%). Among approximately half

of the HTN AE patients (n = 406) with known HTN status before the end of follow-up, 92.3% (n = 375) had HTN resolved within 45 days; only 7.6% (31 patients) were confirmed to have persistent HTN.
Conclusions: Results of this real-world study suggest that after BV treatment, HTN AE occurred in 9.7% of patients with baseline HTN and 28.0% of patients with normal baseline blood pressure. In most cases, the AE is manageable without causing significant interruptions to BV treatment in patients.

1391 POSTER

Osteonecrosis of the jaw (ONJ) in patients with renal cell cancer (RCC) treated with bisphosphonates and sunitinib or other biological agents: Characteristics of 39 cases in a multicenter survey

V. Fusco[1], C. Porta[2], A. Bedogni[3], G. Saia[4], M. Scoletta[5], R. Bonacina[6], P. Vescovi[7], S. Lo Re[8], G. Campisi[9]. [1]*Ospedale Santi Antonio e Biagio, Medical Oncology, Alessandria, Italy;* [2]*IRCCS San Matteo University Hospital Foundation, Medical Oncology, Pavia, Italy;* [3]*Verona University, Maxillofacial Surgery, Verona, Italy;* [4]*Padua University, Maxillofacial Surgery, Padua, Italy;* [5]*Turin University, Oral Surgery, Turin, Italy;* [6]*Ospedale Papa Giovanni XXIII, Dentistry Dept., Bergamo, Italy;* [7]*Parma University, Oral Medicine, Parma, Italy;* [8]*Ospedale di Pordenone, Medical Oncology, Pordenone, Italy;* [9]*Palermo University, Oral Medicine, Palermo, Italy*

Background: Up to 35% of advanced renal cell cancer (RCC) develop bone metasteses and are often treated with Bisphosphonates (BPs), mainly Zoledronic Acid. Osteonecrosis of Jaw (ONJ) is a complication of BP treatment, but it was rarely reported in RCC patients in first years of ONJ observation (2003–2006). Recent studies reported that angiogenesis suppression may play a role in increasing risk of BP-related ONJ. On the other hand, treatment and prognosis of most metastatic RCC patients have improved thanks to availability of 7 novel agents: one anti-VEGF monoclonal antibody (Bevacizumab), 4 Tyrosine Kinase Inhibitors (TKIs), i.e.Sorafenib, Sunitinib, Pazopanib and Axitinib, and 2 mTOR inhibitors, i.e.Temsirolimus and Everolimus. Recently sporadic ONJ cases have been reported in RCC patients receiving both BPs and biological agents, and even Sunitinb alone. An interaction between BPs and biological agents towards an increased ONJ risk has been suggested, underlined by EMA (European Medical Agency) alerts.
Materials and Methods: Three Medical Oncology units and 5 referral Oral Medicine and Surgery centres in Italy were asked to look for cases of ONJ in RCC patients in their database. Collected characteristics: age; sex; BP treatment (type and duration at ONJ diagnosis time); biological agent treatment ongoing at ONJ diagnosis time, its duration, and eventual other targeted therapy administered in the past; basic data about ONJ (site, ONJ risk factors or triggers).
Results: Charts of 39 ONJ patients have been found, treated with BPs (34 receiving Zoledronic Acid only, 1 Ibandronate, 2 Pamidronate, 2 switching from Pamidronate to Zoledronic Acid) and biological agents (27 Sunitinib, 3 Sorafenib, 1 Bevacizumab, 1 Deforolimus, 7 two or more of these agents in sequence) at time of ONJ diagnosis. Patients' characteristics: 32 males/7 females; median age 62 years (range 45−85). BP treatment duration at ONJ onset: median 12 months (range 1−48). Latest biological treatement was Sunitinib on 34/39 cases (87%). Treatment duration of latest biological agent at ONJ onset: median 8 months (range 1−26). Site of ONJ: 20 in mandible, 14 in maxilla, 4 in both (1 unspecified). Possible risk factors or precipitating events (teeth extraction, oral surgery, dental implants, ill-fitting denture, infections, etc.) have been reported on 28/39 cases (72%).
Conclusions: At our best knowledge, only 16 similar ONJ cases in RCC patients have been reported in recent medical literature as case reports worldwide. Furtherly, 5 ONJ cases among 21 patients were recorded by Bozas et al (ASCO 2011) and 5 out of 49 patients by Beuselinck et al (BJC 2012), with high ONJ cumulative hazard after 24 months of treatment with BPs and TKIs. The unexpectedly high number of cases collected in our survey (39 ONJ cases in 8 Italian centers) suggests that ONJ incidence in RCC patients could be largely underestimated in literature and seems to confirm a potential role of antiangiogenic agents and other biological agents in increasing ONJ risk in RCC patients treated with Bisphosphonates.

1392 POSTER

First comparison of biosimilar epoetin alfa and darbepoetin alfa for the treatment of chemotherapy-induced anaemia

A. Lorenz[1], O. Heine[2]. [1]*Private Practice for Gynaecological Oncolgy, Hidburghausen, Germany;* [2]*Private Practice, Private Practice, Suhl, Germany*

Background: A biosimilar epoetin alfa (Binocrit®) was approved in 2007 for the treatment of chemotherapy-induced anaemia (CIA). There is currently little, if any, comparative data on the relative effectiveness of this biosimilar epoetin alfa and darbepoetin alfa in this setting.
Patients and Methods: This was a retrospective, matched-cohort analysis of patients from a single centre with solid tumours and CIA. Patients were treated with biosimilar epoetin alfa 40,000 IU once weekly (n = 95) or darbepoetin alfa 500 μg once every 3 weeks (n = 50), with the aim of achieving a haemoglobin (Hb) level of 12 g/dL. For this analysis, both treatments were assessed against several parameters, including Hb outcomes and red blood cell (RBC) transfusion requirements.
Results: The two cohorts were well matched in terms of tumour type (85% and 81% in the biosimilar epoetin alfa and darbepoetin group, respectively, were patients with breast cancer) and chemotherapy received (>50% in each group received one of the following regimens; docetaxel/adriamycin/cyclophosphamide [TAC] and 5-fluorouracil/doxorubicin/cyclophosphamide [FEC] with or without docetaxel). All patients received concomitant oral iron. Mean (SD) Hb level before erythropoiesis-stimulating agent (ESA) treatment was 9.85 (0.57) g/dL in the biosimilar epoetin alfa group and 9.92 (0.62) g/dL in the darbepoetin group. The mean maximum Hb achieved was 11.91 and 11.93 g/dL in the biosimilar epoetin alfa and darbepoetin group, respectively. The median time to achieve a Hb increase >1 g/dL was 2 weeks in both groups, and median time to achieve an increase >2 g/dL was 4 weeks in both groups. Four patients (4.2%) in the biosimilar epoetin alfa group and 3 (6%) in the darbepoetin group underwent RBC transfusion during their period of ESA therapy. No adverse events were recorded in either group.
Conclusions: The ability of biosimilar ESAs to effectively and safely treat CIA is the subject of debate. These data indicate the real-life clinical effectiveness and safety of managing CIA with biosimilar epoetin alfa (Binocrit®). Once-weekly treatment with this agent appears to be as effective as darbepoetin once every 3 weeks for raising Hb levels and transfusion avoidance in patients with solid tumours and CIA.
No conflict of interest.

1393 POSTER

Utility of 2D-speckle tracking echocardiography in diagnosis of left ventricular dysfunction in anti-ErbB2 therapy

N. Maurea[1], C. Coppola[1], G. Piscopo[1], C. Cipresso[1], D. Rea[2], C. Maurea[1], E. Esposito[3], C. Arra[2], C.G. Tocchetti[1], I. Capasso[3]. [1]*National Cancer Institute Fondazione G. Pascale, Division of Cardiology, Naples, Italy;* [2]*National Cancer Institute Fondazione G. Pascale, Animal Facility, Naples, Italy;* [3]*National Cancer Institute Fondazione G. Pascale, Division of Breast Oncology, Naples, Italy*

Background: ErbB2 is overexpressed in about 25% of breast cancers; in the heart, it modulates myocardial development and function. Trastuzumab (T), an anti-ErbB2 inhibitor, has improved the prognosis of patients with breast cancer, but is related to an increased risk of asymptomatic left ventricular (LV) dysfunction (3−34%) and heart failure (2−4%). Conventional measures of ventricular function, such as fractional shortening (FS) and ejection fraction (FE) are insensitive in detecting early cardiomyopathy induced by antineoplastic therapy.
Here, we aim at assessing whether myocardial strain by 2D-speckle tracking (ST) is able to identify early LV dysfunction in mice treated with doxorubicin (D) and T, alone or in combination (D+T) and to relate data of cardiac function with tissue alterations.
Material and Methods: Cardiac function was measured with FS, by M-mode echocardiography, and with radial myocardial strain with ST in sedated C57BL/6 mice (8−10 wk old) at time 0, 2 and 6 days of daily administration of D (2.17 mg/kg/day), T (2.25 mg/kg/day), D+T (2.17 mg/kg/day + 2.25 mg/kg/day, respectively) and in a control group. In excised hearts, we evaluated TNFα and CD68 by immunohistochemistry; interstizial fibrosis was analyzed with picrosirius red staining.
Results: FS was reduced in group D and D+T at 2 days (52±0.2% and 49±2% respectively), both $p < 0.001$ vs 60±0.4% (sham), while in group T it decreased only at 6 days (49±1.5% vs 60±0.5%, $p = 0.002$). In contrast, after 2 days, myocardial strain was already reduced not only in D and D+T, but also in T alone: 43±3%, 49±1%, and 44±7%, respectively, all $p < 0.05$ vs sham (66±0.6%). Cardiotoxicity was associated with significant alterations in extracellular matrix remodeling as confirmed by an increase of interstizial collagen with D (4.56%), T (2.17%) and D+T (3.77%) at 6

days $p < 0.05$ vs sham (1.17%) and by increased cardiac inflammation, in fact the myocytes were positive for TNFα and CD68 cells/mm^2 at 6 days in group D (16.46% and 155 respectively), in group T+D (12.35% and 74.16) and in group T (5.65% and 72.32) $p < 0.01$ vs sham (0.56% and 2.3).
Conclusions: Myocardial strain identifies LV systolic dysfunction earlier than conventional echocardiography and can be a useful tool to predict cardiotoxicity in this setting.
No conflict of interest.

1394 POSTER

Is there any role of intravenous iron for the treatment of anemia in patients with cancer?

C. Gemici[1], O. Yetmen[1], G. Yaprak[1], H. Tepetam[1], A. Mayadagli[1]. *[1]S.B. Kartal Egitim ve Arastirma Hastanesi, Oncology, Istanbul, Turkey*

Background: Anemia is a major cause of morbidity in cancer patients resulting in poor physical performance, prognosis and therapy outcome. Anemia causing clinical symptoms is characterized as a decline of haemoglobin (Hb) below 12 g/dL. The incidence of anemia in initial diagnosis of cancer is about 50% or more, depending on the type and stage of disease. Iron deficiency as a cause of anemia in oncology can be considered under two main headings, those of reduced iron intake and those of increased iron loss. The aim of this study is to evaluate the effect of intravenous (IV) iron treatment on anemia, blood transfusion rates and survival.
Material and Methods: Anemia is defined by World Health Organization criteria; Hb <12 g/dL in women and <13 g/dL in men, and Iron deficiency was defined as serum ferritin <20 μg/dL. The medical records of 34 patients who had IV iron treatment between January 2008 and October 2012 were reviewed. Of these patients, 11 had metastatic disease receiving palliative treatment while 23 had localized disease receiving adjuvant treatment. Patients with haemoglobin levels between 9 and 10 mg/dL, without anemia symptoms undergoing treatment either with chemotherapy, radiotherapy or both were administered IV iron infusion (100 mg IV iron sucrose in 100 mL of saline solution, in 30 minutes, 5 times in 10 days). All patients were followed regularly by physical examination, complete blood count, serum ferritin and serum iron levels one month after the end of IV iron administration and at every 3 months subsequently. The profile of anemia over 24 months of follow-up was analyzed.
Results: Median age was 57 (range 24−81), 58.8% were female and 25.6% had gastrointestinal cancers. Median follow-up period was 19.5 months. Initial median serum hemoglobin, serum ferritin and serum iron levels were 9.2 g/dL, 63 μg/ml and 30 ng/dL respectively. All patients received IV iron as described above during their planned treatment. Median serum hemoglobin, serum ferritin and serum iron levels 1 to 3 months after intravenous iron treatment were 10.7 g/dL, 259 μg/mL and 63 ng/dL, respectively. During 6 to 12 months of follow up, median serum hemoglobin was 11.4 g/dL, serum ferritin was 138 μg/ml and serum iron was 52 ng/dL. At the end of the follow-up period, only 9 patients needed blood transfusion. In this study, IV iron increased serum hemoglobin, serum ferritin and serum iron levels with decreased necessity of blood transfusion.
Conclusions: IV iron is efficacious and effective for the treatment of anemia in cancer patients under treatment either with chemotherapy, radiotherapy or both. Increase of hemoglobin by IV iron administration is cheap and safe and it may prevent blood transfusion and associated complications.
No conflict of interest.

1395 POSTER

Comparison of the effect of filgrastim vs. lenograstim started during febrile neutropenia attack in patients with solid tumors

O. Uysal Sonmez[1], E. Guclu[2], I. Turker[3], U. Uyeturk[4], O. Bal[3], B. Budakoglu[3], U. Yalcintas Arslan[3], O. Karabay[2], B. Oksuzoglu[3]. *[1]Sakarya University Faculty of Medicine, Department of Medical Oncology, Sakarya, Turkey; [2]Sakarya University Faculty of Medicine, Department of Clinical Microbiology, Sakarya, Turkey; [3]Ankara Dr.A.Y.Oncology Training and Research Hospital, Department of Medical Oncology, Ankara, Turkey; [4]Abant Izzet Baysal University Faculty of Medicine, Department of Medical Oncology, Bolu, Turkey*

Background: Chemotherapy induced Febrile neutropenia (FN) in solid tumors causes mortality and morbidity at a significant rate. In this study, we aimed to compare the effects of filgrastim or lenograstim started with the first dose of antibiotics in patients diagnosed with FN.
Patients and Methods: Between february 2009 and May 2012, one hundred and fifty one patients diagnosed with FN were evaluated retrospectively. Patient's characteristics and other data were collected from patient files. Febrile neutropenia was defined as the number of a single body temperature equal or greater to 38.3ºC measured from mouth or a constant body temperature with equal or greater to 38.0ºC in one hour period in patient with neutropenia which has an absolute neutrofil count less than 500/mm^3. Whenever febrile neutropenia was defined antibiotics to gether with granocyte colony stimulating factors(GCSF) either filgrastim or lenograstim started in 30 minutes.
Results: In this study 175 febrile neutropenia attacks in 151 patients were examined. Seventy three of the patients were male and 78 of them were women. The median age was 53.6 and 53.6 in male and females respectively. The most common solid tumor was breast carcinoma in 38 (25%) patients. One hundres and five FN patients (58%) were patients who received GCSF as primary propylaxis. Demographic characteristics and laboratory findings of patients given Filgrastim and Lenogastrim are represented in Table 1.

Table 1. The characteristics of cases according to the type of GSCF given during febrile neutropenia attack

	Filgrastim use (n = 131)	Lenogastrim use n = 44	P value
Number of cases (M/F)	65/66	21/23	0.82
Age	52.45±15.54	53.13± 17.05	0.76
Days with fever (Mean±SD)	2.27±1.63	2.73±2.40	0.44
Comorbid illness (Y/V)	75/56	23/21	0.56
Number of days in hospital (Mean)	7.79±5.93	7.75±4.63	0.42
Recovery day from neutropenia (Mean)	3.31±1.55	4.00 ±1.79	**0.02**
Number of days given GSCF in hospitalization (Mean)	4.31±2.02	5.46±2.36	**0.002**
Duration of antibiotic treatment (Mean)	7.36 ±5.10	7.66±4.85	0.45

Conclusion: Compared to lenograstim filgrastim shortens the duration of hospitalization time during FN attack by correcting neutropenia faster in solid tumors.

Evaluation of sleep disorders in cancer patients with Pittsburgh Sleep Quality Index

T. Akman[1], T. Yavuzsen[2], Z. Sevgen[3], H. Ellidokuz[4], U.G.U.R. Yilmaz[2]. *[1]Dokuz Eylul University Medical School, Alsancak/Izmir, Turkey; [2]Dokuz Eylul University Medical School, Medical Oncology, Alsancak/Izmir, Turkey; [3]Dokuz Eylul University Medical School, Internal Medicine, Alsancak/Izmir, Turkey; [4]Okuz Eylul University Medical School, Preventive Oncology, Alsancak/Izmir, Turkey*

Background: The estimated prevalence of insomnia in cancer patients varies between 23% and 61%. Insomnia, poor sleep quality, short sleep durations are the most common problems seen in cancer patients. In Turkey, there are not enough studies about sleep disorders of cancer patients and more studies are needed. In our study we aimed to investigate the frequency of sleep disorders and the effects of these problems to the quality of life in cancer patients.
Material and Methods: 314 patients receiving chemotherapy for cancer are involved in our study. After getting informed consent from the patients Pittsburgh Sleep Quality Index (PSQI) was administered as a self-report instrument.
Results: The median age for women was 54.8 while for men the median age was 61.8. 53.2% of patients were female, and 46.8% were male. 33.8% of patients had gastrointestinal system malignancies 22.6% had breast cancer, 21.7% had lung cancer, 8.3% had gynecological and 13.7% had other type of malignancies. From the Psychometric evaluation of the Turkish version of the Pittsburgh Sleep Quality Index (PSQI) in cancer patients, 127 (40.4%) had patients had global PSQI scores >5, indicating poor sleep quality. There were no statistically significant difference in PSQI scores between patients according to sexuality, marital status, stage and chemotherapy type ($p > 0.05$). when PSQI was evaluated according to metastatasis regions the patients with bone and visseral metastasis had more lower PSQI scores (p:0.006). In patients with ECOG scores 3 or more had lower PSQI scores (p: 0.02).
Conclusion: PSQI is short,easy to administer, and has well established validity and reliability. This questionnaire may be used to evaluate the sleep disorders in cancer patients. It is important to determine the sleep disorders in cancer patients and the effect of insomnia to patients'quality of life.

Epidemiological characteristics of febrile neutropenia in medical oncology unit: Torrecardenas Hospital experience

V.E. Castellon Rubio[1], A. Lazo Torres[2], M.A. Esteban Moreno[2], B. Medina Magan[1], F.E. Rosillo Fernandez[1], A. Martinez Guisado[1], P. Reche Molina[1], A. Fernandez Freire-Leal[1], P. Carrillo Ramos[1], L.G. Canosa Ruiz[1]. *[1]Hospital Torrecardenas, Oncology Service, Almeria, Spain; [2]Hospital Torrecardenas, Internal Medicine Service, Almeria, Spain*

Background: Febrile neutropenia (FN) in cancer patients is among the most serious complications related to chemotherapy. In patients with febrile neutropenia are treated with empirical antibiotics until the absolute neutrophil count (ANC) has recovered and the fever has abated. The aim of this study was to analyze the characteristics and infectious complications of neutropenic patients in a referral hospital.
Material and Methods: We retrospectively reviewed 51 patients (pts) diagnosed with febrile neutropenia of Torrecardenas Hospital between January and December 2012. We analyzed: age, sex, neutrophil count, daily living abilities of patients with ECOG performance status (Eastern Cooperative Oncology Group), type of neoplasic, chemotherapy and evolution. We also analyzed the microbiological variables.
Results: The following variables were studied: age 58±13 years, sex 19 males (34%) and 36 females (66%). ECOG performance status: 0 (24 patients: 43.6%), 1 (17 patients: 30.9%), 2 (8 patients: 14.5%), 3 (6 patients: 10.9%). We analyzed the neoplasia type: breast in 25 patients (45.5%), lung in 13 patients (23.6%), gastric in 6 patients (10.9%) and other (ovarian, prostate and pancreas cancer) in 9 patients (16%). Nine (17.5%) had an ANC less 100 cells/mm(3), 12 (23%) one between 100–300 cells/mm(3) and 30 (58%) an ANC greater than 300 cells/mm(3). Thirty five (70%) patients showed ANC recovery in 1−3 days, and 16 (30%) within 4−7 days. The overall mortality was 2 (3.6%) patients. 69.1% (38 patients) received adjuvant chemotherapy. 90% received granulocyte colony stimulating factors (GCSF). Blood cultures were performed in all patients. Only two blood cultures were postive (with methicillin-susceptible staphylococcus aureus). The source of the feber were found in 8 patients: urinary in 2 patients, lung in 3 and abdominal in 3. The most used antimicrobial agents were cefepime and amikacine (65%). 47.3% of patients received antibiotics at discharge (combinations with: fluoroquinolones + amoxicillin clavulanate).
Conclusions: The use of intravenous antibiotics, in addition to GCSF, in treatment of patients with chemotherapy induced febrile neutropenia accelerates neutrophil recovery, and shortens antibiotic therapy and hospitalization.
No conflict of interest.

Dutch multidisciplinary evidence-based guideline 'Malnutrition in patients with cancer'

S. Beijer[1], J. Vogel[2], H. Jager-Wittenaar[3], N. Doornink[4], J. Chua-Hendriks[5], E. Kampman[6], J. Van Esch[7], J.J. Van Binsbergen[8], M.C.C.M. Hulshof[9], A. De Graeff[10]. *[1]Comprehensive Cancer Centre South, Research Department, Eindhoven, Netherlands; [2]Institute Verbeeten, Department of Dietetics, Tilburg, Netherlands; [3]Hanze University of Applied Sciences, Research and Innovation Group in Healthcare and Nursing, Groningen, Netherlands; [4]Academic Medical Centre Amsterdam, Department of Dietetics, Amsterdam, Netherlands; [5]Leiden University Medical Center, Expert Nurse Oncology, Leiden, Netherlands; [6]Wageningen University, Division of Human Nutrition, Wageningen, Netherlands; [7]Laurens Nursing and Reactivation Centre, Location Antonius IJsselmonde, Rotterdam, Netherlands; [8]Radboud University Medical Centre, Department of Primary Care, Nijmegen, Netherlands; [9]Academic Medical Centre Amsterdam, Department of Radiotherapy, Amsterdam, Netherlands; [10]University Medical Center Utrecht, Department of Medical Oncology, Utrecht, Netherlands*

Background: Malnutrition is highly prevalent in patients with cancer, however, a multidisciplinary evidence-based guideline was not available in the Netherlands. Therefore, the aim of this project was to formulate evidence based recommendations for daily practice to support optimal nutritional care.
Material and Methods: With an inventory among patients and professional care givers, the most important bottlenecks concerning malnutrition and cancer were selected. A multidisciplinary expert group was initiated consisting of an oncologist, surgeon, radiation oncologist, general practitioner, nursing home physician, patient, oncology nurses, oncology dieticians, epidemiologist and with process management of IKNL (Cancer Center the Netherlands). Seven research questions were formulated using the PICO method (P=population; I=intervention; C=control group; O=outcome). Thereafter, a systematic literature search was performed in Pubmed, Embase and Cinahl for the period 1995 till 2010. All articles were evaluated on methodological quality and summarized in evidence tables. The recommendations where formulated using the EBGD method.
Results: From the 5250 articles found in the literature search, 320 were used to answer the research questions. For the following topics the multidisciplinairy guideline describes recommendations for daily practice based on the conclusions from the literature and considerations of the expert group.
1. The definition of malnutrition in patients with cancer and the determination of malnutrition.
2. The consequences of malnutrition.
3. The value of early screening of malnutrition and the preferential screeninginstrument.
4. The increase of requirements for energy, protein and other nutrients in cancer?
5. The effect of nutritional counseling and oral nutritional supplements on malnutrition.
6. The effect of enteral and parenteral nutrition on malnutrition during surgery, radiotherapy, chemotherapy and in the palliative stage of disease.
7. The effect of pharmacological interventions on malnutrition in patients with cancer.

Conclusion: The Dutch multidisciplinary evidence-based guideline 'Malnutrition in patients with cancer' describes the definition, prevalence and consequences of malnutrition in patients with cancer and provides recommendations for the diagnosis, early detection (nutritional screening) and interventions which can be used to treat malnutrition. This guideline is being implemented in clinical practice of all professionals dealing with malnutrition in cancer patients.
No conflict of interest.

1399 POSTER

Safe omission of blood test prior to day 8 dose of oral vinorelbine

M. Akhtar[1], P. Calvert[1], M. O'Connor[1], A. Horgan[1], E. Jordan[1], A. Kinneally[1]. *[1]Waterford Regional Hospital, Medical Oncology, Waterford, Ireland*

Background: Vinorelbine is a standard treatment for non small cell lung cancer (NSCLC) and advanced breast cancer (ABC). The main dose limiting toxicity is neutropenia and a blood test is recommended prior to each administration. However the incidence of neutropenia detected following a blood test is not known. In addition, the test requires resource on the day ward and incurs laboratory and transport costs, as well as putting pressure on peripheral veins. As most of the patients receiving vinorelbine are being treated in the palliative setting, it is important to minimise any impact on quality of life. We perceived a low incidence of dose delays and haematological toxicity with vinorelbine so initiated an audit of day 8 blood tests and their consequences, with a view to omission.
Methods: Retrospective review of chemotherapy charts/laboratory results of all patients receiving vinorelbine at the hospital between January 2012 to February 2013. Further patients number until August 2013 will be evaluated and included at the time of presentation.
Results: Twenty-five were identified who received vinorelbine in the selected time frame. Seven patients were male and 18 were female with an age range 39 to 82 years. Thirteen patients were receiving vinorelbine for NSCLC and 12 for advanced breast cancer; 13 received vinorelbine as a 1st line treatment, 5 as 2nd line and 7 as 3rd line. 16 patients received vinorelbine in the oral form and 9 as iv.
Vinorelbine was scheduled 121 times and was deferred on 10 (8.3%) occasions, with only 3 delays due to neutropenia. The absolute neutrophil count was found to be below 1 000/mm (grade 3)on five occasions; however vinorelbine was given on time for two of these following careful clinical assessment.
Conclusion: Our data shows that in 121 cycles of treatment, deferment due to neutropenia was only required on three occasions. On the basis of a low incidence of dose delays and haematological toxicity we plan to initiate a local policy of omitting the day 8 blood test in selected patients. There are five published audits looking at the value of a day 8 blood test with vinorelbine. They have generally concluded that the blood test can be omitted provided that patients are reviewed by an oncologist before a day 1 dose, and undergo a telephone assessment by the Oncology nurse specialist before a day 8 dose. We believe our results will support this recommendation.

Discrepancies in cancer incidence and mortality and its relation to health expenditure among the 27 European Union member states

F. Ades[1], C. Senterre[2], E. De Azambuja[1], R. Sullivan[3], R. Popescu[4], F. Parent[2], M. Piccart[1]. [1]*Institut Jules Bordet, Breast Unit, Brussels, Belgium;* [2]*Universite Libre de Bruxelles, School of Public Health, Brussels, Belgium;* [3]*Kings Health Partners Integrated Cancer Centre, Institute of Cancer Policy, London, United Kingdom;* [4]*Hirslanden Clinic Aarau, Department of Medical Oncology, Aarau, Switzerland*

Background: The European Union (EU) is a political and economic confederation composed by 27 member states (EU-27). EU-27 has established a common market by standardized systems of laws, common policies on trade and legislation in justice and home affairs. The EU-27 is not in charge of promoting health care, this is responsibility of the national governments nevertheless, the Charter of Fundamental Rights of the EU states in article 35, that 'A high level of human health protection shall be ensured.' We aim to evaluate the EU-27 health expenditure and its relation to cancer incidence and mortality.
Material and Methods: This is a descriptive study based on data extracted from the World Health Organization, the International Monetary Fund and the World Bank databanks. To visualize the potential links between cancer indicators and the health expenditure descriptive scatter plots were made. For approximate health expenditures, we have examined countries' population, total and per capita gross domestic product (GDP), percentage and per capita GDP allocated to health and percentage of government health reimbursement.
Results: Health expenditure is higher in Western Europe. The 'cutoff' west-east is around 2600 dollars per capita/year. Higher GDP per capita is related to higher allocation of GDP in health. In both blocks the national governments reimbursed most health expenses. West Europe has higher cancer incidence and lower mortality than East Europe. This discrepancy is more marked in breast cancer.
Conclusion: The 27 EU member states seem to be compliant with article 35 as most of the health costs are reimbursed by the national governments. Higher health expenditure is related to increased cancer incidence and reduced cancer mortality. Although cause-effect cannot be established through this data this is a rational association. We are conducting further studies exploring the relationship of national drug usage with cancer indicators.
No conflict of interest.

State of oncology 2013

P. Boyle[1], R. Sullivan[2], C. Zielinski[3], O.W. Brawley[4]. [1]*International Prevention Research Institute, Lyon, France;* [2]*Kings Health Partners Integrated Cancer Centre, London, United Kingdom;* [3]*Medical University Vienna, Department of Medicine I and Comprehensive Cancer Center, Vienna, Austria;* [4]*American Cancer Society, Atlanta, USA*

Background: The world is facing a developing epidemic of cancer due to the growth and ageing of the world's population coupled with a rapidly increasing incidence and prevalence in many countries which are in formerly lower income regions of the world. This presents serious challenges to provide therapy for patients in countries where income is very modest and spending on health is low. It is also timely since science is starting out in a new era where personalised medicine offers great hope of improving cancer outcome.
Methods: We invited experts to provide brief descriptions of the state-of-the-art of Oncology, from the Clinical, Scientific and patient perspective, as background. We invoked the assistance of experts from many parts of the world to describe the current state of oncology in their region (David Khayat (Europe), Murat Tuncer (North Africa and Middle East), Clement Adebamowo (sub-saharan Africa), Yi-Xin Zeng (South-east Asia), Nise Yamaguchi (Latin America), Fadlo Khuri (North America) and Robert Thomas (Australasia).
Results: Cancer is important from many perspectives particularly for patients and their families. The economic importance cannot be under-estimated. In high-resource countries, while more of the global health budget is spent on vascular disease, one case of cancer costs, on average, more than one case of vascular disease or any other disease. There has been great progress made in treating and curing cancer patients in recent decades. There have been magnificent success stories such as in the treatment of Testicular Cancer, Breast Cancer, GIST tumours and chronic myeloid leukaemia where cure has been established for many patients. Importantly, due to advances in treating and improving survival in advanced disease, there are more and more people with advanced cancer who are living longer and longer with a good quality of life. Unfortunately, many of these advances have not been transferred to cancer patients in many parts of the world.
Conclusions: Not every patient with treatable and curable disease has been able to benefit from such successful treatments as indicated above. These disparities in cancer care, and hence cancer outcome, are increasingly apparent and increasingly unacceptable in modern society. Providing rapid diagnosis and effective treatment at affordable costs for all cancer patients in the world is a major challenge for everyone involved in Oncology.
No conflict of interest.

A meta-analysis on breast and colorectal cancer in diabetic patients: Higher incidences and mortality rates

K. De Bruijn[1], L.R. Arends[2], B.E. Hansen[3], S. Leeflang[4], R. Ruiter[5], C.H.J. Van Eijck[1]. [1]*Erasmus University Medical Center, Department of Surgery, Rotterdam, Netherlands;* [2]*Erasmus University Rotterdam, Department of Biostatistics, Rotterdam, Netherlands;* [3]*Erasmus University Medical Center Rotterdam, Department of Gastroenterology & Hepatology, Rotterdam, Netherlands;* [4]*Jeroen Bosch Hospital, Department of Surgery, Den Bosch, Netherlands;* [5]*Erasmus University Medical Center, Department of Epidemiology, Rotterdam, Netherlands*

Background: Obesity and subsequent diabetes mellitus (DM) are major public health challenges. There is increasing evidence of an association between diabetes and cancer incidence and mortality. Several mechanisms involved in obesity and diabetes, such as those promoting cell proliferation and decreasing apoptosis, may foster carcinogenesis. This meta-analysis provides up-to-date information on cancer incidence and cancer-specific mortality of breast cancer and colorectal carcinoma in relation to DM.
Material and Methods: We conducted a meta-analysis of Level I and II studies published after 2007. Studies were identified searching Embase, Pubmed and the Cochrane Library. We identified twenty studies from which we could extract or calculate hazard ratios (HRs) for the relation between DM and breast and colorectal cancer incidence and cancer-specific mortality.
Summary HRs were calculated using a random-effects model. Sensitivity and subgroup analyses were performed on adjustment for confounders, mode of DM assessment and follow-up time.
Results: A total of twenty studies concerning 1.930.309 patients were included. Analysis of all studies showed an overall HR of 1.23 (95% CI 1.12–1.34) for breast cancer incidence and an overall HR of 1.26 (95% CI 1.14–1.40) for colorectal cancer incidence. Regarding cancer-specific mortality the overall HR was 1.38 (95% CI 1.20–1.58) for breast cancer and 1.30 (95% CI 1.15–1.47) for colorectal cancer. Moreover, there was no evidence of publication bias and no or moderate heterogeneity among studies.
Conclusions: This up-to-date meta-analysis indicates that DM-status increases breast and colorectal cancer incidence and cancer-specific mortality. With the expected rise in numbers of obese and DM patients, awareness and prevention should be incremented. Otherwise, incidences and mortality rates of two of the most common cancers will only tend to increase.
No conflict of interest.

1403 ORAL

The effect of metformin and sulfonylurea derivatives use after colorectal cancer diagnosis on survival

M. Zanders[1], P. Vissers[2], M. Van Herk-Sukel[3], R. Ruiter[4], L. Zandwijk-Hollestein[5], H. Haak[6], R. Herings[3], B. Stricker[4], V. Lemmens[1], L. Van de Poll-Franse[1]. [1]*Eindhoven Cancer Registry, Research, Eindhoven, Netherlands;* [2]*CoRPS- Centre of Research on Psychology in Somatic Diseases, Medical and Clinical Psychology, Tilburg, Netherlands;* [3]*PHARMO Institute for Drug Outcomes Research, Research, Utrecht, Netherlands;* [4]*Erasmus MC, Epidemiology, Rotterdam, Netherlands;* [5]*Erasmus MC, Dermatology, Rotterdam, Netherlands;* [6]*Maxima Medical Centre, Internal Medicine, Eindhoven/Veldhoven, Netherlands*

Background: This observational population-based study aims to assess whether, and to which extent, the use of metformin *after* the diagnosis of colorectal cancer (CRC) is associated with an increased overall survival compared with use of sulfonylurea derivatives.
Methods: Patients with primary CRC stage I−IV diagnosed between 1998 and 2010 in the South-Eastern Netherlands were included from the Eindhoven Cancer Registry (ECR). The included patients were linked to

data on drug dispensing from the PHARMO Record Linkage system. The association between the use of metformin and overall survival in CRC patients, compared with the use of sulfonylurea derivatives, was analysed using Cox proportional hazard models, with cumulative duration of drug use as a time-varying determinant. Patients were censored at the time of start of another diabetes drug than the drug of the first prescription.
Results: In this study, 162 patients started with metformin monotherapy and 105 patients started with sulfonylurea derivatives monotherapy *after* CRC diagnosis. The use of metformin after CRC diagnosis was associated with a lower overall mortality (HR 0.39, 95% CI 0.19–0.79), compared with the use of sulfonylurea derivatives, when adjusting for patient-, tumour-, and co-medication-related variables. In CRC patients who received chemotherapy (n = 71), the use of metformin was associated with a lower overall mortality, compared with the use of sulfonylurea derivatives (HR 0.06, 95% CI 0.01–0.39). When including patients who used a first dose which was higher than the median, again a protective effect of metformin compared to sulfonylurea derivatives was seen (HR 0.14, 95% CI 0.04–0.53) and this effect was not significant in patients with a first dose which was lower-than-the-median dose (HR 0.59, 95% CI 0.22–1.57). The effect of metformin on survival was not significantly different between colon and rectal cancer patients.
Conclusions: The first results of our study showed that cumulative exposure to metformin *after* CRC diagnosis was associated with a lower overall mortality, compared with cumulative exposure to sulfonylurea derivatives *after* CRC diagnosis. This association was strongest in CRC patients who received chemotherapy as initial treatment. However, whether this association could indeed be seen as a direct effect of metformin on survival, or as an effect of confounding by indication, remains to be clarified in a larger study population.
No conflict of interest.

KBP-2010-CPHG: Characteristics of 201 new cases of non-small-cell-lung-cancer (NSCLC) with EGFR mutation

C. Locher[1], C. Neidhardt[2], M. Boutemy[3], A. Belle[4], J. Crequit[5], A.S. Blanchet-Legens[6], J.Y. Tavernier[7], F. Steenhouwer[8], H. Galloux[9], M. Grivaux[1]. *[1]General Hospital, Pneumology, Meaux, France; [2]General Hospital, Pneumology, Mulhouse, France; [3]General Hospital, Pneumology, Saint-Quentin, France; [4]General Hospital, Pneumology, Compiègne, France; [5]General Hospital, Pneumology, Creil, France; [6]General Hospital, Pneumology, Lyon, France; [7]General Hospital, Pneumology, Douai, France; [8]General Hospital, Pneumology, Roubaix, France; [9]General Hospital, Pneumology, Quimper, France*

Background: In 2010, the French College of General Hospital Respiratory Physicians (CPHG) performed KBP-2010-CPHG, a prospective, national, epidemiological study aimed to analyze all new cases of primary lung cancer.
Material and Methods: Data were collected on a standardized form for all patients ⩾18 years with primary lung cancer, histologically or cytologically diagnosed between January 1 and December 31, 2010 and managed in a general hospital.
Results: 7610 patients were enrolled in 119 centers. 7051 from 104 centers were included in the analysis. 6083 included patients had a non small cell lung cancer (NSCLC). Epidermal growth factor receptor (EGFR) mutation was explored in 2105 NSCLC patients. 201 of these patients had an activating EGFR mutation. The main characteristics of included, explored, and mutated patients are compared in the following table.

	Overall population (N = 7051)	EGFR mutation explored (N = 2105)	EGFR mutated (N = 201)
Age (years): mean±SD	65.5±11.3	63.7±11.4*	67.5±12.2**
Female: %	24.3	33.7*	67.7**
Non-smoker: %	10.9	18.4*	64.7**
Performance status 0 or 1: %	68.9	74.2*	76.4
Adenocarcinoma: %	45.4	84.6*	92.0**
Stage IV: %	60.0	70.0*	76.1
1-year mortality rate: %	56.4	53.9	33.3**

*Statistically significant as compared with non-explored patients; **Statistically significant as compared with explored and non-mutated patients.

Conclusions: In France, in 2010, an EGFR mutation was explored in about 1 of 3 patients with NSCLC and found in about 10% of explored patients. The French physicians follow the current French recommendations, exploring mainly patients with advanced adenocarcinoma. Mutated patients were mainly non-smoker women with adenocarcinoma. One-year mortality rate was significantly lower in mutated patients than in the whole population. One-year survival improvement in EGFR mutated patients needs to be further analyzed to evaluate the role of targeted therapy.
No conflict of interest.

Trends in colorectal cancer mortality and screening activities in European countries

P. Autier[1], D. Ait Ouakrim[2], M. Malvezzi[3], H. Bleiberg[4], M. Jenkins[2], M. Boniol[1], E. Negri[3]. *[1]International Prevention Research Institute, Research, Lyon, France; [2]The University of Melbourne Centre for MEGA Epidemiology, Melbourne School of Population and Global Health, Melbourne, Australia; [3]Istituto di Ricerche Farmacologiche 'Mario Negri' − IRCCS, Department of Epidemiology, Milan, Italy; [4]Jules Bordet Institute, Research, Brussels, Belgium*

Background: Randomised trials have shown that fecal-occult-blood-test (FOBT) and endoscopic examinations of the large bowel were able to decrease the risk of CRC death. We examined whether changes in CRC mortality in Europe were associated with a history of screening.
Methods: We used data collected as part of the Survey of Health, Aging, and Retirement in Europe (SHARE) project to extract information on exposure to CRC screening in subjects 50 years old or more living in 11 European countries. Distinct data were collected for endoscopy (colonoscopy or sigmoidoscopy) and FOBT. Using the WHO mortality database on causes of deaths, we fitted linear regressions from 1989 to 2010 and calculated changes in mortality for men and women living in each of the 11 countries. We used least square regression and computed R-square statistics (expressed in %) to provide estimates of the association between screening history and changes in CRC mortality.
Results: Over the 22-year period, changes in age-adjusted CRC mortality rates among males/females were −39/−47% in Austria, −34/-32% in France, −30/-44% in Germany, −26/-35% in Switzerland, −17/-23% in Italy, −14/-18% in Denmark, −10/-8% in Sweden, −4/-10% in the Netherlands, +29/-6% in Spain, and +30/+2% in Greece. In males, reports of ever having had an endoscopic examination of the large bowel ranged from 8% in Greece to 35% in Austria. For females, proportions of ever endoscopic examinations ranged from 8% in Greece to 36% in Austria. FOBT screening over the last 10 years, ranged from 4% in the Netherlands to 61% in Austria for both sexes. In males, a history of one or more endoscopic examination of the large bowel explained 73% of the decrease in CRC mortality. At least one endoscopy or FOBT over the past 10 years explained 54 and 53% of the observed decrease in CRC mortality, respectively. In females, a history of one or more endoscopic examination of the large bowel explained 82% of the decrease in CRC mortality. At least one endoscopic or FOBT over the past 10 years explained 89 and 72% of the decrease, respectively. All R-squares had an associated p value <0.001.
Conclusions: Changes in CRC mortality are correlated with the level of screening uptake. This provides evidence of the effectiveness of screening to prevent CRC mortality in the general population and a strong rationale for current national CRC screening programmes.

Spanish familial pancreatic cancer registry: genomic analysis of affected individuals and screening of high-risk individuals

C. Guillen-Ponce[1], E. Mocci[1], J. Earl[1], C. Gonzalez[2], E. Vazquez[3], A. Sanjuanbenito[4], C. González[5], F.X. Real[6], N. Malats[7], A. Carrato[1]. *[1]Ramon y Cajal University Hospital, Medical Oncology, Madrid, Spain; [2]Ramon y Cajal University Hospital, Radiology Department, Madrid, Spain; [3]Ramon y Cajal University Hospital, Digestive Department, Madrid, Spain; [4]Ramon y Cajal University Hospital, General and Digestive Surgery Department, Madrid, Spain; [5]Ramon y Cajal University Hospital, Pathology Department, Madrid, Spain; [6]CNIO, Epithelial Carcinogenesis, Madrid, Spain; [7]CNIO, Genetic & Molecular Epidemiology, Madrid, Spain*

Background: The prognosis of patients diagnosed with Pancreatic Cancer (PC) is dismal with a 5 year survival rate of around 5%. Familial Pancreatic Cancer (FPC) is an autosomal dominant rare syndrome defined as families with two or more first-degree rela-tives with pancreatic cancer that do not fulfill the cri-teria of any other inherited tumor syndrome. Approximately, 15−20% of families carry germline mutations in BRCA2, PALB2 and ATM, for the majority of families the major underlying genetic defect(s) are unknown. The Spanish familial pancreatic cancer registry, Pan-Gen-FAM

was established in 2008 in order to identify and manage families at high risk of developing PC.
Materials and Methods: The phenotype of families is studied using family history information to determine whether they present PC alone or in combination with other cancer syndromes and this data is combined with genetic testing of known FPC associated genes. The main objectives of this project include the identification of novel mutations or variants that predispose to an increased risk of PC by DNA exome ultrasequencing of both tumor and germline DNA. Furthermore, we offer a clinical follow-up program of high risk individuals with a screening program for the detection of early PC lesions consisting of periodic monitoring by imaging techniques (EUS, CT and MRI) and the evaluation of minimally-invasive tumor biomarkers approaches Circulating Tumor Cells (CTC) and micro RNAs.
Results: To date the registry includes over 100 individuals representing some 33 families presenting with pancreatic cancer aggregation. BRCA2 germline mutations were detected in 4 families and BRCA1 mutations in 1 family. More pancreatic abnormalities were found by EUS (41%) than by CT (12%) or RMI (33%). The most frequent abnormal findings were parenchymal changes associated with chronic pancreatitis (hyperechoic foci, echogenic strands, lobularity, cysts, pancreatic heterogeneity). Overall 14 (39%) patients showed at least 1 of these changes. In total six cystic lesions were identified. One lesion was compatible with a mucinous tumor and another patient underwent EUS-FNA which showed benign cytology. Subsequent EUS one year later identified a well differentiated neuroendocrine tumor in one patient and a mucinous tumor in another. All patients with cystic lesions are undergoing close clinical observation. One CTC was detected is one patient, although this was consistent with the false negative detection rate of the system.
Conclusions: Since this study involves both clinical and basic scientists this means that participating individuals can benefit from a medical screening program as well as the individualized analysis of their genome for the detection of as yet undiscovered genetic determinants. Preliminary data suggest that EUS is the most sensitive method to detect small tumors and premalignant lesions.

1407 POSTER

The difference in mortality between cancer patients with and without venous thromboembolism: A systematic review and meta-analysis

S.M. Baig[1], A.J. Walker[1], M.J. Grainge[1]. *[1]University of Nottingham, Division of Epidemiology and Public Health, Nottingham, United Kingdom*

Background: The risk of developing a venous thromboembolism (VTE) is 4.7 times as high in cancer patients compared to those without cancer. Studies suggest this risk of VTE renders poorer survival in affected patients, but it is still necessary to quantitatively synthesize all available evidence on this association, of which no previous attempts have been made. This would help determine at-risk groups for whom primary prophylaxis would be of value. Thus this review will aim to establish if the mortality risk is higher in cancer patients with VTE than those without, by conducting a systematic review and meta-analysis.
Material and Methods: MEDLINE was searched to identify all relevant cohort studies which presented survival data for cancer patients with and without VTE. We included studies which presented data on all cancers together and then specifically with cancers of the breast, lung, prostate or bowel. Data were extracted using available hazard ratios if available and if not these were estimated from Kaplan–Meier plots. Random-effects meta-analyses were used to estimate pooled hazard ratios and 95% confidence intervals for the mentioned groups and a subgroup of studies where VTE was diagnosed simultaneously or after cancer diagnosis, to see how these results affected heterogeneity.

Table 1. Summary of results

	Hazard Ratio	95% Confidence Interval	I^2(%)
All Cancers	1.60	1.17, 2.17	99.8
Colorectal	1.41	1.15, 1.73	91.0
Breast	1.54	1.06, 2.24	91.9
Lung	1.58	1.23, 2.04	98.7
Prostate	1.75	1.21, 2.54	96.4
VTE after cancer	1.87	1.39, 2.51	98.6

Results: Of 1838 papers retrieved from the search strategy, 21 papers from 18 different cohorts were included in the final analysis. Twelve of these were used to generate results on the meta-analysis of 'all cancers'. Eleven of the papers were conducted in the USA, 3 in Korea, 3 in the UK, 3 in the remainder of Europe, and 1 in South America. All papers had participants with a mean age over 18, and all but three of the papers had participants exclusively over 18. Risk of death was significantly higher in 'all cancer' patients with VTE than those without (HR: 1.60; 95% CI: 1.17, 2.17; I^2: 99.8%). Significant increases in mortality risk associated with a VTE were also found for all the assessed cancer types: colorectal (HR: 1.41; 95% CI: 1.15, 1.73; I^2: 91.0%); breast (HR:1.54; 95% CI: 1.06, 2.24; I^2: 91.9%); lung (HR: 1.58; 95% CI: 1.23, 2.04; I^2: 98.7%); prostate (HR: 1.75; 95% CI: 1.21, 2.54; I^2: 96.4%). In the analysis using papers where VTE was diagnosed simultaneously or after cancer, the hazard ratio was higher than in 'all cancer' patients (HR: 1.87; 95% CI: 1.39, 2.51; I^2: 98.6%). These results are summarised in Table 1.
Conclusions: Patients diagnosed with both VTE and malignancy have a significantly increased risk of death compared to those with malignancy alone. However, high heterogeneity between included studies accompanies these results, the reasons for which offer important information about at-risk groups. This provides a basis for further research clinically relevant to primary targeted prophylaxis.

1408 POSTER

Population-based incidence, treatment and survival of patients with peritoneal metastases of unknown origin

I. Thomassen[1], R.H.A. Verhoeven[2], Y.R.B.M. Van Gestel[2], A.J. Van de Wouw[3], V.E.P.P. Lemmens[2], I.H.J.T. De Hingh[4]. *[1]Comprehensive Cancer Centre South, Eindhoven, Netherlands; [2]Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands; [3]VieCuri Medical Centre, Internal Medicine, Venlo, Netherlands; [4]Catharina Hospital, Surgery, Eindhoven, Netherlands*

Background: Until recently, peritoneal metastases (PM) were regarded as an untreatable condition, however promising treatment options are now available for patients presenting with PM from colorectal, ovarian or gastric carcinoma. Therefore, it is of increasing importance to diagnose patients presenting with PM as accurately as possible. The aim of this study was to investigate the incidence, treatment and survival of patients presenting with PM of unknown origin.
Materials and Methods: Data from patients diagnosed with PM of unknown origin during 1984–2010 were extracted from the Eindhoven Cancer Registry. European age-standardized incidence rates were calculated and data on treatment and survival were analyzed.
Results: In total 1,051 patients were diagnosed with PM of unknown origin. In 606 patients (58%) the peritoneum was the only site of metastasis, and 445 patients also had other metastases. Chemotherapy usage has increased from 8% in the earliest period to 16% in most recent years ($p = 0.016$). Median survival was extremely poor with only 42 days (95% CI 39−47 days) and did not change over time. Median survival of patients not receiving chemotherapy (36 days) was significantly worse than of those receiving chemotherapy (218 days, $p < 0.0001$).
Conclusions: The prognosis of PM of unknown origin is extremely poor, and no sign of improvement is observed over time. Given the recent progress that has been achieved in patients presenting with PM from various origins, more efforts should be undertaken in order to diagnose the origin of PM more accurately and to explore potentially effective treatment strategies in this specific category of patients.

1409 POSTER

Alcohol drinking, smoking, and risk of melanoma

A. Klatsky[1], Y. Li[2], H.N. Tran[3], M.A. Armstrong[1], N. Udaltsova[1], G.D. Friedman[1]. *[1]Kaiser Permanente Division of Research, Oakland, USA; [2]Kaiser Permanente Medical Center, Oncology, Oakland, USA; [3]Kaiser Permanente Medical Center, Medicine, Oakland, USA*

Background: Several reports suggest that risk of melanoma may be increased in alcohol drinkers and decreased in smokers.
Methods: We explored the role of alcohol drinking and smoking in a cohort of 129,917 persons. From baseline data collection in 1978−85 through 2008 melanoma was diagnosed in 1,042 persons. We utilised Cox proportional hazard models that included age, sex, race/ethnicity, marital status, education, and body mass index. Alcohol and smoking were studied categorically, with lifelong abstainers as referent.
Results: In multivariate models the hazard ratios (HR) and 95% confidence intervals (CI) for persons in the alcohol categories were: exdrinkers = 1.2 (0.8−1.8), <1 drink per day = 1.3 (1.1−1.5, $p = 0.005$), 1−2 drinks per day = 1.5 (1.2−1.8, $p < 0.001$), and $\geqslant$3 drinks per day = 1.7 (1.3−2.2, $p < 0.001$). The higher risk of drinkers was generally similar for men, women, invasive and non-invasive tumours, and persons in various baseline smoking categories (never, ex-, current), but was greater for tumours diagnosed

after 10 years (HR = 1.9, p < 0.001) than for those diagnosed within 10 years of baseline (HR = 1.3, ns) and also stronger for drinking wine than for drinking liquor or beer. The HRs (CIs) for persons in smoking categories were: exsmokers = 0.9 (0.8−1.0), <1 pack per day = 0.9 (0.7−1.1), and ⩾1 pack per day = 0.6 (0.5−0.8, p < 0.001). The inverse HR for ⩾1ppd smokers was stronger for men (HR = 0.5, p < 0.001) than for women (HR = 0.8, ns) and also for tumours diagnosed after 10 years (HR = 0.6, p < 0.001) than for those diagnosed within 10 years of baseline (HR = 0.9, ns). Among covariates the risk was higher (p < 0.001) for men vs women, whites (vs each other race), and college graduates (vs no college).
Conclusions: These data about risk of melanoma in a large population show that alcohol drinkers, especially wine drinkers, are at increased risk, while smokers, especially male smokers, are at lower risk.
No conflict of interest.

1410 POSTER

Cancer incidence in the families of children with bone and soft tissue sarcomas

R. Alston[1], A.M. Kelsey[2], S.C. Wallingford[3], J.M. Birch[4]. *[1]University of Manchester, CRUK Paediatric and Familial Cancer Research Group, Manchester, United Kingdom; [2]Central Manchester University Hospitals NHS Foundation Trust, Academic Unit of Paediatric Oncology, Manchester, United Kingdom; [3]University of Manchester, Institute of Inflammation and Repair, Manchester, United Kingdom; [4]University of Manchester, Cancer Research UK Paediatric and Familial Cancer Research Group, Manchester, United Kingdom*

Background: The aims of the study were to investigate the incidence of cancers in the relatives of children with sarcoma.
Materials and Methods: Families of children aged 0 to 14 diagnosed between 1954 and 2008 with Ewing sarcoma (EWS), osteosarcoma/chondrosarcoma or soft tissue sarcoma (STS) from the population-based Manchester Children's Tumour registry were traced. Interviews were conducted and the medical histories taken and, where possible, verified from hospital records for the grandparents of the case and their descendants. The parents and siblings were flagged for continuous notification of cancers and deaths. Expected numbers of cancers aged 0−84 years were calculated using English national cancer registration data.
Results: There were a total of 10,841 relatives among the 629 families in the study. Information was available on 95% of mothers, 91% of fathers and 76% of grandparents. There were significant excesses of cancer in the relatives of STS (observed 280, expected 248, P = 0.03) and osteosarcoma/chondrosarcoma (observed 188, expected 158, P = 0.01) but not EWS (observed 123, expected 137, P = 0.89). The excesses were confined to relatives under 60 with greater relative risk at younger ages (P<0.0001). The Osteosarcoma/Chondrosarcoma families had significant excesses of embryonal tumours (observed 6, expected 0.5, P<0.001), Central Nervous System (CNS) tumours (observed 11, expected 5.0, P = 0.01), STS (Observed 9, expected 4.2, P<0.001) and melanoma (observed 10, expected 4.0, P = 0.01). Overall, the age distribution of the cancers was younger than that expected from national cancer rates (Table 7, P<0.0001) with the embryonal (P = 0.02) and, possibly breast cancer cases (P = 0.07) and leukaemias (P = 0.06) occurring at younger ages than predicted. The STS families had excesses of STS (Observed 12, expected 3.7, P<0.001), embryonal tumours (Observed 5, expected 1.0, P = 0.003), bone tumours (Observed 4, expected 1.1, P = 0.005), stomach (observed 20, expected 10.9, P = 0.01), breast (Observed 56, expected 40.6, P = 0.01) and cervical (Observed 17, expected 7.3, P = 0.001) cancers. The breast cancers (P = 0.03) and possibly STS (P = 0.06) occurred at younger ages than expected. Families of younger STS index cases had higher relative risks of cancer than those of older index cases (P = 0.005). For the relatives of the EWS cases there was an excess of CNS tumours under the age of 60 (observed 7, expected 2.9, P = 0.03), which appeared more concentrated in children (ages 0 to 14, observed 3, expected 0.5, P = 0.02).
Conclusion: The wide range of cancers in excess in relatives of sarcoma cases imply that there may be a variety of either inherited or environmental factors involved. This has implications for both counselling, surveillance and aetiology.
No conflict of interest.

Risk of multiple primary malignancies following treatment of Hodgkin's lymphoma

A. Van Eggermond[1], M. Schaapveld[1], P. Lugtenburg[2], J.P. De Boer[3], A.D.G. Krol[4], J.M. Zijlstra[5], J.M.M. Raemaekers[6], L.C. Kremer[7], B.M.P. Aleman[8], F.E. Van Leeuwen[1]. *[1]The Netherlands Cancer Institute, Epidemiology, Amsterdam, Netherlands; [2]Erasmus MC-University Medical Center Rotterdam, Hematology, Rotterdam, Netherlands; [3]The Netherlands Cancer Institute, Hematology, Amsterdam, Netherlands; [4]Leiden University Medical Center, Radiotherapy, Leiden, Netherlands; [5]VU University Medical Center, Hematology, Amsterdam, Netherlands; [6]Radboud University Nijmegen Medical Centre, Hematology, Nijmegen, Netherlands; [7]Emma Children's Hospital/Academic Medical Center, Pediatric Oncology, Amsterdam, Netherlands; [8]The Netherlands Cancer Institute, Radiotherapy, Amsterdam, Netherlands*

Background: Patients treated for Hodgkin's lymphoma (HL) have a strongly increased risk to develop a 2nd primary malignancy, causing significant morbidity and mortality. The burden of multiple primary malignancies has, however, rarely been studied. We assessed the risk of 2nd, 3rd and subsequent malignancies in a Dutch cohort comprising 2,814 5-year HL survivors, treated before the age of 51 years between 1965–1995.
Methods: Cumulative incidence of a 3rd malignancy was estimated with death as competing event. Using recurrent event analyses, we assessed risk factors for the development of a 3rd malignancy and examined whether the risk of a 3rd malignancy is increased after a second.
Results: After a median follow-up of 22.1 years, 740 (26.3%) patients developed a 2nd primary malignancy. Median follow-up of 1-year survivors of a 2nd malignancy was 5.0 years (interquartile range 2.2–10.4). Ninety-eight patients developed a 3rd malignancy. In women, breast cancer was the most frequently observed malignancy both as a 2nd (n = 148) and as a 3rd (n = 31) malignancy. In men, lung cancer was the most frequent 2nd malignancy (n = 110), and cancer of the gastrointestinal tract the most frequent 3rd malignancy (n = 9). The 10-year cumulative incidence of any 3rd malignancy after a 2nd malignancy was 15.6% (95% Confidence Interval (CI) 11.6–20.1%) in women and 9.0% (95% CI 6.1–12.6) in men.
Only patients who developed a 2nd malignancy after HL treatment before age 25 had an increased risk to develop subsequent malignancies (HR 1.6, 95% CI 1.2−2.3), compared to those who did not develop a 2nd malignancy. Risk of a second solid non-breast tumor was higher for males compared to females (p = 0.007), older patients (>35 years vs. >25 years at HL diagnosis) (p < 0.001), patients who received radiotherapy (p < 0.001) and patients treated with chemotherapy (p = 0.035). Risk factors for 2nd and 3rd malignancies were similar with the exception of radiotherapy ($p_{interaction}$=0.013). While radiotherapy was associated with an almost 3-fold increased risk (95% CI 1.2−3.5) of a 2nd primary malignancy, a stronger association was seen for a 3rd primary malignancy (HR 6.0, 95% CI 1.4–24.9).
Conclusion: Female survivors of a 2nd malignancy have an almost 16% risk to develop a 3rd malignancy within 10 years after the 2nd malignancy. Patients treated before age 25 who develop a 2nd malignancy have a higher risk of developing subsequent malignancies compared with HL survivors who do not develop a 2nd malignancy.
No conflict of interest.

1412 POSTER

Increased risk of urinary tract neoplasm among patients who had ever urolithiasis: A population-based cohort study in Taiwan

C.L. Lin[1], W.T. Huang[1], C.J. Tsao[1], S.H. Lin[2]. *[1]Chi Mei Medical Center, Medical Oncology, Tainan, Taiwan; [2]National Cheng Kung University College of Medicine, Graduate Institute of Clinical Medicine, Tainan, Taiwan*

Background: There were estimated 386,300 new cases and 150,200 deaths from bladder cancer worldwide in 2008. In Taiwan, the crude incidence rate of urinary tract cancer increased from 11.74 to 14.8 during 2000–2009. Though cigarette smoke and occupational exposure are the most documented etiologies, hereditary factor may also play a pivotal role in recent studies. Urolithiasis contributing to neoplasm, especially in upper urinary tract, is controversial till now. Seldom population-based evidences had studied the relationship between urinary stone which can cause chronic inflammation and urinary tract neoplasm.
Materials and Methods: We conduct a national population-based cohort study by applying the Database of National Health Insurance in Taiwan. Patients who were diagnosed as urinary tract stone in admission or in out-patient department above their age of thirty were enrolled in our study

during 2000 to 2011. The compared group was chosen by comparable age, sex and diagnosis time by the ratio of 1:5. All of the patients in this cohort were followed to the event of urinary tract cancer, death or the end of 2011. Cox proportional regression models were used to estimate the hazard ratios and 95% confidence interval for the association between urolithiasis and urinary tract cancer.
Results: In this cohort, the number of patients who had urinary tract cancer followed by urolithiasis is 488, composed of 309 men and 179 women. The adjusted HR in total patients with urinary tract neoplasm is 2.32 (95% CI: 2.10–2.58). In our study, the association between urinary stone and cancer in women (adjusted HR: 2.87, 95% CI: 2.39–3.44) is stronger than in men (adjusted HR: 2.06, 95%: 1.80–2.35). After stratification by age, we discovered that men who had urolithiasis in their forties have higher risk to get urinary tract neoplasm (adjusted HR: 2.82, 95% CI: 1.76–4.49), while women in their fifties (adjusted HR: 3.62, 95% CI: 2.32–5.63).
Conclusions: Our study proved that urinary stone disease is indeed a precipitating factor of urinary tract neoplasm. Among these various factors, urinary tract stone play a role in contributing to malignancy, especially in women and in their middle age (30−49).
No conflict of interest.

1413 POSTER

Effect of chronic comorbidities on risk of chemotherapy-induced febrile neutropenia

C. Chao[1], R. Rodriguez[2], J.H. Page[3], S.J. Yang[1], J. Huynh[4], V.M. Chia[3].
[1]Southern California Kaiser Permanente, Research and Evaluation, Pasadena, USA; [2]Los Angeles Medical Center Kaiser Permanente Southern California, Department of Oncology, Los Angeles, USA; [3]Amgen Inc, Center for Observational Research, Thousand Oaks, USA; [4]Harbor-UCLA Medical Center Los Angeles, Department of Hematology and Oncology, Los Angeles, USA

Background: Chemotherapy-induced febrile neutropenia (FN) is a clinically important complication that impacts a cancer patient's outcome, in part by delaying chemotherapy doses or reducing dose intensity. Risk of FN is known to depend on the chemotherapy regimen and patient-specific factors. In this study, we determined the effects of chronic comorbidities on risk of FN.
Methods: We conducted a cohort study to examine the association between a wide variety of chronic comorbidities and risk of FN in patients diagnosed with cancer (non-Hodgkin lymphoma or cancers of the breast, colon/rectum, lung, ovary or stomach) and treated with chemotherapy from 2000–2009 at Kaiser Permanente Southern California, an integrated healthcare delivery system in United States. We excluded patients receiving primary prophylactic granulocyte colony-stimulating factor (G-CSF), as this alters the risk of FN. History of comorbidities and FN events (based on the juxtaposition of neutropenia with fever and/or infection) were identified using electronic medical records. To assess the association between each comorbidity and FN, a Cox model adjusting for cancer type and the propensity score for the specific comorbidity was used to estimate the summary hazard ratio and 95% CI.
Results: A total of 19,160 patients (mean age of 60 years) were included; 963 (5.0%) patients developed FN in the first chemotherapy cycle. The most common comorbidities were hypertension (39.4%) and diabetes (18.5%). Anemia [HR = 1.24, 95% CI, 1.03–1.49], HIV infection [HR = 3.44 (1.93–5.70)], chronic obstructive pulmonary disease [HR = 1. 30 (1.08–1.57)], congestive heart failure [HR = 1.43 (1.00–1.98)], peptic ulcer disease [HR = 1.57 (1.04–2.26)], renal disease [HR = 1.60 (1.21–2.09)], and thyroid disorder [HR = 1.33 (1.06–1.64)] were all associated with a significantly increased FN risk. FN risk increased with number of comorbidities: HR = 1.21 (1.00–1.46), 1.37 (1.09–1.73) and 1.56 (1.21–2.00) for those who had 1, 2 or 3+ comorbidities compared with those who did not have any of the comorbidities examined.
Conclusion: Our findings suggest that several chronic comorbidities are associated with increased FN risk in the first chemotherapy cycle among patients not already receiving prophylactic G-CSFs. This information may aid clinical decision making with respect to use of prophylactic G-CSF during the chemotherapy course.

1414 POSTER

Anaemia and iron status management in patients with chemotherapy-induced anemia (CIA) − clinical practice in Eastern Europe

M. Aapro[1], A. Snegovoy[2], J. Raynov[3], T. Ciuleanu[4], J. Lange[5], D. Mitchell[5]. *[1]IMO Clinique de Genolier, IMO Clinique de Genolier, Genolier, Switzerland; [2]N. N. Blokhin Russian Cancer Research Center, N. N. Blokhin Russian Cancer Research Center, Moscow, Russian Federation; [3]Military Medical Academy, Military Medical Academy, Sofia, Bulgaria; [4]Institute of Oncology Ion Chiricuta and UMF Iuliu Hatieganu, Institute of Oncology Ion Chiricuta and UMF Iuliu Hatieganu, Cluj Napoca, Romania; [5]Vifor Pharma, Vifor Pharma, Glattbrugg, Switzerland*

Background: Anaemia and iron deficiency (ID) are frequent in cancer patients, particularly during chemotherapy. This study evaluated current practice in diagnosis and treatment of chemotherapy-induced anaemia (CIA) in Eastern Europe.
Material and Methods: Onco-haematologists from Bulgaria, Czech Republic, Poland, Romania, Russia, Slovakia, and Slovenia were surveyed about diagnostic parameters and therapies used for the last five cancer patients that have been treated for CIA in the six months before the survey (Jan-Feb 2012). Data were checked for plausibility; in 15% of cases also by phone calls. Results are shown as total or median of all patients and range across countries.
Results: 176 oncologists reported data of 920 CIA patients (solid tumours 89% [71−97%], metastatic 47% [29−61%], female 54% [46−66%], mean age 57 y [47−63 y]). Hospital-based oncologists provided data from 738 patients (80.2%). At anaemia diagnosis, 98% [91–100%] of patients were tested for haemoglobin (Hb). Serum ferritin and transferrin saturation (TSAT) were tested in 29% (11−64%) and 11% (1−23%), respectively. Median Hb level was 9.0 g/dL (8.8−9.3 g/dL). Among tested patients, median ferritin level was 98ng/mL (32–226ng/mL) and TSAT 20% (6−22%). Moderate-to-severe anaemia (Hb $\leqslant$10 g/dL) was diagnosed in 81% (67−89%) of patients; 16% (7−26%) had Hb $\leqslant$8 g/dL. Insufficient iron for erythropoiesis (TSAT $\leqslant$20%) was seen in 65% of patients and depleted iron stores (serum ferritin $\leqslant$100ng/mL) in 54%. Iron was given to 69% (31−95%) within 12 months before the survey. However, only 15% (2−34%) received intravenous (i.v.) iron whereas 60% (30−75%) received oral iron despite erythropoiesis-stimulating agent (ESA) treatment in 40% (16−70%). Notably, 40% (7−73%) had received blood transfusions (most of them [70%] as regular treatment) and 8% (0−27%) intramuscular iron.
Conclusion: Cancer patients' anaemia and iron status management is far from optimal in some Eastern European countries. In contrast to guidelines, blood transfusions are often used as regular treatment. Despite i.v. iron can reduce transfusion and ESA needs, whereas oral iron is not effective in cancer patients with functional iron deficiency, only a minority of patients had received i.v. iron. The high frequency of ID at anaemia diagnosis suggests insufficient monitoring or repletion of iron status. Broader awareness and implementation of evidence-based recommendations for anaemia and iron status management in cancer patients is needed in Eastern Europe.

1415 POSTER

Prevalence of hypercalcemia of malignancy in the United States: Projection methods using oncology electronic health records (EHR)

V. Gastanaga[1], R. Jain[2], M. Pirolli[3], D. Quach[3], J. Quigley[3], S. Stryker[1], A. Liede[1]. *[1]Amgen Inc, Center for Observational Research, Thousand Oaks, USA; [2]Amgen Inc, Global Development, Thousand Oaks, USA; [3]IMS Health, Advanced Analytics, Plymouth Meeting, USA*

Background: Hypercalcemia of malignancy (HCM; CTCAE grade $\geqslant$1, CSC >10.7 mg/dL) is a serious metabolic complication with unknown prevalence. Rates of HCM differ by tumor type, with highest rates reported in multiple myeloma (MM) and lowest among prostate cancer patients (pts). This analysis estimates the prevalence of HCM utilizing projection methodology developed for oncology EHR from clinics in the US.
Materials and Methods: This retrospective study used the Oncology Services Comprehensive Electronic Records (OSCER) warehouse of EHR including lab values from >640,000 pts treated at 525 oncology outpatient sites. The projection methodology developed to estimate prevalence simultaneously estimates relationships between key data elements and projects these estimates to the entire US population utilizing pt EHR linked to prescription (Rx) and medical office claims data. Rx and medical office claims are projected by tumor type. The claims totals are then used to create factors to project the EHR sample to the US population. These factors are used to project pts by tumor type with lab values that are nationally representative of treated cancer pts. Pts included were $\geqslant$18

years, and had serum calcium (Ca) and albumin (for corrected serum Ca [CSC]) records. Period prevalence was estimated by HCM CTCAE grade, tumor type, and year (2007–2012). Estimates were adjusted to capture pts with HCM outside oncology practices using a subset of pts linkable to office/hospital data.
Results: The analysis included 50912 (2007) to 100449 pts (2012), projected to 3.3 to 3.6 million cancer pts. In 2012, pts with HCM had a median of 5 Ca tests, 54% had chemotherapy, and 35% had bone modifying agents. HCM rates were highest for MM (7.6–10.7%), lowest for prostate (1.4−1.8%). Estimated annual 2007–2012 (adjusted) prevalence of HCM was 72382, 86213, 103746, 105119, 98058, and 98997, respectively. HCM is estimated to affect 2.7% of cancer pts in 2012 (table).
Conclusions: Approximately 100000 pts are affected by HCM in the US each year. The OSCER projection method used has the potential to improve and expedite similar estimates in pharmacoepidemiology studies.
Conflict of interest: *Ownership: Amgen. Other substantive relationships: Amgen*

Table: Prevalence of HCM in 2012 (adjusted estimates)

1416 POSTER

Development in self-reported arm-lymphedema in Danish women operated for breast cancer in 2005 and 2006 − a nationwide follow-up study

R. Gärtner[1], M. Mejdahl[2], K.G. Andersen[2], M. Ewertz[3], N. Kroman[1].
[1]Rigshospitalet, Department of Breast Surgery 3104, Copenhagen, Denmark; [2]Rigshospitalet, Section for Surgical Pathophysiology 7621, Copenhagen, Denmark; [3]Odense University Hospital, Department of Oncology, Odense, Denmark

Background: The population of women treated for breast cancer is steadily growing due to improved survival. One of the most feared complications is lymphedema. The majority of women developing lymphedema do so within the first years, but lymphedema can develop several years after end of treatment. The primary aim of the present nationwide follow-up study was to examine the development of self-reported lymphedema in the population of women operated on in Denmark for breast cancer in 2005–2006 and to assess the impact of axillary lymph node dissection (ALND) and sentinel lymph node dissection (SLND).
Methods: Two identical questionnaires were sent out in 2008 and 2012. All women between 18 and 70 years treated for unilateral primary breast cancer in Denmark in 2005 and 2006, and who participated in the 2008 study, were included. Exclusion criteria were death, recurrent-, new primary-, contralateral, or metastatic disease, other malignant disease, reconstructive/corrective breast surgery, and emigration.
Data regarding diagnosis and treatment was retrieved from The Danish Breast Cancer Cooperative Group, (DBCG), which covers 97% of all women operated on for breast cancer in Denmark.
Results: 2293 women reported on lymphedema in 2008 and 2012. In total, 31% reported lymphedema in 2012, a fall from 37% in 2008. Self perceived severity of lymphedema in 2008 and 2012 can be seen in table 1. 50% of women treated with SLND and reporting lymphedema in 2008 had recovered by 2012 in contrast to 30% treated with ALND. However, 19% of women treated with ALND and not reporting Lymphedema in 2008 had developed Lymphedema by 2012.
Overall, 10% of women who did not have lymphedema in 2008 reported so in 2012. The main risk factor showed to be ALND vs. SLND (adj. OR:4.07;95% CI:2.43–6.80,p < 0.001). In all, 34% of women reporting Lymphedema in 2008 did not report lymphedema in 2012. Recovery from lymphedema was negatively associated with ALND vs. SLND (adj. OR:0.38;95% CI:0.24–0.59,p < 0.001).
Conclusions: Half of women reporting lymphedema 1−3 years after surgery with SLND have spontaneously recovered 4 years later compared to 30% in women undergoing ALND. However, 19% of women undergoing ALND, but initially not reporting lymphedema have developed lymphedema 4 years later.
No conflict of interest.

Table 1. Development in severity of self-reported lymphedema from 2008 to 2012 in 2293 patients operated on for primary breast cancer in 2005–2006.

Intensity of lymphedema in 2008, N (%)	Intensity of lymphedema in 2012 N (%)					
	No lymphedema	Light lymphedema	Moderate lymphedema	Severe lymphedema	Missing	**Total**
No lymphedema	1295 (90)	77 (5)†	54 (4)†	14 (1)†	1 (0)	1441
Light lymphedema	196 (43)¶	178 (39)	59 (13)†	19 (4)†	4 (1)	456
Moderate lymphedema	70 (24)¶	81 (28)¶	108 (37)	33 (11)†	2 (1)	294
Severe lymphedema	16 (17)¶	10 (11)¶	35 (38)¶	30 (33)	1 (1)	92

Comorbidity in lung cancer patients: Trends and effect on prognosis

M.J. Aarts[1], B.E. Van den Borne[2], B. Biesma[3], J.S. Kloover[4], J.G. Aerts[5], V.E.P.P. Lemmens[1]. *[1]Eindhoven Cancer Registry/Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands; [2]Catharina Hospital, Pulmonary diseases, Eindhoven, Netherlands; [3]Jeroen Bosch Hospital, Pulmonary Diseases, 's-Hertogenbosch, Netherlands; [4]St Elisabeth Hospital/TweeSteden Hospital, Respiratory Diseases and Tuberculosis, Tilburg, Netherlands; [5]Amphia Hospital, Respiratory Diseases and Tuberculosis, Breda, Netherlands*

Background: We evaluated the trends in prevalence of comorbidities in a cohort of unselected lung cancer patients. We also evaluated the influence of comorbidity on the prognosis of these patients.
Material and Methods: All patients (n = 21,535) diagnosed between 1995 and 2010 with lung cancer were included, identified from the population-based Eindhoven Cancer Registry, which also registers comorbidity.

Table: Hazard of death for lung cancer patients according to stage at diagnosis, 1995–2010 in the Southern Netherlands.

	HR					
	Non-small cell lung cancer				Small cell lung cancer	
	Stage I	Stage II	Stage III	Stage IV	Limited	Extensive
Comorbidities[#]						
None	1.00	1.00	1.00	1.00	1.00	1.00
1	1.05	0.96	0.98	1.00	1.09	1.01
2 or more	**1.25***	1.26	**1.11**	1.00	**1.22**	1.04
Unknown	1.10	1.44	1.14	1.12	**1.65**	0.87
Type of comorbidities[$]						
Diabetes	**1.15**	1.19	1.05	1.02	1.18	1.07
Other malignancy	**1.15**	0.95	1.06	0.93	1.00	1.01
Pulmonary diseases	1.03	0.96	0.98	0.97	**1.16**	1.02
Cardiac diseases	1.10	1.13	**1.10**	1.03	**1.20**	**1.18**
Vascular diseases	**1.17**	1.28	**1.12**	1.06	1.07	1.04
Hypertension	1.01	**1.40**	0.97	0.97	0.96	0.89
Cerebrovascular diseases	1.08	1.16	**1.20**	1.04	1.26	**1.29**
Digestive diseases	1.07	0.79	1.04	0.97	**0.71**	1.05

* Values in bold are significant (p < 0.05).
# All models are adjusted for sex, age, socioeconomic status, period of diagnosis and therapy.
$ A separate model was built for each comorbid condition with not having that specific comorbid condition as a reference.

Results: The prevalence of comorbidities increased with age from 59% in 1995 to 77% in 2010, and multimorbidity (i.e. 2 or more concomitant diseases) increased from 24% to 49%. Especially cardiac diseases (9% in ⩽59 to 37% in 80+) were more frequently seen. Among males, hypertension, cardiac and vascular diseases became much more common (11% to 29%, 17% to 33% and 11% to 25%, respectively). In females, rates of pulmonary diseases, hypertension, cardiac and vascular diseases also increased rapidly (19% to 28%, 15% to 28%, 11% to 18% and 6% to 15%, respectively). Patterns were similar in non-small cell lung cancer (NSCLC) and small cell lung cancer (SCLC). Presence of 2 or more comorbidities was associated with increased hazard of death in stage I−III NSCLC ($HR_{⩾2\_comorbidities\_vs\_no\_comorbidities}$ 1.11–1.26) and limited stage SCLC ($HR_{⩾2\_comorbidities\_vs\_no\_comorbidities}$ 1.22) (Table). The prognostic impact of specific comorbidities varied for different stages, with the strongest effect of hypertension in stage II NSCLC ($HR_{hypertension\_vs\_no\_hypertension}$ 1.40).
Conclusion: Comorbidity among lung cancer patients is very common and multimorbidity affects survival in non-metastatic disease. The increasing

burden of comorbidity in patients with lung cancer emphasizes the need for more focus on individualized medicine.
No conflict of interest.

Epidemiological studies of sweetened carbonated beverage consumption and cancer risk

P. Boyle[1], A. Koechlin[1], P. Autier[1]. [1]*International Prevention Research Institute, Director, Lyon, France*

Background: There is speculation of possible links between sweetened carbonated beverage consumption and the risk of developing cancer. The aim of this study was to examine the association between sweetened, carbonated beverage consumption and cancer risk.
Methods: PRISMA guidelines of meta-analyses were followed as closely as possible. Over 50 independent estimates of risk were available, 11 for colas specifically. A random effects meta-analysis was performed with tests for publication bias (Begg, Egger, Macaskill) performed as well as Higgins and Thompson's I^2 measure of the percentage of heterogeneity between studies which could not be explained by chance.
Results: Overall the different sites of cancer, the summary relative risk (SRR) when all 56 independent estimates were considered together was SRR = 1.04 (95% CI (0.96, 1.13)). On this overall scale, there appears to be no association between consumption of soft-drinks and the risk of cancer. When individual cancer sites were considered, there was no significant increase, or decrease in the meta-analysis estimate of risk of cancer of the pancreas, bladder, kidney, oesophageal squamous cell or adenocarcinoma, colon, gastric cardia, gastric non-cardia, prostate, breast, larynx and ovary nor from the oral cavity, pharynx, glioma, leukaemia or non-Hodgkin's lymphoma where only one study was available. There was no evidence in a sensitivity analysis from those studies which reported results separately for coke, pepsi or other colas of an associated risk of pancreas cancer (SRR = 1.00, 95% CI (0.61; 1.65)) based on 3 studies. The results for all other forms of cancers were greatly hampered by poor methodology and small numbers of studies (mainly one report on each cancer site studied).
Conclusions: Overall, the findings are reassuring regarding the association between soft drinks, including colas, and cancer risk, although the quality of many of the studies is quite poor by acceptable, modern standards and no study has been conducted with use of carbonated beverages as a primary hypothesis.
No conflict of interest.

1419 POSTER

A history cohort mortality study in Jingchuan of China − the largest nickel population in world

N. Cheng[1], L.I. Ma[1], H. Pu[2], J. He[3], T. Zheng[4], M. Dai[3], Y. Zhang[4], Y. Bai[5]. [1]*Lanzhou University, Center for Cancer Prevent and Treatment of Lanzhou University, Lanzhou, China;* [2]*Jinchuan Group CO.LTD, Workers' Hospital of Jinchuan Company, Jinchuang, China;* [3]*Chinese Academy of Medical Sciences, Cancer Institute and Hospital, Beijing, China;* [4]*Yale University, School of Public Health, New Haven, USA;* [5]*Lanzhou University, Center for Cancer Prevent and Treatment College of Public Health, Lanzhou, China*

Background: Nickel is an essential trace metal used in the occupational setting and is naturally found in the general environment, resulting in both occupational and nonoccupational exposures to individuals at varying levels. Exposure to nickel has been associated with several toxicities and the International Agency for Research on Cancer has concluded that there is sufficient evidence in humans associating exposure to nickel or nickel compounds with risk of lung cancer. We evaluated overall and cause-specific mortality among Chinese workers involved in nickel production or utilisation in order to examine the long-term health effects of occupational exposure to nickel compounds.
Methods: The study design was a retrospective cohort mortality study including 432,526 workers who were involved with nickel mining or smelt between 2001 and 2010. We calculated standardised mortality ratios (SMR) using the death rates of Gansu Province in China, and estimated by the exact probabilities of the Poisson distribution.
Results: Overall, the all-cause mortality was decreased in all workers compared to the general population of Gansu province (SMR= 0.53, 95% CI: 0.51–0.55). Analyses examining cause-specific mortality revealed an increase in the mortality from bronchogenic carcinoma and lung cancer (SMR = 2.05, 95% CI = 1.84–2.29), cor pulmonale (SMR =4.08, 95% CI = 3.25–5.01), and silicosis (SMR = 13.59, 95% CI =11.90–15.52) in the workers exposed to nickel.
Conclusion: This study confirmed a significant excess of mortality from diseases of the lung including silicosis, lung cancer, and cor pulmonale among workers involved in nickel mining or smelt in China.
No conflict of interest.

1420 POSTER

A nickel workers cohort study in China (Jinchuan cohort) − the largest nickel population in world

Y. Bai[1], A. Yang[1], H. Pu[2], J. He[3], T. Zheng[4], M. Dai[3], Y. Zhang[4], Q. Wang[5], N. Cheng[6]. [1]*Lanzhou University, Center for Cancer Prevent and Treatment of Lanzhou University Institute of Epidemiology and Statistics, Lanzhou, China;* [2]*Group Co. Ltd. Jinchuan, Workers' Hospital of Jinchuan, Jinchuang, China;* [3]*Chinese Academy of Medical Sciences, Cancer Institute and Hospital, Beijing, China;* [4]*Yale University, School of Public Health, New Haven, USA;* [5]*group Co. Ltd. Jinchuan, Workers' Hospital of Jinchuan Company, Jinchuang, China;* [6]*lanzhou University, Center for Cancer Prevent and Treatment of Lanzhou University, Lanzhou, China*

Nickel is one of the most widely distributed and used metals in the world and exposure to nickel compounds can result in a variety of adverse effects on human health. In order to evaluate the human health effects associated with joint occupational exposures to nickel and other metals, we are conducting a cohort study of workers in a large nickel plant in China which produces over 90% of the nickel compounds in China. It is estimated that more than 50 000 current or retired workers, who have had exposure to nickel as well as other contaminants and metals in the plant, will be included in The China Nickel Workers Cohort Study (Jinchuan Cohort) Since 2011, all staff and workers have been eligible for a medical examination every 2 years, and these workers who participated in the medical examination will be interviewed in-person with a standardized and structured questionnaire with trained interviewers and will be included in the Jinchuan Cohort study. The medical examination includes a comprehensive physical examination, biochemical examination, epidemiologic survey, and collection of biological samples. The Jinchuan Cohort has the largest data set from a cohort of nickel exposed workers with both questionnaire and laboratory-based information, and the exposure and disease information will be updated every 2 years through the biannual survey and medical examination. The comprehensive epidemiological and biological data will permit the evaluation of a number of hypotheses concerning the health effects in nickel workers resulting from joint exposure to nickel and other metals. The unique repository of blood samples including blood cell, plasma, and serum will provide a population-based platform to examine biological indicators that closely correlate with metal exposure and illness using molecular epidemiologic methods.
No conflict of interest.

1421 POSTER

Time trends in population-based breast cancer survival in Estonia: Analysis by age and stage

K. Innos[1], A. Baburin[1], V. Valvere[2], T. Aareleid[1], P. Padrik[3]. [1]*National Institute for Health Development, Department of Epidemiology and Biostatistics, Tallinn, Estonia;* [2]*North Estonia Medical Centre, Clinic of Hematology and Oncology, Tallinn, Estonia;* [3]*Tartu University Hospital, Clinic of Hematology and Oncology, Tartu, Estonia*

Background: At the end of the 20th century, relative survival from breast cancer (BC) improved steadily in all European countries, although at different rates, with the gap between eastern and western European countries. Survival from BC in Estonia has been in previous comparative analyses among the lowest in Europe. The aim of this study was to examine most recent trends in BC survival in Estonia by age and stage, as considerable changes have occurred both in socioeconomic conditions and availability of diagnostic and treatment options.
Material and Methods: Estonian Cancer Registry data on all cases of BC, diagnosed in women in Estonia during 1995–2007 (n = 7424) and followed up for vital status through 2009 were used to estimate relative survival (RSR). Period hybrid approach was used to obtain the most recent estimates (2005–2009). Stage was classified as localized, local/regional spread or distant.
Results: The distribution of patients shifted towards older age and earlier stage at diagnosis. Overall age-standardized 5-year RSR increased from 63% in 1995−99 to 74% in 2005−09. Younger age groups experienced a more rapid improvement compared to women over 60. Significant survival increase was observed for both localized and locally/regionally spread BC with 5-year RSRs reaching 96% and 70% in 2005−09, respectively; the latest 5-year RSR for distant BC was 11%. Survival for T4 tumors was poor and very large age gradient was seen for locally/regionally spread BC.
Conclusions: Considerable improvement in BC survival was observed over the study period. Women under 60 benefited most from both earlier diagnosis and treatment advances of locally/regionally spread cancers. However, the survival gap with more developed European countries persists. Further increase in survival, but also decline in BC mortality in Estonia could be achieved by facilitating early diagnosis in all age groups,

but particularly among women over 60. Investigations should continue to clarify the underlying mechanisms of the stage-specific survival deficit between European countries.
No conflict of interest.

1422 POSTER

Missing data and survival analysis of central nervous system tumours amongst children and young people in Yorkshire, 1990–2009

M. Van Laar[1], D. Greenwood[2], D. Stark[3], R.G. Feltbower[1]. [1]*University of Leeds, Division of Epidemiology, Leeds, United Kingdom;* [2]*University of Leeds, Division of Biostatistics, Leeds, United Kingdom;* [3]*Leeds Teaching Hospitals NHS Trust, St James Institute of Oncology, Leeds, United Kingdom*

Background: Missing data is a common problem in many areas of research, including cancer registration. Severity of disease at diagnosis is often missing from medical records, and as a result this important prognostic variable is sometimes excluded from analysis. We investigated survival trends of central nervous system (CNS) tumours in children and young adults whilst using multiple imputation (MI) to impute missing values of disease severity (grade) and ethnicity.
Materials and Methods: Children and young people (<30 years) diagnosed with CNS tumours (1990–2009) were identified from a population based cancer register in Yorkshire. Logistic regression models were used to impute missing values of grade (WHO Classification, I−IV) and ethnicity (White, Asian and Other), this process was repeated 40 times. Age, sex, year of diagnosis, deprivation, diagnostic subgroup, relapse status and treatment data were all used as predictors of the missing data. Subsequently, a survival analysis was performed using Cox regression models for each set of imputed data, pooled hazard ratios (HR) were then obtained by averaging over all sets of results.
Results: There were 795 cases of CNS tumours diagnosed in Yorkshire between 1990 and 2009. Missing grade data occurred in 71 (8.9%) cases, and missing ethnicity occurred in 191 (24%) cases. Overall, missing data of one or both variables occurred in 242 (30%) cases. Kaplan–Meier survival curves were significantly lower for cases in which grade and ethnicity was missing, compared to those in which it was recorded (P<0.001). This implies that an analysis on only those with complete data (complete case analysis) would produce biased results towards improved survival over the whole cohort. The complete case survival analysis showed no difference in survival between ethnic groups or over time, however, it did show an increased risk of death for those with grade II, III and IV tumours compared to grade I (HR = 3.7, 7.02, 13.36 respectively). After MI, survival analysis showed an increased risk of death for 'other' compared to 'white' ethnicity (HR = 2.1; P = 0.034), and an increased risk of death for those with grade II, III and IV tumours compared to grade I (HR = 3.5, 6.4 and 10.4 respectively). Additionally, survival improved significantly by 4% over the study period (P=0.001). Age, sex and deprivation did not significantly affect survival in the complete case or MI analysis. MI reduced standard errors of coefficients by an average of 18% when compared to a complete case analysis.
Conclusion: MI was used to minimise bias and enhance the precision of analyses. This technique offers considerable advantages over other approaches such as performing a complete case analysis. Survival rates varied by grade and ethnicity, and showed a significant improvement over time.
No conflict of interest.

1423 POSTER

The risk of hepatocellular carcinoma associated with blood iron profile: Preliminary findings from a prospective cohort study

M. Jenab[1], T. Duarte-Salles[1], M. Stepien[1], I. Romieu[1], C. Bamia[2], A. Trichopoulou[3], on behalf of the EPIC Group[1]. [1]*International Agency for Research on Cancer (IARC-WHO), Section of Nutrition and Metabolism, CEDEX 08 Lyon, France;* [2]*University of Athens Medical School, Department of Hygiene and Epidemiology, Athens, Greece;* [3]*Hellenic Health Foundation, Epidemiology and Public Health, Athens, Greece*

Background: Iron is an essential nutrient but higher levels can catalyze free radical generation, leading to increased oxidative stress and possibly increased risk of cancer at various sites. This may particularly be the case for the liver, which is the main organ of iron storage and metabolism. It has been established that iron overload, for example in Haemochromatosis, is associated with increased risk of hepatocellular carcinoma (HCC). But, it is currently unclear to what extent mild or moderate excesses in body iron status contribute to HCC etiology. Furthermore, since iron is an essential nutrient, it can also be hypothesized that very low body status may be cancer promotive. These questions were explored within the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort.
Materials and Methods: EPIC is a large prospective cohort of over 520,000 subjects from 23 centers in 10 Western European countries. In a nested case-control setting, serum iron, ferritin and transferrin were measured in 121 (n men=82; n women=39) HCC cases and 242 control subjects matched by age, sex, study center and date of blood collection. Conditional logistic regression models were used to compute odds ratios based on quartiles of serum analyte levels.
Results: Compared to serum iron levels in the 2nd quartile, a significant increased risk of HCC was observed in subjects in the lowest (OR:2.10, 95% CI:1.03–4.28) and highest (OR:4.22, 95% CI:2.07–8.56) quartiles. For ferritin, subjects in the highest quartile had a significantly higher HCC risk (OR: 3.34, 95% CI:1.67–6.68) compared to those in the 2nd. For serum transferrin, a similar pattern of results was observed but was not statistically significant.
Conclusions: These findings indicate that serum iron parameters have a J-shaped relationship with HCC risk, and that higher iron status as indicated by serum iron and ferritin is significantly associated with higher HCC risk in this prospective European cohort.
No conflict of interest.

1424 POSTER

Dietary folate intake and risk of hormonal receptor defined breast cancer in the European prospective investigation into cancer and nutrition (EPIC) study

J. De Batlle[1], P. Ferrari[1], V. Chajes[1], J.Y. Park[1], I. Romieu[1], on behalf of the EPIC Group[1]. [1]*International Agency for Research on Cancer (IARC-WHO), Nutrition Epidemiology group, Lyon, France*

Background: Dietary folate has been suggested to be related to Breast Cancer (BC) risk. However, the evidence on the association by menopausal status and hormonal receptor status is limited. We aimed at investigating the relationship between dietary folate and BC risk in the European Prospective Investigation into Cancer and Nutrition (EPIC) study.
Material and Methods: A total of 367,993 women (aged 35−70 years) were recruited in 10 European countries. During a median follow-up of 11.5 years, 11,575 women with invasive BC were identified. Dietary folate was estimated from country-specific dietary questionnaires. Cox proportional hazards regression models were used to quantify the association between dietary variables and BC risk, controlling for energy intake with the residual method. Further analyses were performed by menopausal status, hormonal receptor status, and level of baseline alcohol intake.
Results: A borderline significant overall relationship was observed between dietary folate and risk of BC (HR_{Q5-Q1} = 0.92, 95% CI: 0.84–1.01, p_{trend} = 0.037). However, no significant associations were found according to menopausal status or hormonal receptor status. A 15% reduction of BC risk was found when comparing the highest to the lowest dietary folate intake tertiles in women having a high (>20 g/day) baseline alcohol intake (HR_{T3-T1} = 0.85, 0.75−0.97).
Conclusions: Diets rich in folate intake showed little association with BC risk, independently on menopausal status or hormone receptor expression in the tumors. The combined effect of high folate and high alcohol intake resulted in a 15% reduction in BC risk as compared to high alcohol and medium or low folate intakes, thus suggesting that large folate intake could reduce BC incidence in subjects with large baseline alcohol intakes.
No conflict of interest.

1425 POSTER

Breast cancer biology and risk of venous thromboembolism

A.J. Walker[1], J. West[1], T.R. Card[1], C. Crooks[1], C.C. Kirwan[1], M.J. Grainge[1]. [1]*University of Nottingham, Epidemiology and Public Health, Nottingham, United Kingdom*

Background: Previous reports suggest a worse survival outcome for breast cancer patients with venous thromboembolism (VTE) compared to those without VTE. We determined whether breast cancer stage or biology influenced development of VTE independently of cancer treatment and quantified the impact of VTE on breast cancer survival.
Materials and Methods: Cohort study using the Clinical Practice Research Datalink, linked to Hospital Episode Statistics, Cancer Registry data and Office for National Statistics cause of death data. Our cohort comprised 13,206 patients with a first breast cancer diagnosis between 1997 and 2006 with follow-up for outcomes (VTE and all-cause mortality) continuing to the end of 2010. A multivariable cox regression analysis was performed to determine which demographic, treatment-related and biological factors independently affected VTE risk. Results were subsequently stratified by the 'first 6 months' and 'six months or more' following cancer diagnosis. Cox regression was also used to ascertain whether mortality was higher in patients who developed a VTE.

Results: The overall VTE rate in breast cancer patients was 8.5 per 1000 person years (95% CI, 7.9−9.2). In unavailable analysis, we found that VTE rates increased with increasing age, body mass index, pre-existing comorbidities, cancer stage and chemotherapy (although not radiotherapy and surgery). In the multivariate analysis, chemotherapy (HR 2.29, CI 1.88–2.80) was found to be a more important predictor of VTE risk than metastatic disease (HR 1.53, CI 0.97–2.42) when these variables were mutually adjusted. Estrogen receptor (ER) positive patients had almost half the risk of VTE (HR 0.57, CI 0.39–0.82) in the first six months after cancer diagnosis, but beyond six months from diagnosis, these patients had a higher risk of VTE (HR 1.38; 95% 1.01, 1.90) In the non-metastatic breast cancer subgroup, overall survival was significantly worse in patients with VTE compared to without VTE and this persisted for more than 5 years following breast cancer diagnosis.
Conclusions: Development of VTE in non-metastatic cancer is associated with reduced survival, even several years after diagnosis, and therefore unlikely to be VTE-related mortality. The association between poor prognosis breast cancer phenotypes (ER-ve), development of VTE, and reduced survival supports a symbiotic relationship between thrombosis and breast cancer progression.
No conflict of interest.

The association between sleep disorders and cancers: A nationwide population-based study

H.L. Chiang[1], L.Y. Hu[2], C.J. Liu[3], Y.W. Hu[4], T.J. Chen[5]. *[1]Far Eastern Memorial Hospital, Department of Psychiatry, New Taipei City, Taiwan; [2]Yuli Veterans Hospital, Department of Psychiatry, Hualian, Taiwan; [3]Taipei Veterans General Hospital, Division of Hematology and Oncology Department of Medicine, Taipei, Taiwan; [4]Taipei Veterans General Hospital, Cancer Center, Taipei, Taiwan; [5]Taipei Veterans General Hospital, Department of Family Medicine, Taipei, Taiwan*

Background: To investigate the risk of cancer among patients with non-apnea sleep disorders (SD).
Material and Methods: We recruited newly diagnosed SD patients aged 20 years or older without antecedent cancer from the National Health Institutes Research Database between 2000 and 2010. Standardized incidence ratios (SIRs) of cancers were calculated to compare the cancer incidence of patients with SD to the general population.
Results: During the 10-year study period, 2,062 cancers developed among 63,381 recruited SD patients with a follow-up of 382,826 person-years (median follow-up of 6.23 years). The SIR for all cancers was 1.19 [95% confidence interval (CI) 1.14–1.24]. The SIR was 1.20 (95% CI 1.12–1.28, $p < 0.001$) for men and 1.18 (95% CI 1.11–1.24, $p < 0.001$) for women. Subgroup analyses according to age at diagnosis revealed that patients aged $\geqslant$40 tended to have a greater risk ratio. In regards to specific types of cancer, SD patients had an increased SIR for liver (1.44, 95% CI 1.28–1.61), lung and mediastinum (1.34, 95% CI 1.18–1.51), breast (1.15, 95% CI 1.02–1.29), prostate (1.35, 95% CI 1.08–1.67) and kidney cancers (1.51, 95% CI 1.17–1.92).
Conclusions: The nationwide population-based cohort study found Taiwanese patients with SD have higher risk of overall cancer risk, especially the risk of liver, lung, breast, prostate and kidney cancers.

Breast cancer in Niger: First results from the Niger Cancer Registry

H. Hami[1], S. Mamoudou Garba[2], H. Mahamadou Zaki[2], A. Soulaymani[1], H. Nouhou[2], A. Quyou[1]. *[1]Ibn Tofaïl University, Laboratory of Genetics and Biometry − Faculty of Sciences, Kenitra, Morocco; [2]Abdou Moumouni University, Laboratory of Pathological Anatomy and Cytology − Faculty of Health Sciences, Niamey, Nigeria*

Background: Breast cancer is the most common cause of cancer death in women worldwide. The aim of this study is to determine the frequency and the epidemiological characteristics of breast cancer in Niger.
Material and Methods: This is a retrospective analysis of breast cancer cases, reported between 1992 and 2009 to the Niger Cancer Registry, established in 1992, in the Faculty of Health Sciences at the Abdou Moumouni University in Niamey.
Results: There were 1161 cases diagnosed with breast cancer in Niger, 96.8% in women and 3.2% in men, giving a female-male ratio of 31 and accounting for 16.5% of all new cancer cases reported during 1992–2009. During this period, breast cancer was the first most common cancer and the first leading cause of cancer death in women. About 40% of all breast cancers were invasive ductal carcinomas. The average age at diagnosis was 44±12 years. The risk of developing breast cancer is strongly related to age with 9.6% of new breast cancer cases diagnosed in people younger than 30 years, 82.5% in those aged 30−64 years and 7.9% in those aged 65 years and over. The rates of developing and dying from breast cancer varied among various ethnic groups. Djerma-Sonrai was more likely to get and die of breast cancer than any other ethnic groups, followed by Haoussa. Among all detected cases, 9% died during the study period.
Conclusions: Breast cancer was the leading cause of death from cancer in women. Early detection in order to improve breast cancer outcome and survival remains the cornerstone of breast cancer control.
No conflict of interest.

1428 POSTER

The age distribution and receptor status profile in Egyptian breast cancer patients

M. Mosbah[1], O. Hussein[1], O.M.A.R. Farouk[1], K. Farag[1], A. El-saed[1], A. Abdallah[1], H.I.N.D. Elgenedy[1]. *[1]Mansoura University Oncology Centre, Mansoura, Egypt*

Background: Breast cancer is the most common cancer of women in Egypt. The disease is often advanced at diagnosis. Since molecular profiling is not feasible in routine practice, we sought to characterize the hormone receptor profile in our patients in correlation with disease stage and outcome.

Table 1 (abstract 1426). Standardized incidence ratios (SIRs) for specific cancer types among patients with sleep disorders

Site of cancer	Total			Male			Female		
	Observed	Expected	SIR (95% CI)	Observed	Expected	SIR (95% CI)	Observed	Expected	SIR (95% CI)
All cancers	2062	1738.77	1.19 (1.14−1.24)	906	755.06	1.20 (1.12−1.28)	1156	983.71	1.18 (1.11−1.24)

Prostate	86	63.65	1.35 (1.08−1.67)	86	63.65	1.35 (1.08−1.67)	–	–	–
Bladder	64	51.47	1.24 (0.96−1.59)	43	31.44	1.37 (0.99−1.84)	21	20.02	1.05 (0.65−1.60)

Patients and Methods: Retrospective analysis of all breast cancer patients treated at Mansoura University Cancer Center in the Nile Delta. Tumor clinico-pathological criteria were examined in relation to receptor status. The effect of receptor status on disease relapse and disease-free survival was examined with logistic regression and Kaplan Meier analysis.
Results: Hormone receptor positive tumors constituted 67% of cases, Hormone receptor negative-Her_2/neu positive was 14% and triple negative was 19%. Median age of the patients was 52 years and was equal across all receptor status types. Triple negative status correlated with increased risk of disease relapse (Hazards ratio= 1.8, $p = 0.03$, Logistic regression) and with shortened disease-free survival (Hazards ratio = 2.6, $p = 0.00$, Cox regression).
Conclusion: The age distribution and receptor status pattern in Nile Delta region does not explain the aggressive behavior of the disease. The age of the patients at diagnosis is older than earlier literature from Egypt emphasizing the importance of implementing mammographic screening programs.
No conflict of interest.

1429 POSTER

Peritoneal carcinomatosis of gastric origin: A population-based study on incidence, survival and risk factors

I. Thomassen[1], Y.R.B.M. Van Gestel[2], B. Van Ramshorst[3], M.D. Luyer[4], K. Bosscha[5], S.W. Nienhuijs[4], V.E.P.P. Lemmens[6], I.H.J.T. De Hingh[4]. *[1]Comprehensive Cancer Centre South, Eindhoven, Netherlands; [2]Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands; [3]St. Antonius Hospital, Surgery, Nieuwegein, Netherlands; [4]Catharina Cancer Center, Surgery, Eindhoven, Netherlands; [5]Jeroen Bosch Hospital, Surgery, Den Bosch, Netherlands; [6]Comprehensive Cancer Center South, Research, Eindhoven, Netherlands*

Background: Peritoneal carcinomatosis (PC) is an important cause of morbidity and mortality among patients with gastric cancer. The aim of the current study was to provide reliable population-based data on the incidence, risk factors and prognosis of PC of gastric origin.
Methods: All patients diagnosed with gastric cancer in the area of the Eindhoven Cancer Registry between 1995 and 2011 were included. Incidence and survival were computed and risk factors for peritoneal carcinomatosis were determined using multivariate logistic regression analysis.
Results: In total, 5,220 patients were diagnosed with gastric cancer, of whom 2,029 (39%) presented with metastatic disease. PC was present in 706 patients (14%) of whom 491 patients (9%) had PC as the only metastatic site. Younger age (<60 yrs), female gender, advanced T- and N-stage, primary tumour of signet ring cells or linitis plastica, and primary tumours covering multiple anatomical locations of the stomach were all associated with a higher odds ratios of developing PC. Median survival of patients without metastases was 14 months, but only 4 months for patients with PC.
Conclusion: PC is a frequent condition in patients presenting with gastric cancer, especially in younger patients with advanced tumour stages. Given the detrimental influence of PC on survival, efforts should be undertaken to further explore the promising results that were obtained in preventing or treating this condition with multi-modality strategies.
No conflict of interest.

1430 POSTER

The effect of subsequent independent primary cancers on survival in patients with breast, lung and prostate cancer

A. Merdin[1], H. Bozcuk[2], H. Karakilinc[3], S. Gunduz[2]. *[1]Akdeniz University Faculty of Medicine, Department of Internal Medicine, Antalya, Turkey; [2]Akdeniz University Faculty of Medicine, Department of Medical Oncology, Antalya, Turkey; [3]Antalya State Cancer Registry Office, Antalya State Cancer Registry Office, Antalya, Turkey*

Introduction: Influence of including subsequent primary cancers on survival analyses are not well known. In this study, we planned to evaluate the impact of subsequent multiple primaries on the overall survival.
Methods: We analysed data on 6179 patients, who had lung, breast and prostate cancer as first primary. All patients were recorded in Antalya State Cancer Registry Office(South Turkey Region) between the years 2005 and 2011. Antalya State Cancer Registry Office followed SEER rules for the definition of multiple cancer sites. We utilised Kaplan–Meier survival analysis to compare overall survival figures of single primary tumours and multiple primary tumours. We analysed data with regard to each of the three first primaries. In addition, we stratified data according to age, gender, number of independent primaries, economic status and disease extent of the first primary (metastatic, non-metastatic). Lastly, all potential prognostic factors were separately evaluated in cox-regression models.
Results: 1928 of all patients had breast cancer as first primary and 29 (1.5%) of them had multiple primaries. 2513 of all patients had lung cancer as first primary and 29 (1.15%) of them had multiple primaries. 1738 of all patients had prostate cancer as first primary and 138 (7.94%) of them had multiple primaries. Estimated survival of lung cancer patients with single primaries was shorter than multiple primaries (HR: 2.73(%95 CI: 1.67 to 4.47), P: <0.001). On the other hand, estimated survival of prostate and breast cancer was higher in single primary cancers (HR: 0.75(%95 CI: 0.57 to 1.00), P: <0.051 and HR: 0.40(%95 CI: 0.22 to 0.74), P: <0.003, respectively). When multivariate analysis was done for lung cancer; age, gender, including subsequent primary tumours and disease extent were independently prognostic (HR: 1.02, P: <0.001, HR: 1.24, P: <0.001, HR: 2.53, P: <0.001 and HR: 0.54, P: <0.001, respectively). In addition, for cases with prostate and breast cancer; age, including subsequent primaries and disease extent were independently correlated with survival.
Conclusions: We found that inclusion of subsequent primary cancers in the overall survival analysis, resulted in higher survival for lung cancer primary first patients. Besides, it resulted lower survival for breast and prostate cancer primary first patients.
No conflict of interest.

1431 POSTER

Prospects for stratified cancer follow-up

S.M.E. Geurts[1], F. De Vegt[1], K.K.H. Aben[1,2], K.K.H. Aben[2], V.C.G. Tjan-Heijnen[3], J.A.A.M. Van Dijck[1], A.L.M. Verbeek[1]. *[1]Radboud University Medical Centre, Health Evidence, Nijmegen, Netherlands; [2]Comprehensive Cancer Centre the Netherlands, Registry & Research, Utrecht, Netherlands; [3]Maastricht University Medical Centre, Internal Medicine GROW − School for Oncology and Developmental Biology, Division of Medical Oncology*

Background: Cancer prevalence is expected to increase by more than 50% in the next 10 years. The follow-up burden can be reduced by less frequent testing in patients with a low probability to die of cancer. The prospects for stratified follow-up are illustrated for five common cancer types.
Methods: The Netherlands Cancer Registry provided data on 214,173 patients diagnosed in the period 2003–2009 with in situ and invasive breast, invasive ovarian, invasive lung, or in situ, Ta or invasive bladder cancer, or invasive skin melanoma. Relative survival rates and risks of second primary cancers were calculated. Age and cancer specific co-morbidity rates were obtained from Janssen-Heijnen et al (2005).
Results: Five-year relative survival in early stage breast, bladder and skin cancer, comprising at least 50% of the incident cases, was close to 100%. Sixty five percent of ovarian and 84% of lung cancer patients were diagnosed at an advanced stage with five-year relative survival rates below 30%. Thirty five percent of breast, 47% of ovarian, 63% of lung, 65% of bladder cancer and 26% of skin melanoma patients were aged 80+ years or had at least 1 co-morbidity. Cumulative five-year risks of second primary cancers were below 5%.
Conclusions: Selecting patients for less intensive follow-up based on cancer stage, age and presence of co-morbidity has a large potential to reduce the follow-up burden. Before implementing less intensive follow-up in clinical practice, however, clinical studies are needed to classify patients as having a short life expectancy or low relapse rate.
No conflict of interest.

1432 POSTER

Genetic background and risk of lung adenocarcinoma in never smokers

K. Takamochi[1], S. Oh[1], K. Suzuki[1]. *[1]Juntendo University School of Medicine, General Thoracic Surgery, Tokyo, Japan*

Background: The causative association between tobacco smoking and lung cancer is well-known.
However, the mechanism underlying the pathogenesis of lung adenocarcinoma in never smokers remains unclear. Recently, several driver oncogenes, such as *EGFR* and *EML4-ALK*, have been identified in lung adenocarcinomas of never smokers.
Material and Methods: This was a retrospective review of 588 patients with surgically resected lung adenocarcinomas between February 2009 and October 2012. The clinicopathological factors (age, gender, and pathological stage), *EGFR* and *KRAS* mutation status, a past history of any cancer or benign tumor, a family history of any cancer or lung cancer, and the presence of multiple primary lung cancers were compared between never smokers (n = 306) and smokers (n = 282).
Results: Lung adenocarcinomas in never smokers were more frequently found in females (P <0.001) and in patients with early stage disease ($P = 0.01$) than those in smokers. *EGFR* mutations were detected in 181

(59%) never smokers and in 88 (31%) smokers (P <0.001). *K-ras* mutations were detected in nine (3%) never smokers and in 57 (20%) smokers (P <0.001). The proportion of patients with a past history of any cancer was higher in smokers than in never smokers (28% vs 20%, P = 0.03). This may reflect the fact that tobacco smoking can cause various types of cancers. In contrast, the proportions of patients with any benign tumor and a family history of any cancer were higher in never smokers than in smokers (15% vs 4%, P <0.001 and 19% vs 12%, P = 0.04). These findings may suggest that a certain genetic background is involved in the pathogenesis of lung adenocarcinoma in never smokers. The frequencies of multiple primary lung cancers and a family history of lung cancer were not significantly different between never smokers and smokers (14% vs 11%, P = 0.2, and 7% vs 4%, P = 0.1). In never smokers, the *EGFR* and *KRAS* mutation status were not associated with a past history or a family history of any tumor, or the presence of multiple primary lung cancers.
Conclusions: A certain genetic predisposition is suspected to be involved in the pathogenesis of lung adenocarcinoma in never smokers. Further studies are thus needed to elucidate the genetic alterations associated with the susceptibility to lung adenocarcinoma in never smokers.
No conflict of interest.

1433 POSTER

Which colorectal cancer patients get venous thromboembolism?

A.J. Walker[1], J. West[1], T.R. Card[1], C. Crooks[1], D.J. Humes[1], M.J. Grainge[1]. *[1]University of Nottingham, Epidemiology and Public Health, Nottingham, United Kingdom*

Background: Patients with colorectal cancer are considered at high risk of venous thromboembolism (VTE) and recent NICE guidelines have advised extended prophylaxis for these patients following surgery. The guidelines group highlighted the lack of understanding of which of these patients are at increased risk and what the magnitude of this risk is. The aim of this study was to determine the occurrence of VTE in patients with a diagnosis of colorectal cancer.
Materials and Methods: Population based cohort study using data from 4 linked databases; the Clinical Practice Research Datalink, linked to Hospital Episode Statistics, Cancer Registry data and Office for National Statistics cause of death data. We determined the incidence rates (cases per 1000 person-years) of VTE in colorectal cancer patients according to various risk factors. Data was extracted from 1997–2006.
Results: We identified 10,319 patients with colorectal cancer. The incidence of VTE was 15.8 per 1000 person years (95% Confidence Interval (CI) 14.5–17.1). The incidence increased from 7.3 per 1000 person years (95% CI 5.0–10.7) in Dukes A patients to 41.3 per 1000 person years (95% CI 33.4–51.2) in patients with Dukes D stage. This represented a threefold increased risk when accounting for other risk factors (HR 3.08, 95% CI 1.95–4.84). The risk of VTE following surgery varied by stage of disease. Those patients undergoing emergency surgery had a 40% increase in risk of VTE following surgery compared to those undergoing elective surgery (HR 1.43 95% CI 1.15–1.78). Patients who had chemotherapy had a significantly higher rate of VTE than those who did not (HR = 1.39 CI 1.14–1.69).
Conclusions: Tailoring risk assessment to include stage of disease, timing of surgery and chemotherapy may help identify patients at increased risk of VTE with colorectal cancer and direct appropriate thromboprophylaxis during treatment.
No conflict of interest.

1434 POSTER

Post code lottery in lung cancer incidence

O. Olajide[1], I. Gee[2], E.A. Oladele[3], O. Raji[4]. *[1]Liverpool Community Health, Public Health, Liverpool, United Kingdom; [2]Liverpool John Moores University, Public Health, Liverpool, United Kingdom; [3]FHI 360, Prevention Care & Treatment Department, Abuja, Nigeria; [4]University of Liverpool, The University of Liverpool UK Cancer Research Centre, Liverpool, United Kingdom*

Background: Lung cancer is the most common cancer in the world with an estimated 1.6 million new cases diagnosed in 2008 but its incidence varies considerably within different areas in England. Socio-economic status of an individual has long been established a fundamental determinant factor in the incidence and prognosis of majority of illnesses and the aim of this study is to explore the impact socioeconomic status has on the incidence of lung cancer patients in Liverpool over a 3-year period.
Material and Methods: Hospital Episodes Statistics (HES) data from Liverpool Primary Care Trust (LPCT) was used to identify new cases of Lung cancer patients diagnosed between January 2005 and December 2007. Identified patients were later allocated into 5 classes (Quintiles) based on their residential postcodes using the Index of Multiple Deprivation, developed in 2007 by Department for Communities and Local Government (DCLG). This tool uses a weighting score on 7 aspects of deprivation for small areas (Lower Super Output Areas) and each quintile represents 20% of an identified population with similar deprivation characteristics.
Results: 80% of the patients diagnosed with lung cancer reside in the 5th quintile (the most deprived socioeconomically) and over 93% of the newly diagnosed lung cancer patients live within the 4th and 5th quintiles. There was no single case of a new lung cancer diagnosis from Liverpool residents living in the 1st quintile over the 3-year study (2004–2006) and only 7 (1.61%) cases were recorded in the 2nd quintile.
Conclusion: This study showed that lung cancer predominantly affects people with lower socio-economic status than their affluent counterparts and more public health work should be carried within deprived communities in order to reduce the inequalities gap for lung cancer.
No conflict of interest.

1435 POSTER

Potential risk of residential asbestos exposure: Japanese General Screening Study for Asbestos-related Diseases (JGSARD)

N. Seki[1], T. Yamaguchi[2], K. Eguchi[1], M. Kaneko[3], M. Kusumoto[3]. *[1]Teikyo University School of Medicine, Tokyo, Japan; [2]Tohoku University Hospital, Statistics, Miyagi, Japan; [3]National Cancer Center Hospital, Diagnostic, Tokyo, Japan*

Background: Currently, an argument about health risks by residential asbestos exposure as well as occupational asbestos exposure has been closed up in Japan. Therefore, the latest large-scale CT screening study reflective of a country's general situation of asbestos exposure will help citizens understand significant information about asbestos-related diseases.
Materials and Methods: JGSARD is a prospective cohort study for the general population representative of Japan designed to evaluate the actual situation of asbestos exposure and the prevalence of asbestos-related diseases through chest radiography and low-dose CT (LDCT) at baseline and after 2 years of follow-up. From 2006 to 2008, 9810 subjects (mean age, 57 years; 54% male and 50% smokers) underwent baseline screening in 26 institutions in Japan. Lifetime self-reported history of asbestos exposure (SHAE) was obtained.
Results: Occupational SHAE was definite and possible in 1103 (11.2%) and 1702 (17.3%) subjects, respectively, whereas residential SHAE was definite and possible in 262 (2.7%) and 931 (9.5%) subjects, respectively, although asbestos factory in their residential areas actually existed in 2870 (29.3%) subjects. The false negative rates of residential SHAE in all participants of this study (n = 9810), those with pleural plaque on LDCT (n = 264), and those with pleural plaque without occupational SHAE (n = 83) were calculated as high value of 85.6%, 76.0%, and 87.9%, respectively. Presence of pleural plaque was significantly correlated with male (odds ratio [OR], 2.32), age 60 years and older (OR, 1.75), smoking (OR, 1.60), occupational or residential SHAE (OR, 3.92), residential period in asbestos factory area (OR every 10 years, 1.13), and asbestos-related work period (7 works identified). Lung cancer was identified in 29 (0.3%) subjects. Presence of lung cancer was significantly correlated with age 60 years and older (OR, 2.67) and presence of pleural plaque (OR, 4.17) regardless of occupational and residential SHAE.
Conclusion: Our results indicate the potential risk of residential asbestos exposure and thus the importance of public relations and enlightenment for them among Japanese general population.
No conflict of interest.

1436 POSTER

Statin use as a moderator of metformin effect on overall survival in colorectal cancer patients with diabetes

M. Zanders[1], M. Van Herk-Sukel[2], H. Haak[3], R. Herings[2], V. Lemmens[1], L. Van de Poll-Franse[1]. *[1]Eindhoven Cancer Registry, Research, Eindhoven, Netherlands; [2]PHARMO Institute for Drug Outcomes Research, Research, Utrecht, Netherlands; [3]Maxima Medical Centre, Internal Medicine, Eindhoven/Veldhoven, Netherlands*

Background: Metformin has been associated with a decreased cancer risk and a decreased mortality in cancer patients. Individuals using metformin, frequently use statins as well. This study assessed whether the effect of metformin on overall survival varied by statin use among colorectal cancer patients.
Methods: Patients with primary colorectal cancer diagnosed between 1998 and 2010 in the South-eastern Netherlands were included from the Eindhoven Cancer Registry (ECR). The included patients were linked to data on drug dispensing from the PHARMO Record Linkage system. Colorectal cancer patients who started with diabetes medication in the five years prior to cancer diagnosis were included and the cumulative exposure

to diabetes drugs for this period was calculated. Cox proportional hazard analyses were conducted to assess whether overall mortality varied by statin use in patients using metformin.
Results: 289 colorectal cancer patients started with diabetes medication before cancer diagnosis, of whom 173 (60%) used statins and 220 (76%) used metformin as diabetes medication. Statin use was an effect modifier for the effect of metformin on overall mortality ($p = 0.04$), when taking into account cumulative exposure to the specific drugs and adjusting for patient-, tumour-, and comorbidity-related variables. However, the use of metformin was not significantly associated with a reduced overall mortality among colorectal cancer patients on statins (HR 0.87, 95% CI 0.73–1.03) when adjusting for the variables mentioned above and the additional cumulative use in days of insulin and sulfonylurea derivatives. The prognosis for those taking metformin and statins compared to those taking neither metformin nor statins was significantly better (HR 0.44, 95% CI 0.23–0.83).
Conclusions: The first results of this study showed that the effect of metformin on survival in colorectal cancer patients varied by their statin use. The combination of metformin and statins in colorectal cancer patients effected the prognosis positively in our study and may be due to synergistic effects. However, detailed information on laboratory function, such as LDL and Hba1C, was suboptimal, additional multivariate analyses should be performed and a relatively small number of patients was included.
No conflict of interest.

1437 POSTER

Castration-resistant prostate cancer (CRPC): Understanding disease progression and associated diagnostic procedures through a routine practice study in 13 medium-sized European countries

P. Vrouchou[1], G. Hechmati[1], J. Arellano[2], J. Cristino[1], I. Haynes[3], A. Liede[4], A. Rider[5], A. Worsfold[5], V. Crossland[5], R. Pollard[5]. *[1]Amgen (Europe) GmbH, Zug, Switzerland; [2]Amgen Inc., Thousand Oaks, USA; [3]Amgen Ltd., Uxbridge, United Kingdom; [4]Amgen Inc., San Francisco, USA; [5]Adelphi Real World, Macclesfield, United Kingdom*

Background: To examine CRPC, the natural course of disease progression and associated diagnostic procedures.
Materials and Methods: 167 physicians (100 oncologists and 67 urologists) completed a prospective 5-day workload form, an interview and an average of 8 patient record forms (PRFs, October 2012 through March 2013) for non-metastatic and metastatic CRPC patients. Final data from 142 workloads (not completed by all physicians), 167 interviews and 1,279 PRFs (including 475 CRPC patients at 'high risk' of bone metastases [BM], 505 CRPC patients with BM only, 102 CRPC patients with BM and visceral metastases [VM] and 197 CRPC patients with VM only) from 13 medium-sized European countries are reported.
Results: According to physician interviews, 61% of prostate cancer patients develop castration-resistance (where physicians specified a time-frame, this was most commonly 25−36 months post exposure to hormone therapy). Per the PRF data, multiple factors are involved in the diagnosis of castration resistance, the most common being elevated prostate-specific antigen (PSA) levels (79%), shortened PSA doubling time (39%) and no response to two different types of hormone therapy (32%).
According to the physicians, 78% of CRPC patients develop metastases. These data were further confirmed by the physician's daily workload outcomes which showed that among the CRPC population 82% had metastases. According to physicians, the factors associated with a high risk of developing BM in CRPC patients are: shortened PSA doubling time (78%), Gleason score (77%) and elevated PSA (74%). Per the physician daily workload results, the vast majority of metastatic CRPC patients have BM only or both BM and VM (94%). BM are commonly first suspected due to multiple factors such as symptomatic bone pain (31%), routine bone scan (29%) and elevated PSA (26%). However, BM are predominantly confirmed by a bone scan (69%).
Conclusions: Elevated PSA and shortened PSA doubling are the main factors involved in the diagnosis of CRPC and are also considered, as well as a high Gleason score, to be associated with a high risk of developing BM. Bone scans remain the main diagnostic procedure for confirming BM. These data highlight that the majority of non-metastatic CRPC patients in the 13 European countries will experience disease progression and develop BM in due course. There is a need for novel treatment strategies to delay metastatic progression to bone in patients with CRPC.

Epidemiological characteristics of liver cancer in Niamey

S. Mamoudou Garba[1], H. Hami[2], H. Mahamadou Zaki[1], A. Soulaymani[2], H. Nouhou[1], A. Quyou[2]. *[1]Abdou Moumouni University, Laboratory of Pathological Anatomy and Cytology − Faculty of Health Sciences, Niamey, Nigeria; [2]Ibn Tofaïl University, Laboratory of Genetics and Biometry − Faculty of Sciences Kenitra, Morocco*

Background: In Sub-Saharan Africa, liver cancer is a real public health problem. It is the third most common cancer and the second leading cause of cancer death (GLOBOCAN 2008). The aim of this study is to describe the epidemiological characteristics of liver cancer in Niamey, Niger's capital.
Material and Methods: This is a descriptive retrospective analysis of liver cancer cases, reported between 1992 and 2009 to the Niger Cancer Registry.
Results: A total of 555 liver cancer cases were recorded between 1992 and 2009, constituting 11.2% of all cancer cases reported in Niamey during this period. Of these, 60.7% were farmers. More than two-thirds were males with a male-female ratio of 2.21. The average age at diagnosis of liver cancer patients was 47 ± 14 years. Hepatocellular carcinoma was the most common histological type (98.6%). Among all detected cases, 206 (37.1%) died during the study period. The incidence rate of liver cancer was twice as high for men, with 5.89 cases per 100 000 men, compared with 2.80 cases per 100 000 women. The mortality rate was 1.59 deaths per 1000 000 population.
Conclusions: The absence of appropriate health policy prevents early detection of liver cancer and its management. This has a direct consequence on increasing in cancer incidence. Because of the seriousness of liver cancer in Niger; the health authorities should pay more attention to this pathology through efficient fight strategies.
No conflict of interest.

Cancer in Indians of the Brazilian Amazon

E.R. Nascimento[1], A.V. Wanderley[2], D.F. Costa[2], R.C. Almeida Júnior[2]. *[1]Hospital Santa Casa do Pará, Clínica Médica, Belém, Brazil; [2]Hospital Ophir Loyola, Oncologia, Belém, Brazil*

Background: Cancer is currently a problem public health worldwide and is the second cause of death in many countries. The impact of this disease on indigenous peoples is poorly understood in Brazil and in the Amazon region. This research was conducted with the purpose to characterize the epidemiological profile of cancer in Indians of the Brazilian Amazon.
Methods: We conducted a descriptive, cross-sectional study based on retrospective analysis of medical records of the Indians diagnosed with cancer treated by Hospital Ophir Loyola, a referral center for oncology in the state of Pará, between January 2001 and December 2011. The medical records were evaluated for epidemiological data, diagnostic, and therapeutic response, according the protocol developed after literature review.
Results: We included 47 Indians with confirmed diagnosis of cancer. Women were more affected (68.09%), in the ratio of 2.12:1. The average age was 46.14 years, with the predominant age of 60−69 years (21.28%). Most patients were illiterate (46.81%), smokers (42.55%), from the municipalities of Altamira and Jacareacanga (17% each), of the indigenous ethnic group of Mundurukus (23.4%). Cervical cancer was the most frequent malignant tumour (48.93%), affecting 76.69% of women adults. Among adult men prevailed not any cancer. The haematological malignancies were the most detected in the paediatric age group (83.3%), with 50% of indigenous children diagnosed with Hodgkin's Lymphoma. The vast majority of patients was treated with modality cancer therapy (85.1%) and radiochemotherapy was the most used (23.4%). The time interval between diagnosis and cancer treatment was on average of 113 days; being more than 02 months in 60% of cases. Complete response and partial response was observed over the results after the first treatment (32.5% and 20%, respectively). We recorded 14 deaths among patients investigated.
Conclusions: From these data, it was possible to characterise the clinical and epidemiological profile of indigenous patients with cancer in the Amazon region. The data obtained could help in the implementation of public policies aimed at primary prevention, injury reduction and lower mortality for improvements in indigenous health in Brazil.

1440 POSTER

The effect of prenatal factors on the development of colon cancer

F. Ozdemir[1], K. Ersoy[2], M. Topbas[2], E. Fidan[2], B. Yildiz[2], H. Kavgaci[2], F. Aydin[2]. [1]*Karadeniz Technical University, Trabzon, Turkey;* [2]*Karadeniz Technical University, Medical Oncology, Trabzon, Turkey*

Background: There is some evidence that prenatal factors can play role in development of colon cancer. Children with an old parent age at the time of birth were observed to develop certain childhood cancers more frequently. This trial is designed to investigate the effects of some prenatal factors on colon cancer risk. Particularly, investigation of the effect of advanced parent age on colon cancer development risk was targeted.
Material and Methods: In this study 117 in or out patient diagnosed as colon cancer and 234 control patients included. Definitive diagnostic results and dates of diagnosis were determined from pathological reports. Groups were asked the parenteral age, smoking habits, sociodermographic, environmental, familial and reproductive traits. The results were compared between the patients and the control group.
Results: It was determined that children may have higher risk if mother and father are more than 30 at birth ($p = 0.018$, $p = 0.020$). While the mean mother age at birth was 25.6 ± 5.72 in patients, it was 24.7 ± 6.90 in the controls. The difference was not statistically significant ($p < 0.056$). While the mean father age at birth was 29.4 ± 6.58 in patients, it was 27.4 ± 7.47 in the controls. The difference was statistically significant ($p < 0.001$). Smoking of mother was one of the important risk factors of colon cancer ($p = 0.044$).
Conclusion: Our data supports that some prenatal factors such as high parental age at birth and smoker mother may be risk factors for some cancers for children. This is the first study reports that having high parental age at birth and exposure to smoke prenatally increase the risk or colon cancer.
No conflict of interest.

Pinnacle Study: Epidemiology and characteristics of neutropenic fever (NF) in cancer patients in Spain

P. Gascon[1], E. Aranda[2], J.J. Cruz[3], A. Antón[4], A. Casas[5], B. Massuti[6], C. Camps[7], A. Barnadas[8], F.J. Rebollo[9], J. De Castro[10]. [1]*Hospital Clinic i Provincial, Oncology, Barcelona, Spain;* [2]*Hospital Reina Sofía, Oncology, Córdoba, Spain;* [3]*Hospital Universitario de Salamanca, Oncology, Salamanca, Spain;* [4]*Hospital Miguel Servet, Oncology, Zaragoza, Spain;* [5]*Hospital Virgen del Rocío, Oncology, Sevilla, Spain;* [6]*Hospital General de Alicante, Oncology, Alicante, Spain;* [7]*Hospital General de Valencia, Oncology, Valencia, Spain;* [8]*Hospital Santa Creu i Sant Pau, Oncology, Barcelona, Spain;* [9]*Sandoz Pharmaceutical, Oncology, Madrid, Spain;* [10]*Hospital Universitario la Paz, Oncology, Madrid, Spain*

Background: The Pinnacle study aims to evaluate NF and its clinical management in Spain, further linking action protocols from medical oncologists with a patient's profile. The main objective is to describe the incidence of hospitalizations due to NF. Secondary objectives are to describe the characteristics of patients, NF, and describe its evolution and management.
Material and Methods: This study was designed as a retrospective analysis of hospital admissions of patients who developed NF over a 3-month period, involving 10 national tertiary care centers. Patients were included sequentially after providing informed consent, and data were collected on the underlying disease, treatment received and outcome.
Results: 119 patients were recruited. The most prevalent tumors were lung, breast and colorectal. The incidence of NF was 2.29%. The median duration of hospitalization was 7 days. Only 32% of patients had received prophylaxis with G-CSF, and these patients had a reduced duration of hospitalization (2.5 days shorter). On admission, the median neutrophil count was 260/mm^3. 61% of patients were receiving palliative chemotherapy and the remainder either curative or adjuvant treatment. 14% of patients were admitted without meeting the two NF criteria (temperature of 38.2^{o}C and neutrophil count <500/mm^3). Among patients receiving curative or adjuvant chemotherapy, 11% discontinued chemotherapy as a result of NF, 6% had dose reduction, 16% a dose delay, and 2% a dose reduction + delay (similar outcomes were noted in patients receiving palliative treatment). The most commonly used antibiotics were piperacilin-taxobactam,amoxicilin-clavulanic and cephalosporins. 8 patients died, 2 due to NF, 5 due to disease progression and one due to ventricular fibrillation.
Conclusions: NF is an important cause of chemotherapy delays and dose reductions, which can lead to reduced effectiveness of treatment. It is a serious complication of chemotherapy treatment, with a substantial proportion of death and a hospital stay of about seven days. Moreover, 14% of patients were admitted without fulfilling both NF criteria. Patients who were receiving palliative chemotherapy had a longer hospitalization, and the impact on their chemotherapy was the same as in patients receiving non-palliative treatment. On the other hand, patients receiving G-CSF had a shorter hospitalization. The number of died patients shows that patients with NF are patients mostly in progression and clinical instability.

1442 POSTER

Histopathologic characteristics and related variables in a study of 4,436 patients included in the Registry of Breast Cancer (Registro Cáncer de Mama- RCM) of the Argentine Society of Mastology (SAM)

A. Nuñez De Pierro[1], J. Bustos[2], G. Müller Perrier[3], J. Loza[4], E. González[5], C. Lorusso[6], F. Coló[4], S. Barchuk[1], A. Avegno[7], R. Elizalde[7]. [1]*Hospital Fernandez, Breast Surgery, Buenos Aires, Argentina;* [2]*Hospital Santojanni, Breast Surgery, Buenos Aires, Argentina;* [3]*Hospital Piñero, Breast Surgery, Buenos Aires, Argentina;* [4]*Instituto A. Fleming, Breast Surgery, Buenos Aires, Argentina;* [5]*Instituto A. Roffo, Breast Surgery, Buenos Aires, Argentina;* [6]*Hospital Italiano de Bs. As., Breast Surgery, Buenos Aires, Argentina;* [7]*Hospital Pirovano, Breast Surgery, Buenos Aires, Argentina*

Background: In Argentina, more than 18,000 new cases of breast cancer are diagnosed every year. However, as we do not have adequately powered statistical registries in our country we cannot establish whether our local data are in concordance with international series. We present an analysis of the data collected in the web-database SAM-RCM regarding histopathological characteristics and basic therapeutic approaches.
Material and Methods: Descriptive, cross-sectional study of 4,436 patients (pts) included in the RCM until 31/12/2012.
Results: In this series, 9.8% were in situ carcinomas (Ca), 90.2% invasive Ca.
DCIS: 79.3% were treated with breast-conserving surgery (BCS) and 87.1% of these, with radiotherapy (RT); 20.7% required mastectomy. Regarding estrogen receptors (ER), 76.7% were positive, and 84.4% of them received tamoxifen.
INVASIVE CA: pT1 was found in 57.6% of pts. BCS was used in 81.5% of tumors $\leqslant 3$ cm. In 98.2% of these RT was added. Positivity of ER was similar in pre-(PrM) (78.5%) and post-menopausal pts (PoM) (83.7%), and also similar in the subgroup of age less than 40 years (70.5%). Lobular Ca was more frequently RE+ as compared to ductal Ca (91.6%vs81.3%, $p < 0.0001$). HER2 positivity was 13.5%, unrelated to menopausal status (MS). High Ki67 levels were detected more frequently in PrM as compared to PoM pts ($p < 0.0001$). We detected a direct association between Ki67 levels and tumor grade ($p < 0.0001$). Tumors were triple negative in 12.4% of PrM, 10.4% of PoM and 14.3% of women under 40.
pT1 SUBGROUP: Axillary lymph node involvement was similar for T1a and T1b (8.8%vs10.4%, p=NS), but greater for pT1c ($p < 0.0001$). As to pT1c tumors, PrM pts were node+ in 33.9% of cases and PoM in 26.9% ($p < 0.02$). This was not related to ER status. We found no association between adverse pathological features and MS. Chemotherapy (ChT) was used in 20.0% of stage I and 56.4% of stage IIA. Stratified by stage, ChT was used in a similar proportion in PrM and PoM pts for stage I, but not for stage IIA (74.5% in PrM vs 47.4% in PoM, $p < 0.05$). Hormone therapy was used in 88.3% of ER+ pts, regardless of MS. Only 61.1% of HER2+ pts received trastuzumab.
Conclusions: The variables we studied show no differences with the available published data, thus enabling us to extrapolate international data to our population. We find an exception regarding the lower incidence of HER2+, the higher utilization of BCS in small tumors, and the low use of trastuzumab in our series.
No conflict of interest.

1443 POSTER

Homeostasis model assessment to detect insulin resistance and identify patients at high risk of breast cancer

I. Capasso[1], E. Esposito[2], M. Montella[3], A. Crispo[3], M. Grimaldi[3], E. Cavalcanti[4], G. Esposito[5], M. D'Aiuto[2], G. D'Aiuto[2], G. Ciliberto[2]. [1]*Fondazione Senatore G. Pascale, Napoli, Italy;* [2]*Fondazione Senatore G. Pascale, Senology, Napoli, Italy;* [3]*Fondazione Senatore G. Pascale, Epidemiology, Napoli, Italy;* [4]*Fondazione Senatore G. Pascale, Pathology, Napoli, Italy;* [5]*Fondazione Senatore G. Pascale, Immunohematology, Napoli, Italy*

Background: Altered insulin signalling is thought to play a major part by increasing cancer cell growth, proliferation and survival. Therefore, to investigate clinically the potential role of insulin in breast carcinogenesis we studied a large cohort of breast cancer patients and controls to

assess which correlations existed with MS criteria and, specifically, insulin resistance measured through Homeostasis Model Assessment (HOMA-IR).
Materials and Methods: 975 women have been enrolled of which 410 underwent surgery for breast cancer (cases), whereas 565 were healthy women (controls). After obtaining informed consent, for each woman anthropometric features were measured, arterial blood pressure was taken and venous blood was collected. Insulin levels were defined in the normal range when between 5 and 25 mcU/ml, whereas concentrations above 25 mcU/ml were considered corresponding to hyperinsulinemia. The HOMA-IR index was calculated as the product of the fasting plasma insulin level (mcU/mL) and the fasting plasma glucose level (mg/dl), divided by 405. The cut off value to define insulin resistance was HOMA-IR $\geqslant$2.50. Chi-squared test and logistic regression analyses were used to confirm the association between MS and breast cancer and to calculate the risk. Statistical significance was considered at $p < 0.05$.
Results: We found a higher prevalence of MS (35%) among post-menopausal women with breast cancer compared to healthy women (19%). Waist circumference >88 cm was measured in 53% of cases OR 1.58 (95% CI 0.8−2.8) and in 46% of controls. Hyperinsulinemia was detected in 7% of cases and only in 3% of controls. HOMA-IR was $\geqslant$2.50 in 49% of cases (C.I.95% =0.42 to 0.52) respect to 34% of controls (C.I.95% =0.03 to 0.38), showing a positive trend for breast cancer patients. 80% of insulin resistant cases were postmenopausal, whereas premenopausal were 20%. HOMA-IR and insulin were positively associated to at least three other MS criteria in 89% of cases compared to 50% of controls.
Conclusions: Our results further support the hypothesis that MS, in particular insulin resistance and abdominal fat, can be considered as risk factors for developing breast cancer in postmenopause. Moreover, we suggest that HOMA-IR, rather than fasting plasma glucose and fasting plasma insulin levels, could be a valuable tool to identify patients with subclinical insulin resistance, which could be relevant for primary prevention and for screening of patients at high risk.
No conflict of interest.

1444 POSTER

Pattern of cancer incidence in Yemen (2000–2011)

A. Badheeb[1]. [1]*Hadhramout University, Prince Sultan Cancer Unit, Mukalla, Yemen*

Background: Hadhramout Sector in Yemen constitutes of three governorates (Hadhramout, Shabwa, & Almahra) with a population of 1,684,373 inhabitants. Cancer cases reported from the different health care facilities are registered in Hadhramout Cancer Registry (HCR) as a population based cancer registry. This paper describes the incidence of cancer in the period of 10 years' time (2000–2011).
Methodology: The data was analyzed using the CanReg4 Programme and the incidence rate was calculated based on mid-time total population in each period.
Results: The cancers were more frequent in females with age standardized incidence rate (ASR) for them of (28) while for males was (22.1). The three most common types were breast (15.6%), leukemia (6.2%), and Non-Hodgkin's Lymphoma (6%). In the pediatric group, leukemia (20.5%) was most common cancer.
Conclusions: Breast cancer in females and hematological malignancies in males were the most frequent types of malignancies. Leukemia were the most common cancers in children.
Our results generally indicate that the pattern of the most common registered cancer bears some similarities with the Aden and Gulf's data with some differences that necessitate further evaluation.
No conflict of interest.

1445 POSTER

Epidemiological aspects of breast cancer: Multicentric study of 4,041 patients. Argentine Society of Mastology, RCM (registro cáncer de mama − breast cancer registry)

R. Elizalde[1], L. Barbera[2], B. Naso[3], C. Storino[4], C. Noblia[5], G. Horton[6], R. Castaño[7], A.M. Avegno[1], S. Barchuk[8], A. Nuñez de Pierro[8]. [1]*Hospital Pirovano, Breast Surgery, Buenos Aires, Argentina;* [2]*Clinica Breast, Breast Surgery, La Plata, Argentina;* [3]*Hospital Penna, Breast Surgery, Buenos Aires, Argentina;* [4]*Hospital Durand, Breast Surgery, Buenos Aires, Argentina;* [5]*Centro de Mastologia Uruguay, Breast Surgery, Buenos Aires, Argentina;* [6]*Hospital Marie Curie, Breast Surgery, Buenos Aires, Argentina;* [7]*Hospital Aleman, Breast Surgery, Buenos Aires, Argentina;* [8]*Hospital Fernandez, Breast Surgery, Buenos Aires, Argentina*

Background: In Argentina, more than 18,000 new cases of breast cancer are diagnosed every year. However, we do not have adequately powered statistical registries in our country. For this reason the Argentine Society of Mastology saw the need to create a database. Here we present an analysis of the data we collected in the participating centers in the first two years, describing some epidemiological characteristics, as well as clinical presentation, stage and surgical treatment of breast cancer in Argentine women.
Material and Methods: Descriptive, cross-sectional study, analyzing data of 4,041 patients, which was entered in the web-database RCM until September 30th, 2012.
Results: 99.6% of patients were women, with a mean age of 57.7$\pm$13.2 years. Mean age at menarche was 12.5$\pm$1.4 years, and 48.6$\pm$4.1 years at menopause. Post-menopausal women accounted for 68.8% of patients. Twenty percent of patients were nulliparous. A family history of breast cancer was identified for 19.3% of patients. The main reason for consultation was an unusual finding in breast self-examination (54.3% of patients). Clinical stages were as follows: 11.6% stage 0, 40.6% stage I, 36.5% stage II, 10.3% stage III, and 1.0% stage IV. In 69.4% of cases a segmental resection of the breast was performed. Axillary lymph node dissection was the most frequent treatment of the axilla before the year 2000 (67.9%), but the sentinel lymph node biopsy was used for 63.6% of patients in more recent years.
Conclusion: Demographic variables associated with breast cancer analyzed in this series are no different to those published in most of the literature.
No conflict of interest.

1446 POSTER

Self-examination and risk groups in screening breast cancer

C. Senín Estor[1], N. Garcia Cid[1], A. Alonso Herrero[1], I. Fernández Pérez[1], A. Mateos Martín[2], J. Castellanos Diez[1]. [1]*Complexo Hospitalario Universitario de Vigo, Medical Oncology, Vigo, Spain;* [2]*Complexo Hospitalario Universitario de Vigo, Pathologic Anatomy, Vigo, Spain*

Background: There is a consensus that routine screening mammography should be offered to women ages 50 to 69. Consensus is not as strong for routine screening among women less age 49, over age 70 and for screening with clinical breast examination (CBE) or breast self-examination (SE).
Methods: A retrospective review of firstly diagnosed primarily breast cancer patients over the period 2010–2012 was perform.
We divided patients based on age at presentation: <50, 50−69, >69 and way of presentation of breast cancer: self-examination (SE), mammography (MM) and clinical breast examination (CBE). The research was performed using medical records review.
Results: Among 766 patients diagnosed in this period, the mean age was 60 years (30−93) and 85% of the tumors were invasive ductal carcinomas. Age groups included: 29% <50, 44% 50−69 and 27% >69. Presentation groups included 44% SE, 41% MM and 15% CBE.
Self-palpable mass was the most frequent way of presentation in <50 (50%) and >69 (66%), and the second in 50−69 (27%) after mammography.
More patients in <50 group had had a history of benign breast pathology (20%, $p < 0.01$), no parity (19.5%, $p < 0.01$), age at first birth >30 (39%, $p < 0.05$), use of contraceptive pills (44%, $p < 0.01$) and more breast density on mammography (72%, $p < 0.01$), compared with 50−69 group (13%, 15%, 20%, 23% and 40% respectively).
Tumors diagnosed in <50 group tended to have more aggressive features than those diagnosed in 50−69 group: T3−4 (14% vs 8%, $p < 0.01$), negative hormonal receptors (16% vs 15%, $p = 0.9$), her2 overexpression (30% vs 18%, $p < 0.01$), ki67 $\geqslant$14% (72% vs 60%, $p = 0.04$), high grade (39% vs 27%, $p = 0.04$), positive nodes (44% vs 35%, $p = 0.096$).
Conclusions: A significant number of women were diagnosed out of screening group and with palpable masses or abnormal clinical breast examination, many with aggressive tumors. It would be necessary more studies to better select patients at risk, although they are not included in screening age.
No conflict of interest.

1447 POSTER

Epidemiological aspects of cervical cancer incidence in mountainous region of Kyrgyz Republic

S. Naizabekova[1], P. Shofakirova[1], T.A. Abdyldaev[1]. [1]*National Center of Oncology, Chemotherapy Department, Bishkek, Kyrgyzstan*

Background: To study influence of high altitude on cervical cancer incidence in the Naryn region of Kyrgyz Republic.
Methods: Patients with the primary diagnoses of cervical cancer received treatment at the National Center of Oncology of Kyrgyz Republic during the period of 1996–2005.
Results: Altitude factors in Naryn were divided into 3 levels: first level − up to 2000 meters above the sea level; second level − 2000 to 3000 meters; and third, 3000 meters and higher.

Patients during the treatment period were divided by age: up to 30-years old − 5 cases (1.8%); 31−40-years old − 50 cases (18.5%); 41−50-years old − 140 cases (51.8%); 51−60-years old − 45 cases (16.6%); and, 61-years old and older − 30 cases (11.1%).
Cancer incidence rate for the first altitude level (up to 2000 meters above the sea level) was 18.8 per 100 000 people, for the second (2000–3000 meters) − 23.9; and for the third (3000 and higher) − 4.2 per 100 000 people.
Of the total number of patients with cervical cancer, only 2 patients were registered with I stage of cancer (0.7%); 80 patients were registered with II stage (or, 29.6%); 130 patients had III stage cancer (48.1%); and 58 patients were discovered with IV stage (21.4%).
Conclusion: Accordingly, the incidence rate for cervical cancer in the mountainous region of Naryn is relatively high, at 13.2 per 100 000 people. The highest rate of cervical cancer in the focused region is observed for the age group of 41−50-years olds where patients are mainly diagnosed at the III and IV stages. The study concluded that altitude factors can favorably influence incidence rates of cervical cancer − the higher the altitude above the sea level, the less the incidence rate.
No conflict of interest.

1448 POSTER

21-year-long trends in cancer mortality in Tomsk population

I. Konobeevskaya[1], L.A. Kolomiets[2]. [1]*Cancer Research Institute, Tomsk, Russian Federation;* [2]*Cancer Research Institute, gynecology, Tomsk, Russian Federation*

Background: To study 21-year-long trends in cancer mortality in Tomsk population.
Material and Methods: The study was performed as a part of international investigation 'Epidemiological study of the causes of the dramatic fall in life expectancy in Russia in 1990'. Russian Centers (Moscow, Tomsk, Barnaul, Biisk − prof. D.Zaridze, prof. R. Karpov), centers of France (IARC, Lyon − d-rs P.Bofetta and P.Brennan) and of Great Britain (Oxford University − prof. R.Peto) were participants of the study. The following study steps were used: working meetings in Tomsk, in Moscow and in Lyon (collaboration agreement, contract 043905), training of interviewers (practical seminars for 45 physicians of primary medical stuff for screening population, instructions, using standardized questionnaires, screening families, identity cards), receiving of Ethical Committee permission, informing population (newspapers, radio, TV, advertisement), collaboration with Forensic Medicine Department of experts. Standard protocol was used for the study.
Results: A total of 90 745 persons aged from 15 to 74 years who died in 1990–2010 were investigated. Apart from the standardized questionnaires, we used archival data from Tomsk Statistical Administration, Forensic Medicine Department, and Civil Registry Office. The total mortality rates ranged from 889 to 1588 in men and from 509 to 784 in women per 100,000 of population. Mortality in women was 2-fold lower than in men. Cancer death took the 2nd place (17.5% in women) and the 3rd place (15.7% in men) in the total mortality. Mortality dynamics from neoplasm's varied from 181 (in 1991) to 244 (in 2009) in men and from 127 (in 1992) to 205 (in 2008) in women. It should be noted that mortality in women was by 27% lower than in men. Mortality risk from cancer was associated with smoking, profession status, alcohol and education.
Conclusion: The study showed feasibility of retrospective analysis of death cases in the population of a moderately urbanized city of West Siberia. Methodology of studying death cases was successfully implemented into practical health care system. An array of documents (form of informed consent from family members; informational and methodical instructions for interviewers; questionnaire; other tools for acquiring information about the living and deceased individuals; interviewer's certificate; announcements; etc.) was worked out and implemented in Tomsk hospitals. The cancer mortality rates ranged from 181 to 244 in men and from 127 to 205 in women per 100,000 inhabitants. Mean age of mortality in Tomsk was significantly lower (by 6.6–19.8 years) than in the population of the West.

The role of alcohol consumption on overall and cause-specific mortality in the European Prospective Investigation into Cancer (EPIC) study: A competing risks analysis

I. Licaj[1], I. Romieu[1], P. Ferrari[1]. [1]*International Agency for Research on Cancer, Nutritional Epidemiology Group, Lyon, France*

Background: In 2005, it was estimated that alcohol caused 3.2% of all deaths worldwide (WHO 2007). An exhaustive evaluation on the relationship between alcohol use and mortality was carried out in the European Prospective Investigation into Cancer and Nutrition (EPIC) study, a large prospective cohort in 10 Western European countries, using a competing risks analysis.
Methods: Multivariable Cox regression models were used to quantify the association between baseline alcohol intake and risk of overall and cause-specific mortality, i.e. alcohol-related cancers, cardiovascular disease and deaths due to injuries/violence. Models were adjusted for relevant confounding factors. Participants with prevalent diseases at baseline (anyone of cancer, stroke, heart disease, diabetes, or hypertension) were excluded. The analyses used information on 288,406 study participants with over 3.7 million Person-years and 15,174 fatal events. An augmented dataset was used to evaluate the association categories of baseline alcohol (coded as never, former, (1−5] (reference category), (5−15], (15−30], (30−60], >60 g/day) and cause-specific mortality. The effect of alcohol across causes of death was compared.
Results: A total of 1 781 deaths due alcohol-related cancers (including cancers of upper aero-digestive tract, breast [women], liver and colorectum), 2 613 cardiovascular disease (CVD) deaths, and 694 injuries and violent death were used. In men, alcohol use was positively associated to death due to injuries, and to alcohol-related cancers. In women associations were overall less pronounced. Alcohol consumption showed an inverse relationship with CVD mortality, both in men and women. The alcohol/mortality relationships were heterogeneous ($p < 0.001$) and across specific causes and non-linear, both in men and women. Based on a competing risks analysis, at the age of 60 years a heavy drinker woman had a chance of dying within the next 10 years from an alcohol-related cancer, CVD or injuries/violence equal to about 0.6%, 0.5%, and 0.3%, respectively. Corresponding figures in men were 2%, 2% and 1%.
Conclusion: Alcohol use was positively associated to death due to injuries/violence, and to mortality due to alcohol-related cancers in men. A non-linear J-shaped association was observed for CVD mortality, particularly in men.

1450 POSTER

Triple-negative breast cancer − a Hispanic experience

J. Mortera Casillas[1], P. Cabrera Galeana[1], G. Tellez Trevilla[1], E. Gomez Garcìa[1], R. Serrano Ortiz[2], J.L. Barrera Franco[3]. [1]*ISSSEMYM, Medical Oncology, Estado de México, Mexico;* [2]*ISSSEMYM, Surgical Oncology, Estado de México, Mexico;* [3]*ISSSEMYM, Medical Director, Estado de México, Mexico*

Background: Breast cancer is known to be a heterogeneous group of tumors that gene studies identified in different subtypes. Triple negative (TNBC) reflect the worst prognosis of the disease and represents 15% of all invasive breast cancers, but some studies have suggested that its prevalence differs between races. In Mexico there is a high TNBC incidence reported. There most be an association with risk factors. Although there are multiple risk factors documented with TNBC, age, African-American origin, obesity and overweight, hypertension, diabetes mellitus, smoking and alcoholism, age at menarchea and age at first pregnancy, there is some information of prevalence of TNBC among Hispanic women.
Methods: We identified 145 patients with triple-negative breast cancer collected from 2005 to 2011 in Centro Oncologico Estatal ISSEMyM. All histopathologic and immunohistochemical diagnoses were reviewed by a breast cancer pathologist. The prevalence of TNBC, its association with clinicopathologic characteristics and risk factors were determined.
Results: The mean age at diagnosis of TNBC was 47 years and was more commonly in locally-advanced stages. There was an incidence of 66 patients with body mass index (BMI) >25 kg/m^2 (45%), 35 patients with body mass index (BMI) >30 kg/m^2 (28.1%). BMI mean was 27 kg/m^2. The presence of less than 40 years old was found in 20 patients (13%), all were mexican, 83 patients were with ISSEMyM social securance and 63 with social securance (seguro popular), there were 34 patients documented with hypertension, 18 with diabetes mellitus. The mean age at menarche was 14 years old, first pregnancy mean 20 years (15−41). Clinical stage was distributed as follows: 2.7% of patients had bilateral diseases, 6.8% of patients had stage I disease, 43.4%of patients had stage II disease, 37.9% of patients had stage III disease, and 11% of patients had stage IV disease at diagnosis. 83 patients were able to receive adjuvant treatment and 62 were evaluated after neoadjuvant treatment. Of these patients were histologically documented complete pathological responses 14 (15.3%) and 48 overall responses (52%). Was identified primarily ductal histological type and well differentiated. 26 patients had lymphovascular infiltration. Mean follow-up of our patients was 1184 days, with a median relapse free-survival of 601 days and a median overall survival of 765 days. At the moment of the analysis only 21 deaths were reported.
Conclusions: In our cancer center we observed a similar distribution to that reported in large series of triple negative breast cancer and we also demostrate a high incidence of diabetes and hypertension, both of them relacionated with metabolic syndrome. In our study population, we

observed that the prevalence of TNBC was 8.3% in our cancer center but we detect a high incidence of metabolic syndrome or its variants in the TNBC patients so we need to search strategies in the Hispanic population to improve outcome in TNBC patients.

1451 POSTER

Prevalence of cervical and uterus cancer and ovarian cancer in Andijan region

D. Mamarasulova[1], D. Tursunov[2], Y. Ziyaev[2], D. Yakubova[2]. *[1]Andizhan State Medical Institute, Gynaecology, Andijan, Uzbekistan; [2]Andizhan State Medical Institute, Oncology, Andijan, Uzbekistan*

Objective: To investigate the prevalence of cancer of the cervix and uterus and ovaries in Andijan region.
Materials and Methods: We analysed and compared materials of oncological service bulletins and registration of malignant tumours. 953 records were examined. Age of the patients was ranged from 13 to 86 years.
Results: The highest number of women suffering from various tumours of the reproductive system, are observed in 2011–2012 y (234–216 people per year), the least − in 2008 (145 people). In 2008–2009, the number of women affected was less than 160 per year, and in 2008–2012, respectively 200. The smallest number of women (14), suffering from tumours of the body of uterine, it was in 2008–2009, the highest number − in 2011 (36). In the period 2008–2009, the number of patients was less than 15 per year, and in 2011–2012, more than 30. The smallest number of patients with tumours of the cervix were in 2008 (104), the highest number (149) in 2010. The largest number of women (55) suffering from ovarian neoplasms was revealed in 2011, the lowest (27) in 2008–2009, and over the years there is a tendency to increase, and the rejuvenation of ovarian cancer among women.
The largest number of women suffering from cervical cancer is at the age of 17−49 years (317), and more than half of all patients in the age range 32−59 years (512). The largest number of patients with cancer of the corpus uteri was aged in range of 50−59 years (55), and more than half of all patients are in the age range 50−69 years (81). The largest number of women suffering from ovarian cancer is at the age of 17−49 years (94), the least-in the age range 70 years and over (9) and <17 years (3). More than half of patients with this pathology are in age range from 40 to 59 years inclusive.
Conclusions: The number of people in Andijan region suffering from cancer of the body and cervix of uterus, and ovarian cancer in the last three years has increased dramatically. Women of working age (30 to 59 years) are most susceptible to malignant tumours of the reproductive system.
No conflict of interest.

1452 POSTER

Incidence, survival and clinical characteristics in adult acute lymphoblastic leukemia in a single institution: SOLCA-Guayaquil-Ecuador

K. Garcia[1], K. Posligua[2], M. Barzallo[2], G. Paulson[3], M. Santacruz[3], R. Engracia[3]. *[1]Solca Hospital, Guayaquil, Ecuador; [2]Solca Hospital, Hematology, Guayaquil, Ecuador; [3]Solca Hospital, Oncology, Guayaquil, Ecuador*

Background: Adult patient with Acute Lymphoblastic Leukemia (ALL) were 52.5% of acute leukemias admitted in the Hospital, with an annual incidence of 18 new cases, the objective of the study was to determine incidence, clinical and biological characteristic, treatment response and overall survival with the institutional protocol.
Material and Methods: A retrospective study was conducted from 2008 to 2011, included all adult patients >15 años, with at least cytomorphologic diagnosis of leukemia who received intitutional protocol consists of four phases: Induccion 1, Induccion 2, Early Consolidation and standar maintenance up to 2 years, if found t(9;22), imatinib was added. Data were analyzed by SPSS v13.
Results: 74 patients with ALL >15 years were admitted at Institute from 2008–2011. The median age was 31 years (range: 15 to 81 years) and 48 patients (64.9%) were males. FAB morphologic diagnosis: ALL-L1: 40.5%(30), ALL-L2: 13.5%(12), ALL unspecified: 13.5%(12), according to the immunophenotype: B-common ALL: 50%(37), Pre B-ALL: 12.2%(9), T-ALL: 5.4%(4), and in 32.4% (24) was not performed flow cytometry for economic reasons, molecular biology studies and/or cytogenetic were available only in 37.8% (25), and in 32% was found some alteration: t:(9;22): 20%(5); t:(12;21): 8% (2), inv(16): 4%(1). Unfavorable prognostic factors such as age ocurred in 36.5% (27); leukocytosis $\geqslant$25.000: 60.8% (45), CNS involvement: (2.7%) 2. Sixteen patients (21.6%) died before starting treatment for infectious complications and/or bleeding, one patient received palliative treatment and six patients discontinued treatment. In 51 evaluable patients, 72% achieved complete response (CR) with induction, however during the course of treatment continuous CR only occurred in 13.7% (7) in an median follow-up of 38 months (range: 16 to 59 months), 62.7%(32) relapse/refractory, 23.5%(12) died by toxicity. The median overall survival (OS) was 17.6%; patients with a poor prognosis factor had an OS of 10%, and standard risk factor: 45.5%.
Conclusions: Clinical, immunophenotype and genetic abnormalities are essential to provide treatment according to risk and therapeutic targets. Currently efforts are being made to improve diagnostic techniques in the Institute. In our environment remains an aggravating factor deficiencies economic, isolation measures, availability of blood products, and supportive care, increasing mortality.
No conflict of interest.

1453 POSTER

Strategies to develop personalised screening programmes: A request for discussion

S.M.E. Geurts[1], J.A.A.M. Van Dijck[1], J.M. Broeders[1], A.L.M. Verbeek[1]. *[1]Radboud University Medical Centre, Health Evidence, Nijmegen, Netherlands*

Background: Currently, it is debated whether risk-based screening programmes are more (cost-)effective than 'one-size-fits-all' programmes. Most studies focus on risk stratification according to absolute risk of event. We would like to discuss whether this is the only and best approach.
Methods: We will theoretically compare the potential impact of stratification according to absolute risk of event, screening test characteristics and life expectancy.
Results: In primary and secondary screening event rates are generally low and the discriminating power of predictive profiles limited. As a result, the absolute risk difference between person subgroups with a low or high risk of event is small. This small difference will lead to quite similar 'optimal' screening programmes for low and high risk groups. Besides risk of event, the potential benefit of a screening programme depends on the sensitivity of the screening modality. This sensitivity differs between persons. Therefore, adaptation of screening programmes according to subgroups' sensitivity may result in differential optimal screening programmes. Furthermore, screening may be minimised in persons with a short life expectancy. Co-morbidity, for example, may preclude the benefit of screening initiatives. During the presentation at the ECC2013 conference, we will give illustrations of these three approaches based on published studies.
Conclusions: Stratification attempts based on absolute risk of event will not guide personalised screening if event rates are low. Stratification based on screening test characteristics or identification of persons with a short life expectancy are more promising. *We invite the ECC2013 attendees to discuss strategies to design personalised cancer screening programmes.*

1454 POSTER

PIK3CA mutations, aspirin use and mortality in patients with women's cancers or colorectal cancers treated in early-phase clinical trials

Y. Chae[1], D.S. Hong[2], K.H. Kim[3], G.S. Falchook[2], S.A. Piha-Paul[2], V. Subbiah[2], R.G. Zinner[2], R. Kurzrock[4], R.A. Wolff[2], F. Janku[2]. *[1]UT M.D. Anderson Cancer Center, Cancer Medicine, Houston Texas, USA; [2]UT M.D. Anderson Cancer Center, Investigational Cancer Therapeutics, Houston Texas, USA; [3]UT M.D. Anderson Cancer Center, Houston Texas, USA; [4]UC San Diego, Cancer Center, Houston Texas, USA*

Background: Aspirin reduces the risk and mortality from breast and colorectal cancer (CRC). Aspirin down-regulates phosphatidylinositol 3-kinase activity by inhibiting cyclooxygenase-2 and is associated with improved survival in patients with mutated, but not wild-type *PIK3CA* CRC. The prevalence of *PIK3CA* mutations is known to be high in breast cancer, gynecologic cancer, and CRC.
Material and Methods: Total of 536 patients with CRC (242, 45%), ovarian (137, 26%), breast (65, 12%), endometrial (63, 12%), and cervical cancer (29, 5%) participating in early-phase clinical trials at the University of Texas MD Anderson Cancer Center from 10/2008 were tested for *PIK3CA* mutations and their survival outcomes with respect to regular aspirin use, defined as at least three months of use at the time of initial referral visit, were analyzed. Adjusted hazard ratio (AHR) for mortality was computed controlling for the Royal Marsden Hospital (RMH) score, which was validated in our cohort.
Results: Median age of the cohort was 56 years [range: 20−91 years]. 76% (405) were female and 72% (408) were Caucasian. Median survival was 8.8 months, 10% (54) of patients used aspirin and 17% (88) had *PIK3CA* mutation. Aspirin users and nonusers were similar except for older

age in aspirin users (mean difference of 8 years, p < 0.001). Aspirin use was not associated with difference in survival (AHR 0.82, 95% confidence interval [CI] 0.57–1.18, p = 0.29). However, in patients with breast and gynecological cancers, aspirin use independent of *PIK3CA* status was associated with prolonged survival (AHR 0.59, 95% CI 0.35–0.98, p = 0.04). Of note, in patients with wild-type *PIK3CA* CRC, aspirin was associated with shorter survival (AHR 1.80, 95% CI 1.01–3.23, p = 0.04). In contrast, in patients with mutated *PIK3CA* CRC, aspirin did not impact survival (AHR 0.75, 95% CI 0.17–3.20, p = 0.70).
Conclusions: In early-phase clinical trial setting, aspirin was associated with prolonged survival in patients with breast and gynecological cancers irrespective of *PIK3CA* status and shorter survival in patients with wild-type *PIK3CA* CRC. Larger studies are required to validate possible interactive effect between *PIK3CA* mutations and aspirin use on survival outcome.
No conflict of interest.

1455 POSTER

Genetic variants in the myeloid derived suppressor cells pathway and susceptibility to breast cancer in the Breast Cancer Association Consortium

J. Lei[1], A. Rudolph[1], L.E. Sucheston[2], P. Hall[3], P.D. Pharoah[4], J. Benitez[5], D.F. Easton[4], K. Moysich[2], J. Chang-Claude[1], on behalf of the Breast Cancer Association Consortium. *[1]German Cancer Research Center, Division of Cancer Epidemiology, Heidelberg, Germany; [2]Roswell Park Cancer Institute, Department of Cancer Prevention and Control, Buffalo, USA; [3]Karolinska Institute, Medical Epidemiology and Biostatistics, Stockholm, Sweden; [4]University of Cambridge, Centre for Cancer Genetic Epidemiology, Cambridge, United Kingdom; [5]Spanish National Cancer Research Center, Human Genetics Group Programme of Human Cancer Genetics, Madrid, Spain*

Background: Breast cancer is the most common cancer in women in Europe with an incidence of 425,000 per year. Evading Immune destruction is considered as a new hallmark of cancer. Myeloid derived suppressor cells (MDSCs) promote tumor-associated immune suppression and therefore the MDSCs pathway could harbour susceptibility loci for breast cancer.
Material and Methods: This study included 40,987 invasive breast cancer cases and 39,452 cancer-free controls of European ancestry from 36 studies in the Breast Cancer Association Consortium. 27 candidate genes were identified by extensive literature review and 735 tagSNPs genotyped using the custom Illumina iSelect array passed quality controls. We used logistic regression analysis to assess the main effects of single SNPs for overall breast cancer and for ER+ and ER− subtypes respectively. Furthermore, we applied a new pathway score which models independent signals from the same gene in a regression framework to assess pathway association using the INTERSNP program. All analyses were adjusted for study, age and population structure.
Results: Two SNPs (rs470747 A>G and rs470132 C>A) at 11q22.3 (matrix metallopeptidase-1 gene, *MMP-1*) showed the most significant association with overall breast cancer. They were highly linked, showing linkage disequilibrium (LD) of r^2=0.99 and were associated with elevated per allele ORs of 1.03 (95% CI = 1.01–1.06, p = 0.002). Another SNP (rs7125320 A>C) at the same region but not in LD with the other two SNPs (r^2=0.04) was associated with a reduced OR of 0.95 (95% CI = 0.91–0.99, p = 0.007). *MMP-1* is a zinc-dependent endopeptidase belonging to the Metzincin superfamily and has been reported to play an important role in breast cancer carcinogenesis. In addition, rs25645 (G>A) as well as two other SNPs in high LD located at 17q11.2-q12 (granulocyte colony-stimulating factor gene, *G-CSF*) was also associated with elevated per allele ORs of 1.03 (95% CI = 1.01–1.05, p = 0.004). *G-CSF* can affect myeloid lineage in tumor microenvironment. Analysis of the overall MDSCs pathway did not yield a significant association with breast cancer susceptibility overall (p = 0.12).
Conclusions: Of genes in the myeloid derived suppressor cell pathway, we found strongest evidence of association with susceptibility of breast cancer for *MMP-1* and *G-CSF*. Pathway analysis suggests that genetic variation in the MDSCs pathway may not play a strong role in breast cancer susceptibility.
No conflict of interest.

1456 POSTER

PTCH1 g.79755C>T and g.79456C>T polymorphisms, enrolled in proliferation cell control, are risk factors for head and neck squamous cell carcinoma

E.F.D. Costa[1], L. Lopes-Aguiar[1], T.R.P. Lima[1], G.A.S. Nogueira[1], G.J. Lourenço[1], C.S.P. Lima[1]. *[1]University of Campinas, Faculty of Medical Sciences, Campinas São Paulo, Brazil*

Background: The *PTCH1*, a tumor suppressor gene, encodes a transmembrane protein that controls cell proliferation. Alteration of *PTCH1* expression was associated with the onset of tumors. The roles of the *PTCH1* g.79755C>T (rs16909856) and g.79456C>T (rs16909859) genetic polymorphisms in the risk of head and neck squamous cell carcinoma (HNSCC) have never been described in the literature, and therefore, to analyze their impacts in the disease was the aim of this study.
Materials and Methods: Genomic DNA from 150 HNSCC patients and 150 controls matched to patients by age, gender and race was analyzed by real-time polymerase chain reaction, using TaqMan® genotyping assays. The differences between groups were analyzed by the logistic regression model. Power analysis (PA) was used to verify the effect of sample size on the results obtained in the study.
Results: HNSCC patient's and control's samples were in Hardy–Weinberg equilibrium for *PTCH1* g.79755C>T (χ2= 0.31, *P* = 0.58; χ2= 1.04, *P*= 0.31) and *PTCH1* g.79456C>T (χ2= 2.2, *P* = 0.13; χ2= 1.29, *P* = 0.26) loci. The *PTCH1* g.79755CC (82.0% *vs* 65.3%, *P* = 0.002; PA= 94%), *PTCH1* g.79456CC (82.6% *vs* 66.0%, *P* = 0.003; PA= 92%), *PTCH1* g.79755CC + *PTCH1* g.79456CC (82.9% *vs* 65.7%, *P* = 0.002; PA= 95%) genotypes were more common in patients than in controls. Individuals with the respective genotypes were under a 2.62-fold (95% CI: 1.43–4.80), 2.52-fold (95% CI: 1.37–4.64), and 2.70-fold (95% CI: 1.45–5.00) increased risks for HNSCC than those with the remaining respective genotypes. In addition, the frequency of *PTCH1* g.79755CC genotype was higher in male patients than in female ones (84.3% *vs* 62.5%, *P* = 0.04; PA= 56%). The *PTCH1* g.79755CC genotype in male patients was also more common than in controls (84.3% *vs* 65.3%, P= <0.001; PA= 96%). Male individuals with the *PTCH*1 g.79755CC genotype had a 3.55-fold (95% CI: 1.79–7.04) increased risk for HNSCC than others. Similar frequencies of the *PTCH1* g.79755C>T and *PTCH1* g.79456C>T genotypes were seen in patients stratified by age and race.
Conclusions: Our results suggest, for the first time, that *PTCH1* g.79755CC and *PTCH1* g.79456CC genotypes are important inherited risk factors for HNSCC. Analyzes of proteins encoded by the alleles of the polymorphisms should be conducted to clarify their roles in tumor. We believe that healthy individuals with the above genotypes, particularly males, deserve additional recommendations for disease prevention and early diagnosis.
No conflict of interest.

1457 POSTER

Differences in incidence trends of estrogen receptor positive/ negative breast tumours in the Girona province, 2000–2009

M. Puig-Vives[1], C. Camprubí-Font[1], G. Osca-Gelis[1], A. Izquierdo[1], M. Pollan[2], R. Marcos-Gragera[1]. *[1]Girona Cancer Registry, Epidemiology Unit, Girona, Spain; [2]Instituto de Salud Carlos III, Cancer Epidemiology Unit, Madrid, Spain*

Background: Expansion of mammopgraphy screening and variations in lifestyle risk factors have lead to changes in invasive breast cancer (IBC) incidence trends in several countries. Positive estrogen receptor (ER) cancers have better prognosis than negative ER tumours. The aims were to determine whether clinicopathological features differed among positive and negative ER, and to analyze IBC incidence trends according to ER status in the Girona province, 2000–2009.
Methods: Women diagnosed with primary IBC (*n*=3513) during 2000–2009 were extracted from the population-based Girona Cancer Registry. ER immunohistochemical status was collected from pathological reports. Clinicopathological features (histological grade, stage, age, mean tumour size and positive nodes) were compared among ER positive and negative tumours. The estimated annual percent change (EAPC) was estimated using joinpoint analysis.
Results: The proportions of ER positive, negative and unknown tumours were 70.5%, 18.4% and 11.1%. ER positive tumours correlated to a lowest histological grade, early stage, mean tumour size and mean positive nodes, and a higher mean age compared to ER negative tumours. IBC incidence showed a non-statistically significant EAPC of −1.0% (−2.2; 0.2). Women diagnosed with ER positive tumour showed an upward incidence trend of 1.6% (−0.2; 3.5) and ER negative tumours presented a significant EAPC of −6.0% (−8.6; −3.4).
Discussion and Conclusions: Differences in incidence trends in ER positive/negative tumours could be explained by changes in lifestyle risk factors as obesity. During the study period in Spain the percentage of overweight and obese women has increased. Also, changes in RE immunohistochemical assessment have to be considered.
No conflict of interest.

1458 POSTER

Clinical significance of triple negativity in young breast cancer patients (⩽35 years): A single-institute study from India

A. Gogia[1], V. Raina[1], B.K. Mohanti[2], S.V.S. Deo[3], N.K. Shukla[3], V. Sreeniwas[4]. *[1]All India Institute of Medical Sciences, Medical Oncology, Delhi, India; [2]All India Institute of Medical Sciences, Radiotherapy, Delhi, India; [3]All India Institute of Medical Sciences, Surgical Oncology, Delhi, India; [4]All India Institute of Medical Sciences, Biostatistics, Delhi, India*

Background: Triple negative breast cancer (TNBC) has been identified as an independent poor prognostic factor for survival. The aim of this study was to compare the clinico-pathological characteristics and treatment outcomes of patients with young TNBC (yTNBC) and young non-TNBC (y-non TNBC).
Methods: We carried out a retrospective study of 299 young invasive breast cancer patients registered (whom receptors status were available) between 1999–2012 at Institute Rotary Cancer Hospital, All India Institute of Medical Sciences (AIIMS), India.
Results: One hundred and five patients (35%) had yTNBC and 194 (65%) had y-nonTNB. Patients with yTNBC had significantly lower median age 29 vs 33 yrs ($p = 0.049$) and higher proportion of high grade tumors as compared to y-non TNBC group (40% vs 23.5%; $p < 0.0001$). The median tumor size (5.0 vs 5.1 cms), node positivity rate (61.7% vs 65.2%), stage distribution (2.7%, 27.3%, 53.4%, 16.6% vs 3.3%, 23.6%, 52.7%, 20.2% for Stage I, II, III and IV respectively) were not statistically significant between yTNBC and y-nonTNBC groups. Fifty seven patients presents with upfront metastasis. The most common site of relapse was lung followed by liver and loco-regional. After a median follow-up of 36 months, relapse rate was 33% for yTNBC and 19% for non-yTNBC ($p = 0.003$). The 3 year RFS and OS for non metastatic group was significantly lower in TNBC group (50.2% vs 65%; HR = 2.38, 95% CI:1.21–3.60,$p = 0.001$) and (66.4% vs 77.2%, HR = 1.9, 95% CI: 1.02–2.80, $p = 0.049$) respectively. With a median follow up of 36 months (non metastatic group), three years disease free survival (DFS) and overall survival (OS) was 50% and 60%. Higher Nodal stage, tumor size (>5 c.m) and negative hormonal status (triple negative) predicted poor outcome.
Conclusion: Young breast TNBC constituted 35% cases of young breast cancer patients (</=35 years) and had higher relapse rate and more aggressive clinicopathological characteristics than non TNBCs. Triple negativity is independent prognostic factor for RFS, OS in nonmetastatic and PFS and OS in metastatic setting in young breast cancer patients and might be integrated into risk factor analysis as base line workup.
No conflict of interest.

1459 POSTER

Risk of breast cancer in ovarian cancer patients non-carriers of BRCA1 and BRCA2 mutations with a family history of breast and ovarian cancer: A population-based cancer registry study

A. Musolino[1], D. Boggiani[1], M.A. Bella[1], P. Zanelli[2], N. Naldi[1], B. Bortesi[1], P. Sgargi[3], M. Michiara[3], A. Ardizzoni[1]. *[1]University Hospital of Parma, Medical Oncology Unit, Parma, Italy; [2]University Hospital of Parma, Medical Genetic Service, Parma, Italy; [3]University Hospital of Parma, Parma Province Cancer Registry, Parma, Italy*

Background: A family history (FH) of breast and/or ovarian tumor is a well-established risk factor for breast and ovarian cancer, and for BRCA mutations. BRCA1/2 mutation carriers diagnosed with ovarian cancer (OC) have a strong life time risk of developing breast cancer (BC). No studies to date have examined the predictive contribution of FH in relation to the risk of BC for OC patients in whom no BRCA1/2 mutation has been identified. The objective of this study was to address the risk of BC in OC patients with a FH who test negative for BRCA1/2 mutations.
Materials and Methods: We identified 89 patients (pts) with both OC and BC (OC-BC) from a cohort of 1497 women with a primary OC systematically collected by the Cancer- Registry of Parma Province from 1978 to 2010. We selected women with FH who tested either positive (12 pts with OC-BC vs. 11 control pts with OC) or negative (15 pts with OC-BC vs. 20 control pts with OC) for BRCA1/2 mutations. The association between FH and risk of OC-BC was examined. Age- and family history-specific 10-year cumulative absolute risks of OC-BC were estimated using the entire Cancer Registry cohort.
Results: FH was associated with increased OC-BC risk; risk was highest among young women (<45 years) with first-degree relatives with breast and ovarian cancers. Women diagnosed with OC before age 45 years with a first-degree FH of OC-BC had a 10-year risk of OC-BC of 12.5%.
Conclusions: Young women with ovarian cancer who have a FH of breast and ovarian cancer and who test negative for BRCA1/2 mutations are at significantly greater risk of OC-BC than other OC survivors. This has important implications for the clinical management of these pts.
No conflict of interest.

1460 POSTER

Breast cancer screening controversy: Too much or not enough?

X. Pivot[1], J. Viguier[2], C. Touboul[3], F. Eisinger[4], J.Y. Blay[5], Y. Coscas[6], C. Lhomel[7], J.F. Morère[8]. *[1]Hopital Jean Minjoz, Oncologie, Besançon, France; [2]CHRU Trousseau, Centre de coordination des dépistage des cancers, Tours, France; [3]KantarHealth, Statistiques, Montrouge, France; [4]Institut Paoli Calmette, Inserm UMR 599, Marseille, France; [5]Centre Léon Bérard, Oncologie, Lyon, France; [6]Clinique de la Porte de Saint Cloud, Oncologie, Boulogne Billancourt, France; [7]Roche, Institutionnel, Boulogne Billancourt, France; [8]Hôpital Paul Brousse, Oncologie, Villejuif, France*

Background: The Cochrane analysis revisiting the risk/benefit of breast cancer screening resulted in a worldwide controversy spread by the mass media. The objective of our survey was to assess the impact of this controversy in terms of perception, opinion and intent in the average risk population.
Material and Methods: A nationwide observational study, recorded in the EDIFICE iterative surveys, with a representative sample of 451 women living in France aged 40−75 years old, was carried out in January 2013, using the quota method. The survey questionnaire was conducted using a computer-assisted telephone interviewing technique (CATI) 3 months after the beginning of the controversy. The following analysis focused on women without a history of cancer, taking into account positive awareness (AC+ group) or negative awareness (AC- group) of the controversy.
Results: Among the 405 women with no personal history of cancer, 69 (17%) belong to the AC+ group. There was a negative relationship between awareness of the controversy and being underprivileged, having a lower level of education and lower socioeconomic status. Among the 69 women of the AC+ group, 73% vs. 8% remembered the reasons for and against screening respectively. The most frequent reasons against screening were over-diagnosis (38%), unreliability (16%), and radiation risk (9%). The breast cancer screening limits were better known by the AC+ group, such as undiagnosed cancers (20% vs. 7%, $p < 0.05$) and risk of false positives (20% vs. 2%, $p < 0.05$). In the AC+ and AC- groups, opinion on breast cancer screening did not change in 86% and 88% of cases respectively. Negative opinion increased in the AC+ versus the AC- groups (8% vs. 1%, $p < 0.05$). Nevertheless, In the AC+ group, there was no change in the intention of screening in 91% of cases. In the overall population, only 1% stated that they would plan to attend screening less often.
Conclusion: Few women were aware of the controversy spread by the mass media (17%). The impact of the controversy on screening intention is very low (1%). However, in women with an awareness of the controversy, a better knowledge of the breast cancer screening limits was observed. Unexpectedly, it seems this better knowledge does not impact on the personal decision-making about screening.
No conflict of interest.

1461 POSTER

Trends in cancer care and outcome in the Netherlands: A population based approach

S. Siesling[1], O. Visser[1], G.S. Sonke[1]. *[1]Comprehensive Cancer Centre The Netherlands (IKNL), Registration and Research, Utrecht, Netherlands*

Background: Large variation exists in patterns of cancer care between regions, hospitals, and over time. Monitoring the variation in care delivered and linking this variation to outcome provides important insight into guideline adherence, medical practice in case of clinical equipoise, and implementation of new diagnostic tools and treatments. Valid, reliable and complete data is needed to obtain reliable indicators of cancer care. The IKNL Cancer Registry covers all newly diagnosed cancers since 1989 in the total population of the Netherlands (17 million inhabitants). It gathers data in all hospitals based on pathology reports with increasing data over the years on stage, treatment, and outcome. The IKNL cancer registry enables us to evaluate patterns of cancer care over time and give detailed yearly feedback to hospitals.
Methods: Crucial indicators per tumor type were based on national guidelines for breast, colorectal, pancreas, esophagus, stomach, bladder, kidney, lung, brain, neuroendocrine, melanoma, testis, endometrium, cervix, and lymphoma. Trends over time (2001–2011) between hospital volume and hospital type (academic, top clinical, general) were determined per indicator. Relative survival was determined with complete follow-up until 2013.
Results: Survival has increased over time for almost all tumor types. The number of patients per hospital per tumor type is increasing and the variation in volume is decreasing. These effects are caused by increases in

incidence of various tumor types, hospital mergers, and changing regional referral patterns. The effects are not only seen for low-incidence tumors but also for high-incidence tumors such as breast cancer.
If the national guidelines allow choosing between two or more equivocal treatments, a large variation between treatments provided is indeed seen. In addition, however, variation also exists if the guidelines do provide clear treatment recommendations.
Detailed results per tumor type will be presented during the meeting.
Conclusion: Providing insight in differences in cancer care between hospitals is a strong incentive for hospitals to improve their quality by prioritizing the care they can deliver and choosing whom to refer elsewhere. In addition, it facilitates patients and health insurance companies to choose between hospitals.
No conflict of interest.

1462 POSTER

Time-to-Antibiotics (TTA) and outcomes in cancer patients with febrile neutropenia (FN)

T. Perron[1], S. Ahmed[2]. *[1]University of Saskatchewan, Medicine, Saskatoon (SK), Canada; [2]University of Saskatchewan, Oncology, Saskatoon (SK), Canada*

Introduction: Febrile neutropenia (FN) is an oncologic emergency that requires prompt initiation of antibiotics. A prolong time-to-antibiotic (TTA) may result in adverse outcomes in immune compromised patients. The study aims to determine TTA in hospitalised patients with FN, a quality measure in cancer care, and to assess relationship between TTA and outcomes.
Methods: The study population was comprised of a cohort of adult cancer patients with FN who were hospitalised at a tertiary care hospital between 2010 and 2012. Pearson correlation and multivariate analysis using linear and logistic regression models were done to assess relationship between TTA and length of hospital stay and mortality.
Result: 105 eligible patients with a median age of 60 (18−89) and M:F of 43:62 were identified. 50% had a comorbid illness, 44% had a haematological malignancy and 60% had advanced disease. 85% were presented to the emergency department and remaining were hospitalised from ambulatory clinics. Median TTA was 2.5 hrs (0.03−50). 84% patients were treated with broad spectrum penicillin. 30% patients each received prophylactic filgrastim or antibiotic. Of 105 patients, 75 met American Society of Clinical Oncology (ASCO) criteria for primary prophylaxis with filgrastim and only 24 (32%) received prophylaxis. Median length of stay was 6 days (1−57). 4 patients died and 2 required ICU admission. A source of infection was identified in 23 patients. Pearson correlation between TTA and length of stay was 0.258 ($p = 0.008$). In univariate analysis TTA, known source of infection, filgrastim prophylaxis, anaemia, thrombocytopenia and elevated urea were significantly correlated with length of stay ($P<0.05$). In the multivariate analysis TTA (regression coefficient [RC] 0.335 $\pm$ standard error [SE] 0.092, $p < 0.001$), known source (5.07 ± 1.62, $p = 0.003$), filgrastim prophylaxis (3.93 ± 1.42, $p = 0.007$) and elevated urea (0.312 ± 0.158, $p = 0.05$) were significantly correlated with length of stay. One hr delay in TTA resulted in 8 hrs prolongation of hospital stay. No variable significantly correlated with hospital morality.
Conclusions: A prolonged TTA is independently associated with prolonged hospital stay but not with hospital mortality in cancer patients with FN.
No conflict of interest.

1463 POSTER

Non-AIDS malignancies and co-infections among HIV/AIDS patients in our registry

J. Suvada[1], E. Kaiserova[2], V. Krcmery[3], B. Silharova[4], V. Krcmery[3], B. Silharova[5], S. Aiylchiev[6]. *[1]Children University Hospital, Clinic of Children Hematology and Oncology at Children's Teaching Hospital, Bratislava, Slovak Republic; [2]Children University Hospital, Clinic of Children Hematology and Oncology, Bratislava, Slovak Republic; [3]St. Elizabeth University, Public Health and Social Work, Bratislava, Slovak Republic; [4]St. Elizabeth University, Public Health and Social Work, Buikwe, Sudan; [5]Health Initiatives Association, Public Health and Social Work at John Paul II HIV Clinic, Buikwe Uganda, Sudan; [6]Health Initiatives Association, HIV/AIDS Clinic, Osh Oblast, Kyrgyzstan*

Background: Malignancies among people living with HIV/AIDS as a complication of immunodeficiency have been well described in different studies. In time of the beginning of the HIV epidemic, it was observed high incidence of Kaposi's sarcoma, non-Hodgkin's lymphoma and invasive cervical carcinoma, which strongly suggested a causal relationship between immunodeficiency and the development of these kind of malignancies. The Centers for Disease Control later defined list of the conditions for malignancies in the AIDS definition where called 'AIDS-defining' malignancies. In the era of highly active antiretroviral therapy (HAART) the epidemiology of malignancies among HIV infected population has changed significantly. Currently it's observed rising incidence of non-AIDS-defined malignancies (NADM) among adults but also children.
Method: Between 1/2009 and 2/2013 data collected from 6 International HIV/AIDS Projects (Slovakia, Russia, Romania, Kirgiz Republic, Uganda and Argentina) was analysed on the development of malignancy in HIV positive children, adolescents and adults. The three projects have been oriented to the street and marginal population. After a biopsy were the samples fixed immediately in buffered 5% formalin and embedded in paraffin. Hematoxylin-eosin stain was performed and specimens from tumors or biopsies (e.g. lymph nodes) were separated for DNA preparation. Serum of all patients was collected and investigated at Health Initiatives Association/St. Elizabeth University laboratory to co-infections.
Result: There were enrolled 129 HIV-positive patients with cancer. In this study the majority of patients had NHL, however 23% of the patients were identified with NADM e.g. leukaemia, colorectal carcinoma, breast cancer, hepatocellular carcinoma, rhabdomyosarcoma, melanoma and leiomyosarcoma. We have found also co-infections with HHV-8, EBV, CMV, HBV, HCV and HPV.
Conclusion: Other studies have reported similar EBV findings in NADM among AIDS patients. Thus EBV appears to be an important cofactor in development of malignancy in paediatric and adolescent AIDS patients. Co-infections have shown an important impact on increase rate of the incidence of NADM among this group of vulnerable population.
No conflict of interest.

A professionals education program on cervical cancer prevention: Results of an e-learning experience

A. Company Serrat[1], F.X. Bosch José[2], M. Montserrat Moreno[1], A. Sedano Martínez[1]. *[1]Catalan Institute of Oncology, e-Oncología, L'Hospitalet Barcelona, Spain; [2]Catalan Institute of Oncology, Cancer Epidemiology Research Programme, L'Hospitalet Barcelona, Spain*

Background: Cervical cancer remains the second most important cancer in women worldwide and the cancer priority in most developing countries. Cervical cancer is largely preventable and if diagnosed and treated at an early stage is a highly curable disease. In the absence of efficient preventive action, cervical cancer is usually diagnosed in advanced stages and results in a major cause of death among young women. The advent of HPV vaccines and the impact of HPV technology for cervical cancer screening represent a milestone in our opportunities for prevention. The introduction of a new vaccine targeting women worldwide requires that literally tens of thousands of health professionals and decision makers understand its value and mode of use. Information on a new vaccine and novel screening options should be scientifically accurate, and technically unbiased. A virtual course has been designed to provide such information to health professionals worldwide without costs to the participant and overcoming the limitations of travelling, time availability or language.
Objectives:
1. Create and promote an e-learning educational program on HPV and cervical cancer epidemiology and prevention suitable for a wide audience of health professionals.
2. Create an international network of professionals qualified as key trainers in cervical cancer prevention in critical countries in the world.

The Project was supported by various unrestricted educational grants.
The technological platform and the scientific and pedagogical methodology were provided by e-oncología, the e-learning platform from Catalan Institute of Oncology, (ICO) Barcelona, Spain.
Results: Output was an 18 hours distance course in Spanish, English, French and Russian. The course contents are largely based on the ICO HPV Monograph series. The program was scientifically validated and endorsed by the International Federation of Gynecology and Obstetrics (FIGO), the International Union against Cancer (UICC), the International Atomic Energy Agency (IAEA), the International Agency for Research on Cancer (IARC), and the World Health Organization (WHO), the course is being freely distributed.
In the first 18 months of operation more than 7.000 professionals worldwide have registered to the course, a pool of 32 international tutors have been certified and acted as course professors in their own environment, and 70% of the students have been certified.
Conclusions: E-learning methodology with a tutorial support can be a good and cost affordable solution to the medical education in low income countries. The contents are easily adapted to each country particularities including translation to other languages.
No conflict of interest.

1465 POSTER

Non-presencial genetic counseling for BRCA1/2 families

M. Carneiro[1], C. Simões[2], A. Opinião[2], A. Luís[2], J. Câmara[3], R. Vidal[4], J. Parreira[2], J. Parreira[2], P. Rodrigues[2], F. Vaz[2]. *[1]Hospital Santarem, Santarem, Portugal; [2]Instituto Português de Oncologia, Clínica de Risco Familiar, Lisboa, Portugal; [3]Hospital da Horta, Consulta de Oncologia Médica, Horta, Portugal; [4]Hospital do Divino Espiríto Santo, Consulta de Oncologia Médica, Ponta Delgada, Portugal*

Background: BRCA1/2 genetic screening is recommended when there is a suspicion of breast/ovarian cancer hereditary syndrome. Although commercially available, the decision to screen for BRCA1/2 mutations must be done in the context of appropriate genetic counseling. Several barriers difficult the access to BRCA1/2 genetic counseling: increased demand, reduced number of specialized centers and genetic counselors, schedule of the outpatient visits consultations, and geographic limitations. These difficulties led to the development of new methods of counseling and there is some published data showing satisfactory results with telephonic genetic counseling.
Material and Methods: Review of all cases that included, during the counseling process for BRCA1/2 mutations, some form of non presencial communication. In our Clinic, genetic counseling includes pre and post test counseling and, in BRCA1/2 carriers, distress evaluation one month after the diagnosis disclosure.
Results: Since 2000, and after 2097 pts screened only 9 patients, 4 man and 5 women aged 40−68 years had some non-presencial communication during their counseling (0.4%). All but one were identified as candidates for screening in already registered families; the other was an index pt identified as high-risk by her physician. With 1 pt pre and post test counseling was made by phone, with another one only pre-test was by phone and for 6 pts only post test counseling was made by phone. In two male pts (one BRCA1, the other BRCA2) distress evaluation (validated questionnaire) was sent and returned to the Clinic by mail.
Five pts were cancer survivors of breast or ovarian cancer, one male pt was a prostate cancer survivor and 3 were healthy at risk. Three pts were BRCA2 positive, 1 BRCA1 positive, 1 BRCA1 negative, 1 BRCA2 negative, 2 index pts had inconclusive results(non pathogenic BRCA1/2 mutations). One pt is waiting for the test result.
All non presencial counseling was motivated by geographic limitation. The BRCA1/2 pts evaluated for distress did not have evidence of need for specialized psychological support.
Conclusions: In our practice non presencial genetic counseling is used rarely. This option, however, should be acknowledged as a valid one.
No conflict of interest.

1466 POSTER

Outbreaks of hospital infections at the Institute for Oncology and Radiology of Serbia

A. Jovicevic[1], D. Jovicevic[2], V. Mandic[2], G. Kukic[2]. *[1]Institute of Oncology and Radiology of Serbia, Beograd, Serbia; [2]Institute for Oncology and Radiology of Serbia, Department of Epidemiology and Prevention, Beograd, Serbia*

Background: Active surveillance of hospital infections at the Institute for Oncology and Radiology of Serbia includes monitoring of patients and microbiology reports, outbreak investigations and other activities carried out by the Department for Epidemiology and Prevention in collaboration with hospital wards. From time to time, outbreaks of infections are registered.
Material and Methods: Data from the hospital infections surveillance, including microbiology results of samples taken from patients, staff and environment in the period 2010–2012 were analyzed. Unusual outbreaks of infections or outbreaks that triggered changes in the everyday hospital practice were analyzed.
Results: At the radiotherapy department there is and increasing incidence of Clostridium difficile diarrhoea (CAD)among patients undergoing gynecological radiotherapy. In 2012, an outbreak of CAD cases among patients but also among doctors and nurses was registered.
At the Pediatric oncology department, in 2010 there was an outbreak of 4 febrile neutropenia patients with bloodstream Fusarium infection; all patients had bone tumors and previous surgery in other hospital. This year, 2 strains of multi-resistant bacteria (Pseudomonas, Klebsiella) and Acinetobacter resistant to all antibiotics were isolated from urine and decubital wound of a patient previously treated at other hospitals.
At the Surgical oncology clinic, there were occasional outbreaks of vancomicin-resistant infections, mostly at the post-operative intensive care unit in patients that had gastrointestinal surgery, that required additional education of staff and other measures.
At the Department for radiotherapy of head and neck cancers, tracheostoma colonization and infections are very frequent in patients with tracheostoma. The majority of infections are present on admission. Most frequently, S.aureus and Klebsiella are isolated; occasionally, multi-resistant strains are found, particularly in patients that previously had surgical intervention in other hospitals. Therefore, the sample for microbiology analysis is always taken on admission in order to identify and prevent spread of multi-resistant strains.
Conclusion: In cancer patients there is a higher risk for infections due to the disease and specific treatment modalities. There is also a risk that antibiotic-resistant bacterial strains will be introduced into hospital settings through patients with long-term cancer treatment and interventions in various hospitals. Therefore, active surveillance of hospital infections by a multiprofessional team is necessary.
No conflict of interest.

1467 POSTER

Individualised or guideline concordant G-CSF usage − Data from the non-interventional study HEXAFIL

H. Tesch[1], D.T. Chang[2], B. Ottillinger[3]. *[1]Bethanien Hospital, Cancer Center, Frankfurt, Germany; [2]Hexal AG, Medical Affairs Oncology Biopharmaceuticals, Holzkirchen, Germany; [3]Ottillinger Life Sciences, Hofolding, Germany*

Background: Chemotherapy (CT)-induced neutropenia (CIN) is a common complication of cancer treatment and often leads to CT modifications. Granulocyte-colony stimulating factors (G-CSF) are often used to prevent or treat CIN in cancer patients. The non-interventional observational study HEXAFIL was conducted to provide further insight into the therapeutic efficacy and routine clinical use of biosimilar filgrastim (EP-2006) in Germany, especially in compliance with guidelines on G-CSF use.
Materials and Methods: Data is documented for up to 3 consecutive filgrastim-supported CT cycles. Rates of modified CT treatments (dose modification/discontinuation of drug) are calculated by the number and % of patients affected. A total of 709 breast cancer patients were included in this interim analysis. Data presented are based on the first CT cycle. Inclusion/exclusion criteria: www.germanctr.de.
Results: Only 2% of all patients experienced febrile neutropenia (FN), 8.7% had neutropenic complications and 43.4% had leukopenia CTC 3/4 at nadir. The majority of patients received primary (49.4%, PP) or secondary prophylaxis (33.6%, SP) with biosimilar filgrastim; 17.1% were treated on demand (ie, after having experienced neutropenic complications in the first documented CT cycle or a drop in leukocytes putting the patient at acute risk of neutropenic complications). Median filgrastim treatment duration was 4 d (range 1−14) with median start on day 6 after CT (range 1−21). 96.3% of all documented patients received CT without modification, 3% received a modified CT dose and 0.8% discontinued a CT drug. The following populations were compared to assess the impact of individualised (IND) or guideline-concordant (GUI) filgrastim treatment: patients with FN risk >20% and (1) G-CSF initiation within 5 d after CT (GUI; N = 104) or (2) G-CSF initiation starting at day 6 after CT or later (IND; N = 169). IND patients experienced FN more frequently than GUI patients (4.1 vs 1.9%). CT was modified in 6.5% of IND but only 1% of GUI patients.
Conclusions: 96% of patients received biosimilar filgrastim-supported CT cycles without any modification of the CT regimen. Patients with individualised G-CSF treatment showed more CT disturbances and FN. There remains room for improvement in prevention of CIN/FN in cancer patients as reflected by median start/treatment days and number of neutropenic complications. Further data are warranted to detail the impact of individualised G-CSF treatment.

1468 POSTER

Overview of meta- and pooled analyses of nutrition and breast, colorectal and prostate cancer risk

P. Mullie[1], P. Autier[1], P. Boyle[2]. *[1]International Prevention Research Institute, Research, Lyon, France; [2]International Prevention Research Institute, Director, Lyon, France*

Background: Twenty years ago, recommendations for prevention of cancer by nutritional modification were based on decreased fat consumption, and increased consumption of dietary fibers, fruits, vegetables and vitamins. Subsequent literature is replete with reports of studies of nutrition often containing widely varying advice regarding reducing cancer risk.
Methods: A systematic search in PubMed was conducted to identify meta- and pooled analyses relating breast, colorectal and prostate cancer risk to nutritional components. Cancer risk was related to intake of coffee, dairy, dietary fibers, eggs, fat components, fruits and vegetables, glycemic index and load, meat components, minerals, seafood, soy, tea, and vitamins.

Inclusion criteria were: published in English, time period 2000–2011, and prospective studies. All published relative risks and confidence intervals were abstracted.
Results: The search retrieved 120 meta- and pooled analyses concerning alcohol (7), carbohydrates (1), coffee (7), dairy (9), dietary fibers (4), eggs (1), fat components (15), flavonoids (1), fruits and vegetables (7), glycemic index and load (6), meat (23), minerals (6), proteins (1), seafood (5), soy food (3), sugar-sweetened beverages (1), tea (6), and vitamins (17). In total 1,211 relative risks were computed by meta- and pooled analyses, with 830 (69%) statistically not significant, 164 (14%) showing an increased risk and 217 (18%) showing a decreased risk of cancer. 129 relative risks were less than 0.90 and 83 were greater than 1.25. Of the 70 estimates for alcohol, 44 (63%) showed statistically significant increased risk for breast and colorectal cancer. 9 (64%) of the risk estimates showed an increased risk of prostate cancer with dairy consumption, and 47 (47%) showed a decreased risk for colorectal cancer. Red meat risk estimates related with colorectal cancer were increased in 63%, and for 52% for processed meat. For other food items, proportions associated with non-significant risk were for fat consumption (88%), dietary fibers (60%), fruits and vegetables (74%), glycemic index/load (91%), and vitamins (78%).
Conclusions: No individual nutritional item has been consistently related to cancer risk, but alcohol and meat for which a modest increase of colorectal cancer seems to exist. Probably that energy balance and dietary patterns (eg the Mediterranean diet) rather than food items are the key nutritional aspects relevant to cancer prevention.
No conflict of interest.

1469 POSTER

An innovative approach to raising awareness and encouraging early diagnosis of neuroendocrine cancers in the UK

C. Bouvier[1], M. Sissons[2]. *[1]NET Patient Foundation, Godalming Surrey, United Kingdom; [2]NET Patient Foundation, NET Patient Foundation, Godalming Surrey, United Kingdom*

Early diagnosis of neuroendocrine cancers, and subsequent referral to a multi-professional team, greatly improves the outcome for the patient.
We conducted a nationwide survey of 200 patients with neuroendocrine cancers in the UK to determine routes and challenges to diagnosis. The findings show that a significant number of patients (47%) had to wait at least a year before being diagnosed, and that the majority of patients (51%) visited their GP 4 times or more before being diagnosed. 61% of respondents had been treated for the wrong disease prior to diagnosis.
In response to the survey results we designed a tool to support GPs and encourage the suspicion of a neuroendocrine cancer as a differential diagnosis. In conjunction with the tool, we produced engaging and educational posters about neuroendocrine cancers for GP surgery waiting rooms. In order to save costs whilst ensuring a higher viewing rate than through more traditional distribution methods such as post or email, we sought the help of patients and family members throughout the UK to deliver the materials. This innovative approach has proved to be both cost efficient and highly successful, with these materials having been personally delivered to over 3,500 GP practices since October 2012. Distribution target is 15,000 practices by October 2013.
No conflict of interest.

1470 POSTER

Lung cancer and occupation

M. Rajer[1], M. Zwitter[1]. *[1]Institute of Oncology Ljubljana, Radiotherapy, Ljubljana, Slovenia*

Introduction: Association between tobacco smoking and lung cancer is clear and well-studied. Other factors of importance for prevention, early diagnosis and treatment of lung cancer have received little attention. We present a case-control study focusing on social variables and occupation; comparing lung cancer patients with those with large bowel cancer.
Patients and Methods: A written questionnaire was completed by 377 consecutive patients with lung cancer and 374 patients with large bowel cancer. Data on place of birth, smoking history, diet and alcohol intake, body weight and height, profession, housing conditions and family income were collected and analysed. Statistical analysis was performed by using descriptive statistics, Mann-Whitney U test, chi-square test and logistic regression.
Results: The groups were balanced as regards gender and age distribution. As expected, there were significant differences between the groups regarding smoking status: non-smokers 9.9% vs. 52.1%, ex-smokers 67.9% vs. 36.9%, and current smokers 21.4% vs. 9.9% for lung and large bowel cancer respectively ($p < 0.001$). The proportion of patients working as industrial workers, construction workers or in other polluted working environment was also higher among lung cancer patients, as compared to large bowel patients (65.4% vs. 43.7%%, $p = 0.004$). Especially striking is the difference in metal industry workers (28.2% vs. 15.8%, $p < 0.001$). The share of immigrants, although not statistically significant, was higher (17.1% vs. 12%, $p = 0.08$) in patients with lung cancer. There were no statistically significant differences regarding housing conditions, family income, diet and alcohol consumption. The importance of smoking and polluted working environment was confirmed by a multivariate analysis.
Conclusions: The association between tobacco smoking and lung cancer is clear; more than 80% of lung cancer patients are current or former smokers. This very high figure leads to under-estimation of other preventable co-factors involved in etiology of the disease. Environmental pollution is an independent risk factor for lung cancer, both in smokers and in non-smokers. Our trial confirmed the role of occupational exposure to carcinogens in the etiology of lung cancer. When compared to patients with cancer of the large bowel, the group of lung cancer patients included a higher higher proportion of those working in polluted environment.

1471 POSTER

Long term consumption of flaxseed enriched diet decreased ovarian cancer incidence and prostaglandin E2 in hens

E. Eilati[1], J.M. Bahr[2], D.B. Hales[1]. *[1]Southern Illinois University-School of Medicine, Physiology, Carbondale-Illinois, USA; [2]University of Illinois at Urbana-Champaign, Animal Science, Urbana-Illinois, USA*

Ovarian cancer is the most lethal gynecological malignancy. Prevention of ovarian cancer is the best approach for reducing the impact of this deadly disease. Progress in the treatment and prevention of ovarian cancer has been hampered due to the lack of a valid and appropriate animal model, and absence of effective chemo-prevention strategies. The domestic hens spontaneously develop ovarian adenocarcinomas that are similar in histological appearance to human ovarian carcinomas and share similar symptoms of the disease, such as perfuse ascites fluid and peritoneal metastatic dissemination. Flaxseed is the richest vegetable source of omega-3 fatty acids which may be effective in the prevention of ovarian cancer. There is a link between chronic inflammation and cancer. Prostaglandin E_2 (PGE_2) is the most pro-inflammatory ecoisanoid and one of the downstream products of two isoforms of cyclooxygenase (COX) enzymes: COX-1 and COX-2. Our objective was to determine if long-term consumption of a flaxseed enriched diet decreased ovarian cancer severity and incidence in the laying hen and to investigate its potential correlation with the expression of COX enzymes and PGE_2 concentration. 1200 white Leghorn hens were fed 10% flaxseed-enriched or standard diet for 4 years. The severity and incidence of ovarian cancer were determined by gross pathology and histology. COX-1 and COX-2 protein and mRNA expression and PGE_2 concentrations in ovaries were measured by Western blot, quantitative real-time qPCR and ELISA, respectively. Our results indicated that similar to humans, the incidence of ovarian cancer was increased in hens which further validates the chicken as a suitable model to study human ovarian cancer. In correlation with ovarian cancer incidence, the expression of both COX enzymes and concentrations of PGE_2 were elevated with age. The results demonstrated that there was a reduction in ovarian cancer severity and incidence in hens fed flaxseed diet. In correlation with decreased ovarian cancer severity and incidence, concentration of PGE_2 and expression of COX-2 were diminished in ovaries of hens fed flaxseed. Our findings suggest that the lower levels of COX-2 and PGE_2 are the main contributing factor in the chemo-suppressive role of long-term flaxseed consumption in ovarian cancer in laying hens. These findings may provide the basis for clinical trials of dietary intervention targeting prostaglandin biosynthesis for the prevention and treatment of ovarian cancer.
Supported by NIH (1R01 AT005295) National Center for Complementary and Alternative Medicine Grant AT004085 (DBH) and American Institute for Cancer Research Grant 06-A043 (DBH).

1472 POSTER

Clinico- pathological differences in breast cancer in women from rural and urban areas

A. Kurylcio[1], R. Sitarz[1], A. Majdan[1], J. Mielko[1], W.P. Polkowski[1]. *[1]Medical University of Lublin, Department of Surgical Oncology, Lublin, Poland*

Background: Breast cancer is themost commonly diagnosed neoplasm among women and second cause of death becauseof malignancy. Levels of living conditions and medical education in rural andurban areas may have influence on early cancer detection, access to the medicalcare, screening programs and successful outcome of therapy.
The aim of this studyis to analyze clinical and pathological differences of breast cancers amongoperated women living in rural and urban areas.

Materials and Methods: One thousand fivehundred five women, aged 23 to 93 years (median 56), with breast canceroperated between 2001 and 2011, were evaluated. The analyzed parameters were:place of living (urban/rural), age (in subgroups: 1. <50 y.; 2. between 50and 70 y.; >70 y.), histological type, tumor size (T), state of regionallymph nodes (N), grading (G), estrogen, progesterone and HER2 receptor status,stage of cancer (TNM VII ed. 2010) and type of surgical procedure. The resultswere statistically analyzed by Statistica (Statsoft, ver. 9.0).
Results: Out of1505 patients, 958 (63.6%) lived in urban and 547 (36.3%) in rural areas. Themost common diagnosed histological type of cancer was ductal carcinoma. Amongthe urban patients, most common were Tis and T1 tumours, and in the rural womenT2 and T4 tumors ($p = 0.007$). Proportion of T3 tumors was similar in both groups(1.6% rural vs 2.2% urban). Higher percentage of rural women was diagnosed inII and III stage of cancer (63.4% vs. 58.1%), whereas among urban patientsstages 0 and I were more common (35.9% vs 30.9%; $p = 0.039$). Mastectomies hadbeen proceeded on 50% women from urban and 55% rural patients. Breastconserving treatment was applied to 49% urban and 45% rural women ($p = 0.11$).
Conclusions: Women living in therural areas had significantly higher stage of breast cancer, which may haveinfluence on the prognosis. Major impact should be focused on heath educationand prevention. Women living far from the oncological centers should haveeasier access to the diagnostics and earlier treatment.

1473 POSTER

Quercetin-3-glucoside, a potential dietary supplement to prevent cancer, is secure to normal cells?

D.G. Priolli[1], M.A. Sobreiro[2], A. Della Torre[3], N. Peres Martinez[1], M.E.M.B. De Araujo[1], A.L.T.G. Ruiz[3], P.O. Carvalho[1]. *[1]Sao Francisco University, Postgraduate Program in Health Science, Bragança Paulista, Brazil; [2]Sao Francisco University, Scientific Iniciation Program, Bragança Paulista, Brazil; [3]UNICAMP, cpqba, Paulinia, Brazil*

Background: Cancer is one of the leading causes of death in the human population worldwide. Prevention consisting in a healthy lifestyle and a natural diet is suggested to approaches to reduce cancer risk. In recent years, the use of flavonoids present in foods and dietary supplements has the greatest potential to modulate activity of tumor cell. However, since phytochemicals are foreign compounds, their consumption in large quantities should be carefully considered. The negative properties of these dietary supplements may have origin in their own toxicity, metabolic conversion into cytotoxic or mutagenic agents, induction of carcinogen activating enzymes, or effect on human microflora. The objective of this study is investigate the mutagenicity, antimutagenicity and antiproliferative effects of quercetin-3-glucoside, obtained by rutin hydrolysis with hesperidinase from Penicillium sp.
Materials and Methods: The enzymatic reaction was catalysed by heated hesperidinase from *Penicillium sp* for the bioconversion of rutin to its mono-glycoside form, quercetin-3-glucoside. The antiproliferative activity of the samples was performed on human tumor cell lines [breast (MCF-7), ovarian (OVCAR-3) and resistant ovarian (NCI-ADR/RES), kidney (786−0), prostate (PC-3), colon (HT-29)] and normal human keratinocytes (HaCat). The micronuclei assay (CBMN) had followed OECD guide using normal hamster ovarian cells (CHO-K1).
Results: Q3G exerted antiproliferative effect in human carcinoma cell lines (GI_{50} <10 μg/mL). At 2.5 μg/mL, Q3G did not improve micronuclei incidence besides a protective effect against MMS genotoxic effect.
Conclusion: The Q3G has a great potential to modulate activity of tumor cell lines; moreover, Q3G does not induces mutagenic risk by itself and can protect against xenobiotic mutagenic effect at the concentration considered.
No conflict of interest.

1474 POSTER

Knowledge about smoking-related cancer, health risk perception and role of nurses and physicians in smoking prevention among school children

G. Kuznecova[1], I. Kuznecovs[1]. *[1]Preventive Medicine Research Society, Cancer Research Laboratory, Riga, Latvia*

Background: In Latvia more than 30% of school children (age 13−18) are smokers. Seven in ten have an experience in tobacco smoking at the age of 16. The proportion of smoking girls increased from 2% in 1991 to 24% in 2010. There are several ongoing programs and campaigns focused on decrease of smoking habits among school children, which seem to be not working due to problems in health care system. The aim of this study was to examine knowledge about smoking-related diseases, risk perception and what should be changed in health care workers behavior to increase smoking prevention among school children.
Methods: A questionnaire-based survey was carried out among 566 school children smokers. Knowledge about smoking-related diseases was assessed with a questionnaire created for this study. Children rated their risk perception and role of physician in their health control. A cross-sectional survey was given to 238 nurses and 126 physicians to assess knowledge and identify factors that affect their anti-smoking behavior.
Results: School children are aware that smoking could cause lung cancer (29% of boys and 21% of girls), bladder cancer (6% and 8% respectively), cancer of the larynx and cancer of the oral cavity (10% and 3%), kidney cancer (2% and 1%), cancer of the cervix and uterus (1% and 5%), cancer of stomach and esophagus (2% and 1%), respiratory diseases (4% and 2%), heart diseases (2% and 5%), infertility and pregnancy complications (4% and 10%). Risk perception mean (SD) level was significantly higher in non-smokers school children (age 16−19). About 65% of boy (age 13−15) said they trusted their doctor ‘a lot,’ 30% said they had ‘some’ trust, while only 5% said they didn’t trust the doctor. About 82% of elder teenagers (age 16−19) trust doctors ‘a lot’, 10% have ‘some’ trust and 8% don’t trust the doctor. Cross-sectional survey among health care professionals showed that 147 nurses (61.7%) and 100 physicians (79.3%) neglected to speak about smoking-related diseases with teenagers or ask about smoking habits. Among them ‘was too busy’ were 91% of nurses and 67% of physicians, ‘forgot’ 6% nurses and 32 % of physicians, ‘do not recognize the necessity’ 3% nurses and 1% of physicians.
Conclusions: The results indicate an unsatisfactory knowledge about smoking-related diseases, low risk perception, absence or ignoring of prevention plan among school children as main causes of high prevalence of smoking in schools. Teenagers smokers must be informed about risk of smoking-related diseases by physicians and nurses during annual medical observation or every visit to doctor and educational strategies need to be focus on prevention plan immediately after confirmation of smoking habits. Prevention of smoking in schools does not work because doctors are neglecting their duty to speak with smokers about smoking-related diseases. Nevertheless, the results of this study show that school children respond far better to anti-smoking messages from doctors and nurses than they do from teachers, parents or government anti-smoking programs.
No conflict of interest.

1475 POSTER

Knowledge and awareness of breast cancer and practice of breast self-examination among female health workers in Al-Mukalla city

A. Badheeb[1], W.H.O. Al Shoaeeb[2]. *[1]Hadhramout University, Prince Sultan Cancer Unit, Mukalla, Yemen; [2]Ministry of Health, Mukalla, Mukalla, Yemen*

Introduction: Breast cancer is the most common cancer among women worldwide, comprising 16% of all female cancers. The prevalence of breast cancer in Yemen was 20.8/100 000 women Thus, World Health Organization(WHO) has emphasized raising awareness among women for early detection and reporting of breast cancer in order to increase life quality, survival rate and to overcome the ever-increasing burden of this deadly disease. Therefore, this study was designed to evaluate the knowledge regarding breast cancer (BC) and breast self examination (BSE) and the practice of BSE among female health workers in order to introduce the best intervention.
Methodology: A cross-sectional study was carried out from 15th January to 31st May 2012 in three public hospitals in Al-Mukalla city: Al Mukalla Hospital for Mother & Child, Ibin Sina General Hospital and the University Hospital. All female health workers practicing in hospitals were selected (total number of 182 females employed as doctors, nurses and midwives). The data was collected by pre-tested self report questionnaires. Interpretive description was used in the data analysis.
Results: Out of 182 female health workers registered in hospitals, 151 returned their questionnaires, giving a response rate of 83%. More than half (60%) of the female health workers in Al-Mukalla city had a high knowledge regarding BC and BSE. Doctors had more knowledge than the nurses and midwives. The study found a significant relationship between socio-demographic characteristics and BC knowledge, and also between family history of BC and BC knowledge. Majority of respondents were aware that BSE is a method for early detection of BC. Although only 54% of the female health workers were performing BSE (65% of doctors, 59% of midwives and 37.7% of nurses). Ninety % of those who practice BSE had high knowledge about BSE technique. ‘forgetfulness (43.4%)’and ‘absence of symptoms (40.6%)’ were main reasons that prevented respondents from practicing BSE.There was a statistically significant correlations between BSE practice and educational level, occupation, and level of knowledge.
Conclusion: The results point out that female health workers in Al-Mukalla city have a satisfactory level of knowledge regarding BC and BSE which was reflected in high percentage of practice of BSE. Significant correlation was found between the respondents’ knowledge and BSE practice. Our findings suggest that there is a need for continuing education programs to change attitudes and behavior towards BSE.
No conflict of interest.

Mediterranean dietary pattern and breast cancer in women: the modifying role of physical activity

N. Mourouti[1], M. Kontogianni[1], M. Mitsou[2], E. Samantas[3], C. Papavagelis[1], P. Plytzanopoulou[4], T. Vassilakou[4], N. Malamos[5], A. Linos[6], D. Panagiotakos[1]. *[1]Harokopio University, Department of Nutrition and Dietetics, Kallithea − Athens, Greece; [2]Agricultural University of Athens, Department of Food Technology, Athens, Greece; [3]General Oncological Hospital of Kifissia "Agioi Anargyroi", Third Pathology-Oncology Clinic, Athens, Greece; [4]National School of Public Health, Department of Nutrition and Biochemistry, Athens, Greece; [5]Maternity General Hospital "Elena Venizelos", Pathology-Oncology Department, Athens, Greece; [6]School of Medicine University of Athens, Department of Hygiene Epidemiology and Medical Statistics, Athens, Greece*

Background: The aim of this study was to investigate the association of the adherence to the Mediterranean diet with breast cancer development.
Material and Methods: An age-matched case-control study was conducted; 250 newly diagnosed breast cancer patients (56±12 yrs) and 250 controls were consecutively enrolled during 2010–2012 from 5 major hospitals. Participants completed a standardised questionnaire that also included a validated 86-item food frequency questionnaire. Adherence to the Mediterranean diet was evaluated using the MedDietScore (theoretical range 0−55). Anthropometric characteristics, family history, dietary and smoking habits and physical activity were also evaluated.
Results: Patients with breast cancer were less likely to be adherent to the Mediterranean dietary pattern as compared with controls (Odds ratio by 1-unit increase in the MedDietScore =0.923, 95% CI 0.879–0.968), adjusting for age, socioeconomic level, family history of breast cancer, body mass index (BMI), physical activity (IPAQ score), smoking and menopausal status. Physical activity status seems to enforce the aforementioned results, since adoption of a more physically active lifestyle was associated with greater reduction of the odds of having breast cancer. Specifically, patients with low physical activity status (i.e. IPAQ score<600 MET-minutes/week) were less likely to be adherent to the Mediterranean dietary pattern (OR=0.928, 95% CI 0.868–0.993), moderately physically active (i.e., IPAQ score=600–3000 MET-minutes/week) were 0.909 times (95% CI 0.835–0.989) less likely to be adherent to the Mediterranean dietary pattern, and women with health enhancing physical activity status (HEPA active, i.e., IPAQ score>3000 MET-minutes/week) were 0.847-times (95% CI 0.710–1.00) less likely to be closer to the Mediterranean diet.
Conclusions: These findings highlight the protective effect of the adherence to the Mediterranean dietary pattern in relation to breast cancer, irrespective of physical activity status.
No conflict of interest.

Mediterranean dietary pattern and breast cancer in women: the modifying role of obesity

N. Mourouti[1], M. Kontogianni[1], M. Mitsou[2], G. Aravantinos[3], C. Papavagelis[1], P. Plytzanopoulou[4], T. Vassilakou[4], N. Malamos[5], A. Linos[6], D. Panagiotakos[1]. *[1]Harokopio University, Nutrition and Dietetics, Kallithea − Athens, Greece; [2]Agricultural University of Athens, Food Technology, Athens, Greece; [3]General Oncological Hospital of Kifissia "Agioi Anargyroi", Second Pathology-Oncology Clinic, Athens, Greece; [4]National School of Public Health, Department of Nutrition and Biochemistry, Athens, Greece; [5]Maternity General Hospital "Elena Venizelos", Pathology-Oncology Department, Athens, Greece; [6]School of Medicine University of Athens, Department of Hygiene Epidemiology and Medical Statistics, Athens, Greece*

Background: The aim of this study was to investigate the association of the adherence to the Mediterranean diet with breast cancer development.
Material and Methods: An age-matched case-control study was conducted; 250 newly diagnosed breast cancer patients (56±12 yrs) and 250 controls were consecutively enrolled during 2010–2012 from 5 major hospitals. Participants completed a standardised questionnaire that also included a validated 86-item food frequency questionnaire. Adherence to the Mediterranean diet was evaluated using the MedDietScore (theoretical range 0−55). Anthropometric characteristics, family history, dietary and smoking habits and physical activity were also evaluated.
Results: Patients with breast cancer were less likely to be adherent to the Mediterranean dietary pattern as compared with controls (Odds ratio by 1-unit increase in the MedDietScore =0.923, 95% CI 0.879–0.968), adjusting for age, socioeconomic level, family history of breast cancer, body mass index (BMI), physical activity (IPAQ score), smoking and menopausal status. Obesity status masked the aforementioned results; particularly, adherence to the Mediterranean dietary pattern maintained its protective role in normal weight (BMI<25 kg/m^2) (OR=0.903, 95% CI 0.827–0.987) as well as in overweight women (BMI=25–29.9 kg/m^2) (OR=0.875, 95% CI 0.805–0.950); however, in obese women (BMI>30 kg/m^2) there was no significant association (OR=0.974, 95% CI 0.884–1.073, p = 0.59).
Conclusions: These findings highlight the protective effect of the adherence to the Mediterranean dietary pattern in relation to breast cancer, especially for normal weight and overweight women; and underline the detrimental role of obesity on diet-disease association.
No conflict of interest.

1478 POSTER

Mediterranean dietary pattern and breast cancer in women: the modifying role of menopausal status

N. Mourouti[1], M. Kontogianni[1], A. Tsakla[2], C. Papavagelis[1], P. Plytzanopoulou[3], T. Vassilakou[3], N. Malamos[4], A. Linos[5], D. Panagiotakos[1]. *[1]Harokopio University, Department of Nutrition and Dietetics, Kallithea − Athens, Greece; [2]Agricultural University of Athens, Department of Food Technology, Athens, Greece; [3]National School of Public Health, Department of Nutrition and Biochemistry, Athens, Greece; [4]Maternity General Hospital "Elena Venizelos", Pathology-Oncology Department, Athens, Greece; [5]School of Medicine University of Athens, Department of Hygiene Epidemiology and Medical Statistics, Athens, Greece*

Background: The aim of this study was to investigate the association of the adherence to the Mediterranean diet with breast cancer development.
Material and Methods: An age-matched case-control study was conducted; 250 newly diagnosed breast cancer patients (56±12 yrs) and 250 controls were consecutively enrolled during 2010–2012 from 5 major hospitals. Participants completed a standardised questionnaire that also included a validated 86-item food frequency questionnaire. Adherence to the Mediterranean diet was evaluated using the MedDietScore (theoretical range 0−55). Anthropometric characteristics, family history, dietary and smoking habits and physical activity were also evaluated.
Results: Patients with breast cancer were less likely to be adherent to the Mediterranean dietary pattern as compared with controls (Odds ratio by 1-unit increase in the MedDietScore =0.923, 95% CI 0.879–0.968), adjusting for age, socioeconomic level, family history of breast cancer, body mass index (BMI), physical activity (IPAQ score), smoking and menopausal status. Stratified analysis by menopausal status revealed that the protective role of diet was irrespective of menopausal status (i.e., premenopausal patients were 0.913, 95% CI 0.848–0.983 times less likely and postmenopausal patients were 0.911, 95% CI 0.851–0.975 times less likely to be adherent to the Mediterranean dietary pattern).
Conclusions: These findings highlight the protective effect of the adherence to the Mediterranean dietary pattern in relation to breast cancer, both for pre- and postmenopausal women.
No conflict of interest.

1479 POSTER

Prevalence & predisposing factors for tobacco chewing among secondary school students in Mukalla,Yemen (2012–2013)

A. Badheeb[1]. *[1]Hadhramout University, National Oncology Centre, Mukalla, Yemen*

Objectives: To determine the prevalence & predisposing factors for tobacco chewing among secondary school students in Mukalla, Yemen (2012–2013).
Design: 530 randomly selected secondary school students from 10 schools were included in this cross-sectional study.
Results: The prevalence of tobacco chewing among secondary school students in Mukalla city was 28.7%. Majority of students were highly knowledgeable on relationship between tobacco chewing and occurrence of oral cancer and periodontal diseases (64%). 'Influence of friends' was the most common predisposing factor (66.5%). Appropriate guidance from parents and guardians, Knowing the detrimental health effects, and religious teachings were perceived as a. The tobacco smoking and Qat chewing were significantly higher among students chewed tobacco compared with non-chewed [(25% & 2.9%, P = 0.00) and (30.3% & 4.5%, P = 0.00) respectively.
Conclusions: Despite of the good level of knowledge on the detrimental effects of tobacco chewing on health, a high prevalence of chewers among secondary school students was discovered. Novel approaches involving the religious leaders, parents, school teachers are an urgent need in the country.
No conflict of interest.

New communication strategies of the Italian League against cancer to promote healthy behaviors in the province of Alessandria (Italy)

C. Calvi[1], R. Cuttica[2], M. Brusa[3], C. Angelini[3], A. Pogliano[1], F. Ceravolo[4], P.G. Betta[2]. *[1]University of Piemonte Orientale, Department of Law and Political Economical and Social Sciences, Alessandria, Italy; [2]Italian League Against Cancer, Alessandria Section, Alessandria, Italy; [3]ASL Alessandria, Gruppo PEAS, Casale Monferrato, Italy; [4]University of Pavia, Faculty of Political Sciences, Pavia, Italy*

Background: Primary cancer prevention efforts typically involve the development and distribution of persuasive and informative cancer education programs and materials, as well as the development of specific preventative behavioral interventions to adopt a healthy lifestyle. In the past the Italian League against Cancer, section of Alessandria (LILT Al), tried to persuade the greatest part of the local population to join programs of preventive diagnostic screening, whereas the current priority is to combat against selected behavioral factors, mainly poor diet and not being physically active, implicated in the onset of cancer. In the light of this shift in action, a working group has been recently set up by LILT Al with participants from the Group for Health Promotion and Education, Local Health Authority (PEAS-ASLAl), and the Institute of Sociology, University of Piemonte Orientale at Alessandria. The group is focused on building new strategies for encouraging healthy lifestyle choices by means of interventions capable of being appealing and effective especially among young population.
Material and Methods: At first, an analysis was carried out for the evaluation of previous health education campaigns with special reference to their contents, operating methods and results. Furthermore, the conditions of overweight and obesity have been used as a paradigm to improve our understanding of psychological and social mechanisms (the determiners of behavior) placing people at increased risk of health problems. Biographical interviews were conducted with patients (n = 22) suffering from first degree obesity and attending ambulatory care for dietary therapy. Finally, attention has also been given to the influence of socio-economic and cultural factors on local community health.
Results: Interviewed people appeared to consider themselves at health risk only when additional diseases overlap the condition of overweight or obesity. They did not agree that obesity is a disease and they never internalized the concept of 'obesity' as well as never thought of themselves as 'obese'. Finally, they never let themselves to be influenced by educational campaigns promoting healthy diet and emphasizing obesity as a health risk factor.
Conclusions: Although preliminary and still limited, these results could be useful to develop educational messages appropriate for the new emerging evidences related to the characteristics of the target population of our study. The study was funded in part by CSVA Alessandria through the call 'Bando a scadenza unica 2011'.
No conflict of interest.

1481 POSTER

Number needed to harm in prostate cancer screening with PSA

P. Perrin[1], P. Boyle[2], A. Koechlin[3], A. Ruffion[1], P. Autier[4], M. Boniol[4]. *[1]Hospices Civils de Lyon, Urology, Lyon, France; [2]International Prevention Research Institute, Director, Lyon, France; [3]International Prevention Research Institute, Statistics, Lyon, France; [4]International Prevention Research Institute, Research, Lyon, France*

Background: The United States Preventive Service Task Force (USPSTF) recently recommended against PSA testing for prostate cancer screening in asymptomatic men. Despite this recommendation, the use of PSA tests is still widespread as in France, 55% of men aged 50−60 have a PSA test every year and more than 75 % every 3 years.
Methods: We estimated the number of individuals needed to harm associated with PSA testing by applying different side effect estimates to a virtual population of 1,000 men aged 55−69 exposed to PSA testing and another 1,000 not exposed to PSA testing. Following a systematic literature review, we extracted results of PSA testing, biopsy rates and impact on prostate specific mortality from the European Randomized Study on Screening for Prostate Cancer (ERSPC) which is the study with the most favourable outcome to PSA screening. We also extracted, from reports with such information, data on mortality following prostatic biopsy, on mortality associated with radical prostatectomy as well as side effects of radical prostatectomy and hospitalisation rates following prostatic biopsy.
Results: In the group of 1,000 unscreened men, we estimated that 116 biopsies would be conducted and 60 prostate cancers would be diagnosed. Overall 193 deaths would occur in this group of which 5.17 would be from prostate cancer. In the population exposed to screening, 270 biopsies would be performed, with 96 prostate cancer diagnosed. The mortality would be similar with 191 deaths overall with 4.1 from prostate cancer. For 1 death from prostate cancer prevented among 1,000 men, this population would have to experience an additional 154 biopsies (among which 9 would require hospitalization for severe adverse effect and 0.2 deaths would occur due to biopsy). 35 additional prostate cancers would be diagnosed mainly from low risk men (32 cases). These additional cancers would be associated with 12 additional cases of impotence, 2 cases of incontinence and 1 case of faecal incontinence.
Conclusions: Overall, under the best scenario of screening efficiency, the prevention of 1 death from prostate cancer is associated with a significant additional adverse-effect burden from the biopsy and from the treatment of the additional prostate cancer diagnosed. These will severely impact the quality of life of patients and argues against using PSA testing for mass screening of prostate cancer.
No conflict of interest.

1482 POSTER

Changes in lifestyle in patients with previous diagnosis of colorectal or breast cancer

J. Cano[1], M. Murcia[1], V. Sanchez[1], M.D. Pineda[1], R. Lopez[1], J.C. Villa[1], J. Espinosa[1]. *[1]Hospital General Ciudad Real, Clinical Oncology, Ciudad Real, Spain*

Background: Colorectal and breast cancers are related with risk factors such as overweight, obesity and physical inactivity. Importantly during their follow-up patients should be motivated for adopting a healthy life style (maintain an ideal body weight, BMI 20−25, physical activity, at least 30 minutes five times a week, cessation of smoking, moderate alcohol use, healthy diet adoption). However patients usually are not really aware of its importance and medical oncologists don't insist enough in daily practice.
Material and Methods: We prospectively collected data from 109 patients who came to our consultation for follow-up since January to April 2013. We analyzed baseline comorbidity and changes in lifestyle and comorbidity between first visit in study and second visit (study is planned until July 2013). We also asked for intake of medications like aspirin, statins, beta blockers and ACE inhibitors.
Results: 68 patients had a previous diagnosis of breast cancer and 41 of colorectal cancer. In the group of breast cancer median age was 56 years (range 33−82), 30% had hypertension, 14% type 2 diabetes mellitus, 20% baseline dyslipidemia, 71 % were no smokers, 19 % were former smokers, and 10% active smokers, of whom 75 % reduced their consumption and 25% ceased after diagnosis; 82% were previously abstemious and 18% moderated their alcohol use after diagnosis; baseline BMI was 20−25 in 54%, 25−30 in 31%, and $\geqslant$30 in 15%; at first visit of present study 65 % of patients who were free of tumor recurrence had maintained their weight, 10% had lost weight, and 25% had put on weight; only 15% who had baseline BMI $\geqslant$25 had followed a weight loss diet even if 100% were aware of the importance of maintaining an ideal weight, 85% said exercise regularly and have an adequate intake of fruits and vegetables, only 13% had started smoking again, and most were abstemious or with very moderate intake of alcohol; 71% had screening for other tumors like colon and cervical cancer; 84% said to have been counseled by their medical oncologist on the importance of healthy lifestyle and wellness. Results for the second visit are still incomplete, and for the group of colon cancer the main differences were age (median age 64, range 35−81), baseline smoking status (42% current smokers) and BMI (20−25: 54%, 25−30: 35%, $\geqslant$30: 11%, and 85% had put on weight at first visit).
Conclusions: Medical oncologists should optimize counseling on healthy lifestyles during follow-up of patients treated for breast and colon cancer as important part of their treatment.
No conflict of interest.

1483 POSTER

HIV screening of patients with AIDS-defining cancers: A 10-year retrospective analysis of practices in a Swiss university hospital

V. Mosimann[1], M. Cavassini[2], C. Achtari[3], S. Peters[4], K.E.A. Darling[2]. *[1]Faculty of Biology and Medicine, Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; [2]Centre Hospitalier Universitaire Vaudois, Service of Infectious Diseases, Lausanne, Switzerland; [3]Centre Hospitalier Universitaire Vaudois, Service of Gynaecology, Lausanne, Switzerland; [4]Centre Hospitalier Universitaire Vaudois, Service of Oncology, Lausanne, Switzerland*

Background: Kaposi's sarcoma (KS), invasive cervical carcinoma (ICC) and non-Hodgkin lymphoma (NHL) have been listed by the Centers for Disease Control and Prevention (CDC) as AIDS-defining illnesses since 1993. The European Society of Medical Oncology (ESMO) recommendations mention HIV screening in the case of NHL but not ICC. However, patients with AIDS-defining cancers (ADC) who are HIV-positive

present better outcomes when their HIV infection is treated in parallel to cancer treatment. We examined HIV screening practices at a tertiary oncology centre where local HIV seroprevalence is 0.4%.
Methods: We included all patients with KS, ICC and NHL, and patients with Hodgkin lymphoma (HL), treated at Lausanne University Hospital, Switzerland, between January 2001 and January 2012. HIV testing was considered to be part of the oncology work-up if patients underwent testing at the time of oncological diagnosis, as documented in the central laboratory database or in patient notes. Patients of known HIV-positive status were included in our analysis but excluded from calculations of testing rates: (patients tested/patients treated) x 100.
Results: 880 patients were examined: 10 with KS, 58 with ICC, 672 with NHL and 140 with HL. For these cancer types, HIV testing rates were 100%, 19%, 75% and 74%, respectively. 37 patients (4.2%) were HIV-positive of whom 28/37 (76%) were Swiss and 6/37 (16%) were diagnosed as a result of screening related to the oncology work-up. HIV prevalence among patients with KS, ICC, NHL and HL was 60%, 1.7%, 3.4% and 5%, respectively.
Conclusion: In our study population, HIV prevalence among patients with non-KS cancers is low but higher than the population average. For non-KS cancers, HIV screening was performed in 19−75% of patients. As HIV-positive status impacts on the medical management of cancer patients, we propose that HIV screening should be mentioned in oncology treatment guidelines and that an opt-out approach should be adopted in patients with ADC and HL.
No conflict of interest.

1484 POSTER

The efficacy of MRI and mammography in screening BRCA1 and BRCA2 mutation carriers above 60 years

S. Saadatmand[1], M.J. Hooning[2], J.C. Oosterwijk[3], Hereditary Breast and Ovarian Cancer Group (HEBON)[4], L.B. Koppert[1], C. Seynaeve[2], G.H. De Bock[5], C. Verhoef[1], M. Rookus[6], M.M.A. Tilanus-Linthorst[1]. *[1]Erasmus MC–Cancer Institute, Surgery, Rotterdam, Netherlands; [2]Erasmus MC–Cancer Institute, Medical Oncology, Rotterdam, Netherlands; [3]University Medical Centre Groningen University, Genetics, Groningen, Netherlands; [4]Collaborators and affiliations under acknowledgements, -, Netherlands; [5]University Medical Centre Groningen University, Epidemiology, Groningen, Netherlands; [6]the Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Epidemiology, Amsterdam, Netherlands*

Background: Screening guidelines advise breast cancer screening with yearly MRI and mammography to reduce mortality for *BRCA1* and *BRCA2* mutation carriers (*BRCA1/2*). The Dutch (NABON) and British (NICE) guidelines, recommend screening with only biennial mammography for mutation carriers from the age of 60 years on ($\geqslant$60). But less intensive screening may not be justified, since breast cancer incidence does not decrease in carriers $\geqslant$60. Furthermore, *BRCA1* tumours grow twice as fast as sporadic tumours, and no studies have been performed addressing screening in *BRCA1/2* $\geqslant$60. We assessed the proportion of *BRCA1/2* who did not have bilateral therapeutic or prophylactic mastectomy before the age of 60 to determine for how many screening above 60 years is relevant. Moreover, we compared efficacy of screening with; annual MRI and mammography, annual mammography, and biennial mammography in *BRCA1/2* $\geqslant$60.
Material and Methods: We assessed the proportion of *BRCA1/2* with breast tissue at risk at age 60 of the Rotterdam Family Cancer Clinic and the ongoing nationwide HEBON study. Furthermore, we compared tumour stage at detection between different screening methods in the 98 breast cancers detected in *BRCA1/2* $\geqslant$60 in these databases. Tumours larger than 2 cm, lymph node positive, and/or metastatic disease at detection were defined as 'unfavourable stage'.
Results: Of 413 *BRCA1,* 133 *BRCA2*, and 2 *BRCA1* and *BRCA2* mutation carriers $\geqslant$60 in 2012, 395 (72%) had one or both breasts at age 60. Of the women with breast tissue 20% had a history of invasive carcinoma other than breast or non-melanoma skin cancer. Screening method at detection of the 98 breast cancers was; 11 (11%) no screening, 28 (29%) biennial mammography, 48 (49%) annual mammography, and 11 (11%) annual mammography and MRI. With annual mammography 25% of tumours were detected in an unfavourable stage versus 64% with biennial mammography ($p = 0.001$). Tumour stage did not differ significantly between screening with annual MRI and mammography or mammography alone.
Conclusions: A large part of *BRCA1/2* still has breast tissue at risk at 60 years of age. Annual screening above age 60 detected tumours in a significantly more favourable stage than biennial screening. If life expectancy is good, continuation of annual screening of *BRCA1/2* mutation carriers above age 60 seems worthwhile. We will present updated results, also separately, for *BRCA1* and *BRCA2* mutation carriers.
No conflict of interest.

1485 POSTER

Level of awareness of cervical and breast cancer risk factors and safe practices among college teachers of different states in India: Do awareness programmes have an impact on adoption of safe practices?

A. Shankar[1], G.K. Rath[1], P.K. Julka[1], R. Bhandari[1], K. Kishor[1]. *[1]All India Institute of Medical Sciences, Radiation Oncology, New Delhi, India*

Background: Breast and cervical cancers are the most common causes of cancer mortality among women in India, but actually they are largely preventable diseases. In India, late presentation which is responsible for high mortality and morbidity is attributed to many factors and important being the lack of knowledge and awareness, lethargic attitude towards safe practices. Since, there is limited data from India on this issues, the purpose of this study is to know the impact of awareness program on change in adoption of safe practices in prevention and early detection.
Material and Methods: This assessment was part of pink chain campaign on cancer awareness. During the events in 2011 at various women colleges in India, Pre test related to knowledge, attitude and practices related to cervical and breast cancer was conducted by questionnaire. It was followed by awareness program consisting of lectures on preventive aspects of breast and cervical cancer, Pink Chain − a docu-drama on breast cancer and an interactive session. Post test using the same questionnaire was conducted at the end of interactive session. Literature related to cancer awareness was sent regularly for one year on email ids provided. After completion of 6 months and 1 year, same questionnaires were mailed to the participants to see the change in practice. Data was collected and analysed by using statistical software STATA 10.1. P values less than 0.05 were taken as significant.
Results: A total of 156 out of 182 teachers participated in the study (85.71%). Same questionnaire were responded by 109 and 95 teachers at the end of 6 months and 1 year respectively. Mean age of the study population was 42.46 years (28−59 yrs). For cervical cancer, the correct risk factors mostly indicated by teachers were smoking (53%), family H/O cervical cancer(45%) and genital hygiene(36%). Symptoms of cervical cancer were very less known to teachers (7.69% − 32.05%). Risk factors and symptoms of breast cancer were well known in more than 50% of teachers, except for early menarche (16.66%), late menopause (17.94%) and radiation treatment(14.10%). As for screening methods, BSE, CBE, and Mammography were known modalities for breast cancer in 70%, 45% and 54% of teachers respectively but pap's test was known to only 35%. Magazines and newspapers were source for knowledge regarding screening test for breast cancer in more than 60% of teachers where as more than 75% teachers were educated by doctors regarding pap's test. Post awareness at 6 months and 1 year, there was a significant change in alcohol and smoking habits. There was a significant increase in level of knowledge regarding risk factors, symptoms and screening test for cervical and breast cancer at 6 months and this was sustained at 1 year. There was a significant increase in adoption of BSE where as practice of CBE, mammography and pap's test were increased but not significant. For not doing screening test, major reasons came out to be ignorance (50%), lethargic attitude (44.87%) and lack of time (34.61%).
Conclusions: Level of knowledge of breast cancer risk factors, symptoms and screening methods was high as compared to cervical cancer. Though there was significant change in practices of BSE and pap's test, there was not much improvement in people undergoing screening such as mammography and pap's test. To inculcate safe practices in life style of people, awareness programmes such as pink chain campaign should be conducted more widely and frequently and knowledge attained through them should be reinforced by treating physicians who are at first point of contact with health system. So creating awareness among health care providers is another issue which has to be looked into.

1486 POSTER

Primary efficacy of physical examination combined with ultragraphy and complemented with mammography for breast cancer screening in 280 thousand Chinese women

J. Xu[1], Q. Wang[1], J. Xia[2], Y. Zhang[3]. *[1]Guangdong Maternal and Children Hospital, Breast Center, Guangzhou, China; [2]Guangdong Maternal and Children Hospital, Health Care Center, Guangzhou, China; [3]Bureau of Health of Guangzhou Municipality, Department of Maternal and Child Health Care and Community Health, Guangzhou, China*

Background: Seldom large randomized controlled trials of breast cancer screening had been conducted among Chinese women, and the efficacy of such screening had not been defined yet. Because the high expenses of mammography, we conducted a program to evaluate the efficacy of physical examination combined with ultragraphy and complemented with mammography for breast cancer screening in chinese women.

Methods: We conducted a project of women aged 35 to 59 years who, living in suburb of Guangzhou, were screened with a clinical breast physical examination and ultragraphy. Those whose ultrasound findings categorized as BI-RADS 4c and 5 were biopsied, and those which categorized as BI-RADS 0, 3, 4a and 4b accepted mammography additionally, and those as BI-RADS 1 and 2 were follow-up.
Results: From January 1st,2010 to January 31st, 2012, 284168 women were screened. We identified 151 breast cancers. The detective rate of breast cancer was 53.14/100,000 and had positive correlation with the rate of biopsy(P<0.05). Percentage of stage 0 and I breast cancer were 8.6% and 38.4%,and significantly more stage I patients were detected compared with those in-hospital(P<0.001). The sensitivity was 97.4% and specificity was 99.9%, and the sensitivity was much higher than that of procedures only including physical examination and ultragraphy. The detective rate of the groups aged 35−39, 40−50, 50−59 years was 29.7(1/ 3368),53.0 (1/1885) and 74.7(1/1339) per 100,000 sreening women, whereas the costs for each detective breast cancer was ¥202,000,113,000 and 80,000 respectively. The detective rate of early beast cancer in group aged 50−59 years was significantly much higher than that in other two groups (P<0.001) and the group had the best cost-effectiveness.
Conclusions: Physical examination combined with ultragraphy and complemented with mammography for breast cancer screening can improve the proportion of stage I tumor significantly. It obtained nice sensitivity and specificity. Women aged 50−59 years had the best cost-effectiveness.
No conflict of interest.

Regional experience of the mammographic screening implementation in Western Siberia

N. Zakharova[1], S. Duffy[2], S. Pyankin[3], A. Pestryakova[3].
[1]Khanty-Mansiysk State Medical Academy, Cancer Center Department of Oncology and Radiology, Khanty-Mansiysk, Russian Federation; [2]Queen Mary University of London, Centre for Cancer Prevention Wolfson Institute of Preventive Medicine, London, United Kingdom; [3]State Cancer Registry, Head-office, Khanty-Mansiysk, Russian Federation

Background: Breast cancer is the most common cancer in the female population, and one of the leading causes of cancer deaths in women. Almost 12 million new cancer cases were diagnosed in 2008 across the world and of these, 1.38 million women were diagnosed with breast cancer. In many areas, breast cancer mortality has decreased in recent decades due to improving treatment and implementation of mammography screening. The main aim of this study is to evaluate the results of the Breast Cancer Screening Program implemented in the Khanty-Mansiysky Autonomous Okrug − Ugra in 2007.
Methods: Mammography screening covers women over 40 years old, the screening interval is 2 years, and two-view mammography and single reading. Data number of screened are obtained annually from the reports for the State Healthcare Department. The information on the female population, all screen-detected and symptomatic detected breast cancer cases, deaths cases due to breast cancer has been obtained from the State Cancer Registry for years 2002–2012. The target population of women aged 40+ has increased from 273100 in 2002 to 323285 in 2012. We studied incidence of node positive breast cancer over the years 2002 to 2012, comparing observed incidence in 2007 to 2012 with that expected from the observed trend in 2002 to 2006. We also estimated the effect of screen detection on node positivity in the 3398 cancers diagnosed in the target age group in 2002–2012, using logistic regression and taking account of confounding factors.
Results: During 2007–2012 within the Program, 249106 women were screened in the region. The screening coverage rate is the approximately 67.5%. 9.7% of screened women were referred for further assessment. The prevalence was 2.7 per 1000 screened women. The test sensitivity for the first round was estimated as 80%. The number of node positive breast cancers in 2007 to 2012 was 985, significantly lower than the 1309 expected from the 2002−06 trend. Screen detected cancers were significantly less likely to be node positive after adjusting for district and year of diagnosis, and for tumour size (OR=0.49, 95% CI 0.39–0.62).
Conclusion: The quality evaluation of the Screening Program shows that the main criteria are within the international standards. Mammographic screening has contributed to a major reduction in node positive breast cancer and is likely to produce a corresponding breast cancer mortality reduction in the future.
No conflict of interest.

1488 POSTER

Neighbourhood deprivation and risk of morbidity and mortality in people with lung cancer: A multilevel analysis from Sweden

X. Li[1], J. Sundquist[1], B. Zöller[1], K. Sundquist[1]. *[1]University Hospital of Malmö, Center for Primary Health Care Research, Malmö, Sweden*

Objectives: To analyze whether there is an association between neighbourhood deprivation and morbidity and mortality of lung cancer, beyond individual level characteristics.
Design: The entire Swedish population aged over 50, a total of 3.2 million individuals, was followed from January 1, 2000, until admission due to morbidity or mortality of lung cancer during the study period, or the end of the study on December 31, 2010. Multilevel logistic regression was used in the analysis with individual level characteristics (age, marital status, family income, education, immigration status, urban/rural status, mobility, and comorbidities) at the first level and level of neighbourhood deprivation at the second level. Neighbourhood deprivation was measured at small area market statistics level the use of Care Need Index, combining low educational status, low income, unemployment, and social welfare assistance.
Results: There was a strong association between level of neighbourhood deprivation and morbidity and mortality of lung cancer. In the full model, which took account of individual level characteristics, the risk of morbidity of lung cancer was 1.31 and 1.36 for mortality in the most deprived neighbourhood than in the most affluent neighbourhoods. The variance at neighbourhood level was over twice the standard error, indicating significant difference in morbidity and mortality of lung cancer risk between neighbourhoods.
Conclusions: This study is the largest to date of the influences of neighbourhood deprivation on morbidity and mortality of lung cancer. Results suggest that characteristics of neighbourhood affect risk of morbidity and mortality of lung cancer independently of individual level sociodemographic characteristics. Both individual and neighborhood level approaches are important in health care policies.
No conflict of interest.

1489 POSTER

Epidemiology of primary myelofibrosis (PMF), essential thrombocythemia (ET), and polycythemia vera (PV) in the European Union (EU)

J. Mehta[1], O. Le-Ruyet[2], J. Fryzek[3], S.U. Iqbal[1], R. Mesa[4].
[1]Sanofi-Aventis, Evidence and Value Development, Cambridge, USA; [2]Sanofi-Aventis, Evidence and Value Development, Chilly Mazarin, France; [3]Epidstat Institute, Epidemiology, Michigan, USA; [4]Mayo Clinic, Division of Hematology and Medical Oncology, Arizona, USA

Background: PMF, ET and PV, three classic Philadelphia-chromosome-negative disorders, can cause substantial morbidity and mortality and have no therapeutic options addressing the underlying cause of disease. An evidence based synthesis of EU epidemiology data can inform population health care planning and economic decision for these disorders.
Material and Methods: Since information on MF, ET and PV is not routinely collected in disease registries in the EU, multiple sources are needed to understand the disease burden. Therefore, we conducted reviews of the literature, of disease registries and of online databases updated as of January 2013 to summarize recent data on incidence and prevalence of these disorders.
Results: Ten articles, four hematology or oncology registries and two web-based databases or reports were found to have information on epidemiological estimates for MF, PV and ET. The incidence rate of MF from the online registries or reports ranged from 0.1 per 100,000 per year to 1 per 100,000 per year while the literature estimated an incidence rate of around 0.3 per 100,000 per year. PV and ET incidence estimates were slightly higher. Among the online sources, the incidence of PV ranged from 0.4 per 100,000 per year to 2.8 per 100,000 per year with similar estimates in the literature (0.68 per 100,000 to 2.6 per 100,000 per year). The estimated incidence of ET was between 0.38 per 100,000 per year and 1.7 per 100,000 per year in the online sources and 0.52 to 2.00 per 100,000 in the literature. In contrast to MF and PV, the incidence of ET was higher among women than men. Few resources (n = 2 online resources, 1 registry and 3 articles) reported on the prevalence of MF, PV or ET. The prevalence of MF (range = 0.51 to 2.7 per 100,000) was lower than PV (range = 5 to 30 per 100,000) or ET (range = 1 to 24 per 100,000).
Conclusions: Few publications and registries report epidemiology data for MF, PV or ET and the variation in these estimates is wide across EU data sources limiting an informed application of these data. Additional research using standardized definitions/coding across appropriate real world databases and enhanced tumor registries are needed to add precision to or substantiate these results. Regardless, this review found

that the prevalence of ET/PV may be high enough to deserve resource allocation and attention towards development of national guidelines, development of novel agents, and healthcare planning.

1490 POSTER

The methodology and results of nosocomial infections surveillance at the Institute for Oncology and Radiology of Serbia

D. Jovicevic[1], A. Jovicevic[2], G. Kukic[1], V. Mandic[1]. *[1]Institute for Oncology and Radiology of Serbia, Department of Epidemiology and Prevention, Belgrade, Serbia; [2]Institute for Oncology and Radiology of Serbia, Belgrade, Serbia*

Background: Epidemiological nosocomial infections surveillance imply the systematic gathering, analysis and interpretation of data on nosocomial infections, informing hospital staff and the Hospital Infection Control Committee of the surveillance results with the aim of prevention and control of infections.
Material and Methods: Hospital infections surveillance has been performed by the Department for Epidemiology and Prevention in collaboration with other departments. Monitoring of microbiology results of samples taken from patients, staff and environment is a component of surveillance since 1996; since 2005. all data are entered into the electronic database. Analysis of data for 2011 was performed.
Results: In 2011, 408 samples were taken from the work environment and 66 samples from employees (positive results in 18% and 24 % of samples, respectively). From clinical wards, 4729 samples from patients were sent to microbiological analysis, 26% being positive. The most frequently isolated microorganisms were Staphylococcus aureus, E. coli and Klebsiella Enterobacter. Share of gram-positive bacteria was 32.2%, gram negative 48.1%, and fungi 19.7%. Most frequent analyses were urinoculture, throught swab, hemoculture and nose swab. Urinocultures were positive in 30% of samples, most frequently isolated E.coli and Klebsiella. From hemocultures, postive in 10% of samples, most frequently were isolated KNS and Staph.aureus. Wound swabs were positive in more than 50% of samples, mostly with Staph.aureus, Klebsiella, Pseudomonas and E.coli.
Surveillance of antibiotic-resistance revealed that 7.7% infections were caused by resistant bacterial strains, most frequently VRE (58 samples), Pseudomonas resistant to piperacillin/ciprocinal (21) and MRSA (28 samples).
Conclusion: Regular surveillance of microbiological findings and antibiotic resistance enables efficient treatment and prevention of hospital infections in cancer patients.
No conflict of interest.

1491 POSTER

Are the incremental costs of breast cancer clinical trials higher than standard of care?

B. Jones[1], M. Eliasziw[2], R. Syme[3], B.J. Eigl[4]. *[1]Tom Baker Cancer Centre, Calgary Alberta, Canada; [2]Tufts University, Public Health and Community Medicine, Boston, USA; [3]Alberta Health Services, Research, Calgary Alberta, Canada; [4]BC Cancer Agency, Systemic Therapy Clinical Trials, Vancouver, Canada*

Background: Clinical trials (CT) are an essential element in the improvement of cancer prevention and treatment strategies. A widely held perception is that costs of care for CT patients are higher than standard of care (SOC). There is a paucity of data supporting this assertion.
Material and Methods: A retrospective cohort study was conducted to compare costs incurred by 97 breast cancer patients participating in industry and non-industry sponsored clinical trials with costs incurred by an equal number of eligible nonparticipants who received SOC over a year. Resource utilization was tracked and quantified to standardized price templates.
Results: On average, the costs were marginally higher for CT patients than SOC patients for all seven parameters, as were the mean total costs (Table 1, two-tailed t-test, p-value = 0.046) with pharmacy costs constituting the largest difference between trial and SOC patients (mean difference = $5157, p = 0.08). After excluding drugs that were provided by the pharmaceutical companies at no charge, the remaining average pharmacy costs became more similar between groups (mean difference = $990, p = 0.45). As a result, the mean difference between total costs was reduced by two-thirds, from $6396 to $2227 and significance was lost (p = 0.14).

Table 1. Cost by patient type (Canadian dollars)

Item	Trial patients Mean (SD)	SOC Patients Mean (SD)	Difference Mean (95% CI)	P-value
Tests and procedures	470 (640)	187 (439)	283 (128, 439)	<0.001
Diagnostics and Imaging	948 (945)	440 (626)	508 (281, 735)	<0.001
Physician	338 (303)	192 (238)	146 (69, 224)	<0.001
Nurse	434 (738)	232 (503)	202 (23, 380)	0.03
Pharmacy	10345 (25415)	5188 (14047)	5157 (−657, 10974)	0.08
Radiotherapy	3764 (2939)	3724 (3043)	40 (−807, 887)	0.93
Pathology	117 (168)	60 (132)	57 (15, 100)	0.009
Total	16418 (27186)	10022 (15480)	6396 (131, 12661)	0.046
Pharmacy − Drug-supplied	3846 (8417)	2855 (9611)	990 (−1469, 3549)	0.45
Total − Drug-supplied	9917 (10262)	7690 (10491)	2227 (−711, 5166)	0.14

Conclusions: This study revealed only marginal differences in the cost distribution of patients enrolled in clinical trials versus those receiving the standard-of-care. This is similar to previous results we have seen for prostate cancer patients and further questions the commonly held belief that clinical trials are a burden on a public-payer health-care system. Further research into this area is warranted.
No conflict of interest.

1492 POSTER

The landscape of medical oncology in Europe by 2020

E. De Azambuja[1], L. Ameye[2], M. Paesmans[2], C.C. Zielinski[3], M. Piccart-Gebhart[4], M. Preusser[3]. *[1]Institut Jules Bordet, Medical Oncology Clinic and Breast Data Center, Brussels, Belgium; [2]Institut Jules Bordet, Data Center, Brussels, Belgium; [3]Medical University of Vienna, Department of Medicine, Vienna, Austria; [4]Institut Jules Bordet, Department of Medicine, Brussels, Belgium*

Background: The number of cancer patients is steadily increasing in most countries. In the US, there will be a shortage of medical oncologists (MO) by the year 2020. However, this information is not available in Europe. The aim of this study was to assess the current number of MO in the 27 European Union (27-EU) countries and to predict their availability by 2020.
Material and Methods: Between 06/2012 and 01/2013, a survey was submitted to health authorities or medical oncology societies in all 27-EU countries in order to gather data on the yearly number of MO since 2000. Contacts were made by e-mail, phone calls and research on official websites by two authors (EdA and MPr). Data regarding cancer incidence in 2008 and projections for 2015 and 2020 in all types of cancer for each country, were obtained through Globocan (http://globocan.iarc.fr). The mean annual increase in the number of MO was calculated for each country. The total number of MO by 2015 and 2020 was estimated as (MO in 2012)x(1+ (annual increase x 3)) and(MO in 2012)x(1+ (annual increase x 8)). A ratio of new cancer cases vs. number of MO was calculated for 2008, 2015 and 2020 in each country. A decrease in the ratio was considered a favourable evolution.
Results: Data from 11 countries were not obtained whereas 4 countries provided insufficient data. As a result, 12 countries were included in our analyses: Austria, Belgium, Bulgaria, Finland, France, Germany, Hungary, Italy, Netherlands, Portugal, Sweden and UK. The average mean annual increase in the total number of MO was 5.3% (range 1.8%-8.7%) with Belgium being the lowest and UK the highest. The 2008 ratio of cancer vs. MO was lowest in Hungary (113) and highest in UK (1067). With the exception of Belgium, which is estimated to show a similar ratio in 2015 and 2020 compared to 2008, a favourable decrease in this ratio was estimated in all other countries.
Conclusion: Though our estimates were based on incidence and not on prevalence, the results indicate that availability of MO will probably meet the projected need in most of the surveyed countries provided that (i) these countries maintain their rate of annual increase in MO, and (ii) no unforeseen changes in cancer incidence occur. Unfortunately, minimal information is available for Eastern Europe. Our data call for a prospective and standardised surveillance of cancer burden and MO availability to ensure adequate and equal care for cancer patients throughout Europe.
No conflict of interest.

1493 POSTER

Delivery of health care at the end of life in cancer patients from four Swiss cantons (SAKK 89/09)

K. Matter-Walstra[1], R. Achermann[2], D. Klingbiel[3], A. Bordoni[4], S. Dehler[5], I. Konzelmann[6], G. Jundt[7], K. Clough[8], M. Schwenkglenks[1], B. Pestalozzi[9]. *[1]University Basel, Institute of Pharmaceutical Medicine/ECPM, Basel, Switzerland; [2]Former Helsana, Statistics and Research, Zürich, Switzerland; [3]Swiss Group for Clinical Cancer Research Coordination Center, Statistiks, Bern, Switzerland; [4]Cancer Registry Ticino, Research, Locarno, Switzerland; [5]Cancer Registry Zürich, Research, Zürich, Switzerland; [6]Cancer Registry Valais, Research, Sion, Switzerland; [7]Cancer Registry Baselstadt and Baselland, Research, Basel, Switzerland; [8]National Institute for Cancer Epidemiology and Registration, Research, Zürich, Switzerland; [9]University Hospital Zürich, Oncology, Zürich, Switzerland*

Background: Using claims databases, cancer registries and cancer patient records, it has been shown that the use of chemotherapy at the end of life has increased over time in the USA and European countries. Given a paucity of Swiss data, the objective of this study was to describe delivery of health care during the last month before death of cancer patients in terms of use of medical resources.
Material and Methods: In a retrospective cohort study claims data from a large health insurance company were linked with data from four cantonal cancer registries to identify patients with breast, colon, hematologic, lung, prostate and other cancers deceased in 2006 to 2008. Primary endpoints were hospitalization rates (acute hospitals), delivery of anti-cancer drugs (ACD) and/or of radiotherapy (RT). Multivariate logistic regression was used to assess associations between these endpoints and explanatory variables representing patient and geographic characteristics as well as supplementary hospital insurance (SHI) type.
Results: Of 3809 eligible cancer patients (Basel n = 378, Tessin n = 926, Valais n = 363, Zürich n = 2142) 2608 (68.5%) were hospitalized in their last month of life, 553 (14.5%) received ACD and 293 received RT (7.7%). Hospitalization and treatment frequencies strongly decreased with age. Patients with breast cancer and hematologic cancers had a significantly higher probability of receiving ACD (ORs 1.87, 95% CI 1.08–3.22 and 1.78, 95% CI 1.06–2.99, respectively, compared to lung cancer patients). ACD use was higher in patients with a semi private or private SHI (OR 1.83, 95% CI 1.40–2.38; reference: no SHI) or living in canton Tessin (OR 1.56, 95% CI 1.24–1.96; reference: canton Zürich). Hospitalization rate and receiving RT were also significantly associated with several patient and geographic characteristics and SHI type.
Conclusions: Hospitalization rate and cancer targeted therapies during the last month before death showed substantial variation unexplained by chance. Significant geographic and insurance status variations should be an issue for discussion within Swiss Oncology Centers and Oncologists. However, the interpretation of the data has to be cautious taking into account that there is no benchmark representing optimal treatment intensity.
No conflict of interest.

1494 POSTER

Improving cancer care in The Netherlands: Insight in hospital variation in quality of care leads to national actions

F. Kloosterboer[1], M.L. Jansen-Landheer[2], M.W.J.M. Wouters[3], C.J.H. Van de Velde[4]. *[1]Dutch Cancer Society, Amsterdam, Netherlands; [2]Comprehensive Cancer Centre The Netherlands, Utrecht, Netherlands; [3]The Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Surgical Oncology, Amsterdam, Netherlands; [4]Leiden University Medical Centre, Dept. of Surgery, Leiden, Netherlands*

Background: Quality of cancer care has become an important topic on a national as well as on an international level. The Signalling Committee Cancer of the Dutch Cancer Society commissioned a study to evaluate the quality of cancer care in The Netherlands and recommended strategies for improvement.
Material and Methods: A taskforce 'Quality of cancer care' comprising medical specialists from alle disciplines involved in the care for cancer patients was formed. An extensive review of the literature on infrastructure, volume and specialization on the one hand and outcome on the other was performed. In addition, a meta-analysis of the volume-outcome relationship for pancreatic, bladder, lung, colorectal and breast cancer resections was performed. Furthermore, variation in quality of cancer care between regions, groups of hospitals and individual hospitals in our country was investigated on data from the Netherlands Cancer Registry. For oesophageal and stomach cancer patterns of care and outcomes were compared at an international level with the United Kingdom, Sweden and Denmark. Also an overview of organisations and initiatives contributing to quality improvement in The Netherlands was made. The findings of the taskforce were published in a national report in 2010.
Results: In The Netherlands quality of care varies by hospital and region. These differences are not limited to surgical procedures and postoperative mortality, but are also demonstrated in other parts of the care process. Differences are only partly explained by differences in infrastructure, procedural volume and specialization between hospitals.
Importantly, the publication of the report and recommendations in 2010 has contributed significantly to quality improvement measures such as the development of national multidisciplinary quality standards for a wide range of cancer treatments, including minimal standards for hospital volume. Furthermore, outcome registries have been set up for a number of cancer treatments including surgery for colon, breast, lung and upper-GI cancers. The insight provided by these outcome registries has resulted in significant outcome improvements. Similarly, the minimal standards for hospital volume urged hospitals to either stop certain treatments or specialize in order to meet the volume requirements. The resulting concentration of care improved overall treatment outcome.
Conclusions: Giving insight into the actual quality of cancer care in the Netherlands has resulted in considerable awareness of the importance of quality improvement, underlined the need for action and endorsed the different stakeholders to team up and work on improving quality of cancer care in The Netherlands.
No conflict of interest.

1495 POSTER

Population-based evaluation of economic impact of trastuzumab prescription patterns in Piedmont, Italy

M. Donadio[1], S. Bustreo[1], F. Cattel[2], D. Barilà[2], A. Bianco[2], O. Garrone[3], C. Saggia[4], A. Beano[5], L. Cattel[6], S. Rosso[7]. *[1]Hospital Città della Scienza e della Salute, Breast Unit, Turin, Italy; [2]Hospital Città della Scienza e della Salute, Hospital Pharmacy Unit, Turin, Italy; [3]Hospital Santa Croce, Oncology Unit, Cuneo, Italy; [4]Hospital Maggiore della Carità, Oncology Unit, Novara, Italy; [5]Hospital Valdese, Oncology Unit, Turin, Italy; [6]University of Turin, Post Graduate School of Hospital Pharmacy, Turin, Italy; [7]CPO, Piedmont Cancer Registry, Turin, Italy*

Background: Health economic assessment based on cost-effectiveness analyses were only marginally used by decision makers. The main limitation of studies was their lack of budgetary impact in a real population setting. The main objective of the present study is to provide population based estimates of the treatment costs of HER2+ breast cancer patients in Piedmont that will help local decision makers for resource planning and health care management.
Methods: We estimated the number patients at early stage eligible for Trastuzumab treatment from the Piedmont Cancer Registry incidence data, while number of patients with metastatic breast cancer were estimated from prevalence data, using, as a proxy,those patients who were prone to fail in a mixture cure model. Treatment patterns (i.e. adjuvant, neoadjuvant or metastatic therapy, standard or shorter experimental protocol and average doses), disease stage and clinical characteristics were measured in five of the 24 breast reference centres (GIC) of Piedmont on a sample of 345 patients admitted in 2010 and 2011. From expenditure administrative data of the current and previous two years in Piedmont we measured costs by drug dose, associated cost and cost for other treatments. Model parameters and their distributions were then applied in a Bayesian empirical model for probabilistic sensitivity analysis (PSA) that allowed investigating the impact of different strategies and policies on total expenditures.
Results: Each year, in Piedmont about 685 women with a HER2+ breast cancer undergo chemo-treatment with Trastuzumab, mainly adjuvant or neoadjuvant (74%). Early stages represented about 28% of patients, while advanced stages and metastasis were 31%. 'Shorter' experimental protocol was administered in 16% cases, with an average 2223 mg of total dose: differences in the protocol adoption was found among the breast units. About 8% of patients suspended treatment because of toxicity. In Piedmont, total expenditure for Trastuzumab was about € 11.5 million in 2010.
Conclusions: Costs for HER2+ breast cancer was mostly influenced by the different adoption of treatment protocols. PSA showed that the duration of treatment, especially off-label prolongation of treatment in metastatic patients in the principal component of the increase in the total expenditure for Trastuzumab in a real setting using population-based data.
No conflict of interest.

1496 POSTER

A cost-minimization analysis of NCIC Clinical Trials Group LY.12: A phase III study of gemcitabine, dexamethasone, and cisplatin (GDP) compared to dexamethasone, cytarabine, and cisplatin (DHAP) for patients with relapsed or refractory aggressive histology non-Hodgkin's lymphoma

M.C. Cheung[1], N. Mittmann[2], L. Shepherd[3], N. Risebrough[2], K.R. Imrie[1], A.E. Hay[3], M. Djurfeldt[3], R.M. Meyer[3], B.E. Chen[3], M. Crump[3]. *[1]Sunnybrook Odette Cancer Centre, Hematology, Toronto, Canada; [2]NCIC Clinical Trials Group, Committee on Economic Analysis, Kingston, Canada; [3]NCIC Clinical Trials Group, Hematology, Kingston, Canada*

Background: The NCIC CTG LY.12 study established that for patients with relapsed or refractory aggressive histology lymphoma prior to autologous stem cell transplantation (ASCT), the response rate with GDP (46%) was non-inferior to DHAP (45%). No important differences between these arms were detected for transplantation rate (OR=1.00), event-free (HR = 0.99) or overall (HR = 1.03) survival and GDP was associated with less toxicity (Crump et al. Blood 2012). We completed an economic evaluation from the Canadian societal perspective based directly on LY.12 trial data.
Material and Methods: The primary outcome of the study was a cost-minimization analysis comparing costs associated with GDP versus DHAP. Resource utilization data related to direct medical care, namely chemotherapy (including rituximab given for CD20+ disease), investigations, medications, hospitalizations, outpatient visits, home care visits, and emergency department care were derived from the Canadian subset of enrolled patients that proceeded to ASCT (n = 267). Direct medical costs and indirect costs (from a lost productivity questionnaire) were applied to the resource utilization data. The time horizon for the cost analysis included the time from randomization until the day before stem cell mobilization (or the last dose of salvage chemotherapy). Costs were descriptively presented in 2012 Canadian dollars ($1 CAD = 0.75 Euro) and were disaggregated to highlight the major cost drivers of care.
Results: Utilization data were collected from 267 Canadian patients (43% of the entire study population), 139 assigned to GDP and 128 assigned to DHAP. GDP therapy was associated with fewer total hospitalization days (680 vs. 1,658 days), hospitalization days for administration of chemotherapy (377 vs. 1,361 days), and hospitalization days for toxicity (120 vs. 267 days), compared to DHAP. The mean costs associated with GDP and DHAP-based therapy were $20,420 and $32,256, respectively, resulting in a cost savings associated with GDP of −$11,836 per patient (95% CI −$14,857 to −$8,890; p-value <0.0001). Mean chemotherapy and outpatient drug administration costs were similar for patients receiving GDP compared to DHAP ($12,237 vs. $11,161). However, mean hospitalization costs attributed to the GDP arm ($6,175) were significantly lower than those costs associated with the DHAP arm ($17,481; p < 0.0001). Patients who received GDP also incurred lower costs for transfusions ($285 versus $1,065; p < 0.0001) and concomitant medications ($1,622 versus $2,446; p < 0.0001) compared to DHAP patients. In the subset of patients (n = 211) with lost productivity and caregiver costs collected, no significant differences were detected between arms.
Conclusions: The LY.12 trial demonstrated that GDP was as efficacious as DHAP but provides these results at a much lower cost, predominantly due to lower hospitalization rates for inpatient chemotherapy administration and toxicity.
Conflict of interest: *Advisory board: Dr. Crump − membership on an advisory board for Roche Canada. Other substantive relationships: Dr. Meyer has received consultancy fees from Lilly Canada. The NCIC Clinical Trials Group has received research funding from Roche Canada and Lilly. Dr. Mittmann has received funding for provision of rituximab in patient care (Roche Canada).*

1497 POSTER

Budget impact analysis of a return-to-work intervention for cancer patients

J.C. Mewes[1], I.F. Groeneveld[2], A.G. De Boer[2], M.H. Frings-Dresen[2], M.J. IJzerman[1], L.M. Steuten[1], W.H. Van Harten[1]. *[1]University of Twente, Health Technology and Services Research, Enschede, Netherlands; [2]Academic Medical Center University of Amsterdam, Coronel Institute of Occupational Health, Amsterdam, Netherlands*

Background: Published literature shows that return-to-work interventions effectively support cancer survivors to resume work and potentially increase quality of life. However, return-to-work is currently not, or only partly (i.e. exercise test), reimbursed by health insurers. To ensure optimal support for cancer patients in resuming work, it is essential that hospitals can offer return-to-work in a financially viable way. The study 1) analyses the budget impact of a return-to-work intervention consisting of counselling by occupational physicians and a physical exercise programme; 2) explores how financing of a return-to-work intervention can be arranged.
Methods: A budget impact analysis was performed, comparing costs of return-to-work support for all patients able and willing to resume work versus no standardised support. All costs and financial benefits relevant from a societal perspective were considered, including intervention costs (based on the intervention protocol), productivity losses, social security, unemployment benefits, and patients' costs (based on literature data), and presented for a hypothetical hospital serving a population of 200,000 patients. We identified which stakeholders, including hospitals, employers, health insurances, social security, and patients accrue what costs; and which enjoy the financial benefits under different financing arrangements.
Results: Based on the return-to-work protocol, costs for the intervention are approx. €2,000 per patient. For a hypothetical hospital with 570 cancer patients a year of which 100 patients are eligible and willing to take part, this will result in yearly costs of €193,800. Physical exercise costs as part of the intervention, approx. €1,300 per patient, are in most cases covered by health insurance, leaving €67,800 to be financed by the hospital. Even small improvements in return-to-work and quality of life led to substantial reductions in productivity loss, need for social benefits, and future health care costs. These savings outweigh the costs of the intervention, rendering return-to-work cost-saving from a societal perspective. Several feasible options for distributing costs and benefits among stakeholders are identified.
Conclusion: From a societal perspective, return-to-work is expected to be cost-saving. Hospitals bear approx. €67,800 intervention costs annually (hypothetical hospital, assuming a population of 200,000 patients), while most financial benefits fall upon other stakeholders. Re-distributing costs and financial benefits among stakeholders would result in feasible financing of the intervention.
No conflict of interest.

1498 POSTER

Creating a platform for translational research in The Netherlands

M. Hoozemans[1], W. Timmerman[1], G. Boerrigter[1], J.H.F. Falkenburg[2]. *[1]Dutch Cancer Society, Research, Amsterdam, Netherlands; [2]LUMC, Hematology, Leiden, Netherlands*

Background: In spite of an increased interest in translational research in The Netherlands, multiple roadblocks prevent smooth progression 'from bench to bedside'. The Dutch Cancer Society (DCS) has performed the project 'Translational Research' on behalf of the Dutch National Cancer Control Programme (2005–2010), a collaborative venture of the DCS, the Comprehensive Cancer Centres, the Ministry of Health, Welfare and Sports, the Dutch Federation of Cancer Patients' Organizations and the Dutch Association of Health and Social-Care insurance Companies. The project aims to facilitate translational research by identifying and overcoming hurdles in the translational process.
Objectives: To create a platform for translational research in The Netherlands.
Methods:
– Analysis of DCS research project files to register scientific discoveries with potential clinical application that were terminated during the development process.
– Analysis of roadblocks in 4 case-studies and exploration of solutions in practice.
– Analysis of the regulatory climate concerning cellular therapeutics and the execution of clinical studies.
Results: Various roadblocks in translational research were identified, including limited knowledge of the translation process, financial limitations, complex legislation and regulation, good manufacturing practice, patents and lack of small-scale production facilities. Especially for scientific findings that are not rapidly taken up by the pharmaceutical industry, suboptimal conditions for one or more of these factors stand in the way of obtaining proof-of-principle and further product development. The case-studies showed that roadblocks could be removed by the DCS with relatively small but highly specific tailor-made interventions and investments.
Conclusions: The project has shown that collaboration between research groups, the availability of shared knowledge, additional specifically targeted financial support and tailor-made guidance of research projects are important factors in promoting the translational process. At present, the infrastructure in The Netherlands is insufficiently equipped to offer these solutions on a structural basis. Based on the results of the this project, the DCS is currently innovating her activities regarding translational research.
No conflict of interest.

1499 POSTER

Multidisciplinary teams in cancer care: a systematic review of the evidence

J. Prades[1], E. Remue[2], E. Van Hoof[3], J. Borràs[1]. *[1]Catalan Cancer Plan, Department of Health Catalonia Spain, L'Hospitalet Llobregat; [2]Belgian Cancer Centre, Scientific Institute of Public Health, Brussels, Belgium; [3]Vrije Universiteit Brusel, Faculty of Educational and Psychology Sciences, Brussels, Belgium*

Background: Multidisciplinary teams (MDTs) are considered the best approach to organising care in a way that brings together all the medical specialists involved in cancer diagnosis and treatment, which has led to many cancer plans to incorporate MDTs. The aim of this study was assessing the impact of MDTs on physician practice patterns and patient outcomes in cancer care.
Material and Methods: We conducted a systematic review of the literature. Fifty-one papers were selected from the literature published from November 2005 to June 2012.
Results: MDTs have been shown to improve clinical and process outcomes in cancer-patient management, even though evidence of a causal relationship between this type of intervention and outcomes is still limited. A wide variation in the types of tumours studied has been reported, along with the fact that the scope of the MDTs' work extends to the entire process of care.
Conclusions: Different formats of MDT organisation were found, such as meetings, clinics and online conferences. These organisational patterns are nonetheless driven by the need to align the clinical dimension (effective access to multimodal treatments and palliative care) with the patient-management dimension (MDTs' working roles, and consistent communication between patient and team).
No conflict of interest.

1500 POSTER

Multidisciplinary oncology guidelines: Report of the ECCO guideline forum working group

D. Schrijvers[1], F. Van Hemelryck[1], ECCO Guideline Forum Working Group[1]. *[1]ECCO − the European CanCer Organisation, External Relations, Brussels, Belgium*

Background: Many European organizations are producing guidelines in the field of oncology. To improve European multidisciplinary oncology guideline development and stimulate cooperation among development groups, ECCO – the European CanCer Organisation organized a "Multidisciplinary Clinical Guidelines Forum Working Group" meeting to define quality criteria for the development group and quality measures to be recognized by ECCO as high quality multidisciplinary guidelines.
Methodology: Before the meeting, a questionnaire was sent to the different organizations belonging to ECCO and other organizations involved in cancer care. The questionnaire asked questions in relation to guideline development, specific procedures for guideline development; if multidisciplinary guidelines were produced; if they used specific templates and formats to publish guidelines; and how the quality of the guidelines was evaluated.
A meeting was organized in November 2012 with the aim to hear and learn about each others guideline development as well as to define quality criteria for ECCO-endorsed multidisciplinary guidelines and to define the role of ECCO in the guideline development and implementation process.
Results: *Quality criteria*: ECCO will endorse multidisciplinary guidelines if they fulfill the following quality criteria:
- Guidelines must be multidisciplinary and must involve representatives of the relevant disciplines.
- Validated methodologies must be used and must be explicit and transparent
- A conflict of interest policy must be in place and transparent
- Representatives of patient organizations must be involved.

Role of ECCO: It was concluded that ECCO will not develop clinical practice guidelines but will act as follows:
- ECCO will serve as a switchboard for its members and other European societies to inform each other of the development of new multidisciplinary cancer clinical guidelines so that all interested societies can be involved. This functionality is offered to ECCO members and other European societies as a way to facilitate collaboration between relevant disciplines and develop multidisciplinary guidelines. This will help avoiding redundancies.
- Upon submission by the development group, ECCO will review and endorse multidisciplinary guidelines that fulfill the quality criteria.
- ECCO will disseminate the European multidisciplinary guidelines that have been endorsed. ECCO will create a dedicated webpage for the dissemination and promotion of endorsed guidelines (with links).
- ECCO will represent the voice of oncology on European oncology guidelines at the EU policy level.

Conclusion: Oncology is a multidisciplinary discipline and this should be reflected in multidisciplinary guideline development. In future, ECCO will serve as a switch board for multidisciplinary oncology guidelines and will promote European oncology guidelines fulfilling the ECCO quality criteria.
No conflict of interest.

1501 POSTER

Homecare utilization and costs in stage IV lung cancer: a Canadian public payer experience

N. Mittmann[1], S.J. Seung[1], N. Liu[2], J. Porter[2], R. Saskin[2], N.B. Leighl[3], J.S. Hoch[4], M. Trudeau[5], W.K. Evans[6], C.C. Earle[5]. *[1]Sunnybrook Health Sciences Centre, HOPE Research Centre, Toronto, Canada; [2]Sunnybrook Health Sciences Centre, Institute for Clinical Evaluative Sciences, Toronto, Canada; [3]Princess Margaret Hospital, Ontario Cancer Institute, Toronto, Canada; [4]St. Michael's Hospital, Li Ka Shing Knowledge Institute, Toronto, Canada; [5]Sunnybrook Health Sciences Centre, Odette Cancer Centre, Toronto, Canada; [6]Hamilton Health Sciences Centre, Juravinski Cancer Centre, Hamilton, Canada*

Background: Lung cancer is a leading cause of morbidity and mortality. Individuals may require homecare at some point during the management of their disease. There is limited information on the type, quantity and cost of homecare services in lung cancer. The objective was to determine the utilization and costs of homecare services for a population of individuals with Stage IV lung cancer.
Methods: New cases of Stage IV lung cancer were extracted from a provincial cancer registry (Ontario Cancer Registry, 2005–2009) and linked to the homecare services administrative datasets from the health system payer perspective. The type and proportions of homecare services used were determined by phase of disease (initial⩾6 months after diagnosis;

terminal⩽6 months prior to death; continuation=terminal minus initial). Homecare utilization and costs for cases were determined ($CAN 2012, $1 CAD = 0.75 Euro).
Results: There were 18,187 cases of lung cancer in the cohort. 11,929 were staged. 6,115 (51.3%) were Stage IV lung cancer cases. 75.5% of the Stage IV cases used homecare. Of those using homecare services, there were 66.3 homecare visits per person per annum. The mean cost per person per annum was $6,076. There were 243,236 homecare visits in the cohort, 57.3% of which were nursing visits and 32.8% were homemaking and personal support care visits. There were 5,255 Stage IV cases in the terminal care phase (⩽6 months prior to death), of which 75.8% used homecare services. The mean (95% CI; median) number of homecare visits per 30-day period was 7.7 (7.4−8.0; 4). The homecare cost per 30 days was $798 ($766-$830; $472).
Conclusion: End of life lung cancer patients utilized a number of homecare services resulting in high 30 day and annual costs. Attributable costs and costs for other stages of the disease will be determined.
No conflict of interest.

1502 POSTER

Survival modeling in UK oncology technology appraisals since the publication of good practice guidelines

A. Benedict[1], N. Muszbek[2], K. Perampaladas[2]. *[1]Evidera, London, United Kingdom; [2]Evidera, Health Care Analytics, London, United Kingdom*

Background: To assess the methods used, their implications and the effect of the 2011 guidance published by the National Institute of Health and Care Excellence (NICE) Decision Support Unit (DSU) in the extrapolation of overall survival in oncology in the UK.
Materials and Methods: Though overall survival is one of the most important outcomes used in the assessment of clinical effectiveness and cost-effectiveness in oncology for reimbursement decisions, its evaluation is rarely straightforward with the different methods leading to different conclusions. Although according to NICE methodological guidelines, a lifetime horizon if survival benefit is expected, in oncology, overall survival data from clinical trials are often incomplete (i.e. at the time of trial not all patients experience an event). Thus long term projection of data is required. Although this can have a significant impact, the evidence used prior 2011 was often not fully explored, leading to a DSU guidance.
To assess the currently used methods and the effect of the guidance, a review of oncology technology appraisals published after June 2011 was carried out. A data extraction table was designed to capture the main aspects of the disease and patient population; the technologies assessed and methods used for the extrapolation. The latter included the use of parametric modeling, distributions tested, the basis for final selection including tests for goodness of fit, including graphical and statistical tests; assessment of clinical face validity of findings and external validation. Data was assessed qualitatively and compared to a review conducted prior the guidance.
Results: 21 oncology assessments were identified, including 19 single technology appraisals and two multiple technology assessments (MTAs) covering 6 treatments. While the majority of the assessment incorporated some form of parametric modeling and extrapolation of survival data, the implementation of the full set of recommended steps for the extrapolation were rare. Although the proportion of studies testing all commonly used survival models for fit to the data increased, the majority of them depended mainly of the statistical goodness of fit criteria and testing for clinical face validity and external validation remained rare.
Conclusions: Since the publication of methods guidelines on survival extrapolation, the quality of extrapolations have improved within the oncology technology appraisals in the UK, contributing to more transparent decisions-making. However treating the extrapolation of OS as a statistical exercise without appropriate clinical and external validation requires further improvement.
No conflict of interest.

1503 POSTER

Survival and lifetime costs associated with first-line bevacizumab in older patients with metastatic colorectal cancer

V. Shankaran[1], D. Mummy[1], L. Koepl[1], D. Mirick[1], E. Yu[2], R. Morlock[2], S. Ramsey[1]. *[1]Fred Hutchinson Cancer Research Center, Division of Public Health Sciences, Seattle, USA; [2]Genentech Inc., Health Outcomes, South San Francisco, USA*

Background: The relative costs and benefits of newer agents such as bevacizumab (Bev) in older patients with metastatic colorectal cancer (mCRC) are not well understood. The objective of this study was to investigate clinical effectiveness and incremental lifetime costs associated with first-line bevacizumab in older mCRC treated in community settings, from the United States government healthcare payer (Medicare) perspective.
Material and Methods: Patients diagnosed with mCRC in 2004–2007 were identified from SEER-Medicare, a database which links Medicare claims with a population-based cancer registry representing ~25% of the United States population (SEER). Patients were stratified by first-line treatment strategy (no chemotherapy (CTx), CTx alone, CTx + Bev). Median and mean survival times were determined for each cohort by Kaplan–Meier method. A Cox proportional hazards model was used to determine the relative benefit of Bev, controlling for important demographic and treatment characteristics. Mean lifetime costs were calculated for each cohort using Medicare claims for all services rendered between diagnosis and end of follow up, adjusting for death and censoring.
Results: 4,414 patients (mean age 77.3) were identified, of whom 15% received first-line Bev. Mean duration of first-line Bev was 6.9 months. Receipt of CTx + Bev was associated with an improved survival compared with CTx alone in the Cox model (HR 0.80, 95% 0.71–0.89). Median and mean survival were greatest in patients treated with CTx + Bev relative to CTx alone or no CTx (19.4 (28.0) vs. 15.1 (22.9) vs. 5.7 (14.1) months, $p < 0.001$). Mean lifetime costs were also greatest in the CTx + Bev group compared with CTx or no CTx (mean per patient cost $143,284, $111,280, and $55,504 respectively). Compared with CTx alone, CTx + Bev was associated with a 5.1 month increase in mean survival and $32,004 increase in mean lifetime treatment costs; the relative cost of Bev treatment was $75,303 per life year gained.
Conclusions: The relative benefit of Bev in older Medicare enrollees treated in real world clinical settings in the United States is comparable to the benefit observed in randomized clinical trials but is associated with an incremental cost of $75,303 per life year gained.
Conflict of interest: *Ownership: Elaine Yu has stock ownership in Roche. Corporate-sponsored research: Veena Shankaran, David Mummy, Lisel Koepl, Dana Mirick and Scott Ramsey all received research funding from Genentech, Inc. Other substantive relationships: Robert Morlock is a health economist employed by Genentech, Inc. and Elaine Yu is associated director of the health outcomes program at Genentech, Inc.*

1504 POSTER

Measuring process quality in oncology practices in Germany

W. Baumann[1], H. Hermes[1], A. Zimmermann[1], H. Lebahn[2], B. Otremba[3], H.T. Steinmetz[4], C. Van Roye[5], U.R. Kleeberg[6]. *[1]WINHO, Köln, Germany; [2]Oncology Care Center Friedrichshain, Berlin, Germany; [3]Oncology Practice, Oldenburg, Germany; [4]Group Practice for Oncology and Haematology, Köln, Germany; [5]Practice Clinic for Haematology and Oncology, Koblenz, Germany; [6]Haematology Oncology Practice Altona, Hamburg, Germany*

Background: In 2013, WINHO started its first collection of data for process quality indicators in oncology practices. The WINHO indicators − altogether 46 quality measures − were developed as a tool for self-monitoring, for benchmarking and to enhance quality reporting in the context of outpatient care in medical oncology. In Germany, this is the first analysis of process quality indicators in office-based oncology. While the indicators were developed with regards to treatment processes within oncology practices, they could also be applied in a clinical setting. This presentation provides results from the first two rounds of data collection.
Material and Methods: In the first round of data collection, six quality indicators were examined that address basic documentation (i.e. anamnesis), tumour boards and planning of chemo therapy for breast cancer patients. Information was collected via an online questionnaire from nearly 1900 patient records in 20 oncology practices. The second round of data collection takes place in the second quarter of 2013 and includes 15 indicators that cover basic documentation, therapy planning and psycho-social wellbeing. Further office-based haematologists and oncologists registered for participation in this round.
Results: The results indicate thus far high levels of compliance with regards to indicators of basic documentation. For example, tumour specific anamnesis was documented in 99% of the analysed patient records within the first two doctor's visits, pre-existing illnesses and comorbidities in 85% of the cases. Data for quality indicators for basic documentation could often be collected faster than information about therapy planning. In addition, the results for the indicators for therapy planning are more diverse among the office-based cancer specialists.
Conclusions: This pilot study proves the feasibility of applying process quality indicators in oncology practices and examines differences between office-based haematologists and oncologists in Germany. First results indicate some variance among oncology practices and point to areas where outpatient cancer care could be improved. However, data extraction from patient records is time-consuming as much information is saved in continuous text. In order to use the rich information documented by office-based cancer specialists for the purpose of quality assurance, IT systems in

oncology practices should be optimised to allow more data to be retrieved electronically.
No conflict of interest.

1505 POSTER

Motivations and perceived added value of European cancer centers from participating in an accreditation programme

A. Rajan[1], M. Saghatchian[2], F. Thonon[2], F. Boomsma[3], W. Van Harten[1]. *[1]Het Nederlands Kanker Instituut − Antoni van Leeuwenhoek Ziekenhuis (NKI-AVL), Psychosocial Research and Epidemiology, Amsterdam, Netherlands; [2]Institut Gustave Roussy, Villejuif, France; [3]Integraal Kankercentrum Nederland, Groningen, Netherlands*

Background: The study aimed to understand the motivations, benefits & added value of the OECI (Organization of European Cancer Institutes) accreditation & designation programme as perceived by stakeholders from cancer centres. This can help understand the immediate effects of the accreditation programme & how it might be improved.
Material and Methods: Semi-structured individual interviews of 30 stakeholders: basic research, management, clinicians & nursing from 9 European cancer centres, categorized according to the participating stage: self-assessment, final reporting & accredited for at least one year. Thematic analysis & adapted grounded theory were used for data analysis.
Results: Similarities in the motivation & perceived benefits of cancer centers exist irrespective of accreditation stage e.g. benchmarking against other European Centres judged by a common European standard, becoming a renowned European/International Centre, attracting new opportunities for collaboration/funding; continuous quality improvement in research, education & care. In the 'self-assessment' phase, implementing quality standards & data-integration were important. In the final reporting & accredited stages, achieved benefits were: stimulating critical thinking based on issues identified by peer reviewers; clearer organizational structure & clarification of staff roles; funded collaborative opportunities with research teams both within and outside the centre. Added value from accreditation is achieved in expected (e.g. better communication between researchers & clinicians within/outside the Centre) & unexpected ways (e.g. staff from different disciplines participating in quality improvement programmes despite initial doubts; interest of the Centre to participate in other accreditation programs). For some basic researchers the benefits of accreditation were hard to define. They are seen as mainly issues for managers & clinicians as comprehensiveness is seen as focussing more on the coherence of translational research rather than its individual content.
Conclusion: Participation in accreditation seems to deliver real benefits e.g. better funding opportunities, data integration, standard implementation, multi-disciplinary teams reconstitution, staff engagement etc. But, it is hard to confirm if these are solely attributable to the accreditation programme. Further longitudinal research on the effects of accreditation programmes especially on patient benefits is needed.
No conflict of interest.

Città della Salute e della Scienza, Coes, Torino, Italy; [3]AUSL Rimini-Ospedale Cervesi, Oncologia, Cattolica, Italy; [4]Azienda USL12-Viareggio Ospedale Versilia, Oncologia, Viareggio, Italy; [5]A.O.U. Policlinico S. Orsola Malpighi, Oncologia, Bologna, Italy; [6]A.O.U. Ospedali Riuniti, Oncologia, Ancona, Italy; [7]A.O. Villa Scassi, Oncologia, Genova, Italy; [8]Springer Healthcare Italia, Farmacoeconomia, Milano, Italy; [9]Institut de Cancerologie de l'Ouest-site René Gauducheau, Oncologie, Nantes, France*

Background: Vinorelbine and CDDP are a standard treatment in NSCLC; NVBo is registered in 45 countries. PEM plus CDDP is recommended in front-line chemotherapy of NS-NSCLC. An economic evaluation of NVBo/CDDP versus PEM/CDDP was implemented in NS-NSCLC pts adopting specific costs and clinical settings reflecting the Italian practice.
Materials and Methods: A cost minimisation analysis was conducted from the perspective of the Italian NHS, based on a randomised phase II study in NS-NSCLC (NAVoTRIAL01), randomizing 100 NVBo/CDDP pts (arm A) and 51 PEM/CDDP pts (arm B). Overall, Arm A/Arm B reported respectively: Disease Control Rate including combination (4 cycles) and maintenance periods (%) of 75.0/76.5, and median Progression-Free or Overall Survival of 4.2/4.3 or 10.2/10.8 months.
Costs considered in the analysis were for Anti-Cancer drugs (AC), administration settings (AS, i.e. out-patient/in-patient/at home), and serious adverse events (SAE, defined as involving hospitalization and suspected to be due to AC).
Unit costs used for AC were official ex-factory prices, with further percent deductions enforced by law. The distribution of AS was re-modelled according to the respective frequencies found for the subset of Italian pts participating in NAVoTRIAL01; for out/in-pt settings, DRG and other tariffs (day-hospital or one day admission) were used (no cost was charged when administration was at home). Hospitalization costs were assessed for SAE on the basis of appropriate DRG tariffs.
Results: See the table.

	Average cost per patient (€)		
	Arm A	Arm B	A − B
AC	1,763	13,615	−11,852
AS	1,703	344	1,359
SAE	611	569	42
Total	4,077	14,528	−10,451

In detail, the cost for AC in arm A was € 572 in the four-cycle combination period and € 1,191 in the maintenance period; the analogous cost in arm B was € 6,738 and € 6,877 respectively.
Conclusions: Given the reported efficacy outcomes with both regimens, NVBo/CDDP followed by maintenance with NVBo provides substantial savings (€ 10,451 per patient on average), appearing a cost-effective treatment option in advanced NS-NSCLC. Such results should be confirmed by a phase III trial.
No conflict of interest.

Developing patient reported outcome measures (PROM) for implementation in the Swedish National Breast Cancer Quality Register

Y. Wengström[1], K. Sandelin[2], C. Lagerros[3], L.M. Petersson[4]. *[1]Karolinska Institutet, Huddinge, Sweden; [2]Karolinska Institutet, Department of Molecular Medicine and Surgery, Stockholm, Sweden; [3]Karolinska Instiutet, Regional Cancer Center Stockholm Gotland, Stockholm, Sweden; [4]Karolinska Institutet, Department of Clinical Neuroscience, Stockholm, Sweden*

Background: The local authorities for health and welfare support the introduction of Patient Reported Outcome Measures (PROM) in the quality registers in Sweden. Valid and reliable instruments measuring PROM do not exist that could be used throughout the whole breast cancer process. We sought to develop and implement PROM for breast cancer at different stages in the disease course in different Swedish geographic regions for later use in the Swedish National Quality Register for breast cancer.
The aim was to develop appropriate PROM to assess symptoms and problems among patients with breast cancer about one year after diagnosis.
Materials and Methods: A scoping review and focus group discussions were conducted with women invited by the breast cancer association Amazona (Stockholm). The symptoms that emerged from the scoping review and focus group discussions formed the basis for the development of a web based questionnaire consisting of validated instruments (EORTC QLQ-C30, BR 23, MSAS) for measuring PROM. The women who participated in the focus group discussions were invited to respond to a pilot version of the web based questionnaire. The results were used to revise the web based questionnaire. An invitation was sent to a national random sample from the Swedish National Breast Cancer Quality Register diagnosed one year earlier to respond to the revised version of the web based questionnaire.
Results: The results will present the work process of the development of the PROM as well as plans for further work on the implementation of the PROM in the Swedish National Quality Register for breast cancer. Preliminary data shows that about 70% responded to the revised version of the web based questionnaire. However, some women requested a paper version of the questionnaire mostly because they did not have access to a computer.
Conclusion: In the development of PROM in quality registers it is important to include patients experiences in order to develop relevant outcome measures to influence the quality of the health care delivery.

The Belgian cancer plan: A balanced governmental support of comprehensive cancer care

M. Van den Bulcke[1], E. De Wandeler[1], J. Goolaerts[1], R. Kiasuwa[1], L. Lenaerts[1], B. Mores[1], E. Remue[1], S. Van den Bogaert[2], H. Van Oyen[2]. *[1]Scientific Institute of Public Health, Brussels, Belgium; [2]Federal Public Service Health Food Chain Safety and Environment, Brussels, Belgium*

The Belgian cancer plan was launched on 10/03/2008 by the Minister of Social Affairs and Public Health to improve the fight against cancer in Belgium. It is a long-term plan covering all aspects of the fight against the disease and integrates the support of both physicians and patients and their families. The Belgian government policy was already focused on cancer issues by implementing standards in 2003 that specify the legal requirements of basic cancer care and an oncological care programme. In 2007, the White Paper 'Action against cancer in Belgium: Facing up to the challenges of tomorrow' was published. This document was prepared by a work group consisting of Belgian specialists in oncology and haematology and listed recommendations for improving cancer treatment.
Belgium being a federal country wherein health care is the shared responsibility of the Federal State and the communities/regions opted for an intense consultation with all stakeholders prior to launching the cancer plan. For this, the Minister of Social Affairs and Public Health organized round-table discussions with a variety of stakeholders. A range of priorities was identified as a result of these round-table discussions with experts.
The Belgian cancer plan contains to date 32 actions in 3 domains: 1º) prevention and screening, 2º) care and treatment, and 3º) innovation and research. A specific budget was allocated to each action of the cancer plan and responsibilities for implementation were clearly defined. A regular evaluation of the progress and results of the plan is made by the Belgian Cancer Centre. A first evaluation report was prepared in 2012. Here, we report the main steps in the development of the Belgian cancer plan and describe the first results of its implementation.

1509 POSTER

Quality of the end of life − utility values in advanced solid tumors in technology appraisals in the UK

N. Muszbek[1], A. Benedict[2], L. Hortobagyi[2]. *[1]Evidera, London, United Kingdom; [2]Evidera, Health Care Analytics, London, United Kingdom*

Background: To assess the utility values used in advanced solid tumours in technology appraisals conducted by the National Institute of Health and Care Excellence (NICE) in the UK and to compare them to those of the general population.
Materials and Methods: Through the use of quality-adjusted life-years (QALYs) the importance of quality of life, established using generic instruments resulting in utility values, increased and it became the center of various studies and debates in advanced oncology. The debate eventually led to a differential treatment of technologies aiming to extend life in the last two years by NICE, by placing a higher utility value at the end of life. However issues concerning the magnitude of cancer patients' utilities pre- and post-progression still surface in many appraisals: the measured utility values are often considered high. To assess the magnitude of the issue a literature review of advanced oncology technology appraisals published in the last two years was carried out. A data extraction table was designed to capture the main aspects of the disease and patient population; the technologies assessed; the methods used for the elicitation of utilities, and the values and their evaluation by NICE. Data were assessed both qualitatively and quantitatively.
Results: Thirteen oncology assessments were identified in advanced solid tumours, including 11 single technology appraisals and two multiple technology assessments (MTAs). Four assessments did not report final utility data. The mean utility was 0.77 (standard deviation (SD): 0.056, range: 0.66–0.88) and 0.57 (SD: 0.103, range: 0.47–0.76) for pre- and post-progression respectively. Among the pre-progression utilities 46% was equivalent to the general UK population aged 75 or more, 15% to population 65−74, 30% to 55−64, and 8% to 45−54. EQ-5D, as requested by NICE was the main method of elicitation in 5 assessments, and standard gamble based on the general population was still more common (6 assessments).
Conclusions: The assessment of utilities in advanced oncology indications is although crucial in terms of cost-effectiveness, is in many cases not give emphasis in the design of the phase II clinical trials. Methods of elicitation often does not conform to the NICE reference case and the values reported are very close to those of the general population raising concerns in individual cases indicating the need for additional research and guadance.
No conflict of interest.

Obstacles to delivering optimal care for early breast cancer in Croatia

T. Badovinac Crnjevic[1], Y. Chavarri-Guerra[2], M.J. Higgins[3], P.E.R. Liedke[4], H. Symecko[5], D. Finkelstein[6], J.St. Louis[3], D. Vrbanec[1], P.E. Goss[3]. *[1]University Hospital Zagreb, Oncology, Zagreb, Croatia; [2]Instituto Nacional de Ciencias Medicas y Nutricion, Oncologia Medicina, Mexico, Mexico; [3]Massachusetts General Hospital, Cancer Center, Boston, USA; [4]Affiliation Servico de Oncologia do Hospital de Clinicas, Clínica em Oncologia, Porto Alegre, Brazil; [5]Massachusetts General Hospital, Biostatistics, Boston, USA; [6]Massachusetts General Hospital, Cancer Center Biostatistics, Boston, USA*

Introduction: Unlike decreasing trends in breast cancer (BC) mortality in other high income countries, mortality in Croatia (CRO) is not declining. We conducted a web-based survey among Croatian oncologists to better understand current patterns of care and to identify key obstacles to delivering optimal management.
Methods: A web-based survey was sent from the MGH-AVON International Breast Cancer Center in Boston to 121 members of the Croatian Oncology Society. The survey covered questions on demographics, availability of BC resources and patterns of clinical care. Survey data were anonymised and collected using our Red Cap on-line survey tool. To describe the results we calculated frequencies, percentages and/or mean values for each response on our questionnaire.
Results: 28 of 121 participants responded (23.1%). 75% of respondents practice in public hospitals or academic medical centers, representing a cross-section of oncologists providing cancer care in CRO. Results show 68% of newly diagnosed BC patients present with stage I, II disease and 22% and 10% with stage III or IV respectively. Surgically, 66% are treated by lumpectomy, 22% by mastectomy without reconstruction and 12% by mastectomy with breast reconstruction (12 %). In the absence of palpable lymph nodes 25% undergo sentinel lymph node biopsy while 75% do not. All physicians report having tumour ER, PR and Her2/neu results reported within routine pathology reports. More than 60% of high risk, ER+ patients receive anthracycline/non-taxane regimens due to limited availability of taxanes in CRO. Both tamoxifen and AI's are generally available for ER+ pts. The average wait time for radiotherapy for the majority of patients is longer than 6 weeks (34.3% 6−12 weeks, 25% >12 weeks). 42% of respondents report that they deliver sub-optimal therapy to their patients mainly due to restrictions in available chemotherapies and radiation therapy. Detailed results on adjuvant treatment patterns will be presented.
Conclusions: Despite stage at presentation of BC in CRO being comparable to Western Europe, it is worrisome that mortality rates are not declining comparably. Restrictions in prescribing taxane − containing regimens and long waiting lists for radiation therapy were identified as major obstacles for providing optimal care. These issues require further analysis and action to help improve outcomes of patients with BC in CRO.

1511 POSTER

Diagnostic efficacy of the two week wait referral system for suspected head and neck cancer in the United Kingdom

H. Kayhanian[1], R. Lakhani[1], P. Kothari[1]. *[1]Luton and Dunstable Hospital, ENT Department, Luton, United Kingdom*

Background: The two week wait referral system was introduced by the UK Department of Health in 2000 to help general practitioners identify and urgently refer patients with suspected head and neck cancer. The effectiveness of these guidelines, consisting of 8 symptoms and signs warranting urgent referral, has only been assessed in a few small studies.
Material and Methods: We retrospectively analysed the medical records of 50 patients referred to our department via the 2 week wait pathway from January − December 2012 and collected data on investigations, diagnoses and management plans. We further looked at all head and neck cancer diagnoses between October − December 2012 and identified method of referral for each patient. We made comparisons between stage of cancer for patients referred urgently and those referred routinely.
Results: 98% (49 cases) of patients referred urgently were seen by an otolaryngology specialist within the expected 2 week target wait. The average wait to be seen was 9.8 days. The commonest referral reason was for persistent hoarseness (22%) and unresolving neck mass (22%). 26% (13 cases) of urgent referrals did not meet the referral criteria and of these the most common referral reason was persistent epistaxis (10%). 6 cases of head and neck cancer were identified in 2 week wait referrals equating to a 12% yield. An additional 10 cases of head and neck cancer were identified via routine referral for the corresponding time period. There was

no significant difference in stage of cancer between 2 week wait referrals and routine referrals (Mann Whitney, $p < 0.05$).
Conclusion: Significant numbers of patients with head and neck cancer are being diagnosed via routine referral, whilst those diagnosed via the 2 week wait pathway are not being identified at an earlier stage of disease. Further audit and research is needed to improve the referral criteria and develop a more efficient system.
No conflict of interest.

1512 POSTER

Measuring the financial burden on cancer patients: A randomised study

I. Stoodley[1], E. Devlin[1], K. Spencer[2], P. Hall[3]. [1]*University of Leeds, Medical School, Leeds, United Kingdom;* [2]*Saint James University Hospital, Institute of Oncology, Leeds, United Kingdom;* [3]*University of Leeds, Leeds Institute of Health Sciences, Leeds, United Kingdom*

Background: It is increasingly recognised that cancer and its treatment incurs notable expense to patients, however there is little evidence guiding best methods for the collection of data on patient out-of-pocket expenses. This study compared patient-reported expenses recorded using a recall-questionnaire with those recorded using a daily diary.
Material and Methods: After gaining ethical approval, patients with a diagnosis of cancer were recruited during attendance for chemotherapy or radiotherapy at a single UK Cancer Centre. Consenting patients completed a baseline questionnaire assessing quality of life (EuroQoL EQ-5D) and out-of-pocket healthcare-related expenses (covering seven financial domains) incurred during the preceding month. Patients were then randomised to Arm A: a single repeat questionnaire after 28 days, or Arm B: a daily diary of similar format for 28 days. The primary endpoint was the proportion of questionnaire/diary returns after 28 days (Chi squared test).
Results: In total, 93 patients were recruited. After 28 days, 48% of questionnaires (Arm A) were returned compared with 59% of diaries There was no statistically significant difference in return rates ($p = 0.49$). Mean per-patient expenses over the 28 days were £289 and £290 for Arms A and B respectively. Increasing age, male sex and treatment with radiotherapy were associated with higher expenses.
Conclusions: In this study there is no evidence of a difference in data return when using diaries or questionnaires. Given the relative ease for patients completing a single questionnaire compared to a daily diary, this may be the preferred method.
No conflict of interest.

1513 POSTER

How expensive is a gene signature test for patients with cancer of unknown primary origin (CUP)? An audit of the referral pathway for CUP Multidisciplinary Team

H. Mackinnon[1], C. Moller-Olsen[1], S. Holwill[2], K. Balasubramaniam[3], K. Michaels[4], M. Karina[1]. [1]*The Beacon Centre, Oncology, Taunton Somerset, United Kingdom;* [2]*Musgrove Park Hospital, Pathology, Taunton Somerset, United Kingdom;* [3]*Musgrove Park Hospital, Radiology, Taunton Somerset, United Kingdom;* [4]*Musgrove Park Hospital, Palliative Care CNS, Taunton Somerset, United Kingdom*

Background: Specialised multidisciplinary teams (MDT) for the CUP are a new establishment in the UK. They aim to facilitate the process of referral and improve the time interval from symptom to treatment, which is universally long for CUP patients. The CUP MDT at Musgrove Park Hospital (MPH) started in March 2012. We audited the referral process to explore the time needed for CUP patients from the onset of symptoms to first investigation through to the MDT meeting; and the number and type of investigations these patients went through.
Method: All patients referred to the CUP MDT at MPH over one year were included. We retrieved information from the online pathology database, clinic and referral letters and scan requests and results. For each patient we recorded the date of first symptom, number of blood tests and imaging investigations after the onset of symptoms, date and number of biopsies, number of immunohistochemical markers (IHC) tested, number of other tests performed including endoscopies, the MDT discussions and the overall outcome.
Results: A total of 35 patients were included in the audit, 14 males and 21 females. The median age was 70 years (range 47−91 years). The median number of imaging tests was 5 (range 1−20). The time between the first symptom and the first imaging investigation was 24.35 days (range 0–629 days). The average referral process time, from symptom onset to first CUP MDT discussion, was 58.80 days (range 4–770 days). Of the 35 patients, 21/35 had a referral process of greater than 28 days and 6/35 greater than 100 days. Seven patients had endoscopies and 3/7 had more than 1 endoscopic procedure. Twenty seven patients had a biopsy and for 14/27 it led to a definitive diagnosis, with 11/27 patients having more than 1 biopsy. Three patients' histology samples were sent away for genetic testing. The number of IHC markers tested ranged from 0 to 20 per patient.
Conclusion: The investigation and management of CUP is empirical and the delay in diagnosis is still present. Patients can be faced with a long period of multiple investigations to identify the primary source prior to referring to the CUP MDT. There is a need to identify an alternative way of diagnosing these patients. The gene signature tests available, although validated in literature are not currently funded outside a clinical trial. This audit proves that their cost may be comparable to the actual investigation process. The impact in the patient's life expectancy is invaluable.
No conflict of interest.

1514 POSTER

Growing workload for Dutch medical oncologists caused by increased prescription of systemic therapies

N. Bernards[1], G.J. Creemers[2], A.J. Gelderblom[3], F.L.G. Erdkamp[4], V.E.P.P. Lemmens[1]. [1]*Eindhoven Cancer Registry, Research, Eindhoven, Netherlands;* [2]*Catharina Hospital, Internal Medicine, Eindhoven, Netherlands;* [3]*Dutch Society for Medical Oncology (NVMO), Chairman, Eindhoven, Netherlands;* [4]*Orbis Medical Centre, Internal Medicine, Sittard, Netherlands*

Background: The burden of cancer is rising in the Netherlands as a result of ageing and growth of the population. Concerns are increasing that the number of medical oncologists is insufficient to meet the rising demand. Therefore, the aim of this Dutch population-based study is to evaluate trends in systemic treatment of newly diagnosed cancer patients and illustrate the workload of Dutch medical oncologists.
Material and Methods: All patients with newly diagnosed cancer between 1990 and 2010 were included. To illustrate the workload of medical oncologists, the number of patients receiving systemic treatment within the first six months after diagnosis was calculated. Systemic treatment included chemotherapy and targeted therapy; hormonal therapy was not taken into account.
Results: The number of newly diagnosed cancer patients increased in the southern Netherlands from 8.000 in 1990 to 17.500 in 2010. The rate of prescription of systemic therapy for these patients doubled from 12% to 24% in the above-mentioned period. Consequently, a four fold increase in the absolute number of systemic treated patients was seen. The increased rate of prescriptions was especially large for patients with breast cancer, gastrointestinal cancer and lung cancer. In contrast, the rate of prescriptions decreased in patients with hematologic or gynecologic malignancies. Especially for patients with metastatic disease the administration of systemic therapy increased, from 17% of the newly diagnosed patients with metastatic cancer receiving chemotherapy in 1990, to 45% in 2010. With an increase from 42% to 61%, the increase in percentages of systemically treated was most marked for patients with metastatic colorectal cancer. The percentage of patients with non-metastatic forms of cancer receiving (neo) adjuvant treatment increased from 8% to 17%. The increase was most pronounced among patients with non-metastatic breast cancer, from 12% in 1990 to 41% in 2010. After introduction of targeted therapies around the year 2000, the prescription rates increased rapidly. Nowadays, 23% of the systemically treated patients receives a targeted agent.
Conclusion: The workload of Dutch medical oncologists increased drastically the last two decades. As ageing of the Dutch population will endure, concerns are growing that the number of future medical oncologists is insufficient to meet the future demands. An estimated 70 FTE medical oncologists will be extra needed by 2020 in the Netherlands.
No conflict of interest.

1515 POSTER

Cancer patients and mass media

M. Rajer[1]. [1]*Institute of Oncology Ljubljana, Radiotherapy, Ljubljana, Slovenia*

Background: Nowadays cancer patients tend to be more involved in medical decision process. Active participation improves health outcomes and patient satisfaction. To participate effectively patients require huge amount of information, but time limits make it impossible to satisfy all of information needs at clinics. We explored which kind of media and how often cancer patients use them in information seeking process. We also tried to evaluate how popular is Internet to reach medical information among cancer patients.
Materials and Methods: In this research we invited cancer patients, who had regular clinic examinations at Oncology Institute during 21st and 25th May in 2012 to answer to the anonymous questionnaires. Questionnaire contained questions about which media and how often did

cancer patients use them for disease related information. We analyzed results with descriptive statistics, χ^2-test and t- test.
Results: Patients returned 478 of 919 questionnaires distributed. Mean age was 59.9 (20−88) years. 61% of responders were female, and most common was high school education (33 %). Most common was breast cancer (33 %), followed by gastrointestinal and lung cancer. Television was the most used media for information seeking (84.1% of patients) followed by specialized brochures (78%) and Internet (70.8%). 67.6% of patients searched for disease related information in newspapers, 66.8% in specialized health magazines and 57.5% on radio. Patients most often searched for information regarding treatment options and alternative therapies. Patients who use Internet, most often looked for information on health related sites (60.5%), sites regarding alternative medicine (59.2%) and sites of newspapers and televisions (58.8%). 23.2% of patients responded they do not use media for disease related questions and as reason they specified that this was mainly because they get necessary information from their doctors. Patients who do not use media are older compared to all responders (62.5 mean age, $p < 0.001$).
Conclusions: According to our results, television, printed brochures and Internet are the most used media for information seeking by cancer patients. Information about treatment options is most often needed. Elderly patients search for information less often so they need to get as many as possible information at clinics.
No conflict of interest.

1516 POSTER

Coordination of the outpatient oncology care in Germany

W. Baumann[1], C. Riese[1], U. Borges[1]. *[1]WINHO, Köln, Germany*

Background: Continuity of care is a core value in modern medicine. Coordination in cancer care becomes increasingly important. Because of the complexity of the disease and the specialization of different care providers, it is necessary to ensure the flow of information between physicians. Coordination problems are easily sensed by patients and can therefore be used as a patient related quality measure. In addition to coordination, the survey addressed other issues of the long-term care.
Methods: The study based on Part 4 of the NCQ − questionnaire by Uijen et al. 'coordination of care'. In addition, we examined quality aspects of pratices, supportive care, doctor-patient communication, the level of stress and socio-demographic data of patients. All physicians in the WINHO network (more than 400) were invited to participate in the survey. The survey was conducted in-house with a paper-based questionnaire and the data were analyzed by using SPSS.
Results: A total of 35 oncology pratices, 73 doctors and 3411 patients participated in the survey (response rate 78%). The patients were on average treated 3 years and 4 months. 76% of the patients with a solid tumor who were referred to an office-based oncologist by a certified centre (n = 769) strongly agree/agree that the care providers pass on information to each other very well. Further 65% strongly agree/agree that the care providers always know very well what the other care providers have done. With concern to the course of treatment, 41% of patients reported that their case had been presented to a tumor board meeting. 30% have participated in an rehabilitation programm.
Conclusions: The results show the importance of continuity and some coordination issues in the course of care. With an average of more than 3 years of treatment, many cancer patients experience treatment as a long-time partnership with a single oncologist. The data show that these patients overly perceive a very good coordination of care. The results need to be analysed with regard to comparable studies and the oncologist's role.
No conflict of interest.

1517 POSTER

Tailoring treatment based on risk of relapse in advanced laryngeal squamous cell carcinoma

R. Zaim[1], W.K. Redekop[1], E.R. Velazquez[2], F. Hoebers[2], P. Lambin[2], C.A. Uyl-de Groot[1]. *[1]Erasmus University, Institute of Health Policy and Management/Institute for Medical Technology Assessment, Rotterdam, Netherlands; [2]Maastricht University Medical Center, Department of Radiation Oncology (MAASTRO Clinic), Maastricht, Netherlands*

Background: The aim of this study was to quantify potential health gain and cost consequences by comparing concurrent administration of chemotherapy and radiotherapy (RT) with RT alone in the treatment paradigm of laryngeal squamous cell cancer patients with high-risk of developing relapse.
Materials and Methods: A Markov model was designed for patients with stage III/IV cancer of the supraglottic or glottic larynx, curable with surgery and post-operative RT. Model inputs were derived from the long-term published results of the Radiation Therapy Oncology Group (RTOG) 91−11 trial (Forastiere et al., 2013), literature and publicly available sources. The compared model treatment strategies were concurrent cisplatin/RT and RT alone. Effectiveness measures were locoregional control (LRC), defined as absence of persistent or recurrent disease, and preservation of larynx (LP). The perspective of the Dutch healthcare sector was used. Costs were expressed in 2012 euros. A time horizon of ten years with discounting was applied. Incremental cost-effectiveness ratios (ICERs) were calculated. Sensitivity analyses were performed.
Results: For the LRC end-point of our study, concurrent cisplatin/RT group yielded cost-savings compared with RT alone; in the range of €594-€2,479 per patient. Discounted cost-savings were €465–2,224. The improvement in effects of the concurrent cisplatin/RT group was 1.35 (1.24 discounted) per rate of absence of recurrent disease. For the LP end-point of the study, base-case and discounted results were comparable. The calculated ICERs were dominant and in favor of the concurrent cisplatin/RT group. Sensitivity analyses confirmed the robustness of these findings. The most influential variable was the proportion of patients that underwent salvage surgery. Probability of patients eligible for concurrent cisplatin/RT and management of recurrent disease were other key components which affected per group differences.
Conclusion: Treatment of stage III/IV laryngeal squamous cell cancer patients with concurrent cisplatin/RT is not only clinically favorable but also cost-saving for maintaining LRC and preserving function at the primary site. Intensity-modulated radiation therapy techniques and novel imaging tools for staging and assessment of response would likely improve both therapeutic and cost-effectiveness ratios in future studies.
No conflict of interest.

1518 POSTER

Combining 18F-FDG PET/CT and MRI in monitoring neoadjuvant chemotherapy in breast cancer: Scenarios and decision modeling to inform development decisions in an early stage

A. Miquel Cases[1], L.M.G. Steuten[2], K.G.A. Gilhuijs[3], V.P. Retèl[1], W.H. Van Harten[1]. *[1]Netherlands Cancer Institute, Amsterdam, Netherlands; [2]Twente University, Health Technology and Services Research, Enschede, Netherlands; [3]University Medical Center Utrecht, Utrecht, Netherlands*

Background: Neoadjuvant chemotherapy (NACT) reduces tumor volume before surgery. Scientists are developing monitoring techniques to assess its potential clinical impact. Early health technology assessment (HTA) can support the translation of these technologies to the clinic by providing data on its expected clinical, economic and other impact, from the first development stages. Objectives of this study are to 1) Combine scenario drafting and decision modeling to describe development and adoption scenarios for FDG-PET/CT and MRI in monitoring NACT in breast cancer, and 2) Identify the scenario with the highest expected cost-effectiveness.
Methods: A basic scenario and several 'what-if scenarios' were drafted with principal investigators and breast cancer experts, based on the technology's expected accuracy, competing technologies, regulatory issues and user satisfaction. The likelihood of each scenario was estimated and the most likely scenarios were quantitatively incorporated in a health-economic model. The expected Incremental Cost-Effectiveness of each scenario was estimated.
Results: The basic scenario described increased adoption of FDG-PET/CT+MRI in the hormone positive group. This was influenced by the likelihood of FDG-PET/CT+MRI being more accurate than MRI in 2014 (75%). The resulting ICER of € 111968/quality-adjusted-life-year (QALY)) indicates that PET/CT-MRI is not yet cost-effective compared to MRI alone. Accuracy changes were also the main drivers for the 'what if scenario' of: 'differential adoption in breast cancer subtypes'. The likelihoods of a higher accuracy of FDG-PET/CT − MRI vs MRI of 25% in the HER2 amplified and 50% triple-negative led to ICERs of €11865/QALY and €80560/QALY respectively. Accuracy was seen to affect key opinion leader's attitude, the degree of MRI substitution, and its uptake in clinical guidelines. Another key 'what if scenario' was the role of competing technologies. If technologies such as circulating tumor cells or new imaging discoveries would emerge, they could affect adoption over time.
Conclusions: The combined used of scenario drafting and decision modeling permits estimating the expected ICER of various likely development/adoption scenarios of a technology during translational research. It shows that accuracy of FDG-PET/CT strongly influences its expected cost-effectiveness and herewith its likely adoption in the clinic.
No conflict of interest.

1519 POSTER

Establishing patient and public involvement in cancer research: An integrated approach

N. Pattison[1]. [1]*Royal Marsden Hospital − NHS Trust, Critical Care, London, United Kingdom*

Background: Patient and public involvement (PPI) incorporates and integrates patients' or users' perspectives into research, throughout different stages of research so that cancer research reflects issues that are important and relevant to those whom the research potentially affects.
Methods: A process mapping exercise of how PPI is integrated into all types of research was undertaken with the aim of describing the development of an integrated approach to establishing and developing Patient and Public Involvement (PPI) in Research in the UK's first Biomedical Research Centre (BRC) for Cancer, comprising a large cancer hospital and an academic cancer research institute. This mapping exercise entailed reviewing all PPI activity and processes within the two organisations and was undertaken in conjunction with, and reviewed by, members from the Patient and Carer Research Review Panel. This exercise was then used to develop a PPI strategy which informs the Biomedical Research Centre's research strategy, with patient and public input for the enhancement of research that is truly in the public interest.
Results: The mapping exercise has yielded how several stands of PPI are interwoven to create a culture of patient and public involvement in cancer research. PPI has extended across the research spectrum and included imaging, translational, drug development and health services research. The strands to achieve this include: establishment of a panel to review research; development of open web-resources to engage and involve patients and the pubic, priority setting processes that rank patient and public suggestions for what kinds of cancer research should be undertaken and increasing awareness of how patients and the public can get involved in ground-breaking cancer research. It also extends to advocacy representation in trial steering groups, education events, awareness training and the establishment of a culture that seeks PPI at the early ideas stage. The mapping showed how at present the BRC is at the 'Creative' end of the PPI continuum representing collaboration and co-production of research, where research is shaped by PPI and PPI partner input and insight has made a difference to planned research design. Ultimately, this impacts on what will become the outcomes of future cancer research.
Conclusion: Involving patients and the public in cancer research requires a culture shift across organisations, but the imperative for PPI is compelling and results in research with clinically important and meaningful patient outcomes.
No conflict of interest.

An investigation into the delayed presentation of breast cancer in Lahore, Pakistan

M.A. Pervaiz[1], M.A. Parvaiz[2]. [1]*King Edward Medical University, Department of Surgery, Lahore, Pakistan;* [2]*New Cross Hospital, Department of Surgery, Wolverhampton, United Kingdom*

Background: Due to the inadequacy of screening programmes for early detection of breast cancer in Pakistan and the predominance of advanced cases, a study was conducted to assess the factors responsible for the delayed presentation of breast cancer.
Material and Methods: All consecutive patients with a diagnosis of advanced breast cancer, whether locally advanced or distant metastases, presenting to a university hospital for the first time over a period of twelve month were prospectively included in this study. Factors including age, socio-economic status, education, marital status and lack of access to health care services were assessed.

	Socio-economic category	Patients	
		Number	Percentage
Upper class	A	11	5
Middle class	B	27	12
	C	47	20
Lower class	D	57	25
	E	88	38
Total		230	100

Results: 230 patients were diagnosed with advanced breast cancer during this study period. They were all women. Ninety percent (207/230) were over the age of 35 years. A statistically significant proportion ($p < 0.05$; 63%) belonged to the below poverty socioeconomic group (table). Eighty percent (184/230) of patients were completely illiterate, while 46 patients (20%) had some formal education. 138 patients (60%) associated their late presentation to the lack of access to health care services. Other reasons given for delayed presentation included shyness, little support from family, lack of knowledge of breast cancer symptoms and not familiar with the importance of breast self-examination.
Conclusion: This study found that illiteracy, poverty, shyness and lack of health care facilities in distant areas are mainly responsible for the late presentation of breast cancer in women of Pakistan. Development of a screening programme, public education, school seminars and comprehensive awareness programmes focused on encouraging women to see a doctor promptly for the evaluation of breast symptoms can prevent the delay and improve patient outcome.

1521 POSTER

Therapeutic benefit as a criterion for a prioritization in oncology

M. Otten[1], A. Diederich[1]. [1]*Jacobs University Bremen, School of Humanities and Social Sciences, Bremen, Germany*

Background: In oncology therapeutic benefit is of high importance. Despite the enormous progress in medical cures leading to an increasing life expectancy, some treatments often improve the health status only marginally or cause strong adverse effects. Sometimes they even harm the patient seriously. This study examines preferences of different stakeholder groups with respect to their criteria concerning the allocation of medical resources.
Methods: A questionnaire study with standardized questions including typical questionnaire items, rankings and scenarios was conducted. To date, 123 interviews were carried out with cancer patients and different staff members including medical practitioners, nurses and administrative officers of one of the largest centers for oncological care in Northern Germany. Sociodemographic variables were elicited to serve as covariates in regression models and as variables in contingency analyses to test specific hypotheses and to account for the variability in the data.
Results: Allocating resources according to different criteria gave the following importance ranking: Treatments leading to a full recovery; quality of life; life extension; proved effectiveness of a treatment; patient's commitment and engagement for a treatment (e.g. hospital stay or journeys); age of a patient; and treatment costs. This clearly points out the importance of therapeutic benefit. A ranking evaluating the *degree* of treatment benefits gave the following: Treatments leading to a full recovery; quality of life; fast recovery; life extension; period until next cancer breakout; adverse effects; and psychological well-being. Furthermore, the respondents were asked whether treatments should only be financed by the public health care system, if their effectiveness is positively proven (evidence based medicine). The majority supported this idea but many changed their opinion when effectiveness was embedded in more complex scenarios. One scenario was concerned with an ongoing scientific study accumulating evidence for the treatment. In the second scenario a practitioner believes that the treatment is effective.
Conclusions: The study indicates the importance of therapeutic benefit for allocating health care resources. It shows the difficult situation of evidence based medicine within a discussion of prioritization.
No conflict of interest.

1522 POSTER

Advanced stage presentation of cancer in Eastern India- how is the alternative medicine responsible?

N. Aian[1], A. Karmakar[2], A. Nandi[2], A.N. Sen[3], A. Mukhopadhyay[4]. [1]*Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Medical Oncology, Kolkata, India;* [2]*Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Cell Biology, Kolkata, India;* [3]*Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Surgical Oncology, Kolkata, India;* [4]*Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Haematological Oncology, Kolkata, India*

Background: A majority of Indian cancer patients are often presented with incurable diseases at the latest phase of disease progression. The use of TCAM has been identified by Indian oncologists as a potential factor for the delay in seeking health from medical practitioners but no research has been conducted to verify such claims. The aim of this study is to identify socio-demographic and disease status differences between TCAM and non-TCAM users among cancer patients in India and associated patterns of seeking professional medical help.
Materials and Method: A random survey of 825 cancer patients in one public and one private hospital was conducted in Delhi, India where a list sampling technique was used to interview every patient over a four month period, of response rate 80% where 10,200 cases were registered with age distribution of 1 month to 91 years, mean age 44.2 years. Male (54%)

cancer patients were little predominating compared to the female (46%) patients where in males ca lung (14%), followed by ca oral cavity (11%) ca colon (6%). The most frequent reported malignancy in female was breast (30%), uterine cervix (21%), gallbladder (11%) ovary (10%). In paediatric age group ALL (32.4%), Ewings Sarcoma (21.2%), Rhabdomyosarcoma (16.1%) and Brain tumour (13.6%).
Results: The results showed that 34.3% of cancer patients had used TCAM and demonstrating statistically significant relationship between the use and reported delay in seeking help from clinical medicine ($p < 0.001$). On the other hand, 35.2% users reported seeking help immediately after onset of symptoms, whereas 50% of non-users sought help from conventional medicine and 11.5% of users reported waiting for six months or more after noticing symptoms, while only 2.1% of non-users waited this long.
Conclusion: Overall, early diagnosis and intervention is critical for effective treatment of many malignancies. Delays in presentation related to the use of TCAM may be an important factor relating to the high rates of advanced disease on presentation and low survival rates in the care of Indian cancer patients. Further research is needed to explore the reasons for using TCAM and to ensure existing issues of delays in help seeking are addressed.
No conflict of interest.

1523 POSTER

Cost-effectiveness of denosumab versus zoledronic acid in patients with bone metastases from solid tumours in Spain

I. Duran[1], M.A. Seguí[2], D. Isla[3], I. Oyagüez[4], C. Roldán[4], M.A. Casado[4], M. Lothgren[5], G. Hechmati[5], L. Gutiérrez[6], J.A. Gasquet[7]. *[1]Centro Integral Oncologico Clara Campal, Medical Oncology, Madrid, Spain; [2]Corporació Sanitària Parc Taulí, Medical Oncology, Sabadell, Spain; [3]Clinico Universitary Lozano Blesa Hospital, Medical Oncology, Zaragoza, Spain; [4]Pharmacoeconomics and Outcomes Research Iberia, Madrid, Spain; [5]Amgen (Europe) GmbH, Health Economics, Zug, Switzerland; [6]Amgen SA, Health Economics, Barcelona, Spain; [7]Amgen SA, Medical Development, Barcelona, Spain*

Background: Denosumab was superior to zoledronic acid (ZA) in the prevention of skeletal-related events (SRE) in patients with bone metastasis (BM) from solid tumours in 3 large clinical trials. This study assessed cost-effectiveness of subcutaneous denosumab vs intravenous (IV) ZA in patients with BM from breast cancer (BC), prostate cancer (PC) or other solid tumours (OST) in Spain.
Methods: A Markov model (4-week-cycle duration) was used to estimate lifetime costs, SRE incidence (pathologic fracture, spinal cord compression, bone radiation and surgery) and quality adjusted life years (QALYs) from the Spanish Health System's perspective. Health states considered were 'on treatment', 'off treatment' and 'death'. Transition probabilities (discontinuation and death rates), adverse event (AE) rates and rate ratio (RR) of SRE (denosumab vs ZA) (RR_{BC}=0.77; RR_{PC}=0.82; RR_{OST}=0.85) were obtained from clinical trials. Base case did not consider discontinuation or AE as the overall incidence was similar between the drugs. The analysis included drug, administration, monitoring and SRE management costs. To reflect the potential availability of generic ZA, a 40% discount in ZA branded price was applied. Drug, administration and monitoring costs were based on annual administrations [13 (denosumab); 14.47 used in clinical practice (ZA)]. Denosumab and ZA administration and monitoring costs applied only to doses not synchronised with IV chemotherapy (64.2% [BC]; 68.4% [PC]; 52.6% [OST]). Unit costs (2013 €), utilities and synchronisation were procured from literature and local databases. A 3% annual discount was used in costs and outcomes. Sensitivity analyses (SA) were performed for SRE management costs (±20%), administration and monitoring costs (±50%), using SRE rates from clinical practice and including discontinuation and AE rates in the analysis.
Results: Denosumab yielded 0.044, 0.041 and 0.026 additional QALY; avoided 0.48, 0.35 and 0.22 SRE and was associated with savings of €704 and €606 in patients with BC and PC. Greater variations in SA were related to SRE rates and administration costs. Denosumab was dominant (more efficacious and less costly) in 69% of scenarios and remained cost-effective in 97% (using €30,000/QALY threshold). Denosumab was cost-effective in 100% of the BC and PC scenarios.
Conclusions: Denosumab is cost-effective vs generic ZA in the prevention of SRE in patients with BM from solid tumours and is cost-saving in most scenarios.

1524 POSTER

Cost-benefit analysis for gastric and cervical cancers: Public health oncology in Japan

T. Isshiki[1], Y. Kimura-Nishide[2], T. Komatsu[1]. *[1]Teikyo University Chiba Medical Center, Hematology, Chiba, Japan; [2]Teikyo University Chiba Medical Center, Medical Information System, Chiba, Japan*

Background: Our study objectives were to evaluate medical economy for gastric and cervical cancer prevention in Japan and thereby contribute to cancer care policy decisions. In addition to medical cost, those associated with cancer incidence should include overhead due to income loss, hospital visits, and psychological and social costs. We created presence/absence models for prevention by setting primary prevention for gastric and cervical cancers as *Helicobacter pylori* (Hp) eradication and human papillomavirus (HPV) vaccination, respectively, and performed cost-benefit analyses.
Methods: *1. Model creation*:
Gastric cancer model A: A person was found to be Hp-positive at age 20 and had no gastric cancer onset after eradication.
Gastric cancer model B: A person without eradication or examination had onset of progressive gastric cancer at age 50, received anticancer drug therapy, but died one year later.
Cervical cancer model C: A person received HPV vaccination at age 14, stage 0 cervical cancer was diagnosed at age 40, and cured by conization.
Cervical cancer model D: A person who did not receive HPV vaccination was diagnosed with stage IIIb cervical cancer, underwent radical hysterectomy + irradiation + anticancer drug treatment, but died 3 years later.
2. Cost classification and cost estimate:
We divided the costs of cancer care into seven categories and estimated costs for each model.
3. We performed cost-benefit analyses for Japan as a whole.
Results: 1. Table 1 presents costs for each model.
2. Gastric cancer: Cost was estimated as follows: Hp examination $2{,}926 \times 10^6$ JPY, Hp eradication 708×10^6 JPY; loss due to death $131{,}415 \times 10^6$ JPY; net benefit $127{,}781 \times 10^6$ JPY.
3. Cervical cancer: HPV vaccination $29{,}150 \times 10^6$ JPY; cervical cancer examination $5{,}830 \times 10^6$ JPY; loss decrease due to death $15{,}916 \times 10^6$ JPY. Thus, the estimated net benefit is negative $19{,}064 \times 10^6$ JPY.
Discussion: Prasad et al. conducted cost-benefit analyses of HPV vaccination in Kentucky, USA, and reported it to be cost effective (J KY Med Assoc 2008). We estimated that net benefit will be generated if the HPV vaccination cost decreases to 17,000 JPY. While few cost-benefit analyses have been reported for cancer care, they would be essential for policy determination. Therefore, we hope there will be many reports in the future.
No conflict of interest.

Table 1. Costs for each model (unit:JPY)

Cost classification	model A	model B	model C	model D
Prevention	4,600	0	50,000	0
Mass-screening	2,400	0	55,000	0
Curative treatment	0	0	270,000	0
Palliative care	0	2,760,000	0	1,480,000
Indirect cost	0	70,000,000	365,000	44,070,000
Non-medical cost	0	106,000	25,000	490,000
Psychosocial cost	0	18,840,000	0	46,490,000
Total cost	7,000	91,706,000	765,000	92,530,000

1525 POSTER

Multidisciplinary meetings in the management of patients suffering from cancer

M. Grima[1], R. Grech[1], J. Debono[1]. *[1]Mater Dei Hospital, General Surgery, Msida, Malta*

Background: Cancer multidisciplinary meetings (MDTs) are part of the philosophy of multidisciplinary care. Effective MDTs have positive outcomes for patients receiving the care and for the health professionals involved in providing the care and health services.
An audit was carried out to focus on the management of patients discussed at the general surgery oncology meeting (excluding breast cancer) held at Mater Dei Hospital, Malta every 2 weeks. These meetings are held between the general surgeons, pathologists, oncologists and radiologists taking care of their respective patients.
The audit looked into:
1. The management plan decided during the MDT

2. Whether the treatment was adhered to and if not, the reason behind such a decision.
3. The time between the decision to offer treatment and the initiation of treatment
4. The guidelines used in each decision plan and if none was mentioned the management plan was compared with the European and international guidelines

Material and Methods: The first MDT was organised in early 2010 and since then it has taken place on a fortnightly basis. Data about all patients who were discussed during 2011 and 2012 were collected and processed. About 700 patients were included in the audit. The medical records of each patient were looked into to obtain the data required for this audit. Data was also collected using PACS and iCM software available in Mater Dei Hospital.

Results: The management plan discussed in the MDT was documented in the medical records and in the majority of cases the treatment adhered to European and/or International guidelines. In most of the cases there was written evidence that the patient was informed about the treatment decided in the MDT however most of the time the decision on treatment options was doctor led rather than patient led. In a minority of cases there was a difference between the management decided during the MDT and the treatment provided and this was secondary to patient choice.

During data collection it transpired that there is a need for proper documentation of MDTs. Currently there is no proforma on the documentation submitted prior to and during the MDT. Each surgical firm has his own way of submitting the patient's data and this may lead to lack of information needed for discussion during MDTs. In the medical records, there was a lack of documentation on the discussion that took place and the reasoning behind each particular decision taken even though the management decided upon agreed with the guidelines available.

Conclusions: The MDTs are useful as treatment planning is better coordinated and expedited. There is greater continuity of care and less duplication of services. Communication between care providers improves, and as a result time and resources are used more efficiently for the benefit of the patient.

This audit also highlighted some lacunae which if taken into consideration will improve the multidisciplinary care of the patient suffering from cancer.

No conflict of interest.

1526 POSTER

Content analysis of social media traffic related to the 2012 EORTC-NCI-AACR Symposium on molecular targets and cancer therapeutics

R. Miller[1], M. Gross[2], S. Jhawar[3], S. Madkhali[4], R. Miller[5]. *[1]Lourdes High School, Rochester, USA; [2]University of Florida, College of Medicine, Gainesville FL, USA; [3]New York University, College of Medicine, New York New York, USA; [4]Oxford University, Particle Therapy Cancer Research Institute, Oxford, United Kingdom; [5]Mayo Clinic, Radiation Oncology, Rochester, USA*

Background: Social media has become a major mode of communication, and sites such as Twitter are growing exponentially in both user base and breadth of applications. Medical conference participants and sponsors interact in real time, enriching the conference environment. We explored social media's function as a medium for information exchange associated with the EORTC-NCI-AACR sponsored Symposium on Molecular Targets and Cancer Therapeutics held November 6−9, 2012.

Materials and Method: We used Tweet Archivist (http://www.tweetarchivist.com/), an online analytic tool, to conduct a Boolean search for '#ENA2012' tagged posts on Twitter from 4/11/12 to 10/11/12. Data was gathered on tweet content, attitude, subject, platform, and authorship and analyzed through simple descriptive statistics. #ENA2012 was designated as the official meeting tag prior to the meeting by ECCO (EuropeanCancer).

Results: 258 posts were captured (0−78/day). 34% of posts involved logistics/scheduling, 29% disseminated information, 11% contained commercial content, 9% related personal experience, 7% were press releases, 4% were miscellaneous and 3% were queries. The subject discussed was networking in 34%, general oncology in 14%, miscellaneous in 12%, personal opinions in 9%, clinical trials in 9%, molecular targets in 8%, cancer biology in 7%, conveying expert information in 6% and technology or products in 2%. 10% of all posts were positive, 90% were neutral and none were negative in tone. 43% of tweets contained a hyperlink. 9 of 258 posts referenced specific cancer types, of which 11% referred to leukemia, 67% to prostate cancer, and 22% to miscellaneous cancers. The most common tweeting platform was TweetDeck with 38% of tweets. PC web browsers accounted for 26%, iPhones for 20%, iPads for 6%, BlackBerries for 4%, and Android for 1%. Individual users were the most frequent author type, producing 45% of all posts. The meeting organizer contributed 39% of posts, companies contributed 12%, and professional societies 4%.

Conclusions: Our analysis shows that Twitter is an active communication platform for professional conferences. It is a relatively underutilized sphere for influence and information exchange by stakeholders and professional organizations during these events as individual users and the meeting organizer presently dominate tweet authorship, with an emphasis on networking and conference logistics, respectively. The analysis provided here represents a tool for acquiring instantaneous feedback, mapping information movement, and monitoring the evolution of public opinion, complete with the potential to harness such information to guide and influence the marketplace.

1527 POSTER

Management of medical information between general practitioners and onco-hematologists regarding patients undergoing chemotherapy: Perceptions and realities

S. Abbioui[1], C. Desauw[2], S. Berger[3], N. Cambier[3], L. Pascal[3], E. Bourgeois[3], M. Cliquennois[3], A. Desplechin[3], C. Rose[3]. *[1]Réseau Régional Onco Nord-Pas-de-Calais, Loos, France; [2]CHRU Lille, Service d'Oncologie Médicale, Lille, France; [3]Hôpital Saint Vincent de Paul, Service Onco-Hématologie, Lille, France*

Background: The exchange of information is crucial in the multidisciplinary management of patients. Our aim was to identify communication effectiveness between onco-hematologists and General Practitioners (GPs) who were treating patients with outpatient chemotherapy in Lille (northern France).

Material and Methods: Onco-hematologists of Saint Vincent de Paul Hospital were surveyed after the initial consultation of new patients. For each included patient, GPs were interviewed by phone about 2 weeks after the first chemotherapy session. Mail from GPs and from onco-hematologists regarding first consultation and first chemotherapy were also examined. About ten informations were explored to compare the returns with the reality of exchanges from hospital to GPs, including cancer diagnosis, prognosis, degree of patient information, treatment protocol and timetable, terms of future exams, potential side effects and their management. From GPs to hospital, 14 informations were explored, including medical history, usual treatments, results of previous tests, degree of patient information, degree of autonomy, psychological state and social environment.

Results: From 04/2011 to 02/2012, GPs response rate was 85.2% (n = 69 for 81 new patients). Each GP had a small number of patients being treated by chemotherapy in his patient base: 0.6% (0.1 to 3). Patient was referred for chemotherapy by another physician in 88% of cases (n = 37/42). Communication from all 9 oncologists was deemed adequate by GPs (69.6 to 100%), with exception that prognosis was poorly communicated (37.7%) and difficult to interpret. In comparison with mail, GPs underestimated the level of communication for every informations (from 31.9% to 91.3%), in particular for patient information and side effects. Moreover, mail following the first session of chemotherapy was given to GPs by the patient in only 52.2% of cases (n = 36/69).

According to onco-hematologists, only 0 to 17.4% of the 14 informations were transmitted by GPs. It was confirmed by our analysis of 10 mail sent by GPs. Only 21.7% of initial consultation were accompanied by mail from GPs. Furthermore, 44.9% ignored the identity of their patient's onco-hematologist but 79.7% were in favour to complete a record of medical and social information before initial consultation.

Conclusions: There is a difference between informations provided by the onco-hematologist and their reception by the GP. The difficulty of communication could be due to many patient referred for by another physician. The use of a record of medical and social information, a therapeutic tracking sheet and encrypted messaging system could improve reception of information by GPs during outpatient treatment. Communication devices could secondarily be integrated into the future computer shared patient file.

1528 POSTER

Early integration of palliative care into standard oncologic care: The development of a network for integrated oncology and palliative care in a rural European region

T. Sternfeld[1], U. Vehling-Kaiser[1]. *[1]Onkologisches und Palliativmedizinisches Netzwerk Landshut, Landshut, Germany*

Background: The early integration of palliative care in the course of cancer treatment was discussed recently in the US (1). There is a discussion ongoing in Germany strongly demanding the participation of palliative care teams early in the course of oncological treatment. However, oncological and palliative services differ significantly between the US and the EU and

also within the EU. Furthermore, there are considerable disparities between the rural and urban situation within one health system. Organisational structures cannot easily been transferred or compared. Simple calling for a palliative care physician or palliative care team who cares for the patient in addition to the oncologist does not take into account the different needs in varying tumour entities and disease courses, differences of specialisations of oncologists and health care systems as well as financial aspects. Comprehensive Cancer Centres might be able to provide the whole spectrum of the proposed services, but most of cancer patients in Europe are not treated at these centres. The key elements of early palliative care in the setting of cancer treatment can be realized in different ways.
Results: We report the successful development of an ESMO accredited Designated Centre of Integrated Oncology and Palliative Care (Onkologisches und Palliativmedizinisches Netzwerk Landshut) under limited resources in a rural region of Bavaria. From this experience we conclude the following points to be essential: palliative care should be included in the oncology training, and there should be regular scientific updates for palliative treatments of different cancer types. Important is the principle of continuous care (e.g. the oncologist follows the patient until his death, even when end-of-life care is provided by a palliative care team, and the patient can stay in contact with the doctor seen at time of cancer diagnosis). As part of a network of all required services for palliative care (e.g. ambulatory and inpatient palliative care team, hospice) the oncologist must be able to manage patients' needs, the personal communication between the health care professionals within the network is elementary. Counselling and support for the patients' relatives must be offered. The degree of palliative care versus oncological care should be balanced depending on patients' wish and the stage of the disease.
No conflict of interest.

1529 POSTER

Central unit of cytostatics' preparation in hospitals: Luxury or necessity?

V. Gkogkozotou[1], E. Chiotaki[1], M. Messaritakis[1], D. Frangouli[1], A. Pantazi[1], I. Prinari[1], D. Vryssalis[1], P. Asithianakis[1]. *[1]University Hospital of Crete, Pharmacy, Iraklion Crete, Greece*

Background: University Hospital of Crete (UHC) is the largest general hospital in Crete and among the 5 largest hospitals in Greece. With the implementation of the memorandum in Greece, all operators were asked to reduce their costs, while special emphasis was placed on decreasing healthcare costs. In 2012, in this context, UHC made various attempts to reduce its budget.
Material and Method: Until January of 2012, every oncologic clinic was preparing the drugs for the therapies of its patients at its amenities. One of the actions taken by the UHC was the foundation of a Central Unit for the Cytostatics Drugs' Preparation (CUCDP) where the dilution of all the oncologic drugs for all the therapies in the hospital is taking place. The CUCDP is part of the hospital's pharmacy and it's recruited by a pharmacist, as the scientific supervisor, plus four nurses and a medical laboratory technologist, who cope with the 115 preparations per day for the about 62 daily patients of the 11 associated clinics. The CUCDP personnel has developed a great know-how in dissolving these drugs that enables the quick and safe preparation of the solutions and offers the best quality for the patients' treatment.
Results: In the first year of its operation, over 15.500 therapies were prepared in the CUCDP that correspond to 28.000 different dilutions. 120 different brand-names of cytostatics drugs are used for the injectables oncologic treatments. The good management of the medicines according to their SPC instructions and the economy of scale due to cumulative drugs' preparation succeeded in quantity saving of drugs that were re-entered in pharmacy's stock for use. More than 100.000 units were used and from them 6.000 units were saved and returned at the pharmacy. In a total of 10 million euro that these treatments cost (calculated in hospital price), a cost saving of 850 thousands euro was achieved.
Conclusions: Taking into pharmacoeconomic consideration that the value of these used cytostatic medicines equals to the 1/3 of the total hospital's pharmaceutical expenditure, even if only this CUCDP was the only action taken, a 3% budget decrease would have been accomplished.
No conflict of interest.

Cancer pattern in West Bengal, India: Data from hospital based cancer registry

A. Banerjee[1], J. Basak[1], S. Mukhopadhyay[1], C.K. Basu[2], A. Mukhopadhyay[3]. *[1]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Molecular Biology, Kolkata, India; [2]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Clinical Research, Kolkata, India; [3]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Haematological Oncology, Kolkata, India*

Background: The first Population Based Cancer Registry (PBCR) in India was organized in Mumbai in 1963. Subsequently under National Cancer Registry Programme (NCRP) of Indian Council of Medical research a few more registries was started in different cities of India like Bangalore, Chennai and New Delhi. The 1st PBCR was organized in Kolkata in Chittaranjan National Cancer Institute in 1997. We started our hospital based cancer registry from 2002, Kolkata. The PBCR from different cities has shown the distributions of different cancers are different in different cities because of ethnic and dietary differences. The aim of our study was to show the prevailing cancer pattern from eastern part of India.
Materials and Methods: From our hospital based cancer registry we analyzed all the cancer patients, who attended the out patients and in patients departments of Netaji Subhash Chandra Bose Cancer Research Institute during period from August 2004 to December 2012.
Results: A total of 20,400 cases were registered. The age distribution was 1 month to 91 years, with mean age of 44.2 years. The male (54%) cancer patients were little predominating compared to the female (46%) patients. The most frequent malignancies in males were carcinoma lung (14%), followed by cancer of the oral cavity (11%) and carcinoma colon (6%). The most frequent reported malignancy in female was breast (30%), followed by uterine cervix (21%), gallbladder (11%) and ovary (10%). In paediatric age group the most frequent malignancies were ALL (32.4%), followed by Ewings Sarcoma (21.2%), Rhabdomyosarcoma (16.1%) and Brain tumour (13.6%).
Conclusion: The cancer pattern in eastern India is little different from other parts of India & World cancer registry, because of life style and diet habit of this part of the country.
No conflict of interest.

High incidence of gall bladder cancer in Gangetic West Bengal: A study from a hospital based cancer registry

S. Mukhopadhyay[1], A.N. Sen[2], J. Basak[3], C.K. Basu[4], A. Mukhopadhyay[1]. *[1]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Medical Oncology, Kolkata, India; [2]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Surgical Oncology, Kolkata, India; [3]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Molecular Biology, Kolkata, India; [4]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Clinical Research, Kolkata, India*

Background: Gall bladder cancer accounts for about 1% of all cancer deaths. Incidence varies geographically with higher rates in certain areas and among women is approximately double than that of men. As the incidence of this disease is increasing, a systematic trend analysis may help to understand alterations in incidence with regard to time, place and person distribution, and changing cancer risk. The present communication makes an attempt to analyze the time trends of gallbladder cancer for people of Gangetic West Bengal.
Materials and Methods: From our hospital based cancer registry we analyzed all cancer patients, who attended outpatient and inpatient department of Netaji Subhash Chandra Bose Cancer Research Institute during period from August 2004 to December 2012. A total of 20, 400 cases were registered. We then analyzed the total cancer cases and gall bladder cases belonging to gangetic West Bengal. The Gangetic West Bengal consisted of Malda, Murshidabad, Nadia, Burdwan, Hooghly, Howrah and 24 Pgs(S) through which districts the river Ganga flows. A detailed dietary, water consumption and lifestyle history were noted for those patients.
Result: A total of 20, 400 cases were registered out of which overall gall bladder cancer was 11%. Among all cancer patients residing in Gangetic belt (8,000), gall bladder cancer ranked third and was 16%. The probable reason we noticed a particular dietary habit of Bengalis. They kept fasting for some particular religious reasons till noon and then were habituated to take rice with ghee (full fat dairy product) or fatty diet. They followed fasting for 2 or 3 times a week. Muslim people tend to relish on spicy and fatty foods. Second history we noticed was repeated *Salmonella typhi* infection because of contaminated water supply leading to chronic cholecystitis which led to cancer. Third reason was arsenic contamination of drinking water which was concentrated in gall bladder producing carcinoma. The fourth and one of the most important factors in Gangetic West Bengal

was consumption of polluted drinking water of the river Ganga which the Indians spiritually drink as pure water. The heavy metals deposited, were Molybdenum, Mercury and Lead because of industrial pollution along the river bank.
Conclusion: Statistically, the gall bladder cancer in Gangetic West Bengal was the highest incidence in India and second highest in the World after Japan. This cancer is mostly related to diet and drinking habit. We intend to take preventive measures of gall bladder cancer by proper awareness and changing diet and drinking habit of Bengalis of Gangetic West Bengal.

Patients' preferences for bone metastases treatments in France, Germany and the United Kingdom

G. Hechmati[1], J. Arellano[2], A. Mohamed[3], B. Hauber[3], Y. Qian[2], F. Gatta[1], I. Haynes[4], A. Bahl[5]. *[1]Amgen (Europe) GmbH, Zug, Switzerland; [2]Amgen Inc., Thousand Oaks, USA; [3]RTI Health Solutions, Durham, USA; [4]Amgen Ltd., Uxbridge, United Kingdom; [5]University Hospitals Bristol, Bristol, United Kingdom*

Background: Patients with bone metastases from solid tumors often experience skeletal complications (skeletal-related events [SREs]; commonly defined as pathologic fracture, radiation to bone, surgery to bone and spinal cord compression). Several bone-targeted agents are approved to prevent SREs, but patients' preferences among available options has not been evaluated. The aim of this study was to assess patients' preferences for efficacy, safety, and mode of administration in relation to currently available treatment options in Europe.
Material and Methods: Adults in France, Germany, and the United Kingdom (UK) with a self-reported physician diagnosis of bone metastases secondary to a solid tumor completed a web-enabled discrete-choice experiment survey consisting of a series of 10 choices between pairs of hypothetical medication profiles. Each profile included five attributes with 3 or 4 levels each (primarily based on product prescribing information): months until first SRE (10, 18 and 28 months); months until worsening of pain (3, 6 and 10 months); annual risk of osteonecrosis of the jaw (ONJ; 0, 1 and 5%); annual risk of renal impairment (0, 4 and 10%); and mode of administration (oral tablet, subcutaneous injection, 15-minutes infusion and 120-minute infusion). Choice questions were based on an experimental design with known statistical properties. The survey was pretested with 26 patients using open-ended interviews. A separate main-effects random parameters logit model was estimated for each country.
Results: A total of 159 patients in France, 166 patients in Germany, and 159 patients in the UK completed the survey. Among the attributes included in the survey, months until first SRE, annual risk of renal impairment and time until worsening of pain were the three most important attributes for patients in all countries. For all these attributes better levels of outcomes were significantly preferred to worse levels ($p < 0.05$). In all three countries, a 120-minute infusion every 4 weeks was the least preferred mode of administration. The annual risk of ONJ was judged by patients to be the least important attribute in the UK and Germany and second to least important in France.
Conclusions: When considering treatment choices for preventing skeletal complications associated with bone metastases, patients focused mainly on delaying SRE, avoiding renal impairment as well as delaying pain worsening.

A study of the support and information needs of men using the 'your prostate' service

S. Barber[1], I. Banks[2], E. McCaughan[3], P. Baker[2]. *[1]European Men's Health Forum, Brussels, Belgium; [2]European Men's Health Forum, European Men's Health Forum, Brussels, Belgium; [3]University of Ulster, Institute of Nursing Research, Coleraine, Ireland*

Background: The purpose of the study was to find out what motivated men to use the 'Your Prostate' service.
Prostate cancer incidence is now the main cause of cancer deaths among men in Europe. European Men's Health Forum (EMHF) developed an e-service for men to ask questions about any aspect of their prostate health with the intention of identifying the main concerns men have, the gaps in information and support available to them, and to make an analysis of the language used and to compare this across countries.
Material and Methods: A bespoke database was designed to enable questions and answers to be automatically entered exactly as they had been written into the database and to be analysed.
- Quantitative analysis included how many:
  - Questions were asked and to rank the question by type and the age of the user
  - Users were male/female
  - Users previously sought medication attention and/or received any treatment
  - Users accessed the service from different countries
- Qualitative analysis included textual analysis:
  - categorization of questions by topic
  - language used by men from different countries

Secondary analysis of a review of European (National) Cancer Plans was carried out.
Results: 710 questions were asked between December 2010 and March 2012 by a total of 424 unique users. 391 male, 33 female. 241 had previously sought medical attention; 172 had received treatment; questions received from 17 European countries. Most questions were asked by men aged 50 and over.
The largest group of questions numbered 147, categorized as relating to 'urination' and including: having to rush to the toilet to pass urine; difficulty in passing urine; increased frequency of passing urine, especially at night; pain on passing urine; blood in urine or semen. These symptoms are similar for both prostate cancer and benign prostatic hyperplasia. The next largest group of questions related to treatment being considered (126) followed by erectile dysfunction (87), prostate cancer (80) and then other categories including treatment received previously and potential adverse drug reactions. Difficulties in making a judgement about seeking diagnosis, agreeing to a medical intervention and making a choice among different treatments were commonly expressed. Fear was expressed about making decisions with the potential to make matters worse as well as better and about maintaining personal and sexual relationships.
Conclusions: It is evident from this study that men accessed an online website to gain information regarding their prostate health. The findings indicate that men have unanswered questions and require systems in place to meet this growing need. There is considerable scope for improving information aimed at men who face choices about their prostate health, the support available to them to make choices, and to assist them to recover following treatment. Further research is required to expand this area of practice.

Predicting outcome in onco-geriatric surgical patients: screening tools versus the comprehensive geriatric assessment

M.G. Huisman[1], B.L. Van Leeuwen[1], G. Ugolini[2], I. Montroni[2], C. Stabilini[3], A. Vigano[4], J. Spiliotis[5], N. De'Liguori Carino[6], G.H. De Bock[7], R.A. Audisio[8]. *[1]University Medical Center, Surgery, Groningen, Netherlands; [2]S. Orsola Malphigi Hospital, Surgery, Bologna, Italy; [3]San Martino University Hospital, Surgery, Genua, Italy; [4]McGill University Health Center, Oncology, Montreal, Canada; [5]Metaxa Cancer Hospital/Regional University Hospital, Surgery, Piraeus/Patras, Greece; [6]North Manchester General Hospital, Surgery, Manchester, United Kingdom; [7]University Medical Center Groningen, Epidemiology, Groningen, Netherlands; [8]University of Liverpool St. Helens Teaching Hospital, Surgery, St. Helens, United Kingdom*

Background: In the onco-geriatric surgical population, patients at risk of postoperative complications need to be identified preoperatively to allow for the implementation of preventive measures and to minimize the risk of over- and under-treatment. The comprehensive geriatric assessment (CGA) is useful for the purpose of identifying frail elderly, however it is too time consuming. There is a need for screening tools to identify frail patients, who are at risk of adverse outcome. The aim of this study was to compare the predictive ability of several screening tools to the CGA.
Materials and Methods: In an international prospective cohort, 345 patients $\geqslant$70 years undergoing elective surgery for solid tumors were included. Primary endpoint was the incidence of major complications 30 days post-operatively. Pre-operatively three screening tools were administered and compared to theCGA, which was administered simultaneously. 'Timed Up & Go' (TUG) quantifies functional mobility by means of a walking test, 'Vulnerable Elders Survey' (VES) addresses self-reported health issues to identify vulnerable older people and 'Groningen Frailty Index' (GFI) identifies frail patients by a 15-item questionnaire. Data were analyzed using multivariate logistic regression analyses to estimate odds ratios (OR)

and 95% confidence intervals (95%-CI). Positive Predictive Values (PPV) were calculated.
Results: The median age was 76 years (70−96). The majority of patients underwent major surgery (n = 240; 69.6%). Postoperatively 64 patients (18.9%) experienced major complications. GFI and VES were not associated to 30-day morbidity in a univariate logistic regression analysis (GFI: OR 1.52; 95% CI=0.81–2.87; p = 0.20. VES: OR 1.63; 95% CI=0.85–3.11; p = 0.14). In a multivariate logistic regression analysis, adjusted for center, gender and minor or major surgery, TUG and CGA were predictive of 30-day morbidity (table 1).

Table 1. Results

	OR (95% CI; p-value)	Major complications in patients with	
		Good test results	Poor test results
TUG	3.16 (1.20–8.31; 0.020)	13.6%	45.7%
CGA	3.25 (1.52–6.94; 0.002)	11.9%	36.5%

Conclusions: In onco-geriatric surgical patients the time-saving TUG is an appropriate screening tool with a similar predictive ability as the CGA. TUG identifies even more patients at risk of adverse outcome.
No conflict of interest.

Performance of two geriatric screening tools in older cancer patients

C. Kenis[1], L. Decoster[2], K. Vanpuyvelde[3], J. De Grève[2], G. Conings[2], K. Milisen[4], J. Flamaing[5], J.P. Lobelle[6], H. Wildiers[7]. *[1]University Hospitals Leuven, Department General Medical Oncology and Geriatric Medicine, Leuven, Belgium; [2]Oncologisch Centrum Universitair Ziekenhuis Brussel Vrije Universiteit Brussel, Department Medical Oncology, Brussel, Belgium; [3]Universitair Ziekenhuis Brussel Vrije Universiteit Brussel, Department Geriatric Medicine, Brussel, Belgium; [4]University Hospitals Leuven and KU Leuven, Department Geriatric Medicine and Health Services and Nursing Research, Leuven, Belgium; [5]University Hospitals Leuven and KU Leuven, Department Geriatric Medicine and Department of Clinical and Experimental Medicine, Leuven, Belgium; [7]University Hospitals Leuven and KU Leuven, Department of General Medical Oncology and Department of Oncology, Leuven, Belgium*

Background: To compare the diagnostic characteristics of two geriatric screening tools (G8 and Flemish version of the Triage Risk Screening Tool (fTRST)) to identify patients with a geriatric risk profile and to evaluate their predictive value for functional decline and their prognostic value for Overall Survival (OS).
Patients and Methods: Patients ⩾70 years with a malignant tumor (breast, colorectal, ovarian, lung, prostate cancer and hematologic malignancies) were prospectively included if a new cancer therapy was considered. At baseline, geriatric screening with G8 (cut-off ⩽14) and fTRST (cut-off ⩾1 (= fTRST(1)) and ⩾2 (= fTRST(2)) evaluated) was performed in all patients, as well as a Geriatric Assessment (GA). The GA was used as gold standard and based on the presence of at least 2 of the following 7 criteria: 1/ living alone, 2/ ADL score >6, 3/ IADL score <5(male)/8(female), 4/ MMSE score <24, 5/ GDS-15 score ⩾5, 6/ MNA score <24 and 7/ presence of at least one comorbidity on the CCI. Functionality was reevaluated 2 to 3 months after cancer treatment decision. Functional decline (increase of ⩾2 points for ADL; decrease of ⩾1 point for IADL) and OS were assessed by logistic regression and by Kaplan–Meier method and Cox' regression, respectively.
Results: 937 patients have been included in this study (10/2009−07/2011). A geriatric risk profile according to the gold standard was present in 73.5% of the patients. G8 and fTRST(1) showed high sensitivity (86.5%-91.3%) and moderate NPV (61.3%-63.4%) and specificity (59.3%-41.9%) to detect patients at risk for geriatric profile while fTRST(2) performed worse.
Functional decline for ADL was observed in 17.3%, for IADL in 35.9% of the patients. For prediction of functional decline on ADL and IADL, G8 and fTRST(1) also had higher sensitivity than fTRST(2).
For evaluating OS, the median follow-up is 18.95 months (range: 0–39.7). G8 and fTRST(1;2) all showed a strong prognostic value for OS (logrank p-value <0.0001). However, G8 had higher discriminatory power than fTRST(2) as suggested by Hazard Ratios (HR) for OS: HR G8 negative versus positive 0.38 (95% CI: 0.27–0.52), HR fTRST(2) negative versus positive 0.67 (95% CI: 0.53–0.85), while fTRST(1) was not retained in the stepwise regression.
Conclusion: Both geriatric screening tools, G8 and fTRST, are simple and fast screening tools with great potential for identifying patients with a geriatric risk profile, strongly predict functional decline and have a strong prognostic value for OS.
Note: Cindy Kenis and Lore Decoster have equal contribution for this abstract.

Decreasing resection rates over time among patients with gastrointestinal cancer

A.D. Speelman[1], Y.R.B.M. Van Gestel[2], H.J.T. Rutten[3], I.H.J.T. De Hingh[3], V.E.P.P. Lemmens[4]. *[1]Comprehensive Cancer Centre South, Department Care and Education, Eindhoven, Netherlands; [2]Comprehensive Cancer Centre South, Eindhoven Cancer Registry, Eindhoven, Netherlands; [3]Catharina Hospital, Department of Surgery, Eindhoven, Netherlands; [4]Comprehensice Cancer Centre South, Eindhoven Cancer Registry, Eindhoven, Netherlands*

Background: We evaluated surgical resection rates over time among patients with oesophageal, gastric, colon, rectal, or pancreatic cancer, according to age.
Material and Methods: 41.671 patients diagnosed between 1995–2011 in the Eindhoven Cancer Registry area were included: 3.385 patients with oesophageal cancer, 5.560 with gastric cancer, 18.613 with colon cancer, 10.224 with rectal cancer, and 3.889 with pancreatic cancer.
Age was categorized as <55, 55−64, 65−74, 75−84, and ⩾85 years, period of diagnosis as 1995–1998, 1999–2002, 2003–2006, and 2007–2011. Multivariate logistic regression analysis determined the independent influence of period of diagnosis on the chance of undergoing resection, adjusted for age, gender, tumour penetration depth (cT), lymph node stage (cN), metastatic disease (cM), comorbidity, and socioeconomic status.
Results: Resection rates decreased with increasing age from 40% for patients with oesophageal cancer <55 years to 0% for patients ⩾85 years. For patients with gastric cancer, resection rates decreased with increasing age from 48% to 24%, for colon cancer from 88% to 73%, for rectal cancer from 83% to 44%, and for pancreatic cancer from 15% to 1%, respectively. Resection rates decreased between 1995–1998 and 2007–2011 for gastric, colon, and rectal cancer, most notably for patients with rectal cancer 75−84 years (76% 1995–1998 to 64% 2007–2011), and ⩾85 years (54% to 36%), and for patients with gastric cancer ⩾85 years (33% to 13%). The adjusted odds of undergoing a resection decreased over time for oesophageal (odds ratio (OR) = 0.9, 95% confidence interval (95% CI)=0.7−1.2), gastric (OR=0.6 95% CI=0.5−0.7), colon (OR=0.6, 95% CI=0.6−0.7) and rectal cancer (OR=0.4, 95% CI=0.4−0.5), but increased for pancreatic cancer (OR=3.2, 95% CI=2.1−5.0).
Conclusion: Resection rates decreased over time, especially for elderly patients, except an increase for pancreatic cancer. It should be evaluated to what degree decreased resection rates reflect unjust withholdment of potentially curative treatment, or whether it reflects availability of other treatment options (e.g. chemoradiation) and results in a more adequate selection of patients that might benefit of surgical resection. It should be ascertained that not the increased attention by public, audits, health inspectorate, insurance companies, etc. for mortality rates at individual hospital level, but the improved selection for surgical treatment is the reason for this reduction.
No conflict of interest.

Analysis of docetaxel therapy in elderly (⩾70 yrs) castration resistant prostate cancer (CRPC) patients enrolled in the Netherlands Prostate Study (NePro)

F. Gerritse[1], H.J. Meulenbeld[2], J.M.L. Roodhart[1], A.M.T. Van der Velden[3], R. De Wit[4], M. Los[1]. *[1]St Antonius Hospital, Internal Medicine, Nieuwegein, Netherlands; [2]Gelre Hospitals, Internal Medicine, Zutphen, Netherlands; [3]Tergooi Hospitals, Internal Medicine, Hilversum, Netherlands; [4]ErasmusMC, Internal Medicine, Rotterdam, Netherlands*

Background: Prostate cancer truly is an age-associated disease, approximately half of prostate cancer patients in the Netherlands are aged 70 years or older at the time of diagnosis. Due to the increased life expectancy and more sensitive diagnostic techniques in the Western world, prostate cancer, like most other malignancies, is diagnosed more frequently and with rapidly increasing incidence and prevalence rates. However, age above 70 years has been an exclusion criterion in many clinical trials. Hence the knowledge about chemotherapy tolerance and toxicity in patients aged 70 years and above is limited. This possibly results in mistreatment of cancer patients of advanced age. The aim of this study was to evaluate the influence of age on docetaxel chemotherapy in elderly (⩾70 yrs) castration resistant prostate cancer (CRPC) patients.
Material and Methods: We performed a retrospective analysis of data acquired from the recently published Netherlands Prostate Study (NePro) to evaluate the influence of advanced age on docetaxel therapy (75 mg/m^2) in men with CRPC and bone metastases (mCRPC). For statistical analyses the data was stratified into four categories: <70, 70−74, 75−79, and ⩾80 years of age. Docetaxel tolerance was quantified by assessment of completion of the first three cycles at the intended dose. Common

Terminology Criteria for Adverse Events (CTCAE) version 2.0 was used to grade toxicity. Time to progression (TTP) was assessed as previously described.
Results: We analysed 568 patients (median age 68.1 yrs, range 46−89 yrs, 44.5% aged ⩾70 yrs). There was no relation between dosage and age (p = 0.60). We found no significant differences between the number of dose reductions, TTP, overall survival, chemotherapy tolerance and toxicity up to the age of 80 years. However, when compared to younger men, men aged 80 years or above more frequently experienced grade 3/4 toxicity, were five times less likely to complete the first three treatment cycles at the intended dose (OR 5.34, p = 0.0052) and showed decreased overall survival (15.3 mos versus 24.5 mos in <80 yrs group, p = 0.020).
Conclusions: In mCRPC, and possibly other cancer patients, up to the age of 80 years docetaxel chemotherapy is well tolerated with toxicity levels, tolerance and TTP comparable to that of younger patients. However, for chemotherapeutic treatment of patients aged 80 years and above an individual assessment should be made.
No conflict of interest.

1554 ORAL

Hormone receptor positive breast cancer in patients aged 75 years and older: Limited external validity of clinical trial results

W. Van de Water[1], M. Kiderlen[1], E. Bastiaannet[1], C.J.H. Van de Velde[1], R.G.J. Westendorp[2], C. Seynaeve[3], J.W.R. Nortier[4], A.J.M. De Craen[2], G.J. Liefers[1]. *[1]Leiden University Medical Center, Surgery, Leiden, Netherlands; [2]Leiden University Medical Center, Geriatrics and Gerontology, Leiden, Netherlands; [3]Erasmus MC − Daniel den Hoed Cancer Center, Medical Oncology, Leiden, Netherlands; [4]Leiden University Medical Center, Medical Oncology, Leiden, Netherlands*

Background: Despite comprising a large proportion of all breast cancer patients, elderly are underrepresented in clinical trials. Moreover, inclusion is likely to be selective. This may hamper the generalizability of trial results to the general elderly breast cancer patient. The aim of this study was to evaluate the external validity of a randomized clinical trial which included elderly patients, by comparing characteristics and outcomes of trial patients with patients in a population-based cohort.
Material and Methods: A trial cohort (Tamoxifen Exemestane Adjuvant Multinational (TEAM) trial) and a population-based cohort of elderly breast cancer patients (FOCUS cohort) were included. Inclusion was restricted to Dutch patients aged ⩾65 years at diagnosis, who had non-metastasized breast cancer with positive hormone-receptor status, who completed local therapy with curative intent. Analyses were stratified by age (65−75 years; ⩾75 years). Endpoints were overall mortality, and relative mortality as an approximation of disease specific mortality.
Results: Overall, 2,738 patients were included (TEAM cohort n = 1,325; FOCUS cohort n = 1,413). Irrespective of age, trial patients had fewer comorbid diseases and a higher socio-economic status as compared to patients in the population-based cohort. Trial patients had more often nodal involvement (all p values <0.001). In patients aged 65−75 years, overall mortality was similar for both cohorts (Table 1). Contrary, patients aged ⩾75 years in the population based cohort had an increased risk of death as compared to trial patients of similar age. Irrespective of age, relative mortality was similar for both cohorts.
Conclusions: With increasing age, inclusion in a clinical trial is more selected for general health. Therefore, results obtained in a trial may not necessarily be valid for the general elderly breast cancer patient aged ⩾75 years.
No conflict of interest.

Table: Overall mortality by cohort, stratified by age at diagnosis

	65−75 years			⩾75 years		
	5 years death (%)	HR (95% CI)	p	5 years death (%)	HR (95% CI)	p
Univariate			0.7			**<0.001**
Trial	14	1 (reference)		28	1 (reference)	
Population	14	1.05 (0.80–1.37)		38	1.54 (1.24–1.91)

Low grade toxicities can have significant impact on chemotherapy completion in older patients

T. Kalsi[1], N. Maisey[2], P. Ross[2], S. Hughes[3], P. Fields[4], Y. Wang[5], D. Harari[1]. *[1]Guys & St Thomas' NHS Foundation Trust, Ageing & Health, London, United Kingdom; [2]Guys & St Thomas' NHS Foundation Trust, Medical Oncology, London, United Kingdom; [3]Guys & St Thomas' NHS Foundation Trust, Clinical Oncology, London, United Kingdom; [4]Guys & St Thomas' NHS Foundation Trust, Haematology, London, United Kingdom; [5]Kings College London, NIHR Bimedical Research Centre, London, United Kingdom*

Background: In clinical trials, clinically meaningful toxicity is usually defined as grade 3/4. In clinical practice, however, multiple lower grade toxicities are often considered meaningful. We hypothesise that multiple low grade toxicities may be a common reason for treatment modification/discontinuation in older people. The purpose of this observational cohort study was to identify which level of toxicity (and how many) trigger a) treatment modification (defined as dose reductions, delays or drug omissions) and b) early discontinuation of treatment.
Material and Methods: Patients aged 65+ were recruited via oncology clinics and the chemotherapy day unit in a tertiary referral hospital in central London. The overall study aimed at identifying the comprehensive geriatric assessment needs of older people with cancer (LREC 09H71865). We present a subgroup of 108 patients aged 65+ who were recruited just prior to commencing chemotherapy treatment between October 2010 and July 2012.
Results: Mean age 72.1 ±5 years (range 65−86). 50.9% (55) male with colorectal (33), gynaecological (18), upper GI (16), lung (15) and other cancers (26). Chemotherapy was palliative in 59.3% (64/108) and curative/adjuvant/neoadjuvant in 40.7% (44/108). Mean chemotherapy cycles completed 4.2 ±3. Treatment modifications due to toxicity occurred in 60 patients, 35% (21/60) of whom had no greater than grade 2 toxicity. Of these 21, the mean number of grade 2 toxicities resulting in treatment modification was 2.19+/−1.33, 7 patients had only one grade 2 toxicity. Early treatment discontinuation due to toxicity occurred in 23 patients, 39.1% (9/23) of whom had no greater than grade 2 toxicity. Of these 9, the mean number of grade 2 toxicities resulting in treatment discontinuation was 1.78+/−1.20, 3 had only one grade 2 toxicity, 1 patient only grade 1 toxicities.
Conclusions: In this cohort, many older patients did not complete treatment as planned. Treatment was modified/discontinued even for one or two low grade toxicities. Low grade toxicity resulted in treatment modification for 19.4% (21/108) and treatment discontinuation for 8.3% (9/108) of the whole cohort. Further work is required to clarify whether low grade toxicity has a greater clinical impact in older people, or whether clinicians have a lower threshold for modifying/discontinuing treatment in older people.
No conflict of interest.

Poster Session (Mon, 30 Sep)
Cancer in the Older Patient

1556 POSTER

Association between age at diagnosis and breast cancer outcome among elderly breast cancer patients − a FOCUS population-based study

M. Kiderlen[1], W. Van de Water[1], E. Bastiaannet[1], A.J.M. De Craen[2], R.G.J. Westendorp[3], C.J.H. Van de Velde[1], G.J. Liefers[1]. *[1]Leiden University Medical Center, Surgery, Leiden, Netherlands; [2]Leiden University Medical Center, Gerontology and Geriatrics, Leiden, Netherlands; [3]Leyden Academy on Vitality and Ageing, Leiden, Netherlands*

Background: Almost half of all breast cancers occur among the elderly population (65 years and older). Although tumor biology is often considered more favorable in the elderly, it was recently shown that breast cancer specific mortality was higher and recurrence rate was worse among the oldest elderly in a trial population. However, it is unknown whether this association persists in breast cancer patients in the general population. Therefore, the aim of this study was to explore the association between age and breast cancer outcome in a detailed population-based cohort of elderly breast cancer patients.
Methods: Patients were selected from the FOCUS cohort study, a population-based study of all consecutive elderly breast cancer patients diagnosed between 1997 and 2004 in the South Western part of The Netherlands. All patients with non-metastasized breast cancer who

received at least breast surgery were included in the current study. Primary endpoint was relative mortality (as the ratio between observed mortality in the cohort and expected mortality in the general population). Secondary endpoints were locoregional recurrence, distant recurrence and contralateral breast cancer. The endpoints were compared between the younger elderly (65−74 years) and the older elderly (75 years and older), using multivariable Cox models and Fine and Gray analyses to account for competing risks.
Results: Overall, 3,124 patients with a median age of 74.6 years were included. The oldest age group presented with more comorbidity, more hormone receptor positive cancer and higher disease stage, and they were treated less extensively. Relative mortality was higher for the oldest patients, as compared to patients aged 65−74 (multivariable RER 1.72, 95% CI 1.21–2.44; p = 0.003). The difference in relative mortality was most pronounced among patients with early stage disease. Recurrence free period for the development of locoregional recurrences, distant recurrences or contralateral breast cancer was similar for both age groups.
Conclusions: In the present study, we found an age-specific increase in relative mortality among elderly breast cancer patients. The age-specific increased mortality was not accompanied by a decreased recurrence free period. This may be due to under-registration or under-diagnosis of recurrent disease among elderly.
No conflict of interest.

1557 POSTER

Patient-reported information on diagnosis and cancer treatments in elderly: A cross-sectional analysis of the ELCAPA cohort study

E. Kempf[1], P. Caillet[2], C. Tournigand[1], E. Liuu[2], B. Rousseau[1], J.L. Lagrange[3], S. Bastuji-Garin[4], E. Paillaud[2], A. Le Thuaut[2], F. Canoui-Poitrine[4]. *[1]Hôpital Henri Mondor, Medical Oncology, Creteil, France; [2]Hôpital Henri Mondor, Geriatric Department, Creteil, France; [3]Hôpital Henri Mondor, Radiotherapy, Creteil, France; [4]Hôpital Henri Mondor, Clinical Research Unit, Creteil, France*

Background: Little is known about how the medical information regarding diagnosis and treatment is delivered and reported in elderly cancer patients. The objective was to assess the level and the factors associated with patient-reported information regarding cancer diagnosis and treatment proposal in elderly cancer patients.
Methods: From 2007 to 2012, all consecutive cancer patients aged 70 years or older referred to the geriatric oncology clinic were included in the prospective ELderly CAncer PAtients cohort survey (ELCAPA). Patients were systematically asked about the information received regarding diagnosis and treatment proposal. The interest variable was the level of patient-reported information: fully, partially or not reported. Analysis was done using ordered logistic regression.
Results: From 1103 included patients 691 had available data: mean age 80 (±5.6), 51.4% of men, metastatic 40.8%, colorectal cancer 23.1%, upper gastro-intestinal or liver 17.9%, breast 16.8%, urologic 23.6%. 306 (48.5%) had an anti-cancer treatment proposal with curative intent, 179 (28.4%) with palliative intent, and 146 (23.1%) had exclusive supportive care. 600 (86.8%; 95% CI: 84.3–89.3) reported a complete information, 35 (5.1%; 3.4−6.7) a partial and 56 (8.1%, 6.0–10.1) no information. In multivariate analysis, factors associated with a poorer level of patient-reported information were increasing age (1-year increase: adjusted OR (aOR), 1.07; 95% CI: 1.01–1.13, p = 0.01), type of treatment proposal (palliative vs curative treatment: aOR, 2.83; 95% CI:1.29–6.22, exclusive supportive care versus curative aOR 3.51, 1.57–7.84, p = 0.01), depressive symptoms (mini-Geriatric Depression Scale (⩾1vs<1) aOR, 2.07, 1.12–3.84, p = 0.02), cognitive impairment (MMSE (⩽24vs>24/30), aOR, 2.07, 1.12–3.84, p = 0.02), increasing nb drugs (1-drug increase aOR, 1.09, 0.99–1.22, p = 0.06). Functional status assessed by performance status and Activity Daily Living score was not independently associated with the level of patient-reported information due to a high correlation with the treatment type.
Conclusion: Level of patient-reported information is high in elderly cancer patients. But those with a palliative anti-cancer treatment or exclusive supportive care are less able to report the diagnosis or treatment information than those with a curative intent. Increasing age, depressive symptoms, cognitive impairment and polymedication were independently associated with a poorer patient-reported information.
No conflict of interest.

1558 POSTER

Clinical benefit of a one-day multidisciplinary work-up for risk assessment in unfit cancer patients

P. Boudou-Rouquette[1], A. Thomas-Schoemann[2], A. Chahwakilian[3], L. Cabanes[4], A. Tesniere[5], J. Stephanazzi[5], G. Orvoen[3], H. Mosnier-Pudar[6], J.P. Durand[1], F. Goldwasser[1]. *[1]Cochin Hospital AP-HP Paris Descartes University Sorbonne Paris Cité Paris France, Oncology, Paris Cedex 14, France; [2]Cochin Hospital, Pharmacy, Paris Cedex 14, France; [3]Broca Hospital, Gerontology, Paris Cedex 14, France; [4]Cochin Hospital, Cardiology, Paris Cedex 14, France; [5]Cochin Hospital, Anesthesiology, Paris Cedex 14, France; [6]Cochin Hospital, Diabetology, Paris Cedex 14, France*

Background: Unfit cancer patients are exposed to excessive drug toxicity or suboptimal treatment. The rapidly growing elderly cancer population makes urgent treatment guidelines for patients with comorbidities, polypharmacy or psycho-social frailty.
An early pre-therapeutic multidisciplinary assessment might improve the unfit patient management. We developed an experimental multidimensional program of integrated medicine called ARIANE, and evaluated its impact on treatment decision-making and patient trajectory.
Material and Methods: Unfit patients with an existing defined cancer treatment strategy entered into the program. A one-day multidisciplinary evaluation in outpatient setting combined consultations of cardiologist, geriatrician, diabetologist, anesthetist, pharmacist, pain specialist, dietician, psychologist and social worker. Staff meeting was conducted on a weekly basis. The day ended with a multidisciplinary meeting to decide either no change, or reinforced supportive measures follow-up, or upgrading of the treatment strategy, or less aggressive treatment option.
Results: Between March 2012 and February 2013, 41 patients, median age 76 years (range 25−88), 85% male, 59% PS 0−1, 90% grade 3 or 4 comorbidity in CIRS-G scale, were included. Genito-urinary, lung cancers and sarcoma represented 76% of pts. Eighty-three percent of pts were assessed by at least ⩾7 participants. Identified factors of vulnerability were polypharmacy (n = 34; 83%; >3 drugs), social distress (n = 12; 29%), depression based on GDS-scale or cognitive impairment (both n = 8; 19.5%) and severe malnutrition (n = 7; 17%). We identified drug interaction in 11 pts (27%). Amongst 30 elderly patients, only 9 were frail. The risk assessment resulted in anticancer treatment changes in 27/41 patients (66%): protocol adaptation (n = 10/41; 24%), less aggressive treatment (n = 8/41; 19.5%), or more intensive therapy (n = 9/41; 22%).
Conclusion: A one-day multidisciplinary risk assessment is feasible in the outpatient setting and results in changes in treatment strategy in the majority of unfit cancer patients.
Conflict of interest: *Ownership: none. Advisory board: Nutricia, Frésénius. Board of directors: none. Corporate-sponsored research: none. Other substantive relationships: none.*

1559 POSTER

Correlation of comprehensive geriatric assessment (CGA) with mortality in elderly patients with lung cancer: A single institution cohort analysis

G.Z. Dal Molin[1], G.E. Lima[1], P.S. Iennaco[1], A.T.A.R. Pereira[1], T.C. Felismino[1], H.C. Freitas[1], B.C.M. Figueroa[1], S.M. Sanches[1], M.F. Fanelli[1], A.L.A. Dettino[1]. *[1]AC Camargo Cancer Center, Clinical Oncology, São Paulo, Brazil*

Background: In the last 60 years, >65 y population in Brazil has increased more than eigth-fold, from 1.6 million to more than 13 million people. This shift in demographics has a huge impact in healthcare, specially in oncology. Nevertheless, so far there is no national innitiative focusing oncologic geriatric patients. This study is part of an innitiative to improve oncologic care in geriatric patients in a single institution in São Paulo, Brazil.
Material and Methods: Since March/12, all patients >70 y admitted at AC Camargo Cancer Center have been submitted to CGA tools: Katz, Lawton, Nutritional Status (Mini nutritional assessment), Depression scales (GDS), comorbidities and polypharmacy analysis. The aims of the study were to assess if CGA could be feasible in daily practice and if it could be useful as a tool in treatment decision making. Statistical analysis used chi-square or Fisher exact tests, when indicated. Survival analysis was performed by Kapplan-Meier curve and group's comparison by the log-rank test and Mantel-Cox test. The results here presented refer only to lung cancer patients.
Results: From Mar/12 to Feb/13, 73 lung cancer pts were analyzed. Median age at admission was 75 y, 53% male, 47% female. Histology distribution was 57% adenocarcinoma, 22% squamous cell, 12% other non small cell and 9% small cell. Staging distribution was I (10%), II (8%), III (24%), IV (58%). There was an association between mortality and Katz (A

vs B/C; p = 0.004), Lawton (27 vs <27; p = 0.047), nutrition status (nutrition vs undernutrition/risk for undernutrition; p = 0.004) and performance status (0/1 vs ⩾2; p = 0.013). There was no association between mortality and the other parameters analyzed: number of comorbidities (⩽2 vs >2; p = 0.44), polypharmacy (<5 vs ⩾5; p = 0.73), age (<79 vs ⩾80; p = 0.95) and sex (male vs female; p = 0.52).
Conclusion: In this cohort, the incorporation of CGA tools in daily practice was feasible, able to predict mortality and could be useful in the treatment planning in elderly patients with lung cancer.
No conflict of interest.

Categories	Mean survival (months)	Statistical analysis (p, x^2)
PS 0/1 vs ⩾2	65.5 vs 20.8	p = 0.013, x^2 = 6.16
Katz A vs B/C	72.15 vs 29.42	p = 0.004, x^2 = 8.38
Lawton 27 vs <27	77.84 vs 37.23	p = 0.047, x^2 = 3.94

PS: performance status.

1560 POSTER

Concurrent chemoradiotherapy for elderly (over 75 years of age) patients with esophageal cancer

K. Takashima[1], A. Hata[1], J. Takeshita[1], K. Tanaka[1], R. Kaji[1], S. Fujita[1], K. Takayama[2], M. Kokubo[2], T. Inokuma[3], N. Katakami[1]. *[1]Institute of Biomedical Research and Innovation, Division of Integrated Oncology, Kobe, Japan; [2]Institute of Biomedical Research and Innovation, Division of Radiation Oncology, Kobe, Japan; [3]Kobe City Medical Center General Hospital, Department of Gastroenterology, Kobe, Japan*

Background: Evidence of concurrent chemoradiotherapy (CRT) has been established in younger patients with esophageal cancer (EC), but there is little data on the efficacy and safety of concurrent CRT for elderly patients. Conventional standard dose cisplatin plus 5-FU in CRT is generally not feasible for elders, and optimal chemo-regimens are unknown.
Patients and Methods: Betweeen 2007 and 2012, thirty consecutive elderly (⩾75 years) patients with EC underwent concurrent CRT in our institute. These patients were not considered surgical candidates due to age, comorbidity, patient refusal, or stage IVb. We retrospectively reviewed the efficacy and safety of CRT in the patients. Patients were sorted into two major groups: 5-FU- and taxane-based regimens. Comparison between these chemo-regimens was performed.
Results: Median age was 79 years (range, 75−88). Patient clinical stages were stage I:3; II:5; III:5; IVa:5; and IVb:8. Fourteen 5-FU-based regimens (10 cisplatin plus 5-FU, 3 S-1, and 1 5-FU) or 16 taxane (12 carboplatin plus paclitaxel, 2 paclitaxel, 1 docetaxel, and 1 cisplatin plus docetaxel) were administered as chemotherapies. Median total dose of radiotherapy was 60 Gy (range, 30−66 Gy). Twelve complete response (CR) and 8 partial response were confirmed, and overall response rate was 67%. Median progression-free (PFS) survival was 13.7 months (95% confidence interval, 6.3–32.3 months). Median overall survival was not reached. Regarding grade 3/4 adverse events, 8 (27%) neutropenia, 2 (7%) anemia, 2 (7%) febrile neutropenia, 1 (3%) esophagitis, and 1 (3%) dermatitis cases were observed. Treatment-related death due to broncho-esophageal fistula was suspected in one (3%) patient. Median PFS with taxane-based regimens was 19.1 months, and that of 5-FU-based was 8.4 months (p = 0.2837). Response rates and safety profiles were similar between taxane- and 5-FU-based regimens. Six (50%) of 12 patients who had received carboplatin plus paclitaxel achieved CR.
Conclusions: Our data suggest the efficacy and safety of concurrent CRT in elderly patients with EC. Carboplatin plus paclitaxel may be a potentially optimal regimen for elderly patients in CRT, and warrants future studies.
No conflict of interest.

1561 POSTER

Comprehensive Geriatric Assesment (CGA) based risk factors for caregiver burden amongst elderly asian cancer patients

T. Rajasekaran[1], W.S. Ong[2], T. Tan[1], K.N. Koo[3], D. Poon[4], R. Kanesvaran[5]. *[1]National Cancer Centre Singapore, Medical Oncology, Singapore, Singapore; [2]National Cancer Centre Singapore, Clinical Trials and Epidemiology Unit, Singapore, Singapore; [3]Perdana Medical School Malaysia, Malaysia, Malaysia; [4]Raffles Hospital Singapore, Singapore, Singapore; [5]National Cancer Centre Singapore, Medical Oncology, Singapore, Singapore*

Background: The vital role played by caregivers in supporting elderly cancer patients is well recognized. While a number of caregiver burden analysis tools have been developed, none are based on clinical factors in the elderly cancer patient setting. This study aims to identify CGA based risk factors to help predict caregiver burden among elderly cancer patients.
Materials and Method: 249 newly diagnosed cancer patients aged 70 years and above, who attended the geriatric oncology clinic at the National Cancer Centre Singapore between 2007 and 2010 were evaluated.
Categorical characteristics were compared using Chi-square test or Fisher's exact test. Mann-Whitney U test was used to compare the continuous characteristics. Logistic regression models were fitted to assess the association of the variables with mild to severe caregiver burden. Multivariate analyses were performed on variables significant on univariate analysis.
Results: 244 of 249 patients had available information on caregiver burden. The median age of the patients was 77 and they were mainly males (61.1%).
Factors that were significantly associated with mild to severe caregiver burden on univariate analysis were ADL dependence (odds ratio [OR], 2.60; 95% CI, 1.29–5.24;), cognitive impairment (OR, 2.44; 95% CI, 0.71–8.41;), ECOG performance status 3−4 (OR, 5.14; 95% CI, 2.69–9.83;) higher fall risk (OR, 3.91; 95% CI, 1.52–10.04;), lower scores in dominant hand grip strength test (OR, 0.96; 95% CI, 0.94–0.98;), abbreviated mental test (OR, 0.80; 95% CI, 0.69–0.94;) and mini mental state examination (OR, 1.91; 95% CI, 1.01–3.59;), polypharmacy (OR, 2.22; 95% CI, 1.13–4.34;), higher nutritional risk (OR, 3.99; 95% CI, 1.58–10.05;), lower haemoglobin levels (OR, 3.25; 95% CI, 1.61–6.56;) and geriatric syndromes (OR, 4.60; 95% CI, 2.13–9.91;).
On multivariate analysis, only ECOG performance status of 3−4 (OR, 4.47; 95% CI, 2.27–8.80;) and abnormal haemoglobin levels (OR, 2.38; 95% CI, 1.14–4.99;) were associated with an increased probability of mild to severe caregiver burden.
Conclusion: ECOG performance status and haemoglobin were associated with mild to severe caregiver burden among elderly cancer patients. Using these factors may help clinicians identify caregivers at risk and take preventive action to mitigate that.
No conflict of interest.

1562 POSTER

Determinants of wellbeing in elderly non-small cell lung cancer patients: Are we asking the right questions? An explorative study

H.T.G.M. Scholtens[1], H. Ziengs[1], M. Kok[2], A. Vincent[3], J.P.J. Slaets[2], O. Dalesio[3], H.J.M. Groen[1]. *[1]University Medical Center Groningen, Pulmonology, Groningen, Netherlands; [2]University Medical Center Groningen, Gerontology, Groningen, Netherlands; [3]National Cancer Institute, Biostatistics, Amsterdam, Netherlands*

Purpose: Chemotherapy is used to improve quality of life and median survival. The established quality of life questionnaires focus almost exclusively on parameters of negative wellbeing. The current study is an explorative study into determinants of wellbeing in elderly patients suffering from advanced non-small cell lung cancer (NVALT-3 study).
Patients and Methods: A total of 990 geriatric assessments (MGA) completed by 119 patients within 24 weeks of randomization were included. The analysis consisted of two stages. Items from the repeated MGAs at baseline, during and after chemotherapy, were divided into those with positive and negative wellbeing. Hierarchical cluster analysis was used to determine which items formed wellbeing clusters. During the second stage of analysis, these wellbeing clusters were used to assess patterns of patient wellbeing throughout time, based on similarity in wellbeing domain scores.
Results: Four independent (one positive and three negative) wellbeing clusters were distinguished, which included ninety per cent of all patients. Subsequently, four patterns of patient wellbeing throughout time were observed. The first patient cluster did not benefit from chemotherapy. The second and fourth cluster benefits from chemotherapy. The estimates for cluster 3 are less straightforward: although physical symptoms worsen during treatment, the negative affect improves temporarily.
Conclusion: Four different patient patterns of wellbeing were found throughout chemotherapy. Positive wellbeing is inadequately reflected in quality of life questionnaires.
No conflict of interest.

1563 POSTER

Persistence to aromatase inhibitor therapy among older women with breast cancer

L. Huiart[1], A.D. Bouhnik[2], D. Rey[2], F. Rousseau[3], F. Retornaz[4], M. Meresse[2], M.K. Bendiane[2], P. Viens[5], R. Giorgi[6]. [1]*CHU La Réunion − CHFG, Unité de Soutien Méthodologique, Saint-Denis, France;* [2]*INSERM U912 (SESSTIM), Marseille, France;* [3]*Institut Paoli-Calmettes, Medical Oncology Department, Marseille, France;* [4]*Centre Gérontologique Départemental, Marseille, France;* [5]*Institut Paoli-Calmettes, Marseille, France;* [6]*Université Aix Marseille, Marseille, France*

Purpose Aromatase inhibitor therapy (AI) significantly improves survival in breast cancer patients. Little is known about adherence and persistence to aromatase inhibitors and about the causes of treatment discontinuation among older women. Our objective was to combine multiple sources of data in order to describe adherence and persistence to AI − using prescription refills and patients' questionnaires − in a cohort of post-menopausal women with BC.
Methods: The ELIPPSE 65 cohort was constituted in order to document the medium and long-term psychosocial impact of BC on women over 65. Between 2006 and 2008, 382 women over 65 receiving a first AI therapy for breast cancer were included and followed until June 2011. Women were selected from the French National Health Insurance databases. We used survival analysis methods to study time to treatment discontinuation.
Results: Overall, using pharmacy refills, non-persistence to treatment decreased over time: from 8.7% (95% CI: 6.2–12.1) at 1 year, to 15.6% (95% CI: 12.2–19.8) at 2 years, 20.8% (95% CI: 16.7–25.6) at 3 years, and 24.7% (95% CI: 19.5–31.0) at 4 years. In addition, 13% of the women with positive hormonal receptor status at cohort entry did not fill any prescription for anti-hormonal therapy. During patients' follow-up, 35 of the 382 women switched from AIs to tamoxifen. Among continuous users of AI treatment, 93.5% (n = 357) had more than 80% of days covered by medication.
Using questionnaires, 292 of the 382 women reported taking their medication without outside help. Among them, 10.7% reported having forgotten to take their hormonal treatment at least once. The most frequent reason mentioned (29.7%) was not being at home when supposed to take the treatment. Self report of non-adherence by women was not associated with decreased persistence to treatment measured by pharmacy refills.
Conclusion: In our cohort of older women with BC, AI therapy is discontinued prematurely in a substantial portion of patients,using pharmacy refill data. Combining this information with patient questionnaire will enable us to identify determinants of persistence to AI therapy among the 292 women reporting taking their medication without help. Results will be discussed.
No conflict of interest.

1564 POSTER

Information needs of older women considering breast screening attendance: A mixed methods study

H. Walker[1], K. Collins[2], J.L. Morgan[1], S. Sandhu[1], V. Cox[1], M.W. Reed[1], L. Wyld[1]. [1]*University of Sheffield, Academic Unit of Surgical Oncology, Sheffield, United Kingdom;* [2]*Sheffield Hallam University, Centre for Health and Social Care Research, Sheffield, United Kingdom*

Background: Disease specific survival for older women with breast cancer are reduced compared to younger women. Older women (>70 years) have an increased risk of breast cancer yet have reduced breast symptom awareness and are no longer routinely invited for routine screening. Voluntary uptake rates are poor. There is ongoing debate about the relative risks and benefits of screening in older women and little randomised trial data to inform debate. This study has used mixed qualitative and quantitative methods to explore the information needs and preferences of older women (and health professionals) to aid informed screening decision making.
Methods: Semi structured qualitative interviews with specialist health professionals (breast surgery, radiology, specialist nurse, breast oncology) and women over 70 years were undertaken. These were analysed using framework analysis to identify themes and issues relevant to screening decision making. A bespoke questionnaire was then designed to quantify the importance of each issue in a larger cohort of women.
Results: Interviews were conducted with 23 health professionals and 19 older women (age range 71−84 years, recruited from hospital clinics). These suggested a range of information needs and preferences. A bespoke questionnaire was designed using a mixture of Likert or other quantification techniques and distributed to 177 older women attending a range of hospital clinics. The response rate was 51% (91 of 177). Only 22% (20/91) were aware that breast cancer risk increases with age with 63% (57/91) aware of self-referral service for screening. Women felt screening decision making required information about breast cancer age-specific incidence (71%; 65/91), treatment options following a breast cancer diagnosis (57%; 52/91) and local contact details for the screening unit (73%; 66/91). Screening risks were felt to be less important, and if mentioned, older women preferred risk levels to be quantified as a proportion (34%; 31/91) or statement, e.g. rare/common (34%; 31/91) rather than a percentage. The preferred format for information varied but leaflets were most popular (68%; 62/91). Web-based information was unpopular (12%; 11/91).
Conclusions: Older women have low levels of breast cancer and screening knowledge which may contribute to inferior cancer outcomes. Education may enhance informed screening uptake. This research has identified key informational needs and preferences for older women.
No conflict of interest.

1565 POSTER

Safety and efficacy of bevacizumab (Bv) in elderly patients with NSCLC adenocarcinoma

K. Syrigos[1], D. Vassos[1], M. Panagiotarakou[1], G. Tsoukalas[1], G. Athanasiadis[1], E. Sepsas[1], S. Tsimboukis[1], M. Moutsos[1], A. Charpidou[1], S. Kaltsas[1]. [1]*Sotiria General Hospital Athens School of Medicine, Oncology Unit GPP, Athens, Greece*

Background: Bv is a novel anti-angiogenic agent used in many advanced solid tumours, including non-squamous NSCLC. In contrast to clinical studies where enrolled pts are fit, many elderly NSCLC pts suffer from co-morbidities and often have history of a CVD.
Methods: Medical records of 2672 pts diagnosed with NSCLC between 2001–2012 were screened. We identified and examined pts ⩾75 yrs old treated with bev, for their demographics, clinical data and treatment (Tx) details. We focused on those elderly pts with stable pre-existing cardiovascular disease.
Results: 356/2672 NSCLC pts received Bv at any Tx line. 33/382 (8.6%) were ⩾75 yrs old. Of those, 29 had various co-morbidities including 19 pts with stable CVD on medical Tx. In the 19 pts with CVD the male:female ratio was 17:2 and mean age 77 yrs (range 75−86). 8/19 pts had impaired renal function. All pts were of Performance Status ECOG 0/1. Median number of Bv cycles was 5 (range 2−11). 17/19 pts experienced ⩾1 side effects (11 epistaxis and haemoptysis, 5 proteinuria, 4 hypertension) which led to treatment discontinuation in 5 pts. No major/fatal adverse events were noted. 8/19 pts (42%) showed radiological partial response and 5 (19%) stable disease (total disease control rate 61%). Median survival from initiation of Bv till death/last follow up was 7 months (range 2−28, 95% CI 5.14–12.55).
Conclusion: Treatment with Bevacizumab seems to be safe and effective in elderly NSCLC patients with controlled pre-existing cardiovascular disease and good PS. These patients might benefit from participation in clinical trials similarly to younger NSCLC patients.
No conflict of interest.

1566 POSTER

Safety and efficacy of erlotinib (E) in elderly patients with NSCLC adenocarcinoma

S. Kaltsas[1], I. Gkiozos[1], P. Boura[1], D. Vassos[1], A. Vassias[1], A. Bastas[1], A. Boufas[1], G. Stratakos[1], I. Ntanos[1], K. Syrigos[1]. [1]*Sotiria General Hospital Athens School of Medicine, Oncology Unit GPP, Athens, Greece*

Background: Besides chemotherapy, E is another option in NSCLC pts especially in those with EGFR mutations. Elderly pts enrolled in trials are fit without cM, but in clinical practice most suffer from cM.
Methods: Medical records of 1221 pts diagnosed with NSCLC between 2008–2012 were screened. We examined pts ⩾75 yrs for demographics, clinical data and Tx details.
Results: 233/1221 NSCLC pts received E at any line. 53/233 (23%) were ⩾75 yrs old. Male:female ratio was 34:19 and median age 79 yrs (range 75−88). NSCLC subtypes included 31 adenoca, 8 squamous cell, 9 NOS and 5 others. 50/53 pts had cM (⩾2 in 46 pts, 1 in 4pt). Main cM were cardiovascular disease (n = 41), COPD (n = 14), other cancer (n = 10) and diabetes (n = 8). 8 pts were tested for EGFR mutations (5 -ve, 3 +ve). Performance Status was satisfactory (ECOG 0−1) in 8 pts and poor (2−3) in 45pts. 8pts were treated with E 100 mg and 45 pts with E 150 mg (12 pts needed dose reduction). Complete follow up data were found in 46pts. Mean duration of treatment was 79 days (range 9–662). 35/46 pts experienced side effects (s.e) [rash n = 29, diarrhea n = 17] which led to treatment discontinuation in 12pts. Pts with abnormal creatinine clearance (n = 13) were more likely to stop treatment due to s.e (6/13 versus 6/33). 17/46 pts (37%) achieved disease control (5 PR, 12 SD) and a time to progression (TTP) of 157 days (range 106–662, 95% CI 132.79–270.74) while 22/46 pts had PD as best response (TTP 49d, range 19−88, CI 44.67−64.97). 7pts were not evaluable (stopped Tx due to s.e). All EGFR+ve pts had disease control (2PR, 1SD).

Conclusion: E is a valuable option in elderly NSCLC patients with co-morbidities, especially if they harbor EGFR mutations. Impaired renal function might be associated with propensity to side effects and earlyTx discontinuation.
No conflict of interest.

1567 POSTER

Rectal cancer management in elderly patients: Experience of a single Portuguese institution

I. Miguel[1], T. Marques[1], J. Freire[1]. [1]*Instituto Portugues de Oncologia de Lisboa Francisco Gentil, Medical Oncology, Lisboa, Portugal*

Background: Cancer is the leading cause of death between ages of 60 to 79 years in developed countries. More than a half of all cancer deaths happen in patients with more than 75 years. Colorectal cancer is the second most common neoplasia and a third of cases have origin in the rectum. We aim to evaluate the influence of age and comorbidities in rectal cancer (RC) management in a Cancer Centre in Portugal.
Material and Methods: Retrospective analyses of patients (pts) with rectal cancer aged 75 or more treated in our institution from January 2007 to March 2010. Epidemiological and clinical data were recorded. Charlson Comorbidity Index (CCI) was calculated, along with 1 and 3-year survival.
Results: 82 pts (24.6% of the total RC treated in the institution in that period), 64.6% men, mean age 79.7±3.8 years (75−91). Tumor location: lower rectum-43.9%, midrectum-42.7%, upper rectum-13.4%. TNM Stages: 39%, IIIB, 28% IIA. 74.4% had neoadjuvant treatment: 51.2% chemoradiotherapy (CHRT; protracted 5-FU) and 22% (20 pts) only radiotherapy (9 had short course). Dose reduction was needed in 26.2%. Surgery was performed in 79.3%, 65 pts (of these 73.8% had a low anterior resection). 23.2% had adjuvant chemotherapy (de Gramont regimen 14.6%). Colostomy closure was achieved in 62.5% of suited pts. Grade III/IV toxicities occurred in 17.1%. Survival was 74.4% at 1 year and 40.2% at 3 years. 56.1% are dead, median follow up (40 months). CCI was low (0−1) in 68.3% and high (⩾2) in 31.7%. Age was well balanced between both groups (mean 79.88 *vs.* 79.18 years; P = 0.459). Most frequent comorbidities were: diabetes (18.3%), myocardial infarction (15.9%), congestive heart failure (14.6%) and chronic pulmonary disease (8.5%). Pts with lower CCI scores were treated more aggressively (64.7% *vs.* 36% did CHRT; p = 0.083) and colostomy closed more frequently (81.8% *vs.* 33.3%; p = 0.04). Survival was not affected by comorbidities at 1 year (76.8% with low CCI *vs*. 69.2% with high CCI; p = 0.319) but was a trend toward decreased survival at 3 years (46.4% *vs.* 26.9%; p = 0.075). Pts with survival over 3 years tended to have CHRT more often (71% *vs.* 45.5%; P = 0.073).
Conclusions: Rectal cancer management should always include comorbidities assessment to guide the treatment choice. Our data suggests that low comorbidity elderly patients could be managed with standard treatment. Only high comorbidity patients should be managed with less intense treatment, as there is a trend for shorter survival. In those patients surgery could be simplified if colostomy closure is thought to be unlikely. These results should be viewed with caution, as they need to be tested in prospective randomized trials.
No conflict of interest.

1568 POSTER

Cardio toxicity for older breast cancer patients treated with trastuzumab

A. Bensalem[1], R. Hamdouche[1], A. Bensehamdi[1], A. Boudersa[1], N. Yousfi[1], K. Bouzid[2]. [1]*CHU Dr Benbadis Constantine Algeria, CNE, Algeria;* [2]*CPMC, Medical Oncology, Algiers, Algeria*

Background: Trastuzumab is used in adjuvant setting and metastatic setting of breast cancer who over-expressed Her. The reduction of mortality and recurrence are obtained when used. The incidence of complications, especially cardio toxicity is unknown, especially in older patients. In this study, we evaluated the rates associated with Trastuzumab regimens in older breast cancer patients.
Methods: Breast cancer patient's ⩾65 years old with diagnosed stage III−IV breast cancer, with over expression of HER, in patients between 2010–2012, treated with chemotherapy and Trastuzumab were identified and enrolled in this study.
Results: A total of 28 patients were included. 100% of them received Trastuzumab; 20 patients (71.4%) in adjuvant setting and 8 (28.5%) in metastatic setting. After adjusting for chemotherapy used, patients developed congestive heart failure in 39.2% (11 patients). 21.4% (6 patients) was observed in adjuvant setting and 17.8% (5 patients) in metastatic setting. A comparison was done with younger patients who received Trastuzumab; in adjuvant and metastatic settings. Older age increase the risk of developing congestive heart failure (39.2% Versus 20% in younger patient's). However, there was an increased risk of congestive heart failure associated with anthracycline regimens in older and younger age.
Conclusions: In this study, the risk of cardio toxicity in older breast cancer patients is higher than in younger population. Cardiac comorbidities and other clinical characteristics may identify high-risk patients. More studies and comparison in younger population are needed.
No conflict of interest.

1569 POSTER

Dynamic MRI assessment of response to a new radiosensitization treatment (KORTUC II) in patients with stage I/II breast cancer with advanced age or who refuse surgery

S. Yaogawa[1], Y. Ogawa[2], A. Tsuzuki[1], R. Akima[1], S. Tokuhiro[1], K. Morio[1], H. Yasunami[1], I. Morita[1], N. Hayashi[1], K. Itou[1]. [1]*Kochi Medical School, Diagnostic Radiology, Kochi, Japan;* [2]*Kochi Medical School, Radiation Oncology, Kochi, Japan*

Background: We developed a new tumor-injectable radiosensitizer agent that contains hydrogen peroxide and sodium hyaluronate, which can convert radioresistant tumors into radiosensitive ones. The method was named Kochi Oxydol-Radiation Therapy for Unresectable Carcinomas, Type II(KORTUC II). The advent of this agent has allowed us to perform breast-conserving treatment (BCT) without surgery for patient with stage I/II breast cancer with advanced age or who refuse surgery. Since surgery was not performed, histological confirmation of the primary tumor region following KORTUC II treatment was not possible. Dynamic magnetic resonance imaging (MRI) is highly useful for precise evaluation of the therapeutic response to neo-adjuvant chemotherapy (NAC) and/or induction chemotherapy for patients with breast cancer. Therefore, the purpose of this study was to evaluate the therapeutic response to KORTUC II treatment in patients with stage I/II breast cancer using annual dynamic MRI.
Material and Methods: The study was performed at Kochi Medical School Hospital from 2006 to 2013. Nineteen patients with stage I/II breast cancer and advanced age or who refused surgery were enrolled. Full informed consent was obtained from all patients. Hypofractionated radiation therapy (RT) was administered using a tangential field approach: energy level was 4 MV, the total dose was 44 Gy administered as 2.75 Gy/fraction. RT was performed five times per week for each patient. The new radiosensitizer was injected into the breast tumor tissue twice a week under ultrasonographic guidance, just prior to each administration of RT from the 6th fraction onwards. Chemotherapy was not administered before or after Prior to KORTUC II treatment, either due to advanced age or patient refusal. Following KORTUC II treatment, patients with estrogen receptor-positive tumors were started on endocrine therapy with an aromatase inhibitor. All patients underwent dynamic MRI prior to and every year after KORTUC II treatment. Findings from MRI were compared with those from other diagnostic modalities performed during the same time period.
Results: In all cases, dynamic MRI performed at approximately 1 year following KORTUC II treatment showed disappearance of tumors. The marked therapeutic effects of treatment were also confirmed through other diagnostic modalities performed during the same time period. None of the 19 patients had distant metastasis, and only one patient experienced local recurrence (at 34 months after KORTUC II). The mean follow-up period for patients at the end of February 2013 was 42.6 months.
Conclusions: Dynamic MRI showed that KORTUC II had a marked therapeutic effect in patients with stage I/II breast cancer. These results confirm that BCT without surgery procedure can be safely performed using this new radiosensitization treatment.
No conflict of interest.

Impaired pre-operative nutritional status is a risk factor of adverse outcome in onco-geriatric surgical patients

M.G. Huisman[1], B.L. Van Leeuwen[1], G. Ugolini[2], I. Montroni[2], C. Stabilini[3], A. Vigano[4], J. Spiliotis[5], N. De'Liguori Carino[6], G.H. De Bock[7], R.A. Audisio[8]. [1]*University Medical Center Groningen, Surgery, Groningen, Netherlands;* [2]*S. Orsola Malphighi Hospital, Surgery, Bologna, Italy;* [3]*San Martino University Hospital, Surgery, Genua, Italy;* [4]*McGill University Health Center, Oncology, Montreal, Canada;* [5]*Metaxa Cancer Hospital/Regional University Hospital, Surgery, Piraeus/Patras, Greece;* [6]*North Manchester General Hospital, Surgery, Manchester, United Kingdom;* [7]*University Medical Center Groningen, Epidemiology, Groningen, Netherlands;* [8]*University of Liverpool St. Helens Teaching Hospital, Surgery, St. Helens, United Kingdom*

Background: In the growing onco-geriatric surgical population identifying frail patients is crucial as they are at an increased risk of adverse outcome.

Ageing is characterized by an increased incidence of malnutrition and also cancer patients frequently present in a malnourished state. Our aim was to investigate the incidence of impaired nutritional status and the impact of an impaired nutritional status on short term outcome in onco-geriatric surgical patients.
Methods: In an international cohort, patients ⩾70 years undergoing elective surgery for solid tumors were prospectively recruited. Primary endpoint was the incidence of major complications during the first 30 days after surgery, secondary endpoint was post-operative length of stay (LOS). Patients were classified as having a normal nutritional status, a mildly impaired nutritional status or a moderately or severely impaired nutritional status. This was defined by the decrease of food intake compared to their previous amount of ingestion and the rate and amount of weight loss. Data were analyzed using multivariate logistic regression analyses to estimate odds ratios (OR) and 95% confidence intervals (95%-CI).
Results: Data of 345 patients, with a median age of 76 years (range 70−96), were analyzed. A total of 240 patients (69.6%) underwent major surgery and 64 patients (18.9%) experienced major complications. LOS was more than 7 days in 176 patients (51.3%). Nutritional status was mildly impaired in 87 (26.2%) and moderately or severely impaired in 26 (7.8%) patients. Multivariate logistic regression analyses showed that nutritional status is an independent predictor of the occurrence of major complications and prolonged LOS (table 1).

Table 1. Results

Nutritional status	Major complications OR (95% CI; p-value)[a]	LOS >7 days OR (95% CI; p-value)[b]
Mildly impaired	3.80 (1.76–8.22; 0.001)	2.07 (1.17–3.68; 0.013)
Moderately or severely impaired	3.43 (1.16–10.11; 0.026)	4.16 (1.39–12.43; 0.011)

[a]Corrected for center, gender, age and minor/major surgery.
[b]Corrected for center and age.

Conclusions: Results indicate that impaired nutritional status is a risk factor of adverse postoperative outcome, but more research on the influence of preoperative optimization of nutritional status on postoperative outcome in onco-geriatric patients is needed.
No conflict of interest.

1571 POSTER

Influence of preoperative nutritional screening on treatment planning, and short-term outcome in elderly patients with gastric cancer

T. Palka[1]. [1]*Szpital Miejski w Siemianowicach Slaskie, Siemianowice Slaskie, Poland*

Background: About 30% of all patients in hospital are undernourished. A large part of these patients are undernourished when admitted to hospital and in the majority of these, undernutrition develops further while in hospital. Particularly undernourished patients undergoing surgery treatment due to gastric cancer are exposed to increased risk of severe complications. In Poland in 2011 an obligatory nutritional screening was implemented according to the binding statute. Over 70 years after Hiram Studley's research, do we pay our attention enough to nutritional screening in our everyday practice?
Material and Methods: Retrospective study of 148 cases of gastric cancer patients underwent surgical treatment in the years 2005–2013. Patients treated before 2011 were not screened, and those treated after 2011 were obligatorily examined according to NRS 2002 or SGA scale on admission to hospital.
Results: During the last 8 years 148 patients with gastric cancer underwent surgical treatment. Patients were retrospectively divided into two groups: − before 2011 (121 cases), and without nutritional screening, and − after 2011 (27 cases) examined due to NRS 2002, or SGA scale. The percentage of patients over 65 year (55.6% vs. 57.8%), and average hospital stay (17.8 vs. 17.4 days) were similar in both groups. The percentage of total resections was higher in second group (46.3% vs. 59.3%). 11 patients in second group were estimated 3 or more points in NRS 2002. In 7 cases among screened patients the operative treatment was delayed because of malnutrition (average 7 days after admission to hospital). The most common nutritional support implemented was preoperative oral nutrition with ready-made nutrients. There were no severe complications (perioperative death, anastomotic leakage) noted in second group, and a severe postoperative respiratory failure was sparser (17.6% vs. 12.5%).
Conclusions: Implementation of the obligatory nutritional screening resulted in modification of perioperative planning, and in some cases delayed surgical procedure. However, there was no influence on an average hospital stay. In group of screened patients there were no severe complications (perioperative death, anastomotic leakage) noted until end of this study. However, watchful screening, and monitoring of complications have to be continued.
No conflict of interest.

1572 POSTER

Surgical treatment of patients aged 85 years and over with special consideration to neoplastic disease

D. Koziel[1], R. Stepien[1], M. Kaczmarczyk[1], S. Gluszek[2]. [1]*JK University Kielce, Faculty of Health Sciences, Kielce, Poland;* [2]*Wojewodzki Szpital Zespolony, Surgery, Kielce, Poland*

Background: The growing number of elderly and aged people is noted in the general structure of contemporary societies. At the same time an increase in the risk of the incidence of chronic disease including oncologic ones is observed in elderly and aged patients requiring surgical treatment.
Aim of work/research: The aim of this work/research was an analysis of indications for surgical treatment, results of treatment as well as complications and mortality of patients aged 85 years or older.
Materials and Methods: The study group consisted of patients aged 85 years and older treated on at General, Oncological and Endocrine Surgery Department of the Provincial Polyclinic Hospital in Kielce between 2009 and 2011. All patients underwent analysis of retrospective medical documentation. The research concerned the analysis of indications for surgical treatment, a procedure for surgical intervention, a kind of possible complications and mortality. The results of the research were compared with the ones of a randomly selected control group of patients (n = 98) aged 40−75 years who underwent surgical treatment in the same place and time.
Results: The most frequent indication, urgent for surgical intervention in patients aged 85 years and older was *ileus*/*intestinal occlusion ileus* (34%) caused by colorectal carcinoma, and both abdominal hernias (24%) and cutaneous neoplasms and tumors of subcutaneous tissue (24%) were the planned ones. Surgical interventions most often concerned the large intestine in the age group which was analysed. Postoperative complications occurred *more*/*in larger numbers* in patients who had undergone *surgical intervention*/*surgery* as a matter of urgency, had general character and took the form of circulatory and respiratory insufficiency (7%). Postoperative *mortality*/*death rate* in the group of patients aged 85 years and older was 13%. As a general rule, postoperative complications were of local character in the control group and concerned mainly the course of healing of postoperative wound (4%). *Mortality*/*Death rate* in the postoperative period in this group *constituted*/*was* 1%.
Conclusions: Early diagnostics of neoplastic diseases, especially concerning the large intestine at the stage which do not give symptoms of ileus and enable to perform surgical intervention in a planned procedure is significant in the *surgical oncology care*/*surgical cancer care* of patients aged 85 years and older. Performing surgical intervention as a matter of urgency in aged people significantly increases the risk of postoperative complications, including death.
No conflict of interest.

1573 POSTER

The course of health related quality of life in postmenopausal women with breast cancer from breast surgery and up to five years post-treatment

M. Browall[1], U. Ostlund[1], I. Henoch[2], Y. Wengström[1]. [1]*Karolinska Institutet, Department of Neurobiology Care Science and Society. Division of Nursing, Stockholm, Sweden;* [2]*Institute of Health and Care Sciences, The Sahlgrenska Academy University of Gothenburg, Gothenburg, Sweden*

Background: Cancer treatment of the elderly patients is an increasingly important concern since the risk for developing breast cancer increases with age. The effects of adjuvant chemotherapy on the breast cancer disease seem to be as good for pre and postmenopausal patients, at least for hormone receptor negative patients. However, very few patients older than 65 years are included in randomised studies. In clinical practice, it is common that elderly women are offered less chemotherapy, because of the unsubstantiated belief that they will experience a larger number and more severe adverse effects as well as poor functional outcomes and significant decrements in health related quality of life (HRQOL).
The aim of this study was to follow HRQOL in postmenopausal women (55−80 years) with breast cancer receiving adjuvant treatment after surgery, until five years post-treatment, and compare with a general population.
Patients and Methods: The patient sample included 150 women (adjuvant CT n = 75 and RT n = 75) and two reference samples from the Swedish SF-36 norm database.
Results: The results showed that at baseline the women in the patient sample experienced significantly higher levels of physical functioning and general health compared to the general population. They also experienced

significantly less bodily pain, lower emotional role functioning and mental health. Five years after completion of treatment, the patient sample experienced better HRQOL than the reference sample in all domains, supporting our hypothesis that the impact on HRQOL would have been resolved over time for these patients.
Conclusion: Postmenopausal women (55−80 years) seem to successfully manage the effects of adjuvant treatment on HRQOL.
No conflict of interest.

1574 POSTER

Epoetin biosimilars in the management of chemotherapy-induced anemia in elderly patients: A subanalysis of the ORHEO study

J.E. Kurtz[1], P. Soubeyran[2], M. Michallet[3], E. Luporsi[4]. *[1]Hôpitaux Universitaires de Strasbourg, Service d'Oncologie et d'Hématologie, Strasbourg, France; [2]Institut Bergonié, Département d'Oncologie Médicale, Bordeaux, France; [3]CHU Lyon Sud, Département d'Hématologie, Lyon, France; [4]Centre Alexis Vautrin, Département d'Oncologie Médicale, Nancy, France*

Background: Chemotherapy-induced anemia (CIA) treatment requires transfusion, or epoietin administration. Elderly patients (pts) may experience severe complications from CIA, with fatigue and cardiovascular events.
Methods: ORHEO (place of biOsimilaRs in the therapeutic management of anemia secondary to chemotherapy in HaEmatology and Oncology) was a post-marketing, observational, prospective, multicentric study. Adult CIA (Hb<110 g/l) pts with solid tumors, lymphomas or myelomas and eligible for epoetin alpha biosimilar (EAB) treatment were included to receive EAB according to drugs approval recommendations. Recorded data included demographics, performance status, blood count and iron load profile. Safety (NCI-CTC V2.0) and efficacy were also assessed. The primary study endpoint was the rate of responders (defined as increase in Hb levels to 100 g/l or at least 10 g/l since inclusion visit, or reaching target Hb set at start of study, without any blood transfusions in the 3 weeks prior to measurement) at +3 months (M+3). Other endpoints included safety, patterns of treatment interruption and rate of responders at +6 months (M+6). Here we present data for the elderly (>= 70 years old) pts.
Results: 1,009 pts (54.3% male, 45.7% female) >= 70 y.o. were included in this analysis. Median age was 77 y, range [70−93]. At baseline, 36.3, 57.8 and 3.4% of pts had respectively grade 1, 2 and 3 anemia. Iron supplementation was given in 9.9 (oral) and 16.0% (IV) of pts. At M+3, 84.0% of pts were responders (IC95% 81.4–86.3). Moreover, respectively 241 pts (23.8%) and 139 pts (13.7%) had stopped EAB permanently or temporarily, mainly because of efficacy (45.2 and 79.1% respectively); other reasons were side-effects (2.9 and 0.7% respectively), lack of efficacy (7.0 and 4.3%), and unspecified reason (44.8 and 15.8%). Similar results were observed at M+6 with 86.8% of responders. 17.0% of pts reported side effects (all grades); the most frequent were thromboembolic events (4.5%). No EAB-related death was reported. 94.6% of pts reported being satisfied with EAB therapy at M+3 and M+6 and willing to restart if needed.
Conclusion: EAB therapy is efficacious on CIA management in elderly pts with low toxicity.
No conflict of interest.

1575 POSTER

Current approaches in the treatment of malignant ascites in Germany and Austria

C. Jehn[1], S. Küpferling[2], G. Oskay-Özcelik[3]. *[1]Charite, Hematology/Oncology, Berlin, Germany; [2]Charite, Gastroenterology, Berlin, Germany; [3]Charite, GYN, Berlin, Germany*

Background: Malignant Ascites (MA) is a common manifestation of advanced cancer associated with a poor prognosis and decreased quality of life. Currently there are no evidence based guidelines for the management of MA and only one agent is approved for its treatment. We conducted a survey with physicians throughout Germany and Austria, to get an overview of current approaches and opinions in the treatment of MA.
Methods: 128 medical oncologists (MO), gastroenterologists (GE) and gynecologists (GYN) completed an electronic questionnaire consisting of 33 questions. Answers were evaluated with descriptive statistics.
Results: 90% of the physicians were from Germany, 10% from Austria. 48% of those were MO, 30% were GYN and 14% were GE. Most physicians treated an average of 34 pts/year with MA. 26% of these pts suffered from ovarian, 20% from pancreatic, 17% from gastric and 14% from colorectal cancer. The majority of the physicians associated MA with poor prognosis (92%) and significant reduction in quality of life (87%). One third felt MA was a contraindication for full dosing of systemic chemotherapy. Paracentesis (P) was performed in 70% of pts with with symptom relieve and quality of life being the main reasons. Almost half of the pts required 3−5 P, 50% even more than 5 P during the course of their disease. Only 15% of pts needed multiple P per week, the majority (79%) needed the procedure either once a week or every 14 days. In 61% of pts 3−5 l ascites fluid was drained. Only in 8%, 5 l and more were removed. Volume substitution with IV albumin was performed in 40% of pts. Most pts (55%) had to stay 1−3 h in a healthcare facility for the procedure. However 21% had to stay >1 day. While almost all physicians (89%) performed a P at some point in the treatment of MA, 75% felt that a systemic chemotherapy and 55% thought a concomitant diuretic therapy were a necessary adjunct. 7% of the pts received a targeted treatment with catumaxomab.
Conclusions: Even though repeated P is the main pillar of treatment of MA, its effect is only temporary, must be performed multiple times, requiring hospital resources. Further treatment strategies have to be evaluated in prospective studies. Targeted therapies like catumaxomab should be integrated into these.
No conflict of interest.

1576 POSTER

Phase I trials in patients (pts) >65 years with advanced solid cancers: Do they fare worse than younger patients?

K.H. Khan[1], L.R. Molife[1], S. Bodla[1], A. Zivi[1], A. Smith[1], J. Ang[1], I. Judson[1], U. Banerji[1], J.S. De Bono[1], S.B. Kaye[1]. *[1]Royal Marsden Hospital, GI/Lymphoma Unit, London, United Kingdom*

Background: Individuals ⩾65 years (yr) represent ≈60% of the total cancer population and 80% of the cancer related deaths in Europe and the US. However, pts ⩾65 yrs are generally a small proportion of those enrolled in clinical trials due to the un-proven bias that their tolerability levels are less than that of those <65 yrs. This study aims to compare the experience of pts ⩾65 years (G1) treated in a dedicated Phase I unit with those <65 years (G2) to test the hypothesis that G1 pts have lower level of tolerability and clinical benefit compared to G2.
Methods: Clinical characteristics and outcomes of all the pts treated consecutively in the Drug Development Unit, Royal Marsden Hospital, 2005–2009 were recorded. The outcomes including progression free survival (PFS), overall survival (OS), response rate (RR), clinical benefit rate (CR+PR+SD=CBR) at 6 months (m) along with the detailed toxicity data were compared between G1 and G2.
Results: One thousand and four pts were treated in the phase I unit in 30 Phase I trials, with 315 (31%) pts ⩾65 years. Both groups were balanced with most common tumour types for respective age group, except prostate cancer. Prostate cancer constituted 83 of the 315 cases in G1; excluding these from the analysis, the CR/PR and CBR ⩾6 months rates were 3.6% and 11.2m respectively and PFS/OS were 3.0m and 7.9m. The clinical benefit achieved with and without prostate cancer patients is summarised in table 1. Grade 3/4 toxicities were observed in 24% in G1 (22% in G2) and led to trial discontinuation in 6% (8% in G2); no toxicity-related deaths were recorded in either groups. In G1 9.5% pts had un-planned hospital admissions and 15.6% had serious adverse events (SAE). In a separate multivariate analysis, the previously validated Marsden prognostic index (Arkenau JCO 2009) was examined in G1. This confirmed that as in G2 the serum albumin, number (no.) of metastatic sites, lactate dehydrogenase (LDH) were predictive of PFS and OS and in addition no of previous lines of chemotherapy in both groups and ECOG performance status (PS ⩾2) at inclusion were prognostic of OS; in G1.
Conclusion: Phase I clinical trials should be considered in advanced cancer pts regardless of their age. Acknowledging the impact of pt selection, there is no evidence that the older pts do worse as regards either efficacy or safety compared to the younger counterparts.
No conflict of interest.

	G1 (all tumour types) (Median 69 yrs, range 65−85) n = 315	G1 (without prostate) n = 232	G2 (Median 52 yrs, range 12−64) n = 689	G2 (without prostate) n = 640
CR, % (95% CI)	0.6	0.6	0	0
PR, % (95% CI)	3.5 (1.9−6.3)	3.0 (1.3−6.3)	5.1 (3.5−7.3)	4.5 (3.3−6.8)

1577 POSTER

Reduced risk of distant recurrence after adjuvant chemotherapy in patients with stage III colon cancer aged 75 years or older

F.N. Van Erning[1], G.J. Creemers[2], I.H.J.T. De Hingh[3], O.J.L. Loosveld[4], S.H. Goey[5], V.E.P.P. Lemmens[1]. [1]*Comprehensive Cancer Centre South, Research, Eindhoven, Netherlands;* [2]*Catharina Hospital, Internal Medicine, Eindhoven, Netherlands;* [3]*Catharina Hospital, Surgery, Eindhoven, Netherlands;* [4]*Amphia Hospital, Internal Medicine, Breda, Netherlands;* [5]*TweeSteden Hospital, Internal Medicine, Tilburg, Netherlands*

Background: Little is known about effects of adjuvant chemotherapy (CT_{adj}) on risk of distant recurrence in elderly with colon cancer, treated in daily practice.
Patients and Methods: All patients who underwent resection for stage III ($T_{any}N_{1-2}M_0$) colon cancer diagnosed in the southern Netherlands in 2003–2008 were included. Distant recurrence was defined as a distant metastasis of primary colon cancer in other organs, regional lymph nodes not included, after a primary diagnosis of M0 disease. Propensity score matching (PSM) was applied to create a subsample to reduce bias caused by differences between age groups. For both the total study population and the PSM sample, crude 5-year percentages for distant recurrence were calculated based on Kaplan–Meier curves and Cox regression analyses were used to discriminate independent risk factors for distant recurrence.
Results: 1189 patients were included in the study of whom 60% received adjuvant chemotherapy and 33% developed a distant recurrence. 35% of the study population was aged $\geqslant$75 years. Median follow-up time was 35.2 months. In the PSM sample, 698 patients (59%) of the original study population could be included, with an equal proportion of patients being <75 years and $\geqslant$75 years. 50% received adjuvant chemotherapy and 37% developed a distant recurrence. Adjuvant chemotherapy was correlated with a reduced risk of distant recurrence in both the total study population (hazard ratio (HR) CT_{adj} vs. nCT_{adj} 0.59, 95% CI 0.45–0.76) and in the PSM sample (HR CT_{adj} vs. nCT_{adj} 0.69, 95% CI 0.50–0.96). In separate analyses for patients aged <75 years and $\geqslant$75 years, the effect of adjuvant chemotherapy on the risk of distant recurrence remained comparable for both age groups (HR CT_{adj} vs. nCT_{adj} 0.55, 95% CI 0.40–0.76 and 0.57, 95% CI 0.36–0.90 respectively).
Conclusion: The results of the present study underline that consideration of adjuvant chemotherapy is definitely warranted for all patients aged $\geqslant$75 years with resected stage III colon cancer, as they derive comparable benefit from adjuvant chemotherapy as their younger counterparts with regard to risk of recurrence. However, it remains important to realize that in certain circumstances, withholding adjuvant chemotherapy from elderly may be appropriate, for example in case of short life expectancy or increased risk of serious side-effects.
No conflict of interest.

1578 POSTER

Sorafenib's safety and efficacy are similar in elderly and younger patients treated for hepatocellular carcinoma

J. Edeline[1], L. Crouzet[1], S. Lesourd[2], A. Brunot[1], F. Le Roy[2], C. Cattenoz[3], M. Latournerie[2], D. Gédouin[4], A. Guillygomarc'h[2], E. Boucher[1]. [1]*Centre Eugène Marquis, Oncology, Rennes, France;* [2]*CHU Pontchaillou, Hepatology, Rennes, France;* [3]*CHU La Tauvrais, Gerontology, Rennes, France;* [4]*Regional Onco-gerontology Coordination Unit, Oncology, Rennes, France*

Background: Sorafenib is the standard of care for advanced hepatocellular carcinoma (HCC). The peak incidence of HCC is around 70 years in western countries; however, data are scarce regarding safety and efficacy of sorafenib in the elderly population.
Material and Methods: We retrospectively reviewed data from patients treated with sorafenib for HCC at our institution. We compared baseline characteristics, safety and efficacy data across different age groups. Proportions were compared with a Chi-2 test, survival were compared with the Kaplan–Meier method with a log-rank test.
Results: Since 2008, 129 patients were treated. 78 (60.5%) were <70 years-old (YO), 27 (20.9%) were between 70 and 74, 18 (14.0%) were between 75 and 79 and 6 (4.7%) were $\geqslant$80 YO. Comparisons were primarily done between the 105 (81.4%) <75 YO and the 24 (18.6%) $\geqslant$75 YO patients. Both groups had similar baseline characteristics, except for a trend toward more patients with Child B cirrhosis in the younger group (22.5% vs 5.3%, p = 0.09). The frequency of dose reduction was similar between the 2 groups (52.4% vs 54.2%, p = 0.87), as was the occurrence of severe toxicities (43.8% vs 50.0%, p = 0.58) and the need for hospitalization due to toxicity (10.5% vs 12.5%, p = 0.77). There was a trend toward less frequent interruption of treatment in the younger group (27.6% vs 45.8%, p = 0.08), and less frequent definitive discontinuation of treatment due to toxicity (29.5% vs 45.8%, p = 0.12). Response rates by mRECIST were similar (27.4% vs 35.3%, p = 0.55). Median progression-free survival was 5.4 months in the younger age group vs 7.8 months in the older age group (p = 0.30), while median overall survival were 11.4 months and 9.9 months, respectively (p = 0.17). Results were similar if the thresholds chosen were 70 or 80 YO, except for discontinuation of sorafenib due to toxicity that was significantly less frequent in the <70 YO age group compared with the $\geqslant$70 YO age group (24.4% vs 45.1%, p = 0.01).
Conclusion: In this single-center retrospective study, sorafenib shows similar results in terms of safety and efficacy in the elderly and younger populations. Careful baseline evaluation is needed for patient's selection in the elderly population, as well as active management of toxicity. Elderly patients in our series have been considered fit for sorafenib therapy. Such selection could be improved by implementing geriatric evaluation, which could also prevent complications from other comorbidities.

Overall treatment utility: A novel outcome measure reflecting the balance of benefits and harms from cancer therapy

C. Handforth[1], P.S. Hall[1], H.C. Marshall[2], M. Collinson[2], M. Jones[2], M.T. Seymour[1]. [1]*St James Institute of Oncology, Leeds, United Kingdom;* [2]*University of Leeds, Clinical Trials Research Unit, Leeds, United Kingdom*

Introduction: Established clinical trial endpoints fail to individually capture the balance of benefits and harms from cancer treatments. 'Overall Treatment Utility' (OTU) is a novel composite outcome measure that was developed within the FOCUS2 trial in elderly patients treated with chemotherapy for advanced colorectal cancer. It combines clinical and radiological response, toxicity, adverse events and patient-reported acceptability of treatment. OTU needs further development and validation. This study aimed to test the feasibility and value of measuring OTU in an alternative frail/elderly population with advanced gastric or oesophageal (GO) cancer.
Methods: Patients were randomised between three treatment arms containing triplet, doublet or single agent chemotherapy. Details of the trial and conventional outcomes are reported elsewhere. OTU was scored according to the algorithm used in the FOCUS2 trial which categorises outcome into a three-point ordered categorical scale (good/intermediate/poor). Data return and compliance with the patient-reported component was recorded. Survival analysis was used to correlate OTU with overall survival (OS) and progression free survival (PFS).
Results: The study included 55 patients with a median age of 75 (range 50−87). OTU provided useful information enabling discrimination between treatment arms. OTU was prognostic for OS in patients alive at Week 12 (logrank test for trend p = 0.0001), PFS in patients alive and progression free at week 12 (logrank test for trend p = 0.0003). Radiological response (RECIST) was less prognostic for OS (logrank test for trend p = 0.40). Alternative formulations of OTU were also investigated. The distribution between good, intermediate and poor OTU varied depending on the cut-point in patient question responses.
Conclusion: OTU is a feasible and useful outcome measure that combines objective and subjective information regarding the balance of benefit and harm of treatment in a frail/elderly population with GO cancer. It correlates more strongly with overall survival than radiological response. Further research should focus on establishing the optimal definition and combination of patient reported outcomes.

1580 POSTER

Evaulation of geriatric aged (>65) early stage colorectal carcinoma patients' comorbidity scale

O. Yazici[1], H. Kanmaz[1], S. Aksoy[2], B. Civelek[1], N. Ozdemir[1], N. Zengin[1]. [1]*Ankara Numune Education and Research Hospital, Medical Oncology, Ankara, Turkey;* [2]*Hacettepe University Cancer Institute, Medical Oncology, Ankara, Turkey*

Background: Approximately 60% of newly diagnosed carcinoma patients are older than 65 years age. Many clinicians consider the toxic effects of drugs in elderly population and avoid administering standard dosage chemotherapy. In practice, Eastern Cooperative Oncology Group (ECOG) performance scale is one of cornerstone of chemotherapy planning. Since chronological age and performance scale are insufficient during chemotherapy planning, different comorbidity scales have been developed. Comprehensive Geriatric Assessment (CGA), analyses multiple factors and can detect possible benefits.
Material and Methods: We evaluated the Charlson Comorbidite (CS) Index and Cummulative Illness Rating Scala (CIRS) at colorectal caner patients older than 65 years. We retrospectively examined 527 patients file, older than 65 years age, among 1320 patients who were admitted to

Medical Oncology Department of Ankara Numune Education and Research Hospital with diagnosis of colorectal cancer from March 2003 to December 2012. Two hundred and ten (n = 210) non metastatic operated patients data were recorded, CS and CIRS scores were calculated. At Charlson and CIRS scales, according to comorbide illnesses and stage of comorbide illness and organ dysfunctions, patients get scores between 0−31 and 0−56.

Results: The median age at diagnoses of our study population (n = 210) was 71(65−87) years. One hundred-fifteen (55 %) of the patients were men and 95 (45%) of them were women. Stage I, II, III of colorectal cancer was; 25 (12%), 102 (49%) and 83 (39%), respectively. Hundred-forty (67%) patients were treated with adjuvant chemotherapy and 77 (36.8%) patients were treated with chemoradiotherapy. According to CS and CIRS system minimum and maximum score was as follows, 0 and 5 points, 0 and 12 points. According to CS system the number of patients who had score 0, 1 and 2, 3 or more were, 80 (%39), 107 (%51) and 21 (%10), respectively. According to CIRS system the number of patients who had score 2 or less and 3 or more were, 51(%25) and 158 (%75), respectively. According to comorbidity scales, patients overall survival analysis were done. Although in CS system patients whose score 0 did not reached the median overall survival, score 1 and 2 was 59 months and score 3 or more was 28 months (p = 0.035). According to CIRS system, while median overall survival of patients whose score 2 or less did not reached, score 3 or more was 54 months (p = 0.02).

Conclusion: We demonstrated that geriatric evaluation forms CS, CIRS score systems were effective parameters on overall survival. Due to deficient toxicity data, we could not give any information about the effect of scoring systems in determining adjuvant chemotherapy. CS and CIRS scoring systems can be used in evaluating geriatric patients. Further detailed studies about these tests will increase their practical use and importance.

1581 POSTER

The impact of geriatric assessment on the treatment decision of elderly cancer patients

M. Antonio[1], J. Saldaña[1], P. Fernandez[1], V. Navarro[2]. *[1]ICO-DIR, Medical Oncology, Barcelona, Spain; [2]ICO-DIR, Clinical Investigation Unit, Barcelona, Spain*

Purpose Despite the World population is globally aging, general conditions are also improving. Multidimensional geriatric assessment has been shown to be useful in defining different frailty levels and the treatment strategy by eventually modifying a decision based not only on the chronological age but rather on the type of ageing profile. Our goal is to estimate the impact of a geriatric assessment in the final decision of oncology therapy.

Method: A total of 393 patients aged ⩾75 years with colorectal or lung cancer candidates for specific oncological treatment were prospectively included. All patients underwent Comprehensive Geriatric Assessment (CGA) that incorporated validated instruments to evaluate co-morbidity (number of comorbidities, Charlson Short Index), polypharmacy, functional status (Performance Status, Barthel Scale, Lawton-Brody Scale), geriatric syndromes, cognition (Pfeiffer test) and the vulnerability (Vulnerable Elders Scale (VES-13)). According to CGA results, patients were classified in 3 risk groups (fit, unfit, and frail). We compared the standard treatment plan based on the cancer stage with the one proposed based on the 3 risk groups.

Results: Median age was 79 years (range 75−97) and 277 (70.5%) were men. Disease was non-metastatic (stage I to III) and metastatic (stage IV) in 188 pts. (47.8%) and 205 pts. (52.2%) respectively.

The CGA results are described in table 1.

Table 1. Patient characteristics

Performance Status (0−1 and >1)	252 (64.6%) and 138 (35.4%)
Barthel Index (100 and <100)	169 (43.6%) and 221 (66.4%)
Lawton Index (8 and <8)	98 (31.7%) and 210 (68.3%)
Geriatric syndromes (0 and >0)	181 (48.9%) and 189 (51.1%)
Charlson Index (0 and >0)	140 (36.6%) and 248 (73.4%)
Number co-morbidities (⩽3 and >3)	206 (52.8%) and 184 (47.2%)
Polypharmacy (⩽3 and >3)	127 (32.8%) and 264 (67.2%)
VES-13 (⩽3 and >3)	197 (51.1%) and 195 (49.9%)
Abbreviated Yesavage (>2 vs ⩽2)	135 (35.7%) and 243 (64.3%)

Missing values have not been included in the table.

In up to 30% of the patients, CGA led to a change in based 'standard practice' therapy decision (table 2).

Table 2. Standard practice vs after-CGA plan

Standard practice	Oncogeriatric plan			
(n and % per file)	Radical	Palliative	Symptomatic	Total
Radical	120 (63.8)	59 (31.3)	9 (4.8)	188 (100%)
Palliative	0	115 (73.2)	42 (26.8)	157 (100%)
Symptomatic	0	0	19 (100)	19 (100%)
Total	112	83	73	268 (100%)

*Missing values not included in the table.

Conclusions: CGA had a significant impact on the medical decision. A consensus for developing tools and guidelines in order to better classify elderly cancer patients is warranted. The increasing use of a complete geriatric assessment might lead to a more tailored therapy plan.

No conflict of interest.

1582 POSTER

Neoadjuvant treatment with Taxol®-carboplatin in elderly patients with non-small cell lung cancer stage IIIA N2 disease

V.E. Castellon Rubio[1], J. Carrillo Ramos[1], E. Gonzalez Flores[2], B. Gonzalez Astorga[2]. *[1]Hospital Torrecardenas, Oncology Service, Almeria, Spain; [2]Hospital Virgen de las Nieves, Oncology Service, Granada, Spain*

Background: Lung cancer is one of the most important diseases in the elderly population because of its high incidence and mortality. Treatment in this population is an understudied topic, being excluded from most clinical trials. The aim of this case series is to analyze the toxicity, adherence, response rate, resectability, progression-free survival (PFS) and overall survival (OS).

Material and Methods: Retrospective analysis of 34 patients over 70 years with non-small cell lung cancer (NSCLC) stage IIIA N2 disease treated at the Hospital Virgen de las Nieves (Granada, Spain) between 2010–2011. The treatment consisted of the administration of neoadjuvant scheme with Taxol® 200 mgr/m^2 and carboplatin AUC 6 day 1, every 21 days for 3−4 cycles. After completion of treatment, surgery was evaluated. If surgical resection was possible, radiotherapy was assessed sequentially.

Results: We analyze 34 patients with ECOG 0−1. Median age was 73 years (71−78). 88% were males. 91% were smokers. Regarding histology, 61.8% of squamous cell, adenocarcinoma 17.6% and 20.6% were undifferentiated. 79% received 4 cycles of chemotherapy. Incidence of neutropenia GIII−IV was 35%, with 2 cases of severe febrile neutropenia. Non hematologic toxicity grade III−IV occurred in only 5%. Response rate evaluated by RECIST criteria: complete response ocurred in 1 case (2.9%), partial response in 16 (47%), stable disease in 9 (26.4%) and 8 progressed during treatment (23.5%). Underwent surgery 3 patients (8.8%), 21 patients (61.7%) received radiotherapy sequentially and 4 patients (11.7%) started second line chemotherapy. The median disease-free interval was 8 months and OS was 15 months.

Conclusions: Treatment with neoadjuvant scheme Taxol®-carboplatin in ederly patients with NSCLC was well tolerated. Response rates and OS were similar to younger patients, therefore cancer in the elderly age should not be a barrier to administer active treatment.

No conflict of interest.

1583 POSTER

Impact of the incorporation of comprehensive geriatric assessment tools (CGA) into clinical practice in a developing country

M. Fanelli[1], S.M. Sanches[2], B. Figueroa[2], A.M.M. Leite[2], A.L. Larciprete[2], M.C. Tavares[2], E.C. Pereira[2], R. Yamamura[2], B. Conte[2], M.J. Barros e Silva[2]. *[1]Hospital A C Camargo, SAO PAULO, Brazil; [2]Hospital A C Camargo, Medical Oncology, SAO PAULO, Brazil*

Background: Population ageing is a global phenomenon not restricted to developed nations. In Brazil, more than 18 million people are now over sixty years. Geriatric oncology programs are present worldwide, but still emerging in developing nations. We hypothesized that incorporating CGA into daily practice can improve individualized care in elderly cancer patients.

Methods: The aim of the study was to assess the impact of CGA in the selection of treatment and its ability to predict treatment complications (dose reduction, hospitalization, treatment discontinuation) in a recently implemented Oncogeriatric Unit. From Mar/12 to Jan/13, 622 patients (pts), >70 y, candidates to receive systemic treatment underwent CGA assessment including Katz, Lawton, Nutritional Status and Depression scales, comorbidities and polypharmacy. Patients were classified as fit, frail or borderline. Fit pts received full treatment. For frail/borderline pts, modified treatment and/or specific supportive care (clinical/nutritional/

psychological) was indicated. Statistical analysis used chi-square or Fisher exact tests, when indicated, to evaluate the association of geriatric scales with the outcomes described.
Results: There was association between the choice of oncologic treatment with Katz (p: 0.018), Lawton (p and lt;0.001) and nutrition scales (p: 0.004). Lawton scale was more associated with changes in treatment (78.3% with altered scale received modified treatment). The ability to complete the proposed treatment was correlated with the Lawton scale (p = 0.006) and dose reduction with nutrition scale (p: 0.029). Hospitalization during chemotherapy was associated with presence of comorbidities (p: 0.038) and changes in Katz (p: 0.006) and Lawton scales (p: 0.017).
Conclusions: In this cohort, the incorporation of CGA in daily practice was feasible and useful to predict complications of systemic cancer treatment.
No conflict of interest.

1584 POSTER

The feasibility of using comprehensive geriatric assessment in frail or elderly patients with advanced gastric or oesophageal cancer

C. Handforth[1], P.S. Hall[1], H.C. Marshall[2], M. Collinson[2], M. Jones[2], M.T. Seymour[1]. [1]*St James Institute of Oncology, Leeds, United Kingdom;* [2]*University of Leeds, Clinical Trials Research Unit, Leeds, United Kingdom*

Introduction: The population of elderly patients with cancer is heterogenous. Chronological age alone is a poor predictor of tolerance and outcome from cancer therapies. Comprehensive Geriatric Assessment (CGA) is a process that encompasses somatic, functional and psychosocial domains. It has the potential to be used for prognostication and prediction of benefit from treatment in elderly cancer patients, but may be burdensome to administer. There is a need to define the optimal composition of CGA for each tumour type, and to determine feasibility of administration. This study aimed to test the feasibility of using a questionnaire-based CGA in frail and elderly patients with advanced gastric or oesophageal (GO) cancer in the setting of a randomized controlled trial.
Methods: Eligible patients had a diagnosis of advanced GO cancer and were considered unfit for full-dose triple-drug chemotherapy but fit for reduced intensity chemotherapy. Patients completed a baseline CGA administered by nurses in clinic. This comprised the validated tools of Mini Nutritional Assessment, Charleston co-morbidity index, Nottingham activities of daily living (NADL) and the patient self-reported questionnaires EORTC QLQ C30, QLQ OG25 and EuroQoL EQ5D. A similar reduced assessment was completed at 12 weeks. At completion of the trial a focus group was conducted with clinicians, nurses and patient representatives to obtain feedback on the CGA process.
Results: 55 patients with advanced GO cancer met eligibility and were randomised. The median age was 75 (range 50−87). Performance status was 0, 1 or 2 in 6, 31 and 18 patients respectively. All but one patient completed the CGA at baseline. Average per-question compliance within each questionnaire was 99.5% for NADL, 99% for EQ5D, 98% for QLQ C30 and 95% for QLQ OG25. The Week 12 CGA was completed by 29 of the 42 patients alive at 12 weeks (69%). Average per-question compliance was 95% for NADL, 94% for EQ5D. 95% for QLQ C30 and 96% for QLQ OG25 questionnaires. Feedback suggested that duplication between tools hindered compliance.
Conclusion: In general, compliance with completion of questionnaires was good, but was greater in the initial CGA compared with completion at follow-up. Compliance may be enhanced by avoiding duplication of questions when multiple overlapping validated questionnaires are used. The modification of existing questionnaires requires further testing in clinical practice.
No conflict of interest.

1585 POSTER

Treatment decisions in gastrointestinal cancer patients older than 65 years of age

U. Uyeturk[1], I. Turker[2], O. Bal[2], A. Demirci[2], O. Uysal Sonmez[2], K. Helvaci[2], B. Budakoglu[2], U. Yalcintas Arslan[2], B. Oksuzoglu[2]. [1]*Abant Izzet Baysal University Faculty of Medicine, Department of Medical Oncology, Ankara, Turkey;* [2]*Dr.Abdurrahman Yurtaslan Oncology Training and Research Hospital, Department of Medical Oncology, Ankara, Turkey*

Background: Aging is one of the important risk factor for increased incidence of cancer. Molecular changes and defective immunity associated with aging results in increased susceptibility for many carcinogens to tissues especially to gastrointestinal system (GIS). Co-morbidities and changes in the drug metabolism in the elderly makes the treatment of GIS cancers difficult. In the presenting retrospective study basic characteristics and differences of treatment of the GIS cancers in older age group were evaluated.
Materials and Methods: Between January 2009 and December 2012, seven-hundred and ninety patients who were diagnosed with GIS cancer evaluated retrospectively. Three hundred and eighty six patients older than 65 years of age were of our main interest.
Results: Median age of our elderly patient group was 72 years (Range: 65−90). One hundred and fifty one (39.1%) patients were women and 235 (60.9%) were men. Localisations of the GIS cancers were colo-rectal, gastric, pancreatico-biliary system and primary liver as an incidences of 184 (47.7%), 125 (32.4%), 57 (14.8%) and 15 (3.9%) respectively. In this older age group colo-rectal cancers were the common cancer types in both men and in women [101(43.0%),and 83(55.0%)respectively]. In contrast gastric cancer was more common cancer type in men than in women [92 (39.1%) vs. 33(21.9%)] respectively. The stages of GIS cancers in this age group were mostly advanced stage [stage IV, III,II and I were 190(49.2%), 119(30.8%), 66(17.1%), and 11(2.8%) respectively]. In older patient groups 104 (26.9%) of patients were not received any chemotherapy. Reasons were refusing to chemotherapy, low performance status, no indication to chemotherapy in 65 (16.8%), 17 (4.4%), 22 (5.6%) of patients respectively. Although 279 (72.2%) of patients received chemotherapy, 89 (35.3%) of patients were received inferior chemotherapy regimens rather than standard protocols.
Conclusion: Cancers of GIS are mostly diagnosed in advanced stage in older age patients since fatigue, debility and anorexia are common symptoms in both GIS cancers and senility. Thus screening programs and close monitoring of the symptomatic patients are important. There is a higher tendency to less treat and to deny chemotherapy in elderly. Physiological conditions and co-morbidities are more reliable factors to decide treatment strategies rather than chronological age. Assessment of good performance status by some tests like treadmill may be helpful before planning chemotherapy in this age group. Elderly patients who are in a good performance status should be encouraged for receiving chemotherapy.
No conflict of interest.

1586 POSTER

Predictive value of geriatric assessment for elderly patients, treated with first-line chemotherapy

M. Kwon[1], J. Tae[1], S. Park[1], I. Hwang[2], J. Jang[2]. [1]*Chung-Ang University Hospital, Department of Internal Medicine, Seoul, South Korea;* [2]*Chung-Ang University College of Medicine, Department of Internal Medicine, Seoul, South Korea*

Background: Although comprehensive geriatric assessment (CGA) helps a clinician decision of chemotherapy in the elderly cancer patient, it is uncertain which factor has predictive value. We performed a single-institution retrospective study to determine the predictive factors for elderly cancer patients treated with chemotherapy.
Material and Methods: Between September 2011 and February 2013, 23 patients older than 70 years who were scheduled for first-line palliative chemotherapy for various types of cancer were eligible for the study. Baseline CGA including clinicopathologic factors, Mini Mental State Examination (MMSE) and Geriatric depression scale (GDS) was assessed. Progression free survival (PFS), time to treatment failure (TTF), and overall survival (OS) were measured. Survival analysis was evaluated using the Kaplan–Meier method and the Cox proportional hazard method.
Results: Of the 23 patients, the median age was 74 (rage, 70−84), 52% of patients had mild cognitive impairment (MMSE score $\leqslant$23) by MMSE, and 60% had mild depressive mood by GDS. Median follow-up duration was 3.3 month (range 1.2–13.6 months). Median PFS was 5.2 month (95% confidence interval [CI]: 3.54–6.86), median TTF was 4.6 month (95% CI, 2.35–6.85) and median OS was 12.7 month.
On univariate analysis, PFS was 1.6 months for patients with diabetes and 6.6 months for non-diabetes (p = 0.007), 2.8 months for patients with inferior MMSE score (MMSE $\leqslant$23) and 6.6 months for superior MMSE ($\geqslant$24) (p = 0.021). TTF was 1.4 months for diabetes and 5.2 months for non-diabetes (p = 0.044), 2.6 months for inferior MMSE score and 6.6 months for superior MMSE (p = 0.002), and 5.2 months for patients under age 80 and 1.2 months for over age 80 (p = 0.004). On multivariate analysis, diabetes (hazard ratio, 0.210; 95% CI, 0.046–0.964; p = 0.045) was significant independent prognostic factors for the prolongation of PFS and MMSE was significant for the TTF (hazard ratio, 0.126; 95% CI, 0.027–0.594; p = 0.009).
Conclusion: This study showed that cognitive impairment significantly increased the probability of early treatment failure, and DM was poor prognostic factor in patients greater than 70 years of age with chemotherapy.
No conflict of interest.

1587 POSTER

Analysis of cancer treatment toxicity in patients over 65 years of age

E. Nowara[1], J. Huszno[2], A. Boratyn-Nowicka[2]. [1]*Centrum Onkologii − Instytut im. M.C. Sklodowskiej, Gliwice, Poland;* [2]*Centrum Onkologii − Instytut im. M.C. Sklodowskiej, MSC Memorial Cancer Center and Institute of Oncology Gliwice Branch Gliwice Poland, Gliwice, Poland*

Background: European statistics data show that patients above 65 years of age costitute 63% of adult patients population with cancer (www.eurocare). In Poland, people over 65 years of age account for about 50% of cancer patients (http://epid.coi.waw.pl/krn/).
Material and Methods: The medical records of patients treated in 2011 in Clinical and Experimental Oncology Department were reviewed. The frequency of enrolment for systemic therapy for patients above 65 years of age, treatment course and the incidence of toxicity were analyzed. Toxicity was assessed according to CTCAE (Common Terminology Criteria for Adverse Events). In the present study toxicity $\geqslant$3 were analyzed.
Results: A total of 1102 patients were treated in analyzed period. Patients older than 65 years of age accounted 23% (257). Median age was 72 years (range 65−88). The most common cancers treated were: colon, ovarian and breast cancer, 65 (25%), 45 (18%), 34 (13%), respectively. Median follow up was 29 months. All patients who were enrolled in chemotherapy, chemoimmunotherapy or chemoradiotherapy were in good performance status (ZUBROD 0−1) with no contraindication to the treatment. 98 patients (38%) required a dose reduction during the therapy due to excessive toxicity. The most frequent toxicity reported were: the hematologic, neurological, hepatic, and gastrointestinal ones, 56%, 29%, 28% and 20%, respectively. Premature treatment discontinuation was necessary in 124 patients (48%). During the follow-up 118 patients died, 70% of them due to cancer progression.
Conclusions: The results of the study suggest that in Poland older patients are less frequent diagnosed for neoplasm disease. The frequency of premature treatment discontinuation due to toxicity is high. Older patients cancer diagnosis and treatment needs to be improved in our region.
No conflict of interest.

1588 POSTER

Colorectal cancer in elderly patients: A single center experience

G.P. Piringer[1], S.B. Burgstaller[1], M.P. Pötscher[2], W.S. Schauer[3], W.H. Höbling[4], P.K. Knoflach[5], J.T. Thaler[1]. [1]*Klinikum Wels-Grieskirchen, Internal Medicin IV, Wels, Austria;* [2]*Klinikum Wels-Grieskirchen, CTU, Wels, Austria;* [3]*Klinikum Wels-Grieskirchen, Surgery, Wels, Austria;* [4]*Klinikum Wels-Grieskirchen, Pathology, Wels, Austria;* [5]*Klinikum Wels-Grieskirchen, Internal Medicin I, Wels, Austria*

Background: In Austria more than 40% of cancers occur in adults over the age of 75 years. As the current population ages and life expectancy is increasing, more people with colorectal (CRC) are presenting at an advanced age (>75). Several studies have shown that cancer treatment is beneficial for elderly pts in adjuvant and palliative setting. However, optimal management approach for this group of pts is not well defined as they are underrepresented in clinical trials. We now want to present our own experience in the treatment of elderly pts with colorectal cancer.
Methods: The Klinikum Wels-Grieskirchen collects data on all CRC pts since July 2006 in a clinical tumor registry. Patients were followed for treatment decision, progression free survival and overall survival. In this updated retrospective analysis elderly pts $\geqslant$75 years diagnosed with CRC have been evaluated.
Results: Overall, 277 pts $\geqslant$75 years (range 75−92) with a diagnosis of CRC stage I−IV were recorded from July 2006 − March 2013 in our registry. 132 (47.7%) and 145 (52.3%) out of these pts were men and women, respectively. Stage I has been diagnosed in 35 pts (12.7%), stage II in 89 pts (32.4%), stage III in 85 pts (30.9%) and stage IV in 66 pts (24%). 29.2% (81 pts) had a tumor located in the rectum and 70.8% had colon cancer. 226 out of 277 pts underwent surgery (tumorectomy or colectomy). Hemihepatectomy or lobectomy has been performed in 7 pts. Adjuvant chemotherapy was given in 10 pts with stage II and in 37.5% (32/85 pts) with stage III CRC. Of these, 90.5% received single agent chemotherapy (mostly capecitabine). Two-thirds of pts with metastatic CRC were treated with palliative chemotherapy. Chemotherapy regimens, updated progression free survival and overall survival data will be presented.
Conclusions: Although elderly pts often have co-morbidities and poor performance status, age alone should not determine treatment options and person's eligibility in clinical trials. A careful discussion of treatment risks and benefits, especially in elderly pts, needs to be considered in the therapy decision.
No conflict of interest.

Background: Little is known about specific characteristics of hepatoblastoma in infants. The objectives of this study were to describe clinical characteristics, outcome and toxicity of treatment in patients diagnosed with an hepatoblastoma (HB) before the age of 6 months (m).
Material and Methods: Data collected in SIOPEL database for patients diagnosed with an HB <6 m of age and entered into SIOPEL 1, 2 and 3 trials between 1990 and 2006 were studied.
Results: Among 695 patients included in SIOPEL 1, 2 and 3, 92 met the study criteria: 63 (68%) were male. The age at diagnosis was <1 m in 18 patients, between 1 and 3 m in 22 and between 3 and 6 m in 52. Among them, 13 were premature babies and 6 had Beckwith Wiedemann syndrome.
According to SIOPEL risk stratification, 64 patients were considered standard risk (PRETEXT I, II or III without extrahepatic extension, AFP above normal level for age) and 18 high risk (AFP level within normal range for age (n = 10) and/or metastases (n = 5) and/or PRETEXT IV group (n = 13)). Overall 13 patients had an AFP level under 1000 ng/ml. All patients received a cis-platinum based chemotherapy pre-operative chemotherapy with PLADO (n = 36), Cisplatinum alone (n = 31) or superPLADO (n = 24). All 18 patients <1 m at diagnosis received at least one course of cisplatinum before the end of the first month of life combined with doxorubicin in 2. The mean cumulative dose received during the treatment was 98% of the dose planned in the protocol (dose adjusted for weight in patients under 10 kg). Toxicity pattern was similar to the one observed in older patients except for ototoxicity which seems to be more frequent in this age group: 22/57 (39%) patients with an audiogram after the end of treatment had grade >2 ototoxicity (Brock grading system). Median follow-up is 5.6 years. Overall 8 patients died, 2 of surgical complications and 6 of progressive disease, one of them before the beginning of treatment. Among these latter 8 patients, 6 had an AFP level at diagnosis less than 1000 ng/ml. The 3 year EFS and OS are respectively 87 and 91%. No tumor failure occurred in patients with AFP >1000 ng/ml at diagnosis.
Conclusions: The prognosis of hepatoblastoma in patients less than 6 month at diagnosis is excellent with an overall survival >90% at 3 years. Chemotherapy combining cisplatinum and doxorubicin is feasible in infants but the risk of ototoxicity is high. A reduction of treatment should be considered in patients with no risk factors.

The (EPOC) FP7-funded study of pharmacokinetics and pharmacodynamics of doxorubicin in children with cancer

A. Boddy[1], N. Andre[2], G. Bisogno[3], J. Boos[4], G. Hempel[5], N. Kontny[5], M. Krischke[5], K. Pritchard-Jones[6], A. Steele[1], S. Voeller[5]. [1]*University of Newcastle upon Tyne, Northern Institute for Cancer Research, Newcastle upon Tyne, United Kingdom;* [2]*APHM, Paediatric Oncology, Marseille, France;* [3]*Padua University Hospital, Paediatric Oncology, Padua, Italy;* [4]*Westfalische Wilhelms-Universitat, Paediatric Oncology, Munster, Germany;* [5]*Westfalische Wilhelms-Universitat, Pharmaceutical Chemistry, Munster, Germany;* [6]*University College London, Paediatric Oncology, London, United Kingdom*

Background: Doxorubicin is a key component of a number of treatment regimens used in paediatric oncology, despite the very limited pharmacology data in children on which current dosing regimens are based.

Material and Methods:
- Multicentre, multinational phase II pharmacokinetic study investigating age-dependency in the clearance of doxorubicin in children with solid tumours and leukaemia
- 100 patients treated according to a tumour-specific national or European therapeutic trial, with a particular focus on children less than 3 years
- Blood samples were collected at optimal sampling times during and after doxorubicin administration.
- Concentrations of doxorubicin and its major metabolite doxorubicinol were measured using a validated HPLC method.
- Markers such as troponins and natriuretic peptides were measured to evaluate as clinical markers for cardiotoxicity
- Data were analysed using a population pharmacokinetic approach including pharmacogenetic covariates

Results:
- 100 patients recruited, all data collected and analysed. The target number of patients less than 1 year (5) and 3 years (20) were achieved
- Interim analysis on the first 30 patients indicated that we have sufficient data to address the key question of age-dependent pharmacokinetics
- A population pharmacokinetic model has been developed and validated for application to the full data set.
- Data on cardiotoxicity indicate a detectable acute effect of doxorubicin administration.
- Data on pharmacogenetic influences on pharmacokinetics and toxicity will be presented

Conclusions:
- A multinational study of doxorubicin PK can address issues relevant to the EMA priority list of off-patent medicines
- Results from this study could be used to guide dosing of doxorubicin, especially in very young children

No conflict of interest.

Characterization and activity of a new anti-idiotype antibody in neuroblastoma

H.N. Lode[1], C. Eger[1], D. Seidel[1], D. Brackrock[1], N. Siebert[1]. [1]*University Medicine Greifswald, Pediatric Hematology and Oncology, Greifswald, Germany*

Background: Immunotherapy targeting disialoganglioside GD_2 emerges as an important treatment option for neuroblastoma, a pediatric malignancy characterized by poor outcome. Here, we report the generation and characterization of ganglidiomab, a new anti-idiotype antibody to anti-GD_2 antibodies of the 14.18 family for monitoring of clinical trials and the development of neuroblastoma vaccines.
Material and Methods: Balb/c mice were immunized with 14G2a and splenocytes harvested to generate hybridoma cells. Clones were screened by ELISA for mouse antibody binding to hu14.18. One positive clone was selected to purify and characterize the secreted IgG protein (kappa, IgG1).
Results: This antibody bound to anti-GD_2 antibodies 14G2a, ch14.18/CHO, hu14.18 and to immunocytokines ch14.18-IL2 and hu14.18-IL2 as well as to NK-92 cells expressing scFv(ch14.18)-zeta receptor. Binding of these anti-GD_2 antibodies to the nominal antigen GD_2 as well as GD_2 specific lysis of neuroblastoma cells by NK-92-scFv(ch14.18)-zeta cells was competitively inhibited by ganglidiomab, proving GD_2 surrogate function and anti-idiotype characteristics. The dissociation constants of ganglidiomab from anti-GD_2 antibodies ranged from 10.8 ± 5.01 to 53.5 ± 1.92 nM as determined by Biacore analyses using 'steady state' analysis. The sequences of framework- (FRs) and complementarity determining -regions (CDRs) of ganglidiomab were identified. Finally, we demonstrate induction of a GD_2 specific humoral immune response after vaccination of mice and patients with ganglidiomab effective in mediating GD_2 specific killing of neuroblastoma cells.
Conclusions: We generated and characterized a novel anti-idiotype antibody ganglidiomab for immune monitoring of clinical trials with anti-GD_2 antibodies and provide an important baseline for the development of anti-idiotype vaccines against malignancies expressing GD_2.
No conflict of interest.

1603 ORAL

Disease- and treatment-related factors implicated in late neuroendocrine morbidity after paediatric optic pathway gliomas: a preliminary multivariate analysis of 128 patients over 30 years

H. Gan[1], H.A. Spoudeas[1]. [1]*Great Ormond Street Hospital for Children NHS Foundation Trust, The London Centre for Paediatric Endocrinology and Diabetes, London, United Kingdom*

Background: Low-grade gliomas (LGGs) are the commonest benign childhood brain tumour and have high survival rates. However, their typical suprasellar position affecting the optic and diencephalic pathways renders them less surgically accessible or curable, with tumour and/ or treatment factors contributing to severe, life-threatening neuroendocrine morbidities. In the absence of major longitudinal studies, we sought to evaluate specific disease- and treatment-related risk factors for endocrine morbidity in a large single-centre 30-year paediatric cohort.
Materials and Methods: Multivariate regression analysis of retrospective, longitudinal data from case note review of the first 146/223 randomly audited patients diagnosed with optic pathway and diencephalic LGGs between 1980–2010 at Great Ormond Street Hospital.
Results: Patients were of median age 5.43 (0.18–15.07) years at diagnosis and followed up for a median of 7.75 (0.04–26.60) years. 5-year overall (OS), progression-free (PFS) and endocrine event-free survival (EEFS) were 95.3%, 60.5% and 41.9% respectively. Primary surgical intervention was positively predictive of OS (HR 0.02 (95% CI 0.00–0.72) and PFS (HR 0.16 (95% CI 0.07–0.41), whilst presenting hydrocephalus independently decreased OS (HR 78.03 (95% CI 2.36–2581.45). EEFS continued to decline up to 15 years from diagnosis with 79.4% of survivors experiencing at least one endocrinopathy, being independently predicted by hypothalamic tumour position (HR 7.85 (95% CI 2.48–24.80)) more than radiotherapy (HR 2.38 (95% CI 1.28–4.44). Both radiotherapy (β=0.68 (95% CI 0.44–0.92) and presenting diencephalic syndrome (β=0.51 (95% CI 0.02–0.99) were associated with increased numbers of endocrine deficits, most commonly GH deficiency (38.4%), followed by precocious puberty (24.8%), ACTH deficiency (16.4%), TSH/TRH deficiency (11.6%), LH/FSH deficiency (11.0%) and hyperprolactinaemia (9.6%). 12/18 patients with posterior pituitary dysfunction (9 SIADH, 6 diabetes insipidus, 6 cerebral salt-wasting) developed this peri-operatively (9 after biopsy/ ventricular shunt procedures only), of whom 3 died from resultant cardiovascular instability. 7/15 of the surviving patients had lifelong posterior pituitary dysfunction requiring treatment. 26.0% of patients developed obesity (BMI >98th centile for age), with the risk of insulin-resistance increasing with repeated surgical procedures (OR 1.47 (95% CI 1.02–2.11).
Conclusions: We provide new evidence to suggest a high prevalence of disabling endocrine morbidity in long-term suprasellar LGG survivors. This is more likely to result from hypothalamic involvement by tumour than irradiation. The role of surgery in aiding tumour control needs to be balanced against its significant attendant risks for life-threatening morbidity consequent on hypothalamic and posterior pituitary dysfunction incurred not just after repeated resections but also after minor surgical interventions.
No conflict of interest.

Ethical aspects of clinical trials in paediatric oncology. Two examples of literature reviews in the EU-FP7 ENCCA project

J. Dupont[1]. [1]*Institut Curie, Paris, France*

Background: European public health agencies acknowledge the importance of multi-faceted evaluations of the effectiveness, economic, social and ethical issues of health interventions (as for example within the EUnetHTA consortium). Such evaluations have to meet stringent methodological constraints concerning literature retrieval, analysis of literature samples and drawing of conclusions. The ethics work-package (WP18) of the ENCCA project aims at applying these methods to document the ethical aspects of clinical trials in paediatric oncology.
Material and Methods: Literature retrieval workflows for documenting ethical aspects imply the use of search algorithms in various bibliographical databases. Each step (definition of search algorithms and selection of databases) has to be transparent and well-grounded, as in effectiveness assessments. Main specificity of ethics literature reviews lies in the possibility not to exclude articles based on methodological criteria. Where such criteria are applied, the literature review is systematic; otherwise, it is narrative. One narrative and one systematic review of literature have been performed by ENCCA WP18. The former aimed at identifying the variety of ethical issues in paediatric oncology research and the latter at analysing the debates surrounding the moral justification for making research with children.
Results: Results of each literature review are outlined. Advantages and limitations of both approaches to ethical evaluation are compared with regard to the scientometric analysis and qualitative analysis of literature samples they allowed as well as with regard to the kind of conclusions which could be drawn.
Conclusions: Systematic and narrative literature reviews are relevant for making a state of ethical knowledge, depending on whether conclusiveness or comprehensiveness is privileged. Regardless of their differences, both can fit basic requirements of transparency, pluralism and impartiality. They are therefore useful for professionals, stakeholders and policy makers for they avoid undue value judgements and leave space for decision making.

In counterpart, they clearly do not replace (but complete) normative and empirical ethics.
No conflict of interest.

Visual improvement following Nerve Growth Factor eye-drop administration in patients with optic pathway glioma-associated visual impairment; prelimary results of a double blind trial

R. Riccardi[1], A. Chiaretti[2], D. Rizzo[1], M. Piccardi[3], A. Dickmann[3], I. Lazzareschi[1], A. Ruggiero[1], E.M. Proli[4], L. Manni[5], B. Falsini[3]. *[1]Catholic University "A. Gemelli" Hospital, Department of Pediatric Oncology, Roma, Italy; [2]Catholic University "A. Gemelli" Hospital, Department of Pediatric Sciences, Roma, Italy; [3]Catholic University "A. Gemelli" Hospital, Institute of Ophthalmology, Roma, Italy; [4]Catholic University "A. Gemelli" Hospital, Pharmacy, Roma, Italy; [5]Catholic University "A. Gemelli" Hospital, Institute of Translational Pharmacology, Roma, Italy*

Background: To date, no specific therapy is available for optic pathway glioma (OPG)-associated visual impairment. The aim of this study was to evaluate the effects on visual function of murine nerve growth factor (NGF) eye drop administration in patients with visual impairment due to OPGs.
Methods: A prospective randomized double-blind controlled study was conducted in patients younger than 24 years with OPG-induced visual impairment, without or with NF1. All patients were off-therapy and with stable disease at 2 brain magnetic resonance imaging (MRI) controls, performed at least 6 months apart. NGF eye-drop was prepared by Policlinico Gemelli University Pharmacy according to standard required for human use. The patients were assessed by clinical evaluation and ophthalmological examinations including visual acuity, visual field, photopic negative response (PhNR), visual evoked potentials (PEV), Ganzfeld electroretinograms and optic coherence tomography. All patients were recorded at baseline and 15, 30, and 90 days post treatment. A further evaluation at 180 days is planned but no data are available at this time. Brain MRI was performed at baseline and is planned at 180 days after NGF treatment. All the evaluations were performed by considering the change of parameters values from baseline.
Results: Ten and 8 patients received a single 10-day course of 1 mg murine NGF topical administration and placebo, respectively. Preliminary results (up to 90 days) showed a 40% ($p = 0.02$) and a 50% ($p = 0.09$) improvement of visual field in at least one eye from the baseline evaluations with a better quality of life in the NGF group at 30 and at 90 days post treatment, respectively, compared to a 14% increase in the placebo group. An increase of the mean PhNR amplitude till 90 days was observed in the treated eyes but this was not statistically significant compared to the placebo group; mean PhNR latency increased significantly compared to the placebo group (1.3 vs −1.8 $p = 0.03$) at 15 days but then the difference disappeared. Mean PEV amplitude increase was borderline significant compared to placebo group ($p = 0.06$) at 30 days. No changes in the visual acuity were observed in both groups and no other significant differences were observed for the other ophthalmological examinations.
Conclusions: Preliminary results suggest a visual rescuing mechanism exerted by murine NGF on the residual viable optic pathways. NGF administration appears an effective and safe adjunct therapy in patients with OPG-associated visual impairment.

1606 POSTER

Genomic background of neuroblastomas with intratumour heterogeneity of MYCN amplification

P.F. Ambros[1], D. Bogen[1], C. Brunner[1], G. Amann[2], B. Gürtl-Lackner[3], R. Abbasi[1], T. Martinsson[4], M. Bilban[5], R. Ladenstein[6], I.M. Ambros[1]. *[1]CCRI Children's Cancer Research Institute St. Anna Kinderkrebsforschung, Tumor Biology, Vienna, Austria; [2]Medical University Vienna, Dept. of Clinical Pathology, Vienna, Austria; [3]Medical University of Graz, Institute of Pathology, Graz, Austria; [4]University of Gothenburg, Dept. of Clinical Genetics The Sahlgrenska Academy, Gothenburg, Sweden; [5]Medical University Vienna, Core Facility Genomics, Vienna, Austria; [6]St. Anna Kinderspital, Vienna, Austria*

Background: *MYCN* amplification (MNA) is the most powerful therapy-stratifying marker in neuroblastoma (NB). Although the existence of intratumour heterogeneity of MNA (hetMNA) is well known today, its clinical meaning is still unclear, compromising the patients' assignment to specific treatment strategies. To learn whether the genomic background of hetMNA tumours differ to the genomic background of homogenously MNA (homMNA) tumours and non-amplified NBs, we looked for common segmental and numerical chromosome aberrations, allelic imbalances and the expression of favourable NB marker CD44.
Material and Methods: Ultra high resolution SNParray analyses and interphase FISH on various tumour samples and bone marrows (BM) obtained from 18 NB patients were performed. Median patient age was 13.5 months (range 6–168), 11 patients were below and 7 above 18 months of age. CD44 staining was done by fluorescence labelled antibodies on cryo-sections.
Results: Besides hetMNA, five tumours showed no segmental chromosomal aberrations (noSCA), another five were heterogeneous concerning both, MNA and SCA (hetSCA), and eight exhibited a high number of SCAs (highSCA), one with chromothripsis. Whole chromosome uniparental disomy (wcUPD) occurred in 11/18 tumours (61.1%) hetMNA tumours, in 1/9 homMNA tumours and in 11/36 (30.6%) of the nonMNA NBs. wcUPD of chromosome 11 was exclusively found in the hetMNA group (6/11). The increase of SCA correlated with age (no/hetSCA: 10/11 infants and high SCA: 7/7 patients >18m). By contrast, UPD11 decreased with age (UPD11: 6/11 infants and 0/7 patients >18m), segmental chromosome 11 aberrations, however, increased and were found exclusively in patients >18m (4/7). Furthermore, hetMNA tumours were frequently $CD44^+$, which is not the case in homMNA tumours.
Conclusions: The high frequency of wcUPDs, especially UPD11, in hetMNA tumours has not been described so far and could represent a hallmark of hetMNA NBs. This data provide a more complete picture of the tumour genomics landscape portrayed from single tumour-biopsy.
No conflict of interest.

1607 POSTER

Pharmacogenomic analysis of high-dose methotrexate treatments in children with acute lymphoblastic leukemia treated with ALL-BFM 95 and ALL IC-BFM 2002 protocols

K. Csordas[1], O. Lautner-Csorba[2], A.F. Semsei[2], M. Hegyi[1], O.T. Eipel[1], A. Harnos[3], D.J. Erdelyi[1], C.S. Szalai[2], G.T. Kovacs[1]. *[1]Semmelweis University, 2nd Department of Pediatrics, Budapest, Hungary; [2]Semmelweis University, Department of Genetics Cell- and Immunbiology, Budapest, Hungary; [3]Szent Istvan University Faculty of Veterinary Science, Department of Biomathematics and Informatics, Budapest, Hungary*

Background: High-dose methotrexate (HD-MTX) is the key component of the consolidation therapy of childhood acute lymphoblastic leukemia (ALL). The pharmacokinetics of the drug show large interpatient variability even with the same treatment protocol. The aim of the present study was to investigate the influence of single nucleotide polymorphisms (SNP) in genes of the folate metabolic pathway, transporter molecules and transcription proteins on the pharmacokinetics and toxicity of methotrexate (MTX) and 7-hydroxy-methotrexate (7-OH-MTX) after HD-MTX treatments in children with ALL.
Methods: Totally 463 HD-MTX infusions were analyzed. Data of 48 children treated with 5 g/m^2/24 h and 70 children treated with 2 g/m^2/24 h HD-MTX according to ALL-BFM 95 and ALL IC-BFM 2002 protocols were collected [mean age: 6.4 years (1.1−18 years)]. 63 SNP of 14 genes were genotyped. Hepato-, nephro- and bone marrow toxicities, estimated by routine laboratory parameters were evaluated. Random forest analysis and regression trees were used for variable selection. Linear mixed models were established to prove the significance of the selected variables and to estimate effect sizes. MTX and 7-OH-MTX values were log transformed to ensure correct model diagnostics.
Results: The rs4149056 of SLCO1B1 showed significant association with the serum levels of MTX ($p < 0.001$). SNPs (rs4948502, rs4948496) of ARID5B gene were associated with serum levels of MTX ($P<0.001$), serum levels and AUC of 7-OH-MTX ($P<0.001$) and with hypoproteinaemia ($P<0.001$). Hepato-, nephrotoxicity, granulocytopenia and hypoproteinaemia were associated with novel genetic variations of SLC19A1, SLC22A8, MTR and MTHFD1 genes ($P<0.05$, respectively).
Conclusions: We confirmed the associations of novel genetic variations in folate related and ARID5B genes with MTX plasma levels and the development of acute toxicity. Further analysis and validation in a larger cohort is necessary to determine the predictive value of these associations.
No conflict of interest.

LINES as a paradigm of risk-adapted therapies using prognostic biomarkers: A SIOPEN trial

V. Segura[1], G. Schleiermacher[2], P. Ambros[3], A. Di Cataldo[4], J. Bermúdez[5], V. Mosseri[6], V. Papadakis[7], K. Wheeler[8], R. Ladenstein[9], A. Cañete[10]. *[1]Instituto de Investigación Sanitaria La Fe, Unidad de Ensayos Clinicos, Valencia, Spain; [2]Institut Curie, Laboratoire de Génétique et Biologie des Cancers, Paris, France; [3]Children's Cancer Research Institute, Tumor Biology Department, Vienna, Austria; [4]University of Catania, Pediatric Hematology and Oncology, Catania, Italy; [5]University of Valencia, Departamento de Estadística e Investigación Operativa, Valencia, Spain; [6]Institut Curie, Department of Clinical Research Biostatistical Unit, Paris, France; [7]Aghia Sophia Children's Hospital, Department of Pediatric Hematology- Oncology, Athens, Greece; [8]Oxford Children's Hospital, Department of Paediatric Haematology and Oncology, Oxford, United Kingdom; [9]Children's Cancer Research Institute, St. Anna Children's Hospital, Vienna, Austria; [10]Hospital Universitario y Politécnico La Fe, Paediatric Oncology, Valencia, Spain*

Background: In the framework WP10 (ENCCA PROJECT), the LINES trial uses risk-adapted therapies in low and intermediate-risk Neuroblastoma (NB) according to international standards and regulations. Image defined risk factors, the presence or not of symptoms and for the first time the presence or absence of segmental chromosome aberrations are being used in the decision making process to stratify treatment.
Material and Methods: LINES (EudraCT: 2010–021396−81, ClinicalTrials.gov Identifier: NCT01728155) includes ten separate therapeutic groups, one of them randomised. All the cases are registered at SIOPEN-R-NET with check-points to control the quality of prospectively entered staging data and there is real time central review for biology and histology.
Results: In July 2011, the LINES trial sponsored by IIsLaFE (Spain) obtained approval from the Spanish National Competent Authority and the Ethic Committees of 28 participating Spanish sites. In addition to the Spanish sites the trial is also open in Austria (5 sites), Denmark (3 sites), France (1 site), Norway (4 sites) and Italy (21 sites). Thirty five patients have been enrolled since December 2011. The other 14 SIOPEN countries are still in the process of opening the trial. Under the current European Union (EU) Paediatric Regulation, academic paediatric trials are difficult to implement because of cost, bureaucracy and especially different national interpretations of the current legislation.
Conclusions: It is imperative to review and reassess the current European directive. We hope revision of the EU Clinical Trials Directive will result in minimising the current disparity in the interpretation of the directive that currently exists between different participating countries and therefore expedite the launch of future European academic paediatric trials.
Acknowledgements: European Union's Seventh Framework Programme (FP7 2007–2013) under the project ENCCA grant agreement no. 261743.
No conflict of interest.

1609 POSTER

Neoadjuvant chemotherapy in metastatic medulloblastoma: Changing paradigms

L. Guerrini[1], C. Dufour[1], S. Puget[2], V. Kieffer-Renaux[1], M.A. Raquin[1], P. Varlet[3], C. Sainte-Rose[2], J. Grill[1]. *[1]Institut Gustave Roussy, Pediatric and Adolescent Oncology, Villejuif Cedex, France; [2]Necker Childrens Hospital, Neuro-surgery, Paris, France; [3]St Anna Hospital, Anatomo-pathology, Paris, France*

Background: Treatment-related morbidity is a major concern in medulloblastomas, particularly because of surgical complications. Preoperative chemotherapy may be useful to decrease morbidity and enhance the efficacy of surgery.
Material and Methods: Seventy one children were treated for a metastatic medulloblastoma in a single reference center. We retrospectively compared children treated with 2 strategies according to the refering neurosurgical wards.
Results: Tumor surgery was performed either at the time of the diagnosis (42 patients) or after neoadjuvant conventional chemotherapy with carboplatin and etoposide (29 patients). Hydrocephalus was usually treated with a ventriculocisternostomy before initiatiation of the chemotherapy. In all the 29 cases treated with neoadjuvant chemotherapy, diagnosis was confirmed by a biopsy either of a metastasis during ventriculocisternostomy or directly of the primitive tumor. Children were treated with different post-operative protocols combining chemotherapy, eventually at high-dose with stem-cell rescue and radiotherapy adapted to age. The current retrospective study was designed to define the correlations between the timing of surgery and the post-operatives complications, neuropsychological outcome, and survival.
Chemotherapy decreased disease extension for 25 patients (86%) and delayed surgery allowed a complete tumor excision more often than with first-line surgery (100% vs 64%, $p = 0.002$). Differing the surgery did not have deleterious consequences on the local control of the tumor, on the rate of post-operatives complications and on patients' survival. Moreover, median IQ score was higher in the group 'delayed surgery' (88.5 vs 71.5), especially for children aged under 5 years at the time of the diagnosis ($p = 0.02018$). The IQ score was not associated with the dose of brain irradiation.
Conclusions: When treatment schedules are adapted to risk of disease and age, surgery-related risk factors then become critical for predicting intellectual impairment. Neoadjuvant chemotherapy significantly leads to more frequent complete tumor excision result and decreases the neuropsychological impairment.
No conflict of interest.

1610 POSTER

131I-mIBG therapy in the management of refractory and relapsed neuroblastoma: An individualised approach

S. George[1], S.J. Kirk[1], D. Lancaster[1], S.J. Vaidya[1], H. Mandeville[2], F. Saran[2], S. Chittenden[3], A.D.J. Pearson[1], Y. Du[4], G.D. Flux[3]. *[1]The Royal Marsden Hospital, Paediatric Oncology, Sutton, United Kingdom; [2]The Royal Marsden Hospital, Radiotherapy, Sutton, United Kingdom; [3]The Royal Marsden Hospital and Institute of Cancer Research, Joint Department of Physics, Sutton, United Kingdom; [4]The Royal Marsden Hospital, Nuclear Medicine, Sutton, United Kingdom*

Introduction: An individualised form of ^{131}I-mIBG therapy using whole body dosimetry has been developed at our institution for the management of children with relapsed/refractory neuroblastoma. We report clinical parameters, toxicity and outcome data.
Methods: Case note review of children treated at the Royal Marsden Hospital from 1994–2012. In earlier years an initial tracer study was used to calculate the therapeutic activity needed to deliver a whole body dose (WBD) of 2 Gy, subsequently 4 Gy was delivered in 2 fractions by an initial therapeutic activity of 444mBq/kg followed by dose adjustment according to the measured WBD for the second therapy.
Results: 45 treatments were given to 26 patients. Mean age at diagnosis: 5 years 7 months, mean age at first mIBG: 7 years 5 months. Indication for mIBG therapy: Primary refractory disease (12), relapse (8), other (6). Mean administered mIBG activity: 10951mBq (range 3539–32871mBq), mean mIBG whole body dose 1.8 Gy (1−3.5 Gy).
10 patients received haemopoietic stem cell rescue (HSCR) after mIBG therapy, 5 further patients went straight from mIBG therapy to high dose chemotherapy followed by HSCR.
Grade 3−4 neutropenia was seen following 20/24 treatments, grade 3−4 thrombocytopenia in 20/26 treatments. There were no toxic deaths related to mIBG therapy. In 22/45 treatments there was acute toxicity, which was mainly febrile illnesses/documented infection. The only long term toxicity was prolonged thrombocytopenia in one patient who did not receive HSCR. Response rates on first post treatment mIBG scan were complete response (4.5%), partial response (52%), stable disease (30%), progression (9%) and mixed response (4.5%). 6 patients were alive with disease at last follow up (mean 11 months) and 3 are alive and disease free at last follow up (4 months, 20 months and 10 years).
Conclusions: Children with relapsed/refractory neuroblastoma are a heterogenous group who require an individualised approach to therapy. Personalised ^{131}I-mIBG therapy based on WBD is a viable treatment option which allows administration of relatively high activities. It is well tolerated and haematological toxicity is the dose limiting side effect. Our overall response rate of 57% compares very favourably with the response rates of 27−39% in other series. Prospective European multi-centre clinical trials are in preparation to further define the role of ^{131}I-mIBG therapy.
No conflict of interest.

1611 POSTER

High-resolution genomic profiling of disseminated neuroblastoma cells

M.R. Abbasi[1], C. Brunner[1], I.M. Ambros[1], M. Bilban[2], A. Ziegler[1], R. Ladenstein[3], P.F. Ambros[1]. *[1]Children's Cancer Research Institute, Tumour Biology, Vienna, Austria; [2]Medical University of Vienna, Core Facility Genomics, Vienna, Austria; [3]Children's Cancer Research Institute, Studies & Statistics for Integrated Research and Projects, Vienna, Austria*

Background: Disseminated disease in neuroblastoma (NB) patients is not necessarily associated with an aggressive clinical course. Genomic features, such as amplification of the *MYCN* gene and/or segmental chromosomal aberrations (SCAs), help to separate aggressively behaving

tumours from less aggressive/benign NBs representing excellent markers for therapy stratification. This also applies to the two disseminated stages M and MS. Since tumour tissue is not always accessible, we searched for a bone marrow (BM) enrichment technique enabling detailed genomic analyses of disseminated tumour cells (DTCs).
Material and Methods: Altogether 49 BM and tumour samples from 34 patients were analysed with an ultra-high resolution SNP array technology (2.7 million probes). BM samples with <50% tumour cell content were enriched by magnetic activated cell sorting resulting in an up to four log step increase of tumour cells.
Results: Paired BM and tumour samples from diagnosis at the same time point showed nearly identical SNP array results. We found 30 breakpoints in 22 chromosomes in DTCs of 4 patients at diagnosis and identical SCAs in primary tumours except two more breakpoints in one tumour. DTCs of four other patients at diagnosis compared to tumours after induction chemotherapy three months later, showed 44 breakpoints in 23 chromosomes in tumours and DTCs with the exception of two more breakpoints in DTCs of one patient. In three further patients, primary diagnostic tumour samples were compared to DTCs at relapse, three to six years later. In the primary tumours 28 breakpoints were found, while the relapse DTCs showed 45. 17 breakpoints were identical at both time points. Thus, the frequency of SCAs and breakpoints in the relapse samples clearly differed from that of the diagnostic materials showing an acquisition of SCAs.
Conclusions: Magnetic bead enriched tumour cells from BMs of 'favourable' and unfavourable disseminated diseases (stages M/MS) give excellent and reliable results with SNP array technique providing detailed insights into the tumour genomics. Thus, this technique is suitable for clinical evaluation and genomic-based risk classification.
No conflict of interest.

1612 POSTER

Factors predicting induction outcome in paediatric ALL: Experience from Western India

C.B. Avinash[1], B.J. Parikh[2], P.M. Shah[2], K.M. Patel[2], S.N. Shukla[2], A.S. Anand[2], S.S. Talati[2], A.A. Patel[2], H. Panchal[2], B.B. Parekh[2]. *[1]Apollo BGS Hospitals, Medical Oncology, Mysore, India; [2]Gujarat Cancer and Research Institute, Medical Oncology, Ahmedabad, India*

Background: Failure of induction therapy in paediatric ALL is an uncommon event − most western series report <1% failure rates, but it is still high and variable in Indian series ranging from 2 to 7%. MRD analysis is not available routinely. This study has analysed factors predicting induction outcome in Western Indian paediatric population.
Material and Methods: All newly diagnosed paediatric ALL patients at Gujarat Cancer and Research Institute from 1st October 2009 to 30th September 2011 were included in this study. Baseline data included demographic, clinical, bone marrow, cytogenetics, immunophenotyping characteristics. Induction outcome was defined by standard criteria. Univariate and multivariate analysis was done for factors predicting induction outcome.
Results: A total of 330 children were enrolled in this study. Median age was 6 years. Our patients had higher WBC count compared to western population. Cytogenetic abnormalities were found in 32%. Philadelphia chromosome positivity was seen in 7.3% of cases. Immunophenotypic analysis was done in 198 (60%) patients, and most common subtype was Early Pre B type (49%); T-cell phenotype constituted 20% of patients. Most patients (n = 296) were treated with MCP 841 protocol, few (n = 30) patients with BFM 90 protocol, based on financial, demographic, and subtype of ALL. Infants (n = 4) were treated with Interfant 99 protocol. In our study therapy abandonment rate was very high (17%). CR rate in our study was 87%, which is slightly lower to other Indian studies but far less than that of international trials. Present study had induction failure rate of 6% and induction mortality rate of 7%. Most common cause of induction mortality was infection (80%). On univariate analysis, factors predicting CR were − day 8 peripheral blast count of <1000/mm3, absence of CNS disease, haemoglobin levels of $\geqslant$8 gm/dl ($p \leqslant 0.01$), use of BFM 90 vs. MCP841 protocol ($p = 0.03$). On multivariate analysis, factors predicting induction failure were − day 8 peripheral blood blasts of $\geqslant$1000/mm3 ($p < 0.001$), LDH>500 IU/L ($p = 0.03$) and presence of CNS disease ($p = 0.07$).
Conclusion: The higher failure rates are likely to have arisen from a higher incidence of high-risk disease at diagnosis, intercurrent infections, poor socioeconomic status, level of hygiene achievable at home, and poor access to acute care. This highlights that heterogeneity in the patient population and resources can cause significant differences in outcome.
No conflict of interest.

1613 POSTER

Pediatrics surface osteosarcomas − a French multicenter study (SURFOS)

C. Boulanger[1], M.P. Castex[1], A. Gomez-Brouchet[2], J. Sales De Gauzy[3], C. Munzer[4], A.I. Bertozzi[4]. *[1]Chu Toulouse − Hopital Purpan, Service d'Onco-Hématologie Hopital des Enfants, Toulouse cedex 09, France; [2]CHU Toulouse − Hopital Rangueil, Service d'Anatomopathologie, TOULOUSE, France; [3]Chu Toulouse − Hopital Purpan, Service d'Orthopédie Pédiatrique − Hôpital des Enfants, Toulouse, France; [4]CHU Toulouse − Hopital Purpan, Service d'Onco-Hématologie − Hôpital des Enfants, Toulouse, France*

Background and objectives: The great majority of osteosarcomas (OS) are intra-medullary lesions, but a small proportion arise from the surface of bone. Surface OS can be divided into three distinct histologic subtypes: parosteal OS, periosteal OS and high-grade surface OS. The objective of this study was to review and analyse the treatments of these tumors in order to upgrade and homogenize practises for the managment of surface OS in children.
Methods: We reviewed the therapeutic managment of 28 cases of pediatric (under 18 years) surface OS treated in 11 french Cancer Center between 1990 et 2010.
Results: Eleven patients had parosteal, sixteen patients had periosteal and one patient had high-grade surface OS. The median age at the diagnosis was 14.3 years (range, 5.8−17.9 years). Seven patients were male. None had metastatic disease at diagnosis. All 28 patients were treated with surgery, and 21 (7 with parosteal, 13 with periosteal and 1 with high-grade tumors) received chemotherapy. Three patients relapsed (local relapse for 1 patient with parosteal OS and distant relapses for 2 patients with periosteal OS) and four patients with periosteal OS developped a second cancer (at the origin of the deaths for three of them). The 11-year overall survival rate was 100% for parosteal OS and 63$\pm$18% for periosteal OS.
Conclusions: The histologic grade predicts the clinical behavior of pediatric surface OS. Complete resection is the treatment of choice regardless of tumor subtype. Whereas chemotherapy is not indicated for parosteal OS, its role in periosteal OS remains controversial.
No conflict of interest.

1614 POSTER

Pharmacogenetic analysis of high-dose methotrexate treatment in paediatric osteosarcoma

M. Hegyi[1], K. Csordas[1], O. Eipel[1], E. Csagoly[1], D.J. Erdelyi[1], A.F. Semsei[2], G.T. Kovacs[1]. *[1]Semmelweis University, II. Department of Peadiatrics, Budapest, Hungary; [2]Semmelweis University, Department of Genetics Cell- and Immunobiology, Budapest, Hungary*

Background: High-dose methotrexate (HD-MTX) infusion is a cornerstone of therapy for osteosarcoma. Our aim was to examine the influence of single nucleotide polymorphisms (SNPs) of folate related genes on the pharmacokinetics and toxicity of HD-MTX treatments in children with osteosarcoma.
Materials and Methods: Pharmacokinetic, toxicity and epidemiology data of 929 HD-MTX courses of 98 patients treated with osteosarcoma at the 2nd Department of Paediatrics, Semmelweis University, Budapest were evaluated. Pharmacokinetic parameters (MTX clearance, half-life and area under curve(AUC_{0-48}) of concentration-time function) were calculated based on MTX serum levels measured at 6, 24, 36, 48 hours after the initiation of the infusion. Hepato-, nephro- and myelotoxicity parameters were categorized according to Common Toxicity Criteria v.3.0. Twenty-nine SNPs of 11 genes were genotyped in 62 patients. Frequentist and bayesian statistical analyses were used to evaluate the relationships between the genotypes and the clinical data.
Results: Higher peak MTX concentrations ($p = 0.002$), 48 h MTX serum levels ($p = 0.0034$) and AUC_{0-48} ($p = 0.00001$), and significantly lower MTX clearance ($p = 0.0001$) was correlated significantly with the development of toxicity. Higher 48 h MTX serum levels were associated with a better 5-year overall and event-free survival. The incidence of serious acute hepatotoxicity was less frequent ($p = 0.0033$) and 48 h MTX serum levels were significantly lower ($p = 0.0003$) in patients homozygous for rs3758149 (*GGH*) variant allele than in the others. The frequency of serious acute hepatotoxicity was significantly higher ($p = 0.001$) in patients homozygous for rs1051266 (*RFC1*) variant allele than the others. The rs928256 (*ABCB1*), rs4793665 (*ABCC3*), rs3758149 (*GGH*) and the rs3814058 (*SXR*) SNPs showed significant associations with the pharmacokinetics of MTX according to both single- and multi-variate bayesian analyses.
Conclusions: However longer MTX exposure might lead to serious toxicity, it also improves treatment outcome. Our present results suggest the possibility of a future population pharmacokinetic model with pharmacogenetic data based dose individualization.
No conflict of interest.

1615 POSTER

Early PET-CT importance in determining survival of pediatric Hodgkin's disease

S. Ahmed[1], M.S. Zaghloul Md[1], I.M.A.N. Attia Md[1], A.L.A.A. Hadad Md[1], W. Omar Md[1], S.H. Abouelnaga[1], S. Ezzat PhD[1]. [1]*Children's Cancer Hospital Egypt, Radiotherapy, Cairo, Egypt*

Objective: To determine the effectiveness of Positron emission tomography (PET) as a prognostic predictor for Hodgkin's lymphoma children treated with risk-adapted therapy.
Methods: A prospective single arm study including 156 Hodgkin's disease children and adolescents were treated at Children's Cancer Hospital, Egypt during the period February 2008 to June 2010. The treatment was risk-adopted, receiving 4−6 courses of chemotherapy and involved filed low dose radiotherapy or 8 courses of chemotherapy without radiotherapy. All patients underwent PET-CT prior and after 2 courses of chemotherapy. A third PET-CT was performed at completion of chemotherapy for PET-positive patients.
Result: The 3-year overall survival rate (OS) was 96.8±1.8%. The OS rate were 100%, 94.4%, 81.8% and 69.6% for stages I, II, III and IV respectively. The event-free survival (EFS) was 86.4±5.0% for the whole group and 93.3%, 94.4%, 81.8% and 69.6% for stages I, II, III and IV respectively. All early PET-CT negative patients (after 2 courses) were alive (100%) and their 3-year EFS was 98.5±1.5%, while these who retained positivity had OS of 78.8±13.4% and EFS of 53.3±23.3%. This difference was statistically significant ($p = 0.001$). The OS and EFS for those who retained positivity after PET-CT completion of chemotherapy were both 50.0±25.0%. On the other hand those who showed PET-CT negativity after completion of chemotherapy enjoyed OS and EFS of 100%.
Conclusion: PET-CT is an excellent response-predictor for pediatric Hodgkin's disease who were treated with risk-adapted protocols.
No conflict of interest.

1616 POSTER

Possible influence of the N363S glucocortocoid receptor gene polymorphism on chemotherapy-induced toxicities and on the effect of chemotherapy in children with acute lymphoblastic leukemia (ALL)

O. Eipel[1], K. Németh[1], M. Hegyi[1], K. Csordás[1], D. Török[1], A. Ponyi[1], D.J. Erdélyi[1], M. Csóka[1], G.T. Kovács[1]. [1]*2nd Department of Paediatrics Semmelweis University Faculty of Medicine, Budapest, Hungary*

Background: Altough the fact the cure rate of childhood acute lymphoid leukemia (ALL) is above 80%, chemotherapy-induced toxicities are still concerned as a major challenge during the therapy. This study investigated a possible association between increased glucocorticoid sensitivity due to the N363S polymorphism of the glucocorticoid receptor gene and steroid-related toxicities during pediatric ALL therapy. The possible changing in the effectivity of the chemotherapy were analyzed as well.
Material and Methods: 346 pediatric ALL patients were involved in the present study. N363S polymorphism was identified by allele-specific PCR. We analyzed and compared clinical and laboratory signs of glucocorticoid related toxicities, day 8 prednisone response, and 5-year event-free survival rates retrospectively among carriers and non carriers.
Results: Thirty-two of the 346 patients were heterozygous carriers (9.2%). Glucose metabolism abnormalities (18.8% vs 3.8%, $P = 0.001$, carriers and non-carriers, respectively) and hepatotoxicity (31.3% vs 11.2%, $P = 0.004$, carriers and non-carriers, respectively) occurred more often among 363S-carries. No difference was appeared in the frequency of encephalopathy/psychosis nor of hypertension among carriers and non-carriers. 363S-carrier status is seemed to contributed to have a combination of toxicities. All carriers had good prednisone response (100%) and had more favorable 5-year event-free survival rates (93.1% vs. 71.86%, $P = 0.012$). Among non-carriers there were more poor prednisone responders (8.28%) and worse 5-year event-free survival rates.
Conclusion: In our study N363S polymorphism of the glucocorticoid receptor gene is proved to predispose to more severe steroid-related toxicity during ALL therapy. The identification of a possible 363S-carrier status could be a part of individualized therapy in the future.
No conflict of interest.

1617 POSTER

EPOC-experiences − conducting a multinational clinical trial on the pharmacology of doxorubicin in children with cancer

M. Krischke[1], N. Andre[2], A. Boddy[3], G. Bode[4], M. D'Incalci[5], G. Hempel[6], N. Kontny[6], A. Steel[3], V. Völler[6], J. Boos[7]. [1]*University Hospital Münster, Center for Clinical Trials, Münster, Germany;* [2]*Centre Hospitalier Universitaire AP-HM, Marseille, France;* [3]*Newcastle University, Northern Institute for Cancer Research, Newcastle upon Tyne, United Kingdom;* [4]*International Confederation of Childhood Cancer Parent Organizations, Bonn, Germany;* [5]*Department of Oncology Istituto di Ricerche, Farmacologiche "Mario Negri", Milan, Italy;* [6]*Westfälischen Wilhelms-Universität Münster, Institut für Pharmazeutische und Medizinische Chemie, Münster, Germany;* [7]*University Hospital Münster, Paediatric Haematology and Oncology, Münster, Germany*

Background: EPOC (European Paediatric Oncology off-patent medicines Consortium) is an EU FP7-fundet project with the goal to obtain missing pharmacology data for off-patent drugs for children with cancer to use for paediatric use marketing authorizations (PUMA).
Material and Methods: The first trial performed by EPOC, the 'Doxo-trial' (EudraCT No. 2009–011454−17), is a pharmacokinetic (PK) study of doxorubicin, which was performed in 4 European countries (Germany, UK, France and Italy) and recruited 100 children.
Results: Like most investigator-initiated multinational trials, the Doxo-trial faced a range of difficulties in order to be set up in the various countries. These came from:
– regulatory and ethical issues
– organisation of responsibility
– harmonising trial specific procedures and clinical work flows
– compliance with ICH-GCP, trial protocol and working procedures (WP)
– assurance of adequate patient recruitment.

In addition, it had to be ensured that the trial would fulfil all prerequisites for a PUMA application. To cope with this point, the EMA has been involved in regulatory discussions and a Scientific Advice. Work load and responsibility was split between project management, Sponsor and National Study Managers (NSM). The Sponsor organized all international challenges incl. contracts, insurance and pharmacovigilance. NSM set up the clinical network and dealt with regulatory and ethical issues on the national level. Despite other intention the time span for the first centre initiation to the last reached 18 months. Reasons included contractual issues and dealing with patient insurance.
For a PK trial it was important to harmonize differences in doxorubicin administration and sample handling. A precise WP was therefore written and trained. In enforcing compliance country or centre-specific practical and/or cultural differences were observed. Capillary sampling for example was an acceptable method in some centres but faced great barriers in others.
Conclusions: Organisation of the trial, extent of compliance and reasons for non-compliance to protocol and WPs will be presented and the consequences of this experience discussed for trials in paediatric oncology.
No conflict of interest.

1618 POSTER

Benchmarking teenage and young adult cancer professional developments across Europe: A Delphi Survey

L.A. Fern[1], D.P. Stark[2], B. Phillips[2], S. Morgan[2], A. Azzim[3], F. Gibson[4]. [1]*University College London Hospitals, Oncology, London, United Kingdom;* [2]*St James University Hospital Leeds, Oncology, London, United Kingdom;* [3]*University of Leeds Teaching Hospitals, Oncology, London, United Kingdom;* [4]*London South Bank University and Great Ormond Street Hospitals NHS Foundation Trust, Oncology, London, United Kingdom*

Background: The European Network for cancer research in children and adolescents (ENCCA) is a pan European research initiative aimed to improve outcomes for children and young people with cancer. A multidisciplinary European taskforce has been formed to deliver the remit of work package 17 which is divided into six work streams:
1. Create a European Multidisciplinary Framework for teenage and young adult (TYA) cancer
2. Develop TYA multi-professional education
3. Improve access to clinical trials for TYA
4. Develop a European TYA research initiative
5. Promote healthy lifestyles in TYA population and cancer survivors
6. Establish links to patient and support organizations.

Aims: We aimed to scope out TYA cancer professional, service and research developments to ascertain to what extent the above work streams are being addressed in each of the European Countries with a view to create a consensus of TYA service and research priorities. The exercise

also allows benchmarking and therefore tracking of changes over time within the ENCCA project.
Methods: A 3−4 round Delphi survey is being carried out. Participants were invited through known TYA professional bodies: Teenage and Young Adult Cancer (TYAC) in the UK and SIOP. Participants were encouraged to forward the questionnaire onto colleagues.
Results: A total of 116 questionnaires were returned of which 60 were fully completed and available for analysis in round 1. Respondents were mainly medical (n = 39, 65%) or nursing professionals (n = 12, 20%), and unknown (n = 3, 5.0%) and represented 21 countries. Analysis shows lack of consensus across Europe in a number of areas, including the age criterion, which defines teenagers and young adults with cancer. There is disparity in development of TYA services, research and patient advocacy across Europe. Communication and integration of paediatric, haematology, adult, palliative and primary care services also varied. Differences in research priorities are most likely related to differences in healthcare systems and infancy or development of TYA services.
Conclusion: The second round Delphi survey will be distributed May 2013 and will seek consensus of TYA definition, service configuration and prioritisation of research. This presentation will focus on rounds 1 and 2, present briefly the methodology used, and focus on the emerging trends, differences and similarities that defines the speciality of TYA care across Europe.
No conflict of interest.

1619 POSTER

Child cancer registration in Romania: Unveiling the gap

M. Dragomir[1], M. Bucurenci[2], C. Comsa[1], M. Badoi[1], L. Neamtiu[3], D. Coza[3], R. Cosnarovici[4], S. Arghirescu[5], A. Colita[6], D. Baghiu[7].
[1]Institute of Oncology "Prof. Dr. Al. Trestioreanu", Pediatric Oncology, Bucharest 2, Romania; [2]Synectics4Progres, Bucharest, Romania; [3]Institute of Oncology "I. Chiricuta", Epidemiology, Cluj- Napoca, Romania; [4]Institute of Oncology "I. Chiricuta", Pediatric Oncology, Cluj- Napoca, Romania; [5]Pediatric Hospital Timisoara, Pediatric Oncology, Bucharest, Romania; [6]Clinical Institute Fundeni, Pediatric Oncology, Bucharest, Romania; [7]Pediatric Hospital, Pediatric Oncology, Tg. Mures, Romania

Background: Despite mandatory reporting of all cancers being introduced since 1981, Romania still doesn't rely on a fully operational general cancer registration system, especially in terms of data aggregation, access and utilization. Pediatric oncology centers only have the picture of their own cases and there is no national perspective on child cancer.
Material and Methods: The Romanian Society of Pediatric Hematology and Oncology (RSPHO) has initiated a National Child Cancer Registry since 2009 with voluntary registration for 0−19 year incident cases. 10 out of the 12 pediatric oncology centers in Romania participate, covering approximately 80% of the country pediatric population. Incident cases are notified using the ENCR- recommended form with coding of tumors according to the ICD-O-3 and ICCC-3, and are processed by trained cancer-epidemiology.
Results: Currently the registry contains a number of 1534 notifications for 1186 incident cases (2009–2012), with more than half of the new cases nationwide being reported only by the 2 Oncology Institutes in Bucharest and Cluj. Average incidence rates for 2010 reported new cases were of $7.35_{\%000}$ (for 0−19 years) and $7.48_{\%000}$ for (0−14 years) compared to the $11.6_{\%000}$ expected from GLOBOCAN 2008 estimates. Distribution of new cases by diagnostic group was dominated by leukemia (27.2%), lymphomas (17%), and CNS tumors (17%). 92.7% of the incident cases had histology diagnosis and 29.3% received multimodality treatment. The percentage of stageable new cases that were actually staged raised from 42% in the first year to 67% in 2013. The registry faces major challenges in motivating and supporting voluntary data collection by busy burned out professionals. Difficulties also persist with heterogeneous definitions for staging and relapse as well as inconsistencies in using the fields of the form among participating centers.
Conclusions: Voluntary development of a National Childhood Cancer Registry is a major undertaking for a small organization such as RSPHO. Gaps between the projected and the reported incidence show significant underreporting that needs to be overcome. Existing data provide matters of concern regarding child cancer situation in Romania, in particular regarding delay to diagnosis which fatally alters the survival chances of the new cases.
No conflict of interest.

1620 POSTER

An evaluation of a specialist service for teenagers/young adults with cancer in the United Kingdom

C. Wright[1], D. Stark[2], J. Coad[1], S. Morgan[2], S. Fuller[3], M. Cable[1].
[1]Coventry University, Centre for Child and Family Applied Research, Coventry, United Kingdom; [2]St James's University Hospital, Institute of Oncology, Leeds, United Kingdom; [3]Teenage Cancer Trust, Clinical Services, London, United Kingdom

Background: This paper discusses findings from a formal service evaluation commissioned by the charityTeenage Cancer Trust, of a Teenage Young Adult (TYA) Cancer Service in the Northwest of England. United Kingdom (UK) incidence for cancer in those under age 14 is 134 per million and in age 15 to 24 years is 214 per million with more than 2000 TYA diagnoses per year (Birch 2005). Improvements for TYAs lag behind other cohorts. Suggested reasons include delays in diagnosis, poorer access to clinical trials, rarity of cancer, lack of education and the attention given to TYAs from health services, health professionals and research organisations (Bleyer, Budd & Montello 2006) and lastly their complex psychosocial needs. This evaluation aimed to evaluate the specialist support offered to Teenagers and Young adults with Cancer and their families and carers to strengthen and develop the service whilst informing future developments in service and policy. This project was part of a Knowledge Transfer Partnership in conjunction Coventry University.
Materials and Methods: A theoretical sample included young people aged 14−25 (n = 14), parents and young partners (n = 6) and staff (n = 20). All young people were between 4mths and 4.5 years from the end of treatment. Participant observations, along with semi-structured interviews were the selected methods of data collection. Thematic analysis using NVivo9 as a data management tool was used.
Results: The overarching themes identified included patient experience which was dependant on facilities, environment and social relationships; information sharing which in turn were dependant on multidisciplinary psychosocial support and service cohesion. Overall, patients were satisfied with the specialist service to include the facilities and environment provided, access to the multidisciplinary team with expertise in supporting TYAs with cancer specifically. This wider multi disciplinary team included Youth Support Co-ordinators and Learning Mentors, newer roles in this field of care. Aspects of care that could be enhanced included; the information provision on fertility, particularly for younger females; the support of friendships(existing and new); the cohesion of cross service relationships; the development of improved psychosocial screening processes and tools for both patients and carers; and the transition service for young people finishing treatment.
Conclusions: Findings add to the growing body of literature in this emergent cancer specialism which highlights the need for and value of age appropriate specialist care. Key recommendations will inform research, practice, policy and services for TYA's with cancer in the UK. This is robust evaluative study also assistsTeenage Cancer Trust, whose aim is to improve the quality of life and chances of survival for teenagers and young adults by providing these essential services, substantiate the work that they do and plan for the future.
No conflict of interest.

1621 POSTER

A decade of caring through multidisciplinary collaboration and evidence based practices at the Children's Cancer Center of Lebanon (CCCL)

R. Shahine[1], N.B. Badaro[1], H.S. El-Solh[1], L.K.B. Kurdahi-Badr[2].
[1]American University of Beirut Medical Center, Children's Cancer Center, Beirut, Lebanon; [2]American University of Beirut Medical Center, Nursing Services-Research Department, Beirut, Lebanon

Background: The mission of the CCCL, established in 2002, is to improve the survival rates of children with cancer and provides the best possible treatment and care. The impact of care is focused on a multidisciplinary approach and evidence-based practice and grants treatment without any financial burden on patients. This paper will provide a brief overview of the multidisciplinary team efforts in fostering excellence in patient care and improving quality of life for children with cancer in Lebanon.
Materials and Methods: The CCCL is affiliated with St. Jude Children's Research Hospital in Memphis. The need for CCCL arose due to a lack in such centers in Lebanon for the treatment of children with malignancies. The cure rate was 40% much lower than what was reported in developed countries. Initially, there were 27 staff members and the number of registered patients was limited to 50 per year. In collaboration with the International Outreach Program at St. Jude's, 13 registered nurses, and other members of the multidisciplinary team, were sponsored to go attend pediatric oncology workshops in Memphis. The workshops covered a wide

range of education and hands-on experiences that are currently being implemented as ongoing processes in everyday utilization in clinical work. It was imperative for the team to strive in making the center develop. A Child Life department with psychosocial and educational services was created, encompassing volunteers for the entertainment of the children, as part of a holistic approach to care. A clinical educator, as well as a clinical nurse specialist was hired, respectively to: keep standards of care updated (through continuous staff competency insurance), and address patient needs.
Educational programs for patients and families in Arabic have been provided; evidence-based policies & protocols for treatment of cancer have been implemented, and updated routinely based on current needs as well as published studies. In order to prosper, there was a high need for a centralized research unit. A clinical data management unit, with two Masters-level prepared nurses, was thus established for generating new research, based on patient information.
Results: Since its inception, CCCL employed 76 staff members (33 staff nurses) and treated 880 patients. The cure rate is currently 88% for the highest childhood malignancy occurrence, a two-fold increase since prior to 2002. Ninety-six articles in peer review journals have been published, and over 50 abstracts were presented at national and international conferences. Psychosocial activities have significantly improved the well being of patients. Nurses are more involved in their education; international sessions are being broadcasted through the cure4kids website. Two nurses have become certified in Pediatric Hematology/Oncology. One nurse won the yearly APHON international scholarship award.
Conclusions: The multidisciplinary team efforts are a success story which we are proud of and eager to share.
No conflict of interest.

1622 POSTER

BET bromodomain inhibition as a therapeutic strategy to target N-Myc in neuroblastoma

J. Shahbazi[1], R. Lock[2], T. Liu[3]. *[1]Children's Cancer Institute Australia for Medical Research, Histone Modification Group, Sydney NSW, Australia; [2]Children's Cancer Institute Australia for Medical Research, Leukameia Biology, Sydney NSW, Australia; [3]Children's Cancer Institute Australia for Medical Research, Histone ModificationGroup, Sydney NSW, Australia*

Background: Neuroblastoma is the most common malignancy in infancy and the most common extracranial solid tumor in children. Approximately 50% of human malignancies are characterized by over-expression of oncogenic Myc oncoproteins including N-Myc and c-Myc. Myc oncoproteins induce the initiation and promote the progression of malignancies by modulating gene transcription, leading to cell proliferation.
The bromodomain and extra terminal (BET) family of proteins BRD3 and BRD4 have recently been shown to play critical roles in c-Myc gene transcription, and the BRD3/BRD4 inhibitors JQ1 and I-BET151 considerably reduce c-Myc gene transcription. Importantly, JQ1 and I-BET151 exert significant anticancer effects in mice xenografted with leukaemia, Burkitt's lymphoma and multiple myeloma characterized by pathologic activation of c-Myc. Consequently, pharmaceutical companies are racing to test JQ1 in cancer patients in clinical trials.
Method and Material: We treated two neuroblastoma cell lines with the BET bromodomain inhibitor JQ1 or IBET151.
Results: RT-PCR and immunoblot studies showed that JQ1 and I-BET151 both reduced N-Myc mRNA and protein expression. The two BET bromodomain inhibitors also reactivated the expression of tumor suppressing genes including TP53INP1 which was suppressed by N-Myc in N-Myc amplified nerublastoma cell lines. Genome-wide differential gene expression studies with Affymetric gene array showed that two key oncogenic genes, BCL2 and MYB, were significantly repressed by JQ1 in neuroblastoma cells. Real-time RT-PCR experiments confirmed that BCL2 and MYB mRNA expression was reduced 24 hour after JQ1 treatment in neuroblastoma cells. Additionally, Alamar blue assays showed that treatment with the BET bromodomain inhibitors significantly reduced the number of viable neuroblasotma cells.
Conclusions: BET bromodomain inhibitors could be used as an efficacious therapeutic approach to reduce N-Myc expression, to reactivate the expression of tumour suppresser genes repressed by N-Myc, as well as to reduce the expression of other oncogenes such as BCL2 and MYB.
No conflict of interest.

1623 POSTER

Linc367, a novel long intergenic noncoding RNA, up-regulates N-Myc gene expression and neuroblastoma cell proliferation

P.Y. Liu[1], A. Tee[1], G. Marshall[2], P. Polly[3], M. Wong[1], D. Ling[1], M. Kavallaris[1], G. Perini[4], M.E. Dinger[5], T. Liu[1]. *[1]Children's Cancer Institute Australia for Medical Research, Sydney NSW, Australia; [2]Sydney Children's Hospital, The Centre for Children's Cancer and Blood Disorders, Sydney NSW, Australia; [3]UNSW, School of Medical Sciences, Sydney NSW, Australia; [4]University of Bologna, Department of Biology, Bologna, Italy; [5]Garvan Institute of Medical Research, Sydney NSW, Australia*

Background: Neuroblastoma is the most common solid tumour in early childhood. The worst subtype of neuroblastoma is caused by the N-Myc oncogene. At least 90% of the human genome is transcribed into non-protein-coding (noncoding) RNAs including microRNAs, PIWI-interacting RNAs and long intergenic noncoding RNAs (lincRNA). While numerous studies have associated microRNAs and PIWI-interacting RNAs with cancer, little is known about the expression and functional roles of lincRNAs in cancer, particularly in neuroblastoma. We have found a novel lincRNA, which we have named linc367, is associated with neuroblastoma.
Methods and Results: Using Rapid Amplification of cDNA Ends (RACE) PCR, we verified that linc367 contained three exons and two introns. RT-PCR studies showed that linc367 was highly expressed in N-Myc over-expressing, compared with N-Myc non-detectable, neuroblastoma cells. RT-PCR and immunoblot studies revealed that knocking-down linc367 expression with small interfering RNAs or antisense oligonucleotides significantly reduced N-Myc mRNA and protein expression. Cell proliferation/viability assays showed that linc367 enhanced neuroblastoma cell proliferation and/or survival. Moreover, RT-PCR studies demonstrated that linc367 expression in human neuroblastoma tissues predicted poor patient prognosis.
Conclusions: We have identified the novel long intergenic noncoding RNA linc367, and have demonstrated that linc367 enhances N-Myc gene expression, induces neuroblastoma cell proliferation and/or survival, and is a marker for poor prognosis in neuroblastoma patients.

1624 POSTER

Impact of TH and DCX mRNAs detection in high-risk neuroblastoma patients' outcome

A. Cañete[1], Y. Yáñez[1], E. Grau[1], S. Palanca[2], G. Pérez[2], M.J. Antuña[3], C. Márquez[4], S. Gallego[5], A. Urberuaga[6], V. Castel[1]. *[1]Hospital Universitario y Politécnico La Fe, Oncología Pediátrica, Valencia, Spain; [2]Hospital Universitario y Politécnico La Fe, Laboratorio de Biologia Molecular, Valencia, Spain; [3]Hospital Universitario Central de Asturias, Oncología Pediátrica, Asturias, Spain; [4]Hospital Universitario Virgen del Rocio, Oncología Pediátrica, Sevilla, Spain; [5]Hospital Universitario Vall d'Hebron, Oncohematología Pediátrica, Barcelona, Spain; [6]Hospital Universitario de Cruces, Oncología Pediátrica, Vizcaya, Spain*

Background: Survival rates for children with high-risk Neuroblastoma (NB) remain decisively low despite advances in multimodal treatment schedules. Accurate detection of minimal residual disease (MRD) could be crucial for outcome prediction in those patients. The aim of this study was to determine whether the presence of minimal disease (MD) and MRD is associated with bad prognosis and help us to improve selection of ultra-high-risk patients for new experimental therapies.
Material and Methods: Quantitative reverse transcriptase polymerase chain reaction QRT-PCR was performed for tyrosine hydroxylase (*TH*) and doublecortin (*DCX*) mRNAs detection on peripheral blood (PB) and bone marrow (BM) samples from high risk NB patients at diagnosis, post induction therapy and at the end of treatment. Time to death (overall survival-OS) and time to relapse/progression (Events Free Survival-EFS) were analyzed using the Kaplan–Meier method.
Results: At diagnosis the frequency of detecting *TH* and *DCX* was 67% (n = 86) in BM and 63.2 and 64.7% respectively in PB (n = 68). *DCX* in BM above median indicated worse outcome ($p = 0.03$) as well as *TH* in PB above median ($p = 0.003$). After induction therapy, *TH* and *DCX* were detected in 33.8% and 30.9% of BM (n = 71) and 13.3% and 6.7% of PB (n = 45). Patients with *DCX* and not *TH* positive BM have lower EFS ($p = 0.04$) and OS ($p = 0.02$) compared to patients with *DCX* negative BM. At the end of treatment the 38.1% and 28.6% of BM were positive for *TH* and *DCX* respectively (n = 21) and the 16.7% of PB analysed were positive for both markers. Despite the small number of samples, patients with *DCX* positive BM and *TH* positive PB showed significant lower EFS ($p = 0.02$).
Conclusions: According to our results, high-risk NB patients with high expression levels of *DCX* in BM and high expression of TH in PB at diagnosis would require new therapeutic strategies to avoid relapses and

death. *DCX* detection in BM after induction therapy could be a valuable predictive tool. At the end of treatment, *DCX* detected in BM and *TH* detected in PB might predict outcome. However these results were obtained in a small cohort of patients and require confirmation in multicenter studies.

1625 POSTER

The paradigm in nephroblastoma: neoadjuvant chemotherapy or primary nephrectomy? Single center experience, 20 years of follow up

K. Svojgr[1], K. Pycha[2], R. Kodet[3], V. Smelhaus[1], J. Koutecky[1], J. Snajdauf[2], J. Stary[1], J. Malis[1]. *[1]Faculty Hospital Motol, Pediatric Hematology/Oncology, Prague 5 Motol, Czech Republic; [2]Faculty Hospital Motol, Pediatric Surgery, Prague 5 Motol, Czech Republic; [3]Faculty Hospital Motol, Pathology, Prague 5 Motol, Czech Republic*

Background: Nephroblastoma (Wilms tumor − WT) is the most common tumor of kidney in childhood. In the Czech Republic WT is treated according to SIOP protocols. The hallmark of these protocols is preoperative neoadjuvant chemotherapy (CHT), whereas nephrectomy is performed subsequently. In the present study we compare the survival of patients that underwent primary nephrectomy in comparison of patients treated with neoadjuvant CHT in a single center in more than 20 years period.
Patients and Methods: From 7/1988 to 5/2009 239 patients with WT were treated at Department of Pediatric Hematology and Oncology University Hospital Motol, Prague, Czech Republic. Event free survival (EFS) and overall survival (OS) was analyzed using Stat View statistical program.
Results: Patients we treated according to protocols: SIOP 9 (94 patients), SIOP 93 (80 patients) and SIOP 2001 (65 patients). Median follow-up is 12.5 years (3−21 years). 141 patients were classified as 1st clinical stage, 16 2nd stage, 29 3rd stage, 34 4th stage and 19 patients were 5th stage. 120 patients from 239 (50%) were treated with neoadjuvant CHT, 119 patients (50%) underwent primary nephrectomy. The most common causes of primary nephrectomy were: rupture of tumor or supposed rupture of tumor (23x), massive hematuria and/or anemization (26x), uncertainty of diagnosis (21x) and others. EFS and OS patients treated with neoadjuvant CHT or primary nephrectomy do not differ (EFS 76.6% versus (vs.) 79.8%, $p > 0.05$; OS 85.8% vs. 86.5%, $p > 0.05$). 29 patients from 239 (12%) suffered from tumor spillage, EFS and OS do not differ again (EFS 76.6% vs. 78.8%, $p > 0.05$; OS 83.3% vs. 86.5%, $p > 0.05$). Preoperative tumor spillage was diagnosed in 21 cases (7x abdominal injury in anamnesis); all were treated with primary nephrectomy. Perioperative tumor spillage occurred in 8 cases, only 1 patient was treated with neoadjuvant CHT (1 from 120, 0.8%), 7 of them underwent primary nephrectomy (7 from 98, 7%, $p = 0.02$). EFS of patients with spontaneous tumor spillage is 90% in comparison to 37% with perioperative tumor spillage, $p = 0.001$. OS is 100% vs. 37% $p < 0.001$, respectively.
Conclusions: We did not find any significant difference in EFS and OS in patients treated with neoadjuvant CHT or primary nephrectomy treated according to SIOP protocols at single institution. Patients suffering from perioperative tumor spillage have poor prognosis.

1626 POSTER

Basal neurocognitive function in the children with brain tumors before proton beam therapy

Y. Kim[1], E.S. Yu[2], H.J. Park[3], K.H. Cho[1], H.J. Kim[4], S.H. Shin[3], J.H. Kim[2], J.Y. Kim[1]. *[1]National Cancer Center, Center for Proton Therapy, Goyang-si Gyeonggi-do, Korea; [2]National Cancer Center, Mental Health Clinic, Goyang-si Gyeonggi-do, Korea; [3]National Cancer Center, Center for Pediatric Oncology, Goyang-si Gyeonggi-do, Korea; [4]National Cancer Center, Neurology Clinic, Goyang-si Gyeonggi-do, Korea*

Background: Neurocognitive function was evaluated in children with brain tumors who were planned to receive proton beam therapy (PBT). Clinical parameters associated with basal neurocognitive function was identified.
Materials and Methods: Forty-nine children aged 6−21 who were diagnosed with brain tumors were evaluated for neurocognitive function prior to PBT from March 2007 to December 2012 at National Cancer Center. Neurocognitive function tests included 1) Korean version of Wechsler Intelligence Scale for Children-3rd Edition (or Korean version of Wechsler Adult Intelligence Test): index for intelligence was composed of Full Intellectual Quotient (FIQ), Verbal IQ (VIQ), Performance IQ (PIQ), Verbal Comprehension (VC), Perceptual Organization (PO), Freedom from Distractibility (FD), Processing Speed (PS), 2) Rey-Kim Memory Test: Memory Quotient (MQ), and 3) Kim's Frontal Executive Function Test: Executive IQ (EIQ). All test scores were compared to age-matched standardization norms by *t*-test. The analysis of variance (ANOVA) was used to examine the effects of clinical factors on neurocognitive function.
Results: When compared to the age-matched normal population, patients group showed significantly lower PIQ (p=.007), PS (p=.000) and MQ (p=.031) in the patients<16, and lower MQ (p=.031) in the patients⩾16. Lower PS (p=.018) was noted in male gender. Lower FD (p=.051) was observed in the patients with hydrocephalus. Lower MQ (p=.000) was associated with supratentorial tumor location. Lower FIQ (p=.035) and VC (p=.019) were observed in the patients with lower performance status. Repeated surgeries before PBT was associated with lower FIQ (p=.031). Patients who had previous radiotherapy showed lower VC (p=.029) and FD (p=.039). History of high dose chemotherapy or stem cell transplant, age at diagnosis, surgical extent, and any pre-radiotherapy chemotherapy were not significantly associated with lower neurocognitive function (p>0.050 for all).
Conclusions: Children with brain tumors showed significantly different neurocognitive functions in several indices compared with the age-matched normal population. Our study suggests that clinical characteristics of tumors and surgical intervention before PBT were important determinants of children's neurocognitive function. These factors may need to be integrated in future longitudinal assessment for neurocognitive function after radiotherapy.

1627 POSTER

The spectrum of symptoms and its management in children with an incurable brain tumor; insight in the palliative phase

C.T. Jagt[1], A.Y.N. Schouten-van Meeteren[1], M.D. Vd Wetering[1]. *[1]Academic Medical Center, Pediatric Oncology, Amsterdam, Netherlands*

Introduction: CNS tumors are diagnosed in 25% of pediatric oncology patients leading to a mortality rate of 30%. The aim of this study is to gain insight in how the palliative phase was managed.
Methods: A retrospective review of patients' medical charts from the Emma Children's Hospital who died of a brain tumor between May 2007 and September 2012.
Results: 34 children aged 0.4−17.2 years at time of death were included. After 0–2480 days from diagnosis (median 168) the infaust prognosis was evident with death following after 1–603 (median 80) days. Palliative cancer-directed therapy was given in 68% patients, comprising of chemotherapy solely in 11 (32%), and radiotherapy solely in 5 (15%) patients, while 6 (18%) received a combination of both. Thirty of 34 patients received dexamethasone at any point in the palliative phase. Frequent symptoms in the course were pain (91%), poor mobility (74%), somnolence (71%), disturbed cognition (65%), change of appearance (62%), seizures (56%), and vomiting (53%). Pain was treated satisfactory in 96%, necessitating systemic morphine and sedation eventually in 38% and 15% respectively, for a short amount of time; 0−44 days (median 0) and 0−6 days (median 0) respectively. Hospital visits were kept to a minimum during the palliative phase: the median amount of visits was 0 (range 0−37) and admission days were 5 (range 0−31). The visits and stays were mainly for anti-cancer therapy, supportive therapy such as transfusions and examinations.
A do-not-resuscitate code was discussed with all parents at a median of 2 (range 0–532) days after discussing the infaust prognosis and switch to palliative care which was 0–576 days before death (median 50). Even though the preferred place of death was at home for 33 out of 34 patients, 28 (82%) patients died at home in somnolent state. Six patients were admitted to the hospital for systemic anticonvulsants, pain medication and sedation until death.
Conclusion: A diversity of symptoms occurred during the palliative phase, necessitating intensive symptom management, mostly conducted at home. This knowledge facilitates advanced palliative care planning and helps to prepare parents and professionals to optimize the palliative care.

Quality of life among adult long-term survivors of adolescent Hodgkin lymphoma: A follow-up study

S. Semochkin[1], E.G. Arshanskaya[2], V.M. Sotnikov[3], V.L. Ivanova[2], S.S. Kulikova[1], A.I. Lukina[4], T.N. Tolstykh[4], A.G. Rumiantsev[5]. [1]*Russian National Research Medical University n.a. N.I. Pirogov, Pediatric Oncology and Radiation Therapy, Moscow, Russian Federation;* [2]*City Clinical Hospital n.a. S.P. Botkin, Hematology, Moscow, Russian Federation;* [3]*Russian Scientific Center of Roentgenoradiology, Radiotherapy, Moscow, Russian Federation;* [4]*Federal Research Center for Pediatric Oncology Hematology and Immunology, Adolescent Hematology, Moscow, Russian Federation;* [5]*Federal Research Center for Pediatric Oncology Hematology and Immunology, Director, Moscow, Russian Federation*

Background: The late effects associated with childhood Hodgkin lymphoma (HL) continue to increase. The treatment-related factors have been shown to impact subsequent quality of life (QoL). However, there is little data addressing the longer term outcomes of the adolescent survivors. Generally, data on adolescents lost in those for children. The purposes of the present study were to compare QoL of HL survivors with that of health young adults and to evaluate the relationships between disease/treatment features and QoL in the HL survivors.
Methods: A total of 22 male and 34 female survivors of HL with a median ages 27.5 years (range, 22−41) were evaluated. For comparison 94 (male − 44, female − 50) health subjects with a median ages 28.0 years (range, 22−46) was drawn to the study of QoL. All HL survivors were treated with modified pediatric protocol DAL-HD-90 in 1997–2007 in our clinic. Patients are allocated to three treatment groups (TGs). The original protocol is modified in the following positions: (1) procarbazin was replaced by dacarbazin; (2) young adults received vinblastin instead vincristin; (3) all patients with advanced stages received 2 cycles of ODPA independently from gender; (4) doses of involved field radiotherapy were increased from 20−25 Gy to 30 Gy. QOL was assessed by the Short Form 36 (SF-36), which generate 8 separate scales and 2 general scores (0 = worst health state, 100 = best health state). All survivors have a time of complete remission (CR) of Hodgkin's lymphoma $\geqslant$5 years.
Results: The HL survivors had lower scores than the normal controls on all scales and scores. Statistically significant differences were found in general health − GH (53$\pm$3 vs. 72$\pm$2, P <0.001), vitality − VT (55$\pm$2 vs. 72$\pm$2, P <0.001) and mental health − MH (57$\pm$2 vs. 72$\pm$2, P <0.001). Patients with the international prognostic scores for advanced stages (IPS; Hasenclever, 1998) $\geqslant$4 (n = 7) had the lowest scores in role physical − RF (29$\pm$15 vs. 81$\pm$5, P <0.001) and role emotional limitations − RE (33$\pm$15 vs. 77$\pm$5, P = 0.006). The adverse events including relapsed disease (n = 7) and second malignancies (n = 2) correlated with IPS $\geqslant$4 and reduced QoL. The patients with ages on moment of HL diagnosis $\geqslant$18.5 years (methods of ROC-curves, P = 0.047) have reduced QoL when compared to younger patients in GH (48$\pm$3 vs. 61$\pm$4, P = 0.027), VT (50$\pm$3 vs. 61$\pm$4, P = 0.013) and physical component scale − PCS (48$\pm$1 vs. 53$\pm$2, P = 0.046). Time since diagnosis, ages on QoL evaluation, gender, treatment groups (2, 4 or 6 cycles of chemotherapy plus radiotherapy), Ann-Arbor stages, bulky disease, current married status and education levels were not associated with statistically significant differences in QoL.
Conclusion: Long-term HL survivors have poorer physical and mental QoL than the general population of young adults. The age on moment of LH diagnosis $\geqslant$18.5 years was associated with significant reduced predominantly physical QoL. IPS $\geqslant$4, relapsed HL and secondary malignancies were associated mostly with the deterioration of role physical and emotional functioning, which may indicate a lack of confidence in the future health.
No conflict of interest.

1629 POSTER

Association between MTHFR, SLC19A1 and DHFR genetic polymorphisms and clinical and biochemical parameters of methotrexate induced toxicity in children with acute lymphoblastic leukaemia

J. Lazic[1,2], L. Dokmanovic[1,2], N. Krstovski[1,2], S. Pavlovic[3], B. Zukic[3], N. Kotur[3], G. Milosevic[1], D. Janic[1,2]. [1]*University Children's Hospital, Hematology and Oncology, Belgrade, Serbia;* [2]*Institute of Molecular Genetics and Genetic Engineering, Laboratory for Molecular Biomedicine, Belgrade, Serbia;* [3]*Laboratory for Molecular Biomedicine, Institute of Molecular Genetics and Genetic Engineering, University of Belgrade, Serbia*

Acute lymphoblastic leukaemia (ALL) is the most common paediatric malignant disease, curable in 80% of children. Current protocols are designed to ensure the minimal acute and late adverse effects and to increase the overall survival. Despite improved contemporary guidelines, children are still exposed to chemotherapy induced toxicity. Methotrexate (MTX) is very potent cytotoxic agent, established in paediatric ALL protocols, but also well known for its potential toxicity.
We correlated pharmacogenomic, pharmacokinetic and clinical parameters of toxicity during intravenous MTX therapy in children with ALL. Single nucleotide polymorphisms (SNPs) in *methylene tetrahydrofolate reductase* gene (*MTHFR* 677C>T), *solute carrier family 19, member 1* gene *(SLC19A1* 80G>A) and *dihyfrofolate reductase* gene (*DHFR* −317A>G) were analyzed, due to their role in MTX pathway. Detection of SNPs was performed using PCR-based methodology. Pharmacokinetics of MTX was measured by standard serum concentrations at usual time points, determined by current BFM protocol. We graded clinical signs of MTX toxicity (gastrointestinal (GI), liver, renal, skin and neurological) according to WHO/NCI toxicity scale.
Study enrolled 153 children (62% boys) with *de novo* ALL, diagnosed from January 2003 until January 2012, age ranged from 3 months to 17.5 years, median 5.5 years. Genotype frequencies of *MTHFR* 677TT, *SLC19A1* 80AA and *DHFR* −317AA, for which has been shown that can influence MTX toxicity, were 11.2%, 27% and 30%, respectively. Decreased MTX pharmacokinetics was seen in 15% of children, of which 56.5% carried *DHFR* −317AA, 17.3% *SLC19A1* 80AA and 8.7% *MTHFR* 677TT genotypes. GI toxicity was found in 35.9%, of which 40% had either *SLC19A1* 80AA or *DHFR* −317AA genotypes, liver toxicity in 23.5%, where 50% of children had *MTHFR* 677TT, *SLC19A1* 80AA or *DHFR* −317AA genotypes, neurotoxicity in 5.2%, of whom 75% had *MTHFR* 677TT, *SLC19A1 80AA* or *DHFR* −317AA genotypes, while renal and skin toxicity was observed in less than 2% of all patients. The highest grade of toxicity was seen in 9.6% of children, in whom more than one of the above mentioned genotypes was detected.
We report the relation between pharmacokinetic and clinical markers, as already established parameters of toxicity, with pharmacogenomic ones. Preliminary results of our study revealed the possible role of *MTHFR*, *SLC19A1* and *DHFR* genetic polymorphisms as independent pharmacogenomic markers for prediction of acute MTX toxicity.
No conflict of interest.

The impact of ABCG2 C421A gene polymorphism on high dose methotrexate level in Egyptian Pediatric Acute Lymphoblastic Leukemia patients: Children's Cancer Hospital-Egypt [CCHE] Experience

W. Rashed[1], N. Hamdy[2]. [1]*Children's Cancer Hospital, Clinical Research, Cairo, Egypt;* [2]*Children's Cancer Hospital, Clinical Pathology, Cairo, Egypt*

Background: Acute Lymphoblastic leukemia [ALL] represents 80% of the childhood leukemia. High Dose Methotrexate [HD-MTX] is the cornerstone antineoplastic drug in most of contemporary treatment protocols of pediatric ALL. Among the membrane efflux transporters of MTX, The Human breast cancer resistant protein (BCRP) which is the second member of the G subfamily of ATP-Binding cassette (ABC) efflux; also called (ABCG2). Among polymorphisms in ABCG2 gene, C421A Polymorphism represents 13% in the Middle Eastern population. We studied the effect of this polymorphism o the level of HD-MTX in Egyptian Pediatric ALL.
Materials and Methods: We recruited 200 ALL patients from Children's Cancer Hospital 57357-Egypt homogeneously treated according to modified St Jude TOTAL XV study in the period between 2010 to 2012. The study was approved by the ethics committee and informed consent was obtained. Methotrexate level was done at 23 hr, 42 hr and 68 hr. Also genotyping ABCG2 C421A gene polymorphism of was done.
Results: The age of the patients ranged from 1.0 to 18 years (Median age; 4.5) and 78.5% of the patients were younger than 10 years old. Within B-lineage (84%), the percentage of patients took HD-MTX at 2.5 g/m^2 was 50.6% while those took HD-MTX at 5.0gm/m^2 were 49.4%. For T-lineage, all patients took HD-MTX at 5.0 g/m^2. The Steady State Plasma Concentration (CPss) of HD-MTX in the Low risk group (82 patients) equals 33μM which was achieved in 68 patients (82.9%), while CPss in High/ Standard risk groups (112 patients) equals 66 μM which was achieved in 97 patients (86.6%). We tested the association between ABCG2 C421A genetic variation and the MTX plasma concentration at 23 hour, 42 hour and 68 hour after the intravenous infusion. We found no statistical significance between BCRP C421A polymorphism and MTX toxicity levels for either 2.5 g/m^2 [Low Risk] or 5.0 g/m^2 [Standard /High risk] groups at the various time points tested. Furthermore, No statistical significance was detected between BCRP C421A SNP and the Steady State Plasma Concentration (CPss) of HD-MTX at 23 hr in the two groups.
Conclusion: It is the largest study performed on Acute Lymphoblastic Leukemia Egyptian pediatric patients which showed that there is no significant correlation between the genetic variation of BCRP (C421A) and HD-MTX level. Correlation with other Trans-membrane protein mediated efflux of HD-MTX is needed to determine the mechanism of resistance and the toxicity.
No conflict of interest.

Observer-independent quantitative measurement for the interpretation of 123I-mIBG Scintigraphy in pediatric neuroblastoma (NB)

R. Martínez-Díaz[1], J. Balaguer[2], S. Morillas[1], P. Bello[3], V. Castel[2], A. Cañete[2], A. Rivas[3], L. Sánchez[1], I. Lengua[1], G. Peris-Fajarnés[1]. *[1]UPV Univ. Politècnica de València, Research Group on Graphic Technologies (GITG), Valencia, Spain; [2]HUP La Fe/IIS La Fe, Paediatric Oncology (UOP), Valencia, Spain; [3]HUP La Fe/IIS La Fe, Nuclear Medicine Unit, Valencia, Spain*

Background: 123I-mIBG uptake has been shown to be a highly sensitive and specific method to detect NB and to evaluate response to therapy. The image interpretation is limited due to the resolution and size of the image. An automatic quantitative method has been created in order to measure and compare different scintigraphies in a multicenter setting. A methodology and a mathematical operator and procedure for the quantitative measurements of the areas with 123I-mIBG uptake has been developed and tested over 38 Images. On this paper a new observer-independent quantitative measure unit for uptake level in a single 123I -mIBG Scintigraphy is proposed.
Material and Methods: Medical records and good quality 123I-mIBG Scintigraphies from 19 patients from 2009 to 2013 were restrospectively reviewed. Scans were performed and informed by the Nuclear Medicine Unit of 'La Fe' Hospital. We transformed the values of all pixels of planar images into a normalized scale based on its standard deviation value. At each diagnosed tumour, we used the new values average of tumour's pixels as measurement of uptake in tumour.
Results: By using this new uptake unit, value of uptake of patients body background is constant in every 123I-mIBG Scintigraphy of the whole test set. Quantitative uptake values measured in tumours were correlated with qualitative uptake diagnosis in terms of increase or decrease of intensity observed in lesion area. Quantitative measurement of tumour's uptake could be compared with uptake level of patient's body background for monitoring the evolution of lesion.
Conclusions: A threshold of reference at uptake level of body's body background could be determined by this new quantitative metric and used for quantitative analysis of uptake. This new observer-independent 123-I-mIBG measurement method seems to have good correlation with the qualitative standard one, and could be used in a multicentric setting avoiding inter-observer differences.

1632 POSTER

The impact of cancer on psychological morbidity of adolescent cancer patient: An experience from eastern India

M. Mehnaaz Siddiqi[1]. *[1]Netaji Subhash Chandra Bose Cancer Research Institute, Psycho-Oncology, Kolkata, India*

Background: The morbidity rate is very high among the Cancer patients and it is difficult to analyze the traumatic experience and the changes that happen in the body and mind of the cancer patients.
Materials and Methods: To study the impact of Cancer on Psychological Morbidity of Adolescent Cancer patients(11−20 years) and help them overcome it.
Sample: The sample comprises of 100 Adolescent (boys and girls) Cancer patients within the age group of 11−20 years undergoing treatment and surveillance in the Psycho-oncology department of Netaji Subhash Chandra Bose Cancer Research Institute, Kolkata during the period from January 2012 to December 2012.
Tool: The tools used for this research is General Health Questionnaire (GHQ-28) by Goldberg, D.P and Hillier, V.F and various play materials were used to divert their attention from the disease.
Result: The result explores the overall Mental Health and the four areas of Mental Health i.e somatic symptoms, Anxiety and Insomnia, Social and Cognitive Dysfunction and severe Depression of Cancer Patients. It was found that 60% were suffering from Somatic symptoms, 64.29% boys and 62% girls were suffering from Anxiety and Insomnia. 50%of the patients were experiencing Social and Cognitive dysfunction and majority were depressed. After that they were given psychotherapy in the form of playing carom games, playing on computer, musical instruments and singing songs. 80% of the patients (48) responded well to the therapy and came back to their normal rhythm of life.
Conclusion: The study undertaken showed that they had deterioration in Mental Health and they responded well in the form of psychotherapy. Hence this methodology should be used widely among the Adolescent Cancer patients.

1633 POSTER

Determination of social support needs and expectations of parents of children with cancer from nurses

C. Sari[1], Z. Kisecik[1], E.B.R.U. Kilicarslan Törüner[1], N. Altay[1]. *[1]Gazi University Faculty of Health Sciences, Pediatric Nursing, Ankara, Turkey*

Introduction: Identifying the social needs of families of children with cancer and providing social support is one of the most important responsibilities of the nurses.
Objective: This descriptive study aimed to determine the social support needs and expectations of parents of children with cancer from nurses.
Methods: The study was conducted in pediatric hemato-oncology wards of two hospitals in Ankara, Turkey in 2013. The sample consisted of 80 parents of children aged 0−18. Data were collected with a descriptive form and the Multidimensional Scale of Perceived Social Support (MSPSS) with the three dimensions of support related to family, friends and a special human. High score indicates the higher perceived social support. The highest possible scores for subscales and the total scale are, respectively, 28 and 84. Data were analyzed by percentages and frequency distributions.
Results: The average age of the children was 8.4±5.3 and 58.8% were male. Most of the children followed with the diagnosis of leukemia (46.3%), receiving the first treatment (48.8%). Average disease duration was 1.2±1.8 months. Mothers' and fathers' average ages were, respectively, 34.1±7.11 and38.6±7.2. Almost all of the mothers stayed in hospital with their child. 76.3% of parents stated that their child's disease affected the family budget. Only 20% of working mothers could have continued their works. Most of the parents (70%) stated that they received social support. This support was taken mostly from families (55.0%), physicians (31.3%) and nurses (28.8%). Social support expectations of parents were 72.5% from health care professionals and most of the expectations were about emotional (53.8%) and information (36.3%) support.
It was determined that 45% of parents were knowledgeable about the national social institutions/organizations. Mean total MSPSS score was 50.1±26.1. When dimensions of scale were analyzed, means scores found as 18.7±9.5, for family, 12.2±9.6 for friends, and 19.4±10.6 for special person.
Conclusion: The majority of parents stated their needs about social support. On the other hand, low subscale and total scale mean scores indicated the social support needs of parents. However, parents had little social support expectation from nurses. Nurses have to give importance to parents' social support needs in their interventions.
No conflict of interest.

1634 POSTER

Choroid plexus tumors in children − single center experience

M. Zapotocky[1], M. Churackova[1], B. Malinova[2], J. Zamecnik[3], R. Kodet[3], M. Kyncl[4], M. Tichy[5], A. Puchmajerova[6], J. Stary[1], D. Sumerauer[1]. *[1]Faculty Hospital Motol, Department of Pediatric Hematology and Oncology, Prague, Czech Republic; [2]Faculty Hospital Motol, Department of Radiotherapy and Oncology, Prague, Czech Republic; [3]Faculty Hospital Motol, Department of Pathology and Molecular Medicine, Prague, Czech Republic; [4]Faculty Hospital Motol, Department of Radiology, Prague, Czech Republic; [5]Faculty Hospital Motol, Department of Neurosurgery, Prague, Czech Republic; [6]Faculty Hospital Motol, Department of Biology and Medical Genetics, Prague, Czech Republic*

Choroid plexus tumors (CPT) are rare brain tumors defined as papillary neoplasms derived from choroid plexus epithelium. Three types of CPT can be distinguished, choroid plexus papilloma (CPP), atypical papilloma (APP) and choroid plexus carcinoma (CPC). We have evaluated characteristics, treatment and outcome of patients with CPTs diagnosed within 1982–2013 in our pediatric oncology center. Our cohort consisted of 30 patients (16 boys vs. 14 girls) with CPTs; 14 were CPC, 2 APP and 14 CPP. Median age at the time of diagnosis was 4.1 years (0.25 to 18.3) with 48% of patients younger than 3. The primary tumor site was located predominantly in lateral ventricles (62.5%), less frequently in 4th ventricle (25%), in 3rd ventricle (2 pts) and spinal cord (1 pt). Only one patient with CPC initially presented with metastatic disease, all others had localized disease. Patients with CPP and APP were treated with neurosurgical resection only, except one patient with CPP located in spinal cord, who received focal irradiation (XRT). Two out of 16 patients with CPP and APP died of neurosurgical complications and one patient with APP experienced metastatic recurrence. Patients with CPC were treated with surgery and chemotherapy alone (<3 years) or in combination with focal XRT (⩾3 years). In 45% of patients gross total resection (GTR) was achieved. Six patients with CPC experienced recurrence; four of them were initially resected subtotally (STR). Two patients with CPC developed metachronous tumors (glioblastoma and hemangioendothelioma) and one patient was diagnosed with synchronous adrenal neuroblastoma at the time of diagnosis of CPC. Four patients with

CPC have died, three of them with progressive disease and one of surgical complications. Probability of 5-years EFS of patients with CPC was 35.9% and 5-years OS 77.6%. Six CPC patients were tested for TP53 germ-line mutations and Li-Fraumeni syndrome was confirmed in four of them. Examination of four more patients is currently in process. Experience with our cohort of CPC indicates that patients after STR are in higher risk of recurrence. Some patients with recurrent disease can be cured. Higher 5 y OS observed in our cohort compared to published data is probably caused by lower incidence of metastatic disease among our patients. Furthermore all CPC patients should be tested for TP53 germ-line mutation to reveal Li-Fraumeni syndrome.

Clear cell sarcoma of the kidney

D. Abbas[1], W. Zekri[1], A. Younis[2], M. Elshafie[2], M. Zaghloul[3], H. Taha[4], N. Elkinaee[4], A. Refaat[5], A. Samir[6], D. Yehia[6]. *[1]Children's Cancer Hospital Egypt 57357, Pediatric Oncology, Cairo, Egypt; [2]Children's Cancer Hospital Egypt 57357, Surgical Oncology, Cairo, Egypt; [3]Children's Cancer Hospital Egypt 57357, Radiotherapy, Cairo, Egypt; [4]Children's Cancer Hospital Egypt 57357, Pathology, Cairo, Egypt; [5]Children's Cancer Hospital Egypt 57357, Radiodiagnosis, Cairo, Egypt; [6]Children's Cancer Hospital Egypt 57357, Research, Cairo, Egypt*

Background: Clear Cell sarcoma of the kidney (CCSK) is a rare and aggressive tumor which accounts for 3% of pediatric renal tumors with incidence of 20 cases per year in US. CCSK is known as a Bone metastasizing renal tumor of the childhood with poor prognosis.The purpose of this paper is to show the demographic data of the patients, clinical presentation, staging in correlation with the survival analysis.
Material and Methods: All cases pathological CCSK in the period between I July 2007 till March 2012 at Children's Cancer Hospital − Egypt were reviewed. Patients age, gender, clinical presentation, medical history, CT chest and abdomen,pathological results and management for patients including chemotherapy, radiotherapy and surgery were reviewed.Follow up for those patient was continued till April 2013.
Results: Twenty-five cases of clear cell sarcoma of the kidney were found in the defined time interval, this accounts for 7% from all renal tumors. Mean age 36 month ranging from 1 to 104 months, 13 males and 12 females, Abdominal Swelling, Hematuria, Pain and Fever were the most common presentation found. According to COG staging system, stages I, II, III, IV and V were 9 (36%), 3 (12%), 9 (36%), 3 (12%) and 1 (4%) respectively. Aggressive chemotherapy was given containing Vincristine, Cyclophosphamide, Doxorubicin, Etoposide, and Carboplatin. Abdominal radiotherapy was given for local stage II and III (stage I did not receive radiotherapy). Radiotherapy was given for all sites of metastasis. At time of evaluation twenty two cases were in complete remission (CR), one case in partial remission with regressive course and two patients died due to progression and relapse.Overall survival was 88% and event-free survival (EFS) of 87.8% at 45 months. Stage I disease had overall survival of 100%.
Conclusion: CCSK patients showed an improved overall survival and event free survival when using an aggressive chemotherapeutic regimens and radiotherapy adapted to the stage of the disease, stage I clear cell sarcoma cases showed an excellent survival outcome inspite of not receiving any local radiotherapy.
No conflict of interest.

1636 POSTER

Burden and pattern of childhood malignancies in Western Kenya

F. Musibi[1], N.O. Siro[1], A.K. Rhamzanali[1], G. Kungu[1], C.N. Tenge[2], N.G. Buziba[3]. *[1]Moi University School of Medicine, Eldoret, Kenya; [2]Moi University School of Medicine, Child Health and Paediatrics, Eldoret, Kenya; [3]Moi University School of Medicine, Haematology, Eldoret, Kenya*

Background: Cancer registries worldwide have evolved to provide useful information on the burden and patterns of cancer. Kenya has no national data to provide an accurate view of the cancer situation. However, it is estimated that cancer is the third leading cause of death in the country after infectious diseases and cardiovascular diseases. The health systems in the country have traditionally concentrated on the prevention and control of communicable diseases at the expense of non-communicable diseases such as cancer. This has resulted in major weaknesses in cancer prevention and control initiatives in Kenya. About 80% of reported cases of cancer in Kenya are diagnosed at advanced stages, when very little can be achieved in terms of curative treatment.
Materials and Methods: The objective of this study was to determine the burden and pattern of childhood malignancies in Western Kenya from 2007 to 2010. A hospital based retrospective analysis of health records from Eldoret cancer registry located in Moi University, School of Medicine was done.
Results: Total number of childhood malignancies from 2007 to 2010 was 382 representing 9.3% of all cancers. The top five cancers were Non-Hodgkin lymphoma (22.8%), acute lymphoblastic leukaemia (13.1%), Kaposi sarcoma (7.6%), nephroblastoma (7.3%), rhabdomyosarcoma (5.8%). Male:Female ratio was 1.6:1, with a bimodal peak age distribution at 4 years and 10 years. Eight nine percent of these cancers were diagnosed by histology.
Conclusion: The burden of childhood malignancies is a significant health problem in Western Kenya with hematologic cancers being the most common.
No conflict of interest.

1637 POSTER

Retinoblastoma-clinical spectrum and treatment outcome in developing country

M. Behera[1], S. Dutta[2], P. Julka[1], G.K. Rath[1]. *[1]All India Institute of Medical Sciences, Radiation Oncology, New Delhi, India; [2]North Bengal Medical College, Radiation Oncology, Siligudi, India*

Background: In developing countries usually children present with advanced disease and there is a high prevalence of disseminated extraocular disease. Though therapeutic approaches have been improved for eye preservation, but mortality is higher due to toxicity. In this study we have analysed the clinical spectrum & treatment outcome and evaluated the impact of combined chemotherapy & radiation on visual preservation in patients of retinoblastoma.
Material and Methods: In this retrospective analysis, a total of 61 patients of retinoblastoma were studied from Jan 2004 to Nov 2008. Evaluable 40 patients were analysed for presenting features; sites of involvement, treatment received and stage wise visual preservation. Most common age of presentation was 2−3 years (40%) and leucocoria was the most common finding (75%). More than 50% of the involved eyes had stage III−IV disease. Treatment was multimodal except in stage I and II in which patients received only external beam radiation with a dose of 45 Gy/25#/5 weeks. Rest patients received radiation after chemotherapy with OPEC regimen D_{1-4}, 3 weekly regimen or postoperatively. Following external beam radiation and chemotherapy response assessed by USG, ophthalmoscopy and EUA in ophthalmology department.
Results: With the median follow up of 30 months, this study showed that overall visual preservation rate of 100% in stage I and II, 64% in stage III, 45% in stage IV and 30% in stage V disease. None of the patients reported had significant radiation or chemo induced toxicities.
Conclusion: Visual preservation is excellent in retinoblastoma with current treatment modalities. With the advent of neoadjuvant chemoradiation, treatment goal has now shifted from surgery to visual preservation in most of patients. External beam radiotherapy has a definite role as primary or adjuvant treatment in management of retinoblastoma.
No conflict of interest.

1638 POSTER

Experience of blood, marrow and cellular transplantation at the children's hospital of Pittsburgh, 2000–2010: Family, psycho social issues surrounding adverse events

R. Rohrer[1]. *[1]University of Pittsburgh, Epidemiology, Pittsburgh, USA*

Background: Blood or marrow transplantation, as well as the newer cellular therapies are usually a last resort treatment for children with pediatric malignancies. This study compares the family experience of the United States through selected transplantation programs with those of the National Health Service centers in the United Kingdom in the period 2005–2010. The reporting centers around the issues of medical complications, intensive care experience and psycho social impact overall on patient and caregivers.
Material and Methods: The archival materials and published materials of the UK Medical Research Council and the Children's Oncology Group in the United States are compared as part of this longitudinal study. Parental interviews in the United States and the United Kingdom as permitted through questionnaire are part of the study analysis.
Results: Moderate to severe stress related issues were reported by more than 90 percent of families surveyed. Post traumatic stress syndrome either diagnosed or sub clinical was also nearly 100 percent in these groups. Further analysis by regions over earlier (1980–2005) periods will be particularly useful to compare stress levels as the sophistication of transplantation has developed.
Conclusions: For family members as well as patients the transplantation experience in pediatric oncology is medically and psychologically traumatic.

As transplantation as a treatment continues to expand for both malignant and non malignant pediatric diseases, documenting and evaluating the multi faceted impact on patient and family should become increasingly relevant.
No conflict of interest.

1639 POSTER

Physicians' attitudes towards patient participation in decision making in the pediatric oncology setting and their assessment of patient competency − preliminary findings from a qualitative study

K.M. Ruhe[1], T. Wangmo[1], D.O. Badarau[1], B.S. Elger[1]. *[1]University of Basel, Institute for Biomedical Ethics, Basel, Switzerland*

Background: Children's and adolescents' participation in healthcare decisions depends on their competency. Only if minor patients demonstrate a sufficient level of maturity are they entitled to exercise decision making powers. The gatekeepers to participation are parents and physicians. Especially physician's role is important as parents can feel insecure as to how much to involve their child in decisions surrounding cancer care. Physicians' attitudes and motives towards including children and adolescents in these processes may influence the assessment of minors' competency to make or participate in therapeutic decisions. It thus seems crucial to carefully look at factors that physicians consider when deciding if a minor patient should be involved. This exploratory and descriptive study aims at identifying some of these factors while also capturing various positions pediatric oncologists take on patient participation in decision making.
Method: Semi-structured interviews will be carried out with pediatric oncologists in various children's hospitals in Switzerland. Interviews will be analysed using content analysis to code for general attitudes towards children's and adolescents' participation in decision making as well as for factors that physicians reported to associate with minors' competence.
Results: Findings from the on-going analysis present that physicians report various factors that they relate to competency in children and adolescents. These factors are driven by careful medical considerations, experience, personal attitudes, acknowledgment of other health care colleague's views and not least the parents' opinions. Additionally, positions on patient participation in pediatric oncology decision making differ among practitioners, even when legal provisions on the matter do not vary.
Conclusions: Preliminary results indicate that physicians' perception of skills children and adolescents must possess to be included in therapeutic decision making and of the degree of competency necessary in the oncology setting is crucial. These perceptions might guide physicians' assessment of patient's capacity to participate in decision making and thus ultimately influence recommendations given to parents as to the inclusion of a particular minor. They consequently significantly shape minors' autonomy in healthcare. Furthermore, general attitudes will influence physicians' own behaviour towards the child or adolescent. Thus, these convictions strongly affect aspects of patient care in the oncology setting.
No conflict of interest.

1640 POSTER

Non-Wilms' tumors (NWT) of the kidney in childhood: 15-year experience

V.S.F. Fragkandrea[1], E.S. Smaropoulos[2], S.R. Rupakias[2], G. Frangandreas[3]. *[1]Ippokration General Hospital, Department of Paediatric Oncology, Thessaloniki, Greece; [2]Ippokration General Hospital, Department of Paediatric Surgery, Thessaloniki, Greece; [3]Ippokration General Hospital, 1st Surgical Clinic, Thessaloniki, Greece*

Aims: Wilms' tumor accounts for 7% of pediatric malignancies. Other primary renal pediatric malignancies however represent a much smaller proportion. They constitute a heterogeneous group that includes renal cell carcinoma, clear-cell sarcoma, mesoblastic nephroma, rhabdoid tumor of the kidney and renal medullary carcinoma. The aim of the present study was to investigate the cases of primary malignant NWT treated from 1996 to 2001, and to emphasize the importance of the early surgical excision of the tumor.
Methods: All children with renal malignancies were identified among the 750 patients treated in the Pediatric Oncology Department of our Hospital from January 1st, 1996 to December 31st, 2011. Patientsfiles were reviewed and the following data were collected: gender, age at the diagnosis, clinical presentation, operation and pathology reports, treatment scheme, follow-up and outcome.
Results: During this 15-year period a total of 73 children (29 male) were diagnosed with kidney tumors. Sixty-one had Wilms' tumor and 12 (16.4%) had a NWT. Diagnostic biopsies were performed on all patients and showed: renal-cell carcinoma (2), clear-cell sarcoma (2), rhabdoid tumor of the kidney (2), mesoblastic nephroma (3), cystic-cell nephroma (3). The median age at diagnosis was 2.2 years (range 2 months to 15 years). Four (4) patients, 2 with clear-cell sarcoma and 2 with rhabdoid tumor of the kidney received preoperative chemotherapy according to standard national protocols, followed by surgery. The rest submitted to an early surgical management. Post operative chemotherapy was given to 4 patients. 3 patients also received radiation therapy. 3 to 15 years after the ehd of treatment 10 patients are alive and disease free (median duration of follow-up: 92 months). Two patients died due to the progressive disease.
Conclusions: Non Wilm's renal tumors are rare in children. Nephrectomy as first-line therapy should be seriously considered in compination with pre- and post − operative chemotherapy wherever it needs.
No conflict of interest.

1641 POSTER

Humoral immunity findings in acute lymphoblastic leukemia in children

I. Astigarraga[1], O. Martinez-Mugica[1], J.M. Garcia-Martinez[1], A. Urberuaga[1], A. Echebarria[1], R. Adan[1], P. Oliver[2], L. Dopazo[2], A. Bilbao[1], A. Navajas[1]. *[1]Hospital Universitario Cruces, Paediatrics, Bilbao-Vizcaya, Spain; [2]Hospital Mendaro, Paediatrics, Gipuzkoa, Spain*

Background: Cancer and chemotherapy are frequent causes of secondary immunodeficiency. Acute lymphoblastic leukaemia (ALL) is the most frequent paediatric cancer and the associated immune changes are relevant due to an increased risk of infection and comorbidity. The aim of this study was to analyse the evolution of serum immunoglobulin (Ig) levels from the onset of leukaemia to the end of treatment and to assess the impact of hypogammaglobulinemia on hospital admissions and ALL course.
Material and Methods: A retrospective longitudinal study of 90 children diagnosed with ALL during the last 10 years was conducted. Eleven patients were excluded: 2 Down' syndromes, 2 incomplete medicals records and 7 still on treatment. ALL types, Ig levels (at diagnosis and during chemotherapy) and data on admission for fever, relapse, transplantation, and mortality were analyzed.
Results: Main characteristics of 79 included children were as follows: mean age at diagnosis, 5 years (range 4 months-13 years); 46 boys: 33 girls; 66% had common B ALL; and 46% were classified as high risk. At onset, low levels of at least one Ig (isolated or multiple deficits) were found in 15% of patients. Of the 63 children with no relapses or transplant, 93.6% had low levels during chemotherapy (47.6% of IgG+IgA+IgM). Decreased IgM was often observed both at diagnosis and during treatment. Main reasons for admission were febrile neutropenia and respiratory infections. Ig levels were available in 44% of admissions and were low in 36.5%. No differences in Ig values among children who died (6), relapsed (10) or after transplantation (11) and the others were detected, but the small sample size limits the power for this analysis. Replacement therapy with Ig was given to 6 children with good clinical response. After therapy, gradual recovery was observed, reaching normal values in 12 months except for 4 children.
Conclusions: Reduced immunoglobulin levels are common in children with ALL. At diagnosis, 15% of patients showed one or several decreased Igs. During chemotherapy, low levels were detected in 93.6% of children. Although IgM is the most common affected value, the combination of low IgG-IgA-IgM is often seen during maintenance therapy. Most patients recover normal values after finishing treatment. More complete immunological studies should be included in the management of children with ALL.
No conflict of interest.

1642 POSTER

Low level laser therapy in oral mucositis

R. Cauwels[1], L. Martens[1], V. Van De Velde[2], Y. Benoit[2]. *[1]University Hospital Ghent, Paediatric Dentistry & Special Care PaeCaMeD Research Group, Gent, Belgium; [2]University Hospital Ghent, Paediatric Haemato-Oncology, Gent, Belgium*

Background: Oral mucositis remains a morbid side-effect of anticancer treatments and will complicate recovery due to discomfort and infection. Low Level Laser Therapy (LLLT) can contribute in healing and pain relief. As there are no guidelines available in the world literature it was the goal of this study to focus on the treatment frequency and the released energy related to the healing process.
Material and Methods: Children from the University hospital, department of paediatric oncology, suffering from chemotherapy-induced mucositis were treated. At the intake, prior to the start of the oncologic treatment, all patients were examined by a paediatric dentist and received oral hygiene instructions. The mean age of 9.4 years old. Most of them suffered from

ALL. At baseline, the mucositis grade was evaluated using the WHO-classification. The related discomfort expressed by oral pain was measured by a visual pain scale. An AsGaAl diode laser with 830nm wavelength and a potency of 500mW was used. The energy (J) released depended on the severity of the stomatitis. The children were visited on a regular basis until wound healing occurred. At each visit, the mucositis grade as well as the impact on oral functions was noticed. Pain assessment, before and immediately after treatment, was monitored using an age-adapted pain scale. Information about treatment sequence, treatment sessions and frequencies related to the comfort results were registered. At any visit, related blood cell counts were recorded.
Conclusion: From this survey, it became clear that 2 to 3 treatments per session seems a realistic approach resulting in a advanced healing. All patients recorded a gradual pain relief after each session.
No conflict of interest.

1643 POSTER

Medulloblastoma below the age of 3 years: Treatment and prognostic factors

S. Ahmed[1], M.S. Zaghloul[1], E. Eldebawy[1]. [1]*Children's Cancer Hospital Egypt, Radiotherapy, Cairo, Egypt*

Background: Medulloblastoma patients below 3 years had inferior survival rates due to several reasons.
Aim: To investigate the treatment end-results of medulloblastoma under 3 years of age and determine the factors that affects its prognosis.
Patients and Methods: Eighteen children below the age of 3 years were treated at Children's Cancer Hospital, Egypt during the period from July 2007 and December 2010. Safe maximum resections were attempted in all patients. Gross total resection was performed in 10 children (56%), subtotal excision in 7 children (39%) and biopsy in one patient. Fourteen children (78%) proved to be non-metastatic, while 4 belonged to M3 category (spinal seedling). Eight out of the 18 (44%) children received infantile medulloblastoma chemotherapy protocol, while the other 10 received other chemotherapy protocols. All the 4 metastatic children received craniospinal irradiation (CSI) with boost to the seedling site. Six out of the M0 patients received posterior fossa (PF) irradiation (5580 cgy), while the other 8 received CSI, as they reached the age of 3 years, with booster dose up to 5580 cGy to PF.
Results: The 3-year overall survival (OS) for all children was 55±16%. The OS for non-metastatic was 61±15% and 50±29% for M children. The infantile chemotherapy protocol led to 3-year OS of 71±17% compared to 24±18% for other protocols. The OS for CSI was 71±17% compared to 49±25% for conformal PF irradiation. None of the CSI group developed CNS relapse, while only one (17%) who received PF irradiation had spinal relapse. It is worthnoting that non of the these detected differences were statistically significant. All children tolerated treatment with minimal immediate toxicity and acceptable, so far, late effects.
Conclusions: The 3-year OS of children below 3 years were modest with improved OS in non-metastatic patients who received infantile protocol and CSI.
No conflict of interest.

1644 POSTER

Treatment of paediatric brainstem glioma: A single-institution retrospective analysis

L. Shats[1], G. Radulesku[1], M. Belogurova[1]. [1]*Clinical Hospital 31, Paediatric Oncology and Haematoogy, St. Petersburg, Russian Federation*

Background: The role of chemotherapy in the treatment of children with newly diagnosed brainstem glioma is uncertain.
Materials and Methods: Between 1996 and 2012, 33 children with a defined clinico-radiological diagnosis of brainstem glioma were treated with radiotherapy or radiotherapy and chemotherapy in paediatric oncology department. Seventeen patients underwent biopsy. Histopathological investigation showed low grade gliomas in 2 cases, glioblastoma multiforme (2 pts), anaplastic astrocytoma (13 pts). The study involved 18 males and 15 females (median age, 7 years) with a median follow-up of 10 months (1−84 months). All diagnoses were established using MRI and in 12 patients Methyl-[11C]-L-methionine (MET) positron emission tomography (PET) was used. Twenty MET-PET scans from 12 patients were analyzed. PET was a tool in the monitoring during and after a treatment. Metabolic characteristics assessed with MET standardized uptake values (SUV). In our group SUV was 1.64−3.4 (median 2.1).
Thirty one patients were irradiated and received 53−60 Gy. Eleven children didn't receive any chemotherapy after irradiation (the first group). In two cases radiotherapy was interrupted because of the very fast progression. In the second group 7 patients received temozolomide (TMZ) as single-agent 150–200 mg/m^2 administered on 5 consecutive days every 28 days (number of courses 1−6, median 3), 6 pts also received concurrent chemotherapy during irradiation with TMZ (75 mg/m^2/day). The third group of patients (13 pts) received one of different chemotherapy regimens that contained: cyclophosphamide (or ifosfamide), etoposide, cisplatin and vincristine or ifosfamide, etoposide, carboplatin and vincristine (number of courses 1−17, median 8).
Results: The median OS for the first, second and third group was 6.0 and 8.0 months and 14.5 months respectively. The 1 year and 2 year overall survival in 20 patients that received RT and chemotherapy were 40.8±10.9% and 15.3±8.1%; in 13 patients that received only RT − 18.2±11.6% and 0% ($p = 0.19$). The overall survival rate dependent of the chemotherapy regimen was 11.1±10.5% (second group) and 60.0±15.5% (third group) at 1 year after diagnosis ($p < 0.05$). There are 3 long-term survivals in our group with follow up 64−84 months, who were treated with radiotherapy and intensive chemotherapy (third group).
Conclusion: In our series, TMZ did not result in a better outcome when compared with irradiation alone.
No conflict of interest.

1645 POSTER

Clinical outcomes and prognostic factors of pediatric Wilms tumor with initial metastases: CCHE experience

W. Zekri[1], R.S. Soliman[2], A.Y. Yones[3], M.S. El Shafie[3], M.S.Z. Saad Zaghloul[4], H.T. Taha[5], N.K. El Kinawy[5], A.R. Refaat[6]. [1]*Children's Cancer Hospital Egypt, Pediatric Oncology Department, Cairo, Egypt;* [2]*Children's Cancer Hospital Egypt, Research Department, Cairo, Egypt;* [3]*Children's Cancer Hospital Egypt, Surgical Oncology, Cairo, Egypt;* [4]*Children's Cancer Hospital Egypt, Radiation Department, Cairo, Egypt;* [5]*Children's Cancer Hospital Egypt, Surgical Pathology, Cairo, Egypt;* [6]*Children's Cancer Hospital Egypt, Radiodiagnosis, Cairo, Egypt*

Background: Renal tumors represent 6.3% of cancer diagnoses in children, where Wilms' tumors is the most common. Metastatic Wilms' tumors have the worst outcomes where the lung is the most common site of metastasis, followed by the liver then extra-abdominal lymph nodes.
Material and Methods: Forty-one pediatric patients with Wilms' Tumor having metastases at diagnosis were registered in the Children's Cancer Hospital Egypt (CCHE), between July 2007 and June 2011, and followed up until March 2013. Initial metastases were evaluated by CT chest and abdomen. Patients received pre-operative chemotherapy then response of pulmonary metastases was assessed. Patients were evaluated as either showing Rapid Complete Response (RCR), or Slow Incomplete Response (SIR), where slow responders should be shifted to more intensified chemotherapy and receive pulmonary irradiation. Overall (OS) and event-free survival (EFS) were calculated by Kaplan–Meier curve. Patients' outcomes were correlated with prognostic factors using log-rank test.
Results: 25 patients (60%) were females, while 16 (39 %) were males. Mean age at diagnosis was 4.6 years. 32 patients (78%) presented with pulmonary metastases only, 9 (22%) presented with lung and other metastases in liver. Post-operatively, 5 patients were locally stage I, 2 were locally stage II and 34) were locally stage III. 26 patients (63.4%) showed favorable histology, while 15 patients (36.6%) showed unfavorable histology as anaplasia in 5 cases and Blastemal predominance in 10 cases. 27 patients who presented initially with lung metastases only and showing favorable histology were assessed for their response; 8 patients (19.5%) showed RCR, while 18 patients (80.5%) showed SIR. One patient died before assessment of response due to progressive disease. Patients who showed pulmonary RCR were all in complete remission at final clinical status where 6 of them received pulmonary irradiation. 33 patients received local irradiation, 28 of which were locally stage III. At a median follow-up of 25 months, 5-year OS was 66.1% and EFS was 55.2%. 2 patients relapsed, one locally and lung metastases, and another relapsed as lung metastases only. Other 2 patients never reached complete remission showing progressive disease. The EFS was significantly correlated with histology, where patients with favorable histology showed EFS equals to 75%, compared to 18% in unfavorable histology (p-value= 0.001). OS was correlated with histology, showing 80.8% in favorable histology vs. 35.8% in unfavorable histology (p-value= 0.031). Other prognostic factors as pulmonary response to neo-adjuvant chemotherapy, site of metastases and local staging didn't show any impact on survival.
Conclusions: Initially metastatic wilms' tumor patients with favorable histology have significantly better outcomes compared to unfavorable histology. Response of pulmonary metastases to neo-adjuvant chemotherapy also plays a vital role in predicting disease prognosis.
No conflict of interest.

1646 POSTER

Evaluation of outcome of febrile neutropenic children with hematologic malignancies: The impact of different therapeutic modalities within the ICU environment

K. Fathy Riad[1], S. Abdel Hadi[2], M. Ghazally[3]. *[1]South Egypt Cancer Institute, Pediatric Oncology, Assiout, Egypt; [2]National Cancer Institute, Pediatric Oncology, Cairo, Egypt; [3]Assiut University Hospital, Pediatric Oncology, Assiut, Egypt*

Background: Many studies have succeeded in identifying a subset of children with febrile neutropenia (FN) who are at lower and higher risks of infectious complications and eventual death, but only few discuss the role of ICU and the uses of different modalities in diagnosis and treatment of those children with FN.
Methods: Between January 2009 and July 2011, 200 episodes of FN in 143 children were included in a prospective study in South Egypt Cancer Institute Assiut University, Assiut, Egypt, to evaluate the outcome of febrile neutropenia in children with hematological malignancies and to determine the impact of different therapeutic modalities within ICU environment.
Results: In the present study profound neutropenia (ANC less than 100 cell/m3) was significantly observed in high risk febrile neutropenic patients in comparison to low risk group. Profound neutropenia also was significantly observed to be associated with monocytopenia (96%) in comparison to mild and moderate neutropenia (3%). Patients with profound neutropenia were also significantly observed to be more liable to develop shock (86.6%) more than of that of higher ANC (5%). The outcome of patients with profound neutropenia were 59% improvement and that for mild and moderate neutropenia were 94%.
The outcome of treatment in our study group showed that from 100 episodes of high risk febrile neutropenia 72 (72%) patients improved, 39 (54%) inside ICU and 33 (46%) outside ICU. The low risk group showed that from 100 episodes 93 (93%) improved. Out of 15 patients put in mechanical ventilation 9 patients were improved.
Conclusions:
– From this study the patients of febrile neutropenia may be classified to high risk and low risk according to many clinical and laboratory parameters.
– It was concluded that sepsis level of serum PCT is a useful marker strongly suggestive of severe sepsis and severity of the illness.
– As estimation of serum PCT may predict the outcome its use may support the decision to start antibiotics therapy and ICU admission.
– High serum level of PCT may help in stratification of patients with febrile neutropenia in high risk and low risk group.
– Treatment of patients in a protocol manner according to risk criteria appears to be applicable for patients in the study group.
Recommendations: Profound neutropenia is notably predictive of the outcome in patients with febrile neutropenia. Use of serum PCT level, ANC and AMC in combination with clinical parameters might be useful in management of febrile neutropenia.

Interactive multimedia pediatric surgical oncology

A. Pi Osoria[1], V. López Merino[2], J. Vincecht[2], R. Cabanas Armada[3]. *[1]Pedi Univ Hospital "Juan Manuel Márquez" National Center of Pediatri, Surgery & Morphophysiology, Havana, Cuba; [2]CITMATEL, Multimedia, Havana, Cuba; [3]Ped Univ Hosp Juan M Márquez Nat Ref Center of Ped Oncol, Oncohematology, Havana, Cuba*

Background: The educational need of pediatric surgeons, all the professionals related with child with cancer care and to contribute to supplement the programmes for the studies of medicine and nurse encouraged us to carry out this multimedia. Pediatric malignant diseases in Cuba represents 2% of all the annual cases according to the National Register of Cancer; however, this relative low incidence it is a health problem with a serious impact on the family, the health workers and society as a whole. For more than 20 years, I have worked as pediatric surgeon within a multidisciplinary team to care about children with cancer. That important experience (as national reference center) has allowed to our team to contribute to the results of the National Cancer Program in Cuba whose figures of survival have gradually increased for the last 40 years to more than 70%.
Material and Methods: Our Multimedia consists of five great chapters: Generalities, The Most Important Solid Tumors, Emergencies, The Family and Can Cancer be Cured? The chapter Generalities is about the history of general and pediatric oncology and surgical oncology synthesized up to now, both international and in Cuba; it also deals with general and particular statistics of each area, survival before and after the implementation of the National Program and the main concepts. We clearly and accurately approach the criteria and principles of pediatric surgical oncology, the main achievements, challenges and present difficulties and also our concept of rescue surgery in cancer.
The chapter on 'The most important tumors' deal it Renal Tumors, Embrionary Tumors, Neuroblastoma, Rabdomiosarcoma, Hepatoblastoma, Thyroid Tumors, Metastatic Tumors, among other topics with a comprehensive and up dated approach where we present our selection criteria for surgery treatment based on the cost-benefits-risk balance within the general treatment program, according to the approved protocols for each type of tumors. We present the surgical protocols and the statistic results in most of topics.
The chapter 'Can Cancer be cured?' deals with modern criteria about prognostic, early diagnosis and life quality.
The chapter 'The Family' is about all the issues related with the impact on each members of the family, since the moment of diagnosis to the cure or death and the behavior of the family health staffs.
Results: Through an attractive user interface, with hyperlinks texts, videos of interviews to experts and surgeries in real time, as well wide gallery of pictures charts and diagrams, our Multimedia fulfils the didactic objectives. It so adheres to international standards.
Conclusions: This multimedia mainly addressed to Pediatric Surgeons as ones in charged of one of the treatment modalities. This informatics product has been validated by the Cuban Pediatric Surgery Society, according to the informatics programs used and the contents.
No conflict of interest.

Molecular iodine adjuvancy in the antineoplastic effect of retinoic acid on neuroblastoma cells

B. Godoy-García[1], M. Nava-Villalba[1], G. Delgado[1], C. Aceves[1]. *[1]Instituto de Neurobiología, Department of Cellular and Molecular Neurobiology, Querétaro, Mexico*

Background: Neuroblastoma (NB) is a childhood cancer that arises from precursor cells of the sympathetic nervous system and is responsible for 15% of all childhood cancer deaths. All-trans retinoic acid (ATRA) is an established component of the treatment given to children with high-risk NB to reduce minimal residual disease; however, its use has been limited because, at the therapeutic dose, it rapidly induces toxicity. On the other hand, several studies have demonstrated that molecular iodine (I_2) decreases cell proliferation and induces differentiation and/or apoptosis of several cancer cell lines. Our group has proposed that such actions are exerted by the formation of a lipid known as 6-iodolactone (6-IL), which binds to peroxisome proliferator-activated receptors type gamma (PPARγ); heterodimers of PPARγ, in turn, co-active ATRA receptors.
Materials and Methods: In the present study, we analyzed the antiproliferative (trypan blue assay) and apoptotic effects (AnexinaV/calcein) of I_2 and ATRA alone or in combination in ATRA-responsive (SH-SY5Y) and ATRA-resistant (SK-N-AS) NB cell lines.
Results: Our results confirm previous studies showing that in SH-SY5Y, ATRA induces differentiation (neuritic process), whereas in SK-N-AS ATRA has no effect at any analyzed dose. The molecular iodine supplement is accompanied by moderate, dose-dependent antiproliferative and apoptotic effects in both cell lines. When I_2 and ATRA are added together, a significant adjuvant effect is observed: at 200 μM I_2 is able to reduce the effective dose of ATRA by 1000 fold for induction of differentiation in SH-SY5Y and for the antiproliferative ATRA-response in SK-N-AS.
Conclusions: This finding indicates that I_2 sensitizes NB cells to ATRA and leads us to propose that it be assessed in therapeutic protocols as a possible way to reduce toxicity and avoid side effects. Analyses to determine the molecular pathways involved in this effect are currently underway in our laboratory.

Intracranial atypical teratoid rhabdoid tumour: A single institute experience of fifteen patients from North India

A. Biswas[1], S. Goyal[1], A. Kakkar[2], C. Sarkar[2], S. Bakshi[3], P.K. Julka[1], G.K. Rath[1]. *[1]All India Institute of Medical Sciences, Radiotherapy & Oncology, Delhi, India; [2]All India Institute of Medical Sciences, Pathology, Delhi, India; [3]All India Institute of Medical Sciences, Medical Oncology, Delhi, India*

Background: We intended to assess the clinicopathological features and treatment outcome in patients of intracranial atypical teratoid rhabdoid tumour (AT/RT), a rare malignant tumour of the brain.

Materials and Methods: Medical records were reviewed and clinical data collected on AT/RT in a 6 year period (2006−12). Histopathology slides were reviewed and relevant immunohistochemistry stains were done. Overall survival was analysed by Kaplan–Meier method. Univariate analysis of factors predictive of overall survival was done by Log Rank test.
Results: 15 patients met the study criterion (male: female=4:1). Median age at presentation was 5 years (range 0.8−8 years). Presenting complaints included vomiting (73.33%), headache (46.67%), orbital symptoms (33.33%), motor impairment (26.67%), gait abnormality (20%) and seizure (20%). Median duration of symptoms was noted to be 2 months (range 0.5−6 months). On contrast enhanced MRI of brain, tumour location was supratentorial in 60% patients and infratentorial in 40% patients. Cystic component and hydrocephalus were noted in 73.33% patients each whereas contrast enhancement and calcification were discerned in 53.33% and 40% of the patients respectively. All patients underwent tumour resection − gross total (26.67%), neartotal (13.33%) and subtotal (60%). Histopathology was confirmative of AT/RT with MIB-1 labelling index varying from 11−85% (median 45%). There was lack of immunostaining for INI-1 suggesting INI-1 mutation. Majority of tumours exhibited immunopositivity for EMA (93.33%), synaptophysin (80%), cytokeratin (66.67%), vimentin (66.7%), SMA (60%), GFAP (46.67%). Adjuvant radiation (36 Gy/20#/4 weeks to entire neuraxis followed by local boost 20 Gy/10#/2 weeks) was started in 6 patients (40%) and completed in 5 patients. Young age at presentation and poor performance status precluded the use of radiation in the remainder. Systemic chemotherapy was administered in 10 (66.67%) patients. Median number of cycles given was 3 (range 1−12) with ICE (ifosfamide, carboplatin, etoposide) and VAC (vincristine, dactinomycin, cyclophosphamide) being the common regimens (26.67% and 20% respectively). After a median follow-up of 8.33 months (mean-12.27 months), median overall survival was noted to be 10 months. At last follow-up, 2 patients are in complete response, 1 patient is on treatment, 3 patients are alive with evidence of disease and 9 patients expired due to disease progression. The 1 and 2 year actuarial rate of overall survival was noted to be 48.1% and 24.1% respectively. On univariate analysis, extent of surgery ($p = 0.0149$), use of craniospinal radiation ($p = 0.0087$) and MIB-1 labelling index ($p = 0.0034$) were significant predictors of overall survival while age ($\geqslant$5 years versus <5 years) was of borderline significance ($p = 0.08$).
Conclusion: Median survival of 10 months reflects the aggressive biology of this rare neoplasm. Maximal safe resection followed by craniospinal irradiation and systemic chemotherapy with ICE or VAC regimen is a reasonable treatment strategy in this uncommon malignancy.
No conflict of interest.

1650 POSTER

Clinical outcome of paediatric brainstem glioma treated with concomitant and adjuvant temozolomide: An institutional experience of 40 patients

A.K. Gandhi[1], S. Mallick[1], N.P. Joshi[1], D.N. Sharma[1], G.K. Rath[1], C. Sarkar[2], P.K. Julka[1]. *[1]All India Institute of Medical Sciences, Department of Radiation Oncology, New Delhi, India; [2]All India Institute of Medical Sciences, Department of Pathology, New Delhi, India*

Introduction: Brainstem glioma (BSG) is an aggressive tumour of childhood. Treatment outcomes remain dismal and role of concurrent chemoradiotherapy (CTRT) is not established in these patients. We intended to study the clinical characteristics along with outcome of paediatric BSG patients treated with CTRT.
Methods: We retrospectively evaluated 40 patients, age less than 18 years, with BSG treated at our department in the period Jan 2007 to December 2011. Demographic and disease characteristics in this patient cohort were recorded. Progression free survival (PFS) was estimated by the use of Kaplan Meier method and univariate analysis (log rank test) was done to assess the impact of sex, grade, use of CTRT and adjuvant chemotherapy on PFS. SPSS version 12.0 was used and p value of <0.05 was considered significant for all statistical analysis.
Results: Median age at presentation was 9 years (range 3−18 years), with a male: female ratio of 1.5:1. 8 patients presented with gait ataxia and 16 presented with cranial nerve palsies. 24 patients were diagnosed radiologically as high grade. None of the patient underwent surgery. Radiotherapy dose was 56−60 Gray over 5.5 −6 weeks at 1.8−2 gray/fraction. All patients completed their radiotherapy except 4 patients. 15 patients received concurrent temozolomide (75 mg/m^2), 7 patients received adjuvant temozolomide (150–200 mg/m^2 D1−5 q4 weeks for 3−6 cycles) and 4 patient received both concurrent and adjuvant temozolomide. Median follow up duration was 7 months (range 1−39 months). At last follow up, 17 patients had progressive disease. Median PFS for the entire group was 16.6 months. PFS was significantly poorer in the patients who received concurrent temozolomide than those who did not (median PFS 7.9 vs. 16.7 months; p 0.03) on univariate analysis and also on multivariate analysis (p 0.01). Sex, grade, and adjuvant chemotherapy did not statistically alter treatment outcomes.
Conclusions: Outcome of paediatric BSG remains dismal. CTRT with temozolomide has detrimental effect on survival and its use should be discouraged. Radiotherapy alone with standard fractionation remains the treatment of choice in inoperable paediatric BSG.
No conflict of interest.

1651 POSTER

Paediatric nasopharyngeal carcinoma − management and experience of two Egyptian institutions

H. Abdel Rahman[1], M.S. Zaghloul[1], W. Zekri[1], A. El Gamal[1], M. Moneer[1]. *[1]Children Cancer Hospital Egypt, Paediatric Oncology, Cairo, Egypt*

Background: Nasopharyngeal carcinoma (NPC) is rare in children, accounting for 1% of paediatric malignancy. Neoadjuvant chemotherapy helps to decrease radiotherapy dose, limits its side effects and controls metastases. However, standard treatment as regard the optimal dose of radiotherapy and timing of chemotherapy is still not established yet.
Objectives: To investigate treatment outcome of paediatric NPC patients diagnosed and treated at the Children's Cancer Hospital Egypt 57357 (CCHE) and the National Cancer Institute (NCI), Cairo University during the period between July 2007 and July 2011.
Methods: Retrospective review of patient charts with histologically proven, paediatric NPC diagnosed and treated at CCHE and the NCI during a 4 years period. All patients were followed up till end of July 2012.
Results: Twenty-five patients were included in our study. Age of the patients ranged from 7.8−17 years with a median of 12 years. They were 19 males (76.0%) and 6 females (24.0%). Median follow up period ranged between 6 −54 (median 22 months).
All patients were diagnosed pathologically as WHO type III (undifferentiated NPC).
According to AJCC staging system, 3 patients (12%) were stage II, 6 patients (24%) as stage III and 16 patients (64%) were stage IV; 12 patients (48%) stage IV A:, 2 patients (8%) stage IV B, and 2 patients (8%) stage IV C.
Twenty patients (80%) received neoadjuvant chemotherapy with cisplatin/5-fluorouracil followed by concurrent chemo-radiotherapy in total dose of 61.2 Gy. Five patients (20%) received upfront radiotherapy with carboplatin as radio-sensitizer followed by adjuvant chemotherapy of cisplatin/5-flurouracil.
After completion of treatment, complete response was accomplished in 17 cases (68%), partial response in 3 cases (12%) and 3 patients lost follow up. After the end of follow up period, 4 patients relapsed and another 4 patients had progressive disease, out of those eight patients, six patients died. The 2-year OS and EFS rates were 79.7% and 60.8% respectively. Whereas the 4-year OS was 53.2% and EFS was 60.8%.
Conclusion: In our study, high systemic failure (32%) is still unacceptable and challenging. More efforts should be made to improve survival by investigating other prognostic factors and developing more efficient and less toxic therapeutic strategies.
No conflict of interest.

1652 POSTER

Langerhans cell histiocytosis (LCH) in Egyptian children − a single center experience

M. Sedky[1], H.A.R. Abdel Rahman[1], E.M. Moussa[1]. *[1]Children Cancer Hospital 57357, Pediatric Oncology, Cairo, Egypt*

Background: Langerhans Cell Histiocytosis (LCH) behavior ranges from spontaneous regression to rapid progression and death, or repeated reactivations. Localized disease (skin, bone or lymph node) have a good prognosis without treatment. In contrast, high risk organs (liver, spleen, hemopoietic system) have a poor outcome and may need aggressive chemotherapy.
Materials and Methods: Retrospective review of pediatric LCH patient charts diagnosed and treated at Children Cancer Hospital CCHE in the period between July 2007 and December 2011. Chemotherapy was given according to the LCH III protocol with follow up till 02/2013.
Results: 80 LCH patients, 43 males and 37 females were analyzed. Median age was 4.1 years (3 months − 13.4 y). Patients were stratified into 4 groups: Group I: monostotic lesion n = 14 (17.5%) received no systemic treatment, group II: multisystem with no risk organs (RO -): n = 29 (36%) received Vinblastine (VBL) and Prednisone (PRED) for up to 1 year, group III: multisystem with risk organs (RO+): n = 19 (24%) received (VBL), (PRED) methotrexate (MTX) and 6 mercaptopurine (6-MP) for 1 year and group IV: unisystem multifocal lesions +/− special sites: n = 18 (22.5%) received (VBL) and (PRED) for 6 months. After a minimum 1 year and up to 5.5 year follow up from end of induction, 70 patients (87.5%) were

better with No Active Disease (NAD) or Active Disease Regressive (ADR), 3 patients were intermediate (4%) in Active Disease Stable (ADS), 3 patients were worse (4%) in Active Disease Progressive (ADP). Three patients (4%) died (all in group III). The 5 years Overall Survival (OS) was (96.3%), while the 5 year Event Free Survival (EFS) was (54.7%) distributed per group as follows: Group I 93%, Group II 52%, Group III 47%, Group IV 83% $p < 0.013$. EFS was worse if age <2 years old (38%) compared to 2−10 years (71%) and >10 y (90%) $p < 0.001$. 2) Slow response (need for a 2nd induction) was responsible of a worse EFS (48.7%) in relation to rapid response (80.5%) $p < 0.009$. Reactivation occurred in 25 patients (38%), while post induction progression in 3 patients (4.5%). The probability of reactivation or progression was 47%. Shorter maintenance 8 months mean duration favored reactivation in relation to longer 10 months mean duration p0.043.
Conclusion: In our series, response to induction chemotherapy is satisfactory. Although a greater incidence of reactivation, survival remains the rule. Low age and slow responder carry a worse prognosis.
No conflict of interest.

1653 POSTER

Long term risk of cardiac morbidity after craniospinal irradiation a prospective from a developing nation

A. Sharma[1], I. Amed[1], R. Madan[1], S. Sharma[1], D.N. Sharma[1], P. Julka[1], G.K. Rath[1]. *[1]All India Institute of Medical Sciences, Radiotherapy, Delhi, India*

Background: Craniospinal irradiation is an integral part of management of medulloblastoma. Late toxicity is major concern in long term survivors and significantly affects their quality of life. The purpose of study was to evaluate long term risk of cardiac morbidity for patients treated with 3-DCRT.
Patients and Methods: Study included twelve medulloblastoma patients, assessed as per age & risk stratification. All patients underwent planning CT scan in prone position under thermoplastic immobilization. Organs at risk contoured included heart, lungs, thyroid, esophagus, cochlea, kidney, intestines, stomach and liver. Heart was contoured as per RTOG guidelines. Target delineation generated CTVbrain, CTVspine, CTVposterior fossa. Seven mm margin was given to generate PTV. Dose of 30−36 Gy/20#/4wks was prescribed to spine, whole brain received 30 Gy/20#/4wks, posterior fossa boost was 24 Gy/12#/2.5wks. Planning was done by virtual simulation on eclipse version 6.2 for varian CL2300 linear accelerator with 6MV photons. Single direct spinal field prescribed at 90−95% isodose was used at an extended SSD whereas for cranial fields and posterior fossa boost fields dose was prescribed at 95% isodose. Adequate cranio-spinal junction matching was ensured by collmator angle and half beam block. For evaluation of late cardiac morbidity D_{max}, D_{mean} and volume of heart were recorded. Odds radio for development of late long term cardiac morbidity was calculated by formula OR= $1+ \alpha_1 D + \alpha_2 D^2$ where D was the mean dose of heart and value of α_1=0.19 and α_2=0.002 were used in equation.
Results: Median age of presentation was 7(2−18) years. Nine patients were in standard risk medullblastoma whereas three presented in high risk category. Spinal field were planned at median extended SSD of 115(105–120) cms. Median volume of heart was 291(256–356)cc. D_{max} for heart was 29(27−39) Gy where as D_{mean} was 19(16−24) Gy. Our study recorded substantial higher risk of long term cardiac toxicity median Odds ratio of 5.3 (2.75−5.8) as compared to non-radiated medulloblastoma patients (approx. OR 2.3).
Conclusions: With use of 3DCRT risk of late long term cardiac morbidity is substantially high (OR 5.3). Modern techniques of radiation such as IMRT should be evaluated to reduce the risk late cardio-toxicity.
No conflict of interest.

1654 POSTER

Current management and aspects of acute lymphoblastic and acute myeloblastic leukemia at a hospital based study in Iran

A. Mehrvar[1], M. Faranoush[2], M. Tashvighi[3], A.A. Hedayati Asl[4], M.A. Fazeli[4], N. Mehrvar[5], R. Zangooei[5], M. Alebouyeh[4], P. Vossough[4]. *[1]Mahak's Pediatric Cancer Treatment and Research Center Army Medical University, Oncology, Tehran, Iran; [2]Mahak's Pediatric Cancer Treatment and Research Center Iranian Blood Transfusion Organization, Oncology, Tehran, Iran; [3]Mahak's Pediatric Cancer Treatment and Research Center Islamic Azad University (Ghom Branch), Oncology, Tehran, Iran; [4]Mahak's Pediatric Cancer Treatment and Research Center, Oncology, Tehran, Iran; [5]Mahak's Pediatric Cancer Treatment and Research Center, Research, Tehran, Iran*

Background: One of the main national referral centers for childhood malignancies in the capital city of Iran is MAHAK's Pediatric Cancer Treatment and Research Center (MPCTRC). Due to large number of referrals with leukemia, data compiled at this center can consider as reference for any issues related to managements and long-term effects in order to facilitate and optimize medical services for pediatric malignancies. This report provides data regarding long-term results and management of childhood acute leukemia at MPCTRC.
Materials and Methods: The enrolled patients consisted of 258 childhood acute leukemia cases that have been referred since 2007 to 2010 to MPCTRC. Basic epidemiological information recorded in standard checklist for each individual patient. All of the patients were followed for consideration long-term results.
Results: Out of patients, 198 (76.7%) had ALL and 60 (23.3%) had AML. In the ALL group, 111 were males (56.1%) but In the AML group, 32 were males (53.3%). The mean age in the ALL group was 5.6 ± 0.92 years in the AML group 6.2 ± 0.96 years. Eight (4%) of ALL and seven (11.7%) of AML cases had delayed complications. In ALL group 52 (26.3%) cases died and 4 (2%) were lost to follow-up. In AML group 28 (46.7%) cases died and 1 (1.7%) were lost to follow-up. The three years survival rate of ALL group was 92% and AML group was 85%. The median survival time of all cases was 12 ± 0.05 month.
Conclusions: The medical problem of childhood acute leukemia therapy is long-term effects that persist months or years after treatment and consist of learning problems, fatigue, bone or joint pain, also the risk of secondary cancers. Childhood cancer survivors should have physical examinations yearly. Regular medical follow-up for assessing the effects of therapy can lead to identify recurrence of the disease and long-term effects.
No conflict of interest.

Metronomic chemotherapy in pediatric relapsed or metastatic CNS tumors

M. Dragomir[1], M. Badoi[2], C. Comsa[2], R. Milcu[2], E. Gruber[2]. *[1]Institute of Oncology, Pediatric Oncology, Bucharest 2, Romania; [2]Institute of Oncology "Prof. Dr. Al. Trestioreanu", Pediatric Oncology, Bucharest 2, Romania*

Background: Metronomic chemotherapy uses the very well known cytostatic agents in a new way. Instead of large doses, according to patient's tolerance, there are used small amounts of medication in a daily administration. The goal is to inhibit the angiogenesis, targeting the tumoral endothelial cells more than the tumoral cells. The inhibition of blood-vessel growth and the diminished blood supply could cause the tumor regression with favorable outcome and less toxicity. Recent studies show the efficacy of the metronomic therapy in pediatric solid tumors (neuroblastoma, sarcomas, CNS tumors) which are proved to be resistant to aggressive treatments. The cytostatic drugs have been used in small oral daily doses, in three weeks cycles (cyclophosphamide, etoposide, temozolomide) associated with anti-angiogenetic medication (fenofibrate, celecoxib).
Material and Methods: We have been prescribing the metronomic therapy since 2011 in 14 cases of CNS (medullar or cerebral) tumors which underwent prior surgery and chemo-radiotherapy and are in metastasis after the treatment. The patients have been taking fenofibrate 90 mg/m^2 q.d, celecoxib 100 mg b.i.d and have to rotate the 21-days cycles of etoposide 50 mg/m^2 q.d and cyclophosphamide 2.5 mg/kg q.d. They have been hematological monitored and doses are modified according to patient's tolerance. We have treated 3 cases of ependimoma (one case- medullar metastatic ependimoma, 2 cases of cerebral ependimoma), 4 cases of metastatic medulloblastoma (3 cases with leptomeningeal metastasis) and 7 cases of astrocitar relapsed or metastatic tumors.
Results: The outcome has been favorable in 9/14 cases. The treatment has been administered 2−24 month. Imagistic assessment revealed stable disease (reduction <50 % of the tumoral mass). EFS, psychomotor development and quality of life have been very good.
Conclusions: 1. Metronomic chemotherapy represents a good therapeutic alternative in relapsed or metastatic CNS tumors after the aggressive oncological treatment. 2. Survival with a good quality of life is offered by less toxicity and better tolerance.
No conflict of interest.

1656 POSTER

Prevention of infectious complications in children with bone tumours after the arthroplasty

M. Rykov[1], A. Dzampaev[1], E. Gyokova[2], V. Polyakov[1]. *[1]Institute of Paediatric Oncology and Haematology N. N. Blokhin Cancer Research Centre, General Oncology, Moscow, Russian Federation; [2]Institute of Paediatric Oncology and Haematology N. N. Blokhin Cancer Research Centre, Anaesthesiology, Moscow, Russian Federation*

Background: The treatment of bone tumours in children requires numerous courses of chemotherapy − both before and after surgery. An

initial problem to be solved is providing venous access: comfortable for the patient and entailing minimal risk of infections. This is particularly important to prevent infection of bone implants in the joints. The best option is fully implantable venous port systems.
Materials and Methods: From 2008 to 2012 we observed 175 children with bone tumours of extremities (aged 3 years to 17 years). Sparing surgery (limb arthroplasty) was performed in 167 patients (95.4%): in 2008−24 patients, in 2009−34, in 2010−28, in 2011−44, in 2012−37. The lowest age of the patient, who underwent surgery for knee replacement − 3.5 years, the shoulder joint − 4 years. We have used venous ports since 2010 and implanted them in 80 (45.2%) patients with limb bone sarcomas: in 2010 5 (17.8%) patients, in 2011 39 (88.6%), in 2012 36 (97.2%). Subclavian catheters were implanted in 96 (54.8%) patients.
Results: Infectious complications developed in 18 patients with limb endoprosthesis (10.8%). There were 3 infected implants (12.5%) in 2008, 5 (14.7%) − in 2009, 3 (10.7%) − in 2010, 4 (9.0%) − in 2011, 3 (8.1%) − in 2012. Two-step re-arthoplasty was performed in 11 (61.1%) patients, conservative treatment (antibiotic therapy with Maxipime, Amikacin, Zyvox or Cubicin) helped to keep the implants in 7 patients (38.8%). In this early − developed within 3 months after the operation − infectious complications occurred in 64.3% of patients, delayed − from 3 months up to 2 years − 24.1%, and late − over two years − in 11.6%. Catheter-related bloodstream infection developed in 28 (29.1%) patients with subclavian catheters, while in patients with implantable venous ports such infections were not noted. The most common cause of catheter-related infections − S. epidermidis (71.8%) and S. aureus (18.2%), also inoculated when infected implants.
Conclusion: The introduction of implantable venous port-systems for the treatment of child patients with bone tumours has significantly reduced (1.8 times) the number of infectious complications and infections of limb prostheses, improving quality of life.
No conflict of interest.

1657 POSTER

Study of the role of palliative radiotherapy in the management of incurable pediatric malignancies

P. Kumbhaj[1], R. Sharma[1]. [1]*Sms Medical College & Hospital, Radiation Oncology, Jaipur, India*

Background: Palliative radiotherapy has a important role in the management of the pediatric malignancies, that are not curable and need only palliation for symptom control.
Methods: Patients coming to the department of radiotherapy S.M.S Hospital were included in the study. 36 pediatric patients were selected between nov 2010 to nov 2012. All of theses 36 children received palliative external beam radiotherapy for symptom control. Palliative radiotherapy was given either as single modality or in addition to surgery, chemotherapy and symptom relief drugs. Information recorded for each patient included age, sex, and extent of disease, histological types, symptomatology, treatment methods and symptom relief. The various dose schedules were used (1) 625cGy/week for 3 week, (2)20 Gy in 5 fractions and (3) 30 Gy in 10 fractions.
Results: There were 26 boys and 10 girls in the age group of 1 to 19 years, with a median age of 14 years (range of 1−19 years). Predominant symptoms were swelling with or without pain, bleeding, and weakness of limbs. The median duration of symptoms was 80 days (range of 4−40 days). The diagnosis of these children varied with different histologies, most in the group of malignant round cell tumors (17), retinoblastoma (6), neuroblastoma (5), Ewing's sarcoma (8). All patients presented with advanced stages of disease. Out of 36 patients 18 (50%) had disseminated disease at presentation. Six patients underwent surgery while 30 patients received chemotherapy and all patients received palliative radiotherapy. Three patients showed complete resolution, 18 patients showed good, while 14 patients had little, 1 did not have any relief in their symptoms. At the completion of multimodality treatment, 16 patients had partial response, 6 patients had progressive disease, 8 had stable disease and 2 patients had complete response. The disease status of 4 patients could not be known.
Conclusions: The role of radiotherapy is very important as palliative modality in children with locally advanced lesions. It provides better symptom relief.
No conflict of interest.

1658 POSTER

Obesity in childhood leukemia survivor

T. Arpaci[1], E. Kilicarslan Toruner[1]. [1]*Gazi University Health Sciences Faculty, Nursing, Ankara, Turkey*

Background: Obesity is the one of the most important health problems that increasingly seen in survivors of children with leukemia. Although the etiology of obesity in survivors of leukemia is not yet fully understood, the hypothalamic-pituitary axis affects the treatment methods, lifestyle and genetic factors are thought to be effective in.
Material and Methods: This systematic review was aimed to analyze the obesity situation and effecting factors in survivors of children with leukemia. Review of the literature was made on PUBMED and WILEY INTERSCIENCE databases by using 'child, leukemia, survivor and obesity' keywords. Thirteen descriptive researches which are suitable for criterias of 57 articles were included in research which was published from 2003 to 2013. The sample of it consisted of the patients whose treatment was finished after at least two years to define the frequency of obesity case among the childeren who are still alive from leukemia.
Results: Most of the researchs were done in the USA. Sample size of the all researchs was consisted of 9419 alive children. Most of the children who were alive were observed with the diagnosis of acute lenfoblastik leukemia. The average age of children in the researches was 16.4 and average diagnosis age of children was 4.9 The average age after the treatment was 10.8 years.
The frequency of obesity was between %4.6 and %47.2, the average was %34. The prevalence of obesity showed increases in the kranial radyoterapy and steroid therapy. At the same time, it was found that obesity mostly went on the children who had high body mass indexes during the treatment.
Conclusion: Alive children after a very long time after the treatment are under the risk of obesity according to nomal population. Children should be followed during and after the treatment to decrase the side effects of obesity and promote the healthy weight.
No conflict of interest.

Choice of treatment method in angiofibroma nasopharynx in children and adolescent

N.M. Karimova[1], K.Z. Iskandarov[1], S.B. Shamuratova[1], K.R. Nuritdinov[1]. [1]*National Oncological Research Centre, Paediatric Oncology, Tashkent, Uzbekistan*

Background: To perform analysis of treatment efficiency in angiofibroma nasopharynx in children and adolescent.
Materials and Methods: In 36 patients performed analysis results of angiofibroma nasopharynx in children and adolescent.
All patients examined with clinic-x-ray, endoscopy with tumor biopsy and CT and MRT.
Main symptoms: disorder of nasal breathing (100%), admixture of blood (81.1%), snuffing tinge (86.5%) and impediment of nasal breathing (67.6%). Most of patient's long time treated with rhinitis, pharyngitis, antritis.
In 36 patient performed surgical operations with Muru and bandaging of external carotid artery, part resection of maxilla, moving off tumor. Out of 36 patients in 14 (39%) tumor is spreading base of cranium and performed preoperative radiotherapy with 2 Grey dose, total 40−60 Grey dose. After radiotherapy tumor size decreased, in 14 patient carried out radical surgery operations. In 19(53%) patients performed surgical intervention without radiotherapy. In 3(8%) patients were taken postoperative radiotherapy, 2 grey dose, total dose was 40−60 Grey. Because tumor process was spread to pterygopalatine and subtemporal area.
Results: In 36 patients with nasopharynx benign tumor survival rate was 100%. Out of all patients in control group 3 (8%) revealed recidivating of tumor. In group of preparation's and post operations do not detected any recidivating.
Conclusion: Analysis of treatment results showed that, surgery and radiotherapy is choice of method in angiofibroma nasopharynx in children and adolescent.
No conflict of interest.

1660 POSTER

The use of implantable venous port systems in oncopaediatrics: Implantation technique and tactics of exploitation

M. Rykov[1], E. Gyokova[2], V. Polyakov[1]. [1]*Institute of Paediatric Oncology and Haematology N. N. Blokhin Cancer Research Centre, General Oncology, Moscow, Russian Federation;* [2]*Institute of Paediatric Oncology and Haematology N. N. Blokhin Cancer Research Centre, Anaesthesiology, Moscow, Russian Federation*

Background: Central venous catheterisation − a frequent but dangerous manipulation, requiring general anaesthesia, without which no chemotherapy is possible. Subclavian catheters have a finite period of service and a high risk of complications. Implantable venous port system − stitched in soft tissue chamber connected to the catheter, the distal end of which is located in the superior vena cava (SVC).
Materials and Methods: From 2010 to 2013 we implanted venous ports at 278 cancer patients (aged 4 months to 17 years). All implants were

performed with the use of intraoperative fluoroscopy for inserting port of the catheter into the SVC and precise positioning of the distal end of the catheter above the entrance to the right atrium. To ensure security we punctured internal jugular Vienna (IJV) for insertion of the catheter into SVC only after ultrasound navigation and marking of vessels, and in some complicated cases (thin, mobile vein) the puncture was performed with the use of intraoperative ultrasound imaging of blood vessels. Then in the subclavian area we created a subcutaneous 'pocket' where the portal camera was implanted. The catheter was inserted in a specially created subcutaneous tunnel from the puncture site to the place of the implanted chamber and connected with it. The tissue was then sutured in layers. As a solution to close the systems in time of no use, we applied a medicine containing taurolidine, which prevents the formation of biofilm on the inner surface of the catheter. In case of catheter thrombosis we inserted 3 ml of a fluid containing a 25,000 IU dosage of urokinase into the system, with exposure time of 15 minutes.
Results: No pneumothoraxes were noted. From the first attempt we managed to puncture IJV in 271 cases (97.4%). In this case, inserting a guidewire into ERW from the first attempt succeeded only in 189 cases (67.9%). In 69 cases (24.8%) there was the migration of the guidewire into internal jugular vein against the blood flow in 17 (6.11%) − into the subclavian vein on the side of puncture and in 3 cases (1.07%) − into the IJV on the opposite side. Periportal tissue infection was observed in 2 cases (0.71%). Port catheter thrombosis was observed in 6 cases (2.15%). Catheter-associated bloodstream infections were not reported.
Conclusions: Implementation of implantable venous port systems in oncopaediatrics reduces a number of vein punctures, general anaesthesia, and complications associated with these manipulations.
No conflict of interest.

1661 POSTER

Late effects and survival in children with cancer: A single-center experience

V.E. Castellon Rubio[1], M.A. Vazquez Lopez[2], F. Lendinez Molinos[2], M. Leyva Carmona[2], M.M. Ibañez Alcalde[2], L. Ruiz Tudela[2], J. Lopez Muñoz[2], L.G. Canosa Ruiz[1]. *[1]Hospital Torrecardenas, Oncology Service, Almeria, Spain; [2]Hospital Torrecardenas, Pediatric Onco-Hematology Unit, Almeria, Spain*

Background: High cure rates of childhood cancer entail an increase of sequelae due to the disease or its treatment. Despite the existence of numerous reports on survivors and their clinical, neuropsicological, legal and social status, the real incidence of late effects is unknown and it is probably underestimated due to loss of follow-up data. The objective of this report is to know the evolution of children diagnosed with cancer in our center and to analyze survivors' late effects.
Material and Methods: Cohort study which includes patients aged 0−15 diagnosed with childhood cancer from 1990 to 2008. Age at diagnosis, gender, type of malignancy, treatment received, events appearance (recurrence or exitus) and number, type, severity and likely cause of sequelae were recorded. Kaplan Meier survival analysis was performed.
Results: 248 patients were analyzed (59% were male), with an average age of 5.7±4.2 years. The most frequent diagnoses were leukemia (30.6%), central nervous system malignancy (18.1%), lymphoma (11.3%) and neuroblastoma (12%). 50.6% required surgical treatment, 74% received chemotherapy, 14.9% radiotherapy and 14.6% hematopoietic stem cell transplantation. 21% recurred. The 5-year global survival rate was 71%. Leading cause of death was mostly progressive disease (44%) and infectious causes (30%). Of the 180 survivors, 40% presented some type of sequelae (42% considered as severe), due to surgery (49%), chemotherapy (20%), radiotherapy (13%) and the disease (11.6%). The sequelae were endocrinological (41.8%), neurological (21%), renal (15.5%) and musculoskeletal and aesthetic (both 9.7%). 4.2% developed a second tumor.
Conclusions: Survival rate is similar to that reported in other series. Percentage of severe sequelae is disturbing, due to the incapacity, continued health care needs and repercussion on the professional and personal projection of patients. Multidisciplinary teams promotion and continuous surveillance of childhood cancer survivors is needed to achieve the early detection of illness derived chronic problems and their treatment; as well as to implement programs to facilitate social insertion of these patients.
No conflict of interest.

1662 POSTER

Treatment strategy in children with medulloblastoma

Z. Bekic[1], V. Antunovic[2], L. Paripovic[1], J. Bokun[1], I. Tufegdzic[1], M. Skender[3]. *[1]Institute for Oncology and Radiology of Serbia, Pediatric Oncology, Belgrade, Serbia; [2]Institute for Neurosurgery, Belgrade, Serbia; [3]Institute for Pathology, Belgrade, Serbia*

Background: The aim of our non-randomised study was to evaluate results of treatment and analysis of prognostic factors in patients over 3 years of age with medulloblastoma.
Material and Methods: From 1991 to 2005 we treated 102 patients(pts) with medulloblastoma, median age 8 (range 3 to 15 years). Gross total resection was performed in 43 pts, subtotal resection in 20, and partial in 39 pts. After surgery, all patients were treated with craniospinal irradiation. The majority received full dose neuroaxis radiation therapy, and 55 Gy to the primary site.
Adjuvant chemotherapy regimen Vincristine (Vcr), CCNU was administered in 47 pts, while 55 pts received platinum based adjuvant chemotherapy (Vcr, CCNU, CDDP regimen 44 pts, 8/1 8 pts, Baby brain protocol 3 pts).
Results: During the the 10 to 216 months follow-up period 5-year disease free survival (DFS) rate was 55.8% and 5-year overall survival (OS) rate was 58.8%.
5-year OS rate in adjuvant chemotherapy Vcr, CCNU group was 46.8% and 72.6% in Vcr, CCNU, CDDP group (statistically significant $p = 0.02$), while OS in 8/1 group was 61.7%.
The most significant prognostic factors were extent of surgery, absence of brain stem invasion and M2/M3 stage.
Conclusion: Adjuvant chemotherapy regimen Vcr, CCNU, CDDP is therapy of choice in multidisciplinary treatment of medulloblastoma. Complete resection, absence of brain stem invasion and absence of M2/M3 stage are predictors of better prognosis.
No conflict of interest.

1663 POSTER

Use of brentuximab vedotin in a 10 year old boy with relapsed Hodgkin's lymphoma − clinical case

M. Brito[1], I. Ferreira[2], S. Silva[1], M. Benedito[3]. *[1]Hospital Pediátrico de Coimbra, Pediatrics − Pediatric Oncology, Coimbra, Portugal; [2]Instituto Português de Oncologia Lisboa, Unidade de Transplante de Medula, Lisboa, Portugal; [3]Hospital Pediátrico de Coimbra, Pediatrics − Hematology, Coimbra, Portugal*

Background: Hodgkin's lymphoma has a very good survival rate in pediatric patients. In some cases of relapse is however very difficult to achieve a second remission. New drugs in Pediatric Oncology are introduced sometimes only some years after their introduction in adult context. We present a clinical case of relapse in Hodgkin's lymphoma in a ten year old boy, after 4 lines of therapy, autologous bone marrow transplant and radiotherapy. Brentuximab vedotin (BV) was used as a compassive drug, with good results and very few side effects.
Material and Methods: MFA was diagnosed Hodgkin's lymphoma (nodular sclerosis, Ann Arbor Stage IIA − mediastinum and cervical adenopathies) in July 2008. He started chemotherapy according to institutional protocol (adaptation of Cancer Children's Group protocol 5942), COPP (cyclophosphamide, vincristine, prednisolone, procarbazine)/ABV (doxorubicin, bleomycin, vinblastine) x 6 cycles due to bulky disease; and entered remission. In August 2009 relapsed was diagnosed and he started chemotherapy according to Euro-Net protocol IEP (ifosfamide, etoposide, prednisolone)/ABVD (doxorubicin, bleomycin, vimblastine, dacarbazine) with no response. He then started salvage chemotherapy with DECA (dexamethasone, etoposide, cisplatin, cytarabine). A new adenopathy was found after 2 cycles and he then started vinorelbine/gemcitabine with a slow but gradual response that permitted to proceed with autologous bone marrow transplant in September 2010. In December 2010, before programmed radiotherapy, CT showed multiple pulmonary lesions. Vinorelbine/gemcitabine was again started with partial response and in May 2011 he proceeded with radiotherapy. Disease progressed through radiotherapy. MFA clinical case was submitted to use with BV − compassionate drug use - and approved. He started therapy with BV in September 2011, with response (PET and CT). He had no need for packed red blood cells or platelet transfusions, he had one episode of fever (with pneumonia) and it was possible for him to have a normal life with school attendance during the 16 doses (1.8 mg/kg per dose each 3 weeks) of BV.
Results: Until today he remains in remission, being without treatment since July 2012. No late side effects related to BV have been noted.
Conclusion: Therapy with brentuximab vedotin was feasible in our patient, with anti-tumor activity, even after several lines of therapy and with very few side effects.
No conflict of interest.

1664 POSTER

Metastatic malignant melanoma in children and management of the complications

J. Suvada[1], M. Dzatkova[1], Z. Hlavata[2], I. Beder[3], P. Povinec[4], L. Plank[5], D. Haviar[6], E. Kaiserova[1]. [1]*Children University Hospital, Clinic of Children Hematology and Oncology, Bratislava, Slovak Republic;* [2]*National Cancer Institute, Department of Malignan Melanoma, Bratislava, Slovak Republic;* [3]*Children's Teaching Hospital, Clinic of Children Surgery, Bratislava, Slovak Republic;* [4]*Biont, Department of Radiology, Bratislava, Slovak Republic;* [5]*Bioptic Centre, Department of Pathology, Martin, Slovak Republic;* [6]*Children University Hospital, Department of Radiology, Bratislava, Slovak Republic*

Background: Malignant melanoma is a relatively rare diagnosis for childhood and in the adolescent population as well. Annual percentage change inrising incidence is observed during the past few years also for children older than 10 years of age and for whole group of adolescents. The incidence of malignant melanoma during adolescence has doubled in 10 years. This is not the case for the incidence of melanomas in children younger than 14 years, which seems to be unchanged. Current incidence in Slovakia is unknown. It is necessary to be aware of the risk of malignant melanomas in children after puberty.
Method: We present two casereports of a 16- and 17-years-old boys with metastatic malignant melanoma. The incidence of melanoma grew rapidly in adults over thepast several decades.
Results: Currently we treat 2 patients with metastatic malignant melanoma. Both of them were diagnosed previous in the last 2 years and they were initiated on specific treatment with vemurafenib and they are still in very good response to the therapy with clinically controlled disease without metastases. In the presentation we will discuss difficulties with the diagnostic process (in one from the patients it was initially diagnosed Ewing's sarcoma and after 4th cycle of the chemotherapy there was strong suspicion for double malignancy at once) and management of rare complications among these boys, which have not been published yet in the literature.
Conclusion: Melanoma in children and teenagers differs from melanoma in adults in presentation, complications, and survival. Further investigation is needed to elucidate possible biologic correlates of the unique aspects of melanoma in children and teenagers and to use these findings in therapy.
No conflict of interest.

1665 POSTER

Experience of using implantable peritoneal port systems for regional chemotherapy in patients with malignant peritoneal mesothelioma

M. Rykov[1], A. Ryabov[1], V. Polyakov[1]. [1]*Institute of Paediatric Oncology and Haematology N. N. Blokhin Cancer Research Centre, General Oncology, Moscow, Russian Federation*

Background: Mesothelioma − is a rare form of cancer that develops from transformed cells originating in the mesothelium. Intraperitoneal chemotherapy − one of the essential components of a multi-modal approach in the treatment of this disease. The safest and most comfortable way of its implementation − using implantable peritoneal port inserted as a stage of cytoreductive surgery.
Methods: Since 2011 6 children with peritoneal mesothelioma aged 10 to 14 years receiving treatment underwent peritonectomy with one-stage implantation of peritoneal port systems and intraoperative intraperitoneal administration of the Cisplatin drug at a dose of 120 mg/m^2 at 90 minutes. Patients received adjuvant chemotherapy according to the Alimpta scheme 120 mg/m 2 first day, Cisplatin 75 mg/m^2 in intra-abdominal first day. The interval between courses was 21 days.
The portal body is implanted in the soft tissue of the front abdominal wall in the VIII − X rib area. An approximate 5-cm incision in the skin is made at the selected site. A 'kangaroo' pocket is created approximately two cm away from the incision line and 0.5-cm to 2.0 cm deep into which the portal body is placed. The portal body is fixed in the bottom of the 'pocket'. A catheter is placed into the abdominal cavity and through an opening in the abdominal wall is connected to the portal body. Soft tissue sutured in layers. In the port system Huber needle with a rounded tip is installed, so that it does not cut, but push the silicone chamber membrane.
Results: Patients and medical staff admit ease of the port systems operation. Recurrence of the disease and port systems infection were not noted.
Conclusion: Use of peritoneal ports is easy and safe way of intraperitoneal chemotherapy.
No conflict of interest.

1666 POSTER

Off-label use of bevacizumab in association with irinotecan in pediatric low grade gliomas: Not more than a short-term salvage treatment?

C. Pasqualini[1], A. Cuinet[1], S. Canale[1], A. Christin[1], I. Aerts[2], S. Puget[3], C. Dufour[1], D. Valteau-Couanet[1], J. Grill[1]. [1]*Institut Gustave Roussy, Pediatric and Adolescent Oncology, Villejuif cedex, France;* [2]*Institut Curie, Pediatric and Adolescent Oncology, Paris, France;* [3]*Necker Children Hospital, Pediatric and Adolescent Oncology, Paris, France*

Background: The combination of irinotecan and bevacizumab has shown efficacy in the treatment of some adult and children high and low-grade gliomas. It is now proposed as a new strategy for refractory or recurrent low-grade pediatric brain tumors.
Materials and Methods: Data concerning 26 children with recurrent or refractory primary low-grade glioma (LGG) treated in a single center were reviewed. Patients received treatment at a median age of 6.6 years, range 1.0–19.1 years. The majority had diencephalic tumors, five had disseminated disease, and nine had neurofibromatosis type 1. Six of 26 patients had progressed after at least three chemotherapy regimens (median of 1 line, range 0−5), sixteen had had surgery and no one had received radiotherapy. Intravenous bevacizumab (10 mg/kg) and irinotecan (125 mg/m$^{2)}$ were administered every 14 days, with a median of 15 cycles (range 5−26). Evaluation was carried out using Macdonald response criteria for contrast enhancing lesions and 2D size for the other. Treatment was continued until progression or grade 3 toxicity and usually for a maximum of one year. Primary end point was progression-free survival (PFS). Secondary end points included overall survival (OS) and radiological and clinical response.
Results: 24 patients had a radiological response after 4 cycles (92%) and two patients had a stable disease. Clinical improvements were noted in thirteen, including improved visual acuity (6), improved motor function (2), improved pain control (2), weight gain in two with a diencephalic syndrome, and reversal of psychomotor retardation (1). Five children remained on treatment for at least one year. 4 patients relapsed while on treatment. Response was not durable in the majority of patients (median 0.9 years, range 0.3−1.8).
Two-years PFS and OS rates were 21.5% (95% CI, 6.7 to 51.1%) and 86.7% (95% CI, 62.1–96.1%), respectively. No significant difference for PFS and OS has been showed based on NF1 status, number of previous chemotherapy lines and duration of bevacizumab-irinotecan association treatment. The only dose-limiting toxicity was one grade 3 proteinuria.
Conclusion: Recurrent pediatric LGG appear to be responsive to the combination of bevacizumab and irinotecan. A majority of patients achieve an objective response, whose stability seems, however, to be at short-term. The drug association has been relatively well tolerated, and warrants further study.
No conflict of interest.

Proffered Papers Session (Sat, 28 Sep)
Nursing − Advanced Nursing Roles

The constitution of a "Peripherally Inserted Central Catheters Team" (PICC team) at the Oncology Institute of Southern Switzerland (IOSI): a multidisciplinary approach

M. Bianchi[1], S. Lussu[2], C. Pedrazzani[3], P. Servida[4], D. Valcarenghi[3]. [1]*IOSI -San Giovanni Hospital, Nursing Officer, Bellinzona, Switzerland;* [2]*Istituto Oncologico della Svizzera Italiana, PICC Team, Bellinzona, Switzerland;* [3]*Istituto Oncologico della Svizzera Italiana, Nursing Development and Research Unit, Bellinzona, Switzerland;* [4]*Istituto Oncologico della Svizzera Italiana, Medical Oncology Inpatient Department, Bellinzona, Switzerland*

Background: At the beginning of 2010 the creation of a nursing PICC Team was suggested by the Nursing Officer to the Director of the Oncology Institute of Southern Switzerland (IOSI) in order to offer to patients a different and more suitable vascular device chance and to nurses an opportunity of professional development.
Material and Methods: Four nurses were trained to the specific placement technique, two doctors were identified in order to manage clinical problems due to PICCs (indications and complications) and several nurses and health professionals were trained inside and outside the hospital for the device management.
After a literature review, it was decided initially not to use PICCs with hematological patients because of a higher risk of complications. For each patient, until the catheter removal, data were collected for the management

and continuous evaluation of the process by a multidisciplinary coordination group (nurses and doctors).
Results: At the end of February 2013, 102 PICCs had been placed and removed, out of 124 inserted (93% in oncological patients). On average, every PICC had been on site 87.7 days (range 2–348), with a median of 61.5. In 8 cases (8%) we had mechanical problems (unintentional take off and/or obstructions) and in 6 cases we had symptomatic venous thrombosis (0.67/1000 cath.days), but with negative catheter's tip culture.
Patients satisfaction (38 questionnaires) is high (average of 8.7 out of 10).
The collected data and the comparison with the scientific literature have improved internal guidelines and allowed to extend the PICC use also to hematological patients.
Moreover, by now, 15 training meetings, with around 200 participants, have been provided to internal and external nurses.
Conclusions: The project of a PICC Team constitution, started on the initiative of nurses, has been developed and consolidated thanks to a multidisciplinary collaboration. The PICCs introduction has promoted a development of nurse professional competences and patients have now a higher chance to receive the correct vascular device. The database periodic analysis and the multidisciplinary collaboration have allowed to constantly update the process, contain complications and keep high quality and security standards.
No conflict of interest.

The telephone follow-up as a strategy to improve the adherence to treatments of cancer patients

M. Rihuete[1], A. Rodriguez[1], J.J. Cruz[1]. [1]*Hospital Universitario de Salamanca, Oncology Service, Salamanca, Spain*

Background: Treatment adherence is a subject of great importance in oncology because it impacts on the effectiveness of treatments, patient safety and health costs. Early identification of poor adherence will help to prevent treatment failures. Information and education are the best strategies used by health professionals to ensure adherence to treatments. Telephone follow-up appears to be a good way to share information, provide health education and improve the adherence to treatments. The aim of this study was to evaluate the influence of telephone follow-up information support to promote adherence to treatments of cancer patients.
Material and Methods: An experimental design was used to evaluate our telephone follow-up intervention. Participants were randomized into a control or a treatment group. The independent variable was the telephone follow-up and the dependent variable was the adherence to treatments.
The subjects of experimental group were followed by telephone once a week during 4 week and the subjects of control group were contacted by phone at thirtieth day after discharge. The adherence to treatments was assessed with Morisky-Green test and a weighted scale of adherence to treatment in both groups. We compared the adherence in each patient of the experimental group before and after each intervention and the adherence of all patients of experimental group and control group at thirtieth day after discharge.
The inter group differences were assessed using Student t-test, ANOVA, Mc Nemar test, and Chi-square test. A difference between observed variables was considered statistically significant when $p < 0.05$. Statistical analysis was performed using statistical packages STATA 10.0.
Results: We carried out 319 telephone interventions with a range of 20 and 40 minutes duration. Patients from the experimental group experienced an important increase in their adherence after in each intervention. There are significant differences between the first statement and the following ($p = 0.000$). The patients of experimental group achieved better adherence at 30 days after discharge than subjects of control group at the same period ($p = 0.000$). The same differences were found with the Morisky-Green test ($p < 0.001$).
Conclusions: Our results show that systematic information by telephone follow-up improves the adherence to treatment of cancer patients.
Verification by the health professionals of the correct compliance with medication may motivate and reinforce behavior, and is essential to ensure the maintenance of the adherence.
No conflict of interest.

A telephone hotline for women newly diagnosed with breast cancer

C. Pihlmann[1], B.G. Mertz[2]. [1]*Rigshospitalet, Mamma Kirurgisk Klinik 3103/4 − Breast Surgery, Copenhagen, Denmark;* [2]*Rigshospitalet University Hospital Copenhagen, Section of Breast Surgery, Copenhagen, Denmark*

Background: Telephone contact is widely used as part of psychosocial counselling for breast cancer patients. Few studies have described the topics raised by newly diagnosed breast cancer patients using telephone calls. This study took place at the Department of Breast Surgery where 600 operations are conducted annually in a fast-track concept and examines a telephone hot-line service offered to patients from the day of diagnosis. Our objectives were to register the number of calls and describe the most common problems raised by the patients on the open telephone hot-line.
Material and Methods: This study used a descriptive design. All patients were informed about the telephone hot-line on the day of diagnosis and were free to use it 24 hours a day for the entire stay as an out-or inpatient. For a period of 8 weeks telephone calls were recorded. The recording was conducted by the nursing staff using a chart covering demographic and clinical data as well as detailed registration of the main themes of the conversation. Subsequently the themes were categorised.
Results: A total of 140 calls were included in the study. 56% of calls were questions regarding skin and tissue (e.g swelling, seromas, infection). Psychosocial concerns such as sadness and worry were raised in 18% of the cases and issues related to pain and the use of analgesics counted for 10% of the calls. Another 4% asked questions related to hormonal treatment and finally 18% consisted of various different topics. 6% of the patients reported more than one problem.
Conclusion: The present study evaluates an open telephone hot-line and demonstrates the need for a permanent possibility for newly diagnosed breast cancer patients to contact a breast care specialist. The hot-line provides an opportunity for patients to discuss problems and needs with a nurse. The most frequently reported problems concerned skin and tissue, psychological issues and pain.
The study also provides valuable knowledge about newly diagnosed breast cancer patients informational needs. These findings can be useful for future clinical nursing improvements.
No conflict of interest.

Oncology nursing research: How can we improve it? Results of a project based approach

E. Witkamp[1], W.H. Oldenmenger[2], E. Elfrink[3], C. Verhoeven[3]. [1]*ErasmusMC Cancer Institute, Medical Oncology and Public Health, Rotterdam, Netherlands;* [2]*ErasmusMC Cancer Institute, Medical Oncology, Rotterdam, Netherlands;* [3]*ErasmusMC Cancer Institute, Medical Oncology and Hemato-oncology, Rotterdam, Netherlands*

Background: The implementation of nursing research in oncology nursing is still in its infancy. In the Erasmus MC Cancer Institute professionals and managers were dissatisfied on the utilisation of research by nurses. Improvement in factors promoting research in the organizational context yield the decision to start a project on promoting nursing research and Evidence Based Care (EBC).
Materials and Methods: Between June 2009 and July 2012 we aimed to achieve three objectives:
1. Increased involvement of nurses in nursing or multidisciplinary research, by promoting the use of EBC and improving nurses' access to research findings.
2. A minimum of 4 nursing studies, resulting in publications or presentations, by coaching young scientists in the performance of their study.
3. Policy on oncology nursing research, by optimizing contextual factors, like leadership and culture.

A project was set up, led by a nurse scientist, and with participation of staff nurses, nurse practitioners, nurse scientists, managers, and physicians. We determined an incremental approach, to be able to satisfy the requirements of nurses, nursing teams or others.
Results: During this project many staff nurses were involved in at least eight literature searches on clinical problems. Thirteen nurses started and/or finished a scientific or evaluation study. Five reference meetings were held on study results, in attendance of 10−40 nurses per meeting. Nurses were first, second or last author in >100 presentations and publications, of which nine publications in international peer reviewed journals, and 19 oral and 24 poster presentations on international conferences. Additionally € 142.000 on external funding was raised. In accordance to the Promoting Action on Research Implementation in Health Services (PARIHS) framework, promoting factors and pitfalls of research utilization were examined, and yield to adaptation of the project strategy.
Finally the project resulted in the establishment of the Oncology Care Research Group for oncology nurses and allied healthcare researchers.
Conclusion: These results on the implementation of oncology nursing research show that promoting research utilization can be achieved within a few years. In our project, attention to various promoting factors and pitfalls, and a gradual approach contributed to the success, but the commitment of nurses and managers are essential.

Smileon: supporting innovative learning approaches through mobile integration in the workplace − oncology nursing: Results from the first pilot

P. Fernandez[1], A. Milani[2], M. Markova[3], A. Blazeviciene[4], A. Vaskelyte[4], K. Lokar[5], E. Akgun Citak[6], S. Kav[6]. [1]*Institut Català d' Oncologia, Nursing, Barcelona, Spain;* [2]*Istituto Europeo di Oncologia, Patient Care Services, Milano, Italy;* [3]*National Centre of Nursing and Other Health Care Professions, Nursing, Brno, Czech Republic;* [4]*Lithuanian University of Health Science, Nursing, Kaunas, Lithuania;* [5]*Institute of Oncology Ljubljana, Nursing, Ljubljana, Slovenia;* [6]*Baskent University Faculty of Health Sciences, Nursing, Ankara, Turkey*

Background: Use of mobile technology can allow the learning process to be facilitated outside and beyond the classroom contexts in which most oncology nursing training currently takes place.
Objectives: The aim of the project is to develop a new approach to training using mobile devices to extend learning activity into daily practice. This methodology was supported by a toolkit designed for tablets that use the Android operating system. Using these devices, nurses will be able to communicate in real time in the work place and access relevant content according to their needs.
Material and Methods: The project has involved needs analysis, development of appropriate learning methodology and mobile toolkit to support it. The approach were piloted in each of the partner countries (Spain, Czech, Italy, Slovenia, Lithuania and Turkey). The focus of the first pilot was the validation of the learning methodology and approach. The aim was to ensure that the toolkit and methodology proposed actually do facilitate and enrich the learning experience for the nurses. Sixty-six nurses from partnering countries were involved into first pilot and have been using the system. It was took a period of one month. Data were collected via both quantitative and qualitative; the quantitative instruments were series of questionnaires, based on Likert scale items (0−5) and semi-structure questionnaire were used for qualitative data.
Results: Nurses indicated that this approach was useful (mean = 5) and it was excellent choice for learning, it was relevant and effective (mean = 4). They mostly used tablets at home (mean = 4). They suggested some technical applications such as space for discussion under documents or photos, list of latest news, email notification daily activities etc.).
Conclusions: The methodology was certainly found as positive, relevant and effective in health workplace. Users are able to introduce the use of the methodology in clinical practice (for example for beginning nurses) with some technical modifications.

Understanding nurses' roles in nurse-led chemotherapy clinics: A two phase study using survey and ethnographic observational methods

C. Farrell[1], C. Walshe[2], A. Molassiotis[2]. [1]*Christie Hospital NHS Foundation Trust, Manchester, United Kingdom;* [2]*The University of Manchester, Nursing, Manchester, United Kingdom*

Background: The purpose of this study is to investigate the nursing role within nurse-led oncology clinics. There has been a rapid expansion and development of nursing roles and responsibilities in oncology, but little understanding of how roles are enacted nor their impact on patient experience and outcomes.
Materials and Methods: A two stage approach comprised a phase 1 survey of UK oncology specialist nurses (OSN) followed by a phase 2 ethnographic observational study of nurse roles in nurse led chemotherapy clinics. Ethics approval was obtained prior to each study; research and development approval was obtained from each hospital prior to Study 2. Study 1 used a questionnaire survey to explore the scope of nurses' roles. A purposive sample of OSN was recruited using snowballing methods. Descriptive and inferential statistics were used in data analysis. Study 2 used ethnographic methods to explore nurse-led chemotherapy clinics. A purposive sample of nurses from Study 1 was recruited to ensure geographical representation within the UK. Observations of nurse-led chemotherapy clinics and interviews with OSN were undertaken for data collection. Findings were coded and thematic analysis undertaken.
Results: Study 1 (n = 103 response rate 64%) showed development in nurse roles and services but little congruence between nurses' titles and roles. There were significant differences in practice: clinical examination ($p = 0.004$), history-taking ($p = 0.008$), nurse prescribing ($p < 0.0001$). Study 2 included observations (61 consultations by 13 nurses) and interviews (n = 11). There was variability in patient numbers within nurse-led clinics, identifying implications for service delivery and sustainability. Disparities in nurses' roles and responsibilities revealed 4 different levels of nurse-led chemotherapy clinics, from chemotherapy administration to totally nurse-led clinics. 5 main themes were identified: autonomy, knowledge, skills, power and beliefs. A key finding was reduced emphasis on compassionate care with greater medicalization of nurses' roles.
Conclusions: Despite a great diversity in oncology specialist nurses' roles, the lack of clarity in roles and responsibilities is creating confusion. Similarly the rapid increase in nurse-led chemotherapy clinics has been ad hoc with no formal evaluations. Nurse-led clinics have adopted a medical model of doctor-nurse substitution, which may have led to reduced emphasis on nursing skills and compassionate care.

1706 ORAL

Improving the nursing care of patients with peritoneal surface malignancies who are treated with cytoreduction and hyperthermic intraperitoneal chemotherapy (HIPEC) by use of a phase model clinical pathway

R. Kuin[1], D. Miltenburg[1], P. Bottenberg[1], Y. Winkel te[1], A. Mehta[1]. [1]*The Netherlands Cancer Institute, Oncologic Surgery, Amsterdam, Netherlands*

Background: The relatively low frequency of the HIPEC procedure can lead to indecision in the care process amongst inexperienced ward physicians. This in turn often leads to dissatisfaction amongst experienced nurses.
Also the ward physicians made decisions about nursing actions based on the nurses' observations. This led to delays in the nursing process and therefore in delays of the recovery of the patient.
To improve nursing work satisfaction and reduce patient hospitalization time, a clinical pathway was drafted. Due to the unpredictability of recovery after HIPEC a phase model clinical pathway was developed. In contrary to other pathways this model divides the care process in phases: pre-operative, postoperative and discharge phase.
Method: In April 2009 the phase model clinical pathway was implemented. Details on patient hospitalization were obtained by reviewing charts of a pre-implementation cohort of 10 patients and 2 post-implementation cohorts of 33 and 38 patients.
Open label interviews with nursing staff were conducted to evaluate nurses' sense of autonomy as well as sense of effectiveness of nursing actions. These interviews occurred in 2009 and 2013.
Patient satisfaction will be measured by a patient panel in early summer of 2013.
Results: Mean hospitalization time was 15.6 days in 2012 compared to 23.0 days in 2008: a reduction of **7.4** days.
In 2009, 47% of nurses had a sense of autonomy in decision making; in 2013 this proportion increased to 78%: an improvement of **31%**.
Also in 2009, 59% of the nurses were positive about the effectiveness of their actions, while in 2013 this was 93%: an improvement of **34%**.
The outcome of the patient panel will be presented during the congress.
Conclusion: The development and implementation of a phase model clinical pathway makes it possible to structure unpredictable care. The improvement in nursing care of HIPEC patients brought about by implementation of this pathway has led to a reduction of admission time and enhancement of the nursing work satisfaction.
No conflict of interest.

1707 ORAL

Feasibility and safety of replacing outpatient visit with telephone consultation before administrating chemotherapy in patients with metastatic prostate cancer

S. Møiniche[1], I. Holm Jensen[1], A. Danielsen[2], L. Sengeløv[3]. [1]*Herlev University Hospital, Oncology Department Team UG, Herlev, Denmark;* [2]*Herlev University Hospital, Department of Surgery, Herlev, Denmark;* [4]*Herlev University Hospital, Department of Oncology, Herlev, Denmark*

Background: The work flow of patients receiving chemotherapy is a pre-chemo outpatient consultation with blood test day 1 and treatment day 2. The purpose of this study was to test the feasibility and safety of telephone consultation with nurse specialist instead of visit at the clinic in patients with metastatic prostate cancer receiving palliative chemotherapy.
Methods and Materials: The prospective study included patients with metastatic prostate cancer which was found eligible for palliative chemotherapy with docetaxel every 3 weeks. 33 patients were included in the period may 2011 to march 2012. The median age was 74 (range 51−85) years. The intervention consisted of telephone consultation with specialist nurse instead of outpatient attendance the day before chemotherapy in series 2, 3 and 4. Adverse events were scored according to CTC version 3.0.

More than grade 2 of dose-limiting toxicity resulted in dose reduction or treatment delay and additional consultation (physician) if relevant. The grade of toxicity was confirmed right before chemotherapy was administrated.
Patient satisfaction was recorded by semi-structured interview and by using a 5-step Likert scale from 'very poor' to 'very satisfactory'.
The study recorded the number of minutes the patient spent at attendance for consultation at the clinic before the first series and of phone consultation before the second series of chemotherapy.
Results: A total of 24 patients completed the intervention. 23 were interviewed.
Safety: Grading of patients toxicity in telephone consultation was identical to the grading performed by nurse specialist colleagues. No patients required additional medical consultation. 9 patients had dose reduction due to toxicity.
Patients expressed relief to avoid transportation and stay in the outpatient facility.
21 patients responded 'very satisfactory' and 2 'satisfactory' to phone consultation as a method.
The patient's time spent on telephone consultation was significantly lower than attendance: median (range): 21.5 (9−45) vs. 180 (75–485) minutes. ($P = 0.001$). Patients avoided transportation (median 30 km (range 7–100 km) to the clinic), which reduced private costs.
Conclusion: The method can be considered feasible and safe. Patents expressed great satisfaction with telephone consultation. Especially due to the time saved to transport and shorter stay at the hospital. Further studies must be performed to establish whether the method can be used in other patient populations.
No conflict of interest.

Suffering in silence: A qualitative study on the repercussions of having an adult child with cancer on the life of older parents

L. Van Humbeeck[1], R. Piers[2], L. Dillen[3], M. Grypdonck[4], S. Verhaeghe[4], N. Van Den Noortgate[2]. *[1]Ghent University Hospital, Geriatrics, Ghent, Belgium; [2]Ghent University Hospital, Geriatric Medicine, Ghent, Belgium; [3]Ghent University Hospital, Oncology Centre, Ghent, Belgium; [4]Ghent University, Nursing Science, Ghent, Belgium*

Background: Increased life expectancy enhances the likelihood that older people face a cancer diagnosis in an adult child. Only a minimal amount of research has been directed towards this topic. We aimed to gain insight into the lived experience of the parenting position and role of these older parents of an adult child with cancer.
Material and Methods: Qualitative study using loosely structured interviews to elicit accounts of 20 parents ($\geqslant$70 years). Data were analyzed with support of NVivo 10 using the constant comparison technique, based on the principles of grounded theory.
Results: 'Suffering in silence' emerged as the core category encapsulating parents' experiences of shielding and unwillingly being shielded by their child. Shielding and being shielded contains two broad areas of mutual protection, information and emotion work, both reinforcing their suffering in silence. First, some parents had a feeling of being in the margin of events, as their adult child preferred to divulge information incrementally on a 'here and now' basis. Second, older parents experience a multitude of feelings and considerable distress, often tactfully contained in the presence of their sick child, in order not to stimulate the others' suffering. Older parents consciously suppressed thoughts related to an uncertain future and tried to keep up the façade of normalcy by keeping an optimistic view and displaying upbeat attitudes.
A balancing act of involvement was described between being involved without disturbing and keeping an appropriate distance. Older parents have taken gradual steps back from direct parental care with decreasing levels of parental involvement. Due to illness renegotiation of their position takes place and most parents resume their parental responsibilities by means of 'being there', in many forms and intensities along a continuum. The envisaged parenting is influenced by several factors i.e. their relationship history, their degree of care dependency and the marital status of the adult child. Parents were willing to provide support to their children and grandchildren to the extent permitted by their resources and the nature of their existing relationship with their adult child and partner.
Conclusions: Older parents' situations can be envisioned as facing a delicate balancing act on two areas (1) between shielding their child while being shielded by their child, and (2) between being involved while keeping an adequate distance. Faced with the adult child's illness and possible death, older parents are confronted with overwhelming feelings often underestimated by their close environment. Health care professionals can play a pivotal role in protecting the autonomy and privacy of adult children while practicing family-centered principles.
No conflict of interest.

1709 ORAL

Oncology nurses use of family assessment in the acute care setting

E. Coyne[1], E. Grafton[1], A. Reid[1], A. Marshall[1]. *[1]Griffith University, School of Nursing and Midwifery, Brisbane, Australia*

Background: Family assessment in the oncology setting is a crucial step in determining the appropriate family support and guidance required. Oncology nurses are the coordinators of patient and family support services and are relied upon to identify patient and family concerns. A cancer diagnosis has a physical and emotional impact on the patient, however during this time the family caregivers providing support are often at risk of physical, emotional and practical problems themselves. This study investigated the oncology nurses use of a framework for family assessment, exploring the nurse's experience and perception of family assessment.
Methods: An interpretive study was conducted to investigate oncology nurses' family assessment practices across cancer care inpatient and day-treatment areas of three metropolitan hospitals in South-east Queensland. In total 20 focus groups consisting of 50 oncology nurses were conducted to provide demographic and qualitative data. Using a constant comparative technique, analysis of the nurses' responses was used to identify themes which related to the process of family assessment.
Results: Themes around family assessment related to models of patient care, nurse's philosophy, ward culture and physical environment. Most oncology nurses considered family assessment as their role however family assessment was often conducted informally with no structured framework or documentation. The family assessment process varied according to experience of the oncology nurse with nurses who were less experienced relying on referral to a social worker if they considered the family required support. The participants highlighted that the use of a structured approach would improve their family assessment techniques, suggesting a set of questions to ask the patient and family might help the less experienced oncology nurse.
Conclusion: The informal process of family assessment provides some way of identifying the family's needs, however this was often conducted in an ad hoc manner. A simple framework such as the Calgary Model of Family Assessment may assist nurses in the promotion of appropriate family support.

Quality of life (QoL) assessment in patients with head and neck cancer (HNC): A pilot study comparing touch screen technology and paper questionnaires

C. Verschueren[1], P. Specenier[2], K. Broes[3], D. Van Gestel[4], D. Van den Weyngaert[4], P.H. Van de Heyning[3], J.B. Vermorken[2], M. Peeters[2], C. Van Laer[3], O.M. Vanderveken[3]. *[1]Antwerp University Hospital, Multidisciplinary Oncology Centre Antwerp (MOCA), Edegem, Belgium; [2]Antwerp University Hospital, Oncology, Edegem, Belgium; [3]Antwerp University Hospital, Otorhinolaryngology Head and Neck Surgery, Edegem, Belgium; [4]Antwerp University Hospital, Radiotherapy, Edegem, Belgium*

Background: Health care interventions must be judged not only by their impact on survival, but also on QoL. QoL in HNC patients is frequently impaired by disease and/or treatment which can have impact on general health but also on specific important functions i.e. swallowing and speech. Multiple standardized questionnaires exist for evaluation of general QoL (EQ5D [5L], FACT-G, EORTC QLQ-C30). FACT-H&N and EORTC QLQ-H&N35 are specific questionnaires for HNC patients while SWAL-QOL and Voice Handicap Index (VHI) are questionnaires for the specific evaluation of swallowing function and speech, respectively. Paper questionnaires are less attractive for the patient, difficult to collect, burdensome and costly in terms of data input.
The aim of this pilot trial was to evaluate whether the use of a touch screen technology was feasible in HNC patients visiting the MOCA head and neck outpatient clinic.
Material and Methods: The questionnaires were filled out by the patients either on paper or using a touch screen during the waiting time between registration at the outpatient desk and the visit. Selection of method was at random. For each patient, starting and finishing time were registered. Patients received a short introduction by a qualified nurse. Assistance by a relative was allowed.

Results: 10 evaluable HNC patients (7 male) filled out the paper questionnaires. Median age: 67 years (range: 57−82). 25 evaluable patients (19 male) filled in the touch screen version of all questionnaires. Median age: 67 years (range: 47−76). Median time required for filling in the paper and electronic version was 35 minutes (range: 20−57) and 28 minutes (range:13−53), respectively. Mean times were 38 and 28 minutes, respectively (unadjusted p: 0.016; p adjusted for age: 0.02).
Conclusion: The touch screen technology for the assessment of QoL measures using multiple validated questionnaires is feasible, even in an elderly population of HNC patients. It takes significantly less time to complete the electronic version as compared to the paper version. The calculated output of the questionnaires is immediately available in the electronic patient file and can be used by the physician during the consultation, allowing special attention to particular patient needs. Moreover, the results can be easily extracted for scientific purposes. Further comparisons and intra-patient validation of the 2 methods are planned. Screen shots will be presented at the meeting.
No conflict of interest.

1711 ORAL

Fatigue in informal caregivers of cancer patients during active treatment in the palliative phase

M.E.W.J. Peters[1], M.M. Goedendorp[2], C.A.H. Verhagen[1], G. Bleijenberg[2], W.T.A. Van der Graaf[1]. *[1]Radboud University Nijmegen Medical Centre, Department of Internal Medicine − Division of Medical Oncology, Nijmegen, Netherlands; [2]Radboud University Nijmegen Medical Centre, Expert Centre Chronic Fatigue, Nijmegen, Netherlands*

Background: Fatigue is the most frequently occuring symptom in patients (pts) with advanced, incurable cancer, with a profound effect on daily life. However, hardly anything is known about fatigue of informal caregivers (CG) of these pts and the impact fatigue might have on their experienced burden related to care provision. We investigated the presence of severe fatigue in CG, and studied the relation between fatigue severity of pts and CG, and whether fatigue changed over time. Additionally we wanted to know whether fatigue severity negatively affected the burden experienced by CG, indicated by more strain.
Material and Methods: Pts with advanced, incurable cancer, still on active treatment at the department of Medical Oncology of a University Hospital or a regional hospital in the Netherlands and their CG were asked to participate. Both groups filled in the Checklist Individual Strength (CIS) to measure fatigue severity twice, at T=0 and 6 months later (T1). A score of $\geqslant$35 at the subscale CIS-fatigue was indicative for severe fatigue. To measure the experienced burden CG also filled in the Caregivers Strain Index (CSI) at both time points. Descriptive analyses and regression analysis were performed.
Results: At T0 137 pts and 111 CG participated, at T1 89 pts and 78 CG did so. At T0 90% of CG (n = 100) were the partners of the pts. Of the CG at T0 24% (n = 27) was severely fatigued, at T1: 21% (n = 16). Within subjects we found significant correlations on fatigue severity at T0 and T1 (.645 for CG and. 543 in pts). We did not find a correlation on fatigue severity between pts and CG (at T0:. 057, at T1:. 172). Concerning the impact of fatigue we found that fatigue severity of CG and pts, at both time points significantly correlated with the CSI (in CG; at T0:0 .461 & at T1: 0.505 and in pts at T0; 0.334 & at T1: 0.297). At both time points, 30% of CSI could be explained by fatigue.
Conclusions: A fifth to a quarter of CG of pts with advanced cancer were severely fatigued somewhere during the active palliative treatment phase of the pts. We did not find a relation between fatigue severity of CG and pts. Fatigue severity of pts was related to CG's burden, as was the case with fatigue severity of CG. Fatigue and CG's burden remained relatively stable over time. Remarkably, fatigue severity only explained 30% of the CG's burden, which suggests other factors involved in CG's burden. This observation warrants further research which may finally help to address the needs of the CG.
No conflict of interest.

The AYA box: A patient centered instrument in communication with adolescents and young adults with cancer and their care giving parents

E. Decoene[1], N. Belpame[2], M. Quaghebeur[3], V. Van De Velde[4], L. Dillen[5], A. Raes[5], V. Cocquyt[6], S. Verhaeghe[7]. *[1]University Hospital Ghent, Oncology, Gent, Belgium; [2]University Hospital Ghent, Oncology, Ghent, Belgium; [3]University Hospital Ghent, Hematology, Ghent, Belgium; [4]University Hospital Ghent, Hemato-Oncology Pediatrics, Ghent, Belgium; [5]University Hospital Ghent, Psycho Oncology, Ghent, Belgium; [6]University Hospital Ghent, Oncology Center, Ghent, Belgium; [7]University Ghent, Nursing Science, Ghent, Belgium*

Background: There is a growing recognition that the perception of AYAs diagnosed with cancer is distinctive from that of children or adults. The main objective of this project is understanding how AYAs and their care giving parents experience cancer, diagnosis, hospitalisation, treatment and survivorship to develop a patient centered tool wich can be used by the multidisciplinary team.
Methods: A qualitative study was performed based on the principles of grounded theory. 24 semi-structured interviews were held with AYAs between 15 and 25 years of age. Additionally 21 care giving parents (19 mothers and 2 fathers) were interviewed. Sampling was based on situational diversity (e.g. gender, age, social context, education, time since diagnosis). The interviews were transcribed and coded (NVivo7) and constant comparison was used to analyse the data. Data collection and -analyses took place in a cyclic process.
Results: From the AYAs' perspective, cancer is something temporarily passing their life-path. Their coping strategies are focused on preserving identity and guarding normal life, not only during treatment, but also in follow-up and survivorship. Findings suggest that AYAs prefer care, tailored to their needs. The AYA box has been devoloped to meet these specific needs and to enhance the communication with the AYA. The box belongs to the AYA only and contains a booklet with revealing stories of AYAs' experiences, postcards, a unique AYA tag, useful stickers mention feelings or concern, cards with information or instructions, a brief symptom scale and smart aids in communication with their relatives and professional caregivers. The whole multidisciplinary team work with this instrument and can use it to talk about more difficult or emotional topics.
When confronted with the cancer of AYAs, the care giving parents face various fears and insecurities. In relation to each other findings demonstrate poor communication about emotions between the AYAs and the care giving parents. The box can provide a means to promote this communication.
Conclusions: This study revealed that cancer seems to have a different meaning for AYAs than for their care giving parents. The results are translated in a practical box, based on the experiences of the AYAs and can inspire caregivers to provide patient centered care in accordance to the specific preferences and wishes of the AYA.

Family life when a parent is diagnosed with cancer: Impact of a psychosocial intervention for young children

C. Semple[1], E. McCaughan[2]. *[1]The Ulster Hospital, Cancer Services, Belfast N. Ireland, United Kingdom; [2]University of Ulster, Institute of Nursing & Health Research, N. Ireland, United Kingdom*

Background: In the United Kingdom, 1 in 10 cancer patients are aged 25−50 years and the incidence rate of cancer for this younger patient group has steadily increased over the past three decades. When a parent is diagnosed with cancer it can have a profound impact on the family, especially the children. As a result the family unit can experience major changes in living patterns, roles and relationships and parental cancer has the potential to cause familial dysfunction and distress. The aim of the study was to explore the experience of families when a parent has cancer and evaluate the impact of a psychosocial intervention (CLIMB®) to support young children whose parent has cancer.
Material and Methods: Using a descriptive qualitative design, data was generated from separate focus groups with children (n = 7) and parents (n = 6). One-to-one interviews were conducted with professionals delivering the intervention (n = 2). Interviews were transcribed verbatim to facilitate analysis. Thematic analysis, by two researchers was carried out using methods formulated by Miles and Huberman (1994).
Results: Parental cancer is a challenging life event for the family. Parents clearly articulated the devastation and whirlwind of emotions after finding out they had cancer. They often felt ill-equipped and expressed a lack of confidence and skills as they considered communicating with their children about cancer. Parents were often the gatekeeper to how, when and the context in which children learn about parental cancer.

Children reported that prior to learning about their Mum or Dad having cancer they sensed that something was wrong at home. They had a number of fantasies and misconceptions, including concerns that cancer was contagious and believing they were responsible for their parent's cancer.
The psychological intervention (CLIMB®) normalised the children's experience of parental cancer through peer support. It also improved their understanding of cancer as they learned factual information and it equipped the children with coping strategies to help them deal with negative emotions surrounding parental cancer. Professionals perceived the intervention led to improved family communication. For parents, it provided them with reassurance that some of their child's emotional and informational needs were being met by professionals and provided a vehicle for greater open communication between the children and parents regarding the cancer diagnosis.
Conclusion: Open communication is pivotal for children whose parents have cancer but parents need supported and resourced to promote family coping when diagnosed with cancer.
No conflict of interest.

1714 ORAL

Comparison of the relationship between depressive symptom levels and self-concept in healthy children and children with cancer

N. Altay[1], E. Durualp[2]. *[1]Gazi University Health Sciences Faculty, Nursing Department, Ankara, Turkey; [2]Cankiri Karatekin University School of Health, Department of Child Development, Cankiri, Turkey*

Background: Children with cancer have to cope with the disease, frequent hospitalizations, intensive treatments and the numerous side effects of these treatments. These children may encounter physical, social and psychological problems. These issues may adversely affect children's self-perceptions. Oncological diseases can especially cause low self-perception, depressed mood, anger, despair, and feelings of inadequacy and insecurity in children.
Purpose: The aim of this study was to determine and compare the depressive symptom levels and self-concept in children with cancer and healthy children between 9 and 16 years of age.
Material and Methods: 66 children with cancer and 66 healthy children of the same age and gender were included in the sample. *The* 'Child Introduction Form', 'Children's Depression Inventory' (CDI) and 'Piers-Harris Children's Self-Concept Scale' (PHCSS) were used for data collection. The cut-off point of CDI is 19. The maximum score is 54. A high total score shows a high level of depressive symptoms. The possible scores of PHCSS range from 0 to 80. The scale contains six different dimensions of self-concept (happiness and satisfaction, anxiety, popularity and social appreciation − being the favorite, behavior compliance, physical appearance, intellectual and school status). A high score indicates the presence of a positive and a low score of a negative self-concept.The data were analyzed with the Kolmogorov-Smirnov test, Mann-Whitney U test and Pearson's correlation coefficient.
Results: The mean age of the children with cancer and healthy children was 13.14±2.9 with 53% males. Acute lymphoblastic leukemia (ALL) was present in 31.8% of the children with cancer. A significant difference was found between the self-concept of children with cancer and healthy children ($U=1731.5, p < 0.05$). No significant difference was found between the depressive symptom levels of children with cancer and healthy children ($U=2124$, $p > 0.05$). A moderate, negative and significant relationship was found between the depressive symptom levels and self-concept of children with cancer and healthy children and the depressive symptom levels decreased when the self-concept increased($p < 0.05$).
Conclusions: Our study determined depressive symptoms to increase in children when their self-concept decreased, similar to other studies. We believe that providing psychological assistance according to results of studies on depressive symptom levels and self-concept will have a positive effect on the treatment of children and adolescents with cancer.

Patients with a high-grade glioma and their family caregivers: A qualitative research of their lived experience and needs related to professional care

W. Sterckx[1], A. Coolbrandt[1], S. Borgenon[1], A. Mees[1], M. Decruyenaere[1], P. Clement[1], B. Dierckx de Casterlé[2]. *[1]University Hospitals Leuven, Oncology, Leuven, Belgium; [2]Catholic University Leuven, Leuven, Belgium*

Background: With poor prognosis and disabling symptomatology, diagnosis of a high-grade glioma affects the patient and his family caregivers. Quality care to both parties requires a better understanding of their experience and needs.
Purpose: The aim of this qualitative research is to improve our insight into the experiences and needs related to professional care of patients with a high-grade glioma and of their family caregivers.
Method: The data of this qualitative study, using a Grounded Theory approach, were collected through semi-structured, individual interviews. Data analysis was performed by 3 researchers looking for predominant themes in both the patients' and the caregivers' stories.
Results: Seventeen patients and sixteen caregivers were interviewed. The patients' experience is marked by many losses, and caregivers find it difficult to see their beloved one lose independence and functional capabilities. As a response to these losses, family caregivers perceive a fast growing set of caring tasks, in which they engage almost without limits but to which they feel unprepared and sometimes insecure. Perceived lack of professional support and difficulties in considering or accepting help, add to their feeling to become solely and completely responsible. Patients themselves on the other hand feel as if they are sidelined, not only because of physical or cognitive loss of function, but also because of caregivers taking charge at the expense of the patient's freedom, simply out of worry. At the same time they manage to keep hope, of getting good results, of keeping some abilities.
Patients and caregivers both express the need for information and for willingness to listen. Caregivers underscore the accessibility, availability and expertise of professional caregivers. They also need to feel that professionals are aware of the seriousness of the diagnosis and that they take this into account in their approach of both patient and family caregiver.
Conclusion: Loss and responsibility mark the experiences of patients and family caregivers respectively. The results of this qualitative research enable professionals to provide care from a better understanding of patients' and caregivers' difficulties, strengths and needs.
No conflict of interest.

Implementing the use of survivorship care plans: Understanding the barriers

M.I. Fitch[1], H. Bradley[2], G. Eaton[3], J. Giese-Davis[4], J. Taylor-Brown[5]. *[1]Canadian Partnership Against Cancer, Cancer Journey Action Group, Toronto, Canada; [2]Wellspring, Ontario, Toronto, Canada; [3]Young Adult Cancer Canada, Newfoundland and Labrador, St. John's, Canada; [4]Alberta Health Services, Alberta, Calgary, Canada; [5]CancerCare Manitoba, Manitoba, Winnipeg, Canada*

Background: The number of individuals who are living after a diagnosis of cancer is growing steadily. Unfortunately, cancer survivorship does not come without cost. It is increasingly evident that there are late and long-term effects that cancer survivors experience. These physical and psychosocial effects can compromise quality of life and increase the burden of suffering. The Institute of Medicine has recommended that patients who are finishing their treatment receive a survivorship care plan to assist in their coping with the after effect of treatment and moving on with their lives. To date, few cancer programs utilize survivorship care plans in Canada.
Objectives: The purpose of this work was to create and implement a sustainable survivorship care plan approach. The objective was to learn about the barriers to implementing survivorship care plans in our Canadian health care environment.
Methods: Four jurisdictions were selected through a competitive process to mount survivorship care plan projects. The jurisdictions were selected in part to reflect a broad range of settings for the delivery of care plans and included a community-based agency, a cancer centre, a cancer-centre/community-based consortium (urban/rural), and a national volunteer based organization (on-line). Each designed a unique approach for using a survivorship care plan based on the template draft provided in the call for proposals. Evaluations included patient and staff satisfaction as well as program utilization.
Results: The project illustrated that use of survivorship care plans in Canada was feasible. Survivors reported that the plans helped them in understanding the next steps in their cancer journey. Each jurisdiction reported the following elements were important factors for successful implementation of survivorship care plans: leadership, teamwork and collaboration, tailoring the care plan, education and training, communication and dissemination, and conceptualization of survivorship. Barriers identified included infrastructure support (information technology in particular), process for developing the actual care plan, access to services, and engaging in robust evaluation.

Conclusions: In all cases, the projects served to streamline the transition from treatment to survivorship, and to significantly increase the capacities of patients and health care providers to address this gap in care provision. It is possible that the community, cancer centre, and on-line modalities could all work as complementary systems to bridge the gap for cancer survivors, offering care plan services at a variety of times and places to suit the range of patients' needs along the survivorship trajectory.

Capturing in real time the support needs and the self-management behaviours for prostate cancer survivors: Application of an electronic behavioural diary

C. Paterson[1]. [1]*University of Dundee, Dundee, United Kingdom*

Background: Prostate cancer and its treatments can cause profound physical (urinary, bowel and sexual dysfunction) and psychological sequelae. Men are keen to engage as active partners in the management of their condition, but unmet support needs are prevalent which can make self-management difficult. The aim of this Ph.D. study was to monitor mens' symptoms, support needs, coping efforts and self-management experiences over time as an important step towards the development of a supportive self-management intervention at address areas of unmet need.
Materials and Methods: This study had two phases: phase one was a prospective longitudinal survey (N = 74), and phase two captured real time patient reported outcome measures in the form of an electronic behavioural diary. A sub-sample from the prospective, longitudinal survey (n = 12) completed the electronic behavioural diary in the weeks following treatment. A Research Steering Group (men with prostate cancer and clinicians) informed the development of the electronic behavioural diary. Data collection was managed using the Dell X51 and Pocket Interview Software. Self-reports were collected for 31 days prompted by an audio alarm 3 times per day (a total of 93 data entries) for each of the 12 case studies. Electronic diary data were analysed in SPSS v.17.0 using time series analysis.
Results: The majority of diary completion rates were >90%. Results demonstrated that men used a variety of self-management behaviours to improve their urinary, bowel and sexual dysfunction, but often, with little relief. A common theme across the case studies was that men very frequently experienced symptoms for which they did not perform any self-management. Men reported dissatisfaction with their support over time with particular reference to: informational, practical, emotional and financial support. The most frequent source of self-management suggestions came from mens' partners, and prostate cancer specialist nurses were infrequently reported to provide self-management advice.
Conclusion: This innovative study has demonstrated the acceptability of e-health technology in prostate cancer survivors and may provide a platform to deliver a supported self-management intervention in the future. Real time data collection by means of an electronic behavioural diary, is patient-centred, and enabled men to share their experiences without having to verbalise their concerns aloud.

Czech nurses' knowledge, attitudes and behaviors towards tobacco dependence and treatment

L. Sarna[1], S. Bialous[2], E. Kralikova[3], A. Kmetova[3], V. Falbrova[4], S. Kulovana[4], K. Mala[5], E. Roubickova[6], M. Wells[1], J. Brook[7]. [1]*University of California Los Angeles, School of Nursing, Los Angeles, USA;* [2]*Tobacco Policy International, San Francisco, USA;* [3]*Charles University and the General Hospital, Centre of Tobacco Dependence of the 3rd Medical Department, Prague, Czech Republic;* [4]*General University Hospital, Centre of Tobacco Dependence of the 3rd Medical Department, Prague, Czech Republic;* [5]*Central Military Hospital, Prague, Czech Republic;* [6]*Faculty Hospital Karlovske Vinohrady, Clinic of Radiotherapy & Oncology, Prague, Czech Republic;* [7]*University of California Los Angeles, David Geffen School of Medicine, Los Angeles, USA*

Background: Tobacco use is the top preventable cause of cancer in the Czech Republic and in Europe. Tobacco dependence treatment is a cost-effective strategy to prevent morbidity and mortality. Nurses, the largest group of health professionals, can play a pivotal role in implementing this intervention in clinical practice. The purpose of this report is to describe information about the frequency and correlates of Czech nurses' delivery of intervention in tobacco dependence treatment prior to an educational intervention.
Material and Methods: A train-the trainer program to provide evidence-based tobacco dependence treatment and the nurses' role was developed by tobacco control experts in the US and the Czech Republic, in collaboration with the International Society of Nurses in Cancer Care (ISNCC). The program was delivered by Czech nurses in Czech at the 2012 ISNCC congress to 22 nurses. Subsequently, 10 workshops delivered by the trainees were held throughout the country. Prior to each workshop, participants were asked to complete a survey that included questions about demographics, clinical practice, attitudes about tobacco control, and frequency of delivery of tobacco dependence treatment.
Results: 157 nurses completed the survey. While 63% of nurses 'always/usually' asked patients' about their smoking status, 46% provided advice to quit, 26% assisted in developing a cessation plan, and only 11% always arranged for follow up and referred smokers to the telephone quitline. Few, 22%, reported that nurses could play an important role in helping patients quit; 63% rated their ability to help patients quit as 'fair/poor'. Approximately 30% of nurses were current smokers. Smokers were less likely to 'always/usually' assess ($p = 0.02$), arrange ($p = 0.02$), or recommend a smoke-free environment ($p = 0.002$). The average age of nurses who 'always/usually' arranged or referred was significantly higher as compared to those nurses who did not ($p < 0.01$).
Conclusions: These data indicate that few nurses in the Czech Republic consistently intervene with smokers. The majority underestimated their power to provide effective smoking cessation interventions and assessed that they needed additional training. Although they have potential to significantly contribute to decrease the burden of tobacco-related diseases, they underestimate the importance of their role. Capacity building programs in tobacco control for nurses are critical.

Evaluation of the use of information sources among breast cancer patients during radiotherapy period

M. Siekkinen[1], A. Ryhänen[2], T. Vahlberg[3], S. Pyrhönen[4], H. Leino-Kilpi[1]. [1]*University of Turku, Nursing Science, Turku, Finland;* [2]*City of Turku, Wellfare, Turku, Finland;* [3]*University of Turku, Biostatistics, Turku, Finland;* [4]*Turku University Hospital, Cancer Clinic, Turku, Finland*

Background: The importance of the knowledge of radiotherapy (RT) among breast cancer patients is observed. There is an assumption that patients' sense of empowerment is supported by knowledge. Though professionals cannot empower the patient, they can support the patients to get knowledge to be empowered. There is much evidence describing patients' use of information sources and their preferences for information. Yet little is known about whether breast cancer patients with different preferences for information vary in use of information sources during their radiotherapy (RT) period. Therefore, the aim of this study was to evaluate whether high preferences for information leads to higher amount of information sources.
Material and Methods: Breast cancer patients (n = 128) were followed during RT period. Preferences for information (KHOS-I) pre RT period and information sources during RT period were evaluated. For the associations between use of information sources and preferences for information the statistical analyses were used.
Results: In total, mostly used information source was written patient education material (83 % +/−0) and secondly, patients contacted the personnel of RT department (76 % +/−1). Thirdly, was ranked other professionals on hospital (72 % +/−0.5) and near next were relatives and significant others (70 % +/−2). Internet was a source of information for two of third (65 % +/−0) of the patients, for half (50 % +/−1) public sources like library, television and radio and for third (31 % +/− 2) the local patient associations. Patients with higher preferences for information had significantly higher information seeking on public sources like library, television and radio ($p = 0.0061$) and the personnel of RT department ($p = 0.0359$).
Conclusions: Understanding differences in use of information sources among breast cancer patients during RT period may reflect more effective patient education development for future cancer care.
No conflict of interest.

Exploring patient experiences of neo-adjuvant chemotherapy for breast cancer

K. Beaver[1], S. Williamson[1], J. Briggs[2]. [1]*University of Central Lancashire, School of Health, Preston, United Kingdom;* [2]*Blackpool Teaching Hospitals NHS Foundation Trust, Psychological Services, Blackpool, United Kingdom*

Background: Neo-adjuvant chemotherapy is recommended for locally advanced and inflammatory breast cancers to reduce tumour size (enabling surgery) and assess response to therapy. The advantages for women with *operable* breast cancer are not clearly defined although trials indicate no survival differences between women treated with chemotherapy pre

or post-surgery. Communicating evidence based information to patients is complex and studies examining the patient experience of neo-adjuvant chemotherapy are lacking. In this exploratory study we aimed to examine patient experiences to identify if this patient group had particular information needs and concerns and were receiving the support they needed.
Methods: A qualitative approach was taken using in-depth individual interviews with women (n = 21) who had completed neo-adjuvant chemotherapy for breast cancer, referred from four different hospitals across the North West of England. Interview data were analysed using thematic analysis.
Results: The sample included a relatively young group of women (mean age 49 years), many of whom had young children and/or were caring for elderly parents. The main themes that emerged from the data included: coping with the rapid transition from 'well' to 'ill', challenges of processing complex information, perceived lack of emotional support, needing empathy, impact on family, regaining control, and creating a new 'normal'. This group of women had specific information and support needs related to key time points in the treatment trajectory. In particular, support was needed towards the end of chemotherapy, when side effects were at their most toxic, and when decisions about forthcoming surgery were being made. Information provision and support from health care professionals was reported as variable. While some patients reported adequate support, most reported feeling left alone to cope with debilitating side effects (that often warranted hospital admission) and complex emotional problems. A number of women had been referred to psychological services but this was usually when a crisis point had been reached.
Conclusion: The women in this study were able to identify key timepoints when information and support would have been beneficial. This information is vital in developing services and interventions that will meet the complex needs of these patients and potentially prevent hospital admissions and late referral to psychological services.
No conflict of interest.

Unmet supportive care needs and resilience in cancer patients under early treatment: A descriptive study

M. Eicher[1], J. De Maria[2], C. Dubey[2], C. Hoeppli[3], D. Betticher[3]. *[1]University of Applied Sciences Health, Haute Ecole de Santé Fribourg, Freiburg i. UE., Switzerland; [2]Institute Universitaire de Formation et de Recherche en Soins, Faculté de Biologie et de Médecine Université de Lausanne, Lausanne, Switzerland; [3]Service d'Oncologie, Hopital Fribougeois − Hopital Cantonal, Fribourg, Switzerland*

Background: Patient engagement in healthcare via self-management is recognized as crucial to improve outcomes for cancer patients. Current supportive care still results in high degree of unmet needs and urges for new approaches. The concept of resilience is gaining increasing importance as a key component for self-management support in cancer care but to date has rarely been addressed in studies in adult cancer patients. We explored the potential relationship between resilience and unmet needs in cancer patients under early ambulatory treatment.
Materials and Methods: We conducted a descriptive study. Adult patients with solid tumors, having been diagnosed 4−14 weeks ago with new or recurrent disease and under treatment in ambulatory services at a Swiss cantonal hospital were recruited for the study. They were provided with validated French and German paper and pencil version of the Connor-Davidson-Resilience Scale with 25 items (CD-RISC) and the Supportive Care Needs Survey 34 item (SCNS SF 34) version. Cantonal ethics committee approved the study. Descriptive and correlational statistics were applied.
Results: 30 female and 38 male cancer patients with a mean age of 63.12 (sd 11.3) and of which 20 (29%) had a recurrent disease were included in the study. The highest level of unmet needs, as measured by the SCNS SF 34 (range 0–100), were observed in the psychological (md = 30; IQR = 10), health system and information (md = 27.27; IQR = 14) and physical domains (md = 25; IQR = 17). Resilience scores, measured CD-RISC 25 were significantly lower compared to general population (m = 74.35 SD = 12.612 vs. m = 80.4 SD = 12.80; p = 0.0002). A multiple regression analysis showed resilience decreased with age (−0.295; CI −0.546, 0.43, p = 0.022) and was substantially higher in patients with a recurrent disease (+7.985, CI 1.72, = 14.07, p = 0.013). Low resilience scores were significantly and strongly associated with higher levels of unmet psychological needs (Rho = −0.68, p < 0.001), supportive care needs (Rho = −0.49, p < 0.001) and information needs (Rho = −0.42, p = 0.001), as well as marginally with higher physical needs (Rho = −0.31, p = 0.010).
Conclusion: Our results suggest that patients with higher resilience express lower unmet needs. A longitudinal design would allow the clarification of causal patterns between resilience and supportive care needs. This could be a starting point for developing interventions to enhance resilience and thereby improve patient engagement via self-management.
No conflict of interest.

Patients with cancer fall too: What the evidence tells us about assessing and preventing falls in patients with cancer

C. Brown[1]. *[1]Memorial Sloan Kettering Cancer Center, Nursing, New York, USA*

Background: Falls with injury are common in patients with advanced cancer. It is estimated that approximately 50% of patients with advanced cancer will experience a fall with a high risk of physical injury every year. Moreover, patients with cancer are at a higher risk of falls than patients treated in other acute or settings. Often falls include injuries such as soft tissue, fractures (hip, facial), cranial bleeds, and other detrimental injuries. Falls can result in decreased quality of life, tremendous cost to the health care system, and unfortunately on some occasions, death of the patient. Researchers have estimated that a patient experiencing a fall can cost approximately $13,000 in operating costs and extend a patients hospital stay by over 6 days. Fortunately, there are research studies which suggest effective ways to assess fall risk and provide evidence based interventions which may prevent patients from falling more often.
Material and Methods: This presentation will accomplish the purpose by presenting the current literature in the areas of assessment and intervention in patient falls. Participants will be able to 1) Summarize important variables to assessing patients at risk for falls, 2) Identify falls assessment tools with established validity and reliability and 3) Interpret evidence based patient centered interventions which may prevent patients from falling. This presentation will have two focuses: 1) On the demographic and other factors such as ambulation issues, medications, and prior falls history that should be included in assessment of falls along with an overview of the major falls assessment tools and their respective strengths and limitations 2) On the nurse sensitive patient outcome interventions based in research that may be effective in preventing or lessening patient falls.
Results: The clinical practice outcomes from this evidence based-practice presentation are tremendously important for oncology nurses because of the risk that our patients with cancer face on a daily basis.
Conclusions: Given that patient falls are so significant to those with cancer this presentation will be one of the few which focuses on both the assessment tools and evidenced based interventions which might keep patients with cancer more safe from falls with injury. Participants will be able to translate information from this presentation into their individual practices, creating a safer environment for their patients with cancer.

Experiences of the older person with cancer: A qualitative study of two ward settings

A. Lannie[1], R. Barbour[2], J. Corlett[3]. *[1]University of Dundee, School of Nursing and Midwifery, Fife, United Kingdom; [2]Open University, Social and Health Care, Milton Keynes, United Kingdom; [3]University of Dundee, School of Nursing and Midwifery, Dundee, United Kingdom*

Background: This paper reports on the final stage of a qualitative study that seeks to compare patient and health care professionals' perspectives and experiences of cancer care for the older person. This study seeks to illuminate the experiences of both patients and health care professionals in two hospital wards (a specialist cancer ward and a general medical ward in a general hospital) selected to allow comparisons to be made in terms of the potentially different emphasis given, depending on whether the focus is on cancer treatment or care of the older person.
Material and Methods: The research design, employing focus groups, dissemination focus groups and semi-structured interviews, centres around comparison of a medical and a specialist ward in one hospital − exploring the challenges involved, depending on whether the focus is on the older person or the disease (cancer patient). It also highlights the tensions that may arise − both for patients and professional carers, as they negotiate the potentially contradictory demands of the 'social' and the 'clinical', the 'system' and the patients' life worlds.
Results: Findings were organized around the following themes: 'the ward as a half way house', 'etiquette', 'emotion work' and 'hope'. Dissemination focus group sessions served as dual purpose: to inform participants and to generate further data to establish whether these findings have relevance for them.
Importantly this allowed for the original sample to be augmented (by including new categories of staff and individuals with a remit to work across both wards, who were not involved in the first set of focus groups and interviews).

Integrating analysis of original study transcripts and data generated in dissemination sessions also allows for further interrogation of theoretical frameworks that seek to elaborate the intersection of the older person with cancer.
Conclusion: This study shows the complex and potentially conflicting perspectives of this heterogeneous group of patients and their professional carers, as they respond to the challenges raised by the conjunction of cancer and old age. The implications for health care delivery and professional training for gero-oncology will be considered.
No conflict of interest.

Return to work following cancer: perspectives of survivors, employers, and insurance agencies

M.I. Fitch[1]. [1]*Canadian Partnership Against Cancer, Cancer Journey Action Group, Toronto, Canada*

Background: The number of individuals who are living after a diagnosis of cancer is growing steadily. Unfortunately, cancer survivorship does not come without cost. It is increasingly evident that there are late and long-term effects that cancer survivors experience. These physical and psychosocial effects can compromise quality of life and increase the burden of suffering. In particular, survivors can experience challenges in returning to work after their treatment.
Objective: The purpose of this work is to explore the perspectives of cancer survivors (employees), employers, and insuring agencies about the challenges of returning to work after cancer treatment.
Methods: An environmental scan was undertaken to identify existing programs and resources to assist survivors in their return to work. A literature review and on-line survey were undertaken to document the perspectives of cancer survivors and their family caregivers about the challenges in returning to work after cancer treatment. Focus groups were held with employers, human resource representatives, and insuring agencies to gather their perspectives about employees returning to work after cancer.
Results: 8,385 websites were scanned for relevant materials and 90 were identified with resources to support patients as they return to work following cancer or other chronic illness episodes. Most programs were developed in the last decade. There are a broad range of program delivery modalities making it difficult to identify best practices. Patients (N = 410) described reduction in income, a range of positive and negative experiences in returning to work, and work-related issues dealing with side-effects (fatigue and loss of energy, cognitive changes). Caregivers (N = 60) described their own work-related challenges including reduction in income, loss of concentration and productivity, stress and lack of support from colleagues. Employers, human resource experts, and insuring agency representatives acknowledged the issues related to return to work. They reported that there are very few employees at any one point in time who are returning to work after cancer and this makes it challenging for managers to know how best to support these individuals.
Conclusion: With the increasing number of cancer survivors, return to work is a growing concern. Individuals clearly experience challenges in making this transition. There is a need for resources to be developed to help survivors, health care professionals, and employing agencies become more aware of the challenges survivors experience and be able to deal more effectively with the situation.
No conflict of interest.

Joint Aches Cohort Study (JACS): The impact of joint pain in women on adjuvant therapy for primary breast cancer

D. Fenlon[1], D. Cranfield[1], C. Powers[1], A. Recio-Sauceda[1]. [1]*University of Southampton, Faculty of Health Sciences, Southampton − Hants, United Kingdom*

Background: Joint pains and stiffness have been clearly demonstrated to be a problem for women following treatment for primary breast cancer, and appear to be associated with both hormone therapies, particularly aromatase inhibitors, and chemotherapy (particularly taxanes)(Fenlon et al 2013). However, there is less work available on the impact that this has on women's lives. This study set out to provide detailed information on the extent of the problem in the first year following cancer diagnosis.
Methods: A cohort of 578 women was recruited from hospitals across South England and Wales. Women were asked to complete questionnaires at baseline, three, six, nine, and twelve months. Alongside several validated survey measures, women were invited to write free text on whether they had new joint pain since their breast cancer treatment and the impact of this pain on their lives. The free text comments of a subset of 233 of these from one hospital were analysed using content analysis. The coding process allowed the initial codes to emerge from the data, and these were verified by a second researcher. Emerging themes showed clear parallels to the Brief Pain Inventory (BPI), and hence, subsequent coding used the BPI as a framework, as well as new themes emerging from the data.
Results: Early results suggest that all aspects of quality of life, including mobility, mood, ability to work, enjoyment of life and sleep, are affected by joint pain associated with adjuvant treatment for breast cancer. Additionally, it is clear that further factors like patients' perception of their pain and attitude to it, their ability to manage their own pain, and the ability to manage change and a changing identity, also influences how the patient experiences their quality of life as a survivor of cancer. Full data will be presented at the conference presentation.
Conclusions: Our initial results suggest that joint pain associated with adjuvant treatment can have a profound impact on the lives of women following breast cancer. This may lead to decreased drug compliance or cessation of treatment, despite the known life-lengthening benefits of adjuvant treatment.
No conflict of interest.

1726 ORAL

Support group for lung cancer patients

R. Navon[1], N. Yair[2]. [1]*Sheba Medical Center, Ramat Gan, Israel;* [2]*Sheba Medical Center, Oncology, Ramat Gan, Israel*

Background: Early palliative care among patients with metastatic lung cancer can lead to improvements in both quality of life and mood. Support group for oncology patients provide a place to share common concerns and emotional support, teach coping skills and provide important information. In Israel, there is approximately 1600 newly diagnosed lung cancer patients every year, 370 of them were treated at Sheba Medical Center during 2012. Through 2011–2012 3 time-limited support groups were established for lung cancer patients.
Material and Methods: 34 patients participated in 3 different support groups. One group included stage I+II lung cancer patients and the other two groups included stage III+ IV. Each group met for 2.5 hours session every 2 weeks for 10 sessions. Former to each meeting participants could practice Yoga exercise for 45 minutes with yoga trainer. Topics addressed in the groups were those of concern to the participants and included informational topics such as social rights, medical information of treatment, side effects and symptom management, psychology aspects of disease, intimacy and emotional caregivers support. All groups were led by oncology nurse coordinator from the lung cancer unit, onco- psychologist and a physician who recovered from lung cancer. After each meeting participants were asked to fill in satisfaction questioner.
Results: Participants of all groups claimed that being part of the group made it easier for them to deal with their emotional, medical and social problems concerning their illness. Patients with stage I+II lung cancer showed higher attendance and claimed to be more satisfied from the meetings compering stage III+IV patients. Participants also pointed that yoga exercise helped them to reduce stress. Topics for future improvement pointed by participant were that session being held at the hospital setting.
Conclusions: Support groups for cancer patients are necessary for dealing with their life threatening disease. It is important for nurses to lead such groups and be involved in educating patients and support them at this critical time. Support group for cancer patients provides a place to share common concerns and learn coping skills at a non-judgmental environment and should be an integrative part of the oncology nurse responsibility.
No conflict of interest.

Guilt and shame in end of life care − the next of kin's perspective

C. Werkander Harstäde[1], B. Andershed[2], D. Brunt[1], A. Roxberg[1]. [1]*Linnaeus University, Faculty of Health and Life Sciences, Växjö, Sweden;* [2]*Ersta Sköndal University College, Palliative Care Center, Stockholm, Sweden*

Background: Being next of kin to someone in the final phase of life can be complicated. There can be a will to support the dying person and to make the time for him/her as comfortable as possible. To choose how to be involved can make the situation easier but there is also a responsibility to make a good choice. Choices can create anxiety and feelings of guilt and shame can occur if perceived obligations are not fulfilled. The aim of

the studies have been to explore and describe next of kin's feelings of guilt and shame in end of life care.
Material and Methods: Hermeneutic, and secondary analysis of qualitative interviews. Semantic concept analysis of the concepts guilt and shame.
Result: The result shows categories where guilt is felt: such as not having done/talked enough, being absent at important events, making errors in judgement. Categories where shame is felt: such as feelings of inferiority, being ashamed on behalf of the dying person, family conflicts becoming apparent.
Conclusion: It is important that health professionals are perceptive to next of kin's experiences of guilt and shame in end of life care. To have knowledge about these experiences and to be able to perceive these experiences can be seen as tools that help health professionals to be better able to encounter the next of kin. Identifying next of kin's experiences of guilt and/or shame might also contribute to facilitating a bereavement process, which in turn could be beneficial to public welfare and reduce sick-leave. The findings also have a potential to help next of kin see that experiences of guilt and/or shame are normal and understandable reactions when spending time with and taking care of a loved one in end of life care. It is of uttermost importance to improve end of life care as a whole.
No conflict of interest.

1728 ORAL

Why do they still hope? A qualitative study to explore how caregivers interpret hopefulness in palliative patients

C.A. Nierop-van Baalen[1], M.H.F. Grypdonck[2]. [1]*Diaconessenhuis, Oncology, Leiden, Netherlands;* [2]*Ghent University, Nursing Science, Ghent, Belgium*

Background: Studies on experiences of advanced cancer patients shows that patients do not lose hope, even not hope for a cure and that this hope has positive effects on their mood and quality of life. In the American oncology literature hope is seen as a positive power. Caregivers are taught to encourage the hope. The Dutch oncology literature, however, describes hope rather as a problem about which doctors should do something.
The aim of this study was to explore the opinions of professionals about how to deal with hope in palliative patients.
Methods: Three focus group discussions (a multidisciplinary group, a nursing group and a group with community nurses) of six to ten caregivers were held. Data collection and data analysis took place in a cyclical process. All focus group discussions were recorded and transcribed verbatim. Data analysis used constant comparison between and within interview transcript of the coded material. Researcher triangulation was enhanced validity and reliability.
Results: *Telling the truth* is the central theme. It is seen as countering 'false hope' by information. False hope is hope that is stronger than the medical facts allow. False hope is seen as an impediment to proper dying. False hope is considered an information problem (the patient has not understood the doctor's message), informing the patient (again) as the obvious intervention. Hope is sometimes confused with denial. In their opinion, hope should evolve from hope for cure or longer life to hope for a good death. Situations that do not match this deal are experienced as difficult. This is for instance the case when the patient and his/her relative(s) feel different about whether or not to continue the treatment.
Conclusions: To oncology professionals, hope that does not match the medical facts is seen as a problem in need of remediation. The participants feel they need to make the patient (and his/her family members) see that death is unavoidable and they attribute hope to a lack of understanding of one's situation. This interpretation of the place of hope in terminal palliative care is at odds with the reports of patients about hope and with the findings of North American studies about interventions fostering hope.

The impact of a rehabilitation programme for cancer patients − a story of patients looking back and ahead

E. Decoene[1], I. De Ruysscher[1], I. Jacobs[1], S. Cornelis[1], A. Van Hecke[2]. [1]*University Hospital Ghent, Oncology, Ghent, Belgium;* [2]*University Ghent, Nursing Science, Ghent, Belgium*

Background: Cancer related fatigue, fear of cancer recurrence, long term side effects, changed inter-personal relationships are often major themes in the follow up period after the treatment of cancer. Rehabilitation programmes can help cancer survivors to cope with these problems. It is unclear how patients experience the period after a rehabilitation programme and to which extent they incorporate the lifestyle instructions in their daily lives.
Method: A qualitative study was performed to explore the experiences of breast cancer survivors after following a three month rehabilitation programme and to explore reasons for (non-) adherence to relevant lifestyle instructions for breast cancer survivors. Fifteen breast cancer survivors, treated in a university hospital, were interviewed. A phenomenological approach was used. The interviews were transcribed and coded (NVivo 7) and constant comparison was used to analyse the data.
Results: After ending the programme, patients are confronted with mixed feelings. Patients still experience a lot of symptoms affecting their quality of life (fatigue, cognitive dysfunction, side effects of the endocrine therapy, fear, sleep disturbance). Patients also experience a second 'black period' in which they feel alone and in which the supportive group has often partially disappeared. However, the rehabilitation programme still means a lot for the patient. The programme helps them to get grip on their life, to live in a better (healthier) way to cope with their fears and to handle their daily problems. They are so focussed to survive the cancer. The provided lifestyle instructions enhance being in control of the symptoms that patients experience. For patients it is difficult to adhere to the lifestyle instructions when they have started working again and when social support is scarce.
Conclusion: After a rehabilitation programme, the breast cancer patients experience the rehabilitation programme still as meaningful. They have learned many skills coping with their problems after the cancer treatment. However, they are still searching for answers. Follow up sessions are recommended and a clear survivorship care plan can help to prevent these experienced loneliness.

Supportive self-care strategies during chemotherapy treatment: A longitudinal qualitative exploration of the experiences of patients with breast or colorectal cancer

L. McCann[1], R. Maguire[1], J. Cowie[1], J. Connaghan[1], C. Paterson[1], J. Hughes[1], D. Di Domenico[1], N. Kearney[1]. [1]*University of Dundee, School of Nursing and Midwifery, Dundee, United Kingdom*

Background: The Advanced Symptom Management System (ASyMS) is a mobile phone based system to remotely monitor and manage the toxicities of cancer treatment in the home care setting. ASyMS is being evaluated in a three-phase, multi-site complex intervention study, with a before and after study design. The study is exploring the impact of ASyMS on care delivered to people with breast/colorectal cancer receiving adjuvant chemotherapy. The shift of chemotherapy administration into the ambulatory setting requires patients to engage in self-care activities to prevent or reduce the severity of numerous and possible complex side effects. Phase I of the study is now complete. This paper will present the experiences of patients interviewed longitudinally throughout Phase I in relation to the supportive self-care behaviours and strategies they engaged in during their chemotherapy treatment.
Material and Methods: A total of 141 patients were recruited to Phase I. Of these 141 patients, 23 individuals from across all eight study sites participated in up to seven longitudinal semi-structured interviews each over the course of their entire chemotherapy treatment. The symptom experiences of patients, the role of supportive self-care behaviours and self-care strategies to manage these symptoms, and patients' experiences and perceptions of their care pathways, were explored longitudinally in all patient interviews.
Results: Patients discussed the importance of self-care in the context of their chemotherapy-related symptom experiences. Patients' indicated that adopted self-care behaviours and strategies tended to be triadic in nature: information was provided by health care professional staff, independently sourced from alternative sources, or informed by previous experiential knowledge. For many patients, there were notable changes in the extent to which adopted self-care strategies were embedded in their day-to-day and cycle-by-cycle symptom experiences over the course of their chemotherapy treatment. Often patients elected to self-manage their symptoms at home, rather than report them to health care professional staff.
Conclusions: The findings indicate that patients commonly adopt supportive self-care strategies to manage their chemotherapy-related symptoms whilst at home. As patients' chemotherapy treatment progressed, experiential self-care knowledge was equally important in the management of these symptoms as advice from health care professionals.

Effects of an exercise intervention in early palliative phase for advanced lung cancer patients

M. Quist[1]. [1]*Rigshospitalet, The University Hospital's Centre for Nursing and C, Copenhagen, Denmark*

Background: Lung cancer is the leading cause of cancer-related death worldwide. The majority of lung cancer patients present with advanced,

incurable disease resulting in a median survival of only 9−12 months. In this context, the aim of anti-cancer treatment is to improve or maintain quality of life (QOL), anxiety and depression in addition to prolonging survival. The benefits of physical exercise for cancer patients are described in a series of studies, most of which included patients with breast cancer and haematological neoplasias. Few studies have examined exercise interventions on advanced lung cancer patients although other studies (Jones et al 2011 and Kasymjanova et al 2009) have found a correlation between an increased aerobic capacity (VO_{2peak}), functional capacity and increased survival. Based on these results this study seeks to examine the effect the effect of a 6-week exercise intervention for advanced lung cancer patients.
Material and Methods: Patients with inoperable NSCLC (IIIb-IV) and SCLC (ED) were screened for eligibility. Aerobic capacity (VO_{2peak}), muscle strength (1RM), functional capacity (6MWD), lung capacity (FEV1), HRQOL, cancer related symptoms (FACT-L) and anxiety and depression (HADS) were measured at baseline and 6 weeks.
Results: One-hundred-two patients were included and 72 patients undergoing concurrent systemic treatment were eligible for analysis. There was a significant increase in aerobic capacity − VO_{2peak} ($p = 0.014$) and functional capacity- 6 MWD ($p = 0.006$). There was significant improvement in strength ($P<0.001$). There was a significant change in the parameter for 'emotional wellbeing' ($p = 0.000$) with a moderate effect size of 0.30 and 'social well-being' ($p = 0.000$) with a small effect size of 0.23. However, there was no significant improvement or decline in general QOL. Theere was a significant reduction in anxiety (HADS-A) ($p = 0.008$) a significant change in Psychological Morbidity (HADS-T) ($p = 0.023$). However, there was no significant change in Depression (HADS-D) ($p = 0.124$).
Conclusion: The results from this study shows that it is beneficial for advanced lung cancer patients to participate in a 6 weeks exercise intervention. The significant reduction in anxiety has not been found in other studies with advanced lung cancer patients, further research will show the clinical relevance of these findings.

Cognitive changes following cancer treatment

B. Espersen[1], A.M. Brandborg[1]. [1]*Aarhus University Hospital, Department of Oncology, Aarhus C, Denmark*

Background: Reports suggest that patients with cancer can experience cognitive changes following chemotherapy treatment − the socalled 'chemo brain'. Changes such as memory loss, concentration problems, difficulty in organizing information and ability to work have been reported. The changes are often subtle, but can have a major impact on the quality of life and cause a lot of distress for patients and their relatives.
Healthcare professionals disagree on the causes of the cognitive changes and whether they are the result of chemotherapy or other factors. Patients often complain of the lack of acknowledgement by healthcare professionals concerning their experienced cognitive changes, and lack of information and educational tools.
Purpose: To investigate the knowledge of cognitive changes in connection with cancer and cancer treatment among healthcare professionals at a department of oncology. In adition to investigate the daily practice related to assessment, information and interventions related to cognitive changes.
Method: A total of 308 nurses and doctors from the same oncology department received an electronic questionnaire about patients experiencing cognitive changes in connection with cancer and cancer treatment. The questionnaire included a total of 18 items related to knowledge and awareness of cognitive changes, practice regarding assessment and education of patients and families, and demographic information about participants. Data was categorized into different themes and divided into different profession groups, wards, education and length of employment.
Results and relevance to clinical practice: Cognitive changes during and after chemotherapy were well-known symptoms among the majority of nurses and doctors. Only a minority assessed, informed and intervened to prevent or act, when patients and relatives reported symptoms.
In spite of the healthcare professionals' assessment of the extent and the impact of the problem, this knowledge had no influence on clinical practice. There was an obvious difference between knowledge, awareness and actions in daily clinical practice.
No conflict of interest.

The effect of a pain consult combined with a patient pain education program on patient adherence to analgesics

W.H. Oldenmenger[1], P.J. De Raaf[1], C.C.D. Van der Rijt[1]. [1]*Erasmus MC Cancer Institute, Medical Oncology, Rotterdam, Netherlands*

Background: Optimal pain management is hindered by professional-related barriers, e.g. knowledge deficits resulting in inadequate prescriptions of analgesics, as well as patient-related barriers, e.g. reluctance to report pain or use analgesics. Pain Consult (PC) and Pain Education Programs (PEP) have been studied to overcome these barriers in cancer pain management. PEP had been suggested to improve medication adherence, but only 3/18 previous PEP studies found a significant effect. In the primary analysis of a randomised controlled trial (RCT), we found the combination of PC&PEP to be more effective in decreasing pain than Standard Care (SC). In this secondary analysis of the RCT, we evaluated the effect of PC&PEP to improve oncology outpatients' adherence to their analgesic regimen.
Methods: PEP consisted of patient-tailored pain education and weekly monitoring of pain and side effects. Adherence was measured using a Medication Event Monitoring System (MEMS). The MEMS consists of a medicine container with an electronic circuitry that registers when the lid is opened. Adherence was measured in the time intervals: week 1&2; week 3&4; and week 7&8 after randomization. Between-group differences per time interval were analysed using non-parametric tests. 72 Patients were planned (α=0.029, β=0.80, one-sided t-test). The study protocol was approved by the Institutional Review Board of the Erasmus MC (NTR613). All patients gave written informed consent.
Results: In 54 of the 72 included patients data about adherence were available (SC n = 26; PC&PEP n = 28). Of these 54 patients, 80% had metastatic cancer. At baseline, patients' worst pain was 8.1 (sd=1.2) and average pain intensity was 6.0 (sd=1.5). All but one patients had a prescription for WHO step 1 analgesics and over 60% had a prescription for strong opioids. At week 7&8, adherence increased in PC&PEP group compared to baseline (from 91% to 96%) and decreased in SC group (from 85% to 78%)($P<0.05$). At week 7&8, more patients in the intervention group took their analgesics with the right intervals (78%) compared to SC (64%, $P<0.05$). During the study, patients were more adherent to opioids than to non-opioids.
Conclusions: PC&PEP can increase both taking adherence and timing adherence. Strategies directed at further increasing patient adherence may improve cancer pain treatment.
Study is closed.
This work was supported by the Erasmus MC Health Care Research and the Erasmus MC Revolving Fund.

The development and testing of a PROM to measure symptoms associated with chemotherapy in people with breast and colorectal cancer: The Chemotherapy Toxicity Self-Assessment Questionnaire (CTAQ)

R. Maguire[1], J.P. Connaghan[1], D. DiDomenico[1], J. Hughes[1], L. McCann[1], C. Paterson[1], P. Donnan[2], N. Kearney[1]. [1]*University of Dundee, School of Nursing and Midwifery, Dundee, United Kingdom;* [2]*University of Dundee, Epidemiology and Biostatistics Unit, Dundee, United Kingdom*

Background: In 2008 3.2 million people were newly diagnosed with cancer in Europe for which chemotherapy is a core treatment. Definite advances in survival have been observed as a result of the use of cytotoxic agents, but are associated with significant toxicities that impact negatively on patient outcomes and can lead to death. Toxicities not only occur during the acute phase of treatment but can also persist into survivorship. Poor assessment and management of treatment-related symptoms can have a sustained negative effect on patient outcomes post-treatment and increase supportive care needs, reduce quality of life (QoL) and impede rehabilitation. Patient-reported outcome measures (PROMs) provide an effective way to optimise standard practice and improve the assessment and management of chemotherapy related symptoms. The aim of this study was to develop and measure the reliability of a PROM (Chemotherapy Toxicity self-Assessment Questionnaire − CTAQ) to assess chemotherapy related symptoms in people with breast and colorectal cancer.
Materials and Methods: The CTAQ was developed via two systematic reviews of the literature on the symptoms associated with chemotherapy in people with breast and colorectal cancer and via expert consensus from patient and clinician groups based in 8 hospitals in the UK. People with breast (n = 26) and colorectal cancer (n = 26) completed the CTAQ on paper on two occasions one hour apart. Reliability of the CTAQ was assessed by comparisons of the participants' responses using Cohen's kappa statistic in SPSS v.18.

Results: A total of 52 people with breast (n = 26) and colorectal cancer (n = 26) completed the CTAQ. Agreement was high with many questions having perfect agreement. The lowest Kappas tended to be for questions related to tingling and pain and redness with hands or feet.
Conclusion: The CTAQ is a reliable method for measuring the symptoms associated with chemotherapy in people with breast and colorectal cancer.
No conflict of interest.

1735 ORAL

Use of the rocket IPC in palliative care

S. Onderwater[1]. [1]*Antoni Van Leeuwenhoek Ziekenhuis, Thoraxoncology, Amsterdam, Netherlands*

Background: Although the Rocket IPC (indwelling pleural catheter) is more often used to release symptomatic malignant pleural effusion (MPE), little is known about the clinical outcome, patient satisfaction and complications. Insufficient information can lead to ignorance of this alternative palliative intervention to evacuate malignant pleural effusion. Purpose of this presentation is to increase knowledge and awareness about the Rocket IPC in palliative care.
Method: Between October 2009 and March 2013 all patients in the Antoni van Leeuwenhoek hospital in Amsterdam treated with a Rocket IPC, were included in this prospective observational study. Registered are primary malignancy, date of IPC insertion, use of supplies, complications and patient satisfaction.
Results: Sixty-eight patients were included: 31% non-small cell lung cancer, 30% breast cancer, 14% urogenital cancers, 9% mesothelioma, 9% gastrointestinal cancers and 7% other cancers. The mean overall survival after IPC insertion was 4 months (1−28). Mean monthly use of supplies was 11 bottles (2−65). Patient satisfaction: 76% didn't need home care. Complications: 7% obstruction/dysfunction drain; 3% empyema; 3% infection; 3% pain during effusion; 1.5% pneumothorax and 1.5% metastasis.
Conclusion: In this population the mean use of supplies was low, hardly any serious complications were seen and patient satisfaction was high. The Rocket IPC seems a good palliative intervention for MPE. Furthermore study is needed in patient reported outcome, cost effectiveness and clinical factors to predict treatment outcome.

Symptom management pathways for patients undergoing adjuvant chemotherapy for breast and colorectal cancer: The application of process maps

J. Hughes[1], J. Cowie[1], R. Maguire[1], L. McCann[1], J. Connaghan[1], C. Paterson[1], D. Di Domenico[1], N. Kearney[1]. [1]*University of Dundee, Nursing and Midwifery, Dundee, United Kingdom*

Background: Management of symptoms is an important aspect of care delivery for patients undergoing chemotherapy treatment. Symptoms associated with chemotherapy can be wide ranging, complex, and, if incorrectly managed, life-threatening. The Advanced Symptom Management System (ASyMS) − III study is investigating the impact of ASyMS on the care delivered to people with breast and colorectal cancer receiving adjuvant chemotherapy. Part of this research involves understanding the different models of care employed by different hospitals across the UK in order to evaluate the impact ASyMS has on current care delivery. In this presentation we describe the use of process of care mapping to elicit symptom management care pathways in 8 cancer settings across the UK.
Material and Methods: Hospitals across Scotland, England and Northern Ireland were mapped in a series of dynamic, practical workshops in order to define the series of steps or actions performed in the management of chemotherapy related symptoms. The workshops were conducted with a range of clinicians involved in the delivery of chemotherapy for breast or colorectal cancer. Participant numbers ranged from 3−15 attendees, and involved practitioners such as chemotherapy nurses, consultants, pharmacists and specialist cancer nurses. Maps created in the workshop were digitised using the Microsoft Visio Software.
Results: Process of care mapping proved a useful tool for representing the complexities of chemotherapy symptom management and in providing contextual information for analysing pathways across the NHS. Feedback from participants was positive in terms of the value of the workshop session and all could be involved in the construction of the maps as there were no technological barriers.
Conclusions: The use of Microsoft Visio offered a number of technical benefits which allowed ease of dissemination and modification. The challenge now lies with interpreting the data gathered in the maps, and identifying how we can best evaluate the impact of ASyMS on the process of care pathway.

Aftercare following allogeneic stem cell transplantation: Adjustment to individual needs

F.E. Witkamp[1], M.C.M. Van der Lans[2], A.E.C. Broers[2]. [1]*ErasmusMC Cancer Institute, Medical Oncology and Public Health, Rotterdam, Netherlands;* [2]*ErasmusMC Cancer Institute, Hemato-oncology, Rotterdam, Netherlands*

Background: Allogeneic stem cell transplantation (alloSCT) is an important treatment modality for patients with haematological malignancies. Increased long-term disease free survival forces health care professionals to pay more attention to quality of life after alloSCT.
However, little is known about the problems patients are confronted with following transplantation and the need for support.
Material and Method: In a retrospective qualitative study, patients with a haematological malignancy were interviewed one year post alloSCT in the Erasmus MC Cancer Institute. The interviews were transcribed verbatim and analysed using qualitative content analysis, according to the constant comparative method from the Grounded Theory. Several measures were used to ensure the methodological quality and trustworthiness of the study.
Results: After 10 patients saturation (of the data) was reached. Although fatigue was the most striking problem posttransplant, patients experienced many more changes and problems regarding their physical, psychological, social and spiritual well-being. Although patients went through an individual process of recovery and rehabilitation, a common pattern of five phases could be distinguished: *1) survive*, in which intense fatigue and frequent visits to the outpatient clinic are most prominent; *2) on the receiving end,* when the patient is confronted with additional side effects and complications of the therapy; *3) bring under control,* the phase in which the physical condition starts to improve; *4) start recuperation,* when the patient starts to pick up his roles in daily life; *5) retrospection,* the phase in which the patient starts to look backwards and is able to give a meaning to the experiences. The length of the phases and the severity of problems patients experienced varied, mostly due to differences in the severity of graft-versus-host disease. Although the need of support showed some individual variation, all patients followed the five-phased pattern of recovery and rehabilitation.
Conclusion: Recovery and rehabilitation after alloSCT is an intense process, showing individual variation in a fived-phased common pattern. Posttransplant care can be improved by adjusting care to the need of support within the distinct phases the patient is going through.

Dyadic sleep/wake assessments in cancer care: New insight from a longitudinal study among women with breast cancer and their informal caregivers during adjuvant chemotherapy

G. Kotronoulas[1], Y. Wengström[2], N. Kearney[1]. [1]*University of Dundee, School of Nursing & Midwifery, Dundee, United Kingdom;* [2]*Karolinska Institutet, Department of Neurobiology Care Science & Society Division of Nursing, Huddinge, Sweden*

Background: Alterations in habitual sleep/wake patterns (SWP) of women with breast cancer and their informal caregivers may be concurrently exacerbated and co-vary during the patient's treatment. Taking into consideration the complexity of mechanisms interfering with a care dyad's sleep, the current study set out to longitudinally explore SWP of patient-caregiver dyads in the context of adjuvant chemotherapy (CTh) for breast cancer.
Material and Methods: In this descriptive, observational, repeated-measures dyadic study, 48 newly diagnosed women receiving outpatient adjuvant CTh for early stage breast cancer (stage I−IIIA), and their nominated primary informal caregiver completed self-reported sleep measures at pre-treatment (week prior to CTh), post-CTh cycle 1, post-CTh cycle 4, and approximately 30 days after CTh (total of $\geqslant$6 cycles received). Multivariate hierarchical linear modelling (MHLM) techniques were implemented to analyse dyadic sleep data.
Results: Prior to CTh, 65% of dyads consisted of at least one poor sleeper, a rate further increasing to approximately 88% at CThC4. MHLM revealed curvilinear trajectories for most of dyads' sleep/wake parameters that nevertheless reached significance (p <. 05) only for patients. In both groups, sleep/wake impairment reached its peak at mid-treatment (CThC4); yet, patients consistently reported significantly more sleep problems than their carers. Partial convergence also emerged as suggested by positive correlations and no between-groups differences in daily disturbance, daytime napping duration (NAPTIME), total sleep time, and overall sleep/wake disruption at pre-treatment. At CThC4, rates of change in sleep latency and NAPTIME were also similar.
Conclusions: The current study is one of the first studies to show that a dyadic approach in the assessment of SWP in patients with breast cancer

and their carers is a promising method to enhance exploration of potentially concurrent sleep-impairment. Replication of the current findings in future dyadic sleep research is an absolute priority. Meanwhile, clinicians will need to engage in concurrent systematic and on-going sleep assessments that synthesise and contrast data to establish a care dyad's level of sleep quality.

To be in pain (or not); a computer enables outpatients to inform their physician

W.H. Oldenmenger[1], F.E. Witkamp[1], J.E.C. Bromberg[2], F.J.P.M. Huygen[3], J.L.M. Jongen[4], H. Van Dijk[1], M.A.G. Baan[1], L. Van Zuylen[1], C.C.D. Van der Rijt[1]. *[1]Erasmus MC Cancer Institute, Medical Oncology, Rotterdam, Netherlands; [2]Erasmus MC Cancer Institute, Neuro Oncology, Rotterdam, Netherlands; [3]Erasmus MC, Anesthesiology, Rotterdam, Netherlands; [4]Erasmus MC, Neurology, Rotterdam, Netherlands*

Background: In the outpatient oncology clinic, pain management is inadequate. Incorporating systematic pain management into visits is likely to improve this. In 2009, we started an innovative program, including structured computerized assessment of outpatients' pain intensity, with the aim of improving pain management. In this study, we investigated whether this program improved pain control.
Material and Methods: At eight oncology outpatient clinics, patients were asked to register their pain intensity on a touch screen computer. These scores were automatically copied into their electronic medical records. Additionally, a hospital-wide multidimensional cancer-related pain treatment protocol and web-based patient education were developed. A data warehouse system enabled us to extract patient data from the electronic medical record anonymously and to use them for analysis. The main outcome was the adequacy of pain management; expressed as the percentage of patients with moderate to severe pain (current pain intensity, NRS>4) during the first two weeks and after six months after implementation of the program.
Results: During the first six months after implementation, 4.454 of the 5.989 patients (74%) registered their pain intensity on the touch screen computer. The mean age was 54 years (sd=14) and 53% was male. Fifty-two percent reported to be in pain (NRS>0). During the first two weeks of the implementation, 13.3% scored their pain as moderate to severe. After six months, the prevalence of moderate to severe pain decreased with 30% compared to the start (9% NRS>4).
Conclusion: Although it was difficult to convince patients to adhere, pain registration by patients themselves is feasible, provides insight into patients' pain and may serve as a basis for improved integration of pain treatment into daily oncology care. For both physicians and nurses, the program provides direct insight into patients pain intensity, so that pain treatment can be tailored individually.

1740 POSTER

Nutrition issues in oncological nursing practice: The experience of a focus group

R. Caruso[1], D. Lichosik[1], G. Riverso[2], V. Romano[3], C. Di Pasquale[4], C. Simone[5]. *[1]European Institute of Oncology, Operating Theatre, Milan, Italy; [2]Policlinico San Matteo, Head and Neck, Pavia, Italy; [3]Ospedale San Carlo, Sub-Intensive Unit, Milano, Italy; [4]European Institute of Oncology, Urology and General Surgery, Milano, Italy; [5]European Institute of Oncology, Operating Theatre and Intensive Care Unit, Milano, Italy*

Background: Nurses are responsible for promoting and supporting standards of care and being able to track the results of their assistance to achieve quality outcomes and that is especially newsworthy in the field of nutrition's problems of hospitalised cancer patients. The use of heuristic approaches to answer as best as possible to current patient needs emphasises the many aspects of care that are often overlooked, both under a clinical point of view and also in terms of organization and management of oncological nursing practice. Focus group methodology is one of several tools that nurse can use to generate valid information important to the advancement of programs and organisations to best assess what are the cultural and organisational weaknesses regarding the nutritional care of hospitalised cancer patients.
Material and Methods: We used the focus group methodology in which took part nurses involved in the struggle against cancer under different profiles. Incentive for using this approach was given by the discussion of clinical cases, personal experiences and a literature review about nutritional problems of hospitalised cancer patients. The moderator of the Focus group was a nurse with relevant experience in cancer nursing, and the focus members were six nurses coming from different clinical areas and with different experiences. The focus group session and conversation among participants was recorded, transcribed and analysed. The group explored issues that were analysed and categorised according to the Focus group qualitative method analysis.
Results: The end result is a report, featuring graphs and tables, in which arises seven major categories that summarise the main problems felt by members of the focus:
1. most urgent priorities and activities
2. with so much work there is something you miss
3. intimate need
4. lack of communication
5. poor care planning
6. improper assessment
7. incorrect data collection

It is evident that these categories identified encompass both clinical and organisational aspects of nursing practice. Aspects, such as not giving importance to the nutritional needs or failing in organise activities, were deeply felt by the participants.
Conclusions: All qualitative approaches share control of the research experience with participants and take advantage of spontaneous and unexpected elements. This focus group has produced high quality data, suggestions and proposals, which can and should be used in trying to respond as adequately as possible to the needs of our patients and increase nursing knowledge with more research.

1741 POSTER

The multidisciplinary approach to elder cancer patients: Geriatric assessment and nursing decision making

C. Pedrazzani[1], D. Valcarenghi[1], M. Bianchi[2]. *[1]Istituto Oncologico Della Svizzera Italiana, Ufficio Ricerca e Sviluppo Infermieristico, Bellinzona, Switzerland; [2]Istituto Oncologico Della Svizzera Italiana, Servizio Infermieristico, Bellinzona, Switzerland*

Background: Geriatric assessment in oncology settings has different implications compared with geriatric settings. While in the literature there is general agreement on the importance of a comprehensive geriatric assessment (CGA) in the oncology medical practice, mostly to tailor treatments, the CGA employment and utility for oncology nursing practice is still less explored.
In 2012 in the Oncology Institute of Southern Switzerland (IOSI) within a multidisciplinary project for elder care, a pilot qualitative study exploring how nurses used the CGA in their decision-making, pointed out the use of CGA perceived as not substantially influencing nursing decision-making and elder patient care planning.
The purpose of this project is to promote the correlation between geriatric assessment, as a multidisciplinary instrument, and nursing decision-making process and practice in two oncology outpatient settings.
Methods: The project has involved two IOSI outpatients units. An initial literature review has been done to explore nursing implications of CGA in oncology settings.
Two Group discussions have been set up with nurse teams to lead them to reflect upon their usual decision making process for aged patients and which kind of decisions and interventions a CGA could help them to take and do.
Before instrument implementation, data collected from the Group Discussions and from literature have been shared in an educational meeting with all nurses involved.
Results: Decisions that nurses usually take for elder patients are mainly related to psychosocial aspects, organizational matters, symptoms-side effects and technical aspects on the basis of the initial assessment and individual expertise. CGA can be useful giving additional objective structured data to guide practice, but it's important it's perceived consistent with the decisional order, also avoiding instrument complexity and data repetitiveness. Multidisciplinary collaboration is essential for the utility of collected data.
Conclusions: Nurses have a key role in the multidisciplinary approach to elder cancer patient and the correlation between data collected by geriatric assessment and interventions can lead nurses to more effective and comprehensive decisions but consistent with the specific context in balance between patient needs, professional competences and decisional and organizing framework. From this assumption a work to create conditions promoting nursing decision making orientation is being done in our Institution.
No conflict of interest.

1742 POSTER

Importance of combination therapy in patients with lymphedema

L. Buzea[1], C. Ancuta[1]. [1]*Hospice Casa Sperantei, Home Care, Brasov, Romania*

Aim: This study aims to present the level of lymphedema prevention education in breast cancer patients in Romania, to evaluate present physical and psychological signs at the time of lymphedema onset, and highlight the results obtained by combining several therapeutic methods.
Method: Retrospective study on 50 patients who attended the Hospice 'Casa Sperantei' lymphedema service, weekly or every fortnight, between June2011 and December 2011; data analysis was carried out in SPSS 10. Every patient was interviewed and information was recorded in the patients' files. Assessment of lymphedema evolution was done from medical files, taking into account the measurement done before and 6 months after interventions.
Results: Analyzing data, the moment of lymphedema onset was 1−3 years from surgery in 36% of cases, 4−6 years in 24%, up to 1 year in 18%, over 6 years in 4%, immediately after surgery in 16% and before surgery in 2% of cases. After surgery 46% of patients did exercise; only 8% of them received information on how to prevent lymphedema.
Signs at onset: the modification of limbsize in 26%, and, in addition 28% experienced pain; discomfort and the modification of limb size occurred in 32% of cases and pain with complications in 14%. These patients had combined symptoms of pain, loss of mobility and complications such as infections and thrombophlebitis. The lymphedema location was: hand and forearm 34%, upper limb 32%, arm-forearm 20%, forearm-elbow 4%, arm 2%, hand 2% and thorax and upper limb region 6%.
Regarding the psycho-emotional aspects, patients accepted the situation at a rate of 18%, the rest experienced various feelings and negative emotions. The evolution was favorable for 76% of patients; the correlation between types of interventions and evolution after therapy was: 66% of the patients with exercise − manual lymphatic drainage − elastic sleeve having contraindications for pump, had favorable evolution and 34% of these were stable. Patients with added pneumatic pump treatment evolved favorably in 78% and were stable in 22%.
Conclusions: In Romania post-surgical education of patients regarding lymphedema prevention is still inadequate: there is considerable need of raising the medical staff awareness about the importance of prevention. Considering that lymphedema associate with cancer can't be cured, the aim of the treatment should target the maximum long-term improvement. A combined and sustained therapy brings real benefits to the patients.
No conflict of interest.

1743 POSTER

Competence review of the MANP at the Netherlands Cancer Institute: The position and function of the nurse practitioner in a specialized cancer hospital

M. Keessen-de Vries[1], M. Van Wijngaarden[2], H. Hauer[3], S. Onderwater[4]. [1]*Netherlands Cancer Institute, Clinical Pharmacology, Amsterdam, Netherlands;* [2]*Netherlands Cancer Institute, Gastro-Intestinal Surgery, Amsterdam, Netherlands;* [3]*Netherlands Cancer Institute, Breast Surgery, Amsterdam, Netherlands;* [4]*Netherlands Cancer Institute, Pulmonary Oncology, Amsterdam, Netherlands*

Background: The first Master of Advanced Nursing Practice (MANP), also called nurse practitioner, was introduced in 2001 at the Netherlands Cancer Institute (Amsterdam). Currently, over forty nurse practitioners are appointed in this specialized cancer hospital. They work at 14 different specializations. Within Dutch law the MANP has been accepted as an independent profession since 2010. The MANP roles are, similar to other medical professions, described according to the CanMED competences.
After more than 10 years of settlement the MANP group is now reviewing their function as a basis for future development. The aim of this study is therefore to evaluate the position and function of the nurse practitioner per specialization.
Material and Methods: In June 2013, the 41 nurse practitioners, stemming form 14 specializations, will be invited to complete a questionnaire. In addition, 70 medical specialists (5 per specialization), 70 nurses (5 per specialization), and 300 patients (20 per specialization) will be invited to complete a questionnaire. An adapted version of the Multi Source Feedback questionnaire (a valid instrument to evaluate medical professionals in the Netherlands) will be used to assess competences of the MANP. This questionnaire is based on the CanMED competences, and will be used to assemble 360º feedback.
Results: We expect a minimum response rate of 65% of the colleagues (n = 91/140) and of 75% of the patients (n = 225/300). The results of the questionnaires will be evaluated for the total group, and per specialization. The opinions of the medical specialists, nurses, nurse practitioners and patients about the different CanMeD competences will be compared for each specialization.
Conclusions: The results of this study will give insight in the position and the functioning of the nurse practitioner as a group, and per specialization, in a specialized cancer hospital. The different perspectives from the medical specialists, nurses, nurse practitioners and patients about the current position and functioning of the MANP group will show the strengths and limitations of the CanMED competences of the nurse practitioners in the Netherlands Cancer Institute. These results can be helpful to improve the competences of the nurse practitioners in this hospital, and the results can serve as a model for other hospitals that have introduced this relatively new position in the care for their cancer patients.
No conflict of interest.

1744 POSTER

Education of patients and their families before specific cancer outpatient treatment at the institute of oncology Ljubljana

M. Matkovic[1], K. Lokar[2]. [1]*Institute of Oncology Ljubljana, Oncology Nursing Consultancy, Ljubljana, Slovenia;* [2]*Institute of Oncology Ljubljana, Assistant Medical Director for Nursing, Ljubljana, Slovenia*

Background: Today's patients are aware of their rights and demand a partnership with healthcare professionals. On the other hand increasing of rights and participation brings greater responsibility. To become an equal partner in decision-making an individual should have the information and knowledge. Therefore the priority of the Division of Nursing and Care for Patients at the Institute of Oncology (OI) was to upgrade services of the Oncology nursing consultancy (Consultancy). Consultancy services have been in operation at the OI for about 12 years but some education areas had developed rapidly during this time and they became nowadays independent and essential activities for high-quality treatment and care of cancer patients. On the other hand some education areas diminished for various reasons.
Material and Methods: In January 2012 individual counseling primarily for the patients treated in outpatient units was organized at the OI. These patients were informed about their treatment and care in order to reduce side effects of specific cancer treatment, to solve their individual problems, and to improve the quality of life during the treatment. In 2012 the Consultancy was attended by 169 patients and 134 patients were asked to complete an evaluation questionnaire. Seventy one questionnaires were filled out and returned.
The most important aim of this evaluation was to explore the satisfaction or dissatisfaction with the newly organized Consultancy visit, to identify reasons for the Consultancy visit and to define a standard way of appointments for patients in the Consultancy.
Results: Of those patients who had submitted the questionnaire, 25% highlighted the positive feelings about the Consultancy. Majority of patients required more information about rehabilitation and time after treatment. Patients visited the Consultancy because they were referred (almost 65%) and/or they needed more information about treatment and care (almost 41%). Ninety one percent of those who responded to questionnaire were referred to the Consultancy by nurses and doctors in specialist clinics.
Conclusions: Findings showed that there was necessary to encourage the appointments of patients to the Consultancy and that a standard way of preparing cancer patients for the specific cancer treatment needs to be established, and that nurses who were working in the Consultancy needed additional trainings in area of cancer patient's education.
No conflict of interest.

1745 POSTER

Prognostic factors for mortality within 90 days in phase I oncology trial

K. Rotteveel[1], A. Koenen[2]. [1]*Antoni van Leeuwenhoek Ziekenhuis, Amsterdam, Netherlands;* [2]*Antoni van Leeuwenhoek Ziekenhuis, Phase I, Amsterdam, Netherlands*

Background: A selection criteria for cancer patients with advanced malignancies whom will participate in a phase I trial is an expected survival for more than 90 days that in spite of the difficulty of predicting the overall survival of these patients.
Methods: The data used for this analysis were retrospectively abstracted from 371 medical records of patients enrolled in a phase 1 clinical trial at the Nederlandse Kanker Institute (NKI) in the Netherlands between October 1st 2009 and February 29th 2012. The cohort consisted of 179 men and 192 women aged between 18 and 86 years all with a solid tumor. We used univariate and multivariate logistic regression analysis to validate exciting prognostic factors and prognostic scores.
Results: Analysis of our cohort suggests that the five prognostic factors: hemoglobin, Eastern Cooperative Oncology Group performance status,

albumin, lactate dehydrogenase and number of metastatic sites of disease, should all be included in a prognostic score. These five prognostic factors showed a significant association with mortality. The score from the Princess Margaret hospital in Canada predicted the best the mortality in our dataset with a AIC of 0 compared to the Royal Marsden (AIC 16.2), MD Anderson Cancer Center (AIC 16) and Centre Léon Bérard (AIC 25.1). We produced a new 5 level prognostic score which in our dataset has a greater prognostic value than those previously published.
Conclusion: Our results suggest that patients with a score 4 or more should not be entered into phase I trials as their 90 days survival estimate is only 37% (23%-62%). Similarly patients with a score of 3 may be considered for exclusion, as their 90 days survival is also low, 65% (51% − 82%). Prospective validation of the NKI prognostic score is warranted.
No conflict of interest.

1746 POSTER

Russia's oncological nurses promote prevention and early intervention

N. Biryukova[1]. [1]*ISNCC, World Services of La Crosse, La Crosse, USA*

Cost-effective and affordable measures to prevent many cancers and alleviate suffering of those already diagnosed can be implemented irrespective of the level of resources in any country in every stage of the fight against cancer (prevention, early detection, treatment and palliative care).
This presentation will describe initial changes being implemented in the role of nurses in four primary care clinics in Russia's Saratov Oblast. The project, funded by the Bristol-Myers Squibb Foundation, is exploring the effectiveness of enhancing the role of nurses in prevention and early detection through the following approaches:
– New programs of postgraduate education 'Primary health and prophylactic assistance to the population'
– 'Primary health care for the adult population' − education for nurses working in primary care clinics which also incorporates new standards
– Adaptation of the 'medical home' patient care model which maximizes the application of nursing skills and knowledge to improve patient care.
Changes in practice and the education of nurses are being made by faculty of the Balakovo Secondary Medical College with the support of the Ministry of Health of the Saratov region, and in cooperation with the Committees of health and municipal clinics in the cities of Balakovo and Saratov.
Results: In the pilot clinics nurses provide routine patient education intended to reduce common risk factors: smoking, alcohol, weight, exercise, and other lifestyle factors. To prepare and support nurses in assuming expanded roles and responsibilities in the primary care setting, education and in-service programs have been implemented which include:
– leadership skills, best practices in prevention, screening and patient education;
– procedures to ensure the continuity of treatment between the institutions of primary health care and specialized agencies; and
– nurses as cancer patient advocates.
Conclusions: This project is seeking to implement significant changes in patient care for patients in the primary care setting, with the desired goal of preventing cancers by enhanced patient education, and improving outcomes for those patients diagnosed with cancer by early detection and effective referral for prompt treatment.
Progress in meeting this goal will be monitored by audit of nursing notes to ensure that patient education and screening is being provided according to new standards and the expanded scope of nursing practice. These audits will also document the percentage of patients initiating self care as a result of nursing interventions (i.e. breast self exam, smoking cessation, etc.).
Initial response from patients, physicians and nurses has been promising. A proposal is being developed for consideration by federal education authorities to incorporate expanded nursing practice into the secondary college system's standards.
No conflict of interest.

1747 POSTER

Introducing the nurse practitioner role to Australian regional oncology patients

A. Booms[1]. [1]*Border Medical Oncology, Wodonga, Australia*

Background: For some time in Australia, it has been recognised that the Nurse Practitioner Role offers feasible and cost effective alternatives in the redesign of health care delivery. To improve outcomes for Oncology patients across all health settings, it is paramount for the Oncology Nurse Practitioner (ONP) to have formal collaboration and partnerships with other health care providers.
Methods: A mixed methods design – Gap analysis and Literature Review – was employed by the Oncology Nurse Practitioner; to undertake a needs analysis in the development of the ONP Model of Care.
Results: This study identified gaps in oncology care delivery from Oncologists, General Practitioners and supportive care staff perspectives. Collaborative engagement with internal and external partner and other health care providers determined the ONP model and scope of practice within rural/regional Victoria and Southern New South Wales with the primary aim of improving Oncology patient outcomes.
Conclusions: This ONP model reflects a key strategic objective: To promote access to Quality Specialist Supportive Care for Oncology Patients in regional Australia.
No conflict of interest.

1748 POSTER

Patient education and competence in the oral cancer therapy as a key factor for patient's adherence and safety − aims and results of a cross-sectional survey among medical oncology practices

P. Zamora[1], C. Riese[1], W. Baumann[1], M. Welslau[2]. [1]*WINHO − Scientific Institute of the Office-Based Hematologists and Oncologists, Köln, Germany;* [2]*Office Based Oncologist, Aschaffenburg, Germany*

Introduction: Oral agents for cancer treatment are increasingly prescribed throughout the world, also in Germany. Regardless the benefits of oral agents regarding the convenience of administration for the patient, oral cancer medications have considerable potential for side effects, toxicity and interactions with other drugs. Inadequate use of medication may therefore lead to effect reduction or ineffectiveness of medication and in some cases to premature breakup of therapy. Against this background and because oral agents are usually self-administered or administered by lay caregiver, our analysis assumes that the provision of adequate information to the clinical picture, treatment options, side effects, and the proper handling of medications is crucial for therapy adherence and therefore for therapeutic success. Due to the lack of data on this issue in the context of outpatient care with oral cancer agents in Germany, we conducted a systematic explorative survey on the handling of oral cancer care in oncology practices.
Methods: The study consisted of a representative cross-sectional survey among medical oncology practices (n = 220) in order to systematically describe a) the ambulant care of patients receiving oral cancer agents, and b) the current therapy management and education measures from the point of view of medical oncology practices. Information was collected via questionnaire from nearly 90 oncologists and hematologists.
Results: Data collection took place in the first quarter of 2013. The majority of respondents (74%) have the opinion that nurses should be more involved in the training and guidance of orally treated patients, especially if they have acquired an oncology qualification. Surveyed oncologists consider mainly educative and informative approaches or methods as crucial to ensure treatment adherence. Further details will be presented.
Conclusions: The results confirm the study's assumptions and indicate a need for action regarding the degree of involvement of oncology nurses and the use of systematic education tools for patients receiving oral cancer agents. These findings will be the focus in a new interventional study starting this year.
No conflict of interest.

1749 POSTER

Development and psychometric validation and sensitivity of an evaluation instrument for a breast cancer nursing consult

E. Decoene[1], M. Daem[2], M. Bernaert[3], D. De Meyer[3], M. Grypdonck[3], A. Van Hecke[3]. [1]*UZ University Hospital Gent, Oncology, Gent, Belgium;* [2]*University Hospital, Oncology, Ghent, Belgium;* [3]*University Ghent, Nursing Science, Ghent, Belgium*

Background: A breast cancer consult refers to the meetings in which support is given by the breast care nurse (BCN) attuned to the specific care demands of breast cancer patients. It is essential to assess patients' experiences and perspectives with these nursing consultations in breast cancer care. No validated instrument to evaluate breast cancer nursing consultations is available. The aim of the study is to develop and validate an instrument to evaluate breast cancer nursing consultations.
Methods: *Phase 1: Identification of topics of the instrument.* A review was performed to identify cancer patients' expectations about nursing consultations and to explore their preferred support by healthcare professionals. In addition, data of 4 qualitative studies were integrated: 45 semi-structured patient interviews about breast cancer patients' experiences and 4 focus group interviews with BCN about their perspectives on breast care).
Phase 2: Psychometric validation and sensitivity. Face validity of the instrument was assessed by breast cancer patients, BCN and clinical nurse specialists (CNS), multicentric. Comprehensibility and phrasing of each question was assessed by 8 breast cancer patients. Psychometric validity (internal consistency, stability and construct validity) of the instrument was evaluated in a convenience sample of 104 breast cancer patients.

Sensitivity of the instrument was assessed. 56 breast cancer patients completed the instrument and 19 patients were interviewed using the Q-sort method.
Results: A 78-item instrument was developed based on the review and qualitative data. The items were categorized in 9 topics. The relevance of each item was assessed by 15 BCN. The final instrument consisted of 71 items. The internal consistency (Chronbach alpha) of the 9 topics was between 0.77 and 0.98. Stability was demonstrated for 7 of 9 topics and 2/3 of the items. Ceiling effects of the instrument were apparent. The sensitivity study indicated that 14 items were sensitive for evaluating a breast cancer nursing consultation. One third of the items were interpreted differently or were less or not understood.
Conclusion: This study is the first step in the development of a validated instrument to evaluate breast cancer nursing consultations. The instrument shows a strong internal consistency and a high content validity. This instrument could be used by BCN to optimize their nursing consultations.
No conflict of interest.

1750 POSTER

Implementation of nurse consultations in psychosocial cancer care: Experiences of advanced nurse practitioners

A. Van Hecke[1], V. Dierick[1], M. Daem[2], I. Bocquaert[3], E. Decoene[2].
[1]University Ghent, Nursing Science, Ghent, Belgium; [2]University Hospital Ghent, Oncology, Ghent, Belgium; [3]University Hospital Ghent, Neuro Oncology, Ghent, Belgium

Background: Successful implementation of the role of advanced nurse practitioners (ANPs) is challenging. Less attention is given to the mechanisms used by ANPs to enact their professional role within the multi-professional team, caring for patients with cancer. The aim of this study is to elicit barriers, facilitators and underlying processes in implementing these ANP roles in cancer care.
Methods: A qualitative study was performed to explore experiences and underlying processes in the implementation of a nurse consultation in psychosocial care for patients with cancer and their relatives. Fifteen advanced nurse practitioners involved in psychosocial cancer care working in a university hospital or working in a general hospital were interviewed. A grounded theory approach was used. Interviews were transcribed verbatim. Data collection and analysis took place iteratively and analysis was validated by means of researcher triangulation.
Results: ANPs are often confronted with ambiguity about the role description and role clarity. Resistance from other healthcare professionals is experienced because of unclear role boundaries. Acceptance, especially by physicians, was a main problem when implementing an ANP role. Physicians also extensively influence the ANP role development. ANP's often experience insufficient organizational support for their role and a shortcoming of coaching. To enhance successful implementation, ANPs indicate building relationships with other healthcare professionals as essential. The results indicate an evolution of provider oriented care ('I focus') when starting as an ANP towards a team-oriented care ('my team focus') after several years.
Conclusions: Future approaches should focus on the use of frameworks to facilitate successful implementation of ANP roles in patient cancer care. Support from nurse managers and clinical nurse specialists could also facilitate role clarity, role implementation and role development.
No conflict of interest.

1751 POSTER

Reflections on the position of nurse practitioner breast cancer care in the Netherlands

F. Hoving[1], H.S.A. Oldenburg[1], J.A. Van der Hage[1], E.J.T.H. Rutgers[1], M. Vrancken Peeters[1]. *[1]Antoni van Leeuwenhoekziekenhuis, Breast Cancer, Amsterdam, Netherlands*

Title: Reflections on the position of Nurse Practitioner breast cancer care: a survey in the Netherlands and a comparison to the role of a Nurse Practitioner in an tertiary referral institute.
Background: Every year about a million women are diagnosed with breast cancer worldwide. In The Netherlands 1 out of 8 women will be confronted with this disease.
In 2002 the Antoni van Leeuwenhoek Hospital incorporated the position of Nurse Practitioner in the clinic for diagnostic work-up, treatment and follow-up of breast cancer patients.
In the last 10 years a lot of the Dutch hospitals have adopted Nurse Practitioners in their breast clinics.
Within Dutch law the Nurse Practitioner has been accepted as an independent profession since 2010.
However, no clear data exist concerning the nationwide variability of working activities of nurse practitioners in the Netherlands. Therefore, we performed a survey studying the current role of the nurse practitioner breast cancer care in the Netherlands.
Method: A questionnaire was sent to all hospitals in the Netherlands. Questions about the content of the position of the Nurse Practitioner and which tasks are performed, were included. The results were collected, and analysed and subsequently compared with the role of the Nurse Practitioner in a tertiary referral institute.
Results: Of the addressed hospitals actively participated in the survey in 68.5% of these hospitals, Nurse Practitioners play a vital role in the outpatient clinic activities of the breast clinic, compared to the situation in a specialized center.
Conclusion: By 2010 the position of Nurse Practitioner was fully integrated into the majority of Dutch hospitals. Compared to other hospitals in the Netherlands the Nurse Practitioners in the Netherlands Cancer Institute have a broad spectrum of activities.
No conflict of interest.

Poster Session (Sat, 28 Sep − Mon, 30 Sep)
Nursing − Impact of Cancer on Patients and Families

1752 POSTER

Experience of Iranian men in living with a spouse with breast cancer

F. Taleghani[1], A. Irajpour[1], A.H. Nasiri[1]. *[1]Isfahan University of Medical Sciences, Nursing & Midwifery Care Research Center − Faculty of Nursing & Midwifery, Isfahan, Iran*

Introduction: Breast cancer is the most common cancer among women. In Iran, breast cancer is in the first rank in malignant cancers among Iranian women and has the highest prevalence. Although cancer is a stressful event for all family members, one of the most important social and familial consequences of breast cancer is its effect on the spouses of these patients. Spouses' trust and support are crucial for a patient in stages of diagnosis and treatment of cancer. As patients' spouses often accept the role of a caregiver with the lowest preparation and support, if their concerns, remain unknown, the problems will not be solved, so exploration of men's adaption process to their spouses' cancer can be helpful in provision of care and manner of their dealing with their spouses' disease.
Methods: This is a qualitative study conducted based on grounded theory. Participant comprised the men whose spouses had breast cancer and selected from various social and economic classes and interviewed. Sampling continued until data saturation and ended with total of 26 participants. Constant comparative method was used to analyze the data in this study.
Results: Results of the present study showed that men's adaptation with their spouses' breast cancer is a process which starts from the moment of disease diagnosis and occurs in three stages of *exposure to crisis*, *insertion of life-course disruption* and *struggle to modify disruption in life*. The first stage of men's exposure to their spouses' disease is the exposure to crisis. The happenings in this stage indicate the fact that cancer leaves the spouse in a sudden shock and is accompanied with unpleasant psychological and mental reactions. *Family disruption*, *heavy shadow of disease on marital relationship*, *concerns associated to disease management*, and *resistance against disruption in life* are the main categories which formed the second stage of men's exposure to their spouses' disease. '*Revising the relationship with the relatives*', '*emotional and functional support to the spouse*', '*trying to improve marital relationship*' and '*seeking support to modify disruption in life*' formed the third stage of men's exposure to their wives' breast cancer as 'struggle to modify disruption in life'. Men gradually found out that they could not live in the way before their spouses' disease and had to revise many aspects of their life. Therefore, a struggle to modify disruption in life was administered and they constantly tried to compensate the defects.
Conclusion: Results declared the necessity for these men's support and conduct toward use of efficient coping strategies. Nurses can plan to facilitate the men's adaptation to the conditions by supporting and helping them through an accurate primary and comprehensive assessment of their psychological status, experiences and investigation of their used strategies. Nurses should support men's struggle to modify the disruption in life and facilitate their adaption to the disease of their spouses through appropriate interventions.
No conflict of interest.

1753 POSTER

How to meet the needs and wishes of relatives to cancer patients at an oncology ward − an intervention study by nurses

L. Ankersen[1], J. Orsted[1], L. Thisted[1], P. Thomsen[1], L. Ritzau[1], H. Gyldenvang[1]. [1]*Rigshospitalet, Cancer, Copenhagen, Denmark*

Background: A survey in 2010 of relatives (n = 157) to Danish cancer patients at the Oncology ward of Copenhagen University Hospital, Rigshospitalet, revealed a need for an enhanced focus on their needs. The survey showed that 21% of the relatives believed that they were responsible for the coordination of the patient's treatments and examinations, 58% experienced that the staff only a few times or never had asked to their wellbeing as relatives, and 36% had not been informed about possible offers of support. An intervention study was initiated in 2011 as a part of nurses' focus on cancer patients' daily lives. The aim was to investigate whether an optimized effort from the clinic and their nurses could improve the relatives' experiences and meet their needs.
Materials and Methods: The study was designed as a quality improvement study and goals for the relatives' experiences were set as 80 % know who the patient's devoted nurse/doctor is, 90% experience that the staff is interested in their wellbeing, 80% feel that they are involved in the patients treatment and care at the hospital in the way they prefer, 80% are well informed about how they support the patient and finally 90% have got information about where they can get and seek help as relatives.The model PDSA (Plan − Do − Study − Act) was used for the intervention.The above presented data are baseline data, and the intervention is based on: Evidence-based interventions for relatives to cancer patients, the recommendations and guidelines regarding relatives to seriously ill patients from the Danish National Board of Health, and recommendations from the patient organisation Danske Patienter ('Danish Patients'). The nursing management and the cancer rehabilitation nurse of the hospital are responsible for the intervention.
The intervention included: Inviting and welcoming the relatives to the first contact with the hospital and continuously during treatment and follow-up; Information about supportive services for relatives, Information about the patients' illness and treatment and presumed side effects and complications; Agreements about the relatives' involvement; And presenting the offer of meeting other relatives/peers. Researcher from the Research Unit at the Department of Palliative Medicine at Bispebjerg Hospital collect and analyze the data from a follow-up in the spring of 2013 showing whether the goals are met.
Results: Data collected from relatives in 2013 will be compared with baseline data. We expect to present preliminary results at ECCO, including evaluation from the information meetings for relatives held at the hospital.
Conclusions: This study's impact on clinical nursing practice is to meet not only the patients' needs and wishes but also those of the relatives. However, the evaluation of the intervention has to be based on research data and not just assumptions or subjective experiences. No evidence based intervention for relatives at an oncology ward has previously been tested.
No conflict of interest.

1754 POSTER

Patients' self-assessed knowledge about cancer

L. Sigaard[1], C.L. Madsen[2], J.H. Andersen[2], E. Ellegaard[2], I. Hartmann[2], H.M. Larsen[2], D. Schmidt[2], M.B. Poulsen[2], K.B. Dieperink[2]. [1]*Odense University Hospital, Odense, Denmark;* [2]*Odense University Hospital, Department of Oncology, Odense, Denmark*

Background: Patients' need for information to manage everyday life is increasing. Studies show that especially women retrieves information related to disease and health on the Internet. In addition, this information influences the choices they subsequently make.
This study distinguishes between examining the patient's desire for knowledge held up against the self-assessed current knowledge.
Purpose was to investigate:
- How much knowledge do cancer patients *want to have* about disease and treatment?
- How much knowledge do cancer patients *currently have* about disease and treatment?
- Is there a gender difference in the need of knowledge?

Methods: In total 84 cancer patients (38 men, 46 women) with a median age of 59 years (range 36−83) completed a questionnaire. On a scale from 0−10, patients ranked knowledge about disease and treatment.
Results: In average, women want to have knowledge about *disease* equivalent to 9.3, and men 9.2 ($p = 0.762$). Women actually have knowledge about *disease* equivalent to 8.0, and men 7.2 ($p = 0.006$).
In average, women want to have knowledge about *treatment* equivalent to 9.5, and men 9.8 ($p = 0.094$). Women actually have knowledge about *treatment* equivalent to 8.4, and men 7.5 ($p = 0.002$).
Conclusion: Both male and female patients want to have a high level of knowledge about disease and treatment and no significance difference is found between genders in these wishes.
In this study, the female patients had a significantly higher self-assessed level of knowledge about both disease and treatment than men.
It is relevant to examine what this difference in level of knowledge causes and means.
No conflict of interest.

1755 POSTER

The experience of the changing nature of coping with nodal relapse of malignant melanoma

S. Stothers[1], E. McCaughan[2]. [1]*Ulster Hospital Dundonald, Cancer Services, Belfast N. Ireland, United Kingdom;* [2]*University of Ulster, Institute of Nursing & Health Research, N. Ireland, United Kingdom*

Background: Currently, approximately 132,000 malignant melanoma skin cancers occur globally each year (World Health Organisation, 2012). The incidence of malignant melanoma is now four times higher than 30 years ago, and is predicted to continue to increase.
Despite the significant increase in patients with melanoma there appeared to be no research on the specific needs of patients with nodal relapse. Due to the current gap in the literature this study aimed to provide an essential insight into patients' specific needs when they developed nodal relapse of malignant melanoma. It explored how the patients' experience a transition from curative to nodal relapse and potentially palliative care.This transition was described through the use of an emerging middle-range theory of transitions described by Meleis *et al.*(2000).
Material and Methods: Using a descriptive qualitative design the target population was patients with nodal relapse of malignant melanoma, who had a surgical block dissection of lymph glands in the neck, axilla or groin within the last two years. The sample size was six participants.Interviews were conducted and transcribed verbatim.
The data analysis was based on the constant comparative method (Glaser and Strauss 1967) and was conducted by two researchers.
Results: The participants appeared to have an unpredictable emotional reaction in that they were less shocked at nodal relapse when compared to their reaction to the initial diagnosis. Information gaps were identified which related to the physical effects following surgery, review arrangements such as the format and the language used by health professionals were also identified as well as treatment dilemmas pertaining to Interferon treatment. Hope was the main strategy expressed by the participants. The participants acquired new coping skills from their initial diagnosis of melanoma to nodal relapse and beyond. They continued to develop their coping resources which pre-empted the next transition process regarding their cancer. Nonetheless they had an acceptance and understanding of the threat of even further spread of their disease. Despite this they had a palpable awareness of life and an overriding sense of hope and positivity.
Conclusion: This unique patient group experience a transition from their initial diagnosis of malignant melanoma to nodal relapse and adopt coping mechanisms to respond to their situation. Through identification of the specific information and support needs this provides health care professionals with an in-depth description of the specific physical and psychological impact of nodal relapse of malignant melanoma.
No conflict of interest.

1756 POSTER

Attitude of family caregivers of Egyptian patients with cancer towards cancer diagnosis disclosure

S.S. Abdel-Kareem[1], N.Y. Ibrahim[1], D.E. Farag[1], M.A. Abolkasem[1], S.A. Alsirafy[1]. [1]*Kasr Al-Ainy School of Medicine Cairo University, Palliative Medicine Unit Kasr Al-Ainy Center of Clinical Oncology & Nuclear Medicine, Cairo, Egypt*

Background: Little is known about the communication preferences among Egyptians in the cancer care setting, especially those related to cancer diagnosis disclosure. Family caregivers in Egypt are seen frequently by oncologists as a barrier to effective communication with cancer patients. This study was performed to explore the disclosure preferences of Egyptian family caregivers of patients with cancer.
Materials and Methods: We conducted a structured interview with 288 family caregivers accompanying cancer patients in the outpatient or the inpatient setting in Cairo and Port Said. Caregivers were asked about their preferences regarding cancer diagnosis disclosure to their related patient and their preferences in case they themselves developed cancer.
Results: The median age of caregivers was 35 years (range: 18−70), 58% were females, 51% were offspring of patients, 87% were literate and 70% were living with the patient.
According to the interviewed caregivers, the majority (85%) of patients were aware of their cancer diagnosis. The majority (81%) of caregivers

preferred cancer diagnosis to the patient. Factors associated significantly with the caregiver's preference not to disclose cancer diagnosis to patients were illiteracy of patients, urban residence of patients and having a lung or hematological malignancies ($p = 0.005$, <0.001 and <0.001; respectively). Furthermore, caregivers who preferred not to know their own cancer diagnosis and not to tell their families in case they themselves developed cancer, were more likely to be against disclosure to their related patients ($p < 0.001$). In case they themselves developed cancer, 92% of caregivers wanted to know their cancer diagnosis and 88% wanted to tell their families.
Conclusions: Unlike the impression of oncologists in Egypt and according to the report of interviewed caregivers, the majority of Egyptian patients are aware of their cancer diagnosis and their informal caregivers are not against disclosing diagnosis to them. The results suggest that, in general, informal caregivers of Egyptian cancer patients do not represent a barrier to honest communication with patients. For the group of caregivers who are against disclosure, effective strategies are needed to overcome their negative attitude noting that they may be reflecting their own fears of cancer. Communication with patients with cancer and their informal caregivers in the Egyptian culture is an area that needs further exploration in future studies.
No conflict of interest.

1757 POSTER

Nurse care and resilience in women with breast cancer in adjuvant chemotherapy

M. Menezes[1], D. Sória[2], L. Coutinho[2], S. Souza[2], T. Oliveira[2]. [1]*Instituto Nacional do Câncer (INCA), Continuing Education, Rio de Janeiro, Brazil;* [2]*Federal University of Rio de Janeiro State, Medical and Surgical Nursing, Rio de Janeiro, Brazil*

Background: Breast cancer is the second most common type of cancer worldwide and the most common among women. Resilience is explained as 'processes that explain the 'overcoming' of crisis and adversity in individuals, groups and organizations.' The importance of analyzing the resilience in women with breast cancer can help them and assist them during the treatment. This project discuss about resilience as an element for recovery of women with breast cancer undergoing chemotherapy. Its objectives are to characterize the resilience in women with breast cancer to adjuvant chemotherapy treatment; analyze the risk factors and protective resilience expressed and to discuss the expression of resilience in these women.
Material and Methods: This was a descriptive study with a qualitative approach. We collected data from the interview and there also was used Resilience Scale, and the Wagnild Young, validated by Pesce in Brazil. For data analysis, there was performed interpretative elaboration of subcategories derived from observation, interviews and analysis of the information collected based on the theoretical framework.
Results: The data were collected from fifteen women with breast cancer in adjuvant chemotherapy. Resilience was measured using the Resilience Scale (Wagnild and Young). We considered scores lower than 125 low resilience, from 125 to 145 moderate and higher resilience than 145 high resilience. None was classified as low resilience. Findings were four women with moderate resilience, equivalent to 26.67% and eleven women with high resilience, tabulating 73.33% of them. The treatment was rated as strenuous and as something that takes a long time. Hair loss is also a major downside in cancer treatment. The protection factor was 'Faith in God.' According to these women, faith that moves them to continue and complete the treatment. The family was also cited by many. Mothers, children, grandchildren, make a difference in the lives of these women. Individual willpower makes them go on.
Conclusions: This study contribute to the awareness that nurses can, knowing the concept of resilience associated with nurse care, enlarge the see and do in nurse care or the managerial practice. The perception was evident that women felt victorious to be alive and able to give her account. Risk factors and protective were: chemotherapy, fatigue, sick, time spent in hospital, hair loss, feeling sick, addiction, lack of family support; to hide feelings and 'nothing weakens me'. The contribution for nurse care is that we can take care of our customers in a comprehensive way. A woman with breast cancer undergoing chemotherapy experience unique experiences such as fear, physical pain and the will to live touched on, so people with high chances of being resilient.

1758 POSTER

Everyday life with prostate cancer − female spouses' experiences

B. Ervik[1], T. Nordøy[1], K. Asplund[2]. [1]*University Hospital of North Norway, Oncology, Tromsø, Norway;* [2]*University of Tromsø, Health Science, Tromsø, Norway*

Background: Spouses or partners play an important role in how well patients with prostate cancer manage their illness. Whereas earlier studies mostly included both patients and spouses, this study focuses on the spouses' experiences during the illness trajectory. The objective of the study was to illuminate the daily life experiences of female spouses living with husbands with prostate cancer to determine the spouses' needs for support and improve care for the patients.
Material and Methods: Qualitative interviews were conducted with nine spouses of men receiving potential curative treatment for prostate cancer, i.e., radical prostatectomy or radiation therapy.
Results: Illness was an event that the spouses experienced as part of a couple and as a challenge with significant emotional and practical demands. Spouses suppressed their own anxieties and needs for support and felt overlooked by health care providers. Those spouses living in the situation over a period of years expressed tiredness and a shift in focus from their husbands' needs to their own needs.
Conclusion: Being a spouse to a man with prostate cancer is emotionally and practically demanding. There is a danger of the spouses erasing themselves in the process of supporting their husbands. Spouses may also need support after a prostate cancer diagnosis.
Health care providers should provide support for spouses during a prostate cancer illness trajectory, encourage spouses to participate in spouse-only rehabilitation courses, and be aware of the potential for situational fatigue in spouses after years of dealing with a husband's illness.
No conflict of interest.

1759 POSTER

Reasons for patients' preferences for subcutaneous or intravenous trastuzumab in the PrefHer study

L. Fallowfield[1], V. Jenkins[1], J. Kilkerr[1], C. Langridge[1], K. Monson[1], N. Fitzpatrick[2], S. Osborne[2], X. Pivot[3]. [1]*Sussex Health Outcomes Research & Education in Cancer (SHORE-C), Brighton & Sussex Medical School: University of Sussex, Falmer, United Kingdom;* [2]*F. Hoffmann-La Roche Ltd, Basel, Switzerland;* [3]*CHU Jean Minjoz, Besançon, France*

Background: Subcutaneous (SC) trastuzumab, administered via single-use injection device (SID), was overwhelmingly preferred to intravenous (IV) infusion by patients in the ongoing PrefHer study (NCT01401166, F. Hoffmann-La Roche Ltd). Reasons for patients' preferences were assessed in an exploratory analysis.
Materials and Methods: After completing (neo)adjuvant chemotherapy, patients with HER2-positive early breast cancer were randomised to receive 4 cycles of SC trastuzumab (600 mg fixed dose via the SID) followed by 4 cycles of standard IV or the reverse sequence as part of their adjuvant trastuzumab therapy.
Prior to randomisation and at the end of the cross-over period, patients were interviewed at home by phone by experienced interviewers. Factors potentially influencing preferences, including type of venous access device used and experiences during administration, were collected. After the cross-over period, patients' final preferences, reasons for these and strength of preferences were elicited. Interviews were quality-controlled to ensure impartial questioning.
Four researchers independently coded from verbatim quotes the two primary reasons patients gave for their preferences. These were reconciled and grouped into 10 categories for descriptive analyses.
Results: Of the 236 patients, 216 (92%) preferred SC delivery, 16 (7%) preferred IV and four (2%) had no preference.[1]
The top three categories for SC preference were: (i) time-saving (195/216),[1] e.g. '*It does affect me being there so many hours. With this it was 'Hello' and 'Bye' without having to spend hours with patients,*' (ii) less pain/discomfort (88/216),[1] e.g. '*The SC method was a lot less painful to me and my bruises faded faster than in the case of the IV method,*' and (iii) convenience (35/216),[1] e.g. '*Busy mum with four young children − want to get on with life.*'
The primary reason given by the 16 patients with an IV preference was fewer reactions (pain, bruising, irritation, etc.) (11/16),[1] e.g. '*Irritation due to the SC.*'.
Irrespective of preference, 64% of patients (152/236) said that SC caused least anxiety, 94% (222) found SC to be most convenient and 84% (199) thought that staff usually found SC easiest to administer.
Conclusions: The overwhelming preference expressed by patients for SC delivery of trastuzumab using an SID was mainly due to perceptions that it saved time, caused less pain/discomfort and was more convenient than IV administration.

1760 POSTER

Urology oncology nurses take on the challenge

S. Wildeman[1], L. Bani[1]. [1]*Sint Franciscus Gasthuis, Urology Outpatients Department, Rotterdam, The Netherlands*

Background: The urology outpatients department in St. Franciscus Gasthuis, Rotterdam, has had to deal with a fast increasing amount of urology oncology patients in the past 4−5 years. These patients require more guidance, counselling and psychosocial care. Both factors have contributed to increasing the workload of the urologists. By educating urology nurses in urology oncology and implementing a nurse led clinic, quality urology oncology care can effectively be provided and hopefully decrease the workload of the urologists.
Material and Methods: A literature study was conducted in order to determine exactly what the needs of the urology oncology patient are.
A literature study was conducted to determine if there is a 'right moment' when to discuss sexuality.
A nurse led clinic was implemented based on the needs of the urology oncology patient and evidenced based practice.
A patient survey was conducted to evaluate if our nurse led clinic can provide the necessary urology oncology nursing care, required by this patient group.
Results: 60 questionnaires were handed out to patients who attended the nurse led clinic. 50 were returned and analysed. 75% of the patients who filled out the questionnaire were age 60−80 and 25% of the patients were age 40−60. A score of 8.5 out of 10 was given for the overall appreciation of the nurse led clinic.
The questionnaire was divided into the following themes:
– The expertise of the urology oncology nurse
– Adequate information given
– The quality of information given
– The telephonic availability of urology oncology nurse
– Enough time to ask questions
– The impact of emotions and sexuality
Conclusion: A nurse led clinic can certainly contribute to providing quality urology oncology care and decrease the workload of the urologists.
The psychosocial impact of urology oncology is great and the extra time available for these patients to be able to discuss their diagnosis, information and psychosocial issues, is very much appreciated by the patients.
No conflict of interest.

1761 POSTER

Personalized choice of experience

M. Bisgaard[1], A. Duedal[1]. [1]*Danish Cancer Society, Communication, Copenhagen, Denmark*

Background: It is difficult for patients, relatives and even health care professionals to navigate the Danish health care system obtaining information of where cancer patients are treated and at what level of quality. The management of health care is split in 5 regions in Denmark and there is no central overview.
The purpose of this project is to enable patients and relatives to see where treatments are offered throughout the country, at what level of quality and to which level of satisfaction.
Methods: The Danish Cancer Society has built a website to provide easily accessible information on cancer treatment in Denmark. The Danish Cancer Society is responsible for updating data. The project involves all Danish hospital departments treating cancer patients. 98 departments have contributed to the information on the website.
The authors personally contacted every hospital in Denmark to find out, where cancer patients are treated and what treatments are offered. Each department has appointed a contact person responsible for the project to assure continuous update of the most recent data.
Focus-groups of patients and relatives have participated in interviews on their needs and the usefulness of the website.
Results: The website www.cancer.dk/gps gives an overview of the cancer treatments throughout Denmark. Treatment sites are mapped for each of 33 cancer diagnoses. The website contains information *for each department*, on:
- Treatment offered (surgery, radiotherapy, chemotherapy, medical treatment).
- Available counseling (patient counselor, social worker, priest, psychologist)
- Patient satisfaction surveys (The Nationwide Survey of Patient Experiences).
- Pathways (pathways, waiting times)
- Contact information

In this early version of the website there are approximately 15,000 users per year. Half of them are unique new users. (5 million inhabitants in Denmark.)
Conclusion: The website has proven to help cancer patients get a simple accessible overview of where to receive treatment, which medical facilities are available for the particular cancer diagnosis and at what level of quality (patient satisfaction). It allows cancer patients in a simple way to navigate on-line for information in the complex healthcare system offered, to quickly get in touch with the individual departments and to compare departments. This is an important empowerment of patients, and often during their acute crisis after the initial diagnosis.
No conflict of interest.

1762 POSTER

Bringing patients' intimate cancer experiences closer to nursing students with a new educational approach

M. Kotnik[1], K. Lokar[2], M. Matkovic[3]. [1]*Institute of Oncology Ljubljana, Education and Research, Ljubljana, Slovenia;* [2]*Institute of Oncology Ljubljana, Assistant Medical Director for Nursing − Head Nurse, Ljubljana, Slovenia;* [3]*Institute of Oncology Ljubljana, Oncology Nursing Consultancy, Ljubljana, Slovenia*

Background: Perceptions and personal experiences of patients with cancer about their illness, health care and health care system are important sources of learning for nursing students. In the year 2012 at the Institute of Oncology Ljubljana (IOL) in collaboration with the College of Nursing Jesenice we started to develop an education approach for nursing students. The aim was to bring patients' intimate cancer experiences closer to students.
Material and Methods: In the first part of the project second year nursing students were assigned to read a book written by a cancer patient and to write a reflection on its content. This was a part of the individual work during clinical practice at the IOL. The research instrument for the data collection was students' reflections on the read books. The data analysis was based on the content analysis method with which the categories of content and the frequency of occurrence were analyzed. The first results showed a need for a more focused, question-oriented assignment approach. We upgraded the reflection tool and executed the second part of the project with different student group in year 2013.
Results: The main theme 'Reflection of cancer patients' stories' was studied from the perspective of four different categories: patient's perceptions of the illness, communication, complementary therapies, and students' experiences. In the table are presented and compared the results of both parts of the project.
Conclusions: In comparison with the research from last year, we came to the conclusion that the greater number of students in 2013 experienced positive emotions and thus deeply identified themselves with patients and their experience of illness and the process of healing themselves. As observed in the table, there was a greater gap in the category 'communication' due to a perception of experience working relationships.

Table 1 (abstract 1762). Comparison of the main frequencies of occurrence in the year 2012 and 2013

Year 2012 (105 analysed reflections)		Year 2013 (28 analysed reflections)	
Theme	%	Theme	%
Category 'The patient's perception on the illness'			
Emotional field	57%	Emotional field	46%
Category 'Communication'			
Negative experience between medical staff and patients	50%	Positive experience between medical staff and patients	68%
Category 'Complementary medical treatment'			
Change of lifestyle	52%	Complementary methods of treatment	43%
Category 'Students' experiences'			
Positive emotions	52%	Positive emotions	79%

The results showed that the vast majority of students responded positively to the new educational approach.
No conflict of interest.

1763 POSTER

The importance of nurses in the process of patient care with cutaneous melanoma (SECA-GEMM project)

C. Vena[1]. [1]*Hospital Central de Asturias, Medical Oncology, Oviedo, Spain*

Introduction: Cutaneous melanoma is a malignant tumor that, due to its increasing incidence, mortality and risk factors, currently represents a public health problem. It also involves a wide variety of clinical-care setting from the primary diagnosis to the possible development of mestastases. The purpose of the SECA-GEMM project is to increase awareness of this disease and the involvement of each of the health professionals. In order to carry out a multidisciplinary approach for patiens with melanoma, nursing represents and important role by providing an appropiate response to the needs os each patient.
Objective: To determine, according to the methodology of process managment, the involvement of each of the health professionals involved in the managment of the disease as well as the essential nursing work.
Methodology: The project has been developed by health professionals with experience and knowledge in pathology − dermatologists, oncologists, nurses, hospital pharmacists, plastic surgeons and primary care physicians − who have worked with professionals in the field de process management and sanitary quality. In the methodology, the nursing role is crucial. In the first phase, works with the physician in order to properly asses, care and evaluate the patient. At the beginning of the surgical treatment, the nurse checks both the procedure to be preformed and the control of medication. During follow up treatment, it is essential to make use of the nurse's expertise in the magnament of chemotherapy, immunotherapy or radiotherapy and in the identification and management of potential adverse effects.
Conclusions: The involvement of the nurse in the care of patients with melanoma is crucial from the first contact of the patient throughout the process to completion. Recently, there have been major advances in the treatment of melanoma, with addition to the array of innovate drugs. These developments require that the nurse performs the necessary procedure for the proper monitoring and care patients with melanoma.
No conflict of interest.

1764 POSTER

Improving the practices of nurse leaders with systematic training

M. Bernot[1], K. Lokar[2]. [1]*Onkoloski Institut Ljubljana, Ward H1 Medical Oncology, Ljubljana, Slovenia;* [2]*Onkoloski Institut Ljubljana, Head Nurse, Ljubljana, Slovenia*

Background: Healthcare environment is constantly changing and produces new situations with which a nurse leader must be able to cope. If we want to have in the organization changes in leadership for the better it is essential to invest in the education for effective leadership. In the Division of Nursing and Care at the Institute of Oncology Ljubljana (IOL) we were very much aware of the later so we took a systematic approach toward it. Our previous experiences thought us that models from others could not be simply transferred to our environment, and that to be successful we had to find a way that was right for us.
Material and Methods: In 2011 we started with a two year project on raising the level of nursing leadership. The overall aim of the project was to empower nurse leaders so that they would be able to facilitate the transition from a largely surveillance to leadership roles. The main focus of the training was on learning about the tools and approaches that managers can use in their work.
The project was conducted in two phases: the first phase was carried out in 2011 and the second phase in 2012–2013. The training was executed in the form of intensive interactive workshops, individual coaching, telephone and e-counseling.
Results: Training was based on the Relationship Awareness Theory and Strength Deployment Inventory® (SDI). Through this approach we got to know our profile, our strengths and excessive virtues, and delved into how this affected our approaches of management and leadership, creating relationships with co-workers and the working atmosphere in the team. We looked at the SDI profile of our leadership group and analyzed strengths and drawbacks of our team. We also created competence profile of us as leaders, and performed interactive work on our everyday examples. We learned about and tried out different management tools: conflict resolution strategy, giving feedback, motivating employees and ourselves, taking care of ourselves, what and how to delegate, how to set priorities, development of employees, and the use of a principled approach that was soft to people and hard to the problem.
Conclusions: Only well organized and managed nursing care can lead to a successful meeting of the patients needs. With a good implementation of the project, the nurse leaders gained a sense of how important the role they had as key holders was and that with their approach, activities and acting as role models they shaped the image and success of the organization.
No conflict of interest.

1765 POSTER

The impact of Breast Cancer Patient Pathway (BCPP) to patient's anxiety

A. Ryhänen[1], S. Rankinen[2], M. Siekkinen[2], H. Korvenranta[3], H. Leino-Kilpi[4]. [1]*Turku City Hospital, Turku, Finland;* [2]*University of Turku, Department of Nursing Science, Turku, Finland;* [3]*Turku University Hospital, Turku, Finland;* [4]*University of Turku South-Western Health District of Finland, Department of Nursing Science, Turku, Finland*

Background: The BCPP is an Internet-based patient education tool describing a flow chart of the patient pathway during the breast treatment process, from breast cancer diagnostic tests to the follow-up after treatments. The ultimate goal of this study was to evaluate the effect of the BCPP to the breast cancer patient's empowerment by using the patient pathway as a patient education tool. The essential part of empower process is knowledge. In the model of empowerment by Leino-Kilpi et al. the knowledge is the basic element to empower. As an outcome of empowering patient education patients can have less anxiety. The purpose of this study is to report the results of RCT study that evaluated the effect of BCPP to breast cancer patients' anxiety during treatment process.
Material and Methods: The BCPP program was piloted with 10 breast cancer patients. After that patients were randomised to an intervention group (n = 50) and control group (n = 48) between years 2008–2010 in South-Western health District of Finland. State of anxiety was measured at baseline, before and after surgery, before and after chemotherapy and before and after radiotherapy to indicate the effectiveness of the intervention. Anxiety was assessed with the State Anxiety Inventory (STAI).
Results: Anxiety level was highest (mean 2.53, from scale 1 to 4) at baseline in the intervention group and before surgery in the control group (means 2.41). No statistical differences were found between the groups in anxiety. However, anxiety decreased faster in the intervention group when looking at internal differences between the groups at different measurement times.
Conclusions: Based on the results we can say that the BCPP programme did not decrease anxiety level when compared to controls. However, in the intervention group anxiety level was decreasing during treatment time, while in the control group anxiety level increased before surgery and chemotherapy, and remained at same level during chemotherapy. Further research is needed to find the effect of Internet based patient education to breast cancer patient's anxiety.

Frozen gloves − do they work? For patients with breast cancer being treated with docetaxel

E. Gejsing[1], D.D. Juul[2]. [1]*Århus Universitetshospital, Aarhus, Denmark;* [2]*Århus Universitetshospital, Aarhus, Denmark*

Background: Nail changes and neuropathy are widespread problems in connection with treatment with docetaxel. 85.7% of patients experience first to second degree nail changes (second degree being the highest level of toxicity), and 51 % of patients experience first to fourth degree neuropathy (fourth degree being the highest level of toxicity). Studies have been made, that describe the extent of the problem, but only few studies have considered solutions to the problem. The biggest problem with nail changes and neuropathy occur in patients with breast cancer relapses, where long term treatment with docetaxel is frequently used. The side effect often impair the patients' daily lives, and reduce their quality of life.
Objective: To investigate whether the use of frozen gloves reduces the occurrence and degree of nail changes and neuropathy in connetion with docetaxel treatment in patient with disseminated breast cancer.
Method: 28 patients were included in the study, and they were all treated with docetaxel every third week. Frozen gloves (gel gloves, which are frozen down to −25 degree Celcius) were placed on the patients hands 15 minutes prior to docetxel infusion, during the one hour infusion, and 15 minutes after completion of the infusion. At each treatment a nurse filled out an evaluation form together with the patient. CTC-criteria were

used to evaluate the degree of side effects of nail changes and neuropathy respectively. The results are compared to an earlier study, where the focus was on the extent of the problem.

Results and conclusion:

- Nail changes are significantly reduced by using frozen gloves.
- There are fewer second degree nail changes.
- Longer time elapses before the occurrence of second degree nail changes.
- The occurrence of neuropathy seems to be delayed by the use of frozen gloves, but the effect stops after long term − i.e. 5−6 courses − docetaxel treatment.

Frozen gloves should be offered to disseminated breast cancer patients being treated with docetaxel, because they are often given many treatments and are therefore at greater risk of suffering from nail changes and neuropathy.

No conflict of interest.

1767 POSTER

Moving clinical nursing practice forward − a model developed in the Department of Oncology, Aarhus University Hospital, Denmark

A. Brandborg[1], P. Riis Olsen[1]. [1]*Aarhus University Hospital, Department of Oncology, Aarhus, Denmark*

Background: In the Oncology Department Aahus University Hospital we have developed a model: 'The Umbrella Model'. Under the same theme nurses in all units are involved in development during three years.

Purpose:

- To generate new knowledge and learning strategies to develop nursing care in close collaboration with local needs and to do so in partnership with clinical nurses, nursing leaders and academic nurses.
- To support the development of nurses' competences in using research based knowledge in practice.

Purpose of the current project from 2012–2015: To generate new knowledge and nursing interventions which are practicable in future cancer care characterised by shorter contacts with patients and their relatives.

Material and Methods: Participant oriented learning and practice research, acknowledging that changes are more likely to happen if practice is able to join the research process − from producing research questions, through data collection and analysis to the information and transformation of findings into new methods in practice.

Activities during the three years: 1st year: Preparation; 2nd year: Implementation of projects; 3rd year: Completion.

Workshop days:

- All members of the organisation meet ×4/year
- Sharing processes and experiences
- Theoretical inputs

Continuously:

- Planned time of practice for working with all projects
- Concurrent supervision
- Involvement of colleagues

Termination:

- Writing up projects for publication
- Presenting at local symposia
- Implementation plan

Results: Two projects completed and published in Danish:

1. *Young people with cancer* 2005–2008.
2. *Relatives and the cancer patient's social network* 2009–2012.

Conclusions: The Umbrella Model:

– Helps to organise projects in a large organisation
– Focuses the resources spent
– Engages clinical nurses, nursing leaders and academic nurses in shared projects
– Supports development of new clinical services and interventions
– Contributes with new knowledge
– Develops the nurses' competences
– Other departments seek to implement the model

1768 POSTER

Factors influencing HPV vaccine acceptability among young female college students in Thailand

P. Juntasopeepun[1], N. Suwan[1], Y. Phianmongkhol[1], J. Srisomboon[2]. [1]*Faculty of Nursing Chiang Mai University, Chiang Mai, Thailand;* [2]*Faculty of Medicine Chiang Mai University, Chiang Mai, Thailand*

Objectives: To determine knowledge of Human Papillomavirus (HPV) and cervical cancer, beliefs toward HPV cervical cancer and vaccination, acceptance of the HPV vaccine, and to identify independent predictors associated with the acceptance of the HPV vaccine among young women in upper northern Thailand.

Methods: A convenience sample of young women aged 18−24 years (n = 747) recruited from universities/colleges located in upper northern Thailand. An online questionnaire was carried out to obtain demographics, HPV and cervical cancer-related health characteristics, as well as knowledge and beliefs toward HPV and cervical cancer. Logistic regression analysis was used to determine significant independent predictors of HPV vaccine acceptability.

Results: Knowledge about HPV and cervical cancer was moderate. The mean total knowledge score was 7.5±3.8. HPV vaccine acceptability was significantly associated with having received a recommendation for vaccination (OR 2.12; 95% CI 1.22–3.68), perceived susceptibility to disease (OR 1.37; 95% CI 1.22–1.52), perceived benefits of vaccination (OR 1.33; 95% CI 1.19–1.49), and perceived seriousness of disease (OR 0.90; 95% CI 0.81–1.00).

Conclusion: Understanding variables associated with HPV vaccine acceptability from this study may guide immunization initiatives in increasing the uptake rate of HPV vaccine among young women.

No conflict of interest.

1769 POSTER

Clinical nurse specialist: a key link to manage patients using targeted therapies − experience of Centre Eugene Marquis from Rennes (France)

A. M'Sadek[1], M. Duval[2], J. Edeline[2], C. Lefeuvre[2], T. Lesimple[2], E. Vauléon[2], S. Sizun[2], B. Laguerre[2], E. Boucher[2]. [1]*Centre Eugene Marquis, Rennes Cedex, France;* [2]*Centre Eugene Marquis, Medical Oncology, Rennes Cedex, France*

Background: Cancer targeted therapies are widely used, most of them are oral treatments. Their adverse events are specifics and often unfamiliar to health professionals. Their prescription requires personalized information. In this setting, a new nursing job was established in our center in 2012 complementary to the oncologist consultation.

Patients and Method: Two clinical nurses (with University Degree in Clinical Oncology) offer consultations. They also provide a 'hot line' phone and email address so that patients and their G.P. could reach them easily at office hours. They collaborate with patients' referent oncologist, attending physician, pharmacist and the whole multidisciplinary team. For very patient: (i) An initial consultation allows the nurse to recap with him terms of his treatment and how to prevent side effects. (ii) A weekly telephone appointment, during 2 to 3 months, allows to assess compliance to treatment and to remind preventive care measures. (iii) A follow-up visit, just before the medical consultation for treatment renewal, provides updates on treatment tolerance and compliance. A systematic prospective collection of side effect was initiated in July 2012 (according to NCI CTCAE-VERSION 3.0).

Results: In 2012, nurses followed 148 patients. Mean age was 63 years (21−83), women 42%, men 58%. All have advanced disease: kidney cancer (54), hepatocellular carcinoma (36), breast cancer (24) and melanoma (22).

– Targeted therapies were: sorafenib (50), sunitinib (40), everolimus (32), vemurafenib (22) and lapatinib (8).
– 444 consultations were done, 91 initial consultations and 353 follow-up consultations. They had 1474 phone calls 81.3% of pre-planned calls and 18.7% of calls initiated by the patients
– Among 118 patients followed, 21% presented G3−4 toxicity: asthenia (8.2%), hand–foot syndrome (3.3%), pain (2.2%), diarrhea (2.2%), nausea (2.2%), rash (1.1%), dyspnea (1.1%), hypertension (0.55%), 7 patients (3.8%) were hospitalized because of severe toxicity.

Conclusion: The development of this new activity in our center is relevant. It allows a better follow up of patients, better observance, better knowledge of the treatment by health care professionals.

Despite regular monitoring, some preventive measures remain difficult to adopt by the patients. Therapeutic education seems to hold its full meaning here. The impact of clinical nurse intervention on treatment efficacy and cost effectiveness should be assessed.

No conflict of interest.

1770 POSTER

Oncology nurses' caring behaviours in Hellas

C. Karlou[1], E.D. Papathanassoglou[2], I.G. Kaklamanos[3], C. Lemonidou[3], F. Vouzavali[4], A. Zafiropoulou -Koutrouba[5], C. Adam[6], C. Kouloukoura[7], A. Psychogyiou[6], E. Patiraki[3]. *[1]251 General Air Force Hospital, Athens, Greece; [2]Cyprus University of Technology, Nursing, Lemesos, Cyprus; [3]National and Kapodistrian University, Nursing, Athens, Greece; [4]Vocational High School Assistants & Laboratory Instructor, Nursing, Athens, Greece; [5]Aglaia Kyriakou Children Hospital, Psychology, Athens, Greece; [6]Agio Sava Oncology Hospital, Nursing, Athens, Greece; [7]Agioi Anargyroi Oncology Hospital, Nursing, Athens, Greece*

Background: Caring is an elusive concept, that encompasses a range of behaviours. Perceptions and expressions of caring behaviours are context dependent. The life threatening character of cancer and the far-reaching consequences of the medical treatments make cancer nursing very demanding. Nursing behaviours recognized as caring remain a challenging issue for oncology nurses.
Aim of the study: To identify caring behaviors as perceived by nurses working in cancer care in Hellas.
Method: Methodological triangulation applied separately, by regarding both quantitative and qualitative methods as equally valuable. At first, a descriptive, quantitative study consisted by a convenience sample of 72 nurses, from three oncology centres in Attica area. Data were collected using the validated in Greek language Caring Behaviour Inventory (CBI) consisted of 24 items scored in a six point Likert scale.CBI-24 has four subscales: F1 Assurance of human presence, F2 Knowledge and skill, F3 Respectful deference to others, and F4 Positive connectedness. Collected data were analyzed using SPSS software version 17.0. Level of statistical significance was set at $p < 0.05$.
The second phase was a qualitative descriptive study. A purposive sample of 18 oncology nurses participated in three focus groups. Researchers triangulation was used to analyze the data. Through careful data preparation, coding, and interpretation trustworthiness of the study was achieved.
Results: Subscale F2: knowledge and skill was perceived as the most important (5 ± 0.7) followed by F1 Assurance of human presence (4.8 ± 0.7), F3 Respectful deference to others (4.5 ± 0.8), and F4 Positive connectedness (4.3 ± 0.9). Deductive Content analysis emerged the following categories: Caring as a value, Respect for the person, Creating a therapeutic relationship, being empathetic, communication and information support, the fear of cancer and perception of their role as oncology nurse.
Conclusion: Research into care is possible using quantitative methodology, but qualitative data provide a rich source of individual detail into what care is. As quantitave data has shown oncology nurses value most highly technical skills, however qualitative data shows a plethora of information concerning nurses perceptions of the humanistic and emotional aspects of care. In addition personal beliefs for their role tends to influence their caring behaviors.
No conflict of interest.

1771 POSTER

Peripheral venous catheter-associated complications of patients with solid tumours in a general and oncological hospital in Greece

E. Apostolopoulou[1], V. Papara[2], A. Mpeli[2], X. Konstantinidou[2], E. Samantas[2]. *[1]University of Athens, Nursing Faculty, Athens, Greece; [2]General and Oncological Hospital of Kifissia "Oi Agioi Anargyroi", 3rd Oncology Dept, Athens, Greece*

Background: Several studies suggest that the peripheral venous catheter (PVC)-associated complications are the most common adverse events affecting cancer patients. A prospective study was carried out to investigate the incidence of PVC-associated complications in patients with solid tumours at General and Oncological Hospital of Kifissia 'Oi Agioi Anargiroi' in Athens, Greece from October 2012 to November 2012.
Material and Methods: Peripheral venous catheter-associated complications were grouped as phlebitis, infiltration and extravasation. The definitions of PVC-associated complications were in accordance with the Infusion Nurses Society and Oncology Nursing Society criteria. Neutropenia and anaemia were defined by the National Cancer Institute, Common Toxicity Criteria.
Results: During the study period 14 of 134 patients developed 14 complications (10.4%). The mean age of patients was 63.60 ± 13.16 (range 18−85) years. There were 91 males (67.9%). The most common underlying malignancy was lung cancer in 36 patients (26.9%) followed by colorectal in 25 (18.7%), head and neck in 17 (12.7%) and urinary tract in 16 (11.9%). Recent chemotherapy had been administered in 88 patients (65.8%) and neutropenia was present in 32 patients (23.9%), being grade 4 in 2 of 14 episodes (14.2%). Anaemia stage 4 was present in 1of 14 episodes. The Phlebitis incidence was 7.5% (5 phlebitis grade1; 50% and 5 phlebitis grade 2; 50%), the infiltration incidence was 1.5%, infiltration grade 2 in all episodes (100%) and the extravasation incidence was 1.5%, extravasation grade 4 of infiltration scale in all episodes (100%). Crude mortality in patients with and without complications was 35.7% and 22.5% ($p = 0.280$), respectively. There was significant difference in length of stay between patients with and without complications (9.79 ± 8.28 vs 3.08 ± 3.6% days, $P = 0.001$).
Conclusions: Early identification of the first signs and symptoms and the strict adherence with peripheral vascular catheter care bundle are critical for improving safety and quality of care in patients with solid tumours.
No conflict of interest.

1772 POSTER

Surveillance of infections in patients with solid tumours at a general and oncological hospital in Greece

E. Apostolopoulou[1], M. Lentza[2], N. Mixalopoulou[2], G. Aravantinos[2]. *[1]University of Athens, Nursing Faculty, Athens, Greece; [2]General and Oncological Hospital of Kifissia "Oi Agioi Anargyroi", 2nd Oncology Dept, Athens, Greece*

Background: Cancer patients are at an increased risk of infections, since a weakened immune system during chemotherapy treatments increase susceptibility to infections and can result in hospitalizations and even death. The aim of this study was to investigate the incidence of infections in patients with solid tumours at General and Oncological Hospital of Kifissia 'Oi Agioi Anargyroi' in Athens, Greece from October 2012 to November 2012.
Material and Methods: A standardized survey record form has been used, according to the Healthcare Associated Infections (HAIs) definitions provided by the CDC's National Healthcare Safety Network (NHSN). HAI was defined as the episode developing at the time of hospital admission if the patient had been hospitalized during the preceding 30 days.
Results: During 789 patient-days, 12 out of 163 patients acquired 20 infections (7.4%) or 15.2 infections per 1,000 patient-days. The mean age of patients was 62.43 ± 10.79 (range 30−84) years. There were 104 males (63.8%). The most common underlying malignancy was colorectal cancer (33.7%), followed by head and neck (15.9%) and lung (9.8%). Ten out of 20 infections (50%) were healthcare-associated and 10 (50%) hospital acquired. The incidence rate of wound infection was (5.2%), for urinary tract infections was 3.7%, for bloodstream infection was 2.45% and pneumonia 0.6%. Crude mortality in patients with and without infections was 25,% and 6% ($p = 0.015$), respectively. Furthermore, there was significant difference in length of stay between patients with and without complications (14.42 ± 813.7 vs 4.11 ± 5.57% days, $P = 0.001$). Gram-negative bacteria were isolated in 16 (80 %), with E coli (7 out of 16; 43.7%) and klebsiella pneumonia (41;25%) being the most frequent. Gram-positiveorganisms were isolated in 4 episodes (20%) with St aureus being the most common (50%).
Conclusions: Infections in patients with solid tumours increase the duration of hospitalization and the mortality. Early diagnosis and the early intervention with emphasis to adherence with hand hygiene are optimal for preventing life-threatening infections.
No conflict of interest.

1773 POSTER

Burnout in health caregivers: Experience of a Moroccan anti cancer center

Z. Essaadi[1], R. Belbaraka[2], S. Aloulou[1], Z. Elmoutassim[2], N. Ismaili[2], A. Elomrani[1], M. Khouchani[1]. *[1]Radiotherapy CHU Mohamed VI Marrakech, Department of Radiotherapy, Marrakech, Morocco; [2]Medical Oncology CHU Mohamed VI Marrakech, Medical Oncology, Marrakech, Morocco*

Background: The burnout syndrome or the Professional exhaustion syndrome has become the topic of the day in the world. The burnout can be defined as an emotional exhaustion, a depersonalization of the relations with others, and a decrease in the personal accomplishment.
The aim of this work is to assess the prevalence of burnout syndrome among medical and paramedical staff in the center of hematology-oncology at the University Hospital Mohammed VI Marrakech.
Patients and Methods: A self-administered questionnaire was distributed to 43 persons in the center of hematology and oncology, including Maslach burnout inventory (MBI), sociodemographic and professional features.
Results: Forty three questionnary was correctely completed. The staff participation was: 23.25% physicians and 76.75% nurses. Average age was 27.62 years (23 years − 35 years). According to the criteria of the MBI: about half of the affected professionals had a high level of emotional distress, 30% had a high level of depersonalization and 25% had a low

level of professional fulfillment. The analysis showed that age did not affect the occurrence of burnout. The female is a protective factor of depersonalization, leisure and sporting activities decreased significantly increasing emotional exhaustion and personal accomplishment. Our results corroborate partially with those of the literature and illustrate some parameters that can be the cause of burnout, such as working conditions, role ambiguity, and lack of expérience among the new staff. We also have some heterogeneous conclusion according to literature, this can be explained by various reasons: the average age of the population, workload, socio religious and quality of life.
Conclusion: Any person engaged daily in a helping relationship with others and subjected to chronic stress may one day be achieved from a burnout staff and caregivers should be informed by disseminating information programs to prevent this scourge.
No conflict of interest.

1774 POSTER

Cultural adaptation and validation of spiritual distress scale

A.C. Mesquita[1], T.P. Simão[2], E.C.L. Chaves[2], C.C. Carvalho[2], E.C. Carvalho[1], Y.L.K. Ya-Lie Ku[3], D.H. Iunes[2]. *[1]University of São Paulo, College of Nursing at Ribeirão Preto, Ribeirao Preto − SP, Brazil; [2]Federal University of Alfenas, College of Nursing, Alfenas − MG, Brazil; [3]Fooyin University, College of Nursing, Taiwan, China*

Objective: To adapt and validate the Spiritual Distress Scale for Brazilian culture.
Methodology: A methodological study conducted in 2012, with 150 cancer patients treated in a general hospital. The Spiritual Distress Scale, created in Taiwan, consists of 30 items divided into four domains (individual's relationship with himself, with others, with God and facing death). His response options are presented on a Likert scale of six points. The sum of the items may vary from 30 to 180 points, so that higher values indicate higher level of spiritual distress. The process of cultural adaptation of the scale has the following steps: translation (English-Portuguese) and reverse translation (Portuguese-English), review by committee of judges, cultural equivalence assessment and pre-test. To construct validity divergent applied to Scale Spiritual Well-Being, considered the gold standard in this type of validity. For statistical analysis we used the kappa coefficient, the Cronbach's alpha coefficient and Spearman correlation. Analyses were performed in the application Statistical Package for Social Sciences (SPSS).
Results: Among the items on the scale only 4 had difficulty understanding by patients in the evaluation phase of cultural equivalence, which were modified after review by a panel of judges. The intra-and inter analyzes were satisfactory, since 60% of the items presented kappa coefficient above 0.75. We observed satisfactory internal consistency with a Cronbach's alpha of 0.87. Correlation analysis between the scales has revealed an inverse correlation ($r = -0.468$, $p < 0.001$) there between.
Conclusion: This study has been able to adapt and validate the Spiritual Distress Scale, an instrument capable of identifying the presence of the phenomenon that purports to measure (spiritual distress), as demonstrated validity and reliability.
No conflict of interest.

1775 POSTER

Why bothering? Experience-based co-design makes 1 + 1 = 3

P. Den Hartog[1], J. Van der Klooster[2], W.L.E. Vasmel[2]. *[1]Sint Lucas Andreas Ziekenhuis, Amsterdam, Netherlands; [2]Sint Lucas Andreas Ziekenhuis, Hematology-Oncology, Amsterdam, Netherlands*

Background: For continuous improvement of the service level in hospital care, we use many methods to get feedback from patients. But next, in the requested actions for improvement, the patient is often neglected. In a Dutch teaching hospital we started a project based on EBCD ("experience-based co-design"), developed by the King's Fund/National Health Service, United Kingdom.
Method: EBCD focuses primary on experiences and emotions instead of opinions and views. EBCD involves gathering experiences from patients and staff through in/depth interviewing, observations and group dicussions; identifying key 'touch points' (emotionally significant points) and assigning positive or negative feelings. In an impactful series of photos the service to patients is made perceptible. Staff and patients together identify areas for redesign, and work together to make improvements to the service and to the pathway of care.
Participating patients: Hemato-oncologic patients chronically treated with (immuno-)chemotherapy.
Workingplan: 4 groups were formed (patients; sounding board group and focus group, caregivers and external observators). These 4 groups selected the most important and urgent actions of improvement, based on the jointed experiences. Next 4 newly mixed co-design groups tackled the chosen issues. The patient sounding board group monitored the progression and the results of the actions taken.
Results: With 4 co-design groups, we worked on; (a) a better information regarding visiting the dentist before and during treatment, (b) better communication between family doctor an specialist/hospital, (c) guidance of waiting time during visits, (d) a more pleasant atmosphere and ambience on the out patient department and short stay unit.
Conclusions: The EBCD method offered an effective tool to work on the service level as experienced by our hematology-oncology patients and caregivers together. In a stimulating and valuable cooperation important results have been achieved. Moreover, EBCD offers the opportunity to verify with patients that actions performed indeed succed in improving patients experiences.
No conflict of interest.

1776 POSTER

The effectiveness of integrating oncosexology into cancer care: Changes in attitudes and practices of healthcare professionals

N. Fridriksdottir[1], J.I. Jónsdóttir[2], T. Thórsdóttir[3], A. Sverrisdóttir[4], T. Saevarsdóttir[3], S. Zoega[5], G. Sverrisdóttir[6], G.V. Einarsson[7], S. Gunnarsdóttir[8]. *[1]Landspitali University Hospital and University of Iceland, Medical Oncology|Hematology|Palliative Care, Reykjavik, Iceland; [2]Landspitali University Hospital, Medical Oncology|Hematology|Palliative Care, Reykjavik, Iceland; [3]Landspitali University Hospital, Medical Oncology|Hematology, Reykjavik, Iceland; [4]Landspitali University Hospital, Medical Oncology, Reykjavik, Iceland; [5]Landspitali University Hospital, Surgical Oncology, Reykjavik, Iceland; [6]Landspitali University Hospital, Gynecological Oncology, Reykjavik, Iceland; [7]Landspitali University Hospital, Urological Oncology, Reykjavik, Iceland; [8]Landspitali University Hospital and University of Iceland, Medical Oncology|Hematology|Palliative Care, Reykjavik, Iceland*

Background: Sexuality problems are experienced by 40–100% of cancer patients but healthcare professionals rarely address these issues. In 2012 a two year project was completed integrating oncosexology by training professionals in communication about sexuality issues. The purpose of the study was to evaluate the effectiveness of the intervention by assessing the attitudes and practices of nurses and physicians towards cancer-related sexual health issues.
Material and Methods: The intervention included two workshops for 40 key-staff members from 10 units in one hospital, staff-educational meetings, staff-pocket guides, patient education material, a web-site on sexuality and cancer, and services of a sexuality counselor. A questionnaire assessing common practices, attitudes, and possible barriers to discussing sexuality-related issues in daily work (Hautamäki etal, 2007) was mailed electronically to all nurses and physicians working in medical, surgical, and gynecological oncology, pre-intervention (T1, $N = 206$), after 11 months (T2, $N = 216$), and after 17 months (T3, $N = 210$).
Results: The response rate was 66% at T1, 45% at T2 and 38% at T3. No differences were found between the three time points with regard to background variables. At all time points the majority regarded discussions on sexuality-related issues with patients as a part of their job. Scores on having enough knowledge and training increased both significantly ($p < 0.05$) over time, more for those who attended the workshops. Significant improvements were reported in six of eight practice issues and more by those who attended the training ($p < 0.05$). A total of 10−16% reported discussing sexuality-related issues with more than 50% of patients and the prevalence was higher among trainees (19%) than non-trainees (9%) ($p < 0.001$). The main barriers for discussing sexual issues were lack of time (40%) and privacy (27%) among those who attended the workshops, but lack of training (30%) and not important to discuss (30%) were reported by those who did not attend the training.
Conclusions: The results indicate improvements in both knowledge and practices, but probably for a minority of patients.
No conflict of interest.

1777 POSTER

Determining communication skills and empowerment perceptions of pediatric oncology nurses

E. Akgun Citak[1], E. Kilicarslan Toruner[2], N. Bora Gunes[3]. *[1]Baskent University Health Sciences Faculty, Nursing, Ankara, Turkey; [2]Gazi University Health Sciences Faculty, Nursing, Ankara, Turkey; [3]Kirikkale University Health Sciences Faculty, Nursing, Ankara, Turkey*

Background: Cancer and cancer treatment is a challenging situation for children and their families. For this reason, commutation is especially

important in pediatric oncology nursing. Empowerment of nurses in communication and interaction affects the quality of care in the patients.
Material and Methods: This descriptive study was conducted to determine the communication skills and empowerment perceptions of nurses in a pediatric hematology-oncology hospital, Ankara, Turkey in 2012. Totally 55 pediatric oncology staff nurses worked in the hospital and 48 nurses accepted to participate in the study. Data were collected with a descriptive form for nurses, empowerment perception scale (EPS) (min-max score=0−60) with the four dimensions of empowerment related to meaningful work, competence, self-determination and impact. Communication skills asessment scale (CSAS) scores between 45–225. High points in both scales indicate well perception and good communication skills. Data were analyzed by Pearson test.
Results: Nurses' mean age was 29.06±4.1 and their mean working year as a pediatric oncology nurse was 2.22±1.98. Most of them were women (89.6%). Mean total EPS score was 47.0±5.4. When dimensions of EPS analyzed, meaningful work scores mean was 14.00±1.22; competence scores mean was 12.27±1.84, self determination mean was 11.04±2.03 and impact scores mean was 9.68±2.20.
Mean CSES score was found 185.7±14.7. Low- moderate correlation was found statistically significant between scales of EPS and CSES. ($r = 0.382$, $p = 0.007$). Moderate correlation was found statistically significant between scales of meaningful work ($r = 0.441$, $p = 0.007$), competence($r = 0.336$, $p = 0.01$) and impact ($r = 0.334$, $p = 0.02$) with CSES.
Conclusion: According to the results of the study, it has found that nurses had good communication skills and have positive empowerment perception. Nurses feel mostly empowerment in the meaning of the work and feel less in being able to influence major decisions in an organization. If they have good communication skills, they feel empowerment in meaning of work and reflect confidence in one's ability to perform a job well, and being able to influence major decisions in an organization.
No conflict of interest.

1778 POSTER

How the pluridisciplinary team take care of melanoma: Evaluation, analyse and benefits

C. Bertrand[1], L. Canon[2], I. Tromme[3], P. Richez[3], L. Marot[3], J.F. Baurain[4], F. Cornelis[4], F. Chateau[5], N. Legrand[1], F. Maddelena[1]. *[1]Cliniques Universitaires Saint Luc, Coordinating Care Nurse, Bruxelles, Belgium; [2]Cliniques Universitaires Saint Luc, Quality Support, Bruxelles, Belgium; [3]Cliniques Universitaires Saint Luc, Dermatology, Bruxelles, Belgium; [4]Cliniques Universitaires Saint Luc, Oncology, Bruxelles, Belgium; [5]Cliniques Universitaires Saint Luc, Plastic Surgery, Bruxelles, Belgium*

Context: The oncological context in which we are has evolved and is constantly changing. More and more patients with specific expectations have longer and more complex treatments that are supported by different professional teams with various more or less impacts.
Pioneer regarding multidisciplinary consultations at the cancer center of Cliniques Universitaires Saint-Luc, and concerned to improve the quality of the taking care for its patients, the melanoma clinic wanted to know its patients' opinion.
Objectives: Benefits of the multidisciplinary consultation and evaluation of information tools created.
We created a questionnaire for patients suffering from a melanoma stage 1b needing a sentinel lymph node search. Those patients have seen a dermatologist, an oncologist, a plastic surgeon and a coordinating care nurse during consultations. We were also willing to evaluate the communication tools given to the patients: personalised care planning, treatment monitoring and explanatory brochures.
Finally we wanted to know the consistency of our information.
- Qualitative evaluation concerned each contributor and each tool used.
- The study allowed us to find the patient's entrance, to highlight the relevance of each contributor and for the very first time the role of the coordinating care nurse
- The coordinating nurse gave the questionnaire to 80 patients for a period of 3 months.

Results: The multidisciplinary consultation presents a real advantage for the patients and their family, this kind of consultation reassures them and allows them to feel better supported.
The communication tools are a great help for the patients and help them to feel themselves actors of their own treatment.
This study showed us that 91% of the patients or their family kept in touch with the coordinating care nurse and that this contact was very helpful for them.
Conclusion: That kind of consultation energizes the care team; each one has his own place in such a transversal and multidisciplinary organization to the patient's benefit.
Moreover, it allows a better internal coordination and saves time.
Those results confirm us the real benefit of a multidisciplinary consultation as well as the communication tools put at the patient's service.
The patient's clinical itinerary is clarified.
The study illustrates the complementarity of each contributor.
The profession of the coordinating care nurse in oncology appears to be primordial and shows us how much that person is the privileged one.
No conflict of interest.

1779 POSTER

Sense of coherence − a measurement of successful coping remains stable during the first year after breast cancer surgery

C. Lindblad[1], A. Eklöf Langius[2], L.M. Petersson[3], K.F. Sjölund[4], K. Sandelin[5]. *[1]Karolinska Universitetssjukhuset Karolinska Institutet, Department of Physiology and Pharmacology, Solna Stockholm, Sweden; [2]Karolinska Institutet, Department of Neurobiology Care Sciences and Society, Solna Stockholm, Sweden; [3]Karolinska Institutet, Department of Neuroscience, Solna Stockholm, Sweden; [4]Karolinska Institutet, Department of Physiology and Pharmacology, Solna Stockholm, Sweden; [5]Karolinska Institutet, Department of Molecular Medicine and Surgery, Solna Stockholm, Sweden*

Background: Some women with breast cancer have symptoms attributed to treatment which affects quality of life. Sense of Coherence (SOC) can be measured by a health-related quality of life questionnaire with 13 items that reflect the individual's ability to manage difficulties according to the salutogenesis theory model by Antonovsky. High scoring levels of SOC indicate a better coping strategy to the illness. Preliminary results have shown that SOC was stable over time in a subsample of breast cancer patients. The purpose of the study was to evaluate SOC for stability over time in a large multicenter cohort of women that underwent breast cancer surgery.
Material and Methods: At four Swedish hospitals 567 women were included between 1999–2004 and 417 (74%) completed the SOC questionnaires preoperatively and one year postoperatively. The reliability was tested using Cronbach's alpha reliability coefficient. The intra class correlation (ICC) was measured to evaluate the correlation between SOC pre- and postoperatively. Cohen's effect size was calculated to evaluate the magnitude of mean differences of SOC.
Results: SOC scores did not change during the first yearly assessment, neither individually nor on group level. The internal consistency was adequate. Cronbach's alpha was at T 1 0.816 and at T 2 0.841. The ICC between SOC preoperative and one year postoperative was 0.68 ($p < 0.001$). Cohen's effect size was 0.06 indicating a minimal change over time. The surgical and adjuvant treatment did not affect SOC levels.
Conclusions: This longitudinal prospective study shows that SOC is stable the first 12 months after breast cancer surgery.
No conflict of interest.

1780 POSTER

Use of internet to access health-related information: Perspectives from patients with cancer and other chronic diseases, their relatives and nurses

A. Akman[1], N. Akgul[1], S. Kav[1], N. Elbas[1]. *[1]Baskent University, Department of Nursing, Baglica − Ankara, Turkey*

Background: Internet is used commonly in the world as a powerful communication and information resource. As indicated in the literature, individuals have used internet to get information about their or loved ones' health problems. Especially patient with cancer and other chronic diseases may seek more information due to complexity of the treatment regimens and disease trajectory. It is as simple as to touch a few keys to access the desired information on the internet; however it can be quite difficult to reach accurate, up to date, evidence-based information. Patients and their relatives can easily get confused and this may influence their compliance. Since increased use of internet and availability of the information resources, nurses need to assess whether patients and their relatives seeking information on the internet and provide evidence-based and reliable information resources. We aimed to investigate opinions and experiences towards internet usage for access to health related information from the perspectives of the patient with cancer and other chronic diseases, their relatives and nurses who caring for them.
Material and Methods: This descriptive study is conducted in medical departments and oncology clinics in a University Hospital located in Ankara, Turkey. Following the pilot study, the sample has been calculated as 216 patients and 216 relatives; besides all nurses working in these departments were included. The data has been collected with questionnaires for patients, their relatives and nurses which were developed by the researchers based on the literature. Independent variables of this study include socio-demographic characteristics, disease duration, having

internet access and skills; dependent variables are mean duration of internet usage, the opinions about reliability of the resources and use of internet.
Results: Until now, we have reached 35 cancer patients and their relatives; 40 patients with other chronic diseases and 71 nurses. The study is continued and data will be analysed with descriptive statistics and chi-square tests in SPSS 17.0 program.
Conclusions: This study will contribute to raising awareness about internet usage among patients and their relatives, and provide insights to nurses about current practices. Results from this study will also guide to develop web based educational resources.
No conflict of interest.

Poster Session (Sat, 28 Sep − Mon, 30 Sep)
Nursing − Supportive and Palliative Care

1781 POSTER

Patients attitudes towards follow up

M.L. Bonetti[1], G. Ruggieri[1], C. Moleri[1], F. Bettini[1], M. Cabiddu[2], M. Ghilardi[2], F. Petrelli[2], K. Borgonovo[2], S. Barni[2]. *[1]Azienda Ospedaliera Treviglio, Psychoncology Service Oncology, Treviglio, Italy; [2]Azienda Ospedaliera Treviglio, Oncology, Treviglio, Italy*

Background: The increasing of long survivor's patients (pts) is creating some planning and economical difficulties in Oncology Departments.'Who' and 'how' manage follow-up (FU) is an open discussion, but pts preferences are rarely taken into consideration. With this aim, we started our study.
Material and Methods: We investigated pts feelings before check up, main worries and fears, meaning given to the FU, their relationship with the oncologist and the level of satisfaction about FU procedures. From February 2012 to March 2013, 450 pts in FU (63.3% female; average age 62 -range 34−85; prevailing pathologies: 46.2% gastrointestinal, 42.6% breast) were interviewed using an anonymous structured questionnaire, before the visit with the oncologist.
Pts were divided into three groups, regarding the number of years of their check up: a) less than 5 years (53.5%) b) between 5 and 10 years (33.6%) c) more than 10 years (12.8%).
Results: 62.2% pts feel trust and serenity, 21% feel anxiety and 15% fear and worry. Prevailing worries are linked to disease recurrence (44.9%), 15.3% about surgery and 9.8% chemotherapy. A high percentage is not worried (29.8%).
Most important clinical meanings given to FU are: evaluation of health situation(37.8%) and early detection of disease's relapse (22.4%); 25.5% of pts gives FU a psychological meaning (44% from groups b and c): mantain the relationship with the oncologist and reassure themself. This aspect is confirmed by the choice to consider the oncologist as reference point for every health problems from more than 74% pts of the c group. 72% pts are satisfied about FU procedures, 9.8% would prefer to undergo fewer examinations and 11.6% ask for more meetings with the oncologist.
Conclusions: Our data suggest a deep relationship between pts and oncologist, but also pts' fear to be abandoned. The necessity to move FU to different clinical professionists (pratictioner or trained nurses) should pass throught a strong cohoperations of this figures since the first taking care of pts so to create the feeling of a multidisciplinary equipe.
No conflict of interest.

1782 POSTER

The introduction of an art-therapy program for oncological patients at the Oncology Institute of Southern Switzerland: A pilot study

D. Valcarenghi[1], C. Pedrazzani[1], L. Broggini[2], M. Bianchi[3]. *[1]IOSI -San Giovanni Hospital, Development and Nursing Research, Bellinzona, Switzerland; [2]IOSI -San Giovanni Hospital, Art-therapist, Bellinzona, Switzerland; [3]IOSI -San Giovanni Hospital, Nursing Officer, Bellinzona, Switzerland*

Background: Several studies confirm that art-therapy can give a better psychophysical well-being to patient suffering from different pathologies, oncological patients included.
The various ways of communication of art-therapy (such as drawing, painting, music) stir the creative abilities that every person has and that keeps existing even during difficult and apparently unmanageable moments. In Autumn 2010, it was decided to start a similar program at the Oncology Institute of Southern Switzerland (IOSI), addressed to in-patients and to consider its effects.
Material and Methods: In order to consider the acceptability and the possible benefits expressed by patients, a pilot study was realized from May 23rd until December 18th 2011 with all the new patients in care for more than five days at IOSI. Two questionnaires were created: one given to all new patients in hospital during that period and the other given only to patients that had participated at least at one art-therapy session. A thematic analysis of the drawings had then been made by an art-therapist.
Results: On a sample of 315 patients (481 admissions), 168 had a stay longer than five days and 51 answered the first questionnaire (30.4%). Some of them (28 out of 51) didn't take part in the art-therapy sessions because of different reasons (they didn't like drawing, they thought it was not useful for them, they didn't have time, etc). 23 patients out of 168 participated in art-therapy and the most were women (17), with an average age of 61.4 (range 24−90). The reasons why they took sessions of art-therapy were curiosity (7), to express moods (6) and/or to feel better (6). Practicing art-therapy gave them peace and quiet (6), helped them in communication and relationship with relatives (7) and/or gave them a sense of release (5). All of them would have done it again and some would have kept doing it (13), especially at home (9).
Conclusions: Participants have considered useful art-therapy sessions, because they helped them feeling personally better. The small number of attendances is probably due to context characteristics, both organizational (several admissions of short duration) and cultural (approximate knowledge and patients not used to these kinds of expressive forms).
With the future mind, this projects seems to be indicated only to limited targets of patients, with a long stay in hospital. Due to the study limits, the program wasn't continued after the patients discharge from hospital, despite some wishes expressed.
No conflict of interest.

1783 POSTER

Highly frequent and serious cases of injection site reaction induced by peripheral venous injection of fosaprepitant in anthracycline-treated patients

Y. Sato[1], M. Kondo[2], A. Inagaki[3], H. Komatsu[4], C. Okada[5], T. Sahashi[6], J. Kuroda[2], T. Kimura[2], K. Yamada[1], A. Wakita[3]. *[1]Nagoya City West Medical Center, Department of Pharmacy, Nagoya, Japan; [2]Nagoya City University Hospital, Department of Pharmacy, Nagoya, Japan; [3]Nagoya City West Medical Center, Department of Hematology and Oncology, Nagoya, Japan; [4]Nagoya City University Hospital, Division of Oncology, Nagoya, Japan; [5]Nagoya City West Medical Center, Nursing Department, Nagoya, Japan; [6]Nagoya City University Hospital, Nursing Department, Nagoya, Japan*

Background: Fosaprepitant-associated injection site reaction (ISR) was evaluated in some patients treated with an irritant drug such as cisplatin. Anthracyclines are vesicant drugs that cause severe surrounding tissue damage and necrosis by extravasation. Although little is known about this effect in patients treated with vesicant drugs such as anthracyclines. Therefore, We conducted this retrospective study to clarify the incidence and symptoms of fosaprepitant-associated ISR in patients treated with anthracycline.
Patients and Methods: Incidence and symptoms of ISR were compared between 24 patients with 61 injections of fosaprepitant through peripheral vein (fosaprepitant group) and 40 patients with 98 injections without fosaprepitant (historical control group) before undergoing FEC, AC or (R-)CHOP regimen. We also compared between 16 patients with 28 injections with fosaprepitant and 15 patients with 31 injections of without fosaprepitant before undergoing non-anthracycline regimens such as those containing cisplatin or carboplatin.
Results: There were no statistically significant differences between the fosaprepitant and the historical control groups with regard to background clinical variables (gender, age, BMI, number of prior chemotherapy regimen, chemotherapy regimen used in the present study, and injection site). Both ISR incidence rates per patient and per injection were significantly higher in the fosaprepitant group than in the historical control group (67% *vs.* 15%; *P<0.0001,* 34% *vs.* 8.2%; *P<0.0001*, respectively). By multivariate analysis, fosaprepitant injection was found to be a significant independent variable correlated with ISR risk. Symptoms of ISR observed in 61 injections of fosaprepitant were pain in 14 (23%), redness in 10 (16%), swelling in 6 (10%), and decreased infusion rate in 6 (10%). After an observation period, no ISR occurred when the administration route was changed to central venous injection or oral aprepitant despite continuation of chemotherapy. In the non-anthracycline regimen group, both ISR incidence rates per patient and per injection were no significant differences between the fosaprepitant group and the without fosaprepitant group (31.3% *vs.* 13.3%; *P = 0.3944,* 17.9% *vs.* 6.5%; *P = 0.2398*, respectively).
Conclusion: ISR was induced at high frequency and seriously when fosaprepitant was injected through peripheral vein in patients who received anthracycline. Accordingly, peripheral vein injection of fosaprepitant should be avoided in patients receiving anthracycline-containing chemotherapy.
No conflict of interest.

1784 POSTER

Manual nutrition in cancer

S. Beijer[1], J. Vogel[2], N. Doornink[3], A. Wipkink[4]. [1]*Comprehensive Cancer Centre South, Research Department, Eindhoven, Netherlands;* [2]*Institute Verbeeten, Department of Dietetics, Tilburg, Netherlands;* [3]*Academic Medical Centre, Department of Dietetics, Amsterdam, Netherlands;* [4]*Former Leiden University Medical Centre, Department of Dietetics, Leiden, Netherlands*

Background: In order to give the best nutritional care to cancer patients, dietetic counselling should be based on scientific evidence and best practice. It is important that dieticians, doctors and nurses not only have practical nutritional knowledge of cancer in general, but also have tumour-specific nutritional knowledge and are able to cope with problems that could develop during the different stages and treatment of cancer. Therefore we have developed the Manual for Nutrition in Cancer.
Methods: Thirty-two experienced Dutch dieticians, specialized in oncology, were invited to write a chapter about their field of expertise (expert opinion). To guarantee best evidence, results from the systematic literature search performed for the evidence based Dutch guideline 'Malnutrition in cancer patients' were incorporated and some additional literature searches were executed. The guidelines within the manual have also been approved by the Dutch Dieticians Oncology Group in cooperation with the Surgical Association Dieticians Academic Hospitals and the Dutch Dieticians Haematology and Stem Cell Transplants Group.
Results: The first part of the Manual deals with the role of nutrition during cancer treatment in general. Specific attention is given to (screening for) malnutrition, sarcopenia, energy and nutrient requirements, nutritional complaints and dietetic counselling, clinical nutrition, comorbidity, cancer in the elderly, paediatric oncology, nutritional targets in the period of rehabilitation and in the palliative stage of the disease. The second part of the Manual includes the nutritional problems commonly occurring in 20 tumour types together with the corresponding nutritional advices.
Conclusion: Nutritional care is an important task for dieticians, doctors and nurses. These multidisciplinary guidelines combined in a manual and as a digital guide (www.oncoline.nl) are a very practical tool for all caregivers in the treatment of cancer patients.
No conflict of interest.

1785 POSTER

Recommendation of areas of expertise for nurses in palliative care, at an under-graduate and post-graduate level development of a curriculum, entitled 'Competences for Nurses in Palliative Care' in Denmark

M. Bentzen[1]. [1]*Sankt Lukas Hospice, Hellerup, Denmark*

Background: Surveys carried out by the Danish Knowledge Center for Palliative Care (PAVI) confirm a large variation in education standards in palliative care and medicine in nursing training across Denmark.
Objective: To ensure that palliative patients have equal access to high quality care the Danish Multi-Disciplinary Cancer Group for Palliative Care (DMCG-PAL) prepared a standarised curriculum in order to provide opportunities for nurses to obtain and develop a standardised set of skills in palliative care.
Design and setting: The standardised curriculum of required skills were created, based on a range of national and international palliative care training curricula. The CanMEDS 7-Roles Framework has been adapted to the nursing profession. The required skills have been separated into 4 domains − empirical, ethical, personal and psychosocial. The learning outcomes (knowledge, skills and attitudes) were specified in three levels, in order to show the progression from undergraduate-to postgraduate level of nursing training. The suggested standardised curriculum has been circulated amongst the clinical and educational professional groups in Denmark.
Main outcome measures: The standardised curriculum provides a framework for current and future training of nurses in palliative care and creates a foundation for development and evaluation of professional skills.
Results: 'National Recommendations of Competences for Nurses in Palliative Care' was compiled and published in 2012 with financial support from the Danish Nursing Organisation.
Conclusion: Nursing training in Denmark has been offered a standardised curriculum of required skills in palliative care.
Acknowledgements: The authors are grateful to the Danish Nursing Organisation for their financial support

1786 POSTER

Developing oncology nursing role in palliative care in Serbia

D. Tadic[1]. [1]*Insitute of Oncology and Radiology, Oncology Nursing Section, Belgrade, Serbia*

Palliative care is a relatively new specialty that focuses on promoting the best possible quality of life for patients and family members facing serious, life-threatening illness, through optimal management of physical, psychosocial, emotional and spiritual symptoms. This specialty grew out of the hospice movement and is continuing to evolve as more palliative care teams are integrated into health care systems, more palliative care content is taught in schools of medicine and nursing, and more research is conducted to support an evidence base for palliative interventions. Palliative care of cancer patients is directed to improving quality of life for patients and family members through optimal management of cancer symptoms and complications, adverse effects of its treatment as well as psychosocial, emotional and spiritual problems. Modern oncology advocates the integration of palliative care into specific oncology approach from the time of the cancer diagnosis and continued throughout the course of the illness, across all levels of care and care settings, including inpatients units, ambulatory care clinics, intensive care units, emergency departments, home care, nursing homes, hospices. Nevertheless, comprehensive palliative care of cancer patients requires interdisciplinary approach − the expertise of medicine − oncology, oncology nursing, social work, psychology, counseling, nutrition, special education and rehabilitation, pharmacy, therapists and other health team professionals, to meet the multidimensional needs of patients and their families who are facing serious, life-threatening illnesses. Oncology nursing is the core discipline of palliative care of cancer patients and includes three key elements − working directly with patients and families, working with other health and social care professionals to network and co-ordinate services, and working at an organizational level to plan, develop and manage service provision in local, regional and national settings. Oncology nurse, as a member of palliative care team, must have both basic and very specific knowledge and clinical skills in palliative care in order to be able to meet the needs of patients with chronic and advanced disease improving quality of life for patients and families throughout the experience of illness. Integration of palliative care into the health-care system of the Republic of Serbia is ongoing process and nurses have an important role in supporting that process. Strategy for palliative care (2009–2015) is adopted in accordance with the recommendations from the WHO and Council of Europe, Committee of Ministers 'REC 24 (2003)' regarding organization of palliative care. Palliative care is also included into the National Program "Serbia against Cancer".

1787 POSTER

Unmet supportive care needs in lung and breast cancer: differences by tumour site and by clinical pathways

A. Serena[1], A.C. Griesser[1], M. Eicher[2], V. Sechet[3]. [1]*University Hospital of Lausanne, Medical Directorate, Lausanne, Switzerland;* [2]*University of Applied Sciences and Arts Western Switzerland, Research Development and Services School of Nursing, Fribourg, Switzerland;* [3]*University Hospital of Lausanne, Nursing Directorate, Lausanne, Switzerland*

Background: Supportive care needs assessment aims to identify individuals and subgroups of oncology patients with high levels of unmet needs. This allows targeting appropriate interventions as well as screening and prioritizing specific needs. To date, little is known about differences in supportive care needs of patients with different tumour sites and clinical pathways. Our aim was to explore potential differences in unmet supportive care needs between two of the most common cancers, namely lung and breast cancer.
Material and Methods: This abstract reports a secondary analysis of data collected in two descriptive studies. Both studies recruited a convenience sample of patients in the oncological department of a University Hospital in Switzerland during the chemotherapy phase. Both studies focused on lung (n = 37) or breast (n = 33) cancer patients during the early treatment phase. Unmet needs were measured with the Supportive Care Needs Survey Short Form 34 with 34 items categorised in five domains (psychological, health system and information, physical and daily living, patient care and support, and sexuality needs), measured on a 5-point Likert scale (no need, not applicable=1; satisfied=2; low need=3; moderate need=4; high need=5). The differences between breast and lung cancer patients were tested with Wilcoxon test for the dimensions and with Chi-square test for each dichotomized item (1−2=no need; 3−4−5=need).
Results: Lung cancer patients expressed significantly higher unmet supportive care needs than breast cancer patients on 18 out of 34 items, mostly pertaining to the health system and information ($p = 0.0009$),

psychological (p = 0.0015) and patient care and support (p = 0.0055) domains. Comparing the institution care pathways, breast cancer patients were typically followed in a standardized pathway by a multidisciplinary team (MDTs) composed of specialist physicians and a breast care nurse, while lung cancer patients received unstandardized specialized care without specialised nursing care.
Conclusions: The differences in unmet supportive care needs found in this study could be explained by the differences in tumour site, prognosis and treatment, but also by the differences in clinical pathways. More research is necessary in order to understand the respective role of these factors. Further intervention studies should test whether the counselling by specialized nurses may help reducing unmet supportive care needs.
No conflict of interest.

Nursing − Survivorship and Rehabilitation

1788 POSTER

Implementing a national agenda to achieve person-centered care: the need for multiple strategies

M.I. Fitch[1], I. Nicoll[1], F. Bennie[1]. [1]*Canadian Partnership Against Cancer, Cancer Journey Action Group, Toronto, Canada*

Background: Evidence from patient satisfaction surveys, needs assessments, and stakeholder forums provide a clear picture that cancer patients are not receiving the full range of supportive care services that could be of benefit to them. The cancer system needs to undergo a shift toward person-centered care. Such a cultural shift requires concerted effort and multiple strategies to be successful.
Objective: The purpose of the Cancer Journey Action Group of the Canadian Partnership Against Cancer is to provide leadership to achieve person-centered care in the Canadian cancer care system.
Methods: The Cancer Journey Action Group has developed and implemented several initiatives to demonstrate how person-centered care can be achieved. The initiatives include programs in screening for distress (6^{th} vital sign), patient navigation, on-line support groups, survivorship care plans projects, cancer transition education, and palliative care/end-of-life education. Tools to support this work have been designed including evidence-based practice guidelines, algorithms, and on-line education modules. Evaluation has focused on program uptake, educational effectiveness, inter-professional teamwork and patient satisfaction.
Results: All initiatives have been evaluated by patients/survivors as helpful. Issues of importance to patients/survivors are the focus of conversations with, and assessments by, health care professionals. Critical success factors across the respective programs for achieving person-centered care include clarity of a shared vision, leadership, persistent and concerted effort, and consistent messaging in communications.
Conclusions: Demonstration projects undertaken for each topic area have provided an excellent opportunity to learn about best practices to implement the respective approaches. Guiding principles for implementation and relevant tools/resources have been developed as a result. Although progress toward person-centered care is evident, intentional and concerted efforts are necessary to sustain momentum of these efforts in routine clinical practice.
No conflict of interest.

1789 POSTER

A survivorship screening tool to help identify cancer survivors' needs

L. Beaupin[1], J.A. Hydeman[2], P. Paplham[3]. [1]*Roswell Park Cancer Institute, Buffalo, USA;* [2]*Roswell Park Cancer Institute, Psychosocial Oncology, Buffalo, USA;* [3]*University at Buffalo, School of Nursing, Buffalo, USA*

Background: There are more than 12 million cancer survivors in the United States and they comprise at least 4% of the U.S. population. Cancer survivors report more mental health needs and greater psychological distress compared to the general population, yet many oncologists underestimate distress in their patients' lives and fail to link them to appropriate services when needs are identified. Roswell Park Cancer Institute developed a Survivorship Screening Tool (SST) to identify a cancer survivor's psychosocial, rehabilitative and nutritional concerns.
Methods: The SST was developed by a multidisciplinary team across a range of supportive services, and includes empirically-validated and clinically-relevant questions. Questions are answered using a Likert-type scale, with 0 = No problem and 4 = Severe problem. Two questions elicited feedback regarding the clarity of the instructions and questions, as well as three open-ended questions for patients to share areas that were not addressed, length of time to fill out the measure, and any additional comments. Cutoffs for clinical interventions were developed by each discipline based on research literature.
Results: The SST was piloted in the outpatient Bone Marrow Transplantation Annual Clinic. One hundred and five patients at least 1 year post-transplant were assessed with the SST over a 9-month period. Sixty percent of patients reached the threshold for clinical intervention in at least one area, with 60% of consults triggered for psychosocial oncology. 33% declined consults. Primary concerns identified to trigger clinical intervention included: worry about the future, fatigue, finances, managing work/school/home life, and sexuality/intimacy. Subscales were created to examine concerns related to Physical, Emotional, Practical, and ADL issues. Of note, many patients identified 3+ concerns in each of these areas. The majority of patients (80%) reported <5 minutes to complete the SST and 97% felt that the SST addressed their concerns.
Conclusions: The SST helps identify a cancer survivor's issues. Furthermore, it may allow more efficient use of the patient visit time and will add to the growing literature examining how best to measure and intervene in cancer survivorship.
No conflict of interest.

1790 POSTER

Education − integral part of adult tumour of young adolescents services?

V. Agarwal[1], T. Middle[1], M. Loveday[1], N. Pettitt[1]. [1]*University Hospital Queen Elizabeth, Young Person's Unit, Birmingham, United Kingdom*

Introduction: A patient survey done [CLIC Sargent, (2008), More Than My Illness: Delivering Quality Care for Children with Cancer] among 119 young people with cancer and 91 carers showed that 64% of 16−18 year olds fell behind with studies or did not do as well as they thought they could have, 29% had to leave education and 65% said it was important to get education and training support. Children with cancer rated disruption to education as the second most devastating impact of cancer on them after physical heath [CLIC Sargent (2010), The impact of cancer on a child's world]. Approximately 75% of young people unemployed for more than six months have GCSE qualifications below Level 2 and employment rate of adults with a Level 2 qualification is twice that of those without qualifications [Department of Education, UK, (2011), Building Engagement, Building Futures].
In this study we evaluated the benefits of providing in house educational services offered as an integral part of the adult Tumour and Young Adolescents (TYA) services. To the best of our knowledge, we are the only adult TYA principle treatment centre that provides in house educational services in the UK.
Methodology: Educational services were offered by a qualified teacher to all patients in the TYA unit at the Queen Elizabeth Hospital, Birmingham, UK, as per GCSE syllabus. A total of 52 patients accessed the services (Year 2012–2013) for giving GCSE's or equivalent (functional skills at level 2; n = 34) and for unit accreditation (n = 18). Of the 34 patients who accessed the services for GCSE or equivalent, 29 patients had either left full time education or had level 1 or below qualification. Among the 18 patients who accessed the services for unit accreditation 9 did course work and were assessed by an exam board and 9 of them were teacher assessed.
Results: Among the 29 patients who had left full time education or had level 1 or below qualification, 14 went back to full time education. Fifteen patients sat the GCSE examination or equivalent in the TYA unit. Thirteen patients (86%) achieved level 2 qualifications. All patients who did unit accreditation passed their assessments.
Conclusion: This study demonstrates that providing educational input to patients who are undergoing significant life changing events is possible and an important aspect of the successful patient's rehabilitation and survivorship. The Level 2 Qualification of the TYA students was higher than the national average of 64% (2011–2012).
No conflict of interest.

1791 POSTER

How to endure life during treatment for colorectal cancer

B. Pedersen[1], B. Winther[1], T. Bladt[1], B.K. Hansen[2], A. Norlyk[3]. [1]*Vejle Ygehus, Oncology, Velje, Denmark;* [2]*University College Lillebaelt, Nursing Department in Vejle, Velje, Denmark;* [3]*Aarhus University, Section of Nursing Science, Aarhus, Denmark*

This study explores the post-diagnosis period as experienced by patients with colorectal cancer, who have undergone surgery and/ or medical treatment in outpatient clinics.
The aim was to explore what challenges the patients experienced during treatment and how they coped with their situation. The study was carried

out using a descriptive phenomenological approach. Data were collected from semistructured interviews. Ten patients were interviewed.
The findings showed that the patients' life was characterised by endurance. The patients struggled to endure the omgoing treatment, unpleasant side effects and changes in everyday life related to the disease. Four themes were revealed:coping with bodily changes; reorganisation of everyday life; getting support from close relatives; seeing lift from a different perspective. Daily diarrhoea forced the patients to reorganise everyday life and challanged their body image. Further, every day had to be planned according to the scheduled treatment and prescribed medication. The patients also experienced that the diagnosis involved existential struggling that took great effort and care from close relatives played a sifnificant role for patients'ability to endure treatment and maintain a positive attitude towards life.
Rehabilitative care for patients with colorectal cancer need to be initiated from beginning to end of a treatment course. This includes dialogues about the challenges faced by the patients as supporting the patient in coping with them.
No conflict of interest.

1792 POSTER

The establishment of an oncologic rehabilitation network

N. Bender[1], A. Masullo[1], M. Ghielmini[2], S. Mauri[2]. *[1]Lega Ticinese Contro il Cancro, Bellinzona, Switzerland; [2]IOSI, Medical Oncology, Bellinzona, Switzerland*

Background: It is now recognised that rehabilitation should be part of the oncologic treatment program.New multimodal treatment modalities including surgery, radiotherapy and systemic treatments significantly improved the overall survival, but often at the cost of higher toxicity. This creates new needs of dealing with increased difficulties in professional, social and family life, during and after treatment. We aimed at creating of a network of professionals, which could follow patients from diagnosis to prevent or limit the difficulties due to cancer and its treatment.
Material and Methods: We established a rehabilitation program in one of the IOSI outpatient clinics(Lugano)including prevention, information and support from the initial phase of the illness. We gradually constructed a network of professionals, including specialized nurses, physicians, physiotherapists, ergotherapist, logopedist, nutritionist, psychologist, psychiatrist, social worker, spiritual assistant, stoma therapist, esthetician, hairdresser, stop smocking consultant, volunteers. The coordinating nurse selects the patients, administers a self evaluation form, performs an assessment discussion and organizes the different consultations as needed, tailored to the needs of each single patient and its family. A final evaluation is performed at the end of the treatment.
Results: In 2011, 292 new patients were treated in Lugano, 168 were eligible for the rehabilitation program, and 69 were effectively enrolled in the program. Median age of patients was 64.5 years. The consultations were distributed among the specialists as follows: 25 nutritionist, 25 social worker, 19 physiotherapist, 6 psychologist, 6 esthetician. 28 patients presented a compromised nutritional status at diagnosis and entered a nutrition counseling program, with several benefitting with a weight improvement. The social assistant interventions addressed the economical, organizational or professional reinsertion field. Physiotherapy benefited the physical activities, as demonstrated by measurable performance tests before and after the program. Fatigue was a major limitation to the inclusion in the rehabilitation program.
Conclusions: Despite the limited number of patients and some missing pre- or post-treatment data, we evaluate that this type of multidisciplinary approach is useful for patients and allows an improvement in their quality of life.
No conflict of interest.

1793 POSTER

Age differences in patients salient beliefs about cancer

L. Sigaard[1], A.G. Andreasen[2], E. Ellegaard[2], C.L. Madsen[2], J.H. Andersen[2], H.M. Larsen[2], I. Hartmann[2], D. Schmidt[2], G. Salomonsen[2], K.B. Dieperink[2]. *[1]Odense University Hospital, Odense, Denmark; [2]Odense University Hospital, Department of Oncology, Odense, Denmark*

Background: The number of elderly cancer patients is increasing significantly due to the aging population and the increasing incidence of cancer in general. Our knowledge of elderly cancer patients' thoughts and experiences are sparse.
This project compares two groups of adults and examine whether their thoughts about cancer are identical.
Purpose: To investigate whether there is an age difference in patients' salient beliefs about cancer.
Method: In total 121 patients with different diagnoses in curative cancer therapy completed a self-administered questionnaire. 65 patients <60 years with an average age of 45 years [range 39−59] and 56 patients ⩾60 years with an average age of 69 years [range 60−81].
Only one question was asked: *'What are your thoughts when you hear the word Cancer?'*
The method is based on Salient Belief Assessment (SBA). According to SBA these answers were divided in topics and rated. The first answer on the questionnaire got 10 points, the second 9 points etcetera. The total score was added for each response.
Results: Responses from patients <60 years of age generated in average 4.9 expressions.
Total scores:
Death (7.8)
Disease/Treatment (7.1)
Uncertainty/Insecurity (6.4)
Psychological reactions (5.4)
Hope/fighting spirit (3.7)
Family/Children (3.4)
Loss of control/Powerlessness (2.6)
Responses from patients ⩾60 years of age generated in average 3.5 expressions.
Total scores:
Hope/fighting spirit (7.2)
Psychological reactions (5.1)
Death (4.6)
Uncertainty/Insecurity (4.4)
Disease/Treatment (3.4)
Family/Children (3.1)
Loss of control/Powerlessness (0.7)
Conclusions: Regardless of age, patients' salient beliefs about cancer coincide.
Themes of family/children and psychological reactions have roughly the same score in the two age groups.
Noteworthy is the highest score in patients <60 years is *death*, while the highest score in patients ⩾60 years is *hope/fighting spirit*. In principle, two opposing approaches to cancer.
Salient Belief Assessment requires that clinicians address patients' salient beliefs.
No conflict of interest.

1794 POSTER

Developing and evaluating a self-management psychosocial intervention for men with prostate cancer and their partners: A feasibility study

E. McCaughan[1], K. Parahoo[1]. *[1]University of Ulster, Institute of Nursing, Coleraine, United Kingdom*

Background: The number of men living with prostate cancer and its associated psycho-social problems is rising. Little is known about interventions to help men and their partners cope with the after effects of prostate cancer treatment. This feasibility study aims to develop and pilot a supportive education intervention for men with prostate cancer and their partners.
Methods and Design: This nine week intervention commences on completion of treatment and takes the form of three group and two telephone sessions. The intervention focuses on symptom management, sexual dysfunction, uncertainty management, positive thinking and couple communication. The telephone sessions provide the opportunity for the intervention to be individualised. Twenty Five couples will be assigned to either the intervention or a control group receiving usual care. Participants will be assessed at baseline (on completion of treatment), immediately post-intervention and at one and six months post-intervention. Outcome measures include: self-efficacy (primary outcome), quality of life, symptom distress, uncertainty in illness, benefits of illness, health behaviour and measures of couple communication and support. A caregiver assessment will be completed by the partner. The intervention will also be assessed in terms of structure (cost of the intervention recruitment) and process (experiences and perceptions of facilitators, participants and non-participants).
Conclusion: The feasibility study will provide valuable information on the development and implementation of the intervention. Data on access, recruitment and participation by men and their partners, their views and experience of the different aspects of the intervention and its cost will also be collected. This information will be used to inform a future larger randomised controlled trial with this population.
No conflict of interest.

1795 POSTER

Nurse led rehabilitation consultation

B. Bauer[1], H. Gyldenvang[1], R. Lilleeidet Seest[1], U. Breitenstein Mathiesen[1]. [1]*Rigshospitalet, Oncology, Copenhagen, Denmark*

Background: These years in Denmark there is a huge focus on rehabilitation for cancer patients. In oncology outpatient clinic for women with breast cancer, an increasing portion of our patients receive adjuvant chemotherapy. After completion of chemotherapy women with HER2-positive tumours receive trastuzumab in a group, where rehabilitation needs are addressed. This has gained our interest for investigating the need for rehabilitations among other patients: How they were dealing with side effects in their everyday life, if they had returned to work etc.
Material and Methods: We explored weather patients with HER2-negative tumours would benefit from a nurse led rehabilitation consultation, when they had completed chemotherapy. At June 2012, a pilot project was initiated. A total of 10 women, who had received adjuvant chemotherapy for breast cancer, were invited to tree rehabilitation consultations. The first consultation took place tree weeks after ending chemotherapy and continued after three months and six months respectively. The nurse led rehabilitation consultation was performed by the primary nurse.
The consultations were planned for duration of 30 minutes. Approximately 14 days after each meeting, the women were invited to participate in a phone interview about their experience and outcome of the rehabilitation consultation.
Results: The preliminary results and response from the telephone interviews indicate an immense satisfaction with the rehabilitation consultation. The women have improved their empowerment and they knew where to look for help and support. The rehabilitation consultation increased their feeling of being safe and they felt highly taken care of in the time after the chemotherapy. The women highly recommend that it was their primary nurse, who had followed them through their adjuvant chemotherapy, who led these consultations.
The pilot project is still in process. Updated results will be available in August 2013. The final results will be presented on a poster at ECCO 2013.
Conclusions: If the promising results from the pilot-study are confirmed, we will implement these nurse led rehabilitation consultations in the future as a nursing routine program in our breast cancer oncology outpatient clinic. As a benefit to the nurses, they will be qualified to have a goal-oriented dialog with the patients, about how they are coping with their everyday life and their needs of rehabilitation.
No conflict of interest.

1796 POSTER

Conversations with cancer patients about daily life and rehabilitation needs

L. Ankersen[1], V. Rasmussen[1], P. Thomsen[1]. [1]*Rigshospitalet, Onkologisk klinik afs.5072, Copenhagen, Denmark*

Background: Implementing rehabilitation conversations with cancer patients is a prioritized area at the Oncology Clinic at Copenhagen University Hospital, Rigshospitalet. Our work is based on the assumption that formalized conversations between nurses, patients and relatives about problems, resources and the possibilities for support in everyday life following cancer and cancer treatment, would uncover rehabilitation needs as well as empower the patients and their relatives. By the end of 2012, 56 rehabilitation conversations had been conducted across the six integrated teams at the clinic.
The conversations processes have been different from team to team in terms of patient category, the times at which the conversations were held, informing patients and relatives, the use of interwievguides and the evaluation of the conversations.
The conversations have all been conducted by nurses with extensive oncological experience and training in rehabilitation and communication skills.
The purpose of this study is to describe and evaluate the perceived experience with rehabilitation conversations across the clinic, from three perspectives:
- Nurses' perspective.
- Patients' perspective
- Managerial and organizational perspective

Materials and Methods: The survey was conducted in early 2013 based on four semi-structured focus group interviews, with:
- 11 nurses, who have carried out the conversations about rehabilitation.
- 6 head nurses from each individual team
- 6 nurses who have interviewed patients after completion of the conversations

For all interviews, each lasting one and a half hours, and an interview guide was used.
Other data comprise transcriptions from patient interviews, conducted by phone with patients who have completed the conversations in the individual teams.
Results and Conclusions: The results are preliminary and are being processed; final results and conclusions will be available at the conference. The expected use of our results is:
- Planning future rehabilitation conversations and projects at the Oncology Clinic.
- Asking new questions and creating a foundation for relevant, focused development activities aimed at optimising the rehabilitation effort (hypothesis generating).

No conflict of interest.

1797 POSTER

Sexuality and cancer: information and counselling needs among cancer patients and their significant others

N. Fridriksdottir[1], J.I. Jónsdóttir[2], T. Thórsdóttir[3], A. Sverrisdóttir[4], T. Saevarsdóttir[3], S. Zoega[5], G. Sverrisdóttir[6], G.V. Einarsson[7], S. Gunnarsdóttir[1]. [1]*Landspitali University Hospital and University of Iceland, Medical Oncology/Hematology/Palliative Care, Reykjavik, Iceland;* [2]*Landspitali University Hospital, Medical Oncology/Hematology/Palliative Care, Reykjavik, Iceland;* [3]*Landspitali University Hospital, Medical Oncology/Hematology, Reykjavik, Iceland;* [4]*Landspitali University Hospital, Medical Oncology, Reykjavik, Iceland;* [5]*Landspitali University Hospital, Surgical Oncology, Reykjavik, Iceland;* [6]*Landspitali University Hospital, Gynecological Oncology, Reykjavik, Iceland;* [7]*Landspitali University Hospital, Urological Oncology, Reykjavik, Iceland*

Background: Sexuality problems among cancer patients are well known as well as the need for information and open communication about sexual issues. Cancer patients and significant others are provided with wealth of information and multidisciplinary services, but little is known about how sexuality needs are met. In 2012 a two year project was completed to train professionals in communication about sexuality issues. The purpose of the study was to examine whether cancer patients and their significant others receive too little, adequate or too much information about the effects of cancer/treatment on sexuality; satisfaction with resources offered for sexual problems, and their need for sexuality counseling.
Material and Methods: Patients attending chemotherapy- or radiation outpatient clinics and their significant others were offered to participate in a survey on how information and support needs were met. A self-report questionnaire designed for this study was administered. Data were collected before the initiation of the project (T1, N = 145), after 11 months (T2, N = 134) and after 17 months (T3, N = 166).
Results: 363 patients and 65 significant others participated. Overall almost equal numbers of patients and significant others reported having received adequate information about the effects on physical appearance (80%), fertility issues (70%), sexual functioning (65%) and the effects on relationships/marriage (50%). No difference was found between time points. A total of 60% of patients were satisfied with resources offered for sexuality problems with a 20% increase from T1-T3. The number of patients in need for the service of a sexuality counselor decreased significantly from 69% at T1 to 42% at T3.
Conclusions: The issue of sexuality is as important as other psychosocial needs and should be integrated into daily care. Unmet needs for sexuality-related information and resources ranged from 20−50% for both patients and significant others and did not change over time. Interest in sexuality counseling was expressed by half of patients and decreased significantly over time which may indicate improvements by clinical staff in addressing sexual issues during the project.
No conflict of interest.

Poster Session (Sat, 28 Sep − Mon, 30 Sep)
Nursing − Symptom Management

1799 POSTER

The influence of prayer on the vital signs of patients with cancer undergoing chemotherapy

A.C. Mesquita[1], C. Carvalho[2], E. de Cássia Lopes Chaves[2], T. Prado Simão[2], E. Campos de Carvalho[3]. [1]*College of Nursing University of São Paulo at Ribeirão Preto, College of Nursing, Ribeirao Preto − SP, Brazil;* [2]*Federal University of Alfenas, College of Nursing, Alfenas, Brazil;* [3]*College of Nursing − University of São Paulo at Ribeirão Preto, College of Nursing, Ribeirão Preto, Brazil*

Background: To investigate the influence of prayer on the vital signs of cancer patients undergoing chemotherapy.

Material and Methods: A quasi-experimental study of pre and post-intervention, conducted from February to December 2012, in hospital oncology ward of a general hospital in the south of Minas Gerais. The study population was of 50 patients, the sample selection was done for convenience accounting for 25 subjects. We applied a questionnaire on sociodemographic information and related to spirituality/religiosity, then vital signs were measured − pulse frequency (PF) and respiration (FR), temperature (T) and blood pressure (BP). The intervention was applied for 11 minutes and again the questionnaires were administered and vital signs were measured. Intervention refers to a prayer heard by the patient for a headset. Data were analyzed using the statistical program BioEstat 5.0. The study was approved by the Research Ethics Committee under protocol 063/2011.
Results: Significant differences were observed between the samples before and after intervention for FR ($p = 0.04$) and BP ($P < 0.001$), so that the means of RR and BP before intervention were 20.43 bpm, 122.08 mmHg (systolic) and 80.83 mmHg (diastolic), respectively, after the intervention averages for the same variables were 18.2 bpm, 115.33 mmHg (systolic) and 76.50 mmHg (diastolic).
Conclusions: Prayer has been shown effective in reducing RF and BP. Prayer is a simple practice that provides benefits to the patient and can be used by nurses in providing holistic care.
No conflict of interest.

1800 POSTER

Daily walking during adjuvant chemotherapy for patients with breast and colorectal cancer − a randomized pilot study

M. Backman Malin[1], Y. Wengström Yvonne[1], B. Johansson Birgitta[2], I. Sköldengen Ida[2], A. Berglund Åke[2]. *[1]Karolinska Institutet, Department of Neurobiology Care Science Division of Nursing, Stockholm, Sweden; [2]Uppsala University, Department of Radiology Oncology and Radiation Science, Uppsala, Sweden*

Background: Previous studies have been shown that physical activity during chemotherapy can reduce fatigue, improve symptoms and impact health related quality of life (HRQoL). Challenges associated with intervention studies on physical activity during cancer treatment, relates to good adherence. The aim was to study feasibility and adherence of and physical activity intervention among patients with cancer during adjuvant chemotherapy treatment and to investigate the effects of physical activity on health aspects including fatigue, quality of life and surrogate markers for cardiovascular disease.
Material and Methods: This randomized controlled trial included patients with breast cancer (BRCA) and colorectal cancer (CRC) during adjuvant chemotherapy. HRQoL was assessed using EORTC QLQ- C30 and the EORTC QLQ-BR 23 for specific HRQoL issues relevant to patient with BRCA and the EORTC QLQ − CR38 module for CRC patients. The intervention continued for 10 weeks and included daily walks of 10,000 steps and a weekly supervised group walk. Adherence was assessed by a pedometer and the number of participants who reported step every week and percentage of participants who achieved the target steps every week.
Results: The majority of participants achieved the target step goal every week and in total 76 % completed the exercise intervention. The most common cause of impaired adherence was illness, hassles with the pedometer and experiencing adverse reactions to treatment. The intervention group increases their daily physical activity and significant differences were found for some breast cancer specific symptoms (movement, swelling and pain). All participants gained weight during the intervention; however the weight gain was lower than expected.
Conclusion: Physical activity in the form of walking is a feasible intervention that patients adhere to during treatment. The physical activity increased in the intervention group during the study time, and had positive impact on HRQoL and symptoms.
No conflict of interest.

1801 POSTER

Addressing oral care in cancer: Presenting the work of the United Kingdom oral mucositis in cancer care group (UKOMIC)

B. Quinn[1], J. Treleaven[2], S. Hoy[2], M. Davies[3], E. Riley[4], M. Thomson[5], F. Campbell[5], K. Mais[6], D. Houghton[7], J. Horn[8]. *[1]Ashford and St Peter's NHS Foundation Trust, Cancer, Surrey, United Kingdom; [2]Royal Marsden NHS Foundation Trust, Cancer, Sutton, United Kingdom; [3]The Christie Hospital NHS Trust, Haematology, Manchester, United Kingdom; [4]Pennine NHS Trust, Dentistry, Manchester, United Kingdom; [5]The Beacon NHS Trust, Radiotherapy, Glasgow, United Kingdom; [6]Nottingham University NHS Hospitals, Radiotherapy, Nottingham, United Kingdom; [7]Riverside Hospital, Pharmacy, London, United Kingdom; [8]NHS Grampian Trust, Haematology, Aberdeen, United Kingdom*

It is widely recognised that oral problems including oral mucositis (OM) can be a significant health burden for the individual, while making substantial demands on health care resources. Both these can be greatly reduced by the correct proactive care and treatment of oral problems.
This presentation will give an overview of the work and clinical guidance of the United Kingdom Oral Mucositis in Cancer Care Group (UKOMIC), a multi-professional group of oral care experts working in a variety of cancer and palliative care centres who have been working to raise awareness and address the often under reported impact of oral problems in cancer care.
Recognising that many clinical teams are unsure about the best way to prevent and treat oral problems and drawing upon their expertise and the most up to date evidence, the group developed guidance on the assessment, prevention, care and treatment of oral problems secondary to disease and treatments. These guidelines have been used to guide practice in a number of cancer settings and palliative care settings across the UK.
The development and the implementation of this expert guidance in multiple cancer settings supports the multi-professional team to anticipate, and attempt to minimise oral side effects in all patients undergoing care and treatment for cancer. Along with developing the guidance the group continues to highlight and address oral care in cancer and palliative care by supporting clinical teams through developing and delivering workshops, educational days, an interactive website, and on line teaching package.

Platelet lysate mucoadhesive formulation to treat oral mucositis: A multidisciplinary approach

I. Bernardini[1], A. Dovas[2], M. Marchesi[2], M. Pioppo[1], D. Bologni[1]. *[1]Perugia Hospital, Perugia Hospital, Perugia, Italy; [2]Perugia Hospital, Immunohaematology and Transfusion Service, Perugia, Italy*

Background: Mucositis is an inflammatory-like process of the mucous membranes lining any part of the digestive tract, not only oral and esophageal but also intestinal and rectal tracts, and the clinical aspects of oral mucositis are often dramatic. Typical examples are ulcerative mucositis of the cheek and of the tongue caused by radiotherapy (neck and head cancer) or mieloablative chemotherapy.
Recently platelet lysate (PL), a hemoderivative obtained by platelet destruction by freeze-thawing of a platelet rich plasma (PRP) sample in the presence of an anticoagulant agent, has proved capable of promoting the healing of buccal lesions.
Material and Methods: The present work focuses on the development and testing of few such formulations, in particular a mucoadhesive gel for the treatment of oral mucositis in haematological patients.
Results: The production of the gel is relatively recent in our hospital, but we have obtained a high organizational improvement. In particular, because our patients are strongly immunosuppressed we use an allogenic PL and the whole procedure of PRP is performed under a laminar flow hood with sterile handling techniques. The PRP was transported in sterile conditions and it was directly applied with sterile techniques.
The PRP produced in this way not only provides a very good quality for the high platelets number but also a sterility condition guaranteed by microbiological control and methods of sterilization 'Evidence Based'.
All treated patients have been found an important benefit with pain reduction and newfound sense of taste with a significant improvement in quality of life.
Conclusions: At the present state of knowledge, PL in mucoadhesive formulations opens a simple and economic option to cure mucosal damages otherwise very difficult to treat. At least on the bases of the formulative work performed, it is possible to provide medical doctors with appropriate vehicles for platelet lysate, easily prepared according to good preparation practices, safe and stable in use conditions.

Swedish Emesis Registry (SER) − a web-based quality assurance tool for prevention and treatment of nausea and vomiting associated with chemotherapy

A. Delin Eriksson[1]. [1]*Sahlgrenska Universitetssjukhuset, Department of Oncology, Göteborg, Sweden*

Background: Chemotherapy-induced nausea and vomiting (CINV) is still a common side-effect and have a major impact on patients' well-being. Opportunities to prevent CINV has increased, but despite this, many patients still have problems especially with delayed nausea and vomiting from a few days up to several weeks after treatment.
Patients often receive chemotherapy as outpatients which mean that they need recommendations on how to perform self-care after treatment. International consensus guidelines are available for how nausea and vomiting should be treated, but they are difficult to follow in everyday clinical use. Also, individual risk-modifying factors are not always accounted for in the guidelines. The aim of the SER is to offer patients evidence-based antiemetic guidelines, taking into account individual risk factors, and ensure the quality of antiemetic treatment by standardized monitoring. The goal is to minimize CINV and by that improving patients' well-being and thus quality of life.
Methods: SER is a web-based quality assurance tool for prevention and treatment of nausea and vomiting associated with chemotherapy. SER consists of evidence-based antiemetic guidelines for all common chemotherapy treatments.
Results: An assessment of the individual patient's risk for nausea is performed and the patient receive antiemetics according to the guidelines. A diary is printed from the register in which the patient register degrees of nausea, vomiting and level of wellbeing in the morning and evening for 10 days after chemotherapy. The diary also prescribes the recommended drugs for CINV for the patient to take when required.
The responses from the patient diary are entered into the database and a new diary is given to the patient. If necessary, i.e. if the patient had CINV despite antiemetics the antiemetic prescription is revised according to the guidelines. Each participating clinic can produce graphs in real-time over diary responses both for individual patients and groups of patients which makes reflections over necessary revisions to the guidelines possible. All participating clinics can also easily compare their own data with all participating clinics data. 31771 diaries from 9403 patients is entered into the register. SER is since 2012 a national quality register and there are currently fourteen oncology clinics in Sweden participating in the registry. The Swedish Emesis Group in Cancer Care have also produced a comprehensive course covering CINV, radiotherapy-induced nausea/vomiting and nausea in the palliative care setting.
Conclusion: By providing evidence-based and individual guidelines for prevention and treatment of nausea and vomiting and follow them up in a standarized way, the chances for an improved quality of life for patients increases. We anticipate that the cooperation within the registry will lead to the establishment of national consensus guidelines which would fully guarantee all patients an equal antiemetic treatment.
No conflict of interest.

Improving the patient safety of the Advanced Symptom Management System (ASyMS) using a risk analysis tool

J. Connaghan[1], M. El Harem[2], R. Maguire[1], J. Cowie[1], L. McCann[1], C. Paterson[1], J. Hughes[1], D. Di Domenico[1]. [1]*University of Dundee, School of Nursing & Midwifery, Dundee, United Kingdom;* [2]*University of Dundee, School of Engineering Physics and Mathematics, Dundee, United Kingdom*

Background: The Advanced Symptom Management System (ASyMS) has been developed over the past 10 years and has been used in a number of different cancer care settings. In the latest study the system is being evaluated in a three-phase, multi-site complex intervention study, with a before and after study design. A risk analysis was undertaken to assess the safety features of the system. Failure Modes, Effects and Criticality Analysis (FMECA) is a risk analysis technique originally used in engineering but has recently been applied in a variety of different settings. It is an innovative approach to testing the safety of a new health technology. The aim of the analysis was to identify all of the potential failures in the system as early as possible in order to eliminate them or mitigate their effects in a timely manner. This paper will outline the methodology used to undertake this risk analysis.
Materials and Methods: FMECA is a prospective risk analysis tool. This method is used to identify and categorise all of the potential failures in a product or system and involves a number of pre-determined stages: 1. Define the elements and boundaries of the system. 2. Calculate the functions of the different elements and their acceptable performance levels. 3. Classify the functional failure modes (i.e. functions that fail to reach an acceptable level of performance), and their causes and effects. 4. Devise methods to detect failure modes. 5. Propose corrective actions to eliminate failures or mitigate the effects of failures. 6. Calculate scores for (a) the likelihood of failure occurrence, (b) the likelihood of failure detection and (c) the potential severity of failure. These three scores were multiplied to give a risk priority number (RPN). 7. RPNs were then used to rank failures modes in order of priority for action. 8. Responsibility was assigned to members of the ASyMS team to implement corrective actions by order of priority.
Results: The successful application of this methodology will be presented using some exemplars from the ASyMS study.
Conclusions: The FMECA method has the potential to be used in assessing the safety of future health technologies in a systematic manner that prioritises safety issues by their potential risk level. This analysis can be performed early in the design stage of a product or system, but can also be used throughout its life cycle to address on-going safety issues.

In two independent randomized trials young high risk breast cancer patients with luminal A tumors had benefit from postmastectomy radiation therapy

T. Laurberg[1], T. Tramm[1], K. Gelmon[2], J. Alsner[1], S. Leung[3], T. Sørlie[4], J. Overgaard[1], T. Nielsen[3], M.C.U. Cheang[5]. [1]*Aarhus University Hospital, Department of Experimental Clinical Oncology, Aarhus, Denmark;* [2]*British Columbia Cancer Agency, Department of Medical Oncoloy, Vancouver, Canada;* [3]*British Columbia Cancer Agency, Genetic Pathology Evaluation Centre, Vancouver, Canada;* [4]*Oslo University Hospital, Department of Genetics Institute for Cancer Research, Oslo, Norway;* [5]*University of North Carolina, Lineberger Comprehensive Cancer Center, Chapel Hill, USA*

Background: Luminal A (LumA) tumors are associated with good prognosis, but with substantial risk for late loco-regional relapses. We aimed to test the predictive value of intrinsic subtypes as defined by research-based PAM50 classifier, for predicting adjuvant radiation therapy benefit among pre-menopausal women with node positive tumors from two independent postmastectomy randomized adjuvant radiation trials with more than 20 years follow-up.
Methods: Formalin fixed paraffin embedded (FFPE) tissues (n = 128) were collected from the British Columbia (BC) trial and fresh frozen (FF) samples (n = 87) were available from a similarly designed study by the Danish Breast Cancer Cooperative Group(DBCG 82b). Gene expression profiles were done using Nanostring nCounter® for FFPE samples and the Human Genome Survey Microarray version 2.0 (Applied Biosystem) for FF samples. Tumors were classified into subtypes (LumA, Luminal B (LumB), Her2-enriched (Her2-E), Basal-like (BLBC) and Normal-like) based on the PAM50 classifier. Kaplan–Meier analysis and log-rank test were used to test the differences in local-regional relapse free survival (LRFS) and Overall Survival (OS).

Table 1. LRFS at 20 years across intrinsic subtypes in BC and DBCG 82b-trials

		BC-trial		DBCG 82b	
		CMF	CMF+RT	CMF	CMF+RT
LumA	LRFS	66%	94%	25%	92%
	p:	0.05		0.01	
LumB	LRFS	40%	60%	89%	86%
	p:	0.66		0.82	
Her2-E	LRFS	69%	65%	76%	90%
	p:	0.70		0.42	
BLBC	LRFS	23%	92%	66%	54%
	p:	0.004		0.33	

Results: In both trials, patients received adjuvant CMF (cyclophosphamide, methotrexate, fluorouracil) and were randomized to postmastectomy radiation therapy (RT) or no RT. The BC trial had a second randomization. Patients with estrogen receptor positive tumor were randomized to receive oophorectomy and 42 of them were included in this correlative study. Table 1 summarized the 20-yr LRFS rate according to subtypes. In both studies, LumA tumors (N = 41 (BC) + 20 (DBCG)) had a significantly better LRFS with postmastectomy RT; however, no difference in OS was observed.

There were no statistical significant differences observed for LRFS for other subtypes.
Conclusion: Radiation appears to significantly decrease local recurrence in premenopausal women with node positive and LumA tumors based upon two small but independent series. Though not definitive, our study suggests that these slow growing tumors may obtain the greatest benefit for regional radiotherapy and thus radiation should not be omitted in young patients with high-risk tumors.
Conflict of interest: *Ownership: M Cheang and T Nielsen are Co-inventor for the patent of PAM50 intrinsic subtype classifier.*

Phase III trial evaluating the addition of bevacizumab to endocrine therapy as first-line treatment for advanced breast cancer − final analysis LEA study

S.L. Loibl[1], R.H. De la Haba[2], G.V.M. Von Minckwitz[1], S. Morales[3], C. Crespo[4], A. Antón[5], E. Carrasco[6], B. Aktas[7], K. Mehta[1], M. Martin[8]. *[1]German Breast Group, Medicine and Reserach, Neu-Isenburg, Germany; [2]H Reina Sofia, Oncology, Córdoba, Spain; [3]H Arnau de Vilanova, Oncology, Lleida, Spain; [4]H Ramon y Cajal, Oncology, Madrid, Spain; [5]H U Miguel Servet, Oncology, Zaragoza, Spain; [6]GEICAM, Headquarters, Madrid, Spain; [7]Universitätsklinikum Essen, Frauenklinik, Essen, Germany; [8]Instituo de Investigación Sanitaria Gregorio Marañón, Medicine and Reserach, Madrid, Spain*

Background: We designed the randomized phase III LEA study of bevacizumab (B) in combination with endocrine therapy (ET), to address the hypothesis that anti-VEGF treatment can prevent resistance to endocrine therapy.
Methods: A multicentre, randomised, open label, phase III study investigated the addition of B 15 mg/kg every 3 weeks to ET with either letrozole or fulvestrant (250 mg/4 weeks) as first-line therapy in advanced breast cancer. Postmenopausal pts with HER2-negative and hormone-receptor-positive breast cancer were randomized in a 1:1 ratio after being stratified for prior adjuvant therapy with an aromatase inhibitor (AI); number of involved sites (one/multiple); measurable lesions (yes/no) and country (Spain/Germany). The primary objective was to compare progression-free survival (PFS). Secondary objectives were overall survival (OS), overall response rate (ORR), response duration (RD), time to treatment failure (TTF), clinical benefit rate (CBR) and safety. The safety analysis (Loibl et al. ESMO2012) and the primary endpoint (Martin et al. SABCS 2012) have been reported previously. We here report the final updated analysis.
Results: From 11/2007 to 11/2011, 380 pts were randomised to ET±B (Spain 270; Germany110). Baseline characteristics were well balanced. Median age was 65 years (38−86). 48% had visceral metastases. 19.5% pts had a prior AI. 72% had a performance status ECOG 0 (86% in Germany and 66% in Spain; p = 0.001). 30% had prior chemotherapy in Germany and 52% in Spain (p = 0.001). All other baseline characteristics were well balanced between the countries.
The median PFS was 14.4 months in ET and 17.7 months in ET+B (HR 0.855 [95% CI 0.671–1.088], log-rank p = 0.202).
Addition of B to ET significantly improved PFS in Germany (HR 0.549 [95% CI 0.341–0.884] log-rank p = 0.0012; interaction test p = 0.733). There was no difference within any other predefined subgroup. ORR was 17% with ET and 32% with ET+B (p = 0.001). The CBR was 66% and 78% (p = 0.012), the RD was 47.9 and 30.7 months (p = 0.011), TTF was 13.8 and 14.0 months; p = 0.471 with ET and ET+B, respectively. The median OS was 51.8 months with ET and 52.1 months with ET+B (HR 1.133 [95% CI 0.753–1.703] p = 0.549).
Conclusions: The LEA study failed to demonstrate a statistically significant increase in PFS by adding bevacizumab to ET as first line therapy. OS was also not impacted.
No conflict of interest.

Complex tumor genomes inferred from plasma DNA of patients with metastatic breast cancer by whole-genome sequencing

M. Auer[1], E. Heitzer[1], P. Ulz[1], G. Pristauz[2], E. Petru[2], S. Jahn[3], I. Lafer[1], K. Pantel[4], M.R. Speicher[1], J.B. Geigl[1]. *[1]Medical University of Graz, Institute of Human Genetics, Graz, Austria; [2]Medical University of Graz, Department of Obstretics and Gynecology, Graz, Austria; [3]Medical University of Graz, Institute of Pathology, Graz, Austria; [4]University Medical Center Hamburg-Eppendorf, Department of Tumor Biology, Hamburg, Germany*

With the increasing number of available predictive biomarkers, clinical management of cancer is becoming more and more reliant on the accurate serial monitoring of tumor genotypes. Recent advances in the understanding of the molecular mechanisms of cancer highlight the need for personalized medicine for both diagnostic purposes and the prediction of prognosis. Serial monitoring of blood biomarkers may explain why some patients initially respond well to therapy, but ultimately relapse due to treatment resistance.
We addressed whether complex tumor genomes may be identified non-invasively from the peripheral blood samples of metastatic breast cancer patients. 71 plasma samples of 58 patients were enrolled in the evaluation including several samples from different time points for 8 patients. Plasma DNA concentration and size distribution was determined and followed by qualitative and quantitative analysis for subsequent whole-genome sequencing at a shallow sequencing depth using the Illumina MiSeq® platform to establish genome-wide copy number profiles. Furthermore we used the CellSearch system® (Veridex) for enumeration of circulation tumor cells (CTCs) from blood. For 3 selected cases we performed in addition whole-exome sequencing of serial plasma DNAs and different areas of the respective primary tumors employing the Illumina HiSeq2000® platform.
A subset of metastatic patients had a biphasic size distribution of plasma DNA fragments, which was associated with an increase of CTCs, elevated concentrations of plasma DNA, and a high percentage of mutated DNA fragments. We were able to identify tumor-specific copy number changes (CNVs) in the plasma DNA associated with breast cancer, such as ERBB2 gene amplification or amplified regions including the CCND1 gene. Furthermore, we identified CNVs, which were not observed in the respective primary tumor and which may reflect tumor evolution. Using exome sequencing we identified mutations in the plasma originating from different tumor sites indicating presence of predominant tumor clones.
The techniques used in this study allow serial monitoring of tumor genomes with a simple blood test. The results yield novel insights, which allow us to address basic research questions, such as processes underlying metastasis and tumor evolution. Furthermore, the use of plasma DNA as prognostic and predictive biomarker may lead to individualization of cancer therapies.
No conflict of interest.

Population based study investigating biopsy verifications of "breast cancer recurrences" and biomarker changes

E. Karlsson[1], J. Appelgren[2], A. Solterbeck[3], M. Bergenheim[4], V. Alvariza[5], J. Bergh[6]. *[1]Central Hospital Karlstad Department of Oncology Karlstad, Department of Oncology and Pathology Karolinska Institutet, Stockholm, Sweden; [2]Karlstad University Karlstad, Department of Economics and Statistics, Karlstad, Sweden; [3]Central Hospital Karlstad, Department of Pathology, Karlstad, Sweden; [4]Central Hospital Karlstad, Department of Surgery, Karlstad, Sweden; [5]Central Hospital Karlstad, Department of Oncology, Karlstad, Sweden; [6]Karolinska Institutet and University Hospital, Department of Oncology and Pathology Karolinska Institutet, Stockholm, Sweden*

Background: Evidence indicates discordance of biomarkers between the primary breast cancer and the corresponding relapse however; only few studies have shown prognostic impact. In the present study, we wanted to investigate tumor related events (e.g. relapse, other malignancy, and benign condition) after primary breast cancer. Furthermore, for patients with confirmed relapse, to perform a comparative analysis of estrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor 2 (HER2) and proliferation (Ki67) between the primary tumor and the relapse. Any discordance in hormonal receptor status was to be correlated to survival.
Patient and Methods: The cohort includes 2102 women with primary invasive breast cancer during 2000 to 2011 in Värmland County, Sweden. Immunhistochemical (IHC)/immunocytocheimcal (ICC) methods were used to determine biomarker status and confirmation of HER2 status by fluorescence in situ hybridization (FISH).
Results: 1060 out of 2102 patients have had a biopsy taken after the initial breast cancer diagnosis. 177 patients (8.4%) had biopsy verifications of breast cancer relapse, 93 (4.4%) second cancer, 40 (1.9%) cancer *in situ* and 857 (40.8%) benign lesions. For patients with relapse, ER (n = 127), PR (n = 101), HER2 (n = 73) and Ki67 (n = 55) status in both primary tumor and the corresponding relapse were determined. The discordance of receptor status was 14.2%, 39.6%, 9.6% and 29.1% respectively. A significant impact on overall survival for ER and PR discordances was shown. In fact, loss of ER in the relapse resulted in a significantly increased risk of death (HR 3.62; 95% CI, 1.65–7.94) compared with stable ER positive patients. In addition, loss of PR in the relapse resulted in a significantly increased risk of death from the time of relapse (HR 2.34; 95% CI, 1.01–5.47) compared with stable PR positive patients. Finally, the proportion of patients losing ER was bigger in the group treated with hormonal therapy alone or in combination with chemotherapy, 16.7% and 13.3%, compared

to the group treated with chemotherapy alone or that which received no treatment 4.3% and 7.7% respectively.
Conclusion: This study demonstrates a discordance of biomarkers between the primary tumor and the corresponding relapse in 10−40%. Patients with loss of ER or PR in relapse have poorer survival compared to patients with stable positive biomarkers. Indeed, adjuvant therapy may affect the loss of hormonal receptors.
No conflict of interest.

Circulating tumor cells before and during therapy in metastatic breast cancer: An individual patient data pooled analysis of European studies

F.C. Bidard[1], D.J. Peeters[2], T. Fehm[3], F. Nole[4], J. Vidal-Martinez[5], D. Mavroudis[6], K. Pantel[7], J.Y. Pierga[1], S. Michiels[8], on behalf of the European Pooled Analysis of CTC group[1]. *[1]Institut Curie, Medical Oncology, Paris, France; [2]Oncology Center GZA Hospitals Sint-Augustinus/University of Antwerp, Translational Cancer Research Unit, Antwerp, Belgium; [3]University of Duesseldorf, Gynaecology, Duesseldorf, Germany; [4]European Institute of Oncology, Medical Oncology, Milan, Italy; [5]Hospital Arnau de Vilanova de Valencia, Clinical Laboratory, Valencia, Spain; [6]University Hospital of Heraklion, Medical Oncology, Heraklion, Greece; [7]University Medical Center Hamburg-Eppendorf, Institute of Tumor Biology, Hamburg, Germany; [8]Institut Gustave Roussy, Biostatistics and Epidemiology, Villejuif, France*

Background: CTCs (CellSearch®) counts before or during therapy have been assessed in metastatic breast cancer patients (MBC pts) in only small- to medium-sized studies, with limited statistical power. We aimed to pool all European studies to obtain high-level evidence on the prognostic value of CTCs, CEA & CA15−3 levels, and to investigate their effects across different MBC subtypes and therapies.
Material and Methods: In December 2012, we searched for eligible studies that accrued patients in 2003–2011 and predefined the methods in a protocol. All European laboratories using CellSearch® were contacted. We used likelihood ratio tests (LR) in Cox regression models stratified by study to assess the independent prognostic value of CTC+ (>= 5 CTCs/7.5 mL), CEA+ & CA15−3+ (normalized values) when added to a clinicopathological (CP) model for progression-free and overall survival (PFS and OS). Landmark analyses were used to assess the prognostic effect of early changes in CTC.
Results: We collected individual data of 1944 MBC pts, from 20 different studies (some unpublished), from 17 centers in 7 European countries. We observed 1507 PFS events and 929 deaths. Baseline CTC count was significantly associated with several patient characteristics, such as performance status (PS, $p<10^{-4}$), synchronous metastasis ($p<10^{-2}$) tumor subtype ($p<10^{-4}$), liver & bone metastases ($p<10^{-4}$), CEA & CA15−3 levels ($p<10^{-4}$). The CP model for OS included PS, MBC subtypes, number of previous lines of treatment, patient's age, metastasis-free interval, liver and brain metastases, and treatment modality ($p < 0.01$ for all). At multivariate analysis, baseline CTC+ was a significant independent predictor of OS (n = 1444, HR = 2.7, 95% CI [2.2−3.2], LR $p<10^{-4}$). CEA had a small added effect to the CP plus baseline CTC+ model for OS (n = 747, HR = 1.3 [1.0−1.6], LR p = 0.024). Finally, early changes in CTC+ status at week 3−5 significantly added prognostic information for OS to a model with CP factors and baseline CTC+ (n = 569, HR = 1.8 [2.2−3.2], LR $p < 0.001$). Additional results will be presented at the meeting.
Conclusions: This large pooled analysis has a previously unreached statistical power and provides level-of-evidence 1 on the independent prognostic value of CTCs before and during treatment in MBC.

The 70-gene signature predicts the risk of locoregional recurrence after adequate breast surgery

M.V. Nijenhuis[1], C.D. Drukker[1], S.G. Elias[2], J. Wesseling[3], H. Bartelink[4], P. Whitworth[5], R. Patel[6], L.J. Van 't Veer[7], P.D. Beitsch[8], E.J.T. Rutgers[1]. *[1]Antoni van Leeuwenhoek − Netherlands Cancer Institute, Surgery, Amsterdam, Netherlands; [2]Antoni van Leeuwenhoek − Netherlands Cancer Institute, Epidemiology, Amsterdam, Netherlands; [3]Antoni van Leeuwenhoek − Netherlands Cancer Institute, Pathology, Amsterdam, Netherlands; [4]Antoni van Leeuwenhoek − Netherlands Cancer Institute, Radiotherapy, Amsterdam, Netherlands; [5]Nashville Breast Cancer, Surgery, Nashville, USA; [6]El Camino Hospital Mountain View, Radiotherapy, Mountain View, USA; [7]University of California, Laboratory Medicine, San Francisco, USA; [8]Dallas Surgical Group, Surgery, Dallas, USA*

Background: The possibility of predicting the risk of ipsilateral locoregional recurrence (LRR) after adequate surgery will allow individually tailored treatment. With the 70-gene signature (70-GS) it is possible to predict the risk of distant metastases in breast cancer and select those patients who will have benefit in survival from adjuvant treatment. Given the strong association between LRR and distant metastases, we hypothesize that the 70-GS will also be predictive for LRR.
Methods: Follow-up and radiotherapy details were updated for 1053 individual breast cancer patients, diagnosed and treated at the Netherlands Cancer Institute between 1984 and 2006. All patients were part of various 70-GS studies and were primarily treated with breast-conserving treatment (BCT) or mastectomy (MST). Adjuvant treatment consisted of radiotherapy, chemotherapy and/or endocrine therapy as indicated by guidelines used at the time.
Results: After 10 years of follow-up (median FU: 8.91 years), 89 LRR events had occurred. 70-GS high risk patients had a significantly higher risk of LRR compared to 70-GS low risk patients ($p<0.001$; Table). The 70-GS had a similar prognostic value for patients treated with BCT or MST ($p = 0.002$; Table). When stratifying for nodal status (positive and negative), the significant difference in LRR risk between 70-GS high and low risk remains for lymph node-negative patients treated with BCT and lymph node-positive patients treated with MST. Among lymph node-negative patients treated with MST no difference in risk of LRR was seen. Multivariate analysis identified 70-GS high risk ($p = 0.021$), lack of adjuvant chemotherapy ($p = 0.032$) and young age ($p<0.001$) as predictors of LRR.
Conclusions: The 70-GS is able to predict the risk of LRR. Patients with 70-GS high risk breast cancers may benefit from more extensive adjuvant treatment to reduce the risk of LRR while patients with 70-GS low risk breast cancers may benefit from more limited treatment strategies.

	Cumulative absolute risk of LRR				
	70-GS high risk (n = 492)		70-GS low risk (n = 561)		*p*-value
	5 years	10 years	5 years	10 years	
Entire group (n = 1053)	9.5%	13.0%	2.7%	6.1%	<0.001
Breast-conserving treatment (n = 481)	7.7%	13.2%	1.6%	5.8%	0.002
Node positive (n = 211)	6.5%	11.6%	1.0%	6.6%	0.116
Node negative (n = 264)	9.0%	15.4%	2.0%	4.9%	0.006
Mastectomy (n = 567)	11.2%	13.0%	3.4%	6.0%	0.002
Node positive (n = 323)	13.8%	15.2%	0.6%	2.0%	<0.001
Node negative (n = 244)	7.5%	9.8%	6.8%	11.1%	0.895

Background: Postmastectomy radiation (PMRT) is primarily offered to patients estimated from clinico-pathological variables to have a high risk of local recurrence (LR). Large randomized trials, including the DBCG82 trials (Danish Breast Cancer Cooperative Group), have nevertheless shown a substantial overall survival benefit after PMRT in patients with low risk of LR. Our hypothesis is that a more refined selection of patients likely to benefit from PMRT can be established through identification of a molecular profile predictive of radiosensitivity in terms of local control.
Materials and Methods: The DBCG82bc cohort constitutes high risk patients (tumor size >5 cm and/or positive lymph nodes and/or invasion in skin or pectoral fascia) diagnosed between 1983−89, treated with mastectomy and partial axillary lymph nodes dissection and randomized to +/− PMRT. From 257 DBCG82bc patients, fresh frozen tumor samples were available. Gene expression was measured in 191/257 samples using whole genome arrays. Genes, whose expression levels interacted with PMRT on the association with LR, were identified through a two step Cox Proportional Hazard model with lasso penalty. In the training set, transfer to quantitative Real Time Polymerase Chain Reaction (qRT-PCR) and formalin fixed, paraffin embedded tissue (FFPE) was performed in order to validate the profile in 931 DBCG82bc patients with only FFPE available.
Results: Seven genes, whose expression interacted with the effect of PMRT, were identified and a weighted index was generated. By dividing the index at the upper quartile, the patients were classified into two groups: high index (25% of the patients) and low index (75%). Among patients not receiving PMRT, a low index was associated with a significantly lower local control rate compared to patients with a high index (31% vs. 90%, $p=3*10^{-5}$). PMRT significantly improved local control rate in patients with a low index (31% vs. 85%, $p=2.6*10^{-8}$); equalizing the rate to patients with a high index, who showed no additional benefit from PMRT in terms of local control (86% vs. 90%, $p = 0.93$). The predictive value was independent of known clinico-pathological parameters. In the training set, there was a significant correlation between risk classifications calculated from microarray and qRT-PCR data. Detection of all genes in the profile by qRT-PCR was successful in 116/931 FFPE validation samples, and the prognostic and predictive value was validated in these samples.
Conclusions: The study presents a gene profile consistently predicting local control and benefit from PMRT. The gene profile can be applied to FFPE, and does not require fresh frozen tissue. The gene profile may assist in identifying patients expected to benefit from PMRT.
Conflict of interest: *Other substantive relationships: Patent filed on the presented gene profile*

Can breast IMRT improve patient reported outcome measures? Results from Cambridge breast IMRT trial

M.B. Mukesh[1], J. Wilkinson[1], L. Dorling[2], W. Qian[3], G. Barnett[1], N. Twyman[1], A.M. Moody[1], N.G. Burnet[4], C. Wilson[1], C.E. Coles[1]. [1]*Cambridge University Hospitals NHS Foundation Trust, Department of Oncology Box 193, Cambridge, United Kingdom;* [2]*University of Cambridge, Strangeways Research Laboratory, Cambridge, United Kingdom;* [3]*Cambridge University Hospitals NHS Foundation Trust, Cambridge Cancer Trials Centre/ Cambridge Clinical Trials Unit-Cancer theme, Cambridge, United Kingdom;* [4]*University of Cambridge, Department of Oncology, Cambridge, United Kingdom*

Background: The use of intensity-modulated radiotherapy (IMRT) in breast cancer reduces clinician-assessed breast tissue toxicity including fibrosis, telengiectasia and sub-optimal cosmesis. Patient reported outcome measures (PROMs) are also important as they provide the patient's perspective. This longitudinal study reports on the (a) effects of IMRT on PROMs compared to standard RT and (b) trend of PROMs over 5 years.
Materials and Methods: PROMs were assessed at baseline (pre-RT), 6, 24 and 60 months after completion of RT using global health and four breast symptom questions (BR23). Also, four breast RT-specific questions were included at 6, 24 and 60 months: change in skin appearance, firmness to touch, reduction in breast size and overall change in breast appearance since RT. The benefits of IMRT over standard RT were assessed using generalized estimating equations (GEE) for global health and logistic regression analysis to compare the proportion of moderate-severe changes for eight breast symptoms at 5 years. A repeated measure multivariate analysis using GEE investigated time trend.
Results: 727/815 (89%), 84%, 81% and 60% patients completed questionnaires at baseline, 6, 24 and 60 months respectively. At 5 years, PROMs assessments did not demonstrate a benefit for IMRT for global health ($p = 0.8$) and breast specific questions (table 1). Patients reported worse toxicity for all four BR23 breast symptoms at 6 months, which then improved over time ($p < 0.0001$). Patients reported improvement in skin appearance and breast hardness over time ($p < 0.0001$), with no significant change for breast shrinkage ($p = 0.47$) and overall breast appearance ($p = 0.13$).
Conclusions: Contrary to clinician assessed outcome, breast IMRT did not translate in to improved PROMs in this study. Only a small proportion of patients reported moderate-severe breast changes post radiotherapy with most PROMs improving over time. Patients' perception of toxicity may be influenced by other psycho-social factors, which requires further investigation. A combination of clinician assessment and PROMs appear optimal for evaluating breast toxicity.
No conflict of interest.

Table 1. PROMs comparing proportion of moderate-severe changes between IMRT and standard RT at 5 years

PROMs	Control (%)	IMRT (%)	p-value
Breast pain	5.2	5.8	0.8
Swollen breast	0	0.8	na
Oversensitive breast	4.8	5	0.9
Breast skin problems	4.4	4.2	0.9
Skin changes post RT	4.5	5.5	0.6
Overall breast changes post RT	13	17.7	0.2
Breast became smaller post RT	13.5	13.4	0.9
Breast became firmer post RT	9	6.4	0.2

Clinical and pathological response after neoadjuvant chemotherapy with or without zoledronic acid for patients with HER2-negative large resectable or stage II or III breast cancer

A. Charehbili[1], S. Van de Ven[2], G.J. Liefers[3], V.T. Smit[4], M.N. Wasser[5], E.M. Meershoek-Klein Kranenbarg[3], A.E. Van Leeuwen-Stok[6], C.J.H. Van de Velde[3], J.W.R. Nortier[2], J.R. Kroep[2]. [1]*Leiden University Medical Center, Medical Oncology and Surgery, Leiden, Netherlands;* [2]*Leiden University Medical Center, Medical Oncology, Leiden, Netherlands;* [3]*Leiden University Medical Center, Surgery, Leiden, Netherlands;* [4]*Leiden University Medical Center, Pathology, Leiden, Netherlands;* [5]*Leiden University Medical Center, Radiology, Leiden, Netherlands;* [6]*Dutch Breast Cancer Trialists' Group (BOOG), Leiden, Netherlands*

Background: The role of bisphosphonates when added to the neoadjuvant treatment of BC in enhancing the clinical and pathological response of tumors is still unknown.
Methods: NEOZOTAC is a national, multicenter, randomized study comparing the efficacy of TAC (docetaxel, Adriamycin and cyclophosphamide i.v.) followed by G-CSF on day 2 with or without ZA 4 mg i.v. q 3 weeks in patients (pts) with stage II/III, measurable, HER2-negative BC and absence of prior bisphosphonate usage. Here we present the primary and secondary endpoints of pathological (pCR and Miller and Payne) and radiological (RECIST 1.1) response. Analysis was based on intent-to-treat. An unplanned subgroup analysis of postmenopausal women (PMW; FSH >20 and estradiol <110) was performed.
Results: From July 2010 to April 2012, 250 patients from 26 participating sites were randomized. Clinical and pathological response data of 213 and 237 pts are currently available. Complete clinical response rate was 23.1% for TAC+ZA and 16.5% for TAC only ($P = 0.21$). Overall clinical response (complete and partial response) did not differ between groups (75.9% for TAC+ZA vs. 75.7% for TAC only) pCR rate also was not different across the two study arms (16.2% vs. 17.5% with addition of ZA, $P = 0.80$). However, a numerical benefit in favor of ZA was observed in PMW (10.6% vs. 17.3% pCR). Additional information on bonemarkers will be ready for presentation at ECCO.
Conclusions: In our population treatment with ZA did not make a difference as regards clinical response nor pCR. Addition of ZA to neoadjuvant CT might be effective for enhancing clinical and pathological response in PMW with BC and predictive markers and should be further investigated.
No conflict of interest.

PI3KCA mutations and correlation with pCR in the NeoALTTO trial (BIG 01−06)

J. Baselga[1], I. Majewski[2], P.G. Nuciforo[3], H. Eidtmann[4], E. Holmes[5], C. Sotiriou[6], D. Fumagalli[6], M.C. Diaz Delgado[3], M. Piccart-Gebhart[7], R. Bernards[2]. [1]*Memorial Sloan Kettering Cancer Center, New York, USA;* [2]*The Netherlands Cancer Institute, Division of Molecular Carcinogenesis, Amsterdam, Netherlands;* [3]*Vall d'Hebron Institute of Oncology, Molecular Oncology Lab, Barcelona, Spain;* [4]*University Medical Center Schleswig-Holstein, Campus Kiel, Kiel, Germany;* [5]*Frontier Science, Statistics, Kincraig, United Kingdom;* [6]*Institut Jules Bordet Université Lire de Bruxelles, Translational Breast Cancer Laboratory, Bruxelles, Belgium;* [7]*Institut Jules Bordet Université Libre de Bruxelles, Breast International Group (BIG), Bruxelles, Belgium*

Background: Understanding the mechanism of resistance to human epidermal growth factor receptor 2 (HER2)-targeted agents is a critical step toward identifying the best therapy for individual patients with HER2-positive breast cancer. Activation of the PI3K/AKT survival pathway is one of the molecular mechanisms that contribute to trastuzumab resistance.
Material and Methods: In the present, study we investigated the influence of PI3K pathway mutations (PIK3CA, KRAS, BRAF, AKT1) on sensitivity to trastuzumab (T), lapatinib (L), or both agents (L+T) in combination in early-stage HER2-positive breast cancer patients enrolled the neoALTTO trial. Genotyping was performed using Mass spectrometry in DNA extracted from 355 of 449 randomized patients with available frozen biopsies at baseline. The primary efficacy endpoint was pathological complete response (pCR) at surgery, defined as the absence of tumor in the breast.
Results: PIK3CA mutations were found in 23% of patients (n = 355, all arms), and 23% (29/124), 19% (21/112), and 25% (30/119) in L, T, and L+T respectively. Only 1 patient (0.3%) had KRAS mutation and no patients had BRAF mutation. PIK3CA mutation rate was similar in ER-positive and -negative groups (23% and 22% respectively). PIK3CA mutations were associated with lower pCR and this relationship was evident across the entire patient cohort, but was most pronounced in the L+T arm. In patients treated with L+T, pCR rate was 55.8% in those lacking PIK3CA mutations and 28.6% in those patients with mutations. The pCR rates for the Lapatanib arm was 14.8% for those with PIK3CA mutations and 20.4% for those without. For the Trastuzumab only arm, the pCR rates were 20.0% and 28.4%. A logistic regression model of pCR, which adjusts for treatment arm and ER status, found significant differences between those with and without the PIK3CA mutation (Odds ratio = 0.45, p = 0.015).
Conclusions: These data provide further evidence of the role of PIK3CA mutations in resistance to trastuzumab and lapatinib-based therapies. Thus, assessment of PIK3CA status might be an important tool in identifying patients unlikely to derive substantial benefit from these treatments.
Conflict of interest: *Advisory board: J Baselga and M. Piccart-Gebhart received honoraria/consultancy fees from Roche-Genentech. Other substantive relationships: C. Sotiriou is co-inventor on a provisional worldwide patent filed by the Université Libre de Bruxelles for a PIK3CA mutation associated gene signature*

Overall and subgroup findings of the aTTom trial: A randomised comparison of continuing adjuvant tamoxifen to 10 years compared to stopping after 5 years in 6953 women with ER positive or ER untested early breast cancer

D.W. Rea[1], R.G. Gray[2], S.J. Bowden[1], K. Handley[3], H.M. Earl[4], C.J. Poole[5], T. Bates[6], J.A. Dewar[7], Z. Raytor[8], M. Lee[9]. [1]*University of Birmingham, Cancer Research UK Clinical Trials Unit School of Cancer Sciences, Birmingham, United Kingdom;* [2]*University of Oxford, Clinical Trials Services Unit, Oxford, United Kingdom;* [3]*University of Birmingham, Birmingham Clinical Trials Unit School of Cancer Sciences, Birmingham, United Kingdom;* [4]*University of Cambridge, NIHR Cambridge Biomedical Research Centre, Cambridge, United Kingdom;* [5]*University of Warwick, Department of Medical Oncology, Coventry, United Kingdom;* [6]*William Harvey Hospital, Department of Surgery, Ashford, United Kingdom;* [7]*University of Dundee, Ninewells Hospital and Medical School, Dundee, United Kingdom;* [8]*University of Bristol NHS Trust, Depatment of Surgery, Bristol, United Kingdom;* [9]*NHS Comissioning Board, Arden Herefordshire and Worcestershire, Worcester, United Kingdom*

Background: Tamoxifen given for 5 years after surgery for ER-positive early breast cancer reduces recurrence and breast cancer mortality and is more effective than treatment for shorter durations. It has been uncertain what advantage there may be to extending tamoxifen treatment to 10 years.
Methods: 6953 women with ER+ (n = 2755), or ER untested (4198) invasive breast cancer from 176 UK centres, relapse free after 5 years of prior adjuvant tamoxifen, were randomised to stop tamoxifen or continue to year 10. 53% were node negative, 31% node positive and 16% unknown nodal status. Annual follow-up recorded compliance, recurrence, mortality, and hospital admissions.
Results: Allocation to continue tamoxifen reduced breast cancer recurrence (580/3468 vs 672/3485, p = 0.003). This reduction was time dependent: rate ratio (RR) 0.99 during years 5−6 after diagnosis [95% CI 0.86–1.15], 0.84 [0.73–0.95] during years 7−9, and 0.75 [0.66–0.86] later. Longer treatment reduced breast cancer mortality (392 vs 443 deaths after recurrence, p = 0.05), RR 1.03 [0.84–1.27] during years 5−9 and 0.77 [0.64–0.92] later; and overall mortality (849 vs 910 deaths, p = 0.1), RR 1.05 [0.90–1.22] during years 5−9 and 0.86 [0.75–0.97] later. Non-breast-cancer mortality was little affected (457 vs 467 deaths, RR 0.94 [0.82–1.07]). There were 102 vs 45 endometrial cancers RR = 2.20 (1.31–2.34, p < 0.0001) with 37 (1.1%) vs 20 (0.6%) deaths (absolute hazard 0.5%, p = 0.02). Combining results of aTTom and its international counterpart ATLAS (Lancet 2013) enhances statistical significance of the reductions in recurrence (p < 0.0001), breast cancer mortality (p = 0.002) and overall survival (p = 0.005) from longer tamoxifen. Rate ratios for recurrence from years 2 onwards were not significantly affected by age with RR <55 years 0.70 [0.53–0.92], RR >55 years 0.80 [0.68–0.94] or nodal status: node-negative RR 0.80 [0.64−1.0] node-positive 0.73 [0.58–0.91].
Conclusions: aTTom confirms the recently reported findings of the complementary ATLAS study that, continuing tamoxifen to year 10 rather than just to year 5 produces further reductions in recurrence and breast cancer deaths. The proportional reduction in recurrence was unaffected by age or nodal status. Benefits from continuing tamoxifen treatment beyond year 5 emerge only after 7 years from start of treatment for recurrence and 10 years for mortality.
No conflict of interest.

1861 POSTER DISCUSSION

Comparing the 70-gene signature to the Dutch Breast Cancer guidelines in the prospective RASTER study

C.A. Drukker[1], J.M. Bueno-de-Mesquita[2], V.P. Retèl[3], W.H. Van Harten[3], H. Van Tinteren[4], J. Wesseling[2], L.J. Van 't Veer[5], E.J.T. Rutgers[1], M.J. Van de Vijver[2], S.C. Linn[6]. [1]*Netherlands Cancer Institute, Department of Surgical Oncology, Amsterdam, Netherlands;* [2]*Netherlands Cancer Institute, Department of Pathology, Amsterdam, Netherlands;* [3]*Netherlands Cancer Institute, Division of Psychosocial Research and Epidemiology, Amsterdam, Netherlands;* [4]*Netherlands Cancer Institute, Department of Biometrics, Amsterdam, Netherlands;* [5]*University of California San Francisco, Department of Laboratory Medicine, San Francisco, USA;* [6]*Netherlands Cancer Institute, Department of Medical Oncology, Amsterdam, Netherlands*

Background: The microarRAy-prognoSTics-in-breast-cancER (RASTER) study was the first study specifically designed to prospectively evaluate the performance of the 70-gene signature and compare the risk estimations of the 70-gene signature to clinico-pathological guidelines. The aim of this study is to compare the risk estimations of the 70-gene signature to the Dutch Institute of Healthcare (CBO) guidelines used at the time of the study (2004) and the CBO guidelines used today (2012).
Methods: A 70-gene signature result was available for 427 patients (cT1−3N0M0). Adjuvant systemic treatment decisions were based on the CBO 2004 guidelines, the 70-gene signature, and doctors' and patients' preferences. Five-year distant-recurrence-free-interval (DRFI) probabilities were compared between subgroups based on the 70-gene signature and the CBO 2004 guidelines and the CBO 2012 guidelines.
Results: Median follow-up was 61.6 months. Fifteen percent (33/219) of the 70-gene signature low-risk patients received adjuvant chemotherapy (ACT) versus 81% (169/208) of 70-gene signature high-risk patients. The 5-year DRFI probabilities for 70-gene signature low-risk and high-risk patients were 97.0% and 91.7%. The 5-year DRFI probabilities according to the CBO 2004 and 2012 guidelines were respectively 96.6% (n = 243) and 99.2% (n = 124) for the low risk patients and 91.5% (n = 184) and 92.4% (n = 303) for the high risk patients. For 70-gene signature low-risk − CBO 2012 high-risk patients who had not received ACT (n = 98), 5-year DRFI was 95.5%. According to the CBO 2012 guidelines 303 patients should receive ACT. If patients were treated according to the 70-gene signature result only 184 patients would have received ACT, a reduction of 39%.

Conclusions: In a prospective observational study, the 5-year DRFI probabilities confirmed the additional prognostic value of the 70-gene signature to clinico-pathologic factors. A reduction of 39% in the use of ACT can be achieved when the result of the 70-gene signature is applied. Omission of ACT despite poor clinico-pathological factors, as judged appropriate by doctors and patients, supported by a low-risk 70-gene signature result, did not compromise outcome.

		70-GS Low risk (n = 219)	70-GS High risk (n = 208)	Total (n = 427)
CBO 2004	Low risk	167 (76%)	76 (37%)	243
	High risk	52 (24%)	132 (63%)	184
CBO 2012	Low risk	88 (40%)	36 (17%)	124
	High risk	131 (60%)	172 (83%)	303

Conflict of interest: *Other substantive relationships: L.J. van 't Veer is listed inventor of 70-gene signature and stockholder, co-founder and employee Agendia NV.W.H. van Harten was until recently a non-stakeholding, non-remunerated member of the supervisory board of Agendia NV.*

1862 POSTER DISCUSSION

Receptor conversion between primary ductal carcinoma in situ (DCIS) and corresponding local relapse

E. Karlsson[1], K. Sandelin[2], J. Appelgren[3], Z. Wenjing[4], K. Jirström[5], J. Bergh[6], F. Wärnberg[7]. *[1]Central Hospital Karlstad Department of Oncology Karlstad, Department of Oncology and Pathology-Karolinska Institutet, Stockholm, Sweden; [2]Karolinska University Hospital, Department of Surgery, Stockholm, Sweden; [3]Karlstad University, Department of Economics and Statistics, Karlstad, Sweden; [4]Uppsala University, Department of Surgery, Uppsala, Sweden; [5]Lund University, Division of Pathology Department of Clinical Sciences, Lund, Sweden; [6]Karolinska Instituitet and University Hospital, Department of Oncology and Pathology-Karolinska Institutet, Stockholm, Sweden; [7]Uppsala University Hospital, Department of Surgery, Uppsala, Sweden*

Background: Emerging data propose biomarker change between primary invasive breast cancer and corresponding metastasis; in addition impact on survival has been shown. We wanted to investigate change of hormonal- and human epidermal growth factor 2 (HER2) receptor status between primary ductal carcinoma in situ (DCIS) and corresponding new ipsilateral events.
Material and Methods: The source population includes 1,504 women from two separate cohorts, diagnosed with a primary DCIS between 1986 and 2004. Out of all 274 women developing a local relapse, 135 (49.3%) women developed an *in situ* relapse and 139 (50.7%) an invasive relapse up to 31st of December 2011. TMA-blocks were constructed from both primary DCIS and relapses. Estrogen receptor (ER) and progesterone receptor (PR) were stained for by immunohistochemistry (IHC) and HER2 by silver-enhanced in situ hybridization (SISH) as well as IHC.
Results: ER (n = 112), PR (n = 113) and HER2 (n = 114) status from both primary DCIS and corresponding relapse was assessed and showed altered receptor status in 15.1%, 29.2% and 10.5% respectively. The receptor conversion was both from negative to positive and from positive to negative and we could not find any general pattern for either loss or gain of receptors for the different biomarkers. Primary DCIS was HER2 positive in 40.3% whereas *in situ* and invasive relapses were HER2 positive in 42.9% and 34.5% respectively. The proportion of patients with altered intraindividual ER or HER2 status between primary tumor and relapse was highest in the group not receiving postoperative radiotherapy, 16.5% versus 11.1% and 13.0% versus 3.4%, respectively.
Conclusions: Receptor conversion for ER, PR and HER2 status occurred between primary DCIS and corresponding new ipsilateral events in 10−30%. When stratified for either *in situ* relapse or invasive relapse, no general pattern for the conversion was seen. This study could not confirm that HER2 status in primary DCIS was of any major importance for tumor progression towards invasive cancer, which has been proposed.
No conflict of interest.

1863 POSTER DISCUSSION

Genetic polymorphisms in the vascular endothelial growth factor gene and breast cancer metastases. An update of the Austrian "tumor of breast tissue: incidence, genetics, and environmental risk factors" study

S. Krenn-Pilko[1], E.M. Thurner[1], A. Ehammer-Rosenkranz[1], W. Renner[2], K.S. Kapp[1], U. Langsenlehner[3], T. Langsenlehner[1]. *[1]Medical University of Graz, Department of Therapeutic Radiology and Oncology, Graz, Austria; [2]Medical University of Graz, Clinical Institute of Medical and Chemical Laboratory Diagnostics, Graz, Austria; [3]GKK Outpatient Department, Division of Internal Medicine, Graz, Austria*

Background: Vascular endothelial growth factor (VEGF) is a key regulator of tumor-induced angiogenesis and essential for tumor growth and distant tumor spread. Aim of the present study was to evaluate the role of VEGF polymorphisms and haplotypes for metastatic progression in breast cancer patients.
Patients and Methods: We performed a prospective study including 801 breast cancer patients from the Austrian TIGER ("tumor of breast tissue: incidence, genetics, and environmental risk factors") study. Occurence of metastases was examined in regular follow-up investigations. Seven VEGF polymorphisms were selected and determined by 5′-nuclease assays (TaqMan). Haplotypes and linkage disequilibrium were determined using the Haploview program.
Results: Within a median follow-up time of 84 months, 165 (21%) patients developed distant metastases. In univariate analysis, the CCCCC haplotype formed by five polymorphisms upstream the coding region was significantly associated with distant metastases-free survival (hazard ratio (HR)=0.743; 95% CI 0.579–0.953; p = 0.019). After adjustment for age, tumor stage, grade, lymph node involvement, and hormone receptor status, the HR for the development of distant metastases was 0.757 for carriers of the CCCCC haplotype (95% CI 0.571–1.003; p = 0.052). In postmenopausal patients, a significant association of the CCCCC haplotype and the VEGF −634G>C polymorphism with distant metastases was observed. Multivariate analysis showed a HR of 0.586 (95% CI 0.393–0.873; p = 0.009) for carriers of the CCCCC haplotype and a HR of 0.651 (95% CI 0.447–0.948; p = 0.025) for carriers of the VEGF −634C>G polymorphism.
Conclusion: We conclude that VEGF gene polymorphisms and haplotypes may influence the development of distant metastases in postmenopausal breast cancer patients.
No conflict of interest.

1864 POSTER DISCUSSION

Sentinel node identification with indocyanine green: concordance and validation study by comparison with 99mTc-labelled radiotracer method (Study IEO S562/510 EudraCT Number 2010–021815−18)

B. Ballardini[1], L. Santoro[2], C. Sangalli[1], G. Renne[3], N. Peradze[1], P. Caldarella[1], G. Lissidini[1], C. Blundo[1], A. Del Castillo[1], P. Veronesi[4]. *[1]European Institute of Oncology, Division of Breast Surgery, Milano, Italy; [2]European Institute of Oncology, Division of Epidemiology and Biostatistics, Milano, Italy; [3]European Institute of Oncology, Division of Pathology, Milano, Italy; [4]European Institute of Oncology, Division of Breast Surgery University of Milan School of Medicine, Milano, Italy*

Background: Sentinel node biopsy (SNB) is the standard procedure for staging the axilla in breast cancer. A growing body of evidence supports the feasibility and efficacy of using the fluorescent dye indocyanine green (ICG) to identify the SN, however this method has not been formally and prospectively compared with the gold-standard radiotracer method in terms of SN detection rate. The aim of the present study was assess concordance between the ICG method and gold standard ^{99m}Tc-radiotracer method and hence determine whether ICG can be used alone to identify the SN.
Materials and Methods: Between June 2011 and January 2013, 134 women with clinically node-negative early breast cancer received subdermal/peritumoral injection of ^{99m}Tc -labeled tracer for lymphoscintigraphy, followed by intraoperative injection of ICG for fluorescence SN detection with an exciting light source (near-infrared) combined with a camera. In all patients, SNs were first identified by the fluorescence method (ICG-positive) and removed. A gamma ray-detecting probe was then used to determine whether ICG-positive SNs were hot (^{99m}Tc-positive) or cold (^{99m}Tc-negative). The gamma ray probe was then used to identify and remove any ^{99m}Tc-positive (ICG-negative) SNs remaining in the axilla. The study IEO S562/510 (EudraCT Number 2010–021815−18) was powered to perform an equivalence analysis − i.e. evaluate whether the ICG method was non-inferior and also non-superior to the ^{99m}Tc method in terms of its ability to identify SNs.

Results: The 134 patients provided 246 SNs, detected by one or both methods. One, 2 and 3 SNs, respectively, were detected, removed and examined in 70 (52.2%), 39 (29.1%) and 17 (12.7%) patients; 4−10 SNs were detected and examined in the remaining 8 patients. The two methods were concordant for 230/246 (93.5%) SNs and discordant for 16 (6.5%) SNs. The ICG method detected 99.6% of all SNs, with only 1 (0.4%) SN detected by the ^{99m}Tc and not the ICG method.
The analysis enabled us to conclude that the ICG method was not inferior and at least equivalent to the ^{99m}Tc method.
Conclusions: Fluorescent lymphangiography with ICG allows good transcutaneous visualization of lymphatic ducts and easy identification of axillary SNs at a frequency non-inferior to that of the gold standard ^{99m}Tc-radiotracer method, suggesting the ICG method for hospitals where radioactive tracer user is is not practicable.
No conflict of interest.

1865 POSTER DISCUSSION

Residual breast tissue after mastectomy: How often and where is it located?

M. Griepsma[1], D.B.W. Roy van Zuidewijn de[2], A.J.K. Grond[3], S. Siesling[4], H. Groen[5], G.H. Bock de[5]. *[1]University Medical Center Groningen, Surgery, Groningen, Netherlands; [2]Medical Centre Leeuwarden, Surgery, Leeuwarden, Netherlands; [3]Pathology Friesland, Pathology, Leeuwarden, Netherlands; [4]Comprehensive Cancer Centre The Netherlands, Department of Research and Registration, Utrecht, Netherlands; [5]University Medical Center Groningen, Epidemiology, Groningen, Netherlands*

Background: Residual breast tissue after a mastectomy can lead to a local recurrence (LR) or a (second) primary breast cancer. Findings of normal breast tissue around a LR or the development of breast cancer after prophylactic mastectomy support this assumption. To date, little is known about the prevalence and localization of residual breast tissue. The aim of the present study was to investigate the prevalence and localization of residual breast tissue after a mastectomy.
Methods: A series of 206 women who underwent a mastectomy between January 2008 and August 2009 in 11 hospitals were enrolled in this study, after signed informed consent. From each mastectomy specimen a total of 36 biopsies were obtained from the superficial dissection plane at predetermined locations. The biopsies were analyzed for the presence of benign breast tissue in the inked superficial area. Differences in percentage of positive biopsies were analyzed using generalized Estimating Equations to account for interdependency of biopsies.
Results: 7,374 biopsies from 206 breast specimens of 206 patients were included in the analysis. In 76.2% of the specimens (N = 157) one or more positive biopsies were found. The positive biopsies were found diffusely across the superficial dissection surface of the specimen with a significant predilection for the lower outer quadrant and the middle circle of the superficial dissection plane.
Conclusions: After a mastectomy there is a substantial probability of residual breast tissue. This tissue is predominantly located in the middle circle of the superficial dissection plane and the lower outer quadrant.
No conflict of interest.

1866 POSTER DISCUSSION

[18F]-fluorodeoxyglucose positron emission tomography can contribute to discriminate patients with poor prognosis in hormone receptor-positive breast cancer

S.G. Ahn[1], T.J. Jeon[2], Y.H. Yoo[2], H.M. Lee[1], S.A. Lee[3], E.J. Son[4], J. Jeong[1], H.D. Lee[1]. *[1]Yonsei University College of Medicine, Surgery, Seoul, South Korea; [2]Yonsei University College of Medicine, Nuclear Medicine, Seoul, South Korea; [3]Eulji University College of Medicine, Surgery, Seoul, South Korea; [4]Yonsei University College of Medicine, Radiology, Seoul, South Korea*

Background: Hormone receptor-positive breast cancer patients show a favorable survival. However, among these patients, identifying the patients in high risk of recurrence is a crucial issue in oncologic field. We tested the hypothesis that [^{18}F]-fluorodeoxyglucose positron emission tomography (FDG-PET) scans can help predict prognosis in hormone receptor-positive breast cancer patients.
Materials and Methods: Between April 2004 and December 2008, 307 patients with breast cancer who underwent FGD-PET were enrolled in this study. The patients of luminal B were identified with positive human epidermal growth factor receptor-2 (HER-2) or high Ki67 (⩾14%). A cut-off value of SUV_{max} was defined as 4 according to the previous analysis. Patients were classified according to immunohistochemical (IHC) method or SUV_{max} acquired from FDG-PET.
Results: At a median follow-up of 5.09 years, the patients of luminal B (n = 83) or high SUV_{max} (n = 108) showed a reduced disease-free survival (DFS) ($P = 0.019$ and $P = 0.005$, respectively; all log-rank test). On multivariate analysis, the patients in luminal B showed a poorer disease-free survival independent of tumor size, nodal status, and estrogen receptor status (hazard ratio (HR) 3.05, 95% confidence interval (CI) 1.14–8.16). Instead of luminal B, on the same multivariate analysis with SUV_{max}, high SUV_{max} was demonstrated as a poor prognostic factor (HR 3.61, 95% CI 1.19–11.00). Finally, the patients with luminal B and high SUV_{max} independently showed a worst disease-free survival with 5.88 of HR (95% CI 2.12–16.29). Harrel *c*-indexes were 0.617 with luminal B and 0.656 with SUV_{max}, and 0.699 with the value combined with luminal B and high SUV_{max}, respectively.
Within the group of luminal B, patients with low SUV_{max} showed a significant longer DFS than patients with high SUV_{max} (P = 0.029). In the group of luminal A, patients with low SUV_{max} resulted in better DFS than patients with high SUV_{max} without statistical significance (P = 0.266). Finally, the patients with luminal B and high SUV_{max} independently showed a worst disease-free survival with 5.88 of HR (95% CI 2.12–16.29) compared to the remaining patients. Harrel *c*-indexes were 0.699 with the value combined with luminal B and high SUV_{max}.
Conclusions: Among hormone receptor-positive breast cancer patients, FDG-PET can help discriminate the patients in high risk of tumor relapse.
No conflict of interest.

1867 POSTER DISCUSSION

Minimal molecular alteration in PI3KCA, FGFR1 and CCND1 is associated with increased benefit from everolimus in hormone receptor-positive, HER2− advanced breast cancer: Insights from the BOLERO-2 trial

J. Baselga[1], M. Piccart[2], M. Gnant[3], H. Burris[4], D. Chen[5], D. Robinson[6], A. Huang[6], R. McDonald[6], T. Taran[7], G. Hortobagyi[8]. *[1]Memorial Sloan Kettering Cancer Center, Department of Oncology, New York, USA; [2]Institut Jules Bordet, Medicine, Brussels, Belgium; [3]Medical University of Vienna, Surgery and Comprehensive Cancer Center, Vienna, Austria; [4]Sarah Cannon Research Institute, Oncology, Nashville, USA; [5]Novartis Pharmaceuticals Corporation, Oncology Correlative Service, East Hanover, USA; [6]Novartis Institutes for BioMedical Research Inc., Oncology Correlative Service, Cambridge, USA; [7]Novartis Pharmaceuticals Corporation, BU Oncology, East Hanover, USA; [8]MD Anderson Cancer Center, Department of Breast Cancer & Gynecology, Houston, USA*

Background: In BOLERO-2 (NCT00863655), everolimus (EVE) plus exemestane (EXE) more than doubled progression-free survival (PFS) vs EXE alone in postmenopausal women with hormone receptor-positive (HR^+), $HER2^-$ advanced breast cancer (BC), with consistent benefits in all clinically defined subgroups in this population. Potential molecular markers for predicting EVE benefit were explored by analyzing alterations of a broad panel of cancer-related genes in archival tumor specimens collected from a subset of BOLERO-2 patients.
Material and Methods: Exon sequence and gene copy number variations in 182 cancer-related genes were assessed by next-generation sequencing (NGS). Univariate and multivariate Cox models were used to evaluate correlations with PFS.
Results: Patients with NGS data (>250X coverage; n = 227; 157 in EVE+EXE arm; 70 in EXE-alone arm) had comparable baseline characteristics and PFS outcomes vs the overall trial population (hazard ratio for PFS=0.40 and 0.45, respectively). Treatment benefit with EVE was maintained in almost all subgroups defined by each gene with a mutation rate >10% (eg, PIK3CA, CCND1), or by combined alterations in multiple

genes of the same pathway (regardless of their mutation rates). However, patients with no or only 1 genetic alteration in any of several key signaling or cell cycle genes (PI3K, FGFR1, CCND1) derived a greater PFS benefit from EVE.
In the EVE+EXE arm, patients without PIK3CA mutation trended toward longer PFS than patients with exon 20 mutations, who in turn appeared to have longer PFS than those with exon 9 mutations, suggesting distinct adaptation or feedback mechanisms conferred by variations in PI3K helical and kinase domains upon mTOR inhibition.
Conclusions: This is the first global registration trial in which efficacy-predictive markers were explored by correlating broad genetic variations with clinical efficacy. It demonstrated the feasibility and power of applying NGS in such trials. The observations suggest the potential complex interplay of multiple oncogenic pathways and of different PI3K functional domains in determining EVE sensitivity in HR^+, $HER2^-$ advanced BC. These exploratory results and their implications in testing new hypotheses for targeted combination therapies will be further investigated.

Pattern of rash, diarrhea, and hepatic toxicities secondary to neoadjuvant lapatinib and their association with age and pathological complete response (pCR) in breast cancer (BC) patients: Analysis from the NeoALTTO trial

H.A. Azim Jr.[1], D. Agbor-tarh[2], I. Bradbury[2], P. Dinh[3], J. Baselga[4], S. Di Cosimo[5], J.G. Greger Jr.[6], H. Eidtmann[7], M. Piccart[1], E. De Azambuja[1]. [1]*Jules Bordet Institute, Brussels, Belgium;* [2]*Frontier Science, Kincraig, United Kingdom;* [3]*Breast International Group, Brussels, Belgium;* [4]*Memorial Sloan-Kettering Cancer Center, New York, USA;* [5]*SOLTI Breast Cancer Research Group, Barcelona, Spain;* [6]*GlaxoSmithKline, Collegeville Pennsylvania, USA;* [7]*University Hospital Kiel, Kiel, Germany*

Background: We investigated the pattern of lapatinib-specific adverse events (AEs); rash, diarrhea, and hepatic AEs in BC patients (pts) and their association with age and pCR.
Material and Methods: NeoALTTO (BIG 1−06/EGF106903) is a multicenter phase 3 neoadjuvant trial in which pts with HER2+ early BC were randomized to either: lapatinib (arm A); trastuzumab (arm B); or the combination (arm C) for 6 weeks followed by the addition of paclitaxel for 12 more weeks prior to surgery. In the current analysis, only pts randomized to arm A or C were included. Per protocol, lapatinib was discontinued if pts developed: > grade (Gr) 2 hepatic AEs (elevated liver enzymes and/or bilirubin), Gr4 rash or persistent Gr3−4 diarrhea. We investigated the time to developing and frequency of each AE by CTCAE Gr version 3 according to age ($\leqslant$50 vs. $\geqslant$50), and the association between each AE and pCR in a logistic regression model adjusted for age, hormone receptor status, tumor size, nodal status, planned breast surgery at diagnosis and treatment arm.
Results: 306 pts were included. The median time in weeks to developing rash, diarrhea, and hepatic AEs was 2 (IQR: 1.1−4.2), 2.1 (0.4−7.7), and 6.8 (4.1–10.3), respectively. Younger pts ($\leqslant$50 years) experienced significantly more rash compared to older pts (74.4% vs. 47.9%, $p < 0.0001$). 4% of pts experienced Gr3−4 rash, with low treatment discontinuation and dose reduction rates; 1.3% and 5.8%, respectively. No differences were found according to age regarding the frequency or severity of diarrhea and hepatic AEs. Diarrhea occurred in 78.8% of pts (n = 241), of whom 28% were Gr3−4 (22% of all pts). 28.1% of pts required dose reduction due to diarrhea and 5% discontinued therapy for this reason. Hepatic AEs occurred in 41.2% of pts (n = 126), of whom 36% were Gr3−4 (14.3% of all pts). 10% of pts discontinued therapy (n = 33) and required dose reduction (n = 31) due to hepatic AEs. In a logistic regression model, pts who developed early rash (i.e. before starting paclitaxel) had a significantly higher chance of achieving pCR (OR: 1.71, 95% CI 1.01–2.88, p = 0.044) compared to pts who did not develop an early rash (44.2% vs. 31.8%). No significant association was observed between pCR and diarrhea or hepatic AEs.
Conclusions: Rash is more common in young pts receiving lapatinib. In addition, early development of rash is associated with a higher chance of achieving pCR, independent of age, treatment arm and other clinicopathologic features.

1869 POSTER DISCUSSION

Pre- and postdiagnostic physical activity levels in relation to breast cancer outcome in postmenopausal breast cancer patients − results of the TEAM-lifestyle study

N.A. De Glas[1], D.B.Y. Fontein[1], E. Bastiaannet[1], A. Pijpe[2], A.J.M. De Craen[3], G.J. Liefers[1], J.C.J.M. De Haes[4], C.J.H. Van de Velde[1], F.E. Van Leeuwen[2]. [1]*Leiden University Medical Center, Department of Surgery, Leiden, Netherlands;* [2]*Netherlands Cancer Institute, Department of Epidemiology and Biostatistics, Amsterdam, Netherlands;* [3]*Leiden University Medical Center, Department of Gerontology & Geriatrics, Leiden, Netherlands;* [4]*Academic Medical Center, Department of Medical Psychology, Amsterdam, Netherlands*

Background: Physical activity (PA) has been related to improved physical function, quality of life and overall and cancer specific survival in breast cancer (BC) patients. PA might have an extra value in treatment of elderly BC patients, since high age is associated with comorbidity and poor physical function. Therefore, the purpose of this study was to investigate the recovery of PA levels after BC treatment in different age groups, and to investigate the effects of PA before and after diagnosis on overall survival, BC survival and recurrence in patients of different ages.
Material and Methods: The TEAM-Lifestyle study is a side-study of the TEAM trial and prospectively investigated lifestyle habits of postmenopausal, hormone-receptor positive BC patients (n = 521). PA was assessed at one year after diagnosis (T1) (including an assessment of prediagnostic PA (T0)) and at two years after diagnosis (T2). The influence of age on recovery of PA (defined as an increase of 3 MET-hours or more from T1 to T2) was analysed in a logistic regression model. Cox regression analysis was used to assess the effect of PA on overall survival. Recurrence-free survival and BC specific survival were calculated by Fine and Gray analyses, taking the risk of competing mortality into account. Here, we present our preliminary findings.
Results: The mean PA level strongly decreased after BC diagnosis and treatment in all patients. Elderly (>65 years) were less likely to recover to prediagnostic PA levels after diagnosis than younger patients (OR 0.61, 95% C.I. 0.41–0.89 compared to patients <65). In both analyses using pre- and postdiagnostic PA data, increased levels of PA (i.e. the three highest quartiles of PA) were associated with an improved overall survival (multivariable HR 0.52, 95% C.I. 0.32–0.84 and HR 0.53, 95% C.I. 0.30–0.96 for the three highest quartiles of pre- and postdiagnostic PA levels compared to the lowest quartile). PA was not significantly associated with BC survival and recurrence-free survival.
Conclusions: In conclusion, elderly BC patients were less likely than younger patients to regain their original levels of PA two years after breast cancer diagnosis. Overall survival was higher in patients who had increased levels of PA, pre- or postdiagnostically, while no statistically significant association was observed for BC recurrence and BC specific survival. More research is needed to investigate the feasibility and efficacy of PA programs in elderly BC patients.
No conflict of interest.

1870 POSTER DISCUSSION

Estimation of an overall treatment time factor for local relapse after adjuvant radiotherapy for early breast cancer by the UK START Trialists' Group

J. Yarnold[1], J. Haviland[2], S.M. Bentzen[3], M. Sydenham[2], R. Owen[4], J. Bliss[2]. [1]*The Institute of Cancer Research, Section of Radiotherapy and Imaging, Sutton, United Kingdom;* [2]*The Institute of Cancer Research, Institute of Cancer Research-Clinical Trials and Statistics Unit (ICR-CTSU), Sutton, United Kingdom;* [3]*University of Wisconsin School of Medicine and Public Health, Biostatistics and Medical Informatics, Madison, USA;* [4]*Cheltenham General Hospital, Gloucestershire Oncology Centre, Cheltenham, United Kingdom*

Background: There is level I evidence that overall treatment time affects the local cancer control rate of squamous carcinomas of the head and neck, but there is as yet no evidence for a similar effect in breast cancer.
Methods: 5861 patients entered into the START (ST)-pilot (P), ST-A & -B trials testing hypofractionated radiotherapy after surgery for early breast cancer form the basis of an estimation of the effect of treatment time.

The ST-P and ST-A trials tested 3.0−3.3 Gy against 2.0 Gy fractions in randomised studies in a constant overall treatment time (5 weeks), allowing direct estimates of the fractionation sensitivity of breast cancer (α/β=3.5 Gy, 95% CI 1.2−5.7). Joint analysis of 10-year local cancer control rates in these trials with those of the ST-B trial testing 15 fractions of 2.67 Gy in 3 weeks against 25 fractions of 2.0 Gy over 5 weeks allows estimation of the possible change in treatment effect in a 3-week vs. a 5-week schedule. A Cox proportional hazards regression analysis of time to loco-regional relapse was stratified for trial to allow for possible differences in case mix among trials. The model included terms for total dose, total dose x dose per fraction (Dxd) and a dummy variable for treatment time (0 = 5 weeks, 1 = 3 weeks), these parameter estimates were used in the following formula to estimate the dose recovered per day (in 2 Gy equivalent fractions), assuming a 14-day time difference between the 2 schedules in ST-B:
$D_{prolif} = (\beta_{time}/14)/(\beta_{Dose} + 2\cdot\beta_{Dxd})$.
Confidence limits of the D_{prolif} estimate were derived by bootstrap resampling.
Results: For N = 5831 patients with data for all variables in the model generated a crude estimate for D_{prolif} (unadjusted) = 0.64 Gy/day. Adjusting for prognostic factors for local-regional relapse in 5613 patients with data for all variables included in the model generated D_{prolif} (adjusted) = 0.59 Gy/day. Non-parametric bootstrap estimates of D_{prolif} and (bias-corrected) 95% CI generated a D_{prolif} (adjusted) = 0.60 Gy/day (95% CI 0.10 to 1.18 Gy/day).
Conclusions: A joint, stratified analysis of the START trials supports the hypothesis that overall treatment time is an important determinant of local cancer control after adjuvant whole breast radiotherapy, with potential for a substantial component of the daily dose required to compensate for proliferation. Overall treatment time should be considered when attempting to devise more efficient and convenient dose-fractionation schedules.
No conflict of interest.

1871 POSTER DISCUSSION

Long-term follow up of axillary recurrences after negative sentinel lymph node biopsy: Effect on prognosis and survival

J. Bulte[1], B.J. Van Wely[1], S. Kasper[2], G. Kuijt[3], F.J.H. Van den Wildenberg[1], L.J.A. Strobbe[1], J.H.W. De Wilt[2]. *[1]Canisius Wilhelmina Hospital, General Surgery, Nijmegen, Netherlands; [2]UMC St Radboud, General Surgery, Nijmegen, Netherlands; [3]Maxima Medical Centre, General Surgery, Veldhoven, Netherlands*

Background: As axillary recurrence (AR) after a negative sentinel lymph node biopsy (SLNB) is rare, the prognosis of these patients is unknown. Since treatment paradigms for patients with breast cancer are shifting towards less axillary surgery, the number of ARs might increase. In this study we evaluated primary and salvage treatment as well as long term survival of patients diagnosed with an AR.
Patients and Methods: A retrospective analysis of the cancer registry of 16 breast cancer units in the Netherlands was used to identify patients who developed an AR after a negative sentinel lymph node biopsy (SLNB) performed between 2002–2004. Using local hospital records we recorded primary patient-, tumor- and treatment characteristics, as well as salvage treatment.

Table 1. Treatment after axillary recurrence

ALND performed	45/54 patients
Lymphnodes removed: median (range)	12 (2−27)
Number of positive nodes, median (range)	3 (1−24)
1−3 positive nodes	26
4−9 positive nodes	9
>9 positive nodes	10
Lymphnode ratio	
mean	0.46
standard deviation	0.34
Restaged	50/54 patients
Ipsilateral in breast recurrence	2
Supraclavicular lymphnode metastases	3
Distant metastasis	7
Adjuvant treatment	(52)
External beam radiotherapy	28
Endocrine therapy	24
Chemotherapy	13
Both endocrine- and chemotherapy	10

Results: We identified 54 patients with an AR, median 30 months (range 3−79) after SLNB. Nineteen patients (35%) were initially treated with breast conserving therapy, 17 of whom received external beam radiation therapy (EBRT). Thirty-three patients (61%) did not receive adjuvant systemic treatment. In 45 of the 54 (83%) patients a salvage axillary lymph node dissection (ALND) was performed showing a median of 3 positive nodes (range 1−24). Nine patients (17%) were not treated surgically: 3 were treated with EBRT and 6 with systemic therapy only. At time of detection of the AR, a total of 7 patients (13%) had proven distant metastases. After a median follow up of 47 months (range 3–118) the 5-year 'post-recurrence' distant metastasis free survival was 50% and overall survival was 58%.
Overall survival was significantly worse in patients with an estrogen receptor negative (ER-) primary tumor (p = 0.012), and for patients who initially received chemotherapy (p = 0.021). Survival was not significantly different for patients with different salvage treatment regimens, or with an early versus late recurrence.
Conclusion: AR following a negative SLNB is associated with a 58% 5-year OS. Prognostic factors are ER negative primary tumor and an indication for adjuvant chemotherapy, reflecting an aggressive phenotype. Adequate regional and systemic salvage therapy constitute a chance for long term survival after AR.
No conflict of interest.

1872 POSTER DISCUSSION

Locoregional radiation therapy for left-sided breast cancer: should volumetric modulated arc therapy and breath hold be combined to minimize heart dose?

M. Essers[1], S.O.S. Osman[1], S. Hol[2], P.H. Poortmans[2]. *[1]Dr. Bernard Verbeeten Institute, Medical Physics and Instrumentation, Tilburg, Netherlands; [2]Dr. Bernard Verbeeten Institute, Radiation Oncology, Tilburg, Netherlands*

Purpose: After the presentation of clinical trial results, the interest in optimising locoregional control for breast cancer increased. Since the relative risk of major coronary events increases linearly with the mean dose to the heart by 7.4% per Gy, with no apparent threshold, the dose to the heart should be kept as low as possible during locoregional breast irradiation.
In this study, we evaluated the role of volumetric modulated arc therapy (VMAT) and voluntary moderately deep inspiration breath hold (vmDIBH) for left-sided breast cancer patients treated to breast/chest wall and internal mammary-medial supraclavicular lymph nodes (IM-MS).
Materials and Methods: For 10 patients, CT scans in free breathing (FB) and vmDIBH were acquired. Three-dimensional conformal RT (3D-CRT) and VMAT plans were calculated for a prescribed dose of 42.6 Gy in 16 fractions. Dose volume values for planning target volume (PTV), heart, lungs and contralateral (CL) breast were compared.
Results: A selection of mean values is presented in Table 1. The coverage of the PTV (volume of PTV with >95% of prescribed dose, $V_{95\%}$) is significantly improved with VMAT, especially for the IM-MS. The heart dose is significantly reduced with both VMAT and vmDIBH, with the lowest values for the combination. The dose to the ipsilateral (IL) lung is also reduced with VMAT, however at the expense of a significantly higher mean dose to the CL lung and breast.

Table 1.

	3D-CRT FB	3D-CRT vmDIBH	VMAT FB	VMAT vmDIBH
IM-MS $V_{95\%}$(%)	90.5	94.6	98.9	99.1
Heart D_{mean}(Gy)	8.8	6.0	5.6	4.4
Heart $V_{30\,Gy}$(%)	10.8	6.0	1.2	0.7
IL lung D_{Mean}(Gy)	19.8	18.1	14.7	14.5
CL Lung D_{Mean}(Gy)	0.3	0.4	3.3	2.4
CL breast D_{mean}(Gy)	0.5	0.6	2.6	2.1

Conclusions: VMAT results in improved dose conformity and PTV coverage, as well as a reduction in heart and lung dose, compared to 3D-CRT. These effects are higher for vmDIBH than for FB. We do not advise standard use of VMAT for patients <40 y, because of possible secondary breast cancer induction, but VMAT might be considered for complicated patient geometries. For patients >40 y, we advise a combination of VMAT and vmDIBH for locoregional irradiation of all left-sided left cancer patients.
No conflict of interest.

Poster Session (Mon, 30 Sep)
Breast Cancer − Advanced Disease

1873 POSTER

Adipose-derived stromal cells isolated from adiponectin deficient mice promote the development of metaplastic mammary tumors

J. Chen[1], A. Xu[2], J. Liu[1], K. Lam[2], Y. Wang[1]. [1]*The University of Hong Kong, Pharmacology and Pharmacy, Hong Kong, China;* [2]*The University of Hong Kong, Medicine, Hong Kong, China*

Background: Adiponectin is a 30kDa glycoprotein secreted exclusively from adipocytes. Unlike most of the adipokines, adiponectin has potent insulin-sensitizing, anti-inflammatory, and anti-tumorigenic activities. Breast cancer development in mice lacking adiponectin exhibits aggressive biological characteristics, including unfavorable prognosis, triple-negative breast tumors and lung metastasis. However, the underlying mechanism remains largely uncharacterized. Adipose-derived stromal cells (ASCs), a population of cells resident in adipose, can regulate breast cancer progression by promoting breast cancer cell proliferation, invasion and migration. The present study aims to investigate the role of ASCs derived from adiponectin deficient mice in breast cancer development.
Materials and Methods: ASCs isolated from wild type [PyVT(+/−)/ADN(+/+)] and adiponectin deficient [PyVT(+/−)/ADN(−/−)] FVB/N-Tg(MMTV-PyVT)634Mul/J mice were implanted into NOD/SCID mice together with human breast cancer MDA-MB-231 cells. Tumor growth and metastasis were evaluated. Gene expression was studied using quantitative real time PCR. Western blot and immunofluoresence was applied for evaluating p63 expression patterns. Chromotin immunoprecipitation (ChIP) was performed to assess the effect of transcriptional factor binding on p63 promoter. Protein interactions were analyzed by co-immunoprecipitation and mass spectrometry.
Results: Tumors derived from MDA-MB-231 cells with co-implanted ASCs derived from PyVT(+/−)/ADN(−/-) mice showed metaplastic breast cancer phenotype, including increased expression of metaplastic markers (p63 and CK14) and muscle-like cellular transdifferentiation. Both protein and mRNA levels of dominate negative p63 (DN-p63) were significantly elevated in tumor tissues derived from MDA-MB-231 cells co-implanted with ASCs of PyVT(+/−)/ADN(−/-) mice, when compared to those co-implanted with ASCs of PyVT(+/−)/ADN(+/+) mice. Mechanistically, it was found that a transcriptional factor YY1 modulated the expression of p63. Adiponectin deficiency promoted the association of YY1 with the promoter of DN-p63. The zinc finger domain of YY1 played a key role in silencing DN-p63 expression.
Conclusion: ASCs of adiponectin deficient mice promotes metaplastic breast cancer development in mice.
No conflict of interest.

1874 POSTER

Glucocorticoid influences on breast cancer metastasis: bad, benign or beneficial?

E. Fietz[1], S. Langenbach[1], N. Al-Zaubai[1], C. Johnstone[2], A. Stewart[1]. [1]*University of Melbourne, Department of Pharmacology, Victoria, Australia;* [2]*Peter MacCallum Cancer Centre, Victoria, Australia*

Background: Chemotherapy-induced nausea and emesis is commonly treated by administration of glucocorticoids. Despite being effective anti-emetics, glucocorticoids are also thought to directly modulate tumour cell behaviour. Breast tumour metastasis involves integrated and sequential processes, influenced by tumour cells and surrounding microenvironment, both of which are targeted by glucocorticoids. We have previously identified a class effect of glucocorticoids in inhibiting serum-induced migration in the human metastatic breast tumour cell line, MDA-MB-231, in a 2-dimensional scrape wound healing assay and a 3-dimensional modified Boyden chamber assay. This study has focused on extending the findings in a mouse model of breast tumour metastasis.
Methods: mCherry-expressing 4T1.2 murine breast tumour cells (500,000) were injected into the 4th mammary fat pad of Balb-c mice. Dexamethasone (dex) was administered subcutaneously at 0.1 mg/kg/day, commencing 2 days after a tumour was first palpable. Primary tumour and organs were harvested after a further 23 days. DNA was extracted from lung, spine and femur using phenol-chloroform and levels of mCherry were measured using qPCR along with vimentin as a reference. mCherry content normalised to vimentin was assessed as a measure of metastasis.
Results: Dexamethasone treatment reduced final body weight (Vehicle: 19.0±0.3g, Dex: 18.0±0.3g, $P<0.05$, $n = 24-27$) but there was no effect on primary tumour weight. There was a significant increase in mCherry content (metastasis) in the lungs of dex-treated mice (Vehicle: 1.2±0.3, Dex: 2.4±0.6, $P = 0.01$ Mann-Whitney non parametric test, $n = 24-27$).
Conclusions: Dexamethasone had no effect on primary tumour growth but increased metastasis to the lung. This effect was opposite to expectations based on previous *in vitro* studies. Our findings reveal that dexamethasone promotes tumour spread. Confirmation of these findings in xenograft models of human breast tumours in mice would raise questions about the use of glucocorticoids in treating breast cancer-associated emesis.

1875 POSTER

An in vivo screen to identify novel modulators of cytotoxic chemotherapy response

M. Ashenden[1], A. Van Weverwijk[1], J. Campbell[1], N. Murugaesu[2], M. Iravani[1], C.M. Isacke[1]. [1]*Institute of Cancer Research, Breakthrough Breast Cancer Research Centre, London, United Kingdom;* [2]*UCL Cancer Institute, Research Department of Oncology, London, United Kingdom*

Background: Clinically, development of chemotherapy resistance is an inevitable event in the treatment of patients with advanced breast cancer. Currently, little information is available to guide selection of first line therapy, with anthracyclines and taxanes giving similar benefit to patients. The purpose of this study is first to identify novel targets in chemotherapy resistant advanced breast cancer. Second it aims to identify novel biomarkers of sensitivity or resistance, specifically to anthracycline based chemotherapy.
Methods: In recent years, pooled RNAi screening, combined with next generation sequencing, has allowed high-throughput identification of genes involved in a range of cellular processes. The adaptation of these screens to the *in vivo* setting, while technically challenging, has been shown to allow identification of novel determinants that would have been missed using in vitro approaches. To interrogate resistance mechanisms in advanced breast cancer, an *in vivo* RNAi screen was designed, to discover novel genes involved in the response to anthracycline based chemotherapy. This screen utilized the Cancer 1000 shRNA library targeting 1000 genes of known cancer association.
Results: From this screen, 168 candidate genes were identified as involved in either sensitization or resistance to anthracycline based chemotherapy. These candidates include a number of genes known to be involved in chemotherapy response, including the known target of anthracyclines, *Top2a*. A combination of statistical, pathway, expression and literature analysis has been used to shortlist 7 candidate genes for initial validation studies.
Conclusions: Pooled RNAi screening has allowed identification of novel candidate genes involved in sensitization or resistance to anthracycline based chemotherapy. Further studies are focusing on the validation of these candidates. In addition, it is being investigated as to whether these genes mediate an anthracycline specific response, or a multidrug resistance or sensitivity phenotype. Determination of the mechanism of action will be critical to assess the suitability of these candidates as therapeutic targets and their use as predictors of patient response.

1876 POSTER

Individual risk profiling for breast cancer recurrence: Towards tailored follow-up schemes

J. Kraeima[1], S. Siesling[1], I.M.H. Vliegen[2], J.M. Klaase[3], M.J. IJzerman[4]. [1]*Comprehensive Cancer Centre The Netherlands (IKNL), Registration and Research, Enschede, Netherlands;* [2]*University of Twente, Centre for Healthcare Operations Improvement & Research, Enschede, Netherlands;* [3]*Medical Spectrum of Twente, Surgery, Enschede, Netherlands;* [4]*University of Twente, Department of Health Technology and Service Research (HTSR), Enschede, Netherlands*

Background: Breast cancer follow-up is not tailored to the risk of locoregional recurrences in individual patients or as a function of time. The objective of this study was to identify prognostic factors, and to estimate individual and time dependent locoregional recurrence risk rates, in order to tailor follow-up for the individual patient in terms of intensity and duration.
Material and Methods: Prognostic factors for locoregional recurrence were identified by a scoping literature review, field expert consultation, and stepwise multivariate regression analysis based on 5-years of population data from the Netherlands Cancer Registry from women diagnosed with breast cancer in the Netherlands in 2005 or 2006 ($n = 17762$). Inter-patient variability was elucidated by examples of five-year risk profiles of average, medium, and high risk patients, whereby six-month interval risks were derived from regression estimates.
Results: Eight prognostic factors were identified: age, tumour size, multifocality, gradation, adjuvant chemo-, adjuvant radiation-, hormonal therapy and triple negative receptor-status. The mutual weights of the contribution to the local regional recurrence risks were determined. Risk

profiles of the low-, average-, and high risk example patients showed non-uniform distribution of recurrence risks (2.9%, 7.6%, and 9.2% respectively over a five year period).
Conclusions: Individual risk profiles differ substantially in subgroups of patients defined by prognostic factors for recurrence and over time as defined in six-month time intervals. To tailor follow-up schedules, decrease anxiety in patients and to optimise allocation of scarce resources, risk factors, frequency and duration of follow-up should be taken into account.

Long-term results of reirradiation and hyperthermia in recurrent breast cancer

J. Van der Zee[1], M. Linthorst[1], A.N. Van Geel[2], M. Baaijens[3], W. Ghidey[4], G.C. Van Rhoon[1]. *[1]Erasmus MC − Daniel den Hoed Cancer Center, Radiation Oncology Hyperthermia Unit, Rotterdam, Netherlands; [2]Erasmus MC − Daniel den Hoed Cancer Center, Surgical Oncology, Rotterdam, Netherlands; [3]Erasmus MC − Daniel den Hoed Cancer Center, Radiation Oncology, Rotterdam, Netherlands; [4]Erasmus MC − Daniel den Hoed Cancer Center, Trial and Medical Statistics, Rotterdam, Netherlands*

Introduction: Reirradiation combined with hyperthermia is an effective treatment for recurrent breast cancer. Here we report long-term results of patients treated since 1992.
Materials and Methods: 198 patients with subclinical disease and 250 with irresectable disease were treated, including 36 patients with tissue transfers. All patients were treated with 8 fractions of 4 Gy twice weekly, and 8 (until 1996) or 4 one-hour hyperthermia treatments applied after radiotherapy. Approximately half of the patients received radiotherapy in another institute.
Results: In subclinical disease the 3- and 5-year local control (LC) was 83% and 78%. In patients with irresectable disease complete response was 70%, and 3- and 5-year LC was 40% and 39%. Five- and 10-year overall survival was 60% and 36% for subclinical disease, and 18% and 10% for irresectable disease. Both LC and toxicity in patients with tissue transfers were similar to those in the other patients. Superficially measured temperatures >43ºC were associated with more hyperthermia toxicity.
Patients irradiated elsewhere had a better LC than patients irradiated in the Erasmus MC. For patients with gross disease, the radiating institute was the only singificant factro influencing LC in multivariate analysis. At the same time, patients with subclinical disease irradiated elsewhere had significantly less late grade 3−4 toxicity (7% at 5 years) than patients irradiated in Erasmus MC (15%).
Conclusions: These results again show that reirradiation with hyperthermia is worthwhile for patients with recurrent breast cancer. Patients with transfers can be treated safely. The better results in patients irradiated elsewhere was unexpected. Hyperthermia toxicity may be decreased when superficially measured temperatures are kept below 43ºC.

1878 POSTER

Bevacizumab preconditioning followed by etoposide and cisplatin (BEEP) is a highly effective treatment for brain metastases of breast cancer progressing from radiotherapy − result of a multi-center phase II study

Y.S. Lu[1], W.W. Chen[1], C.H. Lin[1], D.C. Yeh[2], L.M. Tseng[3], P.F. Wu[1], K.M. Rao[4], B.B. Chen[5], T.T.F. Shih[5], A.L. Cheng[1]. *[1]National Taiwan University Hospital, Department of Oncology, Taipei City, Taiwan; [2]Taichung Veterans General Hospital, Department of Surgery, Taichung City, Taiwan; [3]Taipei Veterans General Hospital, Department of Surgery, Taipei City, Taiwan; [4]Kaohsium Chang Gung Memorial Hospital, Department of Oncology, Kaohsiung City, Taiwan; [5]National Taiwan University Hospital, Department of Medical Imaging, Taipei City, Taiwan*

Background: Management of brain metastasis of breast cancer progressing from whole brain radiotherapy (WBRT) remains a severe challenge. We hypothesized that starting bevacizumab (BE) 1 day before chemotherapy could further enhance the activity of etoposide (E) and cisplatin (P), two of the cytotoxic agents that have moderate activity in brain metastases of breast cancer, by increasing drug delivery into tumor tissue via BE-induced vascular normalization. This trial is registered with ClinicalTrials.gov, number NCT01281696.
Material and Methods: Breast cancer patients (pts) with brain metastases and brain lesions progression after WBRT were enrolled. Treatment was given in 21 day cycles: pts received BE 15 mg/kg on day 1, E 70 mg/m^2/day from day 2 to day 4, and P 70 mg/m^2 on day 2 (BEEP regimen), for a maximum of 6 cycles. The primary endpoint was a centrally assessed objective central nerve system (CNS) response, defined as a $\geqslant$50% reduction in the volumetric sum of all measurable CNS lesions in the absence of increasing steroid use, development of new CNS lesion, or progressive neurologic symptoms. An objective CNS response rate of 30% is assumed and 15% as a minimum interest, using a Simon's optimum two-stage design with a significance level α of 0.15 and a power of 80%, a total of 31 assessable pts are required. Serial dynamic contrast enhancement MRI (DCE MRI) 1 hr and 24 hrs after BE infusion were performed in selected suitable pts.
Results: Thirty five pts were enrolled from Jan 2011 to Jan 2013. All pts were included for safety and efficacy analysis (reported by intent to treat analysis). Median age was 54.3 (range 33−75); 6 pts were ER+HER2−, 23 pts were HER2+, and 6 pts were ER−HER2−. The median treatment cycles were 5 (range 1−6). Twenty seven of 35 pts (77.2%; 95% CI 59.9–89.6) achieved CNS response including 12 pts (34.3%) with $\geqslant$80% and 15 pts (42.9%) with 50−80% CNS volumetric reduction, respectively. Six pts (17.1%) had 20−50% CNS volumetric reduction. Six pts had non-CNS disease progression while CNS tumors remained under control. With median follow-up of 11.0 months, the median CNS progression free survival was 6.7 months (95% CI 5.1−8.3), and overall survival was 9.4 months (95% CI 7.3–11.5). Grade 3 /4 toxicities ($\geqslant$1%) included neutropenia, leukopenia, infection, anemia, and thrombocytopenia in 32.1%, 16.4%, 9.5%, 8.2%, and 6.9% per cycles, respectively. One pt died of infection and 1 pt died of tracheo-esophageal fistula. The latter pt had extensive mediastinal lymph node metastases, but her CNS tumors completely resolved after 3 cycles of BEEP. Seventeen pts (48.6%) needed dose reduction of E to 60 mg/m^2 and P to 60 mg/m^2, and 3 pts discontinued from treatment due to toxicity. Eight pts received serial DCE MRI study. In general, tumor vascular normalization could be observed at 1 hr, but become much more obvious 24 hrs after BE infusion.
Conclusions: BE given one day before E and P (BEEP regimen) induces better vascular normalization and significantly improve the efficacy of chemotherapy against brain metastases of breast cancer progressing from previous WBRT.
No conflict of interest.

1879 POSTER

Integrated genomic analysis identify candidates genes in luminal B breast cancer

L. Addou-Klouche[1], A. Bendaoud[1], S. Moulessehoul[1], M. Benali[1], M. Chaffanet[2], D. Birnbaum[2]. *[1]UDL Sba, Biotoxicology, Sidi-Bel-Abbes, Algeria; [2]Institut Paoli Calmettes, Molecular Oncology, Marseille, France*

Background: Breast cancer is a complex and heterogeneous disease. Characterization of genomic alterations such as amplification of oncogenes and loss of tumor suppressor genes (TSG) combined with expression data could identify candidate genes. We focused on luminal B breast cancer molecular subtype whose clinical course is particularly pejorative and for which no targeted therapy exists.
Material and Methods: High-Troughput molecular analysis such comparative genomic hybridization on microarrays (aCGH) was used to characterize the regions targeted by chromosomal alterations in breast cancers. In addition, an integrated analysis of genomic and expression profiling from DNA microarrays has contributed to the identification of candidate genes.
Results: We demonstrate that the candidate gene *L3MBTL4* is targeted by multiple genomic alterations, suggesting its involvement as a potential TSG in luminal B breast cancer molecular subtype. Furthermore, our comparative analyses of integrated profiles of breast cancers identified specific luminal B molecular subtype candidate genes.
Conclusion: High-Troughput molecular analysis of breast cancer has already revealed some part of their potential. Such integrated approaches could contribute to better understand the various levels of the molecular changes in the mammary oncogenesis and identify new markers.

Management of bone metastases secondary to breast cancer: a comprehensive survey of practice patterns in five European countries

A. Casas[1], A. Flinois[2], P. Schoen[3], S. Shepherd[4], I. Haynes[4]. *[1]Servicio de Oncología Médica Hospital Universitario Virgen del Rocío, Sevilla, Spain; [2]Kantar Health France, Montrouge Cedex, France; [3]Amgen (Europe) GmbH, Zug, Switzerland; [4]Amgen Ltd., Uxbridge, United Kingdom*

Background: Bone metastases occur in over 70% of patients with advanced breast cancer. They are frequently associated with debilitating skeletal-related events (SREs; pathologic fracture, need for radiation or surgery to bone, spinal cord compression), which can cause severe pain, immobility and reduced quality of life. Bone-targeted agents (BTAs) delay

and prevent SREs. We evaluated the management of bone metastases in patients with breast cancer.
Material and Methods: Prospective, observational patient record study involving physicians from France, Germany, Italy, Spain and United Kingdom. Data for the patients with breast cancer are reported here. In total, 881 physicians took part, completing brief questionnaires on 3096 patients with breast cancer and bone metastases seen during the observation period, and collecting detailed information on a further 1915 patients. Patient cases were weighted according to the probability of prospective inclusion in the study (i.e. patient consultation frequency and length of observation period).
Results: Only 61% of patients with bone metastases were receiving bisphosphonates (the only BTAs available at the time of this study) and 11% were expected never to receive them. One-fifth of patients had discontinued treatment with bisphosphonates; the most common reason was 'end of treatment as planned'. Of patients who discontinued treatment, 25% stopped due to adverse events of which, 36% experienced renal toxicity. Renal issues were also the main reason physicians expected patients never to receive bisphosphonates, although short life expectancy and poor risk/benefit profile for the patient were also concerns. Treatment patterns were generally consistent across countries, although in Germany patients were more likely to be diagnosed with solitary, rather than multiple, metastasis.
Conclusions: Many patients who could benefit from BTAs are not receiving treatment. Most guidelines do not specify that treatment should have a pre-planned duration; therefore, better education of physicians regarding the risk/benefit profile of BTAs may prevent patients stopping treatment unnecessarily. A considerable number of patients did not receive bisphosphonates due to their renal toxicity, suggesting there is a need alternative treatment options.

Quality-of-life in HER2-positive metastatic breast cancer for patients initiating an oral anticancer drug: results from a French prospective observational study

Y. Merrouche[1], A. Flinois[2], L. Benjamin[3], H. Chabernaud[2], M.C. Woronoff-Lemsi[4], A. Lortholary[5], M. Espié[6]. *[1]Institut De Cancérologie Lucien Neuwirth, Oncologie, Saint-priest-en-jarez, France; [2]Kantar Health, Etudes Oncologie & Hématologie, Montrouge, France; [3]GSK, Gestion Du Risque Pharmacoépidémiologie Et Information Médicale, Marly-le-roi, France; [4]CHU De Besançon, Recherche Clinique Et Innovation, Besançon, France; [5]Centre Catherine De Sienne, Oncologie Médicale, Nantes, France; [6]Hôpital Saint-louis, Centre Des Maladies Du Sein, Paris, France*

Background: The impact of disease on quality-of-life (QoL) is a seldom studied domain. This study aimed at evaluating the evolution of patient's QoL with HER2-positive (+ve) metastatic breast cancer (mBC) between oral treatment initiation and the 6 month of follow-up.
Material and Methods: A prospective observational multicenter study was conducted among 284 HER2+ve mBC patients included by 68 oncologists initiating oral anticancer drug. Data were collected on clinical characteristics, treatment patterns, adherence and QoL. Patients were invited to complete a questionnaire at treatment initiation (T0) and after each 3-month period. QoL was assessed using generic (Short-Form Health Survey, SF-12) and specific (EORTC QLQ-BR23) scales. The general health status was evaluated through an additional question. For comparison purpose, analyses were conducted on the 64 patients who returned their self-questionnaire at T0 and after 6 months (T6).

	T0 (n = 64)	T6 (n = 64)	p-value [1]
EORTC QLQ-BR23, mean (SD)			
Body image	53.3 (29.4)	58.9 (27.7)	0.276
Sexual functioning	25.0 (21.6)	24.9 (22.4)	0.980
Sexual enjoyment *(only if sexual functioning)*	39.7 (27.9) *	40.5 (21.8) **	0.905
Future perspective	35.4 (35.4)	36.4 (29.4)	0.862
Systemic therapy side effects	39.6 (19.8)	32.0 (16.5)	0.023
Breast symptoms	21.5 (26.1)	18.6 (21.0)	0.498
Arm symptoms	24.0 (24.2)	23.2 (22.5)	0.849
Upset by hair loss	45.6 (32.0)	44.4 (19.0)	0.857
SF-12 score, mean (SD)			
Physical component of QoL	37.7 (8.9)	40.2 (7.8)	0.102
Mental and social component of QoL	39.0 (10.4)	40.9 (8.5)	0.272

[1] Student test. *Analyses conducted on 26 patients, **analyses conducted on 32 patients.

Results: Apart from a significant impact of systemic therapy side effects on QoL between T0 and T6, there is no significant difference in the dimensions explored by the QLQ-BR23 scale. The results from the SF-12 scale showed no difference on either dimensions. The additional question showed a significant increase in the proportion of patients stating to be in a 'very good/good health status' (48% of patients at T0 versus 70% at T6 ($p = 0.036$)).
Conclusions: Overall, no significant trend was showed in the QoL evolution possibly due to the low number of patients analyzed as usually seen in such studies. Concurrently results showed stable QoL data on the large majority of criteria. Patients felt an improvement in their general health status over time. Even though this study is not comparative, the convenience of oral anticancer drugs may partly explain stable QoL outcomes across time.

1882 POSTER

Count us, know us, join us global survey: information needs among women living with metastatic breast cancer

D. Corneliussen-James[1], D. Percassi[2]. *[1]METAvivor Research and Support Inc., Annapolis MD, USA; [2]Harris Interactive, Vice President, Rochester, USA*

Background: Advanced breast cancer (stage III and stage IV/metastatic) is the most serious form of breast cancer. Defined by the cancer's spread to distant parts of the body such as the bone or liver, metastatic disease is rarely static, has increasing health implications, requires lifelong treatment, and is ultimately fatal. Support needs for this patient group are unique, yet rarely met. Hoping to identify new approaches to meeting the needs of this community, a global survey was commissioned by Novartis Oncology in partnership with the global advocacy community.
Methods: Harris Interactive conducted an online survey between October 2012 and March 2013. It was completed by 1,273 metastatic breast cancer patients from 10 countries (US, Canada, Mexico, Brazil, Argentina, UK, Germany, Russia, India, and Lebanon), as well as Taiwan and Hong Kong. Total sample data are not weighted and representative only of the individuals surveyed. A global post-weight was applied to ensure all countries received an equal weight in the global and regional data.
Results: Overall, a majority of patients (77%) actively seek out information, but nearly half (45%) say information is hard to find, and more than half (55%) say available information does not address their needs. 72% of patients, especially those in Mexico and Brazil (91% each; n = 102 and n = 100, respectively), feel that resources to help friends and family cope and better understand the disease would be helpful. US women (n = 349) are much more likely to rely on websites (84%), written materials (66%), support groups (60%), scientific journals (33%), and in-person/telephone workshops or conferences (35%), whereas 74% of Russian women (n = 100) rely heavily on non-governmental organizations (NGOs) for information. More than half of the women surveyed indicated Internet-based resources would be helpful, including websites (68%) and social networking tools (52%). Of note, 77% of UK women (n = 66) agree there is enough information available, but also feel overwhelmed by it (64%). Additional results highlight regional differences in gathering and utilizing information.
Conclusions: The means of collecting metastatic breast cancer information varies by region, and there is great global commonality in the type of information sought as well as the need for relevant, easily accessible data. Finding culturally-friendly ways to supply information worldwide is urgently needed.
No conflict of interest.

1883 POSTER

Strong compliance with electronic patient-reported (ePRO) reporting in multinational breast cancer trials

S. Dallabrida[1], S.T. Gary PhD[1], A. Otero[1]. *[1]PHT Corporation, PHT Consulting Services, Boston MA, USA*

Background: Patient Reported Outcomes (PRO) and electronic PRO (ePRO) are increasingly becoming an important aspect of cancer clinical trials and patient care, especially with regard to measuring drug efficacy, patient quality-of-life and drug safety. Subject compliance with completion of PRO/ePRO assessments is an important component for obtaining accurate and high-quality data when conducting clinical trials. It has been hypothesized that patient health status, age, length of time in a trial and country of origin, may affect compliance.
Material and Methods: To address this hypothesis, an operational analysis was conducted to assess oncology subject completion compliance of PRO reports using an electronic tablet to determine its suitability and performance in use. Toward this objective, the compliance of breast cancer patients in completing three electronic questionnaires that were

administered at clinic visits was evaluated. Subjects were asked to complete the EORTC QLQ-C30, EORTC QLQ-BM22, and the EQ-5D. Questionnaires were completed electronically on the tablet. Percent completion was calculated as the number of questionnaires completed divided by the number of questionnaires expected, based on attended clinic visits compiled for this review and the administration schedule for the questionnaires.
Results: This review draws on the experience of over 450 subjects from 16 countries, and describes the individual and overall compliance with the expected questionnaire completion, completion as a function of age, the variance between subsequent visits, and compliance by country. From age 20 to 89 years of age, there was no impact on compliance with overall compliance for all questionnaires between 95% and 100%.
Conclusions: The collection of ePRO using a clinic-based tablet yielded a highly complete data set in breast cancer subjects demonstrating that this is an effective and feasible approach for recording symptoms and quality-of-life assessments.
No conflict of interest.

1884 POSTER

Progression of breast cancer following ipsilateral recurrence: Importance of stage, age and interval time between the two diagnoses

J.C. Melvin[1], A. Purushotham[2], H. Garmo[1], S.E. Pinder[2], W. Fentiman[3], C. Gillet[4], A. Mera[1], L. Holmberg[1], M. Van Hemelrijck[1]. *[1]King's College London, Division of Cancer Studies Cancer Epidemiology Group, London, United Kingdom; [2]King's College London, Division of Cancer Studies Section of Research Oncology, London, United Kingdom; [3]Guy's Hospital, Research Oncology, London, United Kingdom; [4]Guy's Hospital King's Health Partners AHSC, Breast and Tissue Databank, London, United Kingdom*

Background: Studies comparing prognosis of breast cancer (BCa) between women with and without a local recurrence (LR) present conflicting results. We aimed to improve understanding of the biology of LR and its impact on prognosis using a large cohort from Guy's and St Thomas' NHS Foundation Trust.
Methods: Risk factors associated with BCa-specific death were investigated in 5,055 women diagnosed between 1975 and 2007 using Cox proportional hazards regression. BCa-specific death following LR was assessed with Poisson regression.
Results: 552 women (10%) developed LR during a median follow-up time of 4.19 years. Factors associated with BCa-specific death (stage, grade and nodal status) were also associated with risk of LR. For instance, the HR for BCa-specific death among women undergoing mastectomy with $\geqslant$10 positive nodes was2.29 (95% CI: 1.38–3.79) compared to those with no positive nodes. Women with shorter disease-free interval had a worse prognosis. The risk of BCa-specific death following LR occurring <6 years of diagnosis dramatically increased during the first three years, but this levelled off with time.

Table 1. Hazard Ratios (HRs) and 95% confidence Intervals (CI) for risk of BCa-specific death following LR, stratified by surgery type and adjusted for age, tumour grade, nodal stage and treatment of initial BCa.

Time between primary diagnosis and LR	Mastectomy		Breast conservation	
	HR	95% CI	HR	95% CI
<1	5.68	3.42–9.44	9.52	5.35–16.95
1−3	3.04	1.95–4.73	3.79	2.43–5.91
4−6	2.22	1.20–4.13	2.81	1.63–4.83
>6	1.00	(ref)	1.00	(ref)

Conclusion: The sharp increase in risk of BCa-death after LR suggests that some LRs may be components of active disease, particularly for women who have a short interval time between primary diagnosis and LR. These findings have implications for diagnostic work up and treatment of women with LR.
No conflict of interest.

1885 POSTER

Association of genetic polymorphisms in the tumor suppressor ERP29 and in the DNA transcription factor IKBKAP with breast cancer risk

C. Borges Martins de Oliveira[1], C. Cardoso-Filho[2], L.S. Bossi[2], M.S. Costa-Gurgel[2], G.J. Lourenco[1], C.S.P. Lima[1]. *[1]Faculty of Medical Sciences, University of Campinas, Campinas − São Paulo, Brazil; [2]Center of Integral Attention to Women's Health, University of Campinas, Campinas − São Paulo, Brazil*

Background: The *ERP29*, a tumor suppressor gene, and *IKBKAP*, a gene that act in transcriptional process, seems to be related with the onset of tumors. The analysis of the influence of *ERP29* c.*293A>G and *IKBKAP* p.Cys1072Ser polymorphisms in breast cancer (BC) risk has never been performed before and was the aim of the present study.
Materials and Methods: *ERP29* c.*293A>G and *IKBKAP* p.Cys1072Ser genotypes of 742 BC patients (median age: 53 years, 638 Caucasians, 104 non-Caucasians) and 742 healthy women (median age: 40 years, 638 Caucasians, 104 non-Caucasians) were obtained in genomic DNA by polymerase chain reaction in real time using primers and TaqMan® probes. The differences between groups were analyzed by the χ2 test. Power of analysis (PA) was used to determine the effect of sample size on the results obtained in the study.
Results: Patient's and control's samples were in HW equilibrium at *ERP29* c.*293A>G (χ2= 0.14, P = 0.71; χ2= 3.75, P = 0.05) and *IKBKAP* p.Cys1072Ser (χ2= 2.16, P = 0.14; χ2= 2.44, P = 0.12) loci. The frequency of *ERP29* c.*293AG+GG genotype was higher in patients than in controls (36.6% *versus* 30.7%, P = 0.03; PA= 74.0%). Carriers of G variant allele were under a 1.33-fold (95% CI: 1.03–1.72) increased risk for BC than those with AA wild genotype. *ERP29* c.*293AG+GG (62.5% *versus* 32.4%, P<0.0001, PA>99.0%) and *IKBKAP* p. 1072SerSer (50.0% *versus* 34.4%, P = 0.002, PA= 86.2%) genotypes were more frequent in non-Caucasian patients than in Caucasian ones. Besides, *ERP29* c.*293AG+GG genotype was also higher in non-Caucasian patients when compared to controls (62.5% *versus* 30.7%, P = 0.01, PA> 99.0%). Carriers of G variant allele were under a 2.31-fold (95% CI: 1.22–4.39) increased risk for BC development. The frequency of *ERP29* c.*293AG+GG genotype in underweight and normal patients was higher than that found in pre-obese and obese ones (43.9% *versus* 33.0%, P = 0.005, PA= 81.9%), and also than in controls (43.9% *versus* 30.7%, P = 0.003, PA= 96.0%). Underweight and normal carriers of G allele of the above-mentioned gene were under a 1.64-fold (95% CI: 1.19–2.27) increased risk for BC. Moreover, *IKBKAP* p. 1072SerSer genotype was more common among women who breastfed compared to those who did not (6.5% *versus* 2.3%, P = 0.03, PA= 65.4%).
Conclusion: Our data suggest, for the first time, that *ERP29* c.*293A>G and *IKBKAP* p.Cys1072Ser polymorphisms alter the risk of BC and its clinical features. We believe that women with variant alleles of the above-mentioned genes should receive additional medical attention for disease prevention and early diagnosis.

1886 POSTER

How accurately can we pre-operatively stage the axilla for breast cancer?

H. Tafazal[1], H. McMahon[1], R. Blow[1], P. Davies[1], M. Sintler[1]. *[1]Sandwell Hospital, Breast Surgery, Birmingham, United Kingdom*

Introduction: Pre-operative staging of the axilla in breast cancer patients is essential for deciding initial surgical treatment and often avoids the need for a second operation. The aim of this study was to evaluate pre-operative axillary ultrasound imaging +/− ultrasound guided FNAC/biopsy in assessing axillary node status.
Method: We performed a retrospective analysis of 392 patients diagnosed with breast cancer. Data collected included preoperative and postoperative axillary node status, and requirement for further treatment. The proportion of patients that pre-operative staging correctly identified was ascertained.
Results: Axillary disease was present in 147 (39%) patients. Preoperative axillary ultrasound and FNAC/biopsy correctly identified 51 (49%) of these patients. Sensitivity and specificity of pre-operative axillary ultrasound was 48% and 86%, respectively. Sensitivity and specificity of preoperative axillary ultrasound and FNAC/biopsy was 84% and 73%, respectively. On post-operative histology 46 (31%) patients required a further axillary procedure due to negative pre-operative staging.
Conclusion: Axillary ultrasound +/− ultrasound guided FNAC/biopsy determined the correct initial axillary procedure in 278 (73%) of our patients. The percentage of false negative results of ultrasound and ultrasound guided FNAC/biopsy was high at 10% and therefore, remains an inadequate definitive predictor of axillary node involvement.

1887 POSTER

Prognostic factors for survival after recurrent metastasized breast cancer by hormone receptor status

A.B.G. Kwast[1], A.C. Voogd[2], M.B.E. Menke-Pluijmers[3], S. Linn[4], L.A. Kiemeney[5], S. Siesling[1]. [1]*Comprehensive Cancer Centre The Netherlands, Department of Research, Utrecht, Netherlands;* [2]*Maastricht University Medical Centre, Department of Epidemiology, Maastricht, Netherlands;* [3]*Albert Schweitzer Hospital, Department of Surgery, Dordrecht, Netherlands;* [4]*The Netherlands Cancer Institute, Department of Medical Oncology, Amsterdam, Netherlands;* [5]*Radboud University Medical Centre, Department for Health Evidence, Nijmegen, Netherlands*

Background: Metastases after curatively treated breast cancer are considered incurable. Survival among patients with metastases is poor, but varies considerably between patients. Hormone receptor (HR) status is an important prognostic factor for patients with recurrent metastatic breast cancer (MBC). HR status is correlated to other prognostic factors such as age, tumour grade, metastasis-free interval (MFI) and site of distant metastasis. The aim of this nationwide population-based study was to determine the independent prognostic effect of these factors for survival after MBC according to HR status.
Methods: Dutch women diagnosed with breast cancer in the period 2003–2006 treated with curative intent who developed metastatic breast cancer within 5 years of follow-up were selected from the nationwide population-based cancer registry (N = 1,961). Independent prognostic factors for survival were determined by univariable and multivariable cox survival analyses, stratified by HR status.
Results: HR positive patients (65% of total) were younger and had longer metastasis-free intervals (MFI), compared to patients with a HR negative tumour (P<0.001). Their tumours were also more likely to be smaller, low grade, HER2 negative and to be associated with MBC in bones. Median overall survival for HR positive patients was 18 months vs 8 months for HR negative patients. Univariable and multivariable analyses revealed that a longer MFI resulted in better survival for HR negative patients (HR = 0.62; P<0.001), while no significant association was seen for HR positive patients (HR = 0.87; P = 0.052). HR positive patients with a higher grade primary tumour had a worse survival (HR = 1.41; P<0.001), no significant association was seen for HR negative patients (HR = 1.23; P = 0.082). For both HR negative and HR positive patients older age at MBC diagnosis and multiple sites were independent prognostic factors for poorer survival.
Conclusion: The influence of MFI and tumour grade on overall survival of patients with metastatic breast cancer is associated with HR status. The unfavourable prognostic impact of the number of metastatic sites and older age was independent of the HR status. This prognostic information according to HR status may assist physicians in clinical decision making and can support clinical decision making in personalized medicine.

Patterns of disease management for European postmenopausal women with hormone-receptor-positive (HR+), human epidermal growth factor receptor-2-negative (HER2−) advanced breast cancer

N. Marinsek[1], F. Andre[2], P. Neven[3], J. Zhang[4], R. Degun[5], G. Benelli[6], S. Saletan[7], G. Jerusalem[8]. [1]*Navigant Consulting Europe Ltd, Life Sciences, London, United Kingdom;* [2]*Institut Gustave Roussy, Oncology, Villejuif, France;* [3]*University Hospitals Leuven, Oncology, Leuven, Belgium;* [4]*Novartis Pharmaceuticals Corporation, Oncology Franchise Lead, Florham Park, USA;* [5]*Navigant Consulting Inc, Associate Director, London, United Kingdom;* [6]*Novartis Farma S.p.A, Oncology, Saronno/VA, Italy;* [7]*Novartis Pharmaceuticals Corporation, Onco Ex Dir Clinical Res Phys, East Hanover, USA;* [8]*Centre Hospitalier Universitaire du Sart Tilman Liège and Liège University, Oncology, Liège, Belgium*

Background: International guidelines (ESMO, NCCN) for HR^+ advanced breast cancer (ABC) recommend multiple lines of hormonal therapy (HT) if response is observed. Chemotherapy (CT) is recommended for patients with extensive visceral involvement or rapidly progressive disease. This study evaluates actual physician-reported treatments from adjuvant therapy to completion of at least 3 lines of therapy in the ABC setting.
Materials and Methods: Retrospective chart review in Belgium, France, Germany, The Netherlands, and Sweden of 355 postmenopausal women (PMW) diagnosed with HR^+, $HER2^-$ ABC in the past 4 years. Patients had to progress on $\geqslant$1 line of HT and complete $\geqslant$1 line of CT in ABC. Treatment choice was evaluated for each line of therapy. Factors considered for treatment decisions included performance and disease status and change in disease status.
Results: Of 355 patients, 111 (31%) received 1st-line CT whereas 218 (61%) and 26 (7%) switched from HT to CT in 2nd and 3rd line, respectively. More patients receiving 1st-line HT had bone metastases (73% HT vs 27% CT) and strong ER^+ status (92% HT vs 68% CT). Patients treated with 1st-line CT had more brain (0% HT vs 12% CT) or extensive liver (0% HT vs 13% CT) metastases. High (>20%) Ki-67 status was not a strong predictor of CT use. Subgroup analysis of 188 patients with *de novo* metastatic or recurring disease who received 1st-line HT and did not have rapidly recurring disease (ABC diagnosis during/within 1 year of completing adjuvant therapy) found that the majority (89%) of these patients switched to CT in 2nd line. However, among these 167 patients, 27% had no significant changes in metastases between 1st and 2nd line and a mean duration of 1st-line therapy of 9.5 months. Among the 73% (n = 122) of patients who had a significant change in metastases, 20% (n = 24) had no brain or extensive visceral disease and a mean duration of 1st-line therapy of 8.7 months.
Conclusions: Physician-reported use of HT and CT in European PMW with HR^+, $HER2^-$ ABC suggests that the majority of patients receive CT earlier than recommended by treatment guidelines. Our study provides evidence suggesting that the guideline-recommended use of multiple lines of HT may be less than optimal for ABC patients who responded to HT and lacked extensive visceral disease.

1889 POSTER

The number needed to treat for everolimus plus exemestane or fulvestrant relative to exemestane alone from BOLERO-2, EFECT, and SoFEA trials

J. Zhang[1], H. Gao[2]. [1]*Novartis, Oncology Franchise Lead, Florham Park, USA;* [2]*Novartis Pharmaceuticals Corporation, Associate Director, Florham Park, USA*

Background: The phase 3 study Breast Cancer Trials of Oral Everolimus-2 (BOLERO-2; N = 724) at 18 months' median follow-up demonstrated that everolimus (EVE) + exemestane (EXE) more than doubled progression-free survival (PFS) versus placebo (PBO) + EXE in patients with hormone-receptor-positive (HR^+), $HER2^-$ advanced breast cancer (ABC) recurring/progressing on/after nonsteroidal aromatase inhibitor (NSAI) therapy. Number needed to treat (NNT; the reciprocal of absolute risk reduction) is the number of patients who need to be treated with a new therapy to avoid 1 additional event compared with standard therapy. For randomized controlled trials, NNT is a clinically useful measure of treatment effect. The Evaluation of Faslodex versus Exemestane Clinical Trial (EFECT; N = 693) and Study of Faslodex, Exemestane, and Arimidex (SoFEA; N = 723) trials compared fulvestrant (FUL, 500 mg day 1; 250 mg day 15, then monthly) versus EXE (the control arm of BOLERO-2) in a patient population similar to BOLERO-2. Thus, these treatment alternatives were assessed via comparison of the NNTs for both EVE+EXE and FUL versus EXE alone.
Materials and Methods: The NNT for EVE+EXE versus EXE in BOLERO-2 was calculated using survival probabilities for PFS at 12 months for both investigator and central assessment. The NNTs for FUL versus EXE were calculated for time to progression (TTP; EFECT) and for PFS (SoFEA), based on survival probabilities estimated from Kaplan–Meier plots (Johnston S, et al. EBCC 2012 and Chia S, et al. *J Clin Oncol*. 2008;26:1664−70, respectively) using ByteScout software.
Results: At 12 months in BOLERO-2, NNT to prevent progression for EVE+EXE versus EXE was 4.5 (95% confidence interval [CI], 3.5 to 6.2) per investigator assessment and 3.4 (95% CI, 2.6 to 5.1) per central assessment. In comparison, the 12-month NNTs with respect to TTP or PFS for FUL versus EXE from 2 trials in patients with HR^+ ABC after prior NSAI were 36.8 in EFECT and 35.1 in SoFEA. Additionally, 6- and 18-month NNTs from the 3 trials will be presented.
Conclusions: These results support the clinically meaningful improvement in PFS with EVE+EXE versus PBO+EXE in patients with HR^+, $HER2^-$ ABC and recurrence/progression on/after NSAI. The NNT range to prevent progression with EVE+EXE versus EXE alone was 3.4 to 4.5 patients. In contrast, the estimated NNT to prevent progression with FUL versus EXE was 35.1 to 36.8.

1890 POSTER

Breast scintigraphy with 99mTc-MIBI in clinical practice

S. Kanaev[1], S. Novikov[1], P. Krivorotko[2], V. Semiglazov[2], L. Jukova[1], P. Krzhivickiy[1]. *[1]N.N.Petrov Research Institute of Oncology, Radiation Oncology & Nuclear Medicine, Saint-Petersburg, Russian Federation; [2]N.N.Petrov Research Institute of Oncology, Breast Cancer, Saint-Petersburg, Russian Federation*

Purpose: To evaluate different applications of breast scintigraphy (SMG) in routine clinical practice.
Material and Methods: SMG was performed in 232 women with suspect for breast cancer (BrCr). SMG was performed in planar and tomography modes 15 min. after i/v injection of 740–860 MBq 99mTc-sestamibi. Images with focal and scattered patchy uptake were considered as abnormal. All lesions were verified by biopsy and/or by operation.
Results: Sensitivity (Sen), Specificity (Sp) and Accuracy (Ac) of SMG in the whole group was as following: 94.8%, 72.5%, 90.9%. In 36 women with *lesions below 1 cm* SMG revealed 12 of 14 cases of BC and refused malignancy in 16 of 21 women's with benign breast lesions. Sen, Sp and Ac of SMG in this group were 86%, 76% and 80%.
SMG showed moderate Sen, Sp and Ac in diagnosis of axillary metastases (60%, 86%, 76%) but help to detect involvement of internal mammary and/or sub-supraclavicular lymph nodes in 8% and 6.3% cases.
SMG demonstrated high efficacy in diagnosis of multicenter/multifocal BrCr which was revealed in 14.8% cases: 7.4% − multicenter and 7.4% − multifocal. For comparison conventional imagings (US and mammography) were able to detect multicentre/multifocal disease only in 3.7% cases.
Conclusion: SMG is effective tool for diagnosis and staging of BrCr with additional advantages of high accuracy in detection of multicenter/multifocal disease and metastatic involvement of internal mammary and/or sub-supraclavicular lymph nodes.

1891 POSTER

Does the prior chemotherapy treatment sequence affect the overall survival (OS) benefit associated with eribulin?

W. Simons[1], J. Rodriguez-Villanueva[2], R.E. Sheffield[3], J. Rege[3], Y.P. He[4], S. Lin[4]. *[1]Eisai Inc., Value Maximization Systems, Woodcliff Lake NJ, USA; [2]Eisai Farmaceutica S.A., Oncology Business Unit, Madrid, Spain; [3]Eisai Inc., Eisai Value Maximization Systems, Woodcliff Lake, USA; [4]Eisai Inc., Biostatistics Oncology, Woodcliff Lake, USA*

Background: Based on questions from health authorities, prior chemotherapy or sequencing may affect the OS benefit of eribulin. We explored the effects of three prior chemotherapy treatment sequences on the OS benefit of eribulin in locally advanced or metastatic breast cancer patients.
Materials and Methods: Post-hoc analyses were conducted using a phase III multicenter, randomized, clinical trial for the treatment of eribulin versus treatment of physician's choice (NCT00388726). OS was analyzed when the event rate was 54% and 76%, separately. The effects of three chemotherapy treatment sequences prior to eribulin were explored: prior capecitabine (PCAPE), prior vinorelbine (PVIN), and prior capecitabine plus prior vinorelbine irrespective of sequence (PCAPE+PVIN). Kaplan–Meier (KM) plots and the log-rank test were used to assess the difference in OS between patients who received a particular prior chemotherapy sequence versus those who did not. Hazard ratios (HRs) with 95% confidence intervals (CIs) were generated using a Cox model. Interactions between PCAPE or PVIN and treatment were also tested using a Cox model stratified by region and Her2/neu status.
Results: These post-hoc analyses used the 508 eribulin patients for the intent-to-treat (ITT) population. At a 54% event rate, eribulin patients who received prior treatment with PCAPE, PVIN or both did not have a larger OS benefit than eribulin patients who did not*:* PCAPE [HR: 1.09, (0.830, 1.430)]; PVIN [HR: 1.20, (0.946, 1.524)]; and PCAPE+PVIN [HR: 1.24, (0.970, 1.574)]. Statistical analyses at a 76% event rate showed consistent results as the analyses at 54% of event rate: PCAPE [1.26, (1.000, 1.593), p = 0.0489], PVIN [1.16, (0.947, 1.420)], or PCAPE+PVIN [1.23, (1.000, 1.512), p = 0.0495].
Conclusions: Overall these results show that sequencing of prior treatment (i.e., PCAPE, PVIN, and PCAPE+PVIN) does not demonstrate additional OS benefit with eribulin. Therefore the only therapies that should be required prior to the use of eribulin are those required per study inclusion criteria, an anthracycline and a taxane in either the neo/adjuvant and/or metastatic setting.
No conflict of interest.

1892 POSTER

Helical tomotherapy for inoperable breast cancer: a new promising tool

C. Chira[1], Y. Kirova[1], L. Xavier[1], F. Campana[1], N. Fournier-Bidoz[2], M. Amessis[2], R. Dendale[1], A. Fourquet[1]. *[1]Institut Curie, Department of Radiation Oncology, Paris, France; [2]Institut Curie, Department of Medical Physics, Paris, France*

Background: Locally advanced breast cancer (BC) not eligible for upfront radical surgery remains a challenging situation for oncologists, both in a non-metastatic as well as in some metastatic settings (responsive or stable systemic disease). This is a small series of patients treated with preoperative Helical Tomotherapy® (HT) followed by radical surgery.
Material and Methods: Five patients with locally advanced not operable BC received neoadjuvant chemotherapy (NCT) followed by preoperative HT. Four women received concomitant chemotherapy (CCT) using a combination of fluorouracil (5-FU) and vinorelbine (VBN). Irradiated volumes included: whole breast (WB) in all patients, axillary lymph nodes (ALN) in 2 patients, internal mammary lymph nodes (IMLN) in 2 patients, supraclavicular (SCV) and infraclavicular fossa (ICV) in 3 patients. In one patient a simultaneous integrated boost (SIB) dose to GTV (gross tumor volume) was used. Radiation doses are described in detail in table. Toxicity was reported using the CTCAE v.4 scale. Patients were evaluated for surgery at the end of treatment.
Results: Five women with stages IIIA to IV BC (3 right sided and 2 left sided) have been treated. All patients received upfront NCT before HT, median number of delivered cycles was 8 (range: 6−8). HT was associated in 5 patients with CCT. The following regimen was used: 5-FU 500 mg/m^2 days 1−5 and VBN 25 mg/m^2 days 1 and 6, every 21 days. Early toxicity is available in the table. Following treatment, all patients were considered operable and underwent radical mastectomy (RM) and axillary lymph node dissection (ALND). Surgery was performed at a median interval of 43 days (range: 31 to 52) from last day of radiotherapy. Median follow-up from surgery date was 10.6 months (range: 0.8–26.2). Pathological response is summarized in the table.
Conclusions: HT offers several advantages in locally advanced BC: can potentially convert inoperable disease to operable disease, shows good pathological response rates with moderate acute toxicity. These results need confirmation in the setting of a prospective clinical trial.
No conflict of interest.

Table (abstract 1892).

No	TNM stage	Initial largest tumor diameter (mm)	Planned WB doses (Gy)	Helical tomotherapy			CCT	Early toxicity CTCAE grade		Pathological specimen

Low dose radiotherapy and concomitant neoadjuvant chemotherapy for breast cancer: Final results of a phase II study

L. Nardone[1], M.C. De Santis[1], B. Diletto[2], G.R. D' Agostino[1], P. Belli[3], E. Bufi[3], A. Mulé[4], A. Sapino[5], D. Terribile[6], V. Valentini[1]. [1]*Catholic University "A. Gemelli" Hospital, Radiation Oncology, Roma, Italy;* [2]*Catholic University "A. Gemelli" Hospital, Roma, Italy;* [3]*Catholic University "A. Gemelli" Hospital, Radiology, Roma, Italy;* [4]*Catholic University "A. Gemelli" Hospital, Pathology, Roma, Italy;* [5]*Turin University of Medicine, Pathology, Roma, Italy;* [6]*Catholic University "A. Gemelli" Hospital, Surgery, Roma, Italy*

Background: Hyper-radiosensitivity of cancer cell lines at low dose radiotherapy (LDRT) (<0.5 Gy) and chemo-potentiator effect of LDRT have been demonstrated in several *in vitro* and *in vivo* studies. The aim of this phase II study was to evaluate the safety and the efficacy of a neoadjuvant regimen combining LDRT and chemotherapy in breast cancer.
Material and Methods: Eligible patients had histological diagnosis of breast cancer obtained by core-needle biopsy, previously untreated, ECOG <2, no evidence of distant metastases. The accrual was determined by the single proportion powered analysis (α=0.05, power = 0.8); 21 was the number required. Patients received LDRT (40 cGy bid, on day 1 and 2, for 6 cycles, for a total dose of 960 cGy, on PTV: gross tumour volume + 0.5−1 cm margins; by tangential technique) and concurrent neoadjuvant chemotherapy with non-pegilated liposomial anthracycline and docetaxel. After clinical and radiologic rexamination, patients underwent surgery and axillary node dissection. Pathological response was evaluated by the Mandard score and expressed as tumor regression grade (TRG). The evaluation of TRG was confirmed by an external audit.
Results: Twenty-one patients with stage IIA–IIIA invasive ductal and lobular carcinoma were enrolled in the study. Median age was 52 years (range, 34−76). Six patients had grade 1 haematological toxicity. No grade 3−4 haematological and acute skin toxicity was observed. After neoadjuvant chemotherapy and LDRT 18 patients underwent quadrantectomy, and 3 patients underwent mastectomy with breast reconstruction. Overall TRG1 (absence of residual cancer) was achieved in in 3 patients (14.3%), and grade 2 (residual isolated cells scattered through the fibrosis) in 4 patients (19%); TRG3−5 was observed in 14 patients (66.6%). The pathological major response rate (tumor regression grade 1 + 2) was 38%.
Conclusions: Neoadjuvant LDRT and concurrent non-pegilated anthracyclines and docetaxel has a similar toxicity profile to chemotherapy alone. The response rate on primary tumor of this new treatment approach is encouraging, since it was higher than what was reported for chemotherapy alone. Additional investigations about long term results are warranted.
No conflict of interest.

1894 POSTER

Sustainability of a short stay programme after breast cancer surgery in four early-adopting hospitals

F. Gillissen[1], S.M.C. Ament[2], J.M.C. Maessen[2], C.D. Dirksen[3], T. Van der Weijden[2], M.F. Von Meyenfeldt[1]. [1]*Maastricht University Medical Centre, Surgery, Maastricht, Netherlands;* [2]*Maastricht University Medical Centre, Caphri, Maastricht, Netherlands;* [3]*Maastricht University Medical Centre, Kemta, Maastricht, Netherlands*

Background: New treatments and health care care programmes are constantly being developed and introduced to improve quality and efficiency of care. It is highly desirable to maintain achieved quality improvements after an implementation project has ended. However, research shows that it is difficult to sustain change as people tend to relapse into old routines as soon as the change agents have finished their mission. Breast cancer care is a field that is constantly changing. Between 2005 and 2007 a short stay programme in breast cancer surgery was successfully implemented in 4 hospitals. The primary implementation study showed an increase from 45% to 83%. uptake of short stay without a negative effect on the number of readmissions and complications. Overall compliance of the key recommendations increased from 59% in the pre-implementation phase to 76% in the post-implementation phase. The aim of this study was to assess the extent of sustainability of this short stay programme in breast cancer surgery in real world.
Material and Methods: A retrospective audit of 40 consecutive patients undergoing breast cancer surgery was performed 5 years after the original implementation study was ended. Sustainability was assessed by measuring if patients were still treated according the short stay criteria, being day admission or 24 hours admission. Compliance to the key recommendations of the short stay programme was also determined per patient.
Results: The total proportion of patients treated in short stay sustained at an average level of 82% in the retrospective audit phase. The overall proportion of patients treated in day admission however decreased from 33% to 28%, in favor of 24 h admission which increased from 67% to 72%. Compliance to the key recommendations sustained at 78% in the retrospective audit phase. 7 out of 9 key elements fully sustained or improved in the retrospective audit phase compared with the implementation group.
Conclusion: This study shows that the Short Stay Programme after breast cancer surgery was fully sustained in 4 early-adopting hospitals five years after successful implementation. However, the percentage of patients treated in day admission decreased in favor of 24 hour admission. More research is needed to find possible explanations of the decrease in day admissions after breast cancer surgery.
No conflict of interest.

1895 POSTER

RAD001 (everolimus) in combination with letrozole in the treatment of hormone receptor positive HER2-negative postmenopausal women (PMW) with advanced breast cancer (ABC) after failure of endocrine therapy − a phase II study

T. Safra[1], L. Kadouri-Sonenfeld[1], N. Ben Baruch[1], B. Nisenbaum[1], R. Yerushalmi[1], E. Evron[1], L. Ryvo[1], J.G. Greenberg[1], B.K. Kaufman[1]. [1]*Tel Aviv Sourasky Medical Center, Oncology, Tel Aviv, Israel*

Background: Approximately 75% of ABC in PMW are ER+/HER2-. Currently there is an unmet medical need for new treatment modalities after failure of endocrine therapy. Activation of the mTOR pathway is a key adaptive change driving endocrine resistance. Pre-clinical and early clinical data suggest a synergism between RAD001 (Everolimus, a Novartis mTOR inhibitor) and Letrozole resulting in restoration of sensitivity to endocrine therapy.
Our objectives were to assess Overall Response Rate (ORR), Disease Control Rate (DCR), Progression Free Survival (PFS), Overall Survival (OS) and Safety Profile of the combination after failure of one or more endocrine therapies.
Methods: A multi-center (7), Israeli phase II open label study evaluating treatment of RAD001 (oral 10 mg/d) combined with Letrozole (oral 2.5 mg/d) in PMW with ABC after progression on Tamoxifen and/or Anastrozole and/or Letrozole and/or Fulvestant and/or Exemestane.
73 patients were enrolled. Median age was 55 (28−80) years. All had ABC with one to three metastatic sites.
Patients were previously exposed to a median of 2 (1−5) lines of hormonal therapy, 54% to Letrozole.
Results: Analysis was performed on ITT population With a median follow up of 12.23 months (2−22), ORR was 19%(15/73), DCR 58% (43/73) and progressive disease in 25% (18/73) of patients. PFS was 7.9 months (1−22) while 25% (18/73) are still on treatment. OS is too early to evaluate with 78% of patients still alive.
Commonly observed all grade toxicities include: stomatitis (50%), weakness (50%), weight loss (30%), anorexia (27%), anemia (28%), hyperlipidemia (23%), diarrhea (19%), myalgia/arthralgia (16%), and pneumonitis (10%).
Conclusions: Our preliminary results are consistent with BOLERO-2 findings showing significant prolongation of PFS with the addition of RAD001 to an Aromatase Inhibitor in PMW HR+/HER-2 negative ABC patients who have progressed following previous endocrine therapy with an acceptable toxicity profile. Longer follow-up and further evaluation is warranted.
No conflict of interest.

Oral Vinorelbine as a single-agent as first-line chemotherapy for metastatic breast cancer patients with bone metastases: first safety results of an international phase II study (NorBreast-228 trial)

G. Steger[1], I. Glogowska[2], A. Dominguez[3], O. Switsers[4], N. Dobrovolskaya[5], F. Giotta[6], N. Tubiana-Mathieu[7], M. Pecherstorfer[8], G. Villanova[9], A. Ardizzoia[10]. [1]*University Hospital, Medical Oncology, Vienna, Austria;* [2]*Oncology Center M. Curie, Medical Oncology, Warsaw, Poland;* [3]*Cancerologia de Queretaro, Medical Oncology, Queretaro, Mexico;* [4]*Oncology Center F. Baclesse, Medical Oncology, Caen, France;* [5]*Russian Research Center of Roentgenoradiology, Medical Oncology, Moscow, Russian Federation;* [6]*National Cancer Research Center Giovanni Paolo II Cancer Institute, Medical Oncology, Bari, Italy;* [7]*University Hospital Dupuytren, Medical Oncology, Limoges, France;* [8]*Landesklinikum, Medical Oncology, Krems, Austria;* [9]*Institut de Recherche Pierre Fabre, Medical Affairs, Boulogne-Billancourt, France;* [10]*Hospital A. Manzoni, Medical Oncology, Lecco, Italy*

Background: Oral chemotherapy (CT) is an attractive treatment option for hormone receptor positive, metastatic breast cancer (MBC) patients (pts)

pretreated by a hormone therapy. In our phase II study, we evaluated the role of single-agent Oral Vinorelbine (OV) as first-line CT in pts presenting bone metastases without visceral involvement. In this abstract, first safety results of this trial are presented.
Material and Methods: Main eligibility criteria included: age ⩾18 years, documented bone involvement previously untreated by CT, hormone receptor positive disease previously treated by at least one hormone therapy, HER2-negative disease, Karnofsky PS ⩾70 and absence of visceral metastases. All pts received a bisphosphonate during the study. Study treatment (until progression): OV 80 mg/m^2 weekly (following a first cycle at 60 mg/m^2 and dose escalation to 80 in the absence of grade 3 or 4 toxicity). One cycle was defined as four weeks of treatment.
Results: Main pts characteristics in the full population were (n = 70): median age: 60.6 years (34% ⩾65 years); median Karnofsky PS 90%. Prior hormone therapy 100% (53% in advanced setting); prior (neo)adjuvant CT 63%; prior anthracyclines/taxanes 59/24%; prior palliative radiotherapy 41%. Bone involvement 100%; other metastatic sites: lymph nodes 14%, soft tissue 3%. Median duration of treatment 5.5 months (range 0.9–18.3), median number of cycles: 6 (range: 1−18); 61% of pts received at least 6 cycles, 37% of pts received more than 6 cycles and 29% received at least 9 cycles; median relative dose intensity: 83.5%; dose escalation was performed in 79% of pts. Grade 3/4 adverse events per pt: neutropenia 37%, anemia 4%, diarrhoea 3%, nausea 3%, asthenia 1%, liver toxicity 1%, neutropenic infection 1%, non-neutropenic infection 1%. Grade 2 alopecia was reported in 6% of pts. No cases of febrile neutropenia or toxic death had been observed.
Conclusions: In this particular population of metastatic pts, with hormone receptor positive disease and bone involvement, OV showed an optimal safety profile. This data shows that OV is a well tolerated first-line CT option in this setting, allowing prolonged active treatment in non-progressing pts.

Overall survival of metastatic breast cancer patients: the Italian ten-year experience

S. Barni[1], I. Vallini[2], M. Bonotto[3], O. Garrone[4], A. Brunello[5], M. Indelli[6], J. Foglietta[7], S. Saracchini[8], E. Collovà[9], L. Porcu[10]. [1]*Azienda Ospedaliera Treviglio, Oncology, Treviglio, Italy;* [2]*Ospedale di Circolo, Oncology, Varese, Italy;* [3]*Azienda Ospedaliera Universitaria, Oncology, Udine, Italy;* [4]*Ospedale S Croce, Oncology, Cuneo, Italy;* [5]*Istituto Oncologico Veneto, Oncology, Padova, Italy;* [6]*Azienda Ospedaliera, Oncology, Ferrara, Italy;* [7]*Azienda Ospedaliera, Oncology, Perugia, Italy;* [8]*Azienda Ospedaliera, Oncology, Pordenone, Italy;* [9]*Azienda Ospedaliera Ospedale Civile di Legnano, Oncology, Legnano, Italy;* [10]*Istituto Mario Negri, Clinical Research, Milano, Italy*

Background: Several studies suggest that newer therapies can improve survival in metastatic breast cancer (MBC), but a different impact on overall survival (OS) is observed according to histology, extension of disease and prognostic factors. This survey was performed for evaluate Italian experience in cancer treatment in the last ten years.
Methods: We retrospectively collected data from several Italian Medical Oncology Units (OUs); we registered all consecutive patients (pts) with breast cancer who have developed metastasis between 2000 and 2008; demographic data, pathological characteristics and treatments administered were collected; OS was defined as the time from the diagnosis of MBC to death from any cause; the statistical significance was reached with a p-value <5%.
Results: 17 OUs participated and 1998 pts were analyzed; median age 61.7 years (range: 22.7–94.7 years); MBC at diagnosis: 13.1% pts; site of disease recurrence: bone 25.5%, visceral 23.5%, bone and visceral 21.1%, soft tissue 14.0%, soft tissue and visceral 8.0%, bone and soft tissue 7.9%; molecolar classification: luminal A 66.3%, luminal B 14.4%, triple negative 11.7%, HER2+ like 7.6%. Pts received a median of 2 lines of chemotherapy (range 0−10) and 1 line of endocrine therapy (range 0−7); 22.1% received biological drugs. 16.4% of metastatic pts were enrolled in clinical trials. After a median follow up of 6.9 years (range: <0.1–12.9 years) 1657 (82.9%) pts died and the median OS was 2.7 years (95% CI: 2.6−2.9 years); we didn't observe any statistical significant trend in OS for pts divided into 3 groups according to recurrence date (2000–2002, 2003–2005, 2006–2008); a longer median OS was observed in luminal B (3.6 years; 95% CI: 3.3−4.1 years) versus luminal A (2.8 years; 95% CI: 2.5−3.0) and HER2+ like (2.6 years; 95% CI; 2.1−3.1 years) and triple negative disease (1.3 (1.0−1.7 years).
Conclusions: Our survey describe a large number of MBC pts treated in 17 Italian Oncology Units. OS analysis did not show statistically significant differences according to recurrence date, but for different prognostic factors. OS data are superimposable to literature ones, showing a good transfer from clinical trials to clinical practice.
No conflict of interest.

1898 POSTER

A phase I combination study of eribulin mesylate with trastuzumab for advanced or recurrent human epidermal growth factor receptor 2-positive (HER2+) breast cancer

H. Mukai[1], K. Shimada[2], Y. Naito[1], N. Matsubara[1], T. Nakanishi[3], H. Obaishi[3], M. Namiki[4], T. Narita[5], M. Masuda[5], Y. Sasaki[6]. [1]*National Cancer Center Hospital East, Department of Breast and Medical Oncology, Chiba, Japan;* [2]*Saitama Medical University, Department of Medical Oncology, Saitama, Japan;* [3]*Eisai Co. Ltd., Department of Clinical Development, Tokyo, Japan;* [4]*Eisai Co. Ltd., Japan Clinical Pharmacology, Tokyo, Japan;* [5]*Eisai Co. Ltd., Department of Clinical Operation, Tokyo, Japan;* [6]*Showa University School of Medicine, Division of Medical Oncology-Department of Medicine, Tokyo, Japan*

Background: Eribulin mesylate is a novel inhibitor of microtubule dynamics that has demonstrated a survival benefit in patients (pts) with advanced or recurrent breast cancer (BC) previously treated with anthrayclines and taxanes. Trastuzumab is indicated for pts with HER2-positive BC, but the combination of eribulin mesylate with trastuzumab has not been established yet. A phase I study of eribulin mesylate in combination with trastuzumab was conducted to evaluate the dose limiting toxicity (DLT), tolerability/safety, pharmacokinetics and preliminary antitumor activity in Japanese patients.
Methods: Pts with advanced or recurrent HER2-positive BC were enrolled. Eribulin mesylate (1.4 mg/m^2 [equivalent to 1.23 mg/m^2 eribulin expressed as free base]) was administered on Days 1 and 8 every 3-week/cycle and trastuzumab was administered as 4 mg/kg loading dose, 2 mg/kg/weekly (Part 1) and 8 mg/kg loading dose, 6 mg/kg/tri-weekly (Part 2). DLT was evaluated during the first cycle. Left ventricular ejection fraction (LVEF) assessment was conducted on before the treatment, Day 15 of Cycle 1, Day1 of each 4 cycles and if clinically indicated.
Results: A total of 12 pts were enrolled in Part 1 (n = 6) and 2 (n = 6). The median age was 60 years (range 39−72) and the median number of prior chemotherapy regimen was 4.5 (range 1−14). As of 26 Feb 2013, no DLT was observed and the common adverse events were similar in Part 1 and 2, including neutropenia [100% (Gr 3/4: 92%)], leukopenia [100% (Gr 3/4: 75%)], anemia [67% (Gr 3/4: 0%)] and alopecia (67%). The safety and PK profile was similar to the prior clinical study of eribulin mesylate monotherapy. LVEF decreased (Gr 2) was observed in 2 pts (17%) at Day 15 of Cycle 1, but both recovered after 1 week without treatment for it. Current response results according to RECIST v1.1 from 11 evaluable pts were: 1 pt (9%) with PR, 9 pts (82%) with SD (⩾5 weeks) and 1 pt (9%) with PD. Disease Control Rate (CR+ PR+SD ⩾11 weeks) was 64%.
Conclusions: The combination of eribulin mesylate with trastuzumab was considered well tolerated and the neutropenia observed was manageable in Japanese pts with advanced or recurrent HER2-positive BC. No pharmacokinetic drug–drug interaction between eribulin and trastuzumab was observed. Since a transient LVEF decrease was observed in 2 pts, the assessment of cardiac function should be performed routinely in the combination with trastuzumab. The evaluation of long-term safety and efficacy is ongoing.

1899 POSTER

First year daily clinical experience with eribulin in Spain; EUFORIA-1 study (Eribulin Use For the treatment of advanced breast cancer: Observational, Retrospective Analysis)

M. Ruiz-Borrego[1], J.A. Garcia-Saenz[2], F.J. Hornedo[3], I. Calvo-Plaza[4], J. Lao[5], L. Manso[6], A. González-Martín[7], M. Feyjoo-Sous[8], J. Florián[9], J. Rodríguez-Villanueva[10]. [1]*Hospital Virgen del Rocio, Medical Oncology, Seville, Spain;* [2]*Hospital Clínico San Carlos, Medical Oncology, Madrid, Spain;* [3]*Hospital Quirón Madrid, Medical Oncology, Madrid, Spain;* [4]*Hospital San Chinarro, Medical Oncology, Madrid, Spain;* [5]*Hospital Miguel Servet, Medical Oncology, Zaragoza, Spain;* [6]*Hospital 12 de Octubre, Medical Oncology, Madrid, Spain;* [7]*MD Anderson Cancer Center Madrid, Medical Oncology, Madrid, Spain;* [8]*Hospital Sanitas La Moraleja, Medical Oncology, Madrid, Spain;* [9]*Hospital Comarcal de Barbastro, Medical Oncology, Barbastro, Spain;* [10]*Eisai Farmacéutica, Oncology, Madrid, Spain*

Background: Spanish MoH authorized Eribulin use for advanced breast cancer (ABC) patients as per license in 04/2011. Pending reimbursement price, public hospitals have accessed the drug through a national compassionate use program. After 1 year, patient selection criteria and eribulin efficacy and safety results in a representative sample were analyzed to determine whether real world use matched the data from the pivotal phase III study.

Methods: An observational, retrospective study was proposed to the top 20 hospitals by eribulin use, with at least 3 candidate patients who had/could have received ⩾3 cycles of treatment by 03/2012. Patient and disease characteristics, as well as efficacy and safety parameters were obtained. Patients' data were collected until 01/2013. Living patients able to respond at the time of the study signed an informed consent. Study was approved by ethics committees.
Results: Out of 112 screened patients, 104 were enrolled in 19 hospitals. Median age was 56.6 years; 66% were post-menopausal. Visceral disease occurred in 2/3 of patients. ECOG status was ⩽1 in 75.4% of patients. Sixty-four % tumors were ER+; 15.4% overexpressed Her-2 and 29.8% were TNBC. Forty-nine % of patients received 1−5 treatment lines for ABC before eribulin. The mean duration of eribulin treatment was 3 months (4.7 cycles). Disease control rate was 48.8% (1.1% CR, 22.1% PR, 25.6% SD). By end 01/2013, 30.8% patients were still alive, with median OS and PFS of 263 days (95% CI: 210–299) and 97 days (95% CI: 81–129), respectively. 78.8% of patients reported ⩾1 adverse event, being asthenia, neutropenia, anemia, alopecia, nauseas, and mucositis the most frequent ones (⩾10%). Grade ⩾3 adverse events occurred in ⩽5% of patients.
Conclusions: The favorable efficacy and safety profile of eribulin observed in this observational study is consistent with the pivotal phase III study (EMBRACE) and confirms its position for the treatment of ABC. Pre-reimbursement drug request procedures and lack of experience have increased initial eribulin usage in later lines of treatment but use per the licensed indication in 3L is expected to yield additional clinical benefit. A confirmatory observational study (EUFORIA-2) is planned.

1900 POSTER

Adherence and patients' attitude towards oral anticancer drugs: a prospective series of 226 patients focusing onto targeted therapies

P. Barthélémy[1], L.M. Dourthe[2], S. Serra[1], I. De la Porte[1], N. Prim[3], S. Amé[1], V. Litique[4], E. Quoix[3], V. Goldbarg[1], J.E. Kurtz[1]. *[1]Hôpitaux Universitaires de Strasbourg, Service d'Oncologie et d'Hématologie, Strasbourg, France; [2]Groupe Hospitalier Saint Vincent, Oncologie, Strasbourg, France; [3]Hôpitaux Universitaires de Strasbourg, Pôle des Pathologies Thoraciques, Strasbourg, France; [4]CHG Colmar, Service d'Oncologie et d'Hématologie, Colmar, France*

Background: Patients' adherence has been identified as a challenge in oncology and hematology practice. Hormone therapy data in breast cancer suggest insufficient adherence and poor persistence. Limited data is available for targeted therapies such as tyrosine kinase (TK) and mTOR inhibitors whereas poor adherence to TK treatment was linked to treatment failure in GIST and CML.
Methods: We report the result of a prospective survey in 226 patients (pts), with solid tumors and hematologic malignancies receiving oral anticancer therapy including chemotherapy or hormone therapy (CT), and targeted therapies (TT). Treatment duration and setting (adjuvant vs metastatic), cancer type, age, co-medication were analyzed. Patients were given a 15-item questionnaire and asked to anonymously answer questions regarding their attitude towards oral anticancer drugs. To analyze adherence, patients were asked whether they voluntarily or not missed any drug dosing during the last month.
Results: 226 patients (median age 65.5 y.o) participated, 115 with TT and 111 with CT, with a median time of drug intake of 10.5 months. Both TT and CT patients stated to be well informed about treatment modalities in (92%), mostly by their oncologist or hematologist (87%). Written information was more frequently given in TT pts (67.0 vs 27.0%, $p < 0.0001$). TT pts declared to be more often fully adherent to therapy (84.3 vs 66.7%, $p = 0.01$) despite experiencing more side-effects ($p < 0.0001$) and taking more concomitant oral medication ($p = 0.029$). The mean treatment duration was 28.0 vs 20.3 months in TT vs CT pts (NS), but in both groups non-adherence was observed at any time since initial prescription.
Conclusions: Despite advances in patients' information leading to better treatment adherence in TT pts, efforts are still warranted such as the onset of dedicated staff for early and prolonged monitoring of outpatient anticancer oral therapy.
No conflict of interest.

1901 POSTER

Mixed-treatment comparison of second line therapy for postmenopausal women with hormone-sensitive advanced breast cancer: clinical efficacy, persistence on treatment, and tolerability

J. Félix[1], D. Ferreira[2], S. Rabiais[3], B. Vandewalle[3], L. Costa[4]. *[1]Exigo Consultores Lda, Director, Lisboa, Portugal; [2]Exigo Consultores Lda, Outcomes Research, Lisboa, Portugal; [3]Exigo Consultores Lda, Quantitative Methods, Lisboa, Portugal; [4]Centro Hospitalar Lisboa Norte EPE, Serviço de Oncologia, Lisboa, Portugal*

Background: Hormone-sensitive breast cancer (BC) is usually associated with an under expression of human epidermal growth factor receptor 2. For postmenopausal women, international guidelines suggest treatment with non-steroidal aromatase inhibitors as first line. Due to the lack of a preferred regimen for second line treatment (necessary in 20−70% of cases), it is justifiable to perform a mixed treatment comparison (MTC) in order to assess the relative effect of all available options for this population of women.
Methods: Randomized controlled clinical trials (RCT) enrolling post-menopausal women with hormone-sensitive advanced BC were systematically reviewed from the literature. All hormonal and chemotherapeutic agents used as second line treatment were considered. Outcomes reviewed were progression-free survival (PFS), time-to-progression (TTP), overall survival (OS) and discontinuation due to any reason (treatment persistence) and due to adverse events (tolerability). A Bayesian generalized linear model framework for MTC was adopted to pool the evidence from the selected RCT and estimate the relative treatment effects and the probability of each considered treatment being the best.
Results: Of the 235 references identified, 25 RCT met the inclusion criteria and 19 entered the quantitative analysis (coherent evidence network). Treatment options analysed were: aminoglutethimide; anastrozole; everolimus; exemestane (EXE); formestane; fulvestrant; letrozole (LET); megestrol acetate; premarin; vorozole. Everolimus + exemestane (EVE+EXE) was estimated to have the highest probability of being the best treatment in delaying progression and death and maximizing treatment persistence. Compared to EXE single agent EVE+EXE was found to be the only treatment option significantly reducing the risk of progression (HR = 0.45; 95% CI [0.38–0.54]). EVE+EXE and LET 2.5 mg were estimated to show a significantly lower chance of discontinuation due to any reason than EXE (OR=0.46; 95% CI [0.33–0.64] for EVE+EXE, OR=0.49; 95% CI [0.26–0.90] for LET 2.5 mg). With respect to OS and discontinuation due to adverse events, none of the considered treatment options was found to demonstrate a significant reduction in risk, when compared to EXE.
Conclusion: Results suggest superiority in terms of efficacy and treatment persistence of EVE+EXE over other hormonal therapeutic options, for the treatment of postmenopausal women with hormone-sensitive advanced BC after failing a first line of treatment.
Conflict of interest: *Corporate-sponsored research: Unrestricted grant of Novartis Oncology.*

1902 POSTER

Thymidylate synthase expression as a novel predictive factor in metastatic breast cancer patients

H. Seki[1], H. Jinno[2], T. Hayashida[2], M. Takahashi[2], F. Asanuma[1], Y. Yamada[1], M. Osaku[1], Y. Kitagawa[2]. *[1]Kitasato University Kitasato Institute Hospital, Breast Center, Tokyo, Japan; [2]Keio University School of Medicine, Surgery, Tokyo, Japan*

Background: S-1, an oral fluoropyrimidine formulation that combines tegafur, 5-chloro-2,4-dihydroxypryidine, and potassium oxonate in a molar ratio of 1:0.4:1, has been widely used against solid cancers including gastric, colorectal, pancreatic, lung and breast cancer in Japan. In a phase II study, the response rate (RR) was 41.7% and the median survival was 872 days among taxane-pretreated patients with metastatic breast cancer (MBC). However, the predictive factor of S-1 in patients with MBC has not been determined yet. The purpose of this study is to investigate the correlation between 5-FU-related enzyme and clinical efficacy of S-1 in patients with MBC.
Material and Methods: Forty-eight patients with MBC were treated with S-1 twice daily at a dose of 80 mg/m^2 for 4 weeks, followed by a 2-week rest interval at Keio University Hospital from January 2005 to January 2010, excluding the patients who were concurrentry treated with trastuzumab. Laser-captured microdissection was performed from the formalin-fixed, paraffin-embedded tumor sections at surgery and the expression of 5-FU-related enzyme including thymidylate synthase (TS), thymidine phosphorylase (TP) and dihydropyrimidine dehydrogenase (DPD) was evaluated by RT-PCR.

Results: The median age was 49 years (range 30−73) and the median time from diagnosis to metastasis was 49.4 months (range 3.3–286.5). Estrogen receptor (ER), progesterone receptor (PgR), human epidermal growth factor receptor type 2 (HER2) was positive in 63, 38, and 21% of the entire patients, respectively. The median number of pretreated chemotherapy regimens was 2 (range 0−6). The median number of metastatic site was 2 (range 1−4). The sites of metastatic disease were the viceral in 25 patients, bone in 9 patients and soft tissue in 17 patients. The overall response rate (RR) was 22.9% (11/48) and clinical benefit rate was 45.8% (22/48). The median time to tumor progression (TTP) was 14.3 months (range 6.2–22.4). ER, PgR and HER2 status was not significantly correlated with RR (P = 0.724, 0.288, 1.000, respectively). TS expression was significantly associated with clinical efficacy of S-1 (Table 1). Moreover, it is notable that triple negative breast cancer (TNBC) revealed lower TS expression than luminal type (TNBC vs luminal type = 1.03 (0.32–4.70) vs 2.45 (0.42–10.1), P = 0.020). According to the correlation between metastatic sites and RR, better RR was noted for soft tissue metastases (soft tissue vs visceral = 25% (5/20) vs 84% (5/6), OR 15.0 (95% CI 1.40–161.05).
Conclusion: This study demonstrated that TS can be a significant predicitve factor of S-1 in patients with MBC.
No conflict of interest.

Table 1. Correlation between 5-FU related enzyme and clinical response of S-1.

1903 POSTER

Chemotherapy treatment for older women with breast cancer in ELIPPSE 65 French cohort

M. Meresse[1], A.D. Bouhnik[1], M.K. Ben Diane[1], F. Retornaz[2], F. Rousseau[3], D. Rey[1], R. Giorgi[1]. *[1]Ors Paca − Inserm Umr912, Sesstim, Marseille, France; [2]Departemental Geriatric Center, Marseille, France; [3]Institut Paoli-Calmettes, Pilot Unit of Research and Coordination in Geriatric Oncology, Marseille, France*

Background: Since a few years, recommendations have been issued for the treatment of old people with cancer: treatment decision must be based on physiological age instead of chronological age. In the context, our objectives were to determine factors associated with access to chemotherapy in a French cohort of elderly women with breast cancer.
Material and Methods: ELIPPSE 65 is an ongoing cohort of women aged 65 to 80 years, included in 2006–2010 in the month following breast cancer diagnosis. Women were interviewed face-to-face and a mini geriatric assessment was made including ADL and IADL scales, Charlson index, mini Cog and nutritional assessment. Medical information was collected from the physicians. Chemotherapy analysis were performed among all eligible women for treatment according to the French recommendations (n = 234). Logistic regression procedure have taken into account explanatory variables such as age, socio-demographic and medical characteristics, year of diagnostic, functional status, cognitive function and presence of comorbidities. Age at diagnosis was categorized into three classes as follows: 65−70, 70−75 and 75−80. The final model was adjusted for geriatric assessment variables.
Results: Among the 234 patients, 30% were aged between 75 and 80, 68% were living in couple and 91% had children. Concerning geriatric assessment, 68% were considered as 'independent' regarding their functional status, 20% had at least one severe comorbidity and 20% were cognitively impaired. Fifty-seven percent of patients eligible for chemotherapy according to medical criteria received chemotherapy. Factors associated with access to chemotherapy are: tumor stage II/III versus I [AOR (95% CI) = 7.7 (3.6–16.3)], hormone-independent breast cancer [AOR (95% CI) = 9.1 (3.1–26.8)], most recent year of diagnosis [AOR (95% CI) = 4.1 (1.0–16.8)] but also age, with women aged 75−80 having less access to chemotherapy [AOR (95% CI) = 0.3 (0.1−0.6)] than younger ones. None of geriatric assessment variables were associated to access to chemotherapy.
Conclusions: Despite a better consideration of elderly patients by medical staff and the improvement of geriatric medicine in developed countries, chronological age remains a barrier to chemotherapy for oldest women with breast cancer in France. The lack of clinical trials among old cancer patients may explain the reluctance of physicians to offer these heavy therapies to their oldest patients.
No conflict of interest.

1904 POSTER

Out-of-pocket burden and trastuzumab persistence among US managed care patients with presumed HER2+ metastatic breast cancer

M. Brammer[1], D. Lalla[2], Y. Chen[3], V. Schabert[4], E. Santos[2], P. Iversen[5], L. Cen[6]. *[1]Genentech Inc., BioOncology Medical Affairs, South San Francisco, USA; [2]Genentech Inc., Medical Affairs, South San Francisco, USA; [3]IMS Health, Health Economics & Outcomes Research, Alexandria, USA; [4]IMS Health, Health Economics & Outcomes Research, Woodland Hills, USA; [5]IMS Health, Health Economics & Outcomes Research, London, United Kingdom; [6]IMS Health, Health Economics & Outcomes Research, Plymouth Meeting, USA*

Background: Out-of-pocket expenditure (OOP) is deemed as a potential barrier to treatment compliance, particularly for costly-targeted oncology therapies. This study explores the relationship between OOP and trastuzumab persistence in metastatic breast cancer (mBC) patients enrolled in US managed care plans.
Materials and Methods: This retrospective cohort study of the IMS LifeLink™ Health Plan Claims Database included women aged 18+ years; with a first (index) trastuzumab between July 2006 and December 2010; continuous enrollment 180 days pre- to 30–360 days post- index; a primary malignant breast cancer (ICD-9-CM 174.x, 233.0) and a secondary malignant neoplasm (ICD-9-CM 196.x–198.x) pre-index; no trastuzumab pre-index; and no other primary cancer pre- or post-index. Persistence was defined as days from trastuzumab index to discontinuation (90 days of treatment gap) or end of enrollment. OOP post-index was defined as 'allowed amount' minus 'paid amount' summed across claims. Mixed-effects Cox proportional hazard models estimated the relative hazard of trastuzumab discontinuation as a time-varying function of OOP before each 30 days post-index; time-constant covariates included demographic and clinical characteristics, pre-index healthcare spending and Charlson Comorbidity Index score.
Results: 1109 patients (mean age=50.9 years) met all study criteria. OOP was positively skewed for trastuzumab (mean=$2404, median=$68, interquartile range [IQR]=[$0, $1430]) and all medical services (mean=$7828, median=$3049, IQR=[$1407, $5821]). Patients persisted on trastuzumab for a median of 359 days. For patients where trastuzumab OOP was >$2000, there was a predicted higher discontinuation risk vs. trastuzumab OOP ⩽$500 ($2001-$4000: hazard ratio [HR]=1.62 [95% CI 1.12–2.34]; furthermore, for patients where trastuzumab OOP was >$4000: HR = 1.88 [95% CI 1.20–2.94]). OOP for all medical services >$7000 predicted higher discontinuation risk vs. all services OOP ⩽$1000 ($7001-$9000: HR = 2.72 [95% CI 1.60–4.62]; $9001+: HR = 2.32 [95% CI 1.45–3.70]). Covariates in the trastuzumab Cox model that predicted higher discontinuation risk included hospital outpatient treatment setting vs. physician office (HR = 1.57[95% CI 1.06–2.31]) and Medicare Risk vs. commercial payer type (HR = 2.65[95% CI 1.06–6.59]).
Conclusions: 75% of US managed care mBC patients had OOP ⩽$5821 for all medical services and ⩽$1430 for trastuzumab in year one of therapy. OOP exceeding $7000 for overall or $2000 for trastuzumab predicted lower trastuzumab compliance. Monitoring OOP in HER2+ mBC patients may identify those with increased risk for treatment discontinuation.

1905 POSTER

Final results of an international three-arm randomised phase II study evaluating oral vinorelbine plus capecitabine versus paclitaxel plus gemcitabine versus docetaxel plus gemcitabine as first-line chemotherapy in patients with metastatic breast cancer (NorCap-CA223 trial)

S. Cinieri[1], A. Chan[2], K. Altundag[3], N. Tubiana-Mathieu[4], A. Barnadas[5], P. Dodyk[6], S. Lazzarelli[7], M. Botha[8], G. Villanova[9], U. Coskun[10].
[1]San Antonio Perrino Hospital, Medical Oncology, Brindisi, Italy; [2]Mount Hospital Curtin University, Medical Oncology, Perth, Australia; [3]Hacettepe University Medical Center, Medical Oncology, Ankara, Turkey; [4]CHU Dupuytren, Medical Oncology, Limoges, France; [5]Hospital Saint Pau, Medical Oncology, Barcelone, Spain; [6]CER Instituto Medico, Medical Oncology, Buenos Aires, Argentina; [7]Istituti Ospitalieri, Medical Oncology, Cremona, Italy; [8]National Hospital, Medical Oncology, Bloemfontein, South Africa; [9]Institut de Recherche Pierre Fabre, Medical Affairs, Boulogne-Billancourt, France; [10]Gazi University Medical Center, Medical Oncology, Ankara, Turkey

Background: Combination chemotherapy (CT) is among the standard treatment options in metastatic breast cancer (MBC), especially in patients (pts) with visceral metastases or need of rapid symptom or disease control. Full oral combination CT of Oral Vinorelbine (OV) + Capecitabine (C) is a convenient and effective alternative to taxane-based intravenous regimens. Aim of this study was to evaluate the efficacy of a full oral and two full intravenous combinations in MBC.
Material and Methods: Pts with HER2-negative taxane-naive MBC, with an age $\geqslant$18 years were eligible. Pts were randomised to receive, as first-line CT, 3 weekly-cycles of either: ARM A: full oral combination of OV, given as a 80 mg/m^2 dose (following a first cycle at 60 mg/m^2, dose escalation to 80 in the absence of grade 3 or 4 toxicity at cycle 1) D1 & D8 and C 1000 (750 if $\geqslant$65 years) mg/m^2/bid D1 to D14; ARM B: paclitaxel 175 mg/m^2 D1 plus gemcitabine (G) 1250 mg/m^2 D1 & D8; ARM C: docetaxel 75 mg/m^2 D1 plus G 1000 mg/m^2 D1 & D8. Primary endpoint was disease control rate (DCR), defined as complete response + partial response + stable disease $\geqslant$3 months. Pts were stratified according to prior anthracycline CT and age < or $\geqslant$65 years.
Results: 149 pts had been treated (ARM A 49; ARM B 50; ARM C 50). Baseline pt characteristics (Arms A/B/C): median age 58/56/57 years; hormone receptor positive 61/50/66%; prior hormone therapy 59/64/66%; prior (neo)adjuvant CT 49/46/58%; prior anthracycline 39/42/42%; visceral metastases 80/82/74%; $\geqslant$3 metastatic sites 53/44/58%; measurable disease at baseline 94/90/98%. Median number of cycles (range): 6(1−37)/6(1−12)/7(1−25); dose escalation of OV was performed in 78% of pts. Safety: G3/4 adverse events per pt: neutropenia 50/46/86%, anemia 2/4/8%, infections 2/2/10%, diarrhoea 6/4/2%, vomiting 10/2/2%, fatigue 10/12/22%, alopecia (G2) 8/72/76%, febrile neutropenia (pts) 4/0/3, toxic deaths (pts) 2/1/0. Efficacy: DCR in the intent-to-treat population was [95% CI] 73.5 [59−85] /78 [64−88] /80 [66−90] %; progression-free survival: 7.6 /9.0/11.4 months; time to treatment failure: 4.6/4.8/5.2 months; overall survival: 30.2/29.6/31 months.
Conclusion: The DCR as well the OS results reported in this trial confirm that the full oral combination of OV + C is an active combination which can be proposed as an alternative to taxane-based regimens as first-line CT in MBC, allowing to delay the constraints of an intravenous CT. As expected, each regimen presented a specific and particular tolerance profile, with, in particular, a low incidence of alopecia after full oral CT.

1906 POSTER

No difference in prognosis and response to systemic treatment between patients with invasive lobular and invasive ductal hormone receptor positive metastatic breast cancer

D.J.A. Lobbezoo[1], W. Truin[2], R.M.H. Roumen[3], A.C. Voogd[4], G. Vreugdenhil[5], P.G.M. Peer[6], V.C.G. Tjan-Heijnen[1]. *[1]Maastricht University Medical Centre, Medical Oncology, Maastricht, Netherlands; [2]Maastricht University Medical Centre, Surgery, Maastricht, Netherlands; [3]Máxima Medical Centre, Surgery, Veldhoven, Netherlands; [4]Maastricht University Medical Centre, Epidemiology, Maastricht, Netherlands; [5]Máxima Medical Centre, Internal Medicine, Veldhoven, Netherlands; [6]Radboud University Nijmegen Medical Centre, Health Evidence, Nijmegen, Netherlands*

Background: Invasive ductal carcinoma (IDC) and invasive lobular carcinoma (ILC) are the two most frequent histological subtypes of breast cancer and are known to be distinct tumor-biological entities. Response to neo-adjuvant chemotherapy is known to be poorer for ILC than for IDC. More recently, data on the use of chemotherapy in the adjuvant setting showed that patients with ILC did not seem to benefit from the addition of chemotherapy to hormonal therapy. However, data on possible differences between ILC and IDC in the effectiveness of chemotherapy in patients with metastatic breast cancer is lacking.
Patients and Methods: We analyzed 815 consecutive breast cancer patients diagnosed with metastatic breast cancer in eight hospitals between 2007 and 2009. All hormone receptor positive patients with either IDC or with (mixed) ILC were included. Data on patient and tumor characteristics, as well as outcomes and treatments were collected. Survival curves were estimated using the Kaplan–Meier method. Progression-free survival (PFS) on palliative chemotherapy was compared between the two histological subgroups with log-rank test.
Results: A total of 568 hormone receptor positive patients were included; 437 patients with IDC and 131 patients with (mixed) ILC. The median survival after diagnosis of metastatic breast cancer was 25 months (95% confidence interval (CI) 22−32 months) for patients with IDC and 29 months (95% CI 23−37 months) for patients with ILC (log-rank $P = 0.53$).
The hazard ratio for mortality was 0.94 (95% CI 0.72–1.21) for patients with IDC treated with palliative chemotherapy compared to those not treated with palliative chemotherapy, and for patients with ILC this hazard ratio was 1.47 (95% CI 0.92–2.36). There was also no difference in PFS between patients with IDC or ILC for first-line chemotherapy, with 1-year PFS of 52.5% for the patients with IDC and 1-year PFS of 54.0% for patients with ILC (log-rank $P = 0.68$).
Conclusions: In patients with hormone receptor positive metastatic breast cancer no significant differences in survival after diagnosis of metastatic breast cancer were found between ILC and IDC. Furthermore, unlike the findings in the (neo-)adjuvant setting, we did not observe any difference regarding chemotherapy effectiveness between the two histological subtypes.
No conflict of interest.

Hypertension as a predictive marker for bevacizumab in metastatic breast cancer: updated results from a retrospective matched-pair analysis

S.P. Gampenrieder[1], F. Romeder[1], C. Muß[1], M. Pircher[1], S. Ressler[1], G. Rinnerthaler[1], R. Bartsch[2], C. Sattlberger[3], B. Mlineritsch[1], R. Greil[1].
[1]Paracelsus Medical University, 3rd Medical Department, Salzburg, Austria; [2]Medical University of Vienna, 1st Medical Department, Vienna, Austria; [3]Hospital of Vöcklabruck, Department of Surgery, Vöcklabruck, Austria

Background: Several phase-III studies showed improvement in PFS by bevacizumab when added to chemotherapy in advanced breast cancer. However, the extent of improvement varied and no trial showed benefit in OS. To reduce the number needed to treat, predictive markers are urgently required. Therefore, besides effectiveness and safety, we investigated hypertension as potential predictive biomarker for bevacizumab. Here we report the updated results*.
Patients and Methods: All patients with metastatic breast cancer treated with bevacizumab in combination with chemotherapy at our institution between 2005 and 2011 were retrospectively analyzed. A control group was matched according to the following criteria: receptor status, treatment-line, type of chemotherapy, presence of visceral disease, and age.
Results: All 212 patients were evaluable for toxicity, 198 for response; 430 controls allowed a complete matching for 85 patients. The addition of bevacizumab to chemotherapy significantly prolonged PFS and OS. CBR was significantly better in the bevacizumab group, while ORR did not differ significantly. Patients developing hypertension during treatment had a more favorable outcome regarding PFS and OS.

			Hazard ratio (HR) and Relative risk (RR)	P
Matched-pair population	Control (n = 85)	Bevacizumab (n = 85)		
PFS [mo]	7.6	9.3	HR 0.70 (95% CI 0.51–0.97)	0.031
OS [mo]	22.6	28.9	HR 0.67 (95% CI 0.45–0.99)	0.043
ORR CR+PR)	30 (35%)	41 (48%)	RR 1.25 (95% CI 0.85–1.86)	0.210
CBR (ORR+SD)	50 (59%)	64 (75%)	RR 1.28 (95% CI 1.02–1.59)	0.002
Bevacizumab population	No hypertension (n = 91)	Hypertension (n = 56)		
PFS [mo]	6.6	13.7	HR 0.34 (95% CI 0.23–0.49)	<0.001
2-yr-OS	30%	78%	HR 0.20 (95% CI 0.12–0.35)	<0.001
ORR CR+PR)	34 (37%)	29 (52%)	RR 1.39 (95% CI 0.92–2.03)	0.086
CBR (ORR+SD)	56 (62%)	53 (95%)	RR 1.54 (95% CI 1.28–1.67)	<0.001

Conclusion: Bevacizumab in addition to chemotherapy prolonged PFS and OS even in a non-selected, partly intensively pretreated breast cancer population. Hypertension could provide a simple biologic biomarker for bevacizumab efficacy.

Clinical outcomes according to molecular-guided therapy strategies in phase I for breast cancer patients

E. Carton[1], A. Hollebecque[1], F. Roquet[2], M. Arnedos[3], A. Varga[1], E. Lanoy[2], E. Boissier[1], S. Delaloge[3], F. André[3], J.C. Soria[1]. *[1]Institute Gustave Roussy, Sitep, Villejuif, France; [2]Institute Gustave Roussy, Service de Biostatistique et Epidémiologie, Villejuif, France; [3]Institute Gustave Roussy, Département de Sénologie, Villejuif, France*

Background: Over the last decade, the focus of anticancer drug development has shifted from empirical cytotoxic chemotherapy to mechanism-defined molecularly targeted agents. Our study aims to identify a possible association of oriented strategy and patient outcome in patients treated for a metastatic breast cancer in a phase I trial.
Material and Method: We analysed patients with metastatic breast cancer recruited in phase I trial from February 2004 to February 2008 at Gustave-Roussy Institute. Population was divided in two groups: non-oriented therapy or oriented therapy. Baseline was defined as first day of treatment. Overall survival (OS) and progression-free survival (PFS) were estimated using Kaplan–Meier method. Progression was determined by both clinical and radiological assessments. Oriented therapy was defined as any therapy targeting a specific molecular alteration found in the patient's tumor (angiogenesis inhibitors, cellular cycle inhibitors, FGF inhibitors, cell metabolism inhibitors, EGFR/PI3K/Akt/mTOR inhibitors). The effect of oriented therapy on OS and PFS adjusted for prognostic factors (performance status, albumin level, age, body mass index, inhibitor type and previous or concomitant chemotherapies) were assessed using multivariable Cox proportional hazards model. Analyses accounting for HER2 and estrogen-receptors status are currently ongoing.
Results: Among the 78 patients recruited in phase I trials, 64 fulfilled the analysis inclusion criteria. Of them, 52 patients had complete data, including 15 (29%) patients receiving oriented therapy. Median OS and PFS were respectively 11.2 (95% CI=6.9; 33.4) and 3.7 (95% CI=1.6; 7.4) months in the oriented therapy group versus 6.8 (95% CI=5.0; 11.0) and 2.4 (95% CI=1.7; 2.9) months in the non-oriented therapy group. Factors associated with longer OS included oriented therapy HR = 0.40 (95% CI=0.18–0.87, p = 0.02) and high albumin levels HR = 0.24 (95% CI=0.11–0.50, p < 0.001). Factors associated with longer PFS were oriented therapy HR = 0.47 (95% CI=0.23–0.94, p = 0.03) and age <50 years (HR = 0.41; 95% CI=0.19–0.91) versus age 50−60 years-old (HR = 1.04; 95% CI=0.51–2.10; p = 0.05).
Conclusion: Oriented therapy was independently associated with longer OS and PFS in breast cancer patients treated in a phase I trial. However, we cannot rule out the impact of unmeasured indication bias.
No conflict of interest.

Saura[1]. *[1]Vall d'Hebron Institute of Oncology/Vall d'Hebron University Hospital, Medical Oncology Department, Barcelona, Spain; [2]Vall d'Hebron Institute of Oncology, Statistics, Barcelona, Spain; [3]Vall d'Hebron Institute of Oncology/Vall d'Hebron University Hospital, Molecular Pathology Department, Barcelona, Spain; [4]Vall d'Hebron Institute of Oncology/Vall d'Hebron University Hospital, Genomics laboratory, Barcelona, Spain; [5]Vall d'Hebron Institute of Oncology/Vall d'Hebron University Hospital, Translational Research Program, Barcelona, Spain*

Background: Breast cancer (BC) clinical research has evolved into a personalized field with biomarker enrichment strategies and development of oncogene-driven molecular targeted agents (MTA). Our objective was to compare the outcome of BC patients (pts) treated with a MTA with their previous and subsequent unmatched therapies.
Methods: Inclusion criteria: advanced BC pts with molecular alteration in tumor tissue (A) PI3K pathway dysregulation: *PIK3CA*/*AKT* mutation(m) and/or PTEN downregulation (PTENd) (HScore⩽50); (B) *FGFR1* amplification(a), treated ⩾2nd line and matched with MTA-driven phase 1 or 2 clinical trial, received at least >2/3 of the maximum tolerated doses, ECOG 0 or 1.
Results: From 2009 to 2012, 269 BC pts were screened for MTA-driven phase 1/2 trials (60%, primary site; 40%, metastatic site). 43 BC pts received matched therapies, 41.9% *PIK3CA*m (18/43), 30.2% PTENd (13/43), 11.6% *PIK3CA*m and PTENd (5/43), 4.7% *AKT*m (2/43), 7% *FGFR1*a (3/43), 2.3% *PIK3CA*m and *KRAS*m (1/43), 2.3% PTENd and *KRAS*m (4/43). 60.5% matched pts had molecular analysis from a metastatic site. Overall, 43 BC matched pts received 50 MTAs within 15 different trials including pan or alpha PI3K, AKT, mTORC1/2, dual PI3K/mTORC1/2 and FGFR1 inhibitors as single agents or combined with endocrine, chemotherapy or trastuzumab-based therapy. Median age 51.7; ECOG 0 39.5%, ECOG 1 60.5%; ER+/HER2−72%, HER2+ 21%, ER-/HER2−7%; median prior therapies 6. 7 BC pts participated in 2 or 3 trials. Median time-to-treatment failure (mTTF) on MTA was 2.3 months (95% CI 1.9−3.7) *vs.* 5.5 months (95% CI 3.41–7.11) for their previous systemic antitumor therapy (p < 0.001). There were no statistical differences for mTTF on MTA *vs.* subsequent therapy line (N = 34 pts, 4.32 *vs.*7.02 months; 95% CI 0.39–1.07, p = 0.087). Partial responses were seen in 16% (8/50) matches (Table 1). Stable disease >16 weeks was observed in 11/23 matches (47.8%).
Conclusions: In advanced BC, matching molecular profile with the available first-generation MTA phase 1/2 trials does not seem to prolong mTTF as compared to the previous or subsequent unmatched therapy; however, it might confer a clinical benefit for some pts in terms of objective responses and disease stabilization.
No conflict of interest.

Table 1. Partial responses with matched targeted therapy (8/50)

Pt no.	Molecular alteration	Molecular targeted agent	Combination therapy
4	FGFR1 amplification	FGFR1 and VEGFR-1−3 inhibitor	No
5	PIK3CA mutation	pan-PI3K inhibitor	No

16	PIK3CA mutation	pan-PI3K inhibitor	No
21	FGFR1 amplification	FGFR1 and VEGFR-1−3 inhibitor	No
37	PTEN downregulation	PI3K/mTOR dual inhibitor	paclitaxel
42	PIK3CA mutation	PI3K/mTOR dual inhibitor	trastuzumab
45	PTEN downregulation	PI3K/mTOR dual inhibitor	paclitaxel + trastuzumab

1910 POSTER

Role of HER2 FISH ratios in predicting pathological complete response (pCR) to neoadjuvant systemic chemotherapy with trastuzumab in patients with inflammatory breast cancer (IBC) and non-inflammatory locally advanced breast cancer

T. Kogawa[1], T. Fouad[1], D. Liu[2], Y. Shen[2], H. Masuda[1], M. Chavez Mac Gregor[1], R. Alvarez[1], V. Valero[1], G. Hortobagyi[1], N. Ueno[1]. *[1]The UT MD Anderson Cancer Center, Breast Medical Oncology, Houston − TX, USA; [2]The UT MD Anderson Cancer Center, Biostatistics, Houston − TX, USA*

Background: Neoadjuvant systemic chemotherapy with trastuzumab (NST-T), a standard treatment option for patients with HER2-overexpressing (HER2+) primary breast cancer, produces a significantly higher pathological complete response (pCR) rate and has led to better outcomes than NST without trastuzumab. However, whether the HER2 fluorescence in situ hybridization (FISH) ratio is a predictor of pCR rate in patients with primary inflammatory breast cancer (IBC) or non-inflammatory locally advanced breast cancer (Stage III non-IBC) is unknown. We hypothesized that a high HER2 FISH ratio is a predictor of pCR, extended time to recurrence (TTR), and overall survival (OS) in IBC and non-IBC patients taking NST-T.
Material and Methods: In this retrospective review, we included 169 patients with stage III HER2+ IBC and 388 patients with stage III HER2+ non-IBC who were treated with NST and definitive surgery from 1999 through 2012. Trastuzumab was concurrently administered in 121 (71.6%) IBC and 286 (73.7%) non-IBC patients. HER2 was defined as positive if the immunohistochemistry score was 3+ or the FISH ratio was positive (>2.0). FISH ratios were available for 132 (78.1%) IBC and 331 (85.3%) non-IBC patients.
Results: Univariate analysis revealed that age less than 50 years, negative estrogen receptor (ER)/progesterone receptor (PR) status, no lymphatic invasion, non-IBC, and NST-T were significantly associated with high pCR. The median HER2 FISH ratio of the pCR group was significantly higher than of the non-pCR group ($p = 0.0039$). The logistic regression model for pCR demonstrated that a HER2 ratio of ⩾7.0 ($p = 0.0153$), negative ER or PR status ($p = 0.0394$ and $p = 0.0232$, respectively), and no lymphatic invasion ($p<0.0001$) were independent predictors of pCR. In both IBC and non-IBC, NST-T was strongly related with pCR, though this association was not significant ($p = 0.0523$); in non-IBC patients, NST-T

Table (abstract 1911).

	Progression event					
	NM		IPEL		Other	
	E (n = 271)	C (n = 285)	E (n = 147)	C (n = 129)	E (n = 136)	C (n = 134)
Median OS, months (95% CI)	15.5 (14.2, 17.5)	12.9 (11.3, 14.5)	17.4 (14.4, 19.7)	17.4 (15.3, 20.9)	16.7 (14.8, 24.2)	15.5 (11.7, 18.3)
HR (95% CI)	0.81 (0.68, 0.97)		1.13 (0.87, 1.46)		0.78 (0.59, 1.03)	
Nominal p-value	0.02		0.35		0.08	
Time to NM, months (95% CI)	5.8 (5.2, 6.5)	5.2 (4.3, 5.9)				
HR (95% CI)	0.90 (0.77, 1.05)					
Nominal p-value	0.17					

was significantly associated with pCR (p=0.0024). Survival evaluation with univariate analysis revealed that positive ER/PR status, no lymphatic invasion, NST-T, and non-IBC had significant prognostic value for TTR, and the same variables, other than positive PR status, had significant prognostic value for OS. The Cox model showed that a HER2 FISH ratio of $\geqslant$7.0 was a borderline-independent prognostic indicator of TTR and OS (p = 0.0559 and p = 0.0520, respectively). Only lymphatic invasion was a strong independent prognostic factor (p<0.0001 and p = 0.0044, respectively).

Conclusion: A HER2 FISH ratio of $\geqslant$7.0 is an independent predictor of pCR in IBC and non-IBC patients taking trastuzumab-containing neoadjuvant chemotherapy. Prospective evaluation of HER2 FISH ratio of $\geqslant$7.0 is needed. This may be an important stratification factor for randomized clinical trials.

No conflict of interest.

1911 POSTER

New metastases versus increase in size of pre-existing lesions and its correlation with overall survival in patients with MBC treated with eribulin or capecitabine in study 301, a phase III randomised trial

E. Perez[1], J. O'Shaughnessy[2], C. Twelves[3], J. Cortes[4], A. Awada[5], L. Yelle[6], J. Wanders[7], M. Olivo[8], Y. He[9], P.A. Kaufman[10]. *[1]Mayo Clinic, Department of Haematology/Oncology, Jacksonville, USA; [2]Baylor Charles A. Sammons Cancer Center, Texas Oncology and the US Oncology Network, Dallas Texas, USA; [3]Leeds Institute of Cancer and Pathology and St James's Institute of Oncology, Department of Clinical Pharmacology and Oncology, Leeds, United Kingdom; [4]Vall D'Hebron University Hospital, Department of Medical Oncology, Barcelona, Spain; [5]Jules Bordet Institute, Medical Oncology Clinic, Brussels, Belgium; [6]University of Montreal, Department of Medicine, Montreal Quebec, Canada; [7]Formerly of Eisai Ltd, Oncology, Hatfield, United Kingdom; [8]Eisai Inc., Clinical Development, Woodcliff Lake New Jersey, USA; [9]Eisai Inc., Biostatistics, Woodcliff Lake New Jersey, USA; [10]Norris Cotton Cancer Center Dartmouth-Hitchcock Medical Center, Hematology/Oncology, Lebanon New Hampshire, USA*

Background: Improved progression-free survival (PFS) in metastatic breast cancer (MBC) often does not translate into overall survival (OS) benefit. A recent Phase III trial (NCT00337103) in MBC comparing eribulin (E) with capecitabine (C) showed a trend for improved OS (HR 0.88 [95% CI 0.77, 1.00]; p = 0.056) but not PFS (HR 1.08 [95% CI 0.93, 1.25]; p = 0.30) with E. In response to a European Health Authorities request to investigate this apparent discordance, a post-hoc analysis assessed the relationship between OS and the different events defining disease progression: the appearance of a 'new' lesion or metastasis (NM); the increase in size of pre-existing lesions (IPEL); or other (death, clinical progression or censored).

Materials and Methods: Patients (pts) with locally advanced or MBC who had received $\leqslant$3 prior chemotherapy regimens, including an anthracycline and a taxane, were randomised to receive E (n = 554) or C (n = 548). Co-primary endpoints were OS and PFS. In this post-hoc analysis, the relationship between progression events and OS was investigated by Cox regression with a time-dependent covariate; time from randomisation to NM was also analysed.

Results: Progression due to NM or IPEL occurred in 271 and 285, and 147 and 129 of E and C pts respectively. OS by type of progression event is shown in the table. Median OS was similar between arms in pts with IPEL; it was higher in pts with NM treated with E compared with C. Pts who progressed due to a NM were at higher risk of death (HR 2.12 [95% CI 1.84, 2.43]; Wald nominal p < 0.0001).

Conclusions: These results suggest that the conventional PFS definition may not be adequate and that clinically meaningful differences may exist among different MBC 'subsets'. Namely, pts with NM may have a worse prognosis than those with an IPEL. Further, the difference in OS observed in Study 301 may have been driven by pts whose disease progressed due to NM rather than IPEL, and the discordance between PFS and OS may be due to this heterogeneity. These hypotheses are being tested with existing EMBRACE study data and warrant prospective study.

1912 POSTER

BOLERO-2: Efficacy, safety, and quality of life in patients with advanced breast cancer receiving first-line everolimus plus exemestane

M. Campone[1], F. Lebrun[2], P. Neven[3], B. Pistilli[4], H. Rugo[5], J. Baselga[6], T. Brechenmacher[7], T. Taran[8], T. Sahmoud[9], G. Hortobagyi[10]. *[1]Institut René Gauducheau, Medical Oncology, Saint-Herblain Cedex, France; [2]Institut Jules Bordet, Oncology, Brussels, Belgium; [3]UZ Leuven, Oncology, Leuven, Belgium; [4]Presidio Ospedaliero di Macerata-Zona Territoriale 9 di Macerata ASUR Marche-Az, Oncology, Macerata, Italy; [5]UCSF San Francisco Helen Diller Family Comprehensive Cancer Center, Oncology, San Francisco, USA; [6]Memorial Sloan-Kettering, Oncology, New York, USA; [7]Novartis Pharma S.A.S., GMA Lead Statistician, Rueil-Malmaison Cedex, France; [8]Novartis Pharmaceuticals Corporation, Senior Global Clinical Leader, East Hanover, USA; [9]Novartis Pharmaceuticals Corporation, Global Clinical Program Head, East Hanover, USA; [10]The University of Texas MD Anderson Cancer Center, Oncology, Houston, USA*

Background: In the BOLERO-2 study (NCT00863655), the combination of everolimus and exemestane (EVE+EXE) more than doubled progression-free survival (PFS) versus placebo (PBO) and EXE (median PFS 7.8 vs 3.2 mo; hazard ratio = 0.45; P <. 0001). Consistent efficacy results were observed in all predefined subgroups, including patients with visceral metastases and patients whose disease recurred after adjuvant endocrine therapy (alone or with chemotherapy). This analysis of BOLERO-2 examines efficacy, safety, and quality of life (QOL) in the subgroup of patients who received EVE+EXE after adjuvant therapy (ie, as first-line therapy in the advanced setting).

Materials and Methods: BOLERO-2 enrolled patients with hormone-receptor-positive (HR^+) advanced breast cancer who had a recurrence or progressed after prior nonsteroidal aromatase inhibitors, and compared EVE (10 mg/d) + EXE (25 mg/d) versus PBO+EXE. The primary endpoint was PFS by local investigator review. QOL was assessed using the EORTC QLQ C-30 questionnaire, with definitive deterioration defined as a 5% decrease in global health status versus baseline, with no subsequent increase on-study.

Results: Of 724 patients in BOLERO-2, 137 (19%) received first-line EVE+EXE (n = 100) or PBO+EXE (n = 37) in the advanced setting. The EVE+EXE group had significantly longer PFS compared with the PBO+EXE group (by local assessment: 11.50 vs 4.07 mo, respectively; hazard ratio = 0.39; 95% confidence interval, 0.25–0.62; by central assessment: 15.24 vs 4.21 mo, respectively; hazard ratio = 0.32; 95% confidence interval, 0.18–0.57). The safety profile was consistent with the known profiles of each agent. Median time to definitive deterioration in global health status was numerically longer in the EVE+EXE arm compared with the PBO+EXE arm (11.07 vs 7.23 mo, respectively; P =. 1715).

Conclusions: EVE+EXE significantly prolonged PFS while maintaining QOL in patients with HR^+ advanced breast cancer who received this treatment as first-line therapy (ie, disease recurred after adjuvant therapy). The robust results observed in this population (PFS by local assessment 7.4 mo longer with EVE+EXE) support using the combination of EVE+EXE earlier in the advanced setting. An ongoing phase 2 trial, BOLERO-4, is prospectively evaluating the efficacy of EVE plus letrozole as a first-line therapy in patients with HR^+ advanced breast cancer (target N = 200).

Background: The HERNATA study was a randomised phase III study comparing docetaxel plus trastuzumab (DT) with vinorelbine plus trastuzumab (VT) as a first line therapy og metastatic og locally advanced HER2-positive breast cancer (Anderson et al 2010).
No differences in terms of efficacy between DT and VT was demonstrated but toxicity was much more pronounced with DT. Because of this better benefit-risk balance, standard of care has changed at many institutions. A 2 year update of the study is presented.
Materials and Methods: Patients with HER2 positive locally advanced og metastatic breast cancer naive to chemotherapy and trastuzumab, were randomly assigned to docetaxel 100 mg/m^2 day 1 or vinorelbine 30−35 mg/m^2 days 1+8 both combined with trastuzumab 8 mg/kg loading dose and 6 mg/kg maintenance dose day 1 q 3 weeks. Tumor assessments were conducted every 9 weeks. Analyses were according to intention-to-treat. Primary endpoint was time to progression (TTP).
Results: 143 patients were randomly allocated to docetaxel and 141 to vinorelbine. With median follow-up of 68 months, 217 have progressed and 184 died. The median TTP for vinorelbine and docetaxel respectively was 14.9 (95% CI:11.9–18.2) vs. 13.5 (95% CI10.7–16.6) months (hazard ratio (HR) 0.99, 95% CI: 0.76–1.30, p = 0.96), median overall survival was 41.1 (95% CI: 35.3–50.8) vs. 38.1 (95% CI: 33.0–58.4) months (HR 1.05, 95% CI: 0.79–1.40, p = 0.74). 2-year survival rate was 73% in VT arm and 70% in DT arm, whereas 5-year survival rates were 35% and 40% respectively.
Median time to treatment failure for study chemotherapy was 8.3 (VT arm) vs 6.2 (DT arm) months (HR 0.51, 95% CI: 0.39–0.65, p < 0.0001). The investigator assessed overall response rate among 241 patients with measurable disease were 72% for VT and 69% for DT. More patients in the docetaxel arm discontinued therapy due to toxicity (p < 0.0001). More patients had grade III−IV toxicity with docetaxel than with vinorelbine.
Conclusion: The outcome was similar for first line treatment with vinorelbine and docetaxel both combined with trastuzumab but vinorelbine could be asministered for longer time and had a more favourable toxicity profile. It should therefore be considered as a potentially better first line alternative and ad an regimen for future combination with HER2 directed therapy ex. pertuzumab.

1914 POSTER

Clinical significance of p95HER2 Overexpression, PTEN loss and PI3K expression in p185HER2-positive metastatic breast cancer patients treated with trastuzumab-based therapies

D. Tural[1], F. Demirelli[2], S. Serdengecti[2], T. Ozturk[3], S. Ilvan[3], H. Turna[4], M. Ozguroglu[4], E. Buyukunal[4]. *[1]Istanbul University Division of Medical Oncology, Istanbul, Turkey; [2]Istanbul University Division of Medical Oncology, Istanbul, Turkey; [3]Istanbul University Division of Pathology, Istanbul, Turkey; [4]Istanbul University Division of Medical Oncology, Istanbul, Turkey*

Background: Overexpression or amplification of p185HER2 is an established poor prognostic factor in breast cancer portending an aggressive course and potential for early metastasis. On the other hand, monoclonal antibody trastuzumab is widely used in the clinic to target this overexpressed oncogene. Unfortunately, approximately 30−40% of all patients overexpressing HER2 respond to trastuzumab warranting further research regarding the structure and additional modulation of the receptor. In this study, we aimed to investigate the response to trastuzumab in terms of the potential roles of several oncogenic pathways (phosphatase and tensin homolog (PTEN), and phosphatidylinositol 3-kinase(PI3K) and a truncated receptor protein, p95HER2), retrospectively.
Material and Methods: Paraffin embedded primary tumor tissues of hundred HER2 positive metastatic breast cancer patients who received trastuzumab with combination cytotoxic chemotherapy were analyzed with immunohistochemical method for p95HER2, p85 and PTEN. Relationship between variables were tested via chi-square, Fischer's exact test and Mann Whitney U tests, wherever appropriate. Progression free survival (PFS) and overall survival (OS) periods were calculated with Kaplan–Meier method and survival curves of subgroups were compared with log-rank test.
Results: Levels of immunohistochemical expression of p95 and PI3K were 33% and 42%, respectively. In 43% of patients loss of PTEN was observed. p95 expressing tumors had statistically lower response rates for trastuzumab than tumors not-expressing p95 ($p = 0.001$).
On the contrary, PTEN expressing tumors had statistically higher response rates for trastuzumab than tumors not-expressing PTEN ($p = 0.012$). PI3K expression had no significant effect on trastuzumab response. Median PFS for p95 expressing and not-expressing tumors were 8 months (95% CI, 2.5–13.4 months) and 22 months (95% CI, 9.9−34 months), respectively ($p = 0.0001$). Median PFS for PTEN expressing and not-expressing tumors were 15.3 months (95% CI, 12.6−34 months) and 12.1 months (95% CI, 7.9–16.2 months), respectively ($p = 0.04$). Median OS for p95 expressing and not-expressing tumors were 24 months (95% CI, 8.3–40.4 months) and 29.1 months (95% CI, 8.6–43.2 months), respectively ($p = 0.045$). Median OS for PTEN expressing and not-expressing tumors were 25.1 months (95% CI, 7.5–40.1 months) and 26.8 months (95% CI, 8.1−42 months), respectively, which was not statistically significant ($p = 0.5$). Level of PI3K expression had no effect on PFS and OS in our patient population.
Conclusion: Presence of p95 predicted a poorer response to trastuzumab treatment, shorter PFS and OS in our HER2 positive metastatic breast cancer cohort. Additionally, loss of PTEN predicted a poorer response to trastuzumab treatment and shorter PFS but not OS. We could not find an effect of PI3K expression on the above mentioned parameters.

1915 POSTER

Etirinotecan pegol prolongs survival in an experimental model of brain metastasis of human triple negative breast cancer

U. Hoch[1], M.I. Nounou[2], C.E. Adkins[2], T.B. Terrell[2], H. Villalba[2], M.E. Eldon[1], P.R. Lockman[2]. *[1]Nektar Therapeutics, San Francisco CA, USA; [2]Texas Tech University, School of Pharmacy, Amarillo TX, USA*

Background: Incidence of brain metastases of breast cancer (BMBC) in HER2$^+$ and triple negative breast cancer (TNBC) is ~35%. Despite newer targeted therapies, survival for women with BMBC has not dramatically improved. Etirinotecan pegol (EP) is a unique, long acting topoisomerase 1 inhibitor that provides continuous exposure to SN38 with reduced peak concentrations. EP resulted in a RECIST response rate of 39% (7/18) in patients with metastatic TNBC. Here we present encouraging survival and pharmacokinetic (PK) results for EP in an experimental mouse model of TNBC brain metastasis using irinotecan (IRN) as a control.
Methods: For survival, brain seeking MDA-MB-231Br breast cancer cells were injected intracardially and allowed to circulate. After 21-days, mice were randomized (10/ group) and treated IV with vehicle, 50 mg/kg IRN, or 50 mg/kg NKTR-102 IV q7d until death due to brain metastases. For measurement of SN38 in plasma and brain tumors, MDA-MB-231Br cells were injected intracranially and allowed to reach 20−30 mg. Then, 5 mice per sampling time received 50 mg/kg IRN or EP IV and plasma and tumors were harvested between 0–168 hr. SN38 concentrations were determined by LC-MS/MS and PK was assessed with noncompartmental methods.
Results: Plasma and brain tumor SN38 AUCs after IRN and EP are shown (Table). SN38 tumor to plasma ratio was 0.8 after IRN, while a tumor to plasma ratio of 6 after EP indicated preferential SN38 accumulation in brain tumor tissue. In the survival study, vehicle treated animals died on days 16−23 post start of treatment and all IRN animals died on day 21, leading to a median survival of 21 days in both groups. In contrast, 50% of EP treated animals were still alive 61 days after treatment initiation, with a censored median survival of 51 days.

Table: SN38 AUC (ughr/mL) after 50 mg/kg IV of IRN or EP

Trtm	Plasma	Brain tumor	Brain tumor to plasma ratio
IRN	0.13	0.11	0.8
EP	2.1	12	6
EP to IRN Ratio	16	109	–

Conclusions: Tumor SN38 exposure after EP is 6-fold greater than that in plasma and 109-fold greater than after IRN, suggesting that EP penetrates the compromised blood tumor barrier. The higher tumor SN38 exposure after EP appears responsible for the greatly prolonged survival observed in this model of TNBC brain metastasis. Plasma SN38 trough concentrations observed in this model are achieved clinically with 145 mg/m^2 EP used in the Phase 3 BEACON study in patients with metastatic BC, emphasizing the potential translational relevance of these results.

1916 POSTER

Molecularly well-characterized human breast cancer cell lines offer an alternate model system to understand in vivo subtype-specific biology of human breast tumors

M. Riaz[1], B.H. Setyono-Han[1], M.A. Timmermans[1], A.M. Trapman[1], J.B. Vries[1], A. Hollestelle[1], R.C. Janssens[2], M.P. Look[1], M. Schutte[3]. *[1]ErasmusMC JNI, Medical Oncology, Rotterdam, Netherlands; [2]ErasmusMC, Genetics, Rotterdam, Netherlands; [3]The Lorentz Center, Niels Bohrweg 2 2333 CA., Leiden, Netherlands*

Background: Breast cancer (BC) is a disease with intra- and inter-tumor heterogeneity and models representing the complete variety of clinical BC phenotypes are not available. In this study, we explored the tumor growth potential and metastatic behavior of twenty-four human BC cell lines in nude mice and determined whether these cell lines can recapitulate subtype-related biological behavior when implanted under the mammary fat pad of mice.
Material and Methods: Cell lines were transduced using lentiviral particles with a luciferase reporter gene. Subsequently, per cell line 3 independent monoclonal clones with similar luciferase activity and molecular features comparable to the parental lines were selected and implanted orthotopically under the mammary fat pad of nude mice. Xenograft tumor growth was monitored by measuring tumor size twice a week for a period of 12 months. At the end of the experiment, using the IVIS Imaging System, tumor size and presence of distant organ metastases were assessed by measuring the tumor bioluminescence. Subtype-specific differences in tumor growth and mice survival were compared using a Kruskal-Wallis test and Cox regression analysis.
Results: Subtype-specific differences in tumor growth, ability to metastasize to distant sites and tumor-related survival of mice were observed. 87.5% of the cell lines gave rise to xenografts of which 57% showed metastasis to distant sites (mostly lymph node and lungs but rarely bone and brain). A clear difference was observed in growth of xenografts from cell lines of different molecular subtypes ($P = 0.016$; Kruskal-Wallis test). Mice bearing the basal-like and the normal-like xenografts showed poor tumor-related survival (HR: 5.93; $P = 0.007$ and HR: 5.55; $P = 0.009$, respectively) compared with those bearing the ERBB2-positive xenografts, which had the longest survival. Luminal xenografts showed an intermediate behavior. Subtype-specific metastasis to distant sites between xenografts was not however observed. In summary, comparable to clinical behavior in humans, we observed that the basal-like and the normal-like cell lines grew more aggressive in mice than the cell lines of other molecular subtypes. However, in contrast to clinical findings, we observed no relationships between intrinsic subtype and preferences for site of relapse.
Conclusion: In conclusion, we have established xenograft models from 21 phenotypically and molecularly diverse human BC cell lines, which can be exploited as useful tools to perform functional studies and screening of interfering drugs.
No conflict of interest.

1917 POSTER

Analysis of mir-339-5p expression and function in breast cancer

S. Khan[1], C. Brougham[1], D. Wall[2], C. Curran[1], J. Newel[2], M.J. Kerin[1], R.M. Dwyer[1]. *[1]National University of Ireland Galway, Discipline of Surgery School of Medicine, Galway, Ireland; [2]National University of Ireland Galway, Clinical Research Facility and School of Mathematics Statistics and Applied Mathematics, Galway, Ireland*

Background: MicroRNA (miRNA) expression has been found to be altered in many diseases including breast cancer. miRNAs are small non-coding RNA molecules that control gene expression post-transcriptionally. The focus of this study was to quantify expression of miR-339-5p in both tissue and circulation of patients with breast cancer and determine any relationship with clinicopathological characteristics. The effect of miR-339-5p on breast cancer cell proliferation in vitro was also determined.
Materials and Methods: Following informed patient consent and ethical approval, breast tissues (n = 163) were harvested from patients undergoing surgery, including malignant (n = 103), normal (n = 30) and fibroadenoma (n = 35). To determine the level of circulating miR-339-5p, whole bloods were collected from patients with breast cancer (n = 40) and healthy controls (n = 40). miRNA was extracted, reverse transcribed, and the level of miR-339-5p in all samples quantified using RQ-PCR. Results were correlated with patient clinicopathological details. Expression of miR-339-5p was also detected in breast cancer cell lines, and the effect of a miR-339-5p mimic on cell proliferation investigated.
Results: miR-339-5p was detectable in 159/168 breast tissue samples analysed. A significant decrease in miR-339-5p expression in breast cancer was observed (n = 101, Mean(SEM) 2.0(0.06) Log_{10} Relative Quantity (RQ)) compared to both healthy control tissue (n = 24, 2.5(0.1) Log_{10} RQ, $p < 0.01$), and benign tissue (n = 34, 2.45(0.1) Log_{10} RQ, $p < 0.01$). miR-339-5p was also detectable in the circulation of individuals included in the study, although no significant difference was observed between breast cancer patients (n = 40, 1.49(0.05) Log_{10} RQ) and healthy controls (n = 40, 1.59(0.06) Log_{10} RQ, $p = 0.41$). Further investigation revealed no significant association with patient clinicopathological details. Functional assays revealed reduced proliferation following transfection of breast cancer cells with miR-339-5p (T47D; −17% and SK-BR-3; −27%).
Conclusion: Although not a suitable circulating biomarker of the disease, this study highlights miR-339-5p as a tumour suppressor in breast cancer, potentially mediated through knockdown of cellular proliferation. Further investigation is required to determine the target mRNA involved in this response.
No conflict of interest.

1918 POSTER

Co-expression of HER3 in HER2-positive metastatic breast cancer patients is an independent predictor of impaired prognosis

A.S. Berghoff[1], Z. Bago-Horvath[2], M. Preusser[1], G.G. Steger[1], M. Rudas[2], P. Birner[2], C.C. Zielinski[1], R. Bartsch[1]. *[1]Medical University of Vienna, Department of Medicine I, Vienna, Austria; [2]Medical University of Vienna, Institute of Pathology, Vienna, Austria*

Background: Improved understanding of the pathobiology of the metastatic cascade as well as the identification of new prognostic markers may lead the path to the development of novel targeted agents in breast cancer patients (BC pts). Recently, HER3-expression was postulated as independent risk factor for metastatic spread and especially brain metastatic disease.
We aimed to analyze the impact of HER3 expression in terms of occurrence of brain metastases and overall survival in an equally between breast cancer subtypes distributed population.
Methods: Pts of different BC subtypes (luminal, HER2-amplified, triple-negative) with metastatic disease were identified from a breast cancer data base. Tissue of the primary tumor was retrieved from the local pathology institute. Immunohistochemical staining of estrogen-receptor, progesterone-receptor, and HER2 and HER3 was performed, according to standard protocol. In HER2 equivocal cases, subsequent FISH analysis was performed. HER3 FISH was performed for all HER3 positive specimens.
Results: Specimens of 110 pts (36/110 luminal, 35/110 HER2-amplified, 40/110 triple-negative) were available for this analysis. 23/110 (21%) specimens showed strong, complete, membranous staining for HER3 of at least 10% of all tumor cells. HER2/HER3 co-expression was observed in 12/110 (11%) specimens. HER3 showed a statistically significant association with HER2-expression ($p = 0.02$; Chi square test). No correlation was observed for HER3-expression and overall survival (OS), incidence of brain metastases, or time to diagnosis of brain metastases in the entire patient cohort ($p > 0.05$; log rank). In the HER2-amplified subgroup, however, HER3-expression was significantly associated with shorter OS (median 30 vs. 63 months; $p = 0.02$; log rank test) and remained significant when entered into a multivariate model ($p = 0.02$; Cox regression).
Conclusions: HER2/HER3 co-expression is significantly associated with impaired OS in pts with HER2-positive metastatic breast cancer but not with occurrence of brain metastases. Co-inhibition of HER2 and HER3 or inhibition of HER2/HER3 hetero-dimerization could improve prognosis of this patient population.
No conflict of interest.

1919 POSTER

Occurrence of metastasis and in vitro aggressiveness of triple negative breast cancer is related to the glycolytic phenotype, microenvironment metabolism and MCT4 lactic acid transporter

J. Doyen[1], F. Ettore[2], D. Roux[1], S.K. Parks[1], I. Peyrottes-Birtwisle[2], N. Toussant[2], K. Ilc[1], J. Ferrero[3], J. Pouysségur[1]. [1]*Centre Antoine-Lacassagne, IRCAN Institute for Research on Cancer and Aging, Nice, France;* [2]*Centre Antoine-Lacassagne, Pathology, Nice, France;* [3]*Centre Antoine-Lacassagne, Medical Oncology, Nice, France*

Background: Comparing with hormone positive and Her-2 overexpressing breast cancers, triple negative (TNEG) breast cancers are characterized by a more systematic and far stronger 18-FDG uptake that suggests a glycolytic addiction in this tumour subset (PMID: 18098228 and 22011459).
Material and Methods: Correlation between proteins involved in glycolytic metabolism and intracellular pH regulation (c-myc, GLUT-1, LDH-A, MCT1, MCT4, Basigin, CA9) and metastasis has been analyzed in 158 patients with TNEG disease using tissue-micro arrays. Proteins that were indicative of poor prognosis were inhibited or knocked-out *in vitro* to determine potential new targets in TNEG breast cancers.
Results: With a median follow-up of 6 years (0.25–14.4) the metastasis rate was 27.4% at 6-years. Tumours were highly proliferative (70% with Ki-67 staining >20%) and had a glycolytic phenotype with a strong expression of GLUT-1 (78%), LDH-A (78%), MCT1 (60.4%), MCT4 (85.7%), Basigin (78%), CA9 (53.7%) and C-myc (84.2%). The Log-rank test identified as bad prognostic factors for metastasis-free survival (MFS), large pT ($p < 0.001$), positive pN ($p = 0.001$), positive MCT4 ($p = 0.01$) and LDH-A ($p = 0.04$). MCT4 staining and LDH-A staining were even stronger prognostic factors when excluding tumors with stromal staining ($p = 0.001$ and $p = 0.005$ respectively for MFS). Ki-67, age and grade were not correlated with MFS. pT stage, pN and tumoral MCT4 staining were considered as independent prognostic factors in multivariate analysis (Cox regression, HR of respectively 2.4, 2.2 and 2.2, $p < 0.05$). These results were similar for overall and cancer specific survival. *In vitro,* knock-out of MCT4 in a TNEG cell line (HS578t) reduced clonogenic survival by 50%. Use of the strong inhibitor of the mitochondria respiratory chain, phenformin, resulted in a marked reduction of clonogenic survival (by 99%) regardless of MCT4 expression status in normoxia. However, in hypoxia phenformin application prevented clonogenic survival only when combined with MCT4 knock-out.
Conclusions: This study demonstrates the role of glycolytic metabolism in the tumour microenvironment and in the occurrence of metastases of TNEG breast cancer. Our *in vitro* data suggests that targeting this metabolic cancer hallmark in combination with phenformin could provide a potential novel anticancer treatment for TNEGs.
No conflict of interest.

1920 POSTER

Reverse-phase protein array for prediction of patients unlikely to develop bone metastasis from breast cancer

N. Hayashi[1], G.C. Manyam[2], A.M. Gonzalez-Angulo[1], N. Niikura[1], H. Yamauchi[3], S. Nakamura[4], G.N. Hortobagyi[1], K.A. Baggerly[2], N.T. Ueno[1]. [1]*The University of Texas MD Anderson Cancer Center, Breast Medical Oncology, Houston TX, USA;* [2]*The University of Texas MD Anderson Cancer Center, Bioinformatics and Computational Biology, Houston TX, USA;* [3]*St. Luke's International Hospital, Breast Surgical Oncology, Tokyo, Japan;* [4]*The Showa University School of Medicine, Breast Surgical Oncology, Tokyo, Japan*

Background: The aim of this study was to identify bone-metastasis-related markers in patients with primary breast cancer using reverse-phase protein array (RPPA) analysis. RPPAs enable quantification of total and phosphorylated proteins, providing information about their functional status.
Marial and Methods: Tumor samples were obtained from 169 patients with primary invasive breast carcinoma who underwent surgery on an investigational protocol to assess protein expression by RPPA between June 1992 and March 2007. Seventy six patients (45.0%) had hormone receptor-positive tumors and 33 patients (19.5%) had HER2-negative tumors. Clinical characteristics and protein expression (determined by RPPA) were compared between patients who developed breast cancer bone metastasis (BCBM) and no BCBM. Variables identified as significantly correlated with BCBM in univariate logistic regression analyses were then used to build a multivariate model. The models' predictive abilities were assessed using leave-one-out cross-validation.
Results: Twenty one of the 169 patients developed BCBM (a median follow-up time, 47 months; range, 2.5–237 months). Lymph node status ($p = 0.023$) and RPPA expression levels of 22 proteins were significantly correlated with BCBM in univariate logistic regression analyses. After filtering variables through a stepwise algorithm, a final model consisting of 8 proteins and lymph node status After filtering the variables through a stepwise algorithm, the final model consisting of 8 proteins (CDK2, CDKN1A, Rb1, Src, phosphorylated-RSK, HER2, BCL11A, and MYH11) and lymph node status had a sensitivity (positive predictive value) of 30% and specificity (negative predictive value) of 90.5% in cross-validation. Most proteins in the final model are associated with cell cycle or signal transduction.
Conclusions: Our model can potentially identify patients who are unlikely to develop BCBM. Prospective validation of this model can show whether clinical trials excluding these patients have the potential to clarify the benefit of bisphosphonates in the adjuvant setting.
No conflict of interest.

Regulation of MMP-13 (collagenase-3) in human breast cancer cells by the transcription factor Pit-1

J. Sendon Lago[1], S. Seoane[1], N. Eiró[2], B. Fernández-García[2], M. Macía[3], T. García-Caballero[4], F. Vizoso[2], R. Pérez-Fernández[1]. [1]*University of Santiago de Compostela, Endocrine Oncology, Santiago de Compostela, Spain;* [2]*Fundación Hospital de Jove, Research Unit, Gijón, Spain;* [3]*University of Santiago de Compostela, Obstetrics and Gynecology, Santiago de Compostela, Spain;* [4]*University of Santiago de Compostela, Morphological Sciences, Santiago de Compostela, Spain*

An important aspect of cancer cells is its ability to invade other tissues and create metastases. This process involves proteolytic enzymes such as matrix metalloproteinases (MMPs), which have the ability to degrade the extracellular matrix proteins and basement membrane. The Pit-1 transcription factor was originally described in the pituitary gland, but it is also expressed in the mammary gland. Pit-1 overexpression or knockdown in human breast cancer cell lines induces profound phenotypic changes in the expression of proteins involved in cell proliferation, apoptosis, and invasion. Interestingly, patients with breast cancer and elevated expression of Pit-1 showed a significant association with metastasis in lung. In this study we evaluate the possible relationship between Pit-1 and MMPs, specifically with MMP-13 which has been related to breast cancer cell metastasis.
The MCF-7 and MDA-MB-231 human breast adenocarcinoma cell lines were transfected with Pit-1 overexpression vector (pRSV-hPit-1) and 48 hours later MMP-13 mRNA and protein expression were evaluated by real-time PCR and Western blot. MMP-13 enzymatic activity after Pit-1 overexpression was carried out by zymography and ELISA assays. To determine MMP-13 transcriptional regulation by Pit-1, we carried out chromatin immunoprecipitation (ChIP) and luciferase reporter assays. We also evaluate the role of Pit-1 overexpression and MMP-13 knock-down using the severe combined immunodeficient (SCID) mouse tumor xenograft model. Finally, by immunohistochemistry, we correlated Pit-1 and MMP-13 protein expression in human breast tumors samples.
Our data show that Pit-1 overexpression increases MMP-13 mRNA and protein expression and induces significant MMP-13 activation in culture medium. ChIP and luciferase assays demonstrate direct binding and transcriptional regulation of the MMP-13 gene by Pit-1. Knock-down of MMP-13 in Pit-1 overexpressing MCF-7 cells injected in the mammary fad pat of SCID mice significantly decrease the presence of lung metastasis. In patients with breast cancer, high expression of Pit-1 was significantly correlated with MMP-13 positivity.
In summary, our results indicate that Pit-1 transcription factor regulates MMP-13 expression at transcriptional level by binding to the MMP-13 promoter region. This regulation could be related with Pit-1 induction of breast cancer cell metastasis to the lung.
No conflict of interest.

1922 POSTER

IRAK4 modulates growth and migration in breast cancer cells

K. Kimbro[1], L. Cortez[1], S.T. Yeyeodu[1], L.R. Kidd[2], G.M. Oprea[3], B.G. Burns[4], T.T. Vancleave[2], E.N. Rogers[1]. [1]*North Carolina Central University, Julius L Chambers Biomedical and Biotechnology Research Institute, Durham NC, USA;* [2]*University of Louisville, Department of Pharmacology & Toxicology, Louisville KY, USA;* [3]*Emory School of Medicine, Winship Cancer Institute and Biotechnology Research Institute, Atlanta GA, USA;* [4]*Emory School of Medicine, Winship Cancer Institute, Atlanta GA, USA*

Background: Breast cancer (BrCa) is the most prevalent form of cancer among women worldwide. While early detection improves health prospects,

overall medical prognosis continues to be poor. Current studies suggest the innate immune toll-like receptor (TLR) pathway impacts BrCa tumor progression, yet its exact role remains unclear. We have analyzed sixteen single nucleotide polymorphisms (SNPs) from ten TLR-associated genes and found that African American women who possessed the homozygous minor interleukin-1 receptor-associated kinase 4 (IRAK4) rs4251545 allele demonstrated a greater than 4-fold increase in BrCa risk. IRAK4 is a central regulator of the TLR pathway which mediates cell invasion and cytokine and chemokine production. Therefore, this study aimed to assess the molecular involvement of IRAK4 in BrCa development and progression. We hypothesized that functional breast epithelial IRAK4 promotes BrCa growth and migration.
Materials and Methods: To test this hypothesis, triple-positive MCF7 and triple-negative MDA-MB-231 (wild-type IRAK4) and MDA-MB-468 (IRAK4 rs4251545 minor variant expressing) human BrCa cell lines were compared. Cells were treated for 24 hours with or without IRAK1/4 inhibitor. IRAK-1 and −4 protein levels were monitored by western blot. Cell migration and cell growth were examined by wound healing and crystal violet assays, respectively. As a test of metastatic potential, we also used western blot to monitor expression of matrix metalloproteinases 9 (MMP-9) and 13 (MMP-13), both secreted proteinases that participate in the degradation of extracellular matrix prior to metastasis.
Results: All BrCa cell lines expressed comparable levels of IRAK4, whereas IRAK1 expression was reduced in MDA-MBA-231 cells compared to MCF-7 and MDA-MB-468 cells. Treatment with IRAK1/4 inhibitor delayed wound healing and inhibited growth in all BrCa cells lines. While MMP-9 was exclusively expressed in MDA-MB-231 cells, its levels were unaffected by IRAK1/4 inhibitor. In contrast, MMP-13 protein levels were up-regulated in IRAK1/4 inhibitor treated MDA-MB-231 cells. By comparison, the less aggressive MCF7 and MDA-MB-468 cells expressed high MMP-13 levels yet were unresponsive to IRAK1/4 inhibitor.
Conclusion: Together these results indicate that IRAK4 may regulate BrCa growth and migration. Furthermore, the up-regulation of cellular MMP-13 upon IRAK4 inhibition suggests a feedback signal which promotes metastasis. Thus, these findings suggest that IRAK4 and the TLR pathway as promising drug targets to modulate BrCa tumor progression.
No conflict of interest.

1923 POSTER

mRNA expression of p14 ARF and hTERT in human breast cancer: evidence suggestive of an antagonistic relationship

U. Wazir[1], W.G. Jiang[2], H. Yasaei[3], H. Linne[3], R.F. Newbold[3], K. Mokbel[4]. *[1]St George's Hospital, Breast and Endocrine Surgery, London, United Kingdom; [2]Cardiff University School of Medicine Cardiff University, Metastasis and Angiogenesis Research Group, Cardiff, United Kingdom; [3]Brunel University Uxbridge London UK, Brunel Institute of Cancer Genetics and Pharmacogenomics, London, United Kingdom; [4]The Princess Grace Hospital, The London Breast Institute, London, United Kingdom*

Background: p14 has a role in cell cycle regulation, cell senescence. It is characterised as a 15 kDa nucleolar protein, believed to exert the majority of its function through the regulation of p53, which is has a key role in DNA repair, cell cycle regulation and metabolism.
Previous evidence is highly suggestive of a highly significant role for human telomerase reverse transcriptase (hTERT) in human breast cancer.
In this study, we have endeavoured to elucidate the relationships between the mRNA expressions of p14 and the clinicopathological parameters of human breast cancer.
Materials and Methods: Specimens of breast cancer (BC) tissues (N = 127) and normal tissues (N = 23) underwent RNA extraction and reverse transcription. Transcript levels were determined using real-time quantitative PCR. Expression levels were analysed against clinicopathological data accrued over a median follow-up period of 10 years.
Results: Higher p14 mRNA transcript levels were associated with non-cancerous background tissue specimens (median copy numbers: 103 vs. 4, p = 0.0095), with better overall and disease-free survival. The p14 mRNA expression was higher in TNM2 stage tumours compared with TNM1 lesions (TNM2 vs. TNM1, 27.2 vs. 3.5, $p = 0.049$). However, p14 mRNA expression subsequently declined with further tumour progression (TNM1/TNM2 vs. TNM3/4, 26 vs. 2, p = 0.009).
Furthermore, a highly significant correlation between p14 and human telomerase reverse transcriptase (hTERT) levels was seen (r = 0.406, p = 0.00005).
Conclusions: p14 expression seems to increase initially in early breast cancer and decrease with further tumour progression. The correlation p14 with hTERT suggests that p14 may be induced to counteract cell immortalisation due to hTERT surge.

Identification of two novel mutations in exon 20 of brca1 gene among Eastern Indian breast cancer patients

J. Basak[1], A. Chakraborty[1], A. Katarkar[2], K. Chaudhury[2], A. Mukhopadhyay[3]. *[1]Netaji Subhash Chandra Bose Cancer Research Institute, Dept of Molecular Biology, Kolkata, India; [2]Indian Institute of Chemical Biology, Dept of Molecular & Human Genetics, Kolkata, India; [3]Netaji Subhas Chandra Bose Cancer Research Institute, Dept of Medical Oncology, Kolkata, India*

Background: Breast cancer is the most common neoplastic disease in women. In India, breast cancer is the second most common malignant condition among women. Seventy percent of breast cancer is sporadic and 5−10% of the disease is caused by inherited genetic mutations which put women at the threshold of high risk for developing breast cancer. The main purpose of this hospital based study is to identify mutations in exon 20 of BRCA1 gene among breast cancer patients of eastern India having a strong family history.
Materials and Methods: The period of this study is from January 2010 to March 2013. The total number of the patients studied during this period is 106. Point mutation 5382insC in exon 20 of BRCA1 gene was detected by using Amplification Refractory Mutation System based Polymerase Chain Reaction. DNA sequencing was also performed to detect unknown mutations in the above mentioned exon. Attempts are also taken to correlate ER, PR, HER2/neu hormonal status with BRCA1 gene mutation.
Result: Out of 106 patients (age range: 23−54 years) family history was taken from 65 patients. Peripheral blood samples were collected from all these patients and from eight family members. ARMS-PCR was performed for all samples whereas direct sequencing was done for 30 samples. In the present study we reported two novel mutations 1) A5356C and 2) G5329A in exon 20 of BRCA1 gene from two breast cancer patients of 34 years and 39 years old respectively. Substitution of nucleotide A5356C at codon 1746 (CAC>CCC) and G5329A at codon 1737 (AGA>AAA) result the replacement of Histidine by Proline and Arginine by Lysine respectively (NCBI Reference U14680.1). In our hospital based study, we have found a frequency of 0.075 for the mutation 5382insC in exon20 at BRCA1 gene.
Conclusion: To the best of our knowledge A5356C and G5329A, are two novel mutations as they have not yet been reported earlier in any population. Identification of these novel mutations
No conflict of interest.

Beta 3-integrin promotes the reversion of luminal breast cancer cells to a normal like phenotype

D. Barkan[1], H. Abu-Tayeh[1], S. Schif[1]. *[1]Haifa University, Human Biology, Haifa, Israel*

Loss of cell polarization and luminal filling of mammary glands are key structural alterations in breast cancer disease. Recent findings support the notion that disruption of cell-polarity mechanisms plays a causal role in tumor initiation thus, implicating a role of cell and tissue polarity mechanisms as potential non-canonical tumor suppressors. We present here for the first time the role of beta 3 -integrin (Intβ3) in promoting the commitment of luminal breast cancer progenitor like cells to differentiate to polarized acini like structure. Our results demonstrate that overexpression of Intβ3, in MCF-7 cells (MCF-7-Intβ3) promoted their reversion to acini like organoids resembling a normal breast tissue, when cultured in the physiological relevant 3 dimensional basement membrane extract (3D BME system). The phenotypic reversion was demonstrated by the generation of acinus like organoids with apicobasal polarity displayed by the apical expression of GM130 and mucin-1 (MUC1), and basal expression of laminin 5. These organoids gradually progressed into spherical lumen containing structures resembling normal breast tissue. Conversely, control MCF-7 cells stably expressing empty vector (MCF-7-vec) did not undergo phenotypic reversion. Intriguingly, this reversion was driven by cancer progenitor like cells derived from non-adherent mammospheres, (either expressing $CD44^{-/low}$ $CD24^{high}$ or $EpCAM^{high}CD49f^{low}$ phenotype) that expressed Intβ3. Whereas, Intβ3^{-} cancer progenitor like cells could not differentiate to acini like structure in the 3D BME system. Therefore, these results suggest that commitment of the cancer luminal progenitor like cells to differentiate is dependent on Intβ3 expression. Finally, we have preliminary results demonstrating that the reversion of MCF-7-Intβ3 cells to a normal like phenotype induced a dormant state depicted by induction of p21 expression and reduction in Ki67 positive cells compared to MCF-7-vec cells.
Hence, these finding exhibits a novel mechanism to reprogram cancer luminal progenitor like cells to differentiate to a normal like acini by inducing the expression of Intβ3. Therefore, promoting such differentiation of luminal

breast cancer cells in conjunction to their microenvironment, can potentially promote the normalization of their malignant phenotype.

Thirteen miRNAs involved in the response of cancer cells to doxorubicin

E. Tormo[1], B. Pineda[2], E. Serna[3], S. Ballester[4], O. Burgues[5], A. Lluch[6], P. Eroles[4]. *[1]Hosp. Clínico Universitario de Valencia, Valencia, Spain; [2]Hosp. Clínico Universitario de Valencia, Oncology, Valencia, Spain; [3]Universidad de Valencia, Ucim, Valencia, Spain; [4]Hospital Clinico UNiversitario Valencia, Oncology, Valencia, Spain; [5]Hospital Clinico UNiversitario Valencia, Pathology, Valencia, Spain; [6]Hospital Clinico UNiversitario Valencia, Oncology & Haematology, Valencia, Spain*

Background: Mature microRNAs (miRNAs) are a class of naturally occurring, small non-coding RNA molecules, about 21−25 nucleotides. Growing evidence shows that miRNAs exhibit a variety of regulatory functions related to cell growth, development, and differentiation, and are associated with a wide variety of human diseases. Several miRNAs have been linked to cancer; since expression analysis studies have revealed perturbed miRNA expression in tumors compared to normal tissues. As a consequence, human miRNAs are likely to be highly useful as biomarkers, especially for future cancer diagnostics, and are emerging as targets for disease intervention.
Since doxorubicin (DOX) has been used for a long time in breast cancer treatment, and resistance mechanisms are not clear understood, the aim of this work was to find a miRNA expression profile that could explain the regulation in different breast cancer cell lines under DOX treatment.
Methods: Three breast cancer cell lines (MDA-MB-231, MDA-MB-468 and MCF-7) were cultured in normal conditions and also treated with DOX. Total RNA containing small non-coding RNA was isolated and its expression profile was performed by using GeneChip miRNA 2.0 array. Real time PCR validation was carried out to confirm the results.
Results: Principal Component Analysis (PCA) of the small non-coding RNA profiles showed different expression patterns between normal conditions and DOX treatment in each cell line separately. Taken together in a Heat Map, miRNA expression profiles of MDA-MB-231 and MDA-MB-468 cell lines were closer in both normal and DOX treatment conditions, while miRNA expression profile of MCF-7 cell line showed strong differences. Total of 13 common miRNAs between the three cell lines were found to be significantly affected by DOX treatment. PCR validation confirmed the results obtained.
Conclusions: We conclude that 13 common miRNAs are responsables of changes compared to treatment with DOX in breast cancer cell lines MDA-MB-231, MDA-MB-468 and MCF-7. This miRNAs are mainly related with cellular processes such as cell differentiation, vascularisation, apoptosis and cell proliferation and also involved in other cellular processes, such as cell migration.

Alteration in expression of MDR genes in breast carcinoma patients following preoperative chemotherapy is related with clinical response

D. Mamarasulova[1], D. Bobomatova[1], F. Djalalova[1], N. Mamajonova[1], Y. Ziyaev[1], D. Tursunov[1]. *[1]Andizhan State Medical Institute, Gynaecology, Andijan, Uzbekistan*

Drug resistance of tumour cells to chemotherapeutic agents is considered to be one of the most important causes of tumour therapy failure but our understanding of the underlying molecular mechanisms is in complete. The neoadjuvant chemotherapy (NACT) revealed to be suitable model for direct assessment of response to treatment in depends on multidrug resistance (MDR) gene expression before and after NACT. We examined the association between the alteration in MDR gene expression measured both before and after chemotherapy in the short-term response to neoadjuvant chemotherapy in the cohort of IIA IIIC stage breast cancer (BC) patient (n = 84). All patients were primarily treated with two-four preoperative cycles of FAC (Cyclophosphamide, Adriamycin, Fluoracil), CAX (cyclophosphamide, aryamycin, Xeloda), or Taxane regimes. The transcriptional profile of key MDR genes (ABCB1, ABCG1, ABCG2, ABCC1, ABCC2, ABCC3, ABCC5, MVP and GSTP1,)was evaluated in both pre-therapeutically obtained tumour tissue and in specimens removed by final surgery, using a qPCR assay. No significant difference in the average level of MDR-genes expression in paired breast tumours before and after NACT was found when analysed both responsive and nonresponsive patients along. There was no correlation between MDR gene expression in pre-NACT tumour specimens and immediate NACT response. In the group with tumour response, we found a statistically significant down-regulation of the expression of ABCB1, ABCG1, ABCG2, ABCG2, ABCC1, ABCC2, ABCC5, MVP and GSTP1 (67−93% of cases) genes following NACT in BC patient treated with FAC and CAX. In contrast we found up-regulation of these gene expressions after NACT in mostly nonresponsive patients (55−96% of cases). Response to taxotere has been related to reducing mRNA level of ABCB1, ABCG1, ABCG2, ABCC2 and MVP genes in the tumour sample derived following chemotherapy.
No conflict of interest.

Clinical and morphological characteristics of triple-negative breast cancer in patients with different BMI

R. Liubota[1], I. Liubota[2], O. Zotov[1], I. Shchepotin[1], M. Anikusko[3]. *[1]National Medical University, Oncology, Kyiv, Ukraine; [2]Municipal Clinical Oncological Centre, Oncology, Kyiv, Ukraine; [3]Municipal Clinical Oncological Centre, Surgery, Kyiv, Ukraine*

Background: The aim of this retrospective analysis was to investigate the morphological features of triple-negative breast cancer (TNBC) patients with different body mass index (BMI).
Material and Methods: The study included 110 patients with TNBC aged 25 to 76 (54.6±1) years old, who sought medical care in oncology clinic National Medical University named after A.A. Bogomolets in 2005–2006. Morphological characteristics of TNBC were evaluated in relation to BMI.
Results: According to WHO criteria women with TNBC were divided into the 3 groups: group 1−27 patients (24%) were normal/underweight (BMI <25 kg/m^2), group 2−47 patients (43%) were overweight (BMI from 25 to 29.9 kg/m^2), and group 3−36 patients (33%) were obese (BMI $\geqslant$30 kg/m^2). Postmenopausal TNBC is diagnosed in significantly more patients with obesity, and in premenopausal in patients who are overweight. Lobular TNBC was significantly more frequent in patients with obesity (25%) and ductal − in patients in group 1 and 2 in 74% and 77% of cases. Low histological grade (G3, G4) occur in overweight and obese patients (32% and 42%, respectively). Lymph node metastases were often (for 13%) in patients with obesity.
Conclusions: Our study shows an association between high BMI and poor prognostic morphological characteristics in patients with TNBC.

Dietary supplementation with molecular iodine may revert epithelial–mesenchymal transition in human breast cancer

A. Moreno-Vega[1], L. Vega-Riveroll[2], G. Delgado[2], N. Hernandez-Rios[2], C. Aceves[2]. *[1]Instituto de Neurobiología & Centro de Física Aplicada y Tecnología Avanzada, Neurobiología Celular y Molecular, Querétaro, Mexico; [2]Instituto de Neurobiología, Neurobiología Celular y Molecular, Querétaro, Mexico*

Breast cancer is the neoplasia with the highest incidence and mortality rate for women worldwide. Although current therapies have succeeded in increasing survival after diagnosis, relapses occur at a significant rate. Many models have been established in an effort to better understand tumour initiation and growth in order to develop more efficient therapies. The Cancer Stem Cell (CSC) model states that a subpopulation of tumour cells with distinct, stem-like properties drive the tumour initiation, growth, and metastasis. These stem-like characteristics include self-renewal, drug resistance, and migration capacity and may be acquired by mutation of a normal stem cell, or after processes such as the epithelial mesenchymal transition (EMT). In methylnitrosourea (MNU)-induced mammary cancer models, we have demonstrated that dietary supplementation with molecular iodine (I_2) has dose-dependent effects on differentiation and apoptosis. Furthermore, in a human study, women with breast cancer who were supplemented with I_2 during chemotherapy showed no tumour relapse, as compared to 30% relapse observed in placebo-treated patients, suggesting that I_2 may affect CSC populations. To examine this hypothesis we carried out a human study (Hospital General de Queretaro, protocol # 185−09−03) that included 22 women diagnosed with early stage breast cancer (IIa and IIb). Patients were supplemented with I_2 (5 mg daily) or placebo (vegetable dye) for 2−5 weeks before surgery. We identified the CSC populations present in breast tumours by detecting changes in the expression of e-cadherin and vimentin (proteins related to EMT) with immunohistochemistry and confocal microscopy. Preliminary results show that the I_2 supplementation is accompanied by normal e-cadherin and vimentin expression in most tumours, whereas tumours from placebo-treated women show aberrant e-cadherin and vimentin expression. Thus far, our results suggest that I_2 could delay or even revert the EMT process. Additionally, current studies are being carried out to determine such possible effects of I_2 in combination with chemotherapy in advanced breast cancer patients.

We thank Dr. Joel Rojas Aguirre (Hospital General de Queretaro). This work was supported in part by CONACyT 174439, 176911

Pre-diagnostic smoking behavior and poorer prognosis in breast cancer patients from Germany − potential differential effects by NAT2 acetylation status, BMI, and tumor subtypes

P. Seibold[1], A. Vrieling[1], J. Heinz[2], N. Obi[2], H.P. Sinn[3], D. Flesch-Janys[2], J. Chang-Claude[1]. *[1]German Cancer Research Center (DKFZ), Cancer Epidemiology, Heidelberg, Germany; [2]University Cancer Center Hamburg, Hamburg, Germany; [3]University of Heidelberg, Institute of Pathology, Heidelberg, Germany*

Background: Inconsistent results of smoking on breast cancer-specific mortality might be explained by subgroups of patients with different susceptibility to harmful effects of smoking.
Methods: We investigated the effect of pre-diagnostic smoking behavior on breast cancer outcomes (all-cause (OS), breast cancer-specific (BCSS), non-breast cancer cancer-specific survival (non-BCSS), and risk of recurrence) using a German prospective cohort of 3,340 breast cancer patients. The study participants were aged 50−74 years at breast cancer diagnosis and recruited between 2001 and 2005. We assessed effect modification by N-acetyltransferase (encoded by the *NAT2* gene) status, body mass index (BMI), alcohol consumption, and tumor subtypes. Hazard ratios (HR) and 95% confidence intervals (CI) were estimated by multivariable Cox proportional hazards models.
Results: After a median follow-up time of 5.7 years, 449 patients were deceased. Smoking at time of breast cancer diagnosis vs. never/former smoking was significantly associated with poorer OS (HR 1.39, 95% CI 1.10–1.76), which was mainly due to non-BCSS (HR 1.96, 95% CI 1.28–2.99), and non-significantly associated with BCSS (HR 1.23, 95% CI 0.93–1.64) and risk of recurrence (HR 1.29, 95% CI 0.95–1.75). Associations were consistently stronger in NAT2 slow than in fast acetylators for all survival endpoints (e.g. BCSS: HR 1.77, 95% CI 1.13–2.79 vs. HR 1.09, 95% CI 0.60–1.98; $P_{heterogeneity}$ >0.05). There was evidence for effect modification by BMI for non-BCSS (BMI <25 kg/m^2: HR 2.52, 95% CI 1.52–4.15 vs. BMI $\geqslant$25 kg/m^2: HR 0.94, 95% CI 0.38–2.36; $P_{heterogeneity}$=0.04). Smoking at time of diagnosis was also associated with significantly poorer outcomes for triple negative tumors and luminal A tumors (e.g. OS: HR 2.24, 95% CI 1.17–4.30, and HR 2.13, 95% CI 1.43–3.18, respectively) and non-significantly associated for luminal B and Her2 positive tumors.
Conclusion: The harmful effects of smoking may be particularly relevant for certain subgroups of breast cancer patients. If verified in independent study populations, our findings on effect modification by NAT2 status on breast cancer prognosis might have relevant public health implications as the majority of Caucasians (50−60 %) are NAT2 slow acetylators. Smoking should be avoided because of poorer overall outcomes after breast cancer diagnosis.
No conflict of interest.

1931 POSTER

UPR Activation via glucose deprivation and depletion of GRP78 protein (using siRNA) do not alter radiosensitivity in the human breast cancer cell line MCF7

J. Ritchie[1], L. Wyld[2], H.E. Bryant[1]. *[1]Institute of Cancer Studies, Department of Oncology, Sheffield, United Kingdom; [2]Academic Unit of Surgical Oncology, Department of Oncology, Sheffield, United Kingdom*

Background: Adverse metabolic conditions in the tumour microenvironment such as glucose and oxygen deprivation activate cellular stress pathways including the Unfolded Protein Response (UPR), a pathway that confers resistance to some chemotherapeutic agents. Radiotherapy resistance has been associated with adverse metabolic conditions in the tumour microenvironment, but whether this is due to UPR activation or other cellular pathways, has never been studied. This study used both a hypoglycaemic cell culture model and also direct UPR knock down to determine whether glucose deprivation altered radiosensitivity via the UPR.
Material and Methods: The MCF7 (p53 wildtype) breast cancer cell line was used. UPR activation was confirmed by western blotting and qPCR. Hypoglycaemic culture was used at 0.2 mM, a glucose concentration that activated the UPR following 24 hours of culture, and irradiated alongside a normoglycaemic control (25 mM). Survival was determined using clonogenic assay and data is presented as fractions of the untreated control. Transfection of GRP78 siRNA was used to knock down the UPR, and knockdown cells were irradiated alongside the control (transfected with scrambled sequence).
Results: There was no difference in survival between cells cultured in low glucose and their normoglycaemic control at 2.5 Gy (0.27 vs 0.29 p=1) and 5 Gy (0.035 vs 0.058 p = 0.7) (n = 3). Furthermore, there was no significant difference in survival between GRP78 knockdown and control cells at 2.5G y (0.17 vs 0.22 p = 0.7) and 5 Gy (0.01 vs 0.023 p = 0.1).
Conclusions: UPR activation secondary to glucose deprivation does not alter response to irradiation therapy in the MCF7 cell line. The UPR knockdown does not appear to be a potential target for sensitizing to radiotherapy.
No conflict of interest.

1932 POSTER

Prediction of lymph node metastasis with CXCR4 presentation in the breast cancer patient

A. Takahito[1], F. Kimihito[1], T. Rie[1], M. Yukako[1], K. Jyunko[1], Y. Miwa[1], N. Shogo[1], I. Tsuneo[1], F. Takashi[1]. *[1]Aichi Medical University School of Medicine, Breast and Endocrine Surgery, Aichi, Japan*

Background: The expression of CXC chemokine receptor type 4 (CXCR4) is considered to correlated with the degree of axillary lymph node involvement, particularly in hormone receptor negative breast cancer. And it is also reported that CXCR4 play an important role in mediating migration, invasion and adhesion of breast cancer cells, which correlate with cancer cell metastases. The objective of this study is to evaluate the correlation of CXCR4 expression between primary tumors and lymph nodes in primary breast cancers and to know whether the presence of lymph node metastases can be predicted by CXCR4 expression of the primary tumors.
Patients and Methods: Sections of paraffin-embedded tissue samples were obtained from 30 patients who received breast cancer surgery with sentinel lymph node sampling and/or axillary dissection. All clinicopathological data were obtained from the patients' medical records. The expression of CXCR4 was evaluated in the nucleus and cytoplasm. The intensity of staining was graded in negative, positive staining <50%, and positive, >/=50%. The evaluation was performed on the nucleus and cytoplasm in each.
Results: Half of the tumors were shown to be cytoplasmic CXCR4 positive, while 1.3% of the tumors were nuclear CXCR4 positive. Among the 20 cytoplasmic CXCR4 positive patients, 13 patients with lymph node metastases were recognized (P = 0.02), although preoperative clinical diagnosis of them was N0. No significant correlation was recognized between the nuclear stating status and lymph node metastasis.
Conclusions: We found that the elevated level of cytoplasmic CXCR4 was correlated with nodal metastases of breast cancers, meaning cytoplasmic CXCR4 expression predict lymph node metastasis in clinically node-negative patients with breast cancer. Our present study revealed that the cytoplasmic CXCR4 positivity of the primary tumor, even though it might be core needle biopsy specimens, was related to lymph node metastasis of breast cancer and, therefore, could be a useful predictive biomarker of lymph node metastasis of breast cancer. We think that CXCR4 immunohistochemistry might give the additional information to considering sentinel node biopsy. This theory will be discussed with a case control study.

1933 POSTER

Stage, biology and age

H. Kim[1], S.H. Ahn[1]. *[1]Asan Medical Center, Surgery, Seoul, Korea*

Background: Breast cancer subtypes are prognostic and predictive for patients. In this study, prognostic value of TNM stage, intrinsic subtype, and age were compared.
Patients and Methods: We analyzed results from 7,626 breast cancer patients registered on the Asan medical center database between 1999 and 2009. We compared survival according to the TNM stage, intrinsic subtype using ER, PR, Her2− immunohistochemical staining, and age.
Results: Luminal A subtype showed the best survival rates while triple negative subtype showed the worst survival rate amongst intrinsic subtypes. Survival analysis showed that Stage I triple negative breast cancer showed better survival compared to Stage III Luminal A subtype breast cancer (89.0% vs 76.6% P<0.001). Survival differences between intrinsic subtypes were more significant in lymph node positive breast cancer compared to lymph node negative breast cancer. Age did not affect survival between stages and intrinsic subtypes except for the young age subgroup ($\leqslant$35), for whom there was no survival difference amongst intrinsic subtypes.
Conclusion: Staging of breast cancer showed a more direct correlation to survival than known prognosis for intrinsic subtypes, as advanced, good prognostic intrinsic subtype breast cancer had worse survival than early, worse prognostic intrinsic subtype breast cancer. However for the young age group ($\leqslant$35), the survival of all intrinsic subtypes were similar.
No conflict of interest.

1934 POSTER

Cancer testis antigens and topoisomerase 2-alpha expression in triple negative breast carcinomas

A. Juretic[1], I. Mrklic[2], G.C. Spagnoli[3], S. Tomic[2], Z. Pogorelic[4]. [1]*University Hospital Center "Zagreb", Department of Oncology, Zagreb, Croatia;* [2]*Split University Hospital Center, Department of Pathology Forensic Medicine and Cytology, Split, Croatia;* [3]*University Hospital Basel, Department of Surgery Research Laboratory, Basel, Switzerland;* [4]*Split University Hospital Center, Department of Paediatric Surgery, Split, Croatia*

Background: Patients with triple-negative breast cancer (TNBC) generally experience a more aggressive clinical course with increased risk of disease progression and poorer overall survival. Surgery and/or chemotherapy appear to be the only available therapeutic modalities. Doxorubicin is a cytotoxic anticancer agent, but it can also stimulate immunogenic cell death, thus increasing the possibility of tumour-specific immune response. Therefore, our aim is to study the expression of cancer testis antigens (CTA) in the triple negative breast cancer (TNBC) group as well as the expression of topoisomerase 2-alpha (TOPO2A), a well defined molecular target of anthracyclins.
Material and Methods: The study includes 83 patients who underwent surgery between January 2003 and December 2009. Tissue serial TNBC sections were stained with CK5/6, CK14, EGFR, Ki-67, TOPO2A and CTA (MAGE-A1, MAGE-A10, NY-ESO and multi-MAGE-A) specific reagents. Survival time and multivariate survival analysis were also evaluated.
Results: The majority of TNBC were associated with a high histological grade (84.3%), high mitotic counts (25.9; range 2–110) and high proliferative activity, as measured by Ki-67 antigen (53.7; range 3−95). Of the 83 TNBC, 66.3% had BL immunophenotype and 48.2% BL morphology. MAGE-A1 specific staining was most frequently detectable (69.2%), followed by multi-MAGE-A (58%), NY-ESO (27.1%) and MAGE-A10 (16%) specific staining. The median value of TOPO2A positivity was 41.7% (range 5−97). A significant correlation was observed between the expression of MAGE-A10 and NY-ESO, on the one hand, and the expression of TOPO2A ($p = 0.005$, $p = 0.013$), on the other.
Conclusions: The expressions of defined CTA and TOPO2A are significantly correlated in TNBC, which might be of potential clinical relevance. These data also suggest that anthracyclin administration and CTA specific immunotherapy could be advantageously combined in the TNBC group for which therapeutic options are limited.
No conflict of interest.

Intraductal papillomas of the breast: A review of 105 cases

M. Kostanyan[1]. [1]*National Centre of Oncology, Yerevan, Armenia*

Background: The assessment of papillary lesions continues to be a challenging area in breast pathology. Intraductal papillomas are subject to debate in terms of their clinical and pathological significance and management. The purpose of this study was to evaluate the clinicoradiological and pathological data of patients with intraductal papillomas of the breast.
Material and Methods: According to pathology reports from January 1, 2000 to December 31, 2010 we identified 105 cases of intraductal papillomas of breast surgically excised at our institution. For each lesion, medical records, radiological and pathological variables were reviewed.
Patients age ranged from 32 to 72 years (mean 39 years). Most of patients were in premenopausal status (73.3%).
Results: Pathological nipple discharge of serous or serosanguinous character was the most common symptom accounting for 69.5% of patients. 42 patients had palpable lumps. Majority of cases were centrally-located (89 patients).
Imaging modalities used in these patients were mammography and ultrasound. Radiology findings included mass lesions (82.6%), calcifications (7.6%) and cyst-like appearances (92.5%). Mean size of lesion on sonography was 13 mm (range 7−36 mm).
The histopathological findings of the surgically excised lesions revealed intraductal papillomas without atypia in 53 cases, atypical papillomas in 36 cases, malignant transformation was seen in 16 cases (DCIS in 14 patients and 2 invasive carcinomas).
Multiple intraductal papillomas were revealed in 13 cases, among them malignant transformation were revealed in 3 patients (23.1%).
Discordance in the imaging-histological reports was seen in 10 cases.
The upstage rate of intraductal papillomas on biopsy to malignancy on excision was 8.7%.
After a mean follow-up of 4 years no patient developed any breast malignancy.
Conclusion: We recommend that all patients with intraductal papillomas of the breast, especially with multiple lesions or when associated with atypia, undergo wide excision of the lesion with clear margins and that these patients be monitored closely with annual imaging.
No conflict of interest.

1936 POSTER

Evaluation of primary tumour and regional lymph node metastases with FDG PET/CT in breast cancer patients: Prone versus supine position

S. Teixeira[1], B.B. Koolen[1], W. Vogel[1], M.P. Stokkel[1], M.J. Vrancken Peeters[1], E.J.T. Rutgers[1], H. Van Tinteren[1], R.A. Valdes Olmos[1]. [1]*Antoni van Leeuwenhoek − Netherlands Cancer Institute, Nuclear Medicine, Amsterdam, Netherlands*

Aim: For the staging of breast cancer, 18F-FDG PET/CT in supine position has demonstrated clinical value. To assess primary tumor response in patients scheduled to receive neoadjuvant chemotherapy (NAC) MRI is currently performed in prone position. It was postulated that additional PET/CT imaging of the thorax in prone position might also be valuable for the loco-regional assessment of these patients. The objective of this study was to compare PET/CT imaging in prone and supine position in the visualization and uptake parameters of primary tumors and regional lymph node metastases.
Materials and Methods: Between August 2010 and April 2012, 198 patients (mean age 51, range 26−81) with stage II/II breast cancer were included. Approximately 60 minutes after injection with 18F-FDG (180–240 MBq) a prone position PET/CT of the thorax was performed using a mock-up MR coil stripped from all metal parts, with a 3.00 min per bed position PET acquisition and high-resolution (2 mm^3 voxels) reconstruction. Afterwards, a standard PET/CT in supine position form skull base to thighs was performed using 1.30 min per bed position and standard reconstruction (4 mm^3 voxels). The SUVmax of FDG-avid primary tumors as well as axillary- and non-axillary lymph nodes were quantified and compared. The visual accuracy was compared for the detection of tumor multifocality and the occurrence of anatomical mismatch between CT and PET.
Results: The SUVmax values of the primary tumors (average 7.5 versus 6.4) and in non-axillary lymph nodes (average 7.6 versus 6.0) were significantly higher in prone position ($P = 0.015$ and $P < 0.001$). The measured volume of FDG tumour uptake was significantly ($P < 0.001$) larger in prone images (average 9.1 versus 6.24) with a more round form of shape. In four patients multifocality was solely visualized in prone position ($P = 0.134$). A relevant anatomical mismatch between CT and PET was more often identified on supine than on prone images and especially at the location of the non-axillary lymph nodes ($N = 4$ versus $N = 9$).
Conclusion: Optimized PET/CT imaging of the thorax in prone position leads to a sharper tumour delineation, higher quantitative SUVmax values and a more adequate loco-regional assessment in breast cancer patients. This more appropriate correlation of prone MRI and PET/CT may improve therapy response monitoring in breast cancer patients receiving neoadjuvant chemotherapy.
No conflict of interest.

1937 POSTER

Detection of occult N3-disease in breast cancer patients with PET/CT − does it affect survival?

S. Teixeira[1], B.B. Koolen[1], P.H.M. Elkhuizen[2], M.J. Vrancken Peeters[3], M.P. Stokkel[1], E.J.T. Rutgers[3], R.A. Valdes Olmos[1]. [1]*Antoni van Leeuwenhoek − Netherlands Cancer Institute, Nuclear Medicine, Amsterdam, Netherlands;* [2]*Antoni van Leeuwenhoek − Netherlands Cancer Institute, Radiotherapy, Amsterdam, Netherlands;* [3]*Antoni van Leeuwenhoek − Netherlands Cancer Institute, Oncologic Surgery, Amsterdam, Netherlands*

Background: In breast cancer the TNM classification is used for treatment planning and prediction of survival. Undetected lymph node metastases during staging workup results in a higher local recurrence rate (LRR) if left untreated. In our institute, the high positive predictive value of the FDG-PET/CT incentivized us to change the radiotherapy plan when newly N3 disease was detected in breast cancer patients scheduled for neo-adjuvant chemotherapy (NAC). The aim of the present study was to compare the event free survival (EFS), with and without newly detected N3 disease on PET/CT for breast cancer patients treated with neo-adjuvant chemotherapy.
Materials and Methods: Between September 2007 and October 2011 a total of 311 breast cancer patients with a tumour of at least 3 centimetres gave informed consent to receive a baseline PET/CT scan in the context of response monitoring to NAC. Only patients without distant metastases were included. The group was divided in a low- (T0−1N0−1 and T2N0), intermediate- (T2N1 and T3N0) and a high risk group (T2N2−3, T3N1−3, T4). Following detection of N3 FDG-avid lymph nodes on PET/CT patients were reclassified concerning risk of local recurrence. The EFS analysis

was made for patients with at least 3-year follow-up information (N = 104). Newly found distant metastases, local recurrence or death were classified as an 'event'.
Results: Of the risk groups categorized before PET-CT the EFS was 76% for the high risk group (N = 38), 84% for the intermediate risk group (N = 44) and 95% in the low risk group (N = 21). Using PET/CT information, nine patients of the intermediate- and one patient of the low risk group were upstaged to the high risk group. Of these patients who received additional radiotherapy one patient experienced an event. This resulted in an increase of the EFS to 79% for the high risk group and a negligible change for the other groups.
Conclusion: Based on conventional staging procedures and estimated risk for LRR, the EFS after three years of follow-up differed between three risk groups of breast cancer patients. Detection of occult N3 disease with PET/CT caused the upstaging for clinically unsuspected N3 patients to the high risk staging group, enabling adequate treatment with radiotherapy. If these patients would be left untreated a more elevated risk of local recurrence can be expected. Despite a trend in EFS increase the short follow-up time impeded to observe relevant change in the event free survival.
No conflict of interest.

1938 POSTER

25-hydroxy vitamin D levels in patients with breast cancer: Importance of dressing style

G. Alco[1], S. Igdem[2], M. Dincer[1], V. Ozmen[1], G. Demir[3], G. Koksal[1], C. Tecimer[3], D. Selamoglu[1], K. Pilanci[3], S. Okkan[1]. *[1]Florence Nightingale Hospital, Breast Cancer Study Group, Istanbul, Turkey; [2]Istanbul Bilim University, Radiation Oncology, Istanbul, Turkey; [3]Istanbul Bilim University, Medical Oncology, Istanbul, Turkey*

Background: The aim of our study is to determine the prevalence of vitamin D deficiency as measured by serum 25-hydroxyvitamin D (25-OHD) levels in patients with breast cancer and to evaluate the correlation with life-style and treatments.
Material and Methods: This study included stage 0-III breast cancer patients (n = 170) treated with chemotherapy, radiotherapy and/or hormonal therapy at our hospital. Patients and treatment characteristics are listed in Table 1. 25-OHD levels were collected during the follow-up period between 2010–2013. The correlation between serum 25-OHD levels and the supplementation type, age, menopausal status, diabetes mellitus, usage of bisphosphonates, body-mass index, season, and dressing style were investigated. The distribution of serum 25-OHD levels was categorized as deficient (<10 ng/ml), insufficient (10−24 ng/ml), and sufficient (25−80 ng/ml). All statistical analyses were conducted with Fisher's exact test and logistic regression analysis.

Patient/treatment characteristics	Deficient/insufficient vitamin D levels	Sufficient vitamin D levels	Fisher's Exact test
Age			p = 0.127
<51 ⩾51	65 % 53.7	25 % 51	
⩾51	56 % 46.3	24 % 49	
Stage			p = 0.097
0−IIA	85 % 70.2	38 % 77.6	
IIB−IIIC	36 % 29.8	11 % 22.4	
Menopausal status			p = 0.126
Premenopausal	48 % 39.7	21 % 42.9	
Postmenopausal	73 % 60.3	28 % 57.1	
Season			p = 0.084
October–March	79 % 65.3	28 % 57.1	
April–September	42 % 34.7	21 % 42.9	
Dressing Style			p = 0.00001618
Modern	86 % 71.1	48 % 98	
Conservative	35 % 29.1	1 % 2	
Initial Vitamin D supplementation			p = 0.00001612
None or 400–1000 IU/day	120 % 99.2	39 % 79.6	
100.000–300.000 IU/month	1 % 0.8	10 % 20.4	
Time after completion of radiotherapy			p = 0.048
<9 months	69 % 57	22 % 44.9	
⩾10 months	52 % 43	27 % 55.1	
Hormonotherapy			p = 0.902
None	23 % 19	9 % 18.4	
Tamoxifen	58 % 47.9	22 % 44.9	
Aromatase Inhibitors	40 % 33.1	18 % 36.7	
Chemotherapy			p = 0.05
Yes	76 % 62.8	25 % 51	
No	45 % 37.2	24 % 49	
Trastuzumab			p = 0.165
Yes	21 % 17.4	7 % 14.3	
No	100 % 82.6	42 % 85.7	
Diabetes mellitus			p = 0.115
Yes	20 % 16.5	5 % 10.2	
No	101 % 83.5	44 % 89.8	
Body-mass index			p = 0.0071
<25 kg/m^2	42 % 34.7	27 % 55.1	
⩾25 kg/m^2	79 % 65.3	22 % 44.9	
Bisphosphonates			P = 0.0027
Yes	9 % 7.4	12 % 24.5	
No	112 % 92.6	37 % 75.5	

Results: The median age of the patients was 51 years (range, 27−79 years) and 71% of them had deficient/insufficient 25-OHD levels. Forty-two and 79 patients had deficient and insufficient 25-OHD levels, respectively. On univariate analysis, vitamin D deficiency/insufficiency was significantly inversely correlated with the use of chemotherapy, time after completion of radiotherapy, high body-mass index (⩾25), no bisphosphonates usage, and the dressing style. On multivariate analysis, none or low dose vitamin D supplementation, and decreased sun-exposure due to conservative dressing style were found as independent factors increasing risks of vitamin D deficiency/insufficiency 20.9 and 12.8 fold, respectively ($p < 0.05$).
Conclusions: The prevalence of serum vitamin D deficiency/insufficiency is high in our breast cancer survivors. Vitamin D status should be routinely evaluated for all women especially for patients with conservative dressing style.
No conflict of interest.

1939 POSTER

Thoracoscopic internal mammary lymph nodes dissection: A staging tool for internal mammary lymph nodes in breast cancer

H. Soliman[1], W.Y. Gareer[1], H.I. Elsebaie[1], H. Gareer[1], H. Ahmed[1]. *[1]National Cancer Institute, Surgical Oncology, Cairo, Egypt*

Background: The internal mammary lymph node status is a major prognostic factor in breast cancer. If positive, prognosis is less favourable. However, staging this regional nodal basin is not performed routinely, thus discarding additional staging information.
Methods: During the period from June 2004 to May 2007, 50 patients with operable breast cancer underwent modified radical mastectomy (MRM) or breast conserving surgery (BCS), followed by thoracoscopic internal mammary lymphadenectomy, using 3 ports through the skin incision of the MRM or the BCS.
Results: Of total number of 50 patients, the mean age of patients was 44 years (range, 27−60). 40 (80%) had medio-central tumour, 10 (20%) had lateral tumour. 35 (70%) had clinically involved axillary nodes. 16 out of 50 patients received neo-adjuvant CTH. 44 patients underwent MRM and 6 patients underwent BCS. No intra-operative complications occurred. Atelectasis was the only postoperative complication that was encountered, which occurred in 12 cases, and was treated conservatively. The average chest drainage period was 1.2 day (range, 1−2 days). The total number of IMN metastasis was 18 patients (36%). The risk of IMN metastasis was higher; in younger patients (P = 0.03), in medio-central tumours (P = 0.03), in bigger tumours (P = 0.05), with heavier metastasis of axillary LNs (P = 0.001). Knowing the IMN status helped in proper staging of patients, 7 patients showed evident stage migration after adding the IMN analysis to that of primary tumor and axillary LN. During the follow up period (the median = 22 months, range = 7 to 42 months), no patient had pleural dissemination or port-site metastasis.
Conclusions: Thoracoscopic IMN lymphadenectomy is a safe procedure, which can be done without serious additional complications or cosmetic compromise, which allows proper nodal staging, and proper treatment planning.
No conflict of interest.

1940 POSTER

Male breast cancer: A 15-year single institution experience

T. Marques[1], E. Gouveia[1], I. Miguel[1], M. Sousa[1], S. Esteves[2], M.J. Passos[1], A. Moreira[1]. *[1]Instituto Portugues de Oncologia de Lisboa Francisco Gentil, Oncologia Médica, Lisboa, Portugal; [2]Instituto Portugues de Oncologia de Lisboa Francisco Gentil, Gabinete de Investigação Clínica, Lisboa, Portugal*

Background: Male breast cancer (MBC) is rare. Although its frequency has increased in recent decades, it accounts for less than 1% of breast cancers. Unfortunately, the rarity of this condition has hampered the possibility of carrying out large randomized trials. Most of the information is therefore based on small single institution retrospective studies or by extrapolation from breast cancer trials in females. Early diagnosis is the exception and men tend to be diagnosed with breast cancer at an older age than women. The etiology, diagnosis, and treatment of breast cancer in men is similar to that of females and outcomes are similar when survival is adjusted for age at diagnosis and stage of disease. The vast majority of male breast cancers are hormonally sensitive.
Objective: To characterize the clinical and pathologic features of MBC and the overall survival in a single institution.
Methods: We retrospectively reviewed the clinical, pathological and survival data of 78 male patients with breast cancer treated in our institution, between 1997 and 2011. Overall survival was analyzed using Kaplan-Meyer curves.

Results: 78 patients were evaluated with a median age of 68 years [37−89]. Predominant histological type was ductal invasive carcinoma (57 patients, 73.1%), mostly moderately differentiated (42%). Estrogen receptor (ER) was positive in more than 50% of neoplastic cells in 58 (74.3%) patients. Progesterone receptor (PR) was positive in more than 50% of the neoplastic cells in 22 (28.2%) patients. ER e PR were positive in less than 50% of neoplastic cells in 3 and 8 patients, respectively. cErbB2 receptor was positive in only 8 patients. Stage at diagnosis was: IA in 26.9%; IB in 1.3%; IIA in 17.9%; IIB in 2.6%; IIIA in 5.1%; IIIB in 24.4%; IV in 6.4% of the patients (not available in 15.4%).
Modified radical mastectomy was performed in 36 (46%) and conservative surgery in 26 (33%) patients. As far as medical treatment is concerned, 38 patients underwent chemotherapy (49%), 37 patients underwent radiotherapy (47%) and 51 patients underwent hormone therapy (65%). Thirteen patients (17%) relapsed.
Median follow-up was 4.7 years (range 0.09–7.78), with a median overall survival (OS) of 13.34 years and a 73.3% 5-year OS (95% CI: 63.6–84.5%). One third of the patients died (n = 26) during follow-up.
Conclusion: The sample size was relevant. Overall survival was similar to the results of other published series. Prospective studies are needed to better characterize this rare disease.
No conflict of interest.

1941 POSTER

Clinical features and survival of women diagnosed with breast cancer age 40 and younger in a single Asian institute

S. Samphao[1], K. Munkong[1], S. Mahattanobon[1], P. Tanaanantarak[2].
[1]Faculty of Medicine Prince of Songkla University, Department of Surgery, Songkhla, Thailand; [2]Faculty of Medicine Prince of Songkla University, Department of Radiology, Songkhla, Thailand

Background: Recent increases in breast cancer affect women around the world, especially in Asian countries. The Asian women present with the earlier age at diagnosis and higher mortality rate, compared with the older. The prognostic factors include delayed in tumour detection, short tumour doubling times, high lymphovascular invasion and poor hormonal/ErbB2 receptor expression. We examined clinical, pathological and survival data in this population, compared with their older counterparts.
Material and Methods: Records review identified 1,360 women diagnosed with breast cancer from 1998–2007. Women aged ⩽40 (n = 298) and over 40 (n = 1,062) were compared in means of tumour detection, operative procedures, tumour characteristics, adjuvant treatment and survival.
Results: Overall, most of the patients presented with palpable mass. Only half the patients underwent mammography at the time of diagnosis. Younger women had lower rates of BIRADS 4/5, compared with the older (85.4% vs. 92.6%, p = 0.02).
There was no difference in operative procedures between the two groups, in favour of mastectomy with axillary lymph node dissection. Younger women had higher rates of lymphovascular invasion (32.2% vs. 25.2%, p < 0.001) and negative oestrogen receptor status (40.3% vs. 36.4%, p = 0.002). There were no differences in adjuvant chemotherapy (81.2% vs. 78.8%), types of chemotherapy, either anthracycline- or nonanthracycline-based regimens, adjuvant hormonal therapy (68.8% vs. 62.1%) and radiotherapy (38.6% vs. 43.4%) between the two groups.
At a median follow-up of 85 months, there were no differences in 5-year disease-free survival (62.4% vs. 65.7%), distant disease-free survival (65.8% vs. 69.1%) and overall survival (69.1% vs. 74.1%) between the two groups. Pathological staging (stage 3: HR 3.85, 95% CI 2.59–5.73, p < 0.001) and nodal involvement (HR 1.60, 95% CI 1.23–2.08, p < 0.001) were predictive factors for disease recurrence and death.
Conclusions: Younger women with breast cancer have poor tumour detection and more aggressive diseases. With equivalent local and systemic therapy, however, survival is comparable with the older. Pathological staging and nodal status are predictive factors for survival outcomes.
No conflict of interest.

1942 POSTER

Treatment and prognosis of familial breast cancer patients

H. Takuwa[1], T. Inamoto[1], R. Hagiwara[1], S. Takahara[1], A. Yamauchi[1].
[1]The Tazuke Kofukai Medical Research Institute Kitano Hospital, Breast Surgery, Osaka, Japan

Background: Hereditary breast cancer is becoming broadly recognised among professionals and patients, and we experience such cases in clinical situation more often. In spite of strong familial history of breast cancer, genetic tests for confirming diagnosis have not been adopted to those patients because these tests are not insurance adaptation in Japan. Moreover, even if they were diagnosed, it is reported that there is a gap in the treatment and surveillance in specialists against NCCN guideline about HBOCS (hereditary breast and ovarian cancer syndrome) management.
Objective: In this study we picked up 146 cases among 1007 breast cancer patients who met the testing criteria of HBOCS. They included PTEN gene variation; Cowden disease or BRCA2 gene variations. They consists of one male breast cancer patient, 55 bilateral breast cancer patients and 73 of them received operation before 40 years old. 4 patients experienced ovarian carcinoma (3 of them were serous carcinoma). Their mean follow-up period is 87 months (0–648).
Result: The rate of breast conserving mastectomy at the first operation is 58.7% (118/201). Local reccurence rate is 8.0% (16/201), distant metastasis rate is 14.4% (21/146) and mortality rate is 10.3% (15/146). 4 cases who received breast conserving mastectomy for the first operation were tended to repeat breast tumour whose intrinsic subtype differs from the first one. After performing systemic therapy, it would not be a cause of distant metastases. The rate of recurrence of familial breast cancer is almost equivalent to TN diseases of sporadic cases. However, the mortality rates of cases with distant metastasis are high, and the survival time is comparatively short.
Conclusion: Familial breast cancer tends to show multi-centric oncogenesis in many cases, and mastectomy in the first operation should be considered. Because there is no report that they tend to run into distant-metastases, initial systemic therapy is thought to be enough in conventional. But when it comes to metastatic breast cancer, more intentional therapy like PARP-1 inhibitor might be effective. We intend to focus on the patients who really need genetic screening by listening of their familial history even after operation.
No conflict of interest.

1943 POSTER

Sentinel lymph node (SLN) biopsy before neoadjuvant chemotherapy and its impact in reducing secondary lymphedema in patients with early breast cancer

U. Bohn[1], M. Mori[1], M. Cazorla[2], I. Reyes[2], P. Jimenez[2], M. Pachovich[3], M. Lloret[4], C. Bustos[5], M.J. Hernandez[6], T. Baeta[7]. *[1]Hospital Universitario Dr. Negrin, Medical Oncology, Las Palmas de Gran Canaria, Spain; [2]Hospital Materno Infantil, Gynecology, Las Palmas de Gran Canaria, Spain; [3]Hospital Materno Infantil, Pathology, Las Palmas de Gran Canaria, Spain; [4]Hospital Dr. Negrin, Radiation Oncology, Las Palmas de Gran Canaria, Spain; [5]Hospital Materno Infantil, Radiology, Las Palmas de Gran Canaria, Spain; [6]Hospital Insular, Nuclear Medicine, Las Palmas de Gran Canaria, Spain; [7]Canary Health Service, Breast Screening Program, Las Palmas de Gran Canaria, Spain*

Background: Sentinel lymph node (SLN) biopsy is the standard procedure for assessing axillary status in stage I−II breast cancer patients.
The aim of our study was to select patients for axillary lymphadenectomy (AL) after the SLN biopsy followed by primary polichemotherapy (PC) in a group of patients diagnosed and treated at two hospitals in the city.
Methods: To carry out sentinel lymph node study in 50 patients with early-stage breast cancer, followed by polychemotherapy, surgery and axillary clearance (AL) only if nodes +>2 mm, radiotherapy, hormone if positive receptor/s, +/− Trastuzumab. The first 21 patients underwent (AL) to validate the technique.
Chemotherapy regimen: ADR/4EPI + CTX +/− 5FU × 4 cycles, followed by paclitaxel (P) weekly for 8 +/− Trastuzumab.
Results: Between June 2006 and October 2012 were included 50 patients with breast cancer stage IIA−IIB. The mean age was 46 years (range 21−73a). The average palpable tumor size was 3.5 cm (range 1.8 to 6.0 cm) and by ultrasound 2.0 cm (range 1.8−5.0 cm). Stage IIA: 36 (90%), CDI: 47 (93%) G1: 22(42%) ER+: 42(84%), PR+:32 (66%), HER2+:10 (20%); Ki67+:32 (64%), p53+: 31 (62%) and triple negative 6 (12%). All All 50 patients were evaluable for analysis. Median sentinel nodes removed was 2 (range 2−6). The analysis is shown in the tables. Group A (21p). Group B (29p).

Table 1.

	CLN pre PQ (−)	AL (−)	AL (+)	CLN pre PQ (+)	AL (−)	AL (+)
Group A (21p)	9 (42.86%)	9 (100%)	0	12 (57.14%)	8(38.1%)	4(19%)
Group B (29p)	20 (68.97%)	0	0	9 (31%)	7(24 %)	2(6.9)

Table 2.

	pCR	pPR isolated foci	pT <1.0 cm	pT <2.0 cm	pT >2.0 cm
Groups A-B (50p)	9 (18%)	6 (12%)	8 (16%)	18 (36 %)	10 (20 %)

The treatment was well tolerated with grade 3 and 4 neutropenia in 3 and 4 cases respectively.
Conclusions: The primary chemotherapy regimens ADR/4EPI + CTX + /-5FU-P, showed: pCR:18% and pPR:15% as isolated foci. In group B 20/29p with negative pre-chemotherapy sentinel node did not go to AL. To date, we have not seen in any axillary relapse. However there have been four distant relapses and 4 deaths related to its process base. In group B secondary lymphedema was avoided in 66% of cases.
No conflict of interest.

1944 POSTER

Outcome of patients with ductal carcinoma in situ before screening mammography

C. Grasic Kuhar[1], E. Matos[1], M. Unk[1]. [1]*Institute of Oncology Ljubljana, Medical Oncology, Ljubljana, Slovenia*

With screening mammography the incidence of diagnosed ductal carcinoma in situ (DCIS) increases. In Slovenia it was introduced in April 2008. Register based data were analysed for 765 subjects with DCIS, diagnosed between January 1988 and August 2009. We examined the local relapses (LR) and distant metastatic relapses (DMR) after local treatment: mastectomy or breast conserving surgery followed with or without radiotherapy.
DCISs represented less than 4% of all breast cancers diagnosed in Slovenia in period 1988–2009. Median follow-up of our cohort was 9.2 years (min 0.1-max 25). Median age was 55 years (min 18-max 91), 203 (26.5%) grade were III, 283 (37%) were treated by mastectomy (69 and 36 reconstructed by autolog tissue and expander, resp.). Among 454 (60%) patients treated by breast conserving surgery, 146 (19%) and 28 (3%) had inadequate margins or uknown radicality, 217 (48%) had adjuvant radiation therapy. 75 (10%) received adjuvant hormonal therapy with tamoxifen. We found 71 (9.6%) LR, 51 (6.9%) as invasive cancers and 20 (2.6%) as DCIS, 14 patients (1.4%) developed distant metastases. 17 (2.2%) had contralateral breast cancer and 14 (1.8%) other tumor types. At median follow-up 9.2 years LR free survival was 88.6% and DMR free survival was 98.4%. We found no factor (age, grade, radicality, adjuvant radiotherapy or adjuvant hormonal therapy) to significantly correlate with LR or DMR free survival. Only nonradical surgery correlated borderline with DMR ($p = 0.068$).
The outcome of patients with DCIS is good. Distant metastases are rare. The outcome of our cohort is comparable to other reports. With introduction of screening mammography the higher incidence of DCIS is expected.
No conflict of interest.

1945 POSTER

Triple-negative breast cancer: A single-institution retrospective analysis

S. Mallick[1], A.K. Gandhi[1], W. Melgandi[1], N.P. Joshi[1], D.N. Sharma[1], K.P. Haresh[1], P.K. Julka[1], S. Gupta[1], G.K. Rath[1]. [1]*All India Institute of Medical Sciences, Radiation Oncology, New Delhi, India*

Background: Triple negative breast cancer (TNBC) is a distinct entity associated with adverse outcomes. We explored our institutional results.
Methods: We retrospectively analysed our database between 2000 & 2010. The estrogen receptor (ER) & progesterone receptor (PR) status was negative by immunohistochemistry (IHC) while Her2 status was negative by IHC or confirmed negative by fluorescent in-situ hybridisation for equivocal cases. Adjuvant radiation was 50 Gy in 25 fractions after modified radical mastectomy (MRM) or 66 Gy equivalent after wide local excision (WLE). Adjuvant chemotherapy was anthracycline or taxane-anthracycline based. Treatment at relapse consisted of chemotherapy, surgery & radiation as required. Palliative chemotherapy included single agent or combination chemotherapy with paclitaxel, carboplatin, gemcitabine, ixabepilone & capecitabine. Disease free survival [DFS]) were calculated using the Kaplan Meier method. These were correlated with age, menopausal status, clinical & pathological 'T' & 'N' stage (T1 & T2 vs. T3 &T4 or N0 vs. Node positive disease), lymphovascular space invasion, extracapsular spread & type of chemotherapy. Log-rank test was used to compare survival distribution. The data was analysed using SPSS 16.
Results: 218 patients were analysed. TNBCs formed 22% of all breast cancer cases noted. Median follow up was 25.83 months (range: 1−93) Median age at presentation was 45 years (range: 27−58 years). 5 year DFS was 88.5%. Age more than 45 years ($p = 0.096$), post-menopausal status ($p = 0.058$), earlier clinical 'T' & 'N' stage ($p = 0.060$ & $p = 0.057$) & taxane chemotherapy ($p = 0.06$) showed a trend for better disease free survival. Earlier pathological 'T' stage ($p = 0.044$), taxane based chemotherapy ($p = 0.05$) and earlier pathological 'N' stage ($p = 0.001$) had significantly better DFS. Other variables did not correlate significantly with survival data.
Conclusions: Pathological T and N stage remain important predictors of survival for this disease defined on the basis of ER, PR & Her2 status. Taxanes seem to offer better disease free survival.
No conflict of interest.

1946 POSTER

Metaplastic breast carcinoma: A heterogeneous disease

M. Gultekin[1], G. Eren[1], T. Babacan[2], G. Yazici[1], P. Hurmuz[1], F. Yildiz[1], K. Altundag[2], N. Guler[2], Y. Ozisik[2], M. Gurkaynak[1]. [1]*Hacettepe University Faculty of Medicine, Department of Radiation Oncology, Ankara, Turkey;* [2]*Hacettepe University Faculty of Medicine, Department of Medical Oncology, Ankara, Turkey*

Background: Metaplastic breast carcinoma (MBC) is a rare disease which shows an aggressive clinical behavior. It is usually treated with multidisciplinary approach including radiotherapy. The aim of this study is to evaluate clinicopathologic characteristics and the multi-disciplinary treatment results of MBC patients treated in a single institute.
Material and Methods: Seventeen female patients with MBC treated in our department between June 2000 and January 2012 were identified and retrospectively evaluated. The median age at diagnosis was 46 years (range, 26−66 years). Eleven patients (%65) were in premenopausal and 6 (%35) were in postmenopausal status. Nine (53%) patients were classified as purely epithelial; 4 (24%) adenosquamous, 2 (12%) squamous, 3 (17%) adenocarcinoma with spindle cell differentiation and 8 (47%) patients were classified as mixed epithelial and mesenchymal; 5 (29%) carcinosarcoma, 2 (12%) carcinoma with chondroid metaplasia and 1 (6%) metaplastic carcinoma not otherwise specified (NOS). The median tumor size at diagnosis was 3.5 cm (range 1.5−12 cm). Six (35%) patients were treated with BCS and 11 (65%) with mastectomy. Axillary lymph node metastasis was found in 6 (35%) patients. Twelve (71%) patients had triple negative tumors. Postoperative RT and systemic adjuvant treatment was given to all patients according to stage and biological characteristics.
Results: Median follow-up time was 27 months (range, 12–151 months). At the time of this analysis, 14 (82%) patients were alive with no evidence of disease, and 1 (6%) was alive with disease. One patient died with disease. Since the other patient was lost to follow-up, the reason for death was unknown. The 3-year overall survival (OS) was 91% and 5-year 80%, and disease-free survival (DFS) rates were 76% and 76%, respectively. Recurrences were observed in 2 patients. The particular patient died with disease developed brain, lung and bone metastases 14 months after the treatment and palliated with radiotherapy and chemotherapy. She died with disease at the 26th months of follow-up. The other patient with recurrence developed local recurrence at the 15th months and distant metastases at the 19th months of follow-up. She underwent surgery and reirradiation to the chest wall and received chemotherapy. She was alive with disease at the last control which was 25th months of follow-up.
Conclusions: Despite the young age of our patients with mostly high grade tumors, larger tumor size and higher rates of lymph node metastasis, the survival outcomes in our study are more favorable compared to previously reported series. The low incidence of local failure and distant metastases in our study may be attributed to multidisciplinary approach including surgery, chemotherapy and radiotherapy to all patients. Prospective, multicentric and multi-institutional studies are necessary to find out the optimal treatment strategy in these patients.

First analyses of radiotherapy/chemotherapy-related cardiovascular disease in breast cancer patients: A population-based study

N.B. Boekel[1], M. Schaapveld[1], J.A. Gietema[2], M.I.M. Versteegh[3], O. Visser[4], B.M.P. Aleman[5], F.E. Van Leeuwen[1]. [1]*Netherlands Cancer Institute, Epidemiology, Amsterdam, Netherlands;* [2]*University Medical Center Groningen, Medical Oncology, Groningen, Netherlands;* [3]*Leiden University Medical Center, Steering Committee Cardiac Interventions Netherlands, Leiden, Netherlands;* [4]*Comprehensive Cancer Center the Netherlands, Registration and Research, Utrecht, Netherlands;* [5]*Netherlands Cancer Institute, Radiation Oncology, Amsterdam, Netherlands*

Background: Several studies have shown that early breast cancer (BC) treatment may increase the risk of cardiovascular disease (CVD) after $\geqslant$10 years. However, most reports are based on less contemporary treatment regimens.
The aim of this population-based study is to assess the effects of contemporary radiotherapy (RT) and chemotherapy (CT) used to treat BC on cardiovascular morbidity and mortality.
Methods: We have constructed a large population-based cohort of 5-year survivors diagnosed with BC before the age of 75 years, between

1989 and 2004 in the Netherlands (n = 70,230). Information on patient characteristics, primary and secondary malignancies, and basic treatment information were provided by the Netherlands Cancer Registry. For a subgroup detailed treatment information was collected from radiotherapy institutes, clinical trials, and regional studies. Cause of death was acquired through linkage with Statistics Netherland and data on cardiovascular morbidity through linkage with two population-based registries: the Hospital Discharge Diagnoses Registry and the Cardiac Interventions Registry.
Results: The median follow-up was 9.7 years (range 5−21 years), during which 2,411 patients died due to CVD, 1,740 underwent an invasive cardiac intervention (surgical or angioplastic), and 3,800 were hospitalized for CVD. First preliminary analyses show that compared to the general population, BC patients are not at increased risks for cardiovascular death (standardized mortality ratio 0.96 95% CI 0.92–0.99).
When comparing treatment groups within the cohort, we found that CT versus no-CT did not increase the risk of any cardiovascular event (cardiovascular death/hospitalization/surgical intervention; hazard ratio(HR)=1.02 95% CI 0.92–1.13), or ischemic heart disease (HR = 0.83 95% CI 0.69–1.00), but increased the risk of congestive heart failure (HR = 1.61 95% CI 1.24–2.09).
Compared to patients treated with surgery only, RT for left-sided BC increased the risk for any cardiovascular event (HR = 1.25 95% CI 1.15–1.35), ischemic heart disease (HR = 1.31 95% CI 1.13–1.50), and congestive heart failure (HR = 1.48 95% CI 1.22–1.78). Left- versus right-sided RT showed an increased risk for ischemic heart disease (HR = 1.23 95% CI 1.09–1.39).
Conclusion: Contemporary RT and CT used to treat early breast cancer increase the risk of CVD. Results of additional analyses focusing on radiation fields and specific systemic treatments as well as analyses focusing on history of CVD before BC will be presented at the conference.
No conflict of interest.

1948 POSTER

Impact of tumour epithelial subtype on circulating microRNAs in breast cancer

C.L. Brougham[1], P.S. Waters[1], D. Wall[2], M.J. Kerin[1], R.M. Dwyer[1].
[1]National University of Ireland Galway, Discipline of Surgery School of Medicine, Galway, Ireland; [2]National University of Ireland Galway, HRB Clinical Research Facility and School of Mathematics Statistics and Applied Mathematics, Galway, Ireland

Background: microRNAs (miRNAs) are non-coding RNAs approximately 22 nucleotides in length. They are remarkably stable in the circulation, supporting their potential as biomarkers of disease. Breast tumours are divided into epithelial subtypes based on receptor status, with basal subtype being negative for oestrogen and progesterone receptors, and Her2/neu. Basal subtype accounts for ~20% of breast cancers and due to the lack of targeted therapies has a poor survival rate. The aim of this study was to investigate the potential of circulating miR-106a, miR-191 and a novel miR, miR-A, as biomarkers of breast cancer.
Materials and Methods: Following informed patient consent, whole blood was harvested from breast cancer patients (n = 83) and healthy control individuals (n = 83). miRNA was extracted and analysed using RQ-PCR targeting a panel of miRNAs including miR-191 and miR-106a, miR-A and endogenous controls U6, miR-16 and miR-122. Any association with patient clinicopathological details was also investigated.
Results: miR-A, miR-191 and miR-106a were detectable in the circulation of all breast cancer patients and healthy controls included in the study (n = 166). miR-A was significantly up-regulated in the circulation of patients with breast cancer (Mean ± SEM; 2.05±0.06 log10 Relative Quantity (RQ)) compared to healthy controls (1.83±0.05, $p < 0.005$ log10RQ). miR-A displayed no relationship with clinicopathological characteristics. Although not significantly altered overall in breast cancer patients compared to healthy controls, miR-191 and miR-106a were significantly down-regulated in patients with basal breast cancer compared to healthy controls ($p < 0.05$). Further, both miRs displayed differential expression across epithelial subtype (ANOVA miR-191 $p < 0.05$; miR-106a $p < 0.005$).
Conclusion: These findings highlight miR-A as a potential circulating biomarker for breast cancer. Further, the data supports miR-106a and miR-191 as biomarkers for basal breast cancer. These circulating miRNAs have potential for use in conjunction with current screening techniques, and may improve the ability to more accurately detect and classify breast tumours.

Impact of hospital surgical volume on breast cancer outcome: A population based study in the Netherlands

S. Siesling[1], V.C.G. Tjan-Heijnen[2], M. De Roos[3], Y.E.M. Snel[4], T. Van Dalen[5], M.W. Wouters[6], H. Struikmans[7], J.H. Maduro[8], J.J.M. Van der Hoeven[9], O. Visser[10]. *[1]Comprehensive Cancer Centre The Netherlands (IKNL), Registration and Research, Utrecht, Netherlands; [2]Maastricht University Medical Centre, Medical Oncology, Maastricht, Netherlands; [3]Rivierenland Hospital, Surgery, Tiel, Netherlands; [4]Association of General Hospitals, Utrecht, Netherlands; [5]Diakonessen Hospital, Surgery, Utrecht, Netherlands; [6]Netherlands Cancer Institute, Surgical Oncology, Amsterdam, Netherlands; [7]Medical Centre Haaglanden, Radiotherapy, The Hague, Netherlands; [8]University Medical Centre Groningen, Radiotherapy, Groningen, Netherlands; [9]Leiden University Hospital, Medical Oncology, Leiden, Netherlands; [10]Comprehensive Cancer Centre the Netherlands (IKNL), Registration and Research, Utrecht, Netherlands*

Background: For some low-volume tumour types hospital surgical volume is associated with better survival. For breast cancer there is still much debate. The aim of this study is to determine to what extent the yearly surgical hospital volume determines the risk of death in breast cancer patients.
Method: Women diagnosed with primary invasive breast cancer in the period 2001–2005 were selected from the Netherlands Cancer Registry. Hospitals were grouped by their annual volume of surgery for invasive breast cancer. Cox proportional hazard models were performed including all patients with primary non-metastatic breast cancer who underwent breast surgery. Gender, age at diagnosis, morphology, grade, size (pT), number of positive lymph nodes, year of diagnosis and socio economic status (SES) were included as covariates. Follow-up was complete until the 1th of February 2012.

Table: Cox regression multivariable analyses: the relation of the number of surgical treated invasive breast cancer per hospital per year and the risk of death of patients with **non-metastatic** breast cancer in the Netherlands, 2001–2005

Low	15,873	1.11	1.06–1.16

*HR, hazard ratio; 95% CI, 95% confidence interval; **p = 0.052.

Results: In total 55.743 patients with invasive non-metastatic breast cancer were diagnosed during the period 2001–2005. Hospitals were grouped by volume of surgery: less than 75 (n = 19), 76–100 (n = 30), 101–150 (n = 29), 150 and more (n = 23) surgeries per year. Non-metastatic patients had a tendency to a 6% higher risk of death in a low volume hospitals

than a hospital with >150 surgeries per year (HR 1.06, 95% CI 1.00–1.12, p = 0.052). Patient and tumour characteristics like age (HR 1.05, 95% CI 1.05–1.05) and SES (lowest vs highest; HR 1.11, 95% CI 1.06–1.16), grade (low vs high, HR 1.80, 95% CI 1.70–1.91), tumour size (1−2 cm vs 2−5 cm; HR 1.47, 95% CI 1.41–1.53), and a higher number of positive lymph nodes (0 vs 1−3; HR 1.41, 95% CI 1.35–1.48 and 0 vs >10; HR 3.30, 95% CI 3.10–3.51) influenced death to a larger extend than surgical volume.
Conclusion: In the Netherlands, surgical hospital volume influences risk of death only marginally, and far less than patient and tumour characteristics. In 2011 only 9 hospitals had <75 patients per year, resulting in even more comparable risk of death between hospitals in future.
No conflict of interest.

1950 POSTER

Quality of breast cancer care in the Netherlands: Hospital variation in ipsilateral breast tumor recurrence rates

M. Van der Heiden-van der Loo[1], S. Siesling[1], M.W. Wouters[2], T. Van Dalen[3], E.J.T. Rutgers[2], P.H.M. Peeters[4]. *[1]Comprehensive Cancer Centre, Department of Research, Utrecht, Netherlands; [2]Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Department of Surgery, Amsterdam, Netherlands; [3]Diakonessenhuis Utrecht, Department of Surgery, Utrecht, Netherlands; [4]UMC Utrecht, Julius Center of Health Sciences an Primary Care, Utrecht, Netherlands*

Background: As a means of quality assurance, all Dutch hospitals are obliged to report their 5-year ipsilateral breast tumor recurrence (IBTR) rate after breast cancer surgery to the Health care inspectorate. This study assessed IBTR rates in the Netherlands answering two questions: 1) what is the IBTR rate in the Netherlands over time and 2) what is the value of the IBTR rate as indicator for comparing quality of care between hospitals.
Material and Methods: All female breast cancer patients with primary operable breast cancer (pT1−3, any N, M0) who underwent surgery, from 2003 to 2006 in 80 Dutch hospitals were selected from the Netherlands Cancer Registry. Patients were excluded in case of previous cancer, neo-adjuvant chemotherapy, or when treatment did not have a curative intent. Data on 5-year recurrence were retrieved from hospital records by specially trained registrars. IBTR rates were calculated using Kaplan Meier estimates and presented for BCS and mastectomy separately. Hospital variation was presented in funnel plots with a maximum acceptable upper limit value of 5%.
Results: A total of 31,992 breast cancer patients were selected. The overall 5-year IBTR rate was 2.51% (95% CI 2.23–2.71), which was significantly lower for BCS than for mastectomy (table 1; 1.96% and 3.23%, respectively). A decrease of IBTR rates over time was seen in both groups; in 2006 1.49% and 2.71%, for BCS and mastectomy, respectively. IBTR rates varied from 0.82% to 5.40% between hospitals. In one hospital the IBTR rate after mastectomy was significantly higher than the 5% limit.
Conclusions: Our population-based findings show that IBTR rates in the Netherlands are low and rates have improved over time. The IBTR indicator is of limited value for comparing quality between hospitals since the number of patients treated per hospital and the number of recurrences are small, causing wide CI's.
No conflict of interest.

Table 1. IBTR rates of 80 Dutch hospitals according to final surgery, and number of hospitals scoring over 5%

	No. of patients	Follow-up[a]	No. of events	IBTR (95% CI)	No. (%) of hospitals scoring >5%

Breast cancer screening in elderly patients − a FOCUS study analysis

N.A. De Glas[1], E.G. Op 't Land[1], E. Bastiaannet[1], M. Kiderlen[1], W. Van de Water[1], A.J.M. De Craen[2], H.M. Schuttevaer[3], G.H. De Bock[4], C.J.H. Van de Velde[1], G.J. Liefers[1]. *[1]Leiden University Medical Center, Department of Surgery, Leiden, Netherlands; [2]Leiden University Medical Center, Department of Gerontology & Geriatrics, Leiden, Netherlands; [3]Rijnland Hospital Leiderdorp, Department of Radiology, Leiderdorp, Netherlands; [4]University of Groningen University Medical Center Groningen, Department of Epidemiology, Groningen, Netherlands*

Background: One third of the breast cancer patients is older than 65 years at diagnosis and this proportion is still increasing. Few studies have investigated the benefit of the mass screening program in the elderly population. The aim of this observational study was to compare characteristics of elderly breast cancer patients who had a screen-detected versus a non-screen-detected breast cancer, and to evaluate time trends of tumor stage at presentation after extension of the upper age limit of the screening program in the Netherlands to patients aged 70−75 years in 1998.
Materials and Methods: The FOCUS cohort is a detailed retrospective database of all consecutive breast cancer patients aged 65 and older who were diagnosed between 1997 and 2004 in the South-West of the Netherlands. All patients aged 65−75 were included. Differences between patients with screen-detected and non-screen-detected breast cancers were analyzed by logistic regression models. Time trends in tumor stages were analyzed in linear regression models for patients aged 65−69 and patients aged 70−75 separately.
Results: Overall, 1896 patients aged 65−75 were included. Patients with high age, nursing home residents and patients with breast cancer in their medical history were less likely to be diagnosed through the screening program (OR 0.90 (95 % C.I. 0.87–0.93) for each year of increasing age, OR 0.41 (95% C.I. 0.18–0.92) for being a nursing home resident and OR 0.22 (95% C.I. 0.18–0.92) for previous breast cancer respectively). Time trends of different stages between 1997 and 2004 showed a significant increase in early stage breast cancer in patients aged 70−75 after extension of the upper age limit to 75 years in 1998 (p = 0.01), while the number of advanced stage breast cancers did not decrease (p = 0.8). Among patients aged 65−69, the number of both early stage and advanced stage tumors did not significantly change over time.
Conclusions: In conclusion, patients of high age, nursing home residents and patients with breast cancer in their medical history were less often diagnosed through the screening program. We did not observe a statistically significant decrease of advanced stage breast cancer in patients aged 70−75 after extension of the upper age limit of the mass screening program to 75 years, while the number of early stage tumors has significantly increased. Therefore, the value of breast cancer screening in elderly patients deserves further investigation.
No conflict of interest.

1952 POSTER

Survival and contralateral breast cancer in CHEK2 1100delC breast cancer patients: Impact of adjuvant chemotherapy

M. Kriege[1], A. Jager[1], A. Hollestelle[1], E.M.J.J. Berns[1], A.M. Sieuwerts[1], J.M. Collée[2], P. Devilee[3], M.J. Hooning[1], J.W.M. Martens[1], C. Seynaeve[1]. *[1]Erasmus MC- Cancer Institute, Medical Oncology, Rotterdam, Netherlands; [2]Erasmus MC- Cancer Institute, Clinical Genetics, Rotterdam, Netherlands; [3]Leiden University Medical Centre, Human Genetics, Leiden, Netherlands*

Background: Given the function of CHEK2 kinase in DNA repair, it has been hypothesized that breast cancer (BC) patients with a *CHEK2* mutation might have an increased sensitivity to chemotherapeutic agents causing double strand DNA breaks, but clinical data hereon are lacking. Therefore, we assessed the impact of adjuvant chemotherapy on contralateral breast cancer (CBC) rate, distant disease-free survival (DDFS) and breast cancer-specific survival (BCSS) in BC patients with and without a *CHEK2* 1100delC mutation.
Material and Methods: Genotyping for *CHEK2* 1100delC was performed in one hereditary non-*BRCA1/2* cohort (n = 1,220) and in two cohorts unselected for family history (n = 1,014 and n = 2,488). Kaplan–Meier survival analyses were conducted and multivariate hazard ratios (HRs) were calculated using the Cox proportional hazard method for CBC, DDFS and BCSS for carriers vs. non-carriers. All analyses were stratified for adjuvant chemotherapy.
Results: *CHEK2* 1100delC BC patients (n = 193) were younger than non-carriers (50.0 vs. 51.4 yrs.; p = 0.003) and mainly had ER positive disease (89.6% vs.73.9%, p < 0.001). *CHEK2* mutation carriers showed

an increased CBC rate (10-years incidence: 28.9% vs. 8.5%) with a multivariate HR of 3.97 (95% CI 2.59–6.07). The increased CBC rate for *CHEK2* 1100delC carriers was observed in both the group with and without adjuvant chemotherapy (HR 7.0; 95% CI 3.2–15.0 and HR 3.2; 95% CI 1.9−5.4, respectively). No significant interaction between *CHEK2* status and adjuvant chemotherapy was observed (HR 2.2, p = 0.1).
DDFS and BCSS were similar in carriers vs. non-carriers for the first six years after diagnosis (HR DDFS 1.1; 95% CI 0.83−1.4, HR BCSS 1.0; 95% CI 0.71−1.4), but diverged significantly as of six years after BC diagnosis (HR DDFS 2.7; 95% CI 1.8−3.9, HR BCSS 2.1; 95% CI 1.4−2.0). After stratifying for adjuvant chemotherapy, a significantly worse DDFS was observed beyond six years after diagnosis in both the group with (HR 4.5; 95% CI 2.4−8.6) and without chemotherapy (HR 2.3; 95% CI 1.4−3.8). No significant interaction between *CHEK2* status and adjuvant chemotherapy was observed (HR 1.5; p = 0.08). After stratifying for type of chemotherapy and for adjuvant hormonal therapy, results for DDFS were similar.
Conclusion: Compared with non-carriers, *CHEK2* 1100delC BC patients had an increased CBC rate and beyond six years after diagnosis a worse DDFS. Impact of adjuvant chemotherapy on these endpoints was not CHEK2 status dependent.
No conflict of interest.

1953 POSTER

Lower mitotic activity index in BRCA1/2-associated breast cancers detected after risk-reducing salpingo-oophorectomy

V.M.T. Van Verschuer[1], B.A.M. Heemskerk-Gerritsen[2], C.H.M. Van Deurzen[3], A.I.M. Obdeijn[4], M.M.A. Tilanus-Linthorst[1], C. Verhoef[1], M.K. Schmidt[5], L.B. Koppert[1], M.J. Hooning[2], C. Seynaeve[2]. *[1]Erasmus MC − Cancer Institute, Surgical Oncology, Rotterdam, Netherlands; [2]Erasmus MC − Cancer Institute, Medical Oncology, Rotterdam, Netherlands; [3]Erasmus MC − Cancer Institute, Pathology, Rotterdam, Netherlands; [4]Erasmus MC − Cancer Institute, Radiology, Rotterdam, Netherlands; [5]Netherlands Cancer Institute − Antoni van Leeuwenhoek Hospital, Epidemiology, Amsterdam, Netherlands*

Background: Bilateral salpingo-oophorectomy reduces breast cancer (BC) risk in BRCA1/2 carriers by about 50%, especially when performed premenopausally. It has been hypothesised that growth activity of BCs originating after risk-reducing salpingo-oophorectomy (RRSO) is lower. Therefore, we compared tumour characteristics and growth rates of BRCA1/2-associated primary BCs detected after RRSO with those of tumours originating without or before RRSO.
Methods: From a cohort containing 271 female BRCA1/2 mutation carriers with BC, 20 BRCA1/2 mutation carriers with primary BC detected at least 12 months after RRSO were selected (RRSO group). They were matched to 36 BRCA1/2 carriers with primary BC detected without RRSO (non-RRSO group) for age at BC diagnosis (± 2.5 years) and for BRCA1 or BRCA2 mutation (intended matching ratio 1:2). Pathology samples were revised for tumour differentiation grade, ER/PR and HER2 status. Breast MRIs and mammographies made at BC diagnosis as well as previous examinations were revised. Tumour growth rates, assuming exponential tumour growth and expressed as tumour volume doubling times (DT) were calculated.
Results: Median age at primary BC diagnosis was 52.0 years (range 35.0–67.0). In the RRSO group, BC was diagnosed more often by MRI than by mammography, compared to the non-RRSO group in (83% vs. 39% by MRI, P = 0.02). Tumours were smaller at diagnosis in the RRSO group (11.0 mm vs. 17.0 mm, P = 0.01). Mitotic activity index was lower in the RRSO group (12 vs. 22 mitotic counts/2 mm^2, P = 0.02) and PR-status was more often positive (median H-score=3.0 vs. 0.0, P = 0.05). No significant differences in differentiation grade, ER and HER2 status were found. Median DTs were not significantly longer in the RRSO group (DT=124 days, range 55–413) than in the non-RRSO group (DT=93 days, range 15–1317) (P = 0.47).
Conclusion: The lower mitotic activity index suggests a less aggressive biological behaviour in BRCA1/2-associated BCs developing after RRSO. When confirmed in larger series, this may have consequences for BC screening protocols for BRCA1/2 mutation carriers after RRSO.
No conflict of interest.

Pregnancy after breast cancer: Patients' characteristics and pregnancy outcomes

F. Peccatori[1], M.A. Sarno[2], B. Santillo[3], H.A. Azim[4], G. Pruneri[5], B. Di Nubila[6], V. Galimberti[7], L. Chiavari[8], N. Colombo[9], N. Rotmensz[3]. *[1]European Institute of Oncology, Fertility and Procreation Unit-Gynecologic Oncology Division, Milan, Italy; [2]European Institute of Oncology, Fertility and Procreation Unit-Gynecologic Oncology Division, Milan, Italy; [3]European Institute of Oncology, Division of Epidemiology and Biostatistics, Milan, Italy; [4]Jules Bordet Institute, BrEAST Data Center, Brussels, Belgium; [5]European Institute of Oncology, Pathology Division, Milan, Italy; [6]European Institute of Oncology, Breast Radiology Division, Milan, Italy; [7]European Institute of Oncology, Breast Surgery Division, Milan, Italy; [8]European Institute of Oncology, Fertility and Procreation Unit Gynecologic Oncology Division, Milan, Italy; [9]European Institute of Oncology, Gynecologic Oncology Division, Milan, Italy*

Background: With the improvement of survival of young breast cancer patients (pts), the feasibility and safety of conception after breast cancer is of relevance. Evidence suggests that pregnancy after breast cancer is safe, irrespective of ER-status, but few data are available on patients characteristics and pregnancy outcome.
Material and Methods: We retrospectively extracted from our Breast Cancer Institutional database all pts <44 years, with histologically-confirmed primary breast cancer, operated on from Jan 1995 to Dec 2010.
Results: Of 2255 pts, 123 (5.4%) became pregnant after diagnosis. Of these, 69 pts underwent surgery at our Institution and are included here. Median age at diagnosis was 31 y (23−43 y). 60 pts (87%) had a pT1−2 tumor, while 37 pts (53%) had pN0 disease. 38 pts (53%), 12 (17%) and 43 (63%) had HR-positive, HER2-amplified and Ki67>20%, respectively. 11 pts (16%) had triple-negative disease. While systemic adjuvant treatment was suggested to all pts, 58 pts (84%) actually received it. 20 pts (28%) were treated with chemotherapy alone, while 38 pts (55%) received endocrine treatment +/− chemotherapy. Of 27 pts who were prescribed adjuvant tamoxifen, only 12 pts (44%) were compliant. 14/44 pts (31%) received triptorelin concomitant to chemotherapy to reduce gonadal toxicity, but none had oocytes frozen before treatment. Median time to pregnancy was 20 months (5−86 m). Pregnancy was spontaneous in 67 patients, while 3 pts underwent assisted reproduction. 44/69 pts (63%) had a term pregnancy, 14/69 pts (20%) had a first trimester miscarriage, with subsequent term pregnancies in 4 cases, while 11 pts (15%) opted for abortion. Pregnancy course was normal in 46/48 pregnancies, with 1 case of pre-eclampsia and 1 case of premature rupture of membrane. No malformations or neonatal complications were observed. 16/44 mothers (36%) breastfed their babies. With a median follow-up of 113 months, 6/69 patients had a cancer-related event, and 1/69 died.
Conclusions: Young breast cancer survivors who deliver after diagnosis are still a minority. Patients characteristics did not appear to influence the decision to proceed to pregnancy. There was a relatively high rate of non-compliance to adjuvant treatment, which calls for the adoption of tailored strategies for those women desiring subsequent pregnancy. Although a higher rate of miscarriages was observed, pregnancy and neonatal outcome were satisfactory and comparable to the general population.

Manual injection of subcutaneous trastuzumab vs intravenous infusion for HER2-positive early breast cancer: a time-and-motion study

E. De Cock[1], A. Knoop[2], E.H. Jakobsen[3], A.S. Ribecco[4], N. Hauser[5], P. Kritikou[6], D. Millar[7], X. Pivot[8]. *[1]United BioSource Corporation, Barcelona, Spain; [2]Copenhagen University Hospital, Copenhagen, Denmark; [3]Vejle Sygehus, Onkologisk Afdeling, Vejle, Denmark; [4]Azienda Sanitaria di Firenze − Ospedale Santa Maria Annunziata SC Oncologia Medica, Bagno a Ripoli, Italy; [5]Kantonsspital Baden AG, Department of Gynecology and Obstetrics, Baden, Switzerland; [6]United BioSource Corporation, Hammersmith, United Kingdom; [7]F. Hoffmann-La Roche Ltd, Basel, Switzerland; [8]CHU Jean Minjoz, Besançon, France*

Background: Within the ongoing PrefHer trial (NCT01401166, F. Hoffmann-La Roche Ltd), patients and healthcare professionals (HCPs) preferred subcutaneous (SC) trastuzumab via single-use injection device (SID) to intravenous (IV) infusion. We undertook a prospective, observational time-and-motion sub-study to quantify HCP time actively engaged in tasks related to preparation/delivery of IV and SC and the duration that patients sat in infusion chairs.
Materials and Methods: After completing (neo)adjuvant chemotherapy, patients with HER2-positive early breast cancer were randomised to

receive 4 cycles of SC trastuzumab (600 mg fixed dose via SID [Cohort 1] or manual injection [Cohort 2]) followed by 4 cycles of standard IV or the reverse sequence as part of their adjuvant trastuzumab therapy. We report interim Cohort 1+2 IV vs Cohort 2 manual SC data from 13 sites in Denmark (DK), France (FR), Italy (IT) and Switzerland (CH). Cohort 1 SC SID data were reported previously.
Following interviews with a nurse and pharmacy member at each site, generic case report forms for IV, SC and pharmacy management were tailored to reflect site practices. Estimated mean times for a single IV vs SC process (an observation: treatment room plus pharmacy task times, chair time) were calculated per country.
Data collection is ongoing and current results are based on the number of observations achieved to date: 24−58 for IV (CH−IT) and 14−65 for SC (DK−IT). Further data, including 95% CIs and the anticipated impact of a change from IV to either SC method on centre management (elicited via questionnaire), will be presented.
Results: Reduction in mean HCP time with SC ranged from 25−42% (DK−FR), and reduction in mean chair time ranged from 66−80% (IT−DK, Table).

	Mean HCP time (min)			Extrapolated mean HCP time (18 cycles, hours)			Mean chair time (min)		
	IV	Manual SC	IV-SC	IV	Manual SC	IV-SC	IV	Manual SC	IV-SC
DK	23.3	17.6	5.7 (25%)	7.0	5.3	1.7	83.0	16.8	66.1 (80%)
FR	26.1	15.1	11.0 (42%)	7.8	4.5	3.3	82.8	23.1	59.7 (72%)
IT	20.1	12.5	7.5 (38%)	6.0	3.8	2.3	62.5	21.3	41.2 (66%)
CH	26.5	18.1	8.4 (32%)	8.0	5.4	2.5	109.8	29.4	80.4 (73%)

Extrapolated chair time savings for 10 patients receiving 18 cycles each ranged from 15.5–30.1 eight-hour days (IT−DK; mean chair time*10*18/60/8).
Conclusions: Preliminary results indicate that a transition from IV to manual SC trastuzumab injection may lead to a substantial reduction in HCP time and chair time, reducing medical resource use, improving patients' care and increasing staff and centre efficiency.

Efficacy of risk-reducing mastectomy (RRM) on overall survival (OS) in BRCA1/2-associated breast cancer (BC) patients

B.A.M. Heemskerk-Gerritsen[1], M.J. Hooning[1], C.J. Asperen van[2], M.G.E.M. Ausems[3], L. Jansen[4], M. Kets[5], K. Keymeulen[6], H.E.J. Meijers-Heijboer[7], M.A. Rookus[8], C. Seynaeve[1]. *[1]Erasmus MC Cancer Institute, Medical Oncology, Rotterdam, Netherlands; [2]Leiden University Medical Center, Medical Genetics, Leiden, Netherlands; [3]University Medical Center, Clinical Genetics, Utrecht, Netherlands; [4]University Medical Center, Surgical Oncology, Groningen, Netherlands; [5]Radboud University Medical Center, Human Genetics, Nijmegen, Netherlands; [6]Maastricht University Medical Center, Surgical Oncology, Maastricht, Netherlands; [7]VU University Medical Center, Clinical Genetics, Amsterdam, Netherlands; [8]Netherlands Cancer Institute, Epidemiology, Amsterdam, Netherlands*

Background: RRM in BRCA1/2 mutation carriers with a history of unilateral primary breast cancer (PBC) is known to reduce the risk of developing contralateral BC (CBC), but the impact on OS is insufficiently known. Therefore, we studied the efficacy of RRM on OS in BRCA1/2 mutation carriers.
Methods: From a Dutch multicenter cohort study, we identified 565 BRCA-associated PBC patients (439 BRCA1, 126 BRCA2). Eventually 190 BRCA1 and 49 BRCA2 carriers underwent RRM. To avoid overestimation of early PBC-related deaths, patients were only eligible if they were recurrence-free for at least 2 years after PBC. Contribution of person-years of observation (PYO) to the Non-RRM group started 2 years after the date of PBC diagnosis or at the date of DNA diagnosis (whichever came last) and ended on the date of death, RRM, or last contact. Contribution of PYO to the RRM group started at the date of RRM or 2 years after the date of PBC diagnosis (whichever came last) until similar endpoints as described for the Non-RRM group.
Results: Regarding PBC, no significant differences in size, nodal status, differentiation grade, hormone and Her2 receptor status were observed between the Non-RRM and RRM group. Median age at PBC diagnosis was 42 years for Non-RRM and 38 for RRM women ($p < 0.001$). Median time period between PBC and RRM was 2.1 years (range 0.01–20.2). PBC treatment included radiotherapy for 67% of Non-RRM versus 48% of RRM women ($p < 0.001$), and chemotherapy for 50% of Non-RRM versus 66% of RRM women ($p < 0.001$). Use of endocrine therapy was not significantly different (16% and 19%). More RRM women underwent risk-reducing salpingo-oophorectomy (80% versus 69%; $p < 0.001$), while ovarian cancer incidence was not significantly different (4% and 2%). With a median FU of 11.6 years after PBC diagnosis, we observed 64 CBC cases (20%) in Non-RRM women, and 4 CBC cases (2%) after RRM ($p < 0.001$). In the Non-RRM group 56 women died during 2666 PYO versus 18 women in the RRM group during 1837 PYO, yielding mortality rates (per 1000 PYO) of 21.0 and 9.8, respectively (adjusted HR 0.55, 95% CI 0.32–0.94). Fifteen years OS was 81% for the Non-RRM and 90% for the RRM group ($p = 0.006$).
Conclusions: RRM reduces CBC incidence and is associated with improved OS in BRCA-associated BC patients who are recurrence-free at least two years after PBC diagnosis. Further research is needed to identify potential prognostic factors for this survival benefit.

Efficacy of zoledronic acid in postmenopausal Japanese women with early breast cancer receiving adjuvant letrozole: 36-month results

S. Takahashi[1], T. Iwase[2], N. Kohno[3], T. Ishikawa[4], S.J. Kim[5], M. Hosoda[6], J. Horiguchi[7], H. Yamauchi[8], M. Fukunaga[9], S. Noguchi[5]. *[1]Cancer Institute Hospital Japanese Foundation for Cancer Research, Medical Oncology, Tokyo, Japan; [2]Cancer Institute Hospital Japanese Foundation for Cancer Research, Breast Surgery, Tokyo, Japan; [3]Tokyo Medical University Hospital, Breast Oncology, Tokyo, Japan; [4]Yokohama City University Medical Center, Breast and Thyroid Surgery, Kanagawa, Japan; [5]Osaka University Hospital, Breast and Endocrine Surgery, Osaka, Japan; [6]Hokkaido University Hospital, Breast and Endocrine Surgery, Hokkaido, Japan; [7]Gunma University Hospital, Breast and Endocrine Surgery, Gunma, Japan; [8]St. Luke's International Hospital, Breast Surgery, Tokyo, Japan; [9]Kawasaki Medical School, Dean, Okayama, Japan*

Background: We reported 12-month results of upfront zoledronic acid (ZOL) therapy prevented bone loss in postmenopausal Japanese women who were receiving adjuvant letrozole confirming the Z-FAST and ZO-FAST studies results. But the examination in the long term of aromatase inhibitor-associated bone loss has not been proved in the Japanese or Asia women.
Methods: Postmenopausal women with hormone receptor positive early breast cancer (BC) patients receiving adjuvant letrozole were randomly assigned to receive either upfront or delayed-start ZOL (4 mg intravenously every 6 months) for 5 years. The delayed group received ZOL when lumbar spine (L_2-L_4) BMD decreased to less than young adult mean (YAM) − 2.0 S.D or when a nontraumatic fractured occurred. The primary endpoint of this study was to compare the changes in L_1-L_4 BMD at month 12 between the groups. Secondary endpoints, measured at other predetermined timepoints, included comparing changes in L_1-L_4, L_2-L_4 and total hip (TH) BMD and markers of bone turnover, fracture incidence, and time to disease recurrence. We report the results of 36-month interim analysis.
Results: At 36 months, mean change in L_1-L_4 BMD was 10.7% higher in the upfront group than in the delayed group (95% CI, 9.2% to 12.1%; $p < 0.001$), L_2-L_4 BMD was 10.9% higher (95% CI, 9.3% to 12.5%; $p < 0.001$), and TH BMD was 6.7% higher (95% CI, 5.3% to 8.1%; $p < 0.001$). The incidence of fracture was significantly decreased in the upfront group (upfront, 2 (2.0%) vs. delayed, 9 (9.3%), $p = 0.033$). Disease recurrence was reported in 3 upfront (3.1%) and 1 delayed (1.0%) patients. By month 36, 11 patients (11.3%) in the delayed group initiated ZOL therapy. There was no significant difference of adverse events other than fever with ZOL at the first treatment between the two groups.
Conclusion: Upfront ZOL seems to be the preferred treatment strategy versus delayed administration, as it is significantly and progressively increase BMD in postmenopausal Japanese women with early BC who were receiving adjuvant letrozole for 36 months.

1958 POSTER

Adapted physical activity effect on aerobic function and fatigue in patients with breast cancer treated in adjuvant or neoadjuvant phase (SAPA)

T. Cornette[1], F. Vincent[1], M.T. Antonini[1], S. Leobon[2], S. Lavau-Denes[2], N. Tubiana[2]. [1]*CHU Dupuytren, Department of Physiology University Hospital Limoges, Limoges, France;* [2]*CHU Dupuytren, Department of Oncology University Hospital Limoges, Limoges, France*

Background: Research and clinical interest in the therapeutic effectiveness of exercise in breast cancer, during adjuvant or neoadjuvant chemotherapy and radiotherapy, has greatly increased. Use of cardiopulmonary exercise test (CPET) for determination of peak oxygen consumption (VO_{2peak}) provides the gold standard assessment of aerobic capacity. The main aim was to evaluate cardiopulmonary function as measured by VO_{2peak} in breast cancer patients before adjuvant or neoadjuvant chemotherapy and after adapted physical activity (APA).
Our hypothesis was that a home-based training program (aerobic and strength training) in a breast cancer population would resolved in improved cardiovascular fitness, peripheral strength, decreased fatigue and improved quality of life. We performed a phase III study, to assess the effects of a home-based physical activity training program in a breast cancer population treated by adjuvant or neoadjuvant chemotherapy versus no APA.
Methods: The programme was organised as follows: Arm A (aerobic and strength training) during the 27 weeks of treatment (chemotherapy and radiotherapy RT-CT); Arm B (control group). This study included 3 assessments phases (T0: before RT-CT; T1 (week 27) and T2: final evaluation at the 54th week). These assessments included: cardiopulmonary exercise test (CPET) including maximal oxygen uptake test (VO_{2max}), six-minute walk test (6MWT), muscular testing, pulmonary function testing, assessment of physical activity (IPAQ questionnaire), fatigue (MFI20 questionnaire), quality of life (EORTC QLQ C30), anxiety and depression symptoms (HADS) and iDEXA (total body biphotonic absorption).
Results: A total of 44 subjects were included from June 2012 to June 2013. At baseline, the average age was 53$\pm$12.1 years for Arm A versus 49.1$\pm$9.2 years for Arm B. Body Mass Index was 24.96 for Arm A and 26.62 for Arm B.
There was no significant difference in VO_{2peak} between Arm A and Arm B before RT-CT; 23.2 $ml \cdot kg^{-1} \cdot min^{-1}$ and 22.9 respectively ($P = 0.44$).
Walking distance on 6MWT of the two group assessed 515m for Arm A and 532m for group B ($P = 0.37$). The percentage of theoretical distance is similar.
Results in VO2peak, 6MWT, QLQC30, IPAQ and HADS performed after APA will presented in September 2013.
